Edinburgh: Privately Printed
MCMVI

THE TREES OF GREAT BRITAIN AND IRELAND

QUEEN BEECH AT ASHRIDGE

From a Drawing lent by the Earl Brownlow.

A detailed botanical illustration of tree branches. The top half shows several catkins, some with bright red flowers and others with green, fuzzy catkins. The bottom half shows a branch with large, green, serrated leaves and a small, reddish-brown bud. The entire illustration is enclosed in a thin black rectangular border.

PREFACE

THE United Kingdom offers a hospitality to exotic vegetation which finds no parallel in the Northern Temperate region of the globe. Never parched by the heat of a continental summer, the rigour of winter is no less tempered by its insular position. The possession of land still ensures the residence on their properties of a large number of persons of at least moderate affluence. The most modest country house possesses a garden, and not rarely some sort of pleasure ground; and this usually reaches the dimensions of a park in the case of the larger mansions. While forests for the commercial production of timber such as are found in foreign countries hardly exist, and the methods of their scientific management are little recognised, arboriculture of some sort may be almost said to be a national passion. In all but purely agricultural districts the free and unrestrained growth of trees enhances, if it does not create, the natural beauty of the landscape. The Roman occupation brought to our shores our fruit-trees and others whose names of Latin derivation bear witness to their foreign origin. One of these, the so-called "English Elm," dominates the landscape of Southern England. Yet, while it perfects its seed on the Continent, it rarely does so in this country, and it holds its own by root suckers, the tenacity of which is all but ineradicable.

Down to the reign of Henry the Eighth the native forests supplied the timber necessary for construction. It was not till their area became restricted that planting was commenced to maintain the supply. And if this has never developed into a scientific system as it has done abroad, the reason may be found in the abandonment of wood as fuel for coal, and the facilities for external supply of over-sea water-carriage which attach to a maritime country.

From an early time with the growth of continental intercourse, the contents of foreign gardens had gradually been transferred to those of the wealthy at home. The taste, however, for cultivating foreign trees and shrubs simply for their interest, and apart from any useful purpose they might serve, is not more recent than the seventeenth century. The pioneer in this branch of English arboriculture was Henry Compton, Bishop of London, who planted in the garden of Fulham Palace "a greater variety of curious exotic plants and trees than had at that time been collected in any garden in England." Hitherto the European continent had

been the only hunting ground. To this was now added in striking contrast the resources of the North American forests.

In the eighteenth century the practice of planting foreign trees became in some degree a fashion amongst wealthy landowners, though still mainly for ornament. This was due in large measure to the example of Archibald, third Duke of Argyll, who formed a large collection at Whitton. After his death in 1762 all that were removable were transferred to Kew, where an Arboretum had been commenced by the Princess Dowager of Wales.

An intelligent taste for arboriculture was at any rate for a time firmly established. Those who care to trace its further history more in detail will find abundant information in Loudon's *Arboretum et Fruticetum Britannicum*, a work which, though published more than half a century ago, must always remain indispensable to any student of the subject. Parks and pleasure grounds throughout the country were stocked with specimens of new and interesting trees. And though often neglected and even forgotten, we now possess a wealth of examples which have attained adult development. Loudon catalogued with indefatigable industry every tree or shrub known to be tolerant of the climate of the British Isles. It might have been thought that this laborious undertaking would have excited a new interest in planting. But it began to languish with the beginning of the last century, and Loudon's labours from their very completeness, perhaps, deterred many from engaging in an occupation where more than moderate success would seem costly and laborious, and anything beyond almost unattainable. In 1845 a National Arboretum was projected at Kew, and commenced the following year on a plan prepared by W. A. Nesfield.

The latter half of the last century saw a remarkable development of open-air horticulture. In so far as this included woody plants, it was limited to shrubs. Broad-leaved trees were little cared for. The rarer kinds were little in request, and those that were planted were too often drawn from the ill-named stock of some convenient nursery. The neglect was increased when conifers became a fashion. This led, no doubt, to many fine Pinetums being planted, the interest and importance of which will increase with age. But it led also to much unconsidered and scattered planting of trees which, attractive enough in a juvenile state, are often less sightly as they grow older, and can never blend with their broad-leaved neighbours into stately umbrageous masses.

If the planting of broad-leaved trees as distinguished from conifers has for the moment fallen into neglect, we still inherit the results of the labours of our predecessors. The British Isles for the last two centuries have, in fact, been the seat of an experiment in arboriculture without parallel elsewhere. And the very neglect into which tree-planting has fallen, paradoxical as it may seem, adds to the interest and value of the experiment. For the trees that have come down to us from the

past have been subjected to the least favourable conditions, and have had in effect to survive a somewhat rigorous process of natural selection.

In taking stock of the results, the task which my friend Mr. Elwes has set himself differs, if I understand his intention rightly, somewhat widely from that which Loudon accomplished. That amounted to little more than a descriptive catalogue of every woody plant the cultivation of which had been attempted in this country. The present work aims at ascertaining the practical results. What are the most favourable conditions for the growth of each species? What in turn are the most suited for different circumstances? And what, if any, profit can be derived from their cultivation on a large scale?

And to accomplish or even attempt such a task appears to me no small public service. The depreciation of the value of agricultural land has turned the thoughts of many landowners to the possibility of growing timber as a crop for profit. So far little attempt has been made to depart from tradition. Yet it cannot be doubted that there must be many trees suited to our climate whose commercial possibilities are still unascertained. Apart from the larger uses of timber its employment for minor industries is still little regarded among us. If but a single tree can be added to the list of those which can be profitably cultivated the labour spent on the quest will not be unrequited.

W. T. THISELTON-DYER.

KEW, November 1905.

INTRODUCTION

THE object of this work is to give a complete account of all the trees which grow naturally or are cultivated in Great Britain, and which have attained, or seem likely to attain, a size which justifies their being looked on as timber trees; but does not include those which are naturally of shrubby or bushy habit.

Although sixty years have passed since Loudon's great work was published, no book has been written which describes in full the species which in his time were unknown, or so recently introduced that their cultural requirements and economic or ornamental value had not been tested.

Many deciduous trees, which were commonly planted before his time, have gone out of popular favour, and are almost forgotten; whilst the rage for conifers which sprang up about seventy years ago has led to the introduction of almost every species which can be grown in this country; and many of these have now reached an age at which their value can be accurately judged of.

Special books dealing with conifers have appeared which may satisfy the wants of a horticulturist, but none exists that at all meets the requirements of land-owners, foresters, and arboriculturists, and will enable them to distinguish the species with certainty, or guide them in selecting the species the best suited for economic culture in different parts of England.

Forestry is at last making headway as a science in this country, but too many of the books recently published on the subject have been based on continental experience, which is not directly applicable to the very different conditions of climate, soil, labour, and market existing here. In the cultural part of the work we base our conclusions on home experience and practice; and in this connection it may be stated that for almost every exotic species there are older specimens of individual trees and of plantations in these islands than on the Continent. After having seen the trees of every country in Europe, of nearly all the States of North America, of Canada, Japan, China, West Siberia, and Chile, we confidently assert that these islands contain a greater number of fine trees from the temperate regions of the world than any other country. Descriptions of the best examples of all of these and of interesting woods and plantations will be a prominent feature of the book.

We have the special qualification that we have seen with our own eyes and studied on the spot, both at home and abroad, most of the trees which will be included in the book.

Knowing how difficult it is for the general public to understand the descriptions of nearly allied species, usually made by compilers who are unacquainted with the crucial points of distinction, we hope to supply this information in concise, clear, and simple language. What we understand by scientific knowledge is accuracy, expressed in plain words; and in order to ensure this we have copied nothing from other authors that we could verify for ourselves.

In order to give a history of the finest trees in this country, we have visited during the past five years nearly every important place in England, Scotland, Wales, and Ireland where large and rare trees are found; and have received from land-owners, estate agents, foresters, and gardeners an amount of information and assistance which justifies us in believing that our work will be generally appreciated. Though the historic trees of some places in England and of more in Scotland have been described in scattered publications, those of Ireland have been almost totally neglected; and Dr. Henry has paid special attention to the many interesting properties in that country.

A prominent feature of the work will be the illustrations. Modern photography enables the authors to give accurate pictures of the trees as they grow. Almost all the photographs of trees and of forest scenes have been taken by skilful photographers specially engaged for the purpose. In dealing with about 300 species of trees, many of which will require several illustrations to show the best specimens both as park and forest trees, the authors have accumulated a large number of photographs, which are being reproduced by the Autotype Company of London, who guarantee their permanency.

With regard to these illustrations we desire to say, that though in some cases they may not be perfect from the point of view of the photographic artist, yet the amount of time, skill, and money that has been spent on them is very far beyond what would be imagined by any one who has not had experience of the difficulty of securing good negatives of trees scattered over so large an area, under all conditions of light and weather, and in situations often extremely difficult to the photographer.

In some cases two or three special journeys have been made to obtain a photograph of one tree only, as the object has been to show the finest individual trees known to the authors rather than to make pretty pictures of scenery.

Besides these reproductions of photographs there will be lithographed drawings of seedlings, buds, leaves, flowers, and fruit, so far as is necessary to distinguish the trees in winter and in summer. These original drawings have all been done under the personal supervision of Dr. Henry, who has carefully studied the material, living and dead, that exists in the unrivalled establishment at Kew.

All measurements have been taken by the authors themselves with Stanley's Apomecometer, or by practical foresters on whose accuracy they could rely, and though in many cases errors to the extent of a few feet may have been made, owing to the shape or position of the tree measured, we believe them to be as accurate as possible under the conditions.

FAGUS

THE NORTHERN BEECHES

Fagus, Linnæus, *Syst. ed. 1. V. Monœcia* (1735); Bentham et Hooker, *Gen. Plant.* iii. 410 (1880).

THE genus, as understood by Bentham and Hooker, included all the beeches, those of the southern as well as of the northern hemisphere. Blume¹ separated the southern beeches as a distinct genus, *Nothofagus*; and his arrangement, on account of its convenience, will be followed by us. *Fagus* belongs to the family *Quercineæ*, which includes the oaks, chestnuts, castanopsis, and beeches. The genus, limited to include only the northern beeches, consists of large trees with smooth bark and spindle-shaped buds arranged alternately on the twigs in two rows. Leaves: deciduous, simple, pinnately-nerved, folded in the bud along the primary nerves. Flowers monœcious: the staminate flowers numerous in pendulous globose heads, the pistillate flowers in pairs in involucre. The male flower has a 4 to 8 lobed calyx with 8 to 16 stamens. The female flower has a 6 lobed calyx, adnate to a 3 celled ovary, with 2 ovules in each cell; styles 3, filiform. On ripening, the involucre is enlarged, woody, and covered with bristly deltoid or foliaceous processes; it dehisces by 4 valves, allowing the 2 fruits enclosed to escape. Each fruit is 3 angled and contains 1 seed, which has no albumen.

Seven distinct species of *Fagus* have been described, of which three, the European beech, the American beech, and the peculiar *Fagus japonica* are recognised by all botanists as good species. The Caucasian beech, the two Chinese beeches, and the common beech of Japan are considered by some authorities to be mere varieties of *Fagus sylvatica*; but these can all readily be distinguished, and in the following account will be treated as independent species.

KEY TO THE SPECIES OF FAGUS.

I. *Nuts projecting out of the top of the involucre.*1. *Fagus japonica*. Japan.

Involucre very small, covered externally with small deltoid processes, and borne on a very long slender stalk. Leaves with 10-14 pairs of nerves, which bend round before quite reaching the slightly undulating margin.

¹ Blume, in *Mus. Lugd. Bat.* i. 306.

2 The Trees of Great Britain and Ireland

II. Nuts enclosed in the involucre.

A. Involucres with linear, awl-shaped, bristly appendages. Species 2, 3, and 4.

2. *Fagus sylvatica*. Europe.

Fruit-stalks short and pubescent throughout.

Leaves: under surface glabrous except on the nerves and midrib; lateral nerves 5-9 pairs; margin not regularly serrate.

3. *Fagus ferruginea*. North America.

Fruit-stalks short and pubescent throughout.

Leaves: under surface glabrous except on the nerves and midrib; lateral nerves 10-12 pairs, ending in the teeth; margin serrate.

4. *Fagus sinensis*. Central China.

Fruit-stalks short, pubescent only close to the involucre.

Leaves: minutely pubescent over their whole under surface; lateral nerves 9-10 pairs ending in the teeth; margin serrate.

B. Involucres with their lower appendages dilated and foliaceous. Species 5, 6, 7.

5. *Fagus orientalis*. Caucasus, Asia Minor, N. Persia.

Fruit-stalks long (twice the length of the involucre or more) and very pubescent throughout.

Leaves: broadest above the middle; lateral nerves about 10 pairs, bending round before quite reaching the undulate margin; under surface glabrous except on the midrib and nerves.

6. *Fagus Sieboldi*. Japan.

Fruit-stalks short (as long as the involucres) and pubescent throughout.

Leaves: broadest below the middle; lateral nerves 7-10 pairs, bending round before quite reaching the margin, which is crenate; under surface glabrous beneath except on the nerves and midrib.

7. *Fagus Engleriana*. Central China.

Fruit-stalks very long (five times the length of the involucre) and quite glabrous.

Leaves glabrous and glaucescent underneath; lateral nerves 13 pairs, bending round before quite reaching the undulate margin.

FAGUS FERRUGINEA. American Beech.

Fagus ferruginea, Dryander, in *Ait. Hort. Kew.* iii. 362 (1789); Loudon, *Arb. et Frut.* iii. 1980 (1838); Mayr, *Wald. von Nordamerika*, 176 (1890).

Fagus sylvatica atropunicea, Marsh. *Arb. Am.* 46 (1785).

Fagus silvestris, Mich. fil. *Hist. Arb. Am.* ii. 170, t. 8 (1812).

Fagus atropunicea, Sudworth, *Bull. Torrey Bot. Club*, xx. 42 (1893).

Fagus americana, Sweet, *Hort. Brit.* 370 (1826); Sargent, *Silva of N. Am.* ix. 27 (1896).

The American beech ranges, according to Sudworth, from Nova Scotia to north shore of Lake Huron and Northern Wisconsin; south, to western Florida; and west, to south-eastern Missouri and Texas (Trinity River). Mayr¹ says it is at

¹ Mayr, *l.c.*

Fagus

its best in the northern deciduous forest, where it is a stately tree, *e.g.* at Lake Superior. The finest individual trees occur on the small hills of the Mississippi valley, but the timber is not so good as that of trees farther north. Pure woods of American beech rarely if ever occur.¹ Elwes saw the American beech principally near Boston and in Canada, and remarked one peculiarity which may not be found in all places. This was its tendency to throw up suckers from the roots, a feature which is very marked in Professor Sargent's park at Brookline, and in the beautiful grounds of the Arnold Arboretum. There is a group of beech here by the side of a drive, of which the largest was 65 feet by 7 feet 8 inches, surrounded by a dense thicket of suckers. Beech seedlings, however, seem to be much less common here than in Europe, and on moist ground are often suppressed by maple and other trees. The rate of growth of young trees in the Arboretum was about equal to that of the European beech at twenty years, and the bark of the latter was darker in colour. Near Ottawa Elwes gathered ripe fruit of the American beech²—which here is not a large or tall tree—in the end of September; the mast was smaller and less abundant than in the European beech, and the tree—as near Boston—did not seem to have the same tendency to outgrow and suppress other hardwoods which it shows in Europe. The roots, judging from seedlings sent from Meehan's nurseries at Philadelphia, are larger, deeper, and less fibrous than those of the European beech, though this may be caused by a deep soil. A good illustration of the American beech in the open is given in *Garden and Forest*, viii. 125, taken from a tree at South Hingham, Massachusetts.

The American beech is rare in collections in England. We have only seen specimens at Kew Gardens, Beauport, Tortworth, and Eastnor Castle. In no case do these attain more than 15 feet in height. As the tree, no doubt, was often planted even a century ago, and no large trees are known to exist in this country, it is very probable that, like many other species from the Eastern States, it will never reach timber size in this climate. The specimen from Eastnor Castle has very dull green leaves, somewhat cordate at the base, and probably belongs to the following variety.

Var. *caroliniana*, Loudon, *ex Lodd. Cat.* (1836).—In cultivation in Europe, distinguished from the common form by the leaves being more rounded at the base, said to be more dwarf in height, and to come out in leaf fifteen days before ordinary *Fagus ferruginea*.³

FAGUS ORIENTALIS. Caucasian Beech.

Fagus orientalis, Lipski, *Acta. Hort. Petrop.* xiv. 300 (1897).

Fagus sylvatica, Linnæus, β *macrophylla*, DC., and γ *asiatica*, DC. (*ex parte*), *Prod.* xvi. 2, 119 (1864).

Lipski says that the beech which occurs in the Caucasus, Asia Minor, and

¹ But Sargent says that it attains its largest size in the rich land of the Lower Ohio valley, and in the Southern Alleghanies, and that it often forms pure forests. He quotes an old author (Morton) as follows:—"Beech there is of two sortes, red and white, very excellent for trenchers or chaires, also for oars," and says that these different coloured woods, recognised by lumbermen, are produced by individual trees, which are otherwise apparently identical, and for which Michaux and Pursh tried to find botanical characters which he cannot allow to be specific.

² Sargent says that the sweet nuts are sold in Canada, and in some of the middle and western states.

³ Jouin, "Les Hêtres" in *Le Jardin* (1899), p. 42.

North Persia, is a peculiar species. Radde,¹ while not admitting it to be a distinct species, considers that it is a form which approaches the Japanese *Fagus Sieboldi*, Endl., rather than the typical European beech, which occurs in the Crimea. Specimens in the Kew herbarium from the Caucasus, Paphlagonia, Phrygia, and Ghilan (a province of North Persia), differ markedly in fruit from the common beech. This tree occurs throughout the whole of the Caucasus, both on the north and south sides, often ascending to the timber line, but descending in Talysch to the sea-level. On the north side of the Caucasus the beech reaches to 5900 feet altitude; while in the Schin valley, on the south side of the range, it attains 7920 feet. It occurs mixed with other trees, or forms pure woods of considerable extent. It sometimes occurs in the forests in the form of gigantic bushes (springing from one root), of which the individual stems measure 6 feet in girth, and are free from branches to 30 or 40 feet. The largest trees recorded by Radde were:—one 380 years old, 7 feet in girth, and 123 feet high; and another 250 years old, 8 feet 4 inches in girth, and 120 feet high, which contained 370 cubic feet of timber.

This species has been introduced into cultivation on the Continent, and is said² to have a crown of foliage more slender and more pyramidal than the common beech.

FAGUS JAPONICA. Small Beech of Japan. (Native name, *Inubuna*.)

Fagus japonica, Maximowicz, *Mél. Biol.* xii. 542 (1886).

Shirasawa, *Iconographie des Essences Forestières du Japon*, vol. i. t. 35, figs. 1-13 (1900).

This species is much rarer in Japan than *Fagus Sieboldi*, and was not seen by Elwes or Sargent, who says that it had not been collected since a collector in Maximowicz's employ found it on the Hakone mountains, and in the province of Nambu. Very little is known about it, and it has not been introduced into Europe. Shirasawa, however, says it has the same distribution as *Fagus Sieboldi*, and grows almost always in mixture with it, but beginning at a lower level; and that it often occurs in a bushy form, and does not attain the dimensions of the other species.

FAGUS SIEBOLDI. Common Beech of Japan. (Native name, *Buna*.)

Fagus Sieboldi, Endlicher, *Gen. Suppl.* iv. 2, 29 (1847).

Fagus sylvatica, L., γ *asiatica*, DC. *Prod.* xvi. 2, 119 (1864).

Fagus sylvatica, L., δ *Sieboldi*, Maximowicz, *Mél. Biol.* xii. 543 (1886).

Shirasawa, *l.c.* t. 35, figs. 14-26.

This is the common beech which occurs in Japan, and it is considered by Japanese botanists³ to be only a variety of the European beech. Shirasawa⁴ has given some details concerning its distribution, in connection with a figure which illustrates well the botanical characters of the species. Sargent⁵ was doubtful if the common beech in Japan was not quite identical in all respects with the European beech.

Elwes saw it in many places in Central Japan, but not in Hokkaido. Near Nikko it grows to a large size at 2000-4000 feet, but not in pure woods, being, so

¹ Radde, *Pflanzenverbreitung in den Kaukasusländern*, 182 (1899).

² Schneider, *Laubholzkunde*, 152.

³ Matsumura, *Shokubutsu-me-i*, 123.

⁴ Shirasawa, *l.c.* 86.

⁵ Sargent, *Forest Flora of Japan*, 70.

far as he saw, always mixed with other trees, though Goto says¹ that it occurs in Honshu and in the southern half of Hokkaido in almost unmixed woods, and that in Aomori, Iwate, Echigo, and Yamagata, pure woods of vast dimensions are seen in the mountains above 1000 feet elevation. It is one of the most important trees for firewood and charcoal, but little valued for building. It grows well in shade, and continues to grow to a great age, sometimes attaining enormous size. The Ainos in old Japan are said to have used the tree for dug-out canoes. The largest trees measured by Elwes were in the Government forest of Atera, in the district of Kisogawa, where there were tall straight trees in mixed deciduous forests of beech, magnolia, oak, birch, and maple, about 100 feet high and 9-10 feet in girth. Here the wood was not of sufficient value to pay the expense of carriage.

FAGUS SINENSIS.

Fagus sinensis, Oliver, in Hook. *Icon. Plant.* t. 1936 (1891); Diels, *Flora von Central China*, 284 (1901).

Fagus sylvatica, L., var. *longipes*, Oliver, in sched. ad Hook. *Icon. Plant.* t. 1936 (1891); Franchet, *Jour. de Bot.* 1899, p. 90.

Fagus longipetiolata, v. Seemen, in Engler, *Bot. Jahrb.* xxiii. *Beibl.* 57, p. 56 (1897).

This tree was discovered by Henry in the mountains south of the Yangtse, near Ichang, in Central China. It occurs scattered in deciduous forests at 3000-4000 feet altitude, and sometimes attains a considerable size, one tree being noted as 15 feet in girth. Von Rosthorn subsequently found the same species in the mountains south of Chungking, in Szechuan.

FAGUS ENGLERIANA.

Fagus Engleriana, v. Seemen, in Diels, *Flora von Central China*, 285, cum figurâ (1901).

Fagus sylvatica, L., var. *longipes*, Oliver, "var. *bracteolis involucri exterioribus spatulatim dilatatis*," Oliver, in sched. ad Hook. *Icon. Plant.* t. 1936 (1891).

Fagus sylvatica, L., var. *chinensis*, Franchet, *Jour. de Bot.* 1899, p. 201.

This species was also discovered by Henry, but in the mountains north of the Yangtse from Ichang in Central China. Subsequently specimens were sent to Europe by Père Farges from North-East Szechuan, and by von Rosthorn from Southern Szechuan. It is a smaller tree than *F. sinensis*, and was seen by Henry on wooded cliffs.

Neither of the Chinese beeches form pure woods. A beech of considerable size was seen by Henry in Yunnan, in a mountain wood near Mengtse, at about 5000 feet elevation, and is possibly a distinct species. This rare tree is remarkable in that it extends the southern limit of the northern beeches to as low as 23° N.

¹ *Forestry of Japan* (1904), p. 22.

FAGUS SYLVATICA, COMMON BEECH

Fagus sylvatica, Linnæus, *Sp. Pl.* 998 (1753). Loudon, *Arb. et Frut. Brit.* iii. 1950 (1838).

A large tree, commonly 100 feet high (attaining 130 to 140 feet under very favourable conditions), with a girth of 20 feet or more. Bark¹ usually grey and smooth, but often in old trees becoming fissured and scaly, especially near the base. Branchlets of two kinds; the short shoots ringed and bearing only a terminal bud in winter and one, two, or three leaves in summer; the long shoots slender, glabrous, with many leaves in two lateral rows (in winter the buds are seen arising from the upper side of the twig, the leaf-scars being on the lower side).

Leaves: deciduous, alternate, two-ranked, varying in size with altitude and vigour, those of trees at high elevations being much smaller; generally oval, somewhat acuminate at the apex, slightly unequal at the base, undulate or toothed in margin, with 6-10 pairs of lateral nerves, which with the midrib are raised on the under surface of the leaf, and are more or less pubescent.

Flowers: arising in the axils of the leaves of the young shoots; the male heads by long pendulous stalks, the female involucre by short erect stalks above the male flowers on the same branchlet or on separate branchlets. The true fruits are usually two together enclosed in a woody involucre, which is beset by prickles. Each fruit contains a seed, triangular in shape like the fruit containing it. The seed hangs from the top of the cell and has no albumen.

Seedling: the seedling of the beech² has a long primary root and a stout radicle, 1-2 inches long, bearing 2 large sessile oval cotyledons, which are dark green above and whitish beneath. The first true leaves of the beech are opposite, ovate, obtuse, and crenate, borne on the stem an inch or so above the cotyledons. Above this pair other leaves are borne alternately, and the first season's growth terminates in a long pointed bud with brown imbricated scales.

The common beech is distinguishable at all seasons by its bark, which is only simulated by the hornbeam; but in the latter tree the stem is usually more or less fluted. In winter the pointed buds, arranged distichously on the long shoots and composed of many imbricated scales, are characteristic; while in length they exceed

¹ There is much difference in the colour and roughness of the bark, which varies with age, soil, situation, and exposure. On the dry, sandy soil of Kew Gardens this bark of the beech is so different from that seen on calcareous soils that it might almost be mistaken for a hornbeam, and Elwes has observed the same in the Botanic Gardens at Edinburgh, where the trees are exposed to the salt east wind. These variations are not, however, entirely caused by local conditions, but are sometimes found in trees standing close together. Professor Balfour pointed out to Elwes two beeches in the Edinburgh garden of which one has the bark rough and scaly, and regularly comes into leaf fifteen to twenty days before another tree similar in size which grows next to it, whose bark is smooth and silvery. Whether these variations are correlated with any differences in the wood does not seem to have been proved in England; but it is evident that for cold and exposed situations it would be advantageous to sow only the seed of the late leafing and flowering trees.

² The beech seedling has its cotyledons green and above ground; those of the oak and chestnut remain in the soil. In the hornbeam, hazel, and alder, the cotyledons are aerial, but the first pair of true leaves above them are alternate.

those of any tree ordinarily cultivated in England, being about $\frac{3}{4}$ inch long. The buds of the European beech are wider at the middle than at either end; while in the American beech they are as narrow in the middle as they are at the base.

VARIETIES

A great number of varieties of the common beech occur, some of which have originated wild in the forests, whilst others have been obtained in cultivation.

Var. *purpurea*, Aiton, Purple Beech. A complete account of the origin of this variety appeared in *Garden and Forest*,¹ 1894, p. 2. From this it would appear that a purple beech² discovered in the eighteenth century in the Hanleiter forest near Sondershausen in Thuringia, is the mother tree of those which now adorn the pleasure grounds of Europe and America. This is the only authenticated source from which horticulturists have derived their stock. The purple beech was, however, long known before the Thuringian tree was discovered. In Wagner's *Historia naturalis Helvetiæ curiosa* (Zurich, 1680) mention is made of a beech wood at Buch, on the Irchel mountain in Zurichgau (commonly called the Stammberg), which contains three beech trees with red leaves, which are nowhere else to be found. These three beeches are again referred to in Scheuzer's *Natural History of Switzerland*, published in 1706; and the legend is stated that according to popular belief five brothers murdered one another on the spot where the trees sprang up. Offspring of these trees were carried into a garden, where they still retained their purple colour. The purple beech has also been observed in a wild state in the forest of Darney in the Vosges.

The purple beech has delicate light red-coloured foliage, which is of a pale claret tint in the spring, becoming a deep purple in summer. In early autumn the leaves almost entirely lose their purple colour, and change to a dark dusky green. The buds, young shoots, and fruits are also purple in colour. The involucre are deep purple brown in autumn, becoming browner with the advance of the season. The purple beech often fails to fruit regularly; still many individuals of this variety do produce fruit, and this has been sown, and in some cases produced plants almost all with purple leaves, not 5 per cent reverting to green.³ The colour in the leaves, etc., is due to a colouring matter in the cells of the epidermis. The variety submits well to pruning or even to clipping with the shears; and may therefore, if necessary, be confined within narrow limits or grown as a pyramid in the centre of a group of trees.

A fine purple beech⁴ grows in Miss Sullivan's garden, Broom House, Fulham, which is 82 feet high and 12 feet 2 inches in girth.

¹ See also *Gartenflora*, 1893, p. 150.

² This tree is still living. See Lutze, *Mitth. des Thüringer Bot. Vereines*, 1892, ii. 28.

³ Elwes saw at the Flottbeck Nurseries near Hamburg, formerly occupied by the celebrated nurseryman John Booth, a fine hedge of purple beech, which Herr Ansorge told him was raised from a cross between the purple and the fern-leaved beeches. Of the produce of this cross 20 to 30 per cent came purple, but none were fern-leaved. This coincides exactly with his own experience in raising from seed. But in *Mittheilungen Deutschen Dendrologischen Gesellschaft*, 1904, p. 198, Graf von Schwerin describes as *F. sylvatica ansorgei* a hybrid from these two varieties which seems to combine the characters of both.

⁴ Figured in *Gard. Chron.* 1898, xxiv. 305. See also *ibid.* 1903, xxxiii. 397, for notes on sub-varieties of the purple beech.

Another occurs at Hardwick, Bury St. Edmunds, the seat of G. M. Gibson Cullum, Esq., which in 1904 was 11 feet 9 inches in girth, and about 80 to 90 feet in height. Bunbury¹ considered this to be the finest purple beech in England, and says it produces abundance of fruit, from which young trees have been raised.

Var. *cuprea*, Loddiges, Copper Beech.—This is only a sub-variety of the purple beech, distinguished by its young shoots and leaves being of a paler colour. The largest purple or copper beech which Elwes has seen is in the park at Dunkeld, Perthshire, not far from the Cathedral. This measures 86 feet high, with a girth of 15 feet 3 inches, and does not show any evidence of having been grafted. There is a very fine one at Corsham Court, the seat of General Lord Methuen, 85 to 90 feet high, by 14 in girth, forking at about 10 feet. At Scampston Hall, Yorkshire, Mr. Meade-Waldo tells us of two large spreading trees on their own roots, 11 feet 6 inches and 10 feet 6 inches in girth respectively. At Beauport, Sussex, the seat of Sir Archibald Lamb, Bart., a copper beech measured 12½ feet in girth in 1904. At Syston Park, Lincolnshire, the seat of Sir John Thorold, Bart., there is one nearly as large (12 feet 2 inches girth). A copper beech at Bell Hall, York, which was planted in 1800, measured in 1894, 9 feet in girth, the diameter of the spread of the branches being 74 feet. At Castle MacGarrett, Claremorris, Ireland, the seat of Lord Oranmore, there is a beautiful copper beech, which in 1904 was 70 feet high and 9 feet 10 inches in girth. In Over Wallop Rectory grounds, in Hampshire, a copper beech measured 9 feet 4 inches in 1880.

Two fine trees occur at Clonbrock, in Co. Galway, the seat of Lord Clonbrock. One measured in 1904 a length of 76 feet and a girth of 12 feet 9 inches. The other was 7 feet 6 inches girth in 1871, and in 1880 it had increased to 8 feet 5 inches.

The copper beech² is rarely used as a hedge, but there is one in the gardens of Ashwellthorpe Hall, Norwich, which is 138 yards long, 8 feet high, and about 5 feet through. It was planted about seventy years ago from seedlings by the Hon. and Rev. R. Wilson. The colouring in spring is very beautiful.

There is a sub-variety³ of the copper beech in which the leaf is edged with pink whilst young, but later in summer it becomes nearly like the type. This variety has been called *Fagus purpurea roseo-marginata*, and it has been recommended as a hedge-plant, to be clipped two or three times during summer so as to obtain several crops of young shoots.

Var. *atropurpurea*.—The leaves in this are of a darker colour than in the ordinary purple beech.

Var. *atropurpurea Rohani* is quite different from the last, as the form of the leaves is similar to that of the fern-leaved beech, but their colour is like that of the copper beech.

Var. *purpurea pendula*.—This is a weeping form of the purple beech. It is of slow growth.

¹ *Arboretum Notes*, p. 117.

² *Garden*, July 30, 1904, Answers to Correspondents.

³ *Gard. Chron.* June 23, 1888, p. 779.

Var. *Zlatia*, Späth,¹ Golden Beech.—This was found wild in the mountains of Servia by Professor Dragashevitch. It is known in Servia as *Zladna bukwa* (golden beech).

Var. *striata*, Bose.¹—This was discovered many years ago in a forest in Hesse. Soon after opening, the leaves show a regular golden striation parallel with the nerves, and this appearance lasts till the leaves fall off in autumn. It was introduced in 1892 by Dippel.

Various other coloured varieties have been obtained by horticulturists. In var. *variegata* the leaves are particoloured with white and yellow, interspersed with some streaks of red and purple. In var. *tricolor* the leaves are dark purplish green, spotted with bright pink and shaded with white. There are also gold-striped (var. *aureo-variegata*) and silver-striped (var. *argenteo-variegata*) varieties.

Var. *heterophylla*, Loudon, Fern-leaved Beech.—The leaves are variously cut, either in narrow shreds like some ferns, or in broader divisions like the leaves of a willow. This variety has received a great number of names, as *laciniata*, *comptoniaefolia*, *incisa*, *salicifolia*, *asplenifolia*, etc. The tree occasionally bears normal and cut leaves on the same twig, or normal and cut leaves on different twigs. It bears fruit occasionally, which, according to Bunbury,² is smaller than that of the common beech, the cupule being shorter in proportion to the nuts. The leaf-buds are considerably smaller than those of the common form; and the twigs are often very pubescent. The origin of this variety is unknown.

There is a good specimen of this tree at Devonhurst House, Chiswick, which measured in 1903 55 feet in height, and 8 feet 2 inches in girth at 3 feet, just under a great horizontal branch.

At Barton, Bury St. Edmunds, a fern-leaved beech in 1904 was 53 feet high, with a girth of 5 feet 1 inch. This tree² was planted in 1831, but grew slowly, in 1869 being only 15 feet high, with a trunk 3 feet round. In 1868 the tree bore some twigs with ordinary leaves; and it first fruited in 1869, the crop being a very small one.

There are large and well-shaped trees of this form at Strathfieldsaye measuring 50 feet by 7 feet 5 inches; at Fawley Court of the same size exactly, and weeping to the ground; and at Stowe near Buckingham.

Var. *quercooides*, Pers., Oak-leaved Beech.—The leaves in this variety are long-stalked, with an acute base and acuminate apex; margins pinnately and deeply cut, the individual segments being acute.

Var. *cristata*, Lodd. (also known as var. *crispa*).—Small and nearly sessile leaves, crowded into dense tufts, which occur at intervals on the branches. This form rarely attains a large size.

Var. *macrophylla* (also known as *latifolia*).—The leaves in this form are very large. In a specimen at Kew, from the garden of the Horticultural School at Vilvorde, they attain 7 inches in length and 5 inches in width. A large specimen of this tree, some fifty years old, occurs at Enys in Cornwall. The buds, as might

¹ *Gard. Chron.* 1892, xii. 669. This is an account of Späth's novelties by Dr. Edmund Göze of the Greifswald Botanic Gardens.

² *Arboretum Notes*, p. 118.

be expected, in this variety are considerably larger than those of the ordinary form.

Var. *rotundifolia*, Round-leaved Beech.¹—The leaves are very small, round, and bright green, and are set close on the twigs. This variety has an upright habit of growth, and was introduced in 1894 by Jackman of Woking.

Var. *grandidentata*.—A form with conspicuously toothed leaves.

Var. *pendula*, Loddiges, Weeping Beech.—Several forms of this variety occur, but in all the smaller branches hang down. The main branches are irregularly disposed, so that the tree often has a very rugged outline. This variety should be grafted at a good height, as otherwise many of the pendulous branches will lie upon the ground; and the main branches, if they show a tendency to droop too much, should be supported. Weeping beeches may be tall and slender, or low and broad, or quite irregular, depending upon the direction of the larger branches, which may grow outwards or upwards, or in almost any direction; the smaller branches only are uniformly pendulous.

The weeping beech has been observed wild in the forest of Brotonne, in Seine-Inférieure, France.

A good example of a tall, slender, weeping beech may be seen near Wimbledon Common, on the estate lately owned by Sir W. Peek. A fine specimen occurs at Barton, which in 1904 was 77 feet high and 5 feet 2 inches in girth. Elwes has noted a very picturesque and well-shaped one at Endsleigh, near Tavistock, the Devonshire seat of the Duke of Bedford. Several have been figured in the *Gardeners' Chronicle*, e.g. a group of three trees² at Ashwick Hall, Gloucestershire, which were planted about 1860. In the Knap Hill Nursery³ at Woking, and in the nursery⁴ of R. Smith and Co. at Worcester, there are fine specimens. Another good specimen,⁵ occurring in Dickson's nursery at Chester, is figured in the *Garden*.

Many forms of weeping beech have been described as sub-varieties, as *purpurea pendula*, mentioned above; var. *miltonensis*, with branches less pendulous, found wild in Milton Park, Northamptonshire; var. *borneyensis*, found wild in the forest of Borney, near Metz, and described as having an erect stem and distinctly pendulous branches; var. *pagnyensis*, discovered in the forest of Pagny in the department of Meurthe-et-Moselle in France; var. *remillyensis*, found in the forest of Remilly, near Metz.

Var. *tortuosa*, Parasol Beech.⁶—In this curious form, the branches, both large and small, and the branchlets are all directed towards the ground. It is not to be confounded with the preceding variety, in which only the slender branches are pendulous; and is analogous rather to the weeping ash. Beeches of this form have, even in old age, a very short and twisted stem, with a hemispherical crown, which sometimes touches the ground; and it scarcely ever grows higher than 10 feet. This variety has been found wild in France, in the forest of Verzy, near Rheims, and also

⁴ *Ibid.* Dec. 29, 1900, suppl.

⁵ *Garden*, Dec. 5, 1903, p. 167.

⁶ For a complete account of the occurrence of this curious form in the forests of the east of France, see Godron, *Les Hêtres tortillardés des environs de Nancy*, Mém. de l'Acad. de Stanislas, Nancy, 1869. Godron says that their growth is infinitely slower than that of normal beech. See also *Rev. Hort.*, 1861, p. 84, and 1864, p. 127.

in the neighbourhood of Nancy. Fruits of this form have been sown in the garden of the Forest School of Nancy, and have reproduced the twisted form in about the proportion of three-fifths; the other two-fifths of the fruit produced form like the common beech and intermediate varieties.¹

Many other varieties have been described; and other forms possibly occur wild which have not been noticed. Major M'Nair sent to Kew in 1872 from Brookwood, Knaphill, Surrey, a specimen from a tree growing there, and reported to be in vigorous health, in which the leaves are remarkably small and have only four pairs of lateral nerves.

(A. H.)

DISTRIBUTION

The beech is indigenous to England. Remains of it have been found in neolithic deposits at Southampton docks, Crossness in Essex, in Fenland, in pre-glacial deposits in the Cromer forest bed, and at Happisburgh, Norfolk.² Names of places of Saxon origin, in which the word beech occurs are very common, as Buckingham, Buxton, Boxstead, Boxford, Bickleigh, Boking, etc. The existence of the beech in Britain in ancient times has been questioned on account of the statement by Julius Cæsar³ that *Fagus* did not occur in England. H. J. Long⁴ has discussed what tree the Romans meant by *Fagus*, and the evidence is conflicting. Pliny⁵ described as *Fagus* a tree which is plainly the common beech. However, Virgil's⁶ statement that *Castanea* by grafting would produce *fagos* indicates rather that *Fagus* was a name used for the sweet chestnut; and this view is confirmed by the fact that out of the wood of *Fagus* the Romans made vine-props and wine-casks. The Latin word *Fagus* is derived immediately from the Greek *φηγός*; and the *φηγός* of Theophrastus is certainly the chestnut, probably the wild tree which is indigenous to the mountains of Greece. Cæsar's statement probably implies that in his day the sweet chestnut did not occur in Britain.

The beech is not believed to be indigenous in Scotland and Ireland,⁷ and no evidence is forthcoming of its occurrence in prehistoric deposits in those countries. An able writer in *Woods and Forests* (1884, June 11, p. 404) contests this view, and speaks of the existence of two beech woods in the north of Scotland, not 10 miles from the most easterly point of Britain, where the trees were larger than any other timber tree, not excepting the Scotch fir, and where it produced fertile seed, while that of the oak was abortive. These woods were high and exposed, but the soil was good. In view of the way in which the beech ascends in the Vosges and the Jura to cold, bleak situations, finally becoming at 4000 feet a dwarf shrub, which

¹ The parasol beech, or a form closely like it, has been found in Ireland, according to a correspondent of *Woods and Forests*, Jan. 1885, who writes as follows:—"Near to Parkanour, in Tyrone, the residence of Mr. J. Burgess, stand two beeches, which at a short distance resemble heaps of leaves more than trees. They were found in the woods sixty years since, and are from 6 feet to 8 feet in height and 15 feet diameter, and of dense drooping habit. Upon creeping inside, I found them to branch off at 2 feet or 3 feet from the ground, where one was nearly 5 feet in circumference. The arms and branches are not unlike corkscrews. The inferior branches and matted rubbish, if cleared out, would greatly improve their appearance, as the singular growth would then be visible. They might, if sent out, become a valuable adjunct to the upright yew, which flourishes in Ireland, the finest of which I have yet seen being 24 feet high and 12 feet through, and well filled in the centre.—C. I."

⁶ *Georg.* ii. 71.

⁷ The name in Irish is *crann sleamhain*, the "slippery tree," so-called from the smoothness of the bark.

forms the timber line, it would be remarkable if the beech had not in early days gained a footing in Scotland and Ireland. The mere negative evidence is of little value, as scarcely any scientific work has yet been done in the way of exploration of the peat-mosses and other recent deposits; and the woods, from which are made the handles of numerous prehistoric implements preserved in our museums, have rarely been examined.¹

The beech occurs in a wild state throughout the greater part of Northern, Central, and Western Europe, usually growing gregariously in forests which, when undisturbed by man, have a tendency to spread and take the place of oak, which, owing to its inability to support such dense shade, is often suppressed by the beech.

In Norway, according to Schubeler,² it is called bok, and is wild only near Laurvik, where he believes it to be truly indigenous, and is a small tree, the largest he measured being 7 feet 4 inches in girth. At Hosanger, however, a planted beech had in 1864 attained 75 feet at 81 years old, with a diameter of 27 inches. It ripens seed as far north as Trondhjem in good years, and exists in Nordland as far north as lat. 67°.56.

In Sweden its most northerly wild habitat is Elfkalven, lat. 60°.35, though it has been planted as far north as lat. 64°.

In Russia the beech extends only a little way,—its eastern limit in Europe passing the Prussian coast of the Baltic between Elbing and Königsberg, about 54° 30' N. lat., and running south from Königsberg, where the last spontaneous beeches occur on the Brandenburg estate, continuing through Lithuania, eastern Poland, Volhynia, where beech woods still occur between lat. 52° and 50°, and Podolia to Bessarabia. It is absent from the governments of Kief and Kherson, but reappears in the Crimea, where, however, it is only met with in the mountains of the south-east coast. In the Caucasus, Persia, and Asia Minor it is replaced by the closely allied species, *Fagus orientalis*.

In Finland and at St. Petersburg it exists as a bush only, but is not wild. On the southern shores of the Baltic it forms large forests, and in Denmark is one of the most abundant and valuable timber trees, growing to as large a size and forming as clean trunks as it does farther south. Lyell speaks of it as follows:³—"In the time of the Romans the Danish isles were covered as now with magnificent beech forests. Nowhere in the world does this tree flourish more luxuriantly than in Denmark, and eighteen centuries seem to have done little or nothing towards modifying the character of the forest vegetation. Yet in the antecedent bronze period there were no beech trees, or at most but a few stragglers, the country being then covered with oak."

At page 415 he says further—"In Denmark great changes were taking place in the vegetation. The pine, or Scotch fir, buried in the oldest peat, gave place at length to the oak; and the oak, after flourishing for ages, yielded in its turn to the

¹ In a paper by H. B. Watt on the "Scottish Forests in Early Historic Times," printed in *Annals of the Andersonian Nat. Soc.* ii. 91, Glasg., 1900, which contains many interesting particulars of the oak and other trees, no mention is made of the Beech. In the Highland Society's *Gaelic Dictionary* (1828), *faidhbhile* is given as the word for beech; here *faidh* is cognate with *fagus*, *bhile* being one of the Gaelic terms for *tree*. This name is also known in Ulster.

² Schubeler, *Viridarium Norvegicum*, vol. i. 521.

³ Lyell, *Antiquity of Man*, 2nd. ed. 1873, pp. 17, 415.

beech; the periods when these three forest trees predominated in succession tallying pretty nearly with the ages of stone, bronze, and iron in Denmark."

All over Germany, except in the sandy plains of the north, it is one of the principal forest trees; but, so far as we have seen, does not—or is rarely allowed to attain—such a great size as in England. In Central and Southern Germany and in Eastern and Southern France it seems to be indigenous only in hilly districts and mountains.

In the north of France it attains perfection, and forms very large forests, usually mixed with oak, which sometimes contain trees of immense height, but is not planted as an ornament to parks as much as in England.

According to Huffel's *Economie Forestière*, 362 (1904), the finest beech forest in France is that of Retz, also called Villers Cotterets, which contains 37,000 acres, on a soil composed of deep sand, mixed with a slight proportion of clay. The trees consist almost entirely of beeches, there being only a small number of oaks and hornbeams. In the best plot of this forest, the canton of Dayancourt, which is 30 acres in extent, there were, in 1895, 1998 beech trees, 20 oaks, and 16 hornbeams. The beeches contain 329,433 cubic feet of timber, and reach a height of nearly 150 feet with clean stems of 80 to 90 feet. Their age in 1895 was 183 years, and they were considered to have reached their maximum development and to be on the point of going back.

In an account of the beech, Mr. Robinson has stated in *Flora and Sylva* that in the forest of Lyons-la-Forêt, near Rouen, beeches of 160 feet in height are found; but on asking my friend M. Leon Pardé, inspector of forests at Beauvais (Oise), near Paris, whether this statement could be confirmed, he was good enough to send me a letter from the forest officer there, who says that the tallest beech known in France is the one which I saw in the Forêt de Retz, when the English Arboricultural Society visited France in 1903,¹ the height of which was given as 45 metres, about 147 feet. This tree measured 13 feet 2 inches in girth, and was straight and clear of branches to 91 feet. It was estimated by the English measurement to contain 560 cubic feet to the first branch, or 700 feet in all. This letter goes on to say that the tallest trees at Lyons-le-Forêt do not, in his opinion, exceed a total height of 35 metres, though one has doubtfully been stated to attain 37½ metres.

Two of the finest and tallest beeches in France are the one called "La Bourdigalle" in the Forêt de Lyons at La Haye (Seine Inf.), which is 35.80 metres high by 5.55 metres at 1 metre, and is supposed to be from 375 to 575 years old.²

Another called "Le Trois Hêtres," in the forest of Brotonne at Guerbaville (Seine Inf.), has three straight clean stems rising from a single base to a height of nearly 35 metres, with a girth at 1 metre of about 18 feet. This very remarkable tree is figured on plate xi. of the work cited below.²

In Switzerland pure beech forest is found as high as 4500 feet, and at 5000 assumes a shrubby habit.

In the Austrian Alps and Carpathians it is also a common tree, forming vast forests, which are sometimes pure, sometimes mixed with other trees.

¹ *Trans. Eng. Arb. Soc.* v. pt. ii. p. 209.

² Gadeau de Kerville, *Les Vieux Arbres de la Normandie*, 143 (1893).

In Italy it is found only in the mountains; in the Apennines it is one of the dominant trees at from 3000 to 5000 feet. In the Sila mountains of Calabria, Elwes found it covering the mountains above the limit of chestnut, at from 3000 to 5000 feet and upwards. It is usually coppiced for charcoal and firewood; but it attains a considerable size, the largest measured being about 90 feet by 10-12 in girth. Here it is often mixed with the Calabrian pine. In Sicily it finds its southern limit on Mount Etna, where it ascends to 7200 feet.

In Spain the beech occurs in the Pyrenees and in the northern provinces only, its most southerly known habitat being in lat 40° 10' east of Cuença. In Portugal it has not, so far as we know, been recorded to exist.

The finest natural beech forests seen by us in Europe are on the northern slopes of the Balkans, where it grows as pure forest from near the foot of the mountains up to about 4000 feet. The trees are very straight and clean, but are being rapidly felled in those places where they are most accessible. Boissier¹ says that the beech occurs in northern Greece on Mounts Pindus and Pelion. Elwes found it in Macedonia, on the north side of Mount Olympus.²

(A. H. and H. J. E.)

CULTIVATION

Seed is without doubt the best means of reproducing the tree, and I am inclined to think that the best and cleanest trunks are produced by seedlings which have never been transplanted, but opinions differ on this question. Seed is only produced in quantity at intervals of several years, and in some years a large proportion of the seeds, even in districts where the beech grows well, are mere empty husks.

The season of 1890 was probably the best for beech-mast in England which had occurred for many years, and I took particular pains, by enclosing certain spots where I found a number of germinating seeds in the following April, to protect them. But a severe frost, which occurred in the middle of May, destroyed all or nearly all the seedlings in the open, and those whose germination had been delayed by dense shade, or a thick covering of leaves, mostly withered away in the dry summer which ensued, before their rootlets had become established in the ground. Notwithstanding this, in most woods where rabbits, pheasants, and wood-pigeons are not so abundant as to devour all the seedlings and seeds, a good number of seedling beech of the year 1901 may still be found, and in the New Forest and elsewhere the ground in suitable spots is covered with seedlings.

Whether the seed should be sown when ripe or kept until the following spring is a question which must be decided by local conditions and experience, but where the danger of late spring frosts is great, I should prefer keeping it in an airy, dry loft spread thinly on a floor until April, or even the first week in May, as if February and March are mild, it will germinate in March and run great risk of being frozen in April or May. On March 11, 1901, I found a quantity of

¹ *Flora Orientalis*, iv. 1175.

² Halácsy, *Cousp. Flor. Græcæ*, iii. 124 (1904), says that the beech forms in Greece large woods in the mountains, and gives its distribution as follows:—Thessaly—Mountains of Pindus, Chassia, Olympus, Ossa, and Pelion; Acarnania—Mount Kravara; Ætolia—Mount Oxyes.

beech-mast on the lawn at Heythrop Park which had already germinated and had the radicle protruding as much as $\frac{1}{2}$ inch. I gathered a basketful and sowed it two days later, covering the drills with beech-leaf mould. Most of this was above ground in April, and where not protected by branches over the beds, was destroyed by frost. Stored seed sown at the same time was almost all devoured by mice and rooks, which seemed to follow the drills with great care, whilst seed sown broadcast on a freshly ploughed surface and covered by one turn of a harrow, produced a certain number, but still a very small proportion of plants. These were, in June 1904, still very small and stunted, not more than 3-5 inches high, whilst seedlings of the same age raised on good rich sandy soil in an Edinburgh nursery were from $1\frac{1}{2}$ to 2 feet high.

In the autumn of 1902 I found it impossible to procure any beech-mast in Great Britain, and after many inquiries procured some German seed early in April. Part of this was dibbled in a field of wheat, but so few plants could be found when the wheat was cut that the experiment was a practical failure. I sowed a part of this seed early in May in the garden, which germinated in June, and thus escaping spring frosts it grew without a check, and the seedlings were 4 to 6 inches high in the autumn.

Judging from these results it appears to me that, except in woods or where there is shelter, it is not economically desirable to raise beech from seed where it is to grow, and that spring sowing is preferable to autumn.

Seedlings are easy to transplant if their roots are not allowed to become dry, and the percentage of loss in 20,000 sent to me from Edinburgh in the winter 1902-3 was not more than 5 to 10 per cent. But if the trees are older and the roots are bad or have been heated in transit, or exposed too long to the air, the loss will be very great; and in most cases I should not plant out on a large scale trees of over two years old two years transplanted, though for specimen or lawn trees they may be safely moved when 6 to 10 feet high, or even more, if properly transplanted every two years.

SOIL AND SITUATION

Though the beech will grow on almost any soil except pure peat and heavy wet clay, it comes to its greatest size and perfection on calcareous soil or on deep sandy loam, and usually in pure woods unmixed with other trees.

The finest beech woods in England are, or rather were, in the Chiltern Hills, Bucks, in the neighbouring counties of Oxford and Herts; in the valleys of the Cotswold Hills; and in Sussex.

Sir John Dorington, M.P., tells me that he cut 2 acres 1 rood 13 poles of beech on a steep bank opposite his house at Lypiatt Park, Stroud, in 1897, growing on thin oolite limestone brash, which at 1s. 2d. per foot produced £562, equal to about 9634 feet. And off 4 acres of the same wood in 1875 he sold beech to the value of £1100, being at the rate of £275 per acre. This was supposed to be about 150 years old, and is the best actual return of value from timber on such land which I know of. He also bought a beech wood of 26 acres growing on similar soil in 1898, on which the timber, supposed to be about seventy years old, was valued at £2200, equal to £85 per acre. He cut £600 worth of thinnings out of it the year

following; and as the trees are growing fast, considers that it might now be valued at the same price per acre. Sir John considers, from experience in his own plantations, that planted beech will do as well as when naturally seeded. His old woodman, now dead, was for long of a contrary opinion, but changed his mind latterly from his own experience.

It is necessary to say something about the actual conditions and returns from the Buckinghamshire beech woods, which have been held up by some writers as an example of what may be done by following the system known as *jardinage* in France, which consists in thinning out the saleable trees every ten or twelve years and allowing natural seedlings to come up in their places.

During a visit of the Scottish Arboricultural Society on July 30, 1903, to this district, in which I took part, it was stated by one of the principal land agents in the district that £2 per acre was a common return over an average of years on woods managed on this system, which seems to have grown up during the last sixty years, partly through the legal disability of the owners to make clear fellings, and partly owing to the regular demand for clean beechwood of moderate size for chair-making. But what I saw myself led me to believe that though such a return may have been obtained for a short period on the best class of beech woods, it is not likely to continue, and that if an owner had a free hand and was not liable for waste, clear felling of the mature timber about once in 60-100 years would probably in the long-run be a better system. And this opinion was confirmed by Mr. George James, agent for the Hampden estate, who thinks that 15s. per acre, which is about the average rateable value of these woods, is as much as they are actually worth, and that when you get fine timber clean and well grown, as on Mr. Drake's estate at Amersham, many natural seedlings do not occur, but that on Earl Howe's estate at Dunn where, forty years ago, all or nearly all of the timber was cut, there is a good growth of young seedlings.

Professor Fisher of Cooper's Hill has written a very instructive article¹ on the Chiltern Hill beech woods, in which he states that these are probably the northern and western British limit of the indigenous beech forest, which was probably eradicated during the glacial period in the north of England; though remains found in the submarine forest-bed at Cromer, in Norfolk, prove that it existed before this period farther east. He quotes measurements taken by Mr. A. S. Hobart Hampden, now director of the Forest School at Dehra Dun, India, which show that on the average it takes ninety years in this district for beech to attain 3 feet in girth at breast height, and that a full crop of seed cannot be expected from trees much younger than eighty years when grown in dense order. He agrees with me that in many of the woods, including those which belong to Eton College, over-thinning has been prevalent, and states that rabbits and brambles have in many cases prevented the natural regeneration from being as complete as it must be to keep such woods in profitable condition under the decennial selection system.² And as

¹ *Land Agent's Record*, April 9 and 16, 1904.

² A paper by Mr. L. S. Wood, in the *Trans. Eng. Arbor. Soc.* v. 285 (1903), gives many particulars of the beech woods in this district.

the furniture factories of High Wycombe are now largely supplied with American birch and other foreign timber, which can be imported at a cheaper rate than beech is locally worth, I am inclined to think that where these woods have become too thin to be profitable, they would pay better if the seeding of ash—which grows well on this land though not to the largest size—was encouraged, and the vacant spaces filled up with larch, which, when mixed with beech, usually keeps healthy and grows to a larger size than it does alone.

It is probable, however, that as our coal supplies diminish, the value of firewood in England will increase, and as beech is one of the best firewoods we have, and one of the most economical to convert into suitable sizes, I should advise its being more largely planted in districts where coal is distant and costly.

As a nurse to other forest trees, especially larch and oak, it has a value greater than any deciduous tree, because, if not allowed to overtop its neighbours, its shade and the decay of its leaves preserve the soil in a cool, moist, and fertile condition. On poor calcareous and chalk soil it is specially valuable, and should be planted in mixture with most kinds of other trees, provided rabbits can be permanently excluded; but on account of its thin bark it is never safe in a deep snow or in hard winters from rabbits, which will bark the roots of trees 100 years old as readily as young trees.

The distance apart at which beech should be left in plantations, must depend on the goodness of the soil and on the size at which the trees can be most profitably cut. The better the land the thicker it may stand, but on really poor soil it grows so slowly if crowded, that as soon as it has attained a sufficient height and cleaned itself from branches up to 30-50 feet, it should be thinned to about 150 trees or even less to the acre. And I have often observed that on soils which are not naturally favourable for beech, it will not under any circumstances grow so straight and clean as in woods where natural regeneration is easy.

Notwithstanding what Loudon and some German foresters say about the beech being unfit for coppice-wood, I can show beech stools of considerable age which have been regularly cut over at intervals of about eighteen years for at least a century; whilst the growth of shoots from the stool on the dry rocky bank in Chatcombe Wood, near Seven Springs, on the Cotswold Hills, is faster than that of ash similarly treated. In the mountains of Calabria also, I have seen hillsides covered with beech scrub which appeared to have been coppiced for firewood for a very long period. Therefore, in cases where the beech has been planted merely as a nurse to oak or other trees, and there is no deciduous tree better adapted to this purpose, I should not hesitate to cut over the trees if they seemed likely to smother their neighbours, with the expectation of getting a quantity of excellent firewood or small poles fit for turning, fifteen to twenty years later.

As a clipped hedge the beech is useful, but does not grow so fast at first as the hornbeam. An excellent example of this fact may be seen near the entrance to Dr. Watney's place at Buckholt, near Pangbourne, where the two are growing in the same hedge; the beech treated in this way keeps its leaves all the winter and makes good shelter.¹

¹ Cf. Loudon, *loc. cit.* p. 1965.

BEECH AVENUES

Sir Hugh Beevor has sent me a photograph of a remarkable avenue of beech trees called Finch's Avenue, near Watford, which is composed of straight, clean, closely planted trees up to 120 feet high (Plate 2).

As an avenue tree the beech is one of the most stately and imposing that we have; but probably because of the difficulty of getting tall, straight standards from nurseries, and their tendency to branch too near the ground when planted thinly, they are not so much in vogue as they were two centuries ago. One of the finest examples I know of in England is the grand avenue in Savernake Forest, the property of the Marquess of Ailesbury. This was planted in 1723, and extends for nearly 5 miles from Savernake House to the hill above Marlborough. It is described and figured in the *Transactions of the English Arboricultural Society*, v. p. 405, and though the trees are not individually of quite such fine growth as those at Ashridge, yet, forming a continuous green aisle meeting overhead, for such an immense distance, it is even more beautiful than the elm avenue at Windsor, or the lime avenue at Burghley, and surpasses both of them in length. The Savernake avenue, however, is not like those above mentioned, planted at regular distances, but seems to have been cut out of a belt.

The beech avenue at Cornbury Park, the property of Vernon Watney, Esq., to whom I am indebted for the following particulars, is, on account of the great size of the trees, one of the most imposing in England. It was probably planted or designed by John Evelyn, whose diary, 17th October, 1664, says: "I went with Lord Visct. Cornbury to Cornbury in Oxfordshire, to assist him in the planting of the park, and beare him company, dined at Uxbridge, lay at Wicckam (Wycombe)." They reached Cornbury the following day, and among the entries for that day is the following: "We designed an handsom chapell that was yet wanting as Mr. May had the stables, which indeed are very faire having set out the walkes in the park and gardens." This Lord Cornbury who, after his father's death, became Lord Clarendon, records in his diary, "1689, September 25. Wednesday.—The elms in the park were begun to be pruned." This avenue is 800 yards long, and runs from the valley where the great beech grew, up the hill to the house. Many of the trees seem to have been pollarded when young at about 15 feet high, but have shot up immense straight limbs to a height of 100 to 110 feet, some even taller.

The Ten Rides in Cirencester Park affords a good illustration of the value of the beech for bordering the broad rides through a great mass of woodland; but the trees here, as at Cornbury and in so many of our old parks, have seen their best days, and when blanks are made by wind or decay, it is beyond the power of man to restore the regular appearance of such a vista.

Whatever pains may be taken to replant the gaps, the trees never seem to run up as they do when all planted together, and the art of planting avenues does not seem to be so well understood or so much practised now, as it was in the seventeenth and eighteenth centuries.

REMARKABLE TREES

As an instance of the rapid growth of the beech, I will quote from a letter of Robert Marsham of Stratton Strawless, near Norwich, to Gilbert White, dated 24th July 1790, in which he says: "I wish I had begun planting with beeches (my favourite trees as well as yours), and I might have seen large trees of my own raising. But I did not begin beeches till 1741, and then by seed; and my largest is now at 5 feet, 6' 3" round, and spreads a circle of + 20 yards diamr. But this has been digged round and washed, etc." In Gilbert White's reply to this letter, dated Selborne, 13th August 1790, he says: "I speak from long observation when I assert, that beechen groves to a warm aspect grow one-third faster than those that face to the N. and N.E., and the bark is much more clean and smooth."

Marsham, replying to White on 31st August (it seems to have been at least fifteen days' post in those days from Norfolk to Hants), says: "Mr. Drake has a charming grove of beech in Buckinghamshire, where the handsomest tree (as I am informed by a friend to be depended on) runs 75 feet clear, and then about 35 feet more in the head. I went on purpose to see it. It is only 6 F. 6 I. round, but straight as possible. Some beeches in my late worthy friend Mr. Naylor's park at Hurstmonceux in Sussex ran taller and much larger, but none so handsome." In a later letter he speaks of one being felled here in 1750 which "ran 81 feet before it headed."

Sir Hugh Beevor informs me that he found it impossible to identify with certainty the trees measured at Stratton Strawless by Marsham, which we shall have occasion to allude to later.¹

It would be impossible to mention more than a few of the finest beech trees in this country, but the photographs which have been reproduced represent a few of those which I have seen myself.

In Hants there are many fine beeches in the New Forest, of which the wood called Mark Ash contains some of the most picturesque, and is to my eyes one of the most beautiful woods from a naturalist's point of view in England, or even in Europe, though it is, like so many of the fine old woods in the New Forest, deteriorating from causes which are described elsewhere. One of the finest trees here is over 100 feet high and 24 feet in girth, dividing at about 10 feet into six immense erect limbs, and entirely surrounded, as are many of the trees in this wood, by a dense thicket of holly.

There is another beech in Woodfidley in the New Forest which Mr. Lascelles considers the finest beech in the forest, and of which the measurement as given by him is 120 feet high, 14 feet 6 inches in girth at 5 feet, carrying its girth well up, with an estimated cubic content of 650 feet.

In Old Burley enclosure is another magnificent beech, rather shut in by other trees, and therefore difficult to measure for height. I estimated it at 110 feet high. The girth was 18 feet, dividing at about 25 feet into two main trunks, which carried a

¹ Cf. *Trans. of the Norfolk and Norwich Nat. Soc.* ii. 133-195.

girth of perhaps 8 feet up to a great height. I have no doubt this tree contains 700 to 800 feet of timber.

At Knole Park, near Sevenoaks, there are some splendid trees of the park type, with very wide-spreading limbs, two of which are known as the King and Queen Beeches. The King Beech is surrounded by a fence, and many of its branches are supported by chains. Strutt, who figures it, gives its height as 105 feet by 24 in girth at 13 feet. When I measured it in 1905 it was about 100 feet by 30 in girth at 5 feet, with a bole 10 feet high. It has the largest girth of any beech I know of now standing in England (Plate 12). The Queen Beech is 90 to 100 feet high and 28 feet in girth. I am not sure whether this or the last is the one recorded by Loudon, iii. 1977, as having a diameter of 8 feet 4 inches, a height of 85 feet, and a spread of branches of 352 feet diameter.

There are many fine tall beeches in the park of Earl Bathurst at Cirencester, of which Plate 1 gives a good idea, and shows the reproduction from seed in this part of the park to be very good, though a considerable number of other trees, such as ash and sycamore, are growing as well or better than the young beeches under the shade of the tall ones, which in this view are not so remarkable for their size as for their clean cylindrical trunks.

At Ashridge Park, Bucks, the property of Earl Brownlow, are perhaps the most beautiful and best grown beeches in all England, not in small numbers, but in thousands. Though the soil is neither deep nor rich, being a sort of flinty clay overlying limestone, it evidently suits the beech to perfection, and in some parts of the park there is hardly a tree which is not straight, clean, and branchless for 40 to 60 feet, whilst in other parts, where the soil is heavier and wetter, and where oaks grow among the bracken to a great size, the beeches are of a more branching and less erect type.

The largest and finest beech, from a timber point of view, at Ashridge, known as the King Beech, was blown down about 1891, and was purchased for £36 by Messrs. East of Berkhamstead. Loudon says that this tree in 1844 was 114 feet high, with a clear trunk of 75 feet, which was 5 feet 6 inches in girth at that height. Evidently this was less than its real height. Mr. Josiah East tells me that as it stood it had about 90 feet of clean trunk, of which the lower 15 feet was partly rotten and not measured. The sound part was cut into three lengths as follows:—

17 feet × 29 inches, $\frac{1}{4}$ girth	= 99 cubic feet.
28 " × 25 " "	= 136 " "
30 " × 23 " "	= 110 " "
butt, say, 15 " × 36 " "	= 135 " "
<hr/>						<hr/>
90						480

The branches were partly rotten and much broken in falling, so that they were only fit for firewood. But the celebrated Queen Beech remains, and though in one or two places it shows slight signs of decay, it may, I hope, live for a century or more, as it is in a fairly sheltered place, and has no large spreading limbs to be torn off by the wind. This extremely perfect and beautiful tree was photographed with great

care from three positions by Mr. Wallis (Plate 3), and as carefully measured by Sir Hugh Beevor and myself in Sept. 1903. We made it as nearly as possible to be 135 feet high (certainly over 130), and this is the greatest height I know any deciduous tree, except the elm, to have attained in Great Britain. Its girth was 12 feet 3 inches, and its bole straight and branchless for about 80 feet, so that its contents must be about 400 feet to the first limb.¹ Other extraordinary beeches at Ashridge are figured. Plate 4 is an illustration of natural inarching of a very peculiar type: the larger tree is 17 feet 6 inches in girth, the smaller, 4 feet 9 inches, and the connecting branch 12 feet long. It passes into the other tree without any signs to indicate how the inarching took place, and might almost have been a root carried up by the younger tree from the ground, as it has no buds or twigs on it. There are several beeches at Ashridge with very large and curious bosses on the trunk; one of these (Plate 5) at the base measured 21 feet over the boss, another had a large burr growing out of the side of a straight, clean, healthy tree at 40 feet from the ground. Such burrs are formed on the trunks of healthy as well as of diseased beeches, but I am not sure whether they ever have their origin in injuries produced by insects, birds, or other extraneous causes. Sometimes they have a horny or almost coral-like growth. Such burrs when cut through have an ornamental grain, which might be used for veneers when sufficiently compact and solid, but are left to rot on the ground by timber merchants, who as a rule place no value on such products.

In some parts of this park the beeches show a remarkably wide-spreading network of snake-like roots on the surface, which, though not uncommon in this tree when growing on shallow soil, are here unusually well developed. There is a remarkable beech clump to the east of the house containing 26 trees in a circle of 197 paces (11 of them grow in a circle of 78 paces), of which every tree is large, clean, and straight. The largest of them is about 125, perhaps 130, feet high, and 13 feet 10 inches in girth, and the average contents of the trees probably over 200 feet. I do not think I have ever seen in England such a large quantity of timber on so small an area.

But though it is doubtful whether any place in England can boast so many perfect beech trees as Ashridge, this park contains also some of the finest limes, the largest horse-chestnuts, and the most thriving and bulky chestnuts; and in a wood not far off is an ash which is much the best-grown tree of its species, if not the largest, that I have seen in England. All things considered, I doubt whether there is a more interesting and beautiful type of an English park than Ashridge, for though it contains few exotic trees, and no conifers except some Scotch pines, it has a magnificent herd of red, of Japanese, and of fallow deer, as well as flocks of St. Kilda sheep and of white Angora goats.

At Rotherfield Park, Hants, there is an immense pollard beech, of which I have a photograph kindly sent me by the owner, Mr. A. E. Scott, who gives its girth as 28 feet 3 inches at the narrowest point, 3 feet from the ground.

¹ According to Loudon, iii. 1977, this tree was in 1844 110 feet high, 10 feet in girth at 2 feet, and 74 feet to the first branch.

At Slindon Wood, near Petworth, Sussex, between the South Downs and the sea, which is seven miles distant, on the property of Major Leslie, there was in 1903 one of the finest beech woods in England, growing on chalk soil, of which I have particulars from Mr. C. H. Greenwood, and of which I give an illustration from a photograph sent me by him (Plate 6). Mr. Greenwood states that 634 trees were recently cut and sold in this wood, many of them being 70 and several 80 to 90 feet long to the first limb, and quarter girthing 20 inches in the middle. One tree now standing measures, without the top, $70' \times 26'' = 320$ feet, and on one acre at the east side of the wood are standing 60 which would average 150 feet each, making 9000 cubic feet to the acre. The tallest tree is 90 feet to the first bough, with 21 inches $\frac{1}{4}$ girth = 275 feet. This is perhaps the largest yield of beech per acre of which I have any record in England.

In Windsor Park there are some fine old beeches, of which three are figured by Menzies.¹ His plate 4 shows a remarkable old pollard at Ascot Gate 30 feet in girth, which he supposed to be 800 years old, and another, his plate 6, on Smith's lawn, of similar age and 31 feet 9 inches in girth. The third, Queen Adelaide's Beech, is a tree of no great size or beauty. It measured in 1864 8 feet 6 inches in girth, when supposed by Menzies to be 140 years old. In 1904 it had only increased 10 inches in girth. The finest beech now growing at Windsor—Mr. Simmonds, the deputy-surveyor of the Park, who was good enough to show it to me, agrees in this—is a tree near Cranbourne Tower, which in March 1904 measured 125 feet by 15, with a fine clean bole, but not equal to that of the Queen Beech at Ashridge.

The two largest beech trees, of whose measurement I have exact particulars, were both blown down in the heavy gale of September 1903, I believe on the same night. One of these was at Cowdray Park in Sussex, the property of the Earl of Egmont, and grew on sandy soil near the top of the great chestnut avenue at a considerable elevation, perhaps 400 feet. I saw it lying on the ground not long after, and obtained from Mr. Barber, steward on the estate, the following careful measurements:—

Butt 22 feet by 72 inches $\frac{1}{4}$ girth = 792 feet. Limbs measured down to 9 inches $\frac{1}{4}$ girth only, 43 in number, contained 924 feet 6 inches. Total 1716 feet 6 inches. Measured on the ground 21st September 1903.

The other was the great beech at Cornbury Park, of which I give a photograph taken after its fall (Plate 7), that gives an idea of its immense size. I saw the stump of this tree two years afterwards, and counted about 230 rings in it, which justify the belief that it may have been planted by Evelyn. Mr. C. A. Fellowes, agent for the property, had the tree carefully measured after its fall, and gives its height as 120 feet, girth 21 feet 4 inches. Cubic contents 1796 feet (nothing under 6 inches quarter girth being measured).

A magnificent beech growing in Studley Park, the seat of the Marquis of Ripon, was figured by Loudon, iii. 1955, and is there stated to have been 114 feet high.

¹ *History of Windsor Great Park and Windsor Forest, 1864.*

Mr. O. H. Wade, agent for the estate, tells me that this tree cannot now be identified.

Another celebrated tree, mentioned by Loudon as Pontey's Beech, was measured for him in 1837 by the direction of the Duke of Bedford in the Park at Woburn Abbey. It was then 100 feet high, with a clean bole of 50 feet, and was 12 feet 6 inches in girth at 4 feet. When visited in July 1903 it was about the same height and 14 feet 6 inches in girth, and was estimated to contain nearly 600 cubic feet.

A tree known as the Corton Beech at Boyton, Wilts, once the home of Mr. Lambert, author of the *Genus Pinus*, and mentioned by Loudon as one of the largest in England, was blown down a few years ago, and I have not been able to get its dimensions.

There were some very fine beeches at Castle Howard, Yorkshire, the seat of the Earl of Carlisle, one of which Loudon gives as 110 feet by 14 feet 2 inches, with a clean bole of 70 feet, and the other as containing 940 feet of timber, but when I visited this fine place in 1905 I could not identify either of these trees as still standing, though I saw many in Raywood of great size, with clean boles of 50 to 60 feet. A tree standing outside the garden wall was remarkable for the very rugged bark on its trunk, which up to 8 to 10 feet from the ground was more like that of an elm than a beech.

In Scotland, though the beech does not attain quite the same height and size as in some parts of England, it is a fine and commonly planted tree.

The self-layered beech at Newbattle Abbey near Dalkeith, the property of the Marquess of Lothian, eight miles from Edinburgh, must be looked on as the most remarkable, if not the largest, of all the beeches of the park or spreading type now standing in Britain; and though difficult to represent such a tree by photography in a manner to show its great size, every pains has been taken by Mr. Wallace of Dalkeith to do it justice (Plates 8 and 9). This splendid tree is growing in light alluvial soil in front of the house, and not far from the banks of the North Esk river, and may be 300 years old or more. It was in Loudon's time 88 feet high, and the trunk 9 feet in diameter (probably at the base), with a spread of branches of 100 feet. When I visited it in February 1904 under the guidance of Mr. Ramsay, who has known the tree for many years, I made it about 105 feet high, with a girth at about 5 feet—which is near the narrowest part of the bole—of 21 feet 6 inches. The trunk, as will be seen from the figure, is unusual in shape, and shows no sign of decay except where one large limb has been blown off, and this has been carefully covered with lead. But the numerous branches which have drooped to the ground, taken root, and formed a circle of subsidiary stems round the main trunk, are its most peculiar feature, and may remain as large trees for centuries after the central stem decays. The first of these has produced 7 stems of various sizes growing into fresh trees, at a distance of 8 to 12 yards from the trunk. The second has 2 large and 3 smaller stems. The third has 3 large stems about 30 to 40 feet high and 3 to 4 feet in girth. The fourth has 3 large and 6 smaller ones. The fifth is not yet firmly rooted, but is fastened down in several places to prevent the wind from moving it. The total circumference of

these branches is about 400 feet. Detailed measurements by Mr. Ramsay are given below.¹

A similar instance of self-layering, perfectly natural, was to be seen in the Kew Gardens, where a very fine beech, though by no means such a giant as the Newbattle tree, was surrounded by a fence in order to protect it. This tree, however, having become seriously decayed, had its main stem cut down in 1904.

Among the best specimens I have seen in Scotland are those at Hopetoun House, near Edinburgh, the seat of the Marquess of Linlithgow, where I measured a tree 110 feet high, with a clean bole of about 50 feet, and a girth of 12 feet. At Blair Drummond, near Perth, the seat of H. S. Home Drummond, Esq., Henry measured one of 117 feet high by 16 feet 6 inches in girth, and at Methven Castle, the seat of Colonel Smythe, another which is 120 feet high by 17 feet 2 inches in girth. This tree divides into three stems at about 20 feet, and is the tallest of which we have any certain record in Scotland. At Gordon Castle is a very fine beech with spreading roots (Plate 10) measuring 95 feet by 15 feet 8 inches. At Castle Menzies, Perthshire, the property of Sir Neil Menzies, is a very fine beech, which is described by Hunter² as a vegetable "Siamese Twins." Whether originally two trees or one is difficult to say, but it seemed to me to be from a single root which had forked a little above the ground and then grown together again, leaving an opening through which Hunter says an ordinary sized person might pass, but which in 1904 was smaller. At Inverary Castle is another example of an inoculated beech, known as the Marriage Tree, which, from a photograph published by Valentine, does not seem to be so striking as the one at Castle Menzies.

¹ Newbattle Abbey, Midlothian, N.B. Measurement of the great beech tree, August 25, 1903, by Mr. John Ramsay. Girth in feet, inches, etc., of trunk—

At the ground	43 feet 8 inches.
About 1 foot up	37 "
" 2½ feet "	27 " 8 "
" 3 " "	25 " 9½ "
" 4 " "	23 " 1½ "
" 4½ " "	21 " 11½ "
" 5 " "	20 " 3½ "
" 6 " "	19 " 7½ "

The ground measurement was taken by allowing the tape to lie on the roots as near to the uprising of the buttresses as possible, and is necessarily vague. The measurement at 6 feet up is the most correct, being taken on a line marked at intervals all round with white paint for future comparison.

Circumference of foliage fully 400 feet; diameter of foliage averages 130 to 140 feet; height, 112 feet.

The following are a few of the branches with the girth of them, and the girth of the branches springing up from the main branches rooted in the ground:—

No. 1.—Branch girth, 1 foot 10 inches, with two branches growing up from it; girth of both these new branches, 4 feet 5 inches each.

No. 2.—Branch girth, 1 foot 8 inches, having three branches springing up from it, one 5 feet 5 inches, one 5 feet 1 inch, one 23 inches by 1 foot 11 inches in girth.

No. 3.—Branch girth, 12½ inches, having three branches springing up from it, one 4 feet 7½ inches, one 24½ inches, one 4 feet 4 inches in girth.

No. 4.—Branch girth, 12 inches, with two branches springing up from it, one 2 feet 8½ inches, one 12 inches in girth.

No. 5.—Branch girth, 1 foot 7 inches, with three branches springing up from it, one 2 feet 4½ inches, one 12 inches, one 18 inches in girth.

No. 6.—Branch girth, 2 feet 4 inches, with five branches springing up from it, one 4 feet 4 inches, one 3 feet 8 inches, one 4 feet, one 3 feet 4 inches, one 1 foot 11 inches in girth.

² Hunter, *Woods, Forests, and Estates of Perthshire*, 1883, p. 397.

There are two beeches standing on a mound near the road to Lochfynehead in the Park at Inverary, which are known as the Doom trees, because in former times they were said to have been used as a gibbet for criminals; the largest of them measures 75 feet by 16 feet 5 inches. The Duke of Argyll, however, doubts this tradition.

There is another very fine beech, the largest I know of in the West Highlands, at Ardkinglas, at the head of Lochfyne, under which Prince Charles's men are said to have camped in 1745. Though of no great height it has a girth of 18 feet 8 inches, and spread of branches 30 yards in diameter.

In Ayrshire the largest beech is at Stair House. According to Renwick,¹ in 1903 it was 100 feet high, and 18 feet 9 inches at 4 feet 3 inches above the ground. At Kilkerran, in the same county, Renwick records a beech 21 feet 3½ inches at 3 feet from the ground, which, however, had a bole of only 4 feet. Other large beeches in Scotland occur at Eccles in Dumfriesshire and at Belton in East Lothian. The Eccles Beech, according to Sir R. Christison, was little inferior to the Newbattle Beech; according to Hutchinson, in 1869 it was 20 feet in girth at 4 feet up. I learn from Dr. Sharp that it has been dead for some years. The Belton Beech in 1880 was 20 feet 4 inches girth at 5 feet, with a 13-foot bole and a height of 63 feet.

One of the most striking effects produced by the beech in Scotland is the celebrated beech hedge of Meikleour, in Perthshire, on the Marquess of Lansdowne's property. An account of this hedge is given in the *Gardeners' Chronicle*, Dec. 15, 1900. This hedge forms the boundary between the grounds and the highway, and has to be cut in periodically, which is done by men working on a long ladder, from which they are able to reach with shears to about 60 feet. Local history says that this hedge was planted in 1745, and that the men who were planting it left their work to fight at the battle of Culloden, hiding their tools under the hedge, and never returning to claim them.² It is 580 yards long, and composed of tall, straight stems planted about 18 inches apart, and nearly touching at the base. The average height of the trees, as I am informed by Mr. Donald Matheson, is 95 feet, and their average girth at 3 feet is 18 to 36 inches. He adds that "close to the ground they are as fresh and green as a young hedge." An illustration of this hedge, taken specially for our work by Mr. D. Milne of Blairgowrie, gives a good idea of its appearance in October 1903 (Plate 11).

I am informed by Sir Herbert Maxwell, M.P., that a remarkably similar occurrence is on record at Achnacarry, on the property of Cameron of Lochiel; here the trees were laid in ready to plant in 1715, and the men were also called off to take part in the rebellion of that year. The trees were never planted, and have grown up in a slanting position close together just as they were left.

In a paper on the "Old and Remarkable Trees of Scotland," published in 1867 by the Highland and Agricultural Society of Scotland, many other remark-

¹ Renwick in *British Association Handbook*, p. 140 (1901). We are much indebted to Mr. John Renwick for measurements and descriptions of large and interesting trees in the south-west of Scotland.

² Hunter, *loc. cit.* 379.

able beeches are mentioned, of which one at Edenbarnet in the parish of Old Kilpatrick, Dumbartonshire, is said to be 140 feet high; but the measurements of many of the trees in this compilation are so unreliable that I cannot believe them without confirmation.

J. Kay, in *Scottish Arb. Soc. Transactions*, ix. p. 75, mentions a tree in the Beech Walk at Mount Stuart in Bute, which in 1881 was 120 feet by 11 feet 9 inches, with a clean bole 60 feet high, and contained 450 feet of timber.

In Ireland the beech is probably not a native tree. According to Hayes¹ it was first introduced at Shelton, near Arklow, where, in 1794, there were beech trees as much as 15 feet in girth, and many carrying a girth of 10 feet for more than 40 feet high. Another growing at Tiny Park was 16 feet 3 inches in girth, and continued nearly of that girth for 36 feet. Hayes also mentions, as an instance of the rapid growth of the beech in Ireland, "several at Avondale, which were transplanted within thirty years on a swelling ground at that time much exposed to storm, are now (1793) from 7 feet 6 inches to 6 feet 6 inches at a foot from the ground, and continue nearly of that size from 8 to 20 feet in height. Of two which were planted in a richer soil near the river, and are now (1793) just fifty-four years from the mast, one measures 9 feet round, the other 9 feet 6 inches."

The finest beeches in Ireland, probably, are those occurring at Woodstock (Co. Kilkenny), the seat of E. K. B. Tighe, Esq.—a property which is remarkable all round for magnificent trees of many kinds, and which is in the possession of a family that for generations has been deeply interested in forestry and arboriculture. The measurements of many trees have been taken periodically for nearly a century. The best beeches on this beautiful property occur in the meadow land by the River Nore, close to the village of Inistioge. The following table gives an interesting series of measurements of these beeches:—

No.	GIRTH.						HEIGHT.	
	1825.	1830.	1834.	1846.	1901.	1904.	1901.	1904.
A ₃	ft. in. 10 9	ft. in. 11 1	ft. in. 11 6	ft. in. 12 6	ft. in. 20 6	ft. in. 20 7	81	86
C ₇	12 7	17 3	17 9	97	99
B ₃	12 5	14 0	...	91	...
B ₅	12 1	12 10	14 4	15 4	18 9	18 10	113	117
B ₆	11 10	12 3	13 8	14 10	17 9	...	108	...
B ₂	11 4	11 11	12 10	13 8	15 8	16 4	112	109
B ₁	11 0	11 6	12 7	13 8	16 6	...	106	...
B ₉	11 9	...	12 9	14 0	16 7	...	120	...
B ₈	9 5	10 1	12 3	...	100	...

The measurements up to 1901 are from the foresters' records; those of 1904 were taken by Henry. The beech A₃ has a great bole, dividing into three limbs at 18 feet up, and is a very wide-spreading tree. C₇ is pressed on each side by two lime trees, and is narrow in shape. The most remarkable of all is B₆, which is probably the tallest beech in Ireland.

¹ Hayes, *A Practical Treatise on Planting* (1794), pp. 109, 118.

As showing the rate of growth of the beech in Co. Galway, a beech measured by Lord Clonbrock at Clonbrock was 11 feet 3 inches in girth in 1871, and 15 feet in 1903. A beech hedge at Kilruddery, Co. Wicklow, the seat of Lord Meath, said to be 300 years old, was measured by Henry in 1904, when it was 18 feet through and 29 feet high. It is clipped regularly, and forms a dense, impenetrable mass.

BEECH COCCUS

We are indebted to Mr. R. Newstead of the Grosvenor Museum, Chester, for particulars of the coccus which in some seasons, and in certain parts of England, has been of late years very injurious to the beech. A fuller account of this insect has been written by him in *Journ. R. Hort. Soc.* 1900, vol. xxiii. p. 249, and in a leaflet recently published by the Board of Agriculture. From this we take the following precis:—

The trunks and, less frequently, the main branches of good-sized beech trees are often covered, to a greater or less extent, with irregular spots of a white cottony substance. The latter is really the covering of white felted wax fibres secreted by the felted beech coccus (*Cryptococcus fagi*, Bärensprung), a minute, hemispherical, lemon-yellow insect, about one twenty-fifth of an inch long, without legs, but furnished on the underside with a well-developed beak, which it buries in the bark for the purpose of sucking up the juices of the tree. When once a tree is attacked the number of individuals of the pest becomes in time so great that it is doubtful whether a badly-infected tree ever recovers unless active measures be taken against the insect. The waxy covering of the latter is sufficient to protect it against the effects of any of the insecticides usually applied by spraying, and its habit of preferring the deepest part of the fissures in the bark makes it difficult to remove with certainty. The only remedy at all likely to succeed is that of thoroughly scrubbing the bark with a stiff brush and soap and water, the latter mixed in the proportion of half a pound of soft soap to each gallon of water; and the success of this treatment depends for the most part on the amount of care taken to dislodge the insects by means of the brush.

TIMBER

The timber of the beech is not valued so highly in England as abroad, where it is considered as the best fuel in general use, and is little used in carpentry or building, as it is hard, brittle, and liable to be attacked by beetles. It weighs when green about 65 lbs. to the cube foot, when dry about 50. Its durability is said to be increased by seasoning it in water, and it is more durable when entirely under water than most timbers, being highly recommended by Matthews and Laslett for planking the sides and bottoms of ships. In France it is used, when creosoted, for railway sleepers, but requires more than twice as much creosote to preserve it as oak does, and is not used in England, so far as I know, for this purpose. It is also used for tool handles, rollers, butchers' blocks, brush heads, planes, and general turnery, but decays rapidly when exposed to the weather.

28 The Trees of Great Britain and Ireland

The principal centres for beechwood furniture in England are at High Wycombe, and Newport Pagnell in Bucks, and the price of clean trunks in these districts is from 1s. to 1s. 6d. per cube foot standing, according to the situation. Beechwood is also used largely for making saddle-trees, and in consequence of the great demand for these during the South African war, went up to a very high price in 1901, when I was offered 1s. 4d. a foot standing for beech trees which in ordinary times would not be worth more than 8d. or 9d. a foot. Being easy to split it is, where there is a demand for firewood, easier to dispose of the branches and rough parts of the tree for this purpose, but the amount of waste is much greater in the beech than in some other trees, unless grown in thick woods. For more minute particulars of the characters and uses of this timber, Stone's *Timbers of Commerce*, p. 231, and Loudon, pp. 1959-64, may be consulted with advantage. (H. J. E.)

AILANTHUS

Ailanthus, Desfontaines, *Mém. Acad. Paris*, 1786 (1789), 263, t. 8; Bentham et Hooker, *Gen. Pl.* i. 309 (1862); Prain, *Indian Forester*, xxviii. 131, Plates i. ii. iii. (1902).

LOFTY trees with very large alternate imparipinnate leaves. Flowers small, polygamous, bracteolate, in panicles. Calyx 5-toothed, imbricate. Petals 5, valvate, disk 10-lobed. Stamens 10 in the staminate flowers, 2-3 in the hermaphrodite flowers, and absent in the pistillate flowers. Ovary present in pistillate and hermaphrodite flowers, rudimentary in staminate flowers, deeply 2-5 cleft with connate styles: ovules 1 in each cell. Fruit of 1-5 samaras, with large membranous wings, each samara containing 1 seed.

Ailanthus belongs to the Natural order Simarubaceæ, and consists of about eleven species occurring in India, Indo-China, China, Java, Moluccas, and Queensland. Most of the species are tropical trees, *Ailanthus glandulosa* being until lately the only species which was known to occur in temperate regions; but *Ailanthus Vilmoriana*, Dode,¹ must be here mentioned. This is a tree remarkable for its prickly branchlets, of which only one specimen is known, namely, a young, healthy, vigorous tree grown in M. de Vilmorin's garden at Les Barres.² It was raised from seed sent by Père Farges in 1897 from the mountains of Szechuan in Central China;³ and is certainly a very distinct species. I saw it in the summer of 1904, and in general aspect there is little to distinguish it from the common species. It is now about 20 feet in height. The leaflets in this species are less abruptly acuminate, not falcate, much duller above and paler beneath, with larger glands than in *Ailanthus glandulosa*. All the parts of the tree are much more pubescent than in that species.

Ailanthus grandis,⁴ Prain, a new species from Sikkim and Assam, which attains 120 feet high, may be here mentioned, as it is possible that it might be grown in Cornwall or in Kerry. It has not yet been introduced.

¹ *Revue Horticole*, 1904, p. 445, fig. 184.

² Figured in *Fruticetum Vilmorinianum*, 1904, p. 31; where it is called *Ailanthus glandulosa*, var. *spinosa*.

³ Mr. E. H. Wilson informs us that it is very common in the valleys of the Min, Tung, and Fou rivers, between 2000 and 4500 feet. He says that it is much more spiny in the young than in the adult state, and that it has much larger foliage than the common species. A plant is now growing at Kew, and is referred to by Mr. Bean in *Gardeners' Chronicle*, xxxviii. 276 (1905).

⁴ *Indian Forester*, xxviii. 131, Plate i. (1902).

AILANTHUS GLANDULOSA, AILANTHUS TREE

Ailanthus glandulosa, Desfontaines, *Mém. Acad. Paris.* 1786 (1789), 263, t. 8; Loudon, *Arb. et Frut. Brit.* i. 490 (1838); Britton and Brown, *Illustrated Flora of the Northern United States and Canada*, ii. 355, Fig. 2272 (1897).

A tree attaining 100 feet in height and 13 feet in girth; branches massive and forming an oval crown, which becomes flattened at the top in old trees. Bark smooth, grey, or dark brown, and marked by longitudinal, narrow, pale-coloured fissures, which are very characteristic.

Leaves deciduous, compound, 1-3 feet long, imparipinnate, with 7-9 (sometimes even 20) pairs of leaflets, which are either opposite or nearly so, shining above, pale and glabrous (occasionally slightly pubescent) beneath, and unequally divided by the midrib. Each leaflet is stalked, ovate, or ovate-lanceolate, acute or acuminate at the apex, cordate or truncate at the base, entire in margin, except that near the base there are 1-4 pairs of glandular teeth. Stipules absent. The leaves appear late in spring, and exhale when rubbed a disagreeable odour which renders them distasteful to animals. They fall off late in autumn, absciss layers being formed at the base of the leaflets as well as of the main stalk; the former usually drop first.

Flowers appearing in July and August in large panicles at the summit of the branchlets, either unisexual or hermaphrodite; but as a rule the trees are practically dioecious, and those bearing staminate flowers give off an objectionable odour.

Fruit, 1-5 keys, resembling those of the ash, linear or oblong, membranous veined, with a small indentation above the middle on one side, close to where the seed is located; and the wings on both sides of the seed are slightly twisted, so that the fruit in sailing through the air moves like a screw. The keys are bright red or purplish brown in colour, and are very conspicuous amidst the green foliage.

Seedling: the cotyledons appear above the soil on a caulicle about an inch long and are foliaceous, coriaceous in texture, oboval, obtuse, shortly stalked, entire in margin, and pinnate in venation. The stem above them is pubescent, and at a short distance (about $\frac{1}{2}$ inch) up bears two leaves, which are trifoliolate and long-stalked, the terminal leaflet being lanceolate, acuminate, and entire, the two lateral shorter and toothed.¹ Higher up ordinary pinnate leaves are borne. Plate 15 A shows a seedling raised by Elwes from seed ripened on a tree overhanging Dr. Charles Hooker's garden at Cirencester in 1900;² sown November 26, germinated under glass in May 1901, and photographed on August 28 of the same year, when it measured about a foot high; the roots, which were very succulent and brittle, were 13 inches long. The seedlings were planted out in May 1902, and grew very rapidly, attaining 5 feet in height, but did not ripen their wood, which was killed back in some cases nearly to the ground. They are now (January 1905) 4-6 feet high.

¹ See Plate 14, fig. B.

² As I know of no other tree in the neighbourhood this case seems to confirm Bunbury's observation that the tree in some cases is capable of self-fertilisation.—(H. J. E.)

IDENTIFICATION

In summer the Ailanthus is readily distinguished from all other trees cultivated in England by its large pinnate leaves, which have *at the base of the leaflets on each side one or two glandular teeth*. The black walnut, butternut, and *Cedrela sinensis* have somewhat similar foliage; but in these the glandular teeth are wanting. The bark of Ailanthus is quite peculiar, and when once seen cannot be confounded with that of any other tree.

In winter Ailanthus is easily recognised by its bark in trees of a certain size; but in all stages of growth it is well marked by the characters of the buds and branchlets.

The buds are alternate, uniform in size, small and hemispherical, and show externally 2 or 3 brown tomentose scales.¹ The buds are set obliquely on the twigs just above the leaf-scars. The latter are large, heart-shaped, and slightly concave; and on their surface may be seen about 7 little elevated cicatrices which correspond to the vascular bundles of the fallen leaves. No true terminal bud is formed; and at the apex of the twig there is an elevated small circular scar, which marks the spot where the tip of the branchlet fell off in summer. The twigs are very coarse, glabrous, or finely pubescent, shining and brown in colour, with a few plainly visible lenticels. The pith is large, buff or yellowish in colour, showing clearly on section the medullary rays. In *Cedrela* there is a large terminal bud, and the leaf-scar has 5 cicatrices. The chambered pith of *Juglans* will readily distinguish the black walnut and butternut.

VARIETIES

Several varieties are mentioned in books; *aucubæfolia*, *pendulifolia*, *rubra*, and *flavescens* being recognised by Schelle;² but it is doubtful if any of these are sufficiently marked to deserve recognition. The *Ailanthus flavescens*³ of gardens was determined by Carrière to be *Cedrela sinensis*. A form with variegated leaves is mentioned by Koch,⁴ but it is exceedingly rare. The Kew Hand-list only admits one variety, *pendula*, a form somewhat weeping in habit.

DISTRIBUTION

Ailanthus glandulosa has been only found truly wild on the mountains of the province of Chihli in Northern China; but it is cultivated in most parts of China, and doubtless was once a constituent of the forests of the northern coast provinces, most of which have been destroyed by the Chinese. I never saw it wild in any of the mountain forests of Central or Southern China. When first introduced

¹ A plate showing buds will appear in a later part.

² *Laubholz-Benennung*, 279 (1903).

³ See article on the "Ailanto or Tree of Heaven" by Nicholson, in *Garden*, 1883, xxiv. 63, with figure of flowers, fruit, and foliage, and many interesting details concerning propagation, etc.

⁴ Koch, *Dendrologie*, i. 569 (1869).

into Europe it was supposed to be the species of *Rhus* which yields Japanese varnish or lacquer; and even now it is often called in France *Vernis du Japon*. The tree, however, is unknown wild in Japan, and is seldom or never cultivated there. The Chinese in classical times were well acquainted with *Ailanthus*, which they called *ch'u*, a word explained as meaning "useless wood," as it was in ancient times (as well as at present) used only for firewood.¹ Popularly *Ailanthus* and *Cedrela* are now called *ch'un* trees, the former being distinguished as the "stinking *ch'un*," and the latter as the "fragrant *ch'un*."

In China the *Ailanthus* grows to be a large tree; but the timber is little valued. The root-bark is used, as a strong infusion, in cases of dysentery.² In the Pharmaceutical Museum, London, there are several specimens of barks bearing the Chinese name for *Ailanthus*; but these are doubtfully referable to that species; and the whole subject of the use of *Ailanthus* bark for dysentery requires further investigation.³

In the Kew Museum there are specimens of silkworms (*Attacus Cynthia*, Drury), which feed on the leaves of *Ailanthus* in North China; and there are also samples of the "wild silk" produced, which is made into one kind of pongee. This species of silkworm was introduced into France in 1858; and large numbers of *Ailanthus* trees were planted with a view to the feeding of the silkworms. The winter of 1879 killed off all the silkworms; and apparently the cultivation of the tree in France for the production of silk is a thing of the past.

In the Kew Museum there is a note attached to a specimen of the wood of *Ailanthus glandulosa* from Tuscany, which says that the bark yields a resinous juice; but there is no account of such a resin from Chinese sources; and exudation from the bark has not been observed in trees growing in England or in France. In India, however, the resin, called *muttee-pal*, is derived from the bark of *Ailanthus malabarica*, and is used both as an incense and as a remedy for dysentery.

INTRODUCTION

Ailanthus glandulosa was first introduced from China in 1751. In *Hortus Collinsonianus*,⁴ p. 2, a memorandum is copied which was left by Collinson, stating: "A stately tree raised from seed from Nankin in 1751, sent over by Father d'Incarville, my correspondent in China, to whom I sent many seeds in return; he sent it to me and the Royal Society." Père d'Incarville⁵ was a French Jesuit missionary, who died at Peking in 1757. In *Trans. Phil. Soc.*, 1757, a paper is printed, which was read on 25th November 1756, being a letter from John Ellis to P. C. Webb; and it mentions two trees which were growing, one in Webb's

¹ In the *Shu-Ching*, it is said: "In the ninth month they make firewood of the *ch'u* tree."

² On the therapeutical value of this drug, see articles by Drs. Dudgeon and Robert, in *London Pharmaceutical Journal*, ser. iii. iv. 890, and vii. 372.

³ The bark has been found to be an excellent vermifuge in cases of tapeworm. See Hætet, in *U.S. Dispens.* 15th edition, 1564.

⁴ Compiled by L. W. Dillwyn, and published at Swansea in 1843.

⁵ In Cibot, *Mém. Conc. Chinois*, ii. 1777, 583, d'Incarville's "Mémoire sur les vers à soie sauvage" is published, in which he speaks of the *Ailanthus* as the *frêne puant* (stinking ash) of North China.

garden at Busbridge, near Godalming, and another in the Chelsea Physic Garden, both raised from the seed sent by Père d'Incarville. The tree is here first described as *Rhus sinense foliis alatis, foliolis oblongis acuminatis ad basin subrotundis et dentatis*.¹

TREE OF HEAVEN

This name is often given to the tree in England, corresponding to the German *Götterbaum*. It is not the translation of any Chinese name, as has often been erroneously stated. Desfontaines' original description occurred in a rare book which has not been looked up by most writers on the tree. He was well aware that the tree came from China, but in selecting a name for the genus he took it from another species which he found figured in Rumphius' *Hortus Amboinensis*, v. cap. 57, tab. 132. This species, left undescribed by Desfontaines, is *Ailanthus moluccana*. Rumphius calls it *arbor cæli*, the equivalent of the native name in the Amboyna language, *Aylanto*, which signifies "a tree so tall as to touch the sky." "Tree of Heaven" is accordingly a translation of the name of Rumphius, and is more properly applied to the tall tropical species than to *Ailanthus glandulosa*, which does not attain any remarkable height.

CULTIVATION

The *Ailanthus* is easily propagated from seeds; but as trees bearing male flowers are objectionable on account of their odour, it is preferable to propagate the tree from root-cuttings obtained from female trees. In addition to the disagreeable odour of the male flowers, there may be some foundation for the belief prevalent in the United States that they cause stomachic disturbance and sore throat. The pollen from staminate flowers, doubtless, occasions a kind of hay fever.

The tree suckers freely from the root and to a great distance, as far as 100 feet from the parent stem. At Kew these suckers frequently appear between the tiles of the floor of one of the buildings near which an *Ailanthus* stands. At Oxford² a root-sucker sent up a flowering shoot, and, what is more remarkable, produced simple leaves, giving some support to the idea that plants with compound foliage originated from those with simple leaves. The tree has extraordinary vitality. Dr. Masters² gives an account of a tree which was cut down, the stump being left in the ground below the surface. Several years elapsed during which nothing was observed, but after about ten years suckers were seen coming up in a gravel path adjacent, and these, being traced, were found to issue from the old stump.

Ailanthus reproduces itself freely from stools, and the coppice shoots thus obtained are very vigorous.

It was long supposed that *Ailanthus* would succeed even on the worst soils, but this is an error. It only does well on permeable soils, which are fairly moist,

¹ In the herbarium of the British Museum there is a specimen labelled *Hort. Busbridge*, which is undoubtedly from the original tree. It was cut down in 1856 owing to the great amount of shade it produced near the house (*Gard. Chron.* 1857, p. 55). There is another specimen from Kew Gardens, 1779, showing that the tree was cultivated early there.

² *Gard. Chron.* 1887, ii. 364.

and for this reason it is successfully used to cover railway and road embankments in France. It will not grow well on compact clay or on chalky or absolutely poor soils. In England it has only been planted as an ornamental tree, and it is very suitable for planting in towns, as it is not injured by smoke and is free from insect attacks and fungous diseases. Though it suckers freely, this is no objection in streets, where the pavements or wheel traffic prevents them from making an appearance. The young shoots are often killed by frost, but this only serves to keep the tree within bounds without the use of the pruning knife. The *Ailanthus* only makes one shoot annually, late in the spring, which continues to grow till October or November, and this is the reason why it is spring tender, as the tips of the shoots do not become properly lignified. The tree, however, bears the greatest cold in winter, and was not injured by the severe frost of 1879.

The tree produces flowers in England when it is about 40 feet high; and it fruits pretty frequently, but the seeds are often infertile.

When the *Ailanthus* is cut back annually, it grows rapidly and produces foliage of enormous size, suitable for the so-called tropical garden. Leaves of plants so treated have measured as much as 4 feet long and 15 inches wide.

The *Ailanthus* succeeds in a great variety of climates, and is planted in regions so diverse as Northern India, the United States, France, Germany, and Italy. In France it has not been successful as a forest tree, as it is not a social species, and is speedily dominated by native trees, if it survives the seedling stage, when it is sensitive to spring frosts. In warmer climates it easily regenerates by seed, and in consequence has become naturalised in many parts of Europe (as on the arid slopes of Mount Vesuvius, where it stands very well the drought), and in the United States,¹ where it often runs wild in old fields. American writers praise the tree for the value of its wood and the rapidity of its growth, as it is said to make timber faster than any of the native trees that are used for firewood.

The wood is yellowish or yellowish green, and is not clearly distinguishable into well-marked heart and sap woods, though in old trees the centre of the stem becomes deeper in colour. The wood has a specific gravity of 0.6, and is easily worked, taking a good polish. It rives easily. It is used by wheelwrights as a substitute for elm and ash; but is inferior to these, as it does not possess their elasticity or their capability of resistance to fracture. It is said, however, to bear well alternations of dry and wet.

Mr. J. A. Weale of Liverpool, who has paid great attention to the study of timbers, and knows more about them than any one in the trade in this country, writes to us that this wood resembles that of the ash so closely in structure, that the only real difference between the two is in the large cellular compound pores which are formed in the *Ailanthus*, as shown in the microscopical section which he enclosed.

Elwes is assured by Prof. C. S. Sargent that it makes nice furniture, and he has a specimen from a large tree which was cut down in the Palace Gardens at Wells, Somerset, of which the timber was bought by Mr. Halliday, a cabinetmaker, for £8.

¹ Also in Southern Ontario. See Britton and Brown, *loc. cit.*

REMARKABLE TREES

The largest *Ailanthus* was that at Syon, which was 70 feet high in Loudon's time, and nearly 100 feet in 1880.¹ It is now dead.

At Kew a vigorous tree is growing in the garden behind the Palace, which measures 73 feet high and 8 feet in girth. Not far off a number of *Ailanthus* trees of varying size, but none very large, occurs in a group, and they seem to be root-suckers; probably one of the original trees was planted in this spot in the eighteenth century.

At Milton Rectory, Steventon, Berks, there are two trees of equal height (78 feet), one girthing 9 feet 1 inch, and the other 8 feet 6 inches. Both these trees bloom freely every year, producing fruit of a bright red colour on the south side of the trees; and the seeds, as they fall in the garden near hand, produce seedlings which are very vigorous.²

At the Mote, Maidstone, there are two large trees, one of which is 70 feet high and 8 feet in circumference.

At Linton Park, Maidstone, is a tree growing in a shrubbery which was nearly 80 feet high by 6 feet 6 inches in 1902.

At Broom House, Fulham, the residence of Miss Sullivan, is a tree 80 feet high, with a bole 9 feet long and 10 feet in girth, which divides into two main stems (Plate 13).

At Fakenham, Norfolk, Sir Hugh Beevor has measured a tree 75 feet by 8 feet 11 inches.

At Barton, Bury St. Edmunds, an *Ailanthus* which was planted in 1826³ measured in 1904 55 feet high, with a girth of stem of 5 feet 2 inches. Bunbury says that it is perfectly hardy at Barton, and did not suffer in the least from the severe winter of 1860. It was 3½ feet girth at 3 feet from the ground in 1862. It flowered abundantly in August of 1861, the greater part of the flowers being hermaphrodite, and a considerable number of fruits were formed, but all dropped off before coming to maturity. It fruited abundantly in 1868. Bunbury says, generally there is only one samara to each flower, but not unfrequently two or three; he never saw more than three.

At Belton Park, the seat of Earl Brownlow, is a fine specimen of the tree, for a photograph of which (Plate 14) we are indebted to Miss F. Woolward, who gives its height as 83 feet, and its girth as 6 feet. This seems to be the tallest tree recorded in England.

At Burwood House, Cobham, Surrey, the seat of Lady Ellesmere, Colonel H. Thynne has measured an *Ailanthus* 71 feet high by 10 feet 10 inches girth, which, though partly fallen down and supported by a prop, is still a fine tree.

The tree seems to require a climate which is at once both warmer and drier in summer than that of the northern and western counties of England, and we do not know of any trees of any great size now existing in Scotland, Ireland, or Wales, though Loudon states that there was one at Dunrobin Castle, Sutherlandshire, 43 feet high.

(A. H.)

SOPHORA

Sophora, Linnæus, *Gen. Pl.* 125 (1737); Bentham et Hooker, *Gen. Pl.* i. 555 (1865).

TREES, shrubs, or perennial herbs, with naked buds and imparipinnate leaves. Flowers papilionaceous, in simple racemes or terminal leafy panicles. Calyx five-toothed, imbricate. Stamens ten, not united together, or rarely sub-connate. Ovary short-stalked, with many ovules. Pod moniliform, indehiscent, or tardily dehiscent.

The name *Sophora* was taken by Linnæus from the Arabic word *Sophera*, which indicated some leguminous tree. The genus belongs to the tribe Sophoreæ (Natural order Leguminosæ, division Papilionaceæ) characterised by imparipinnate leaves and ten free stamens. There are about twenty-five species of *Sophora*, generally spread throughout the tropical and warm temperate regions of the globe. The only species of importance which attain to timber size are *Sophora japonica* and *Sophora platycarpa*. *Sophora macrocarpa* from Chile and *Sophora tetraptera* from New Zealand are shrubs or small trees, which are frequently cultivated in the southern counties of England, and do not come within the scope of our work, although they are said to attain a height of 50 feet in the wild state.

Sophora platycarpa, Maximowicz, in *Mel. Biol.* ix. 70 (1873), (*Fuji-ki* in Japan), only lately¹ introduced into cultivation in England; but in the United States, where it has been grown for some time, it is said to have proved hardier than *Sophora japonica*.² It is a tree of considerable size, occurring in woods in Japan on the side of Fusiyama and in Nambu. It is similar in leaves and flowers to *Sophora japonica*; and, as will be pointed out in our account of that species, has been probably confused with it by writers on Japanese trees. The leaves are larger than in *Sophora japonica*, the leaflets being 2 to 3½ inches long, alternate, acuminate, glabrous or nearly so. The flowers are ½ inch long, white, and loosely arranged. The main difference is in the pod, which is membranous, flat, narrowly winged on each side, and irregularly constricted.³

¹ There are two plants at Kew which were raised from seeds obtained in 1896 from Späth of Bertin. See *Mittheil. der Dendr. Dendr. Gesell.* 1896, p. 27.

² A. Rehder in Bailey's *Cyclopædia of American Horticulture*, p. 1684 (1902).

³ *Sophora shikokiana*, Makino, in *Tokyo Botanical Magazine*, 1900, p. 56 (*Yuko-noki* in Japan), is described as a species closely allied to *S. platycarpa*, and as being widely distributed throughout the mountain districts of Japan. It is said to be a tree of considerable size.

SOPHORA JAPONICA, SOPHORA TREE

Sophora japonica, Linnæus, *Mantissa* i. 68 (1767); Loudon, *Arb. et Frut. Brit.* ii. 563 (1838); Shirasawa, *Iconographie des Essences Forestières du Japon*, i., Text, p. 86, Plate 50 (1900).

A large tree, with a straight cylindrical stem of considerable height in some cases, but more often in cultivated examples dividing at no great distance above the base; branches tortuous, with pendent tips; crown of foliage, large, broad, and rounded in shape. Bark brown or greyish and scaly, fissured longitudinally, but to no great depth; on young shoots and older branchlets, smooth and dark green.

Leaves deciduous, alternate, unequally pinnate, with nine to fifteen leaflets, which are sub-opposite, oval, pointed at the apex, often ending in a short bristle, dark green and opaque above, glaucous beneath. In the ordinary cultivated form they are apparently glabrous, but with a lens minute hairs may be detected on both surfaces. The petiolules are velvety; the main stalk is greenish, swollen at the base, and slightly pubescent. In certain wild specimens from China they are green and not glaucous beneath; and in Hupeh a well-marked variety occurs, in which the under surface of the leaflets, the petiole, and young shoots are densely white pubescent.

Flowers in large, loosely branched terminal panicles. They are somewhat variable in colour; in Central China white, at Canton a bright yellow, in cultivation in England pale yellow, sometimes tinged with purple. Calyx small, bell-shaped, five-toothed. Corolla, standard large, obtuse, round, recurved; wings oval-oblong; keel semi-orbicular, rounded, and of the same length as the wings. Pod long-stalked, 1 to 2 inches long, glabrous, fleshy, compressed, with a beak at the apex, and constricted between the seeds, which are one to five in each pod, dark brown in colour and kidney shaped.¹

In England the tree produces flowers regularly, late in the season, in August, September, and October, but seldom if ever fruits.

IDENTIFICATION

Sophora japonica is readily distinguished in summer by the leaves, the characters of which have been already given, and by the branchlets, which are angled, very smooth and dark green, both in the young shoots and those of the second year. When the young shoots are cut they emit a strong peculiar odour. In winter the characters of the buds and branchlets must be noted. The buds are spirally arranged on the shoots; solitary or in pairs, one placed above the other; naked, *i.e.* not surrounded by any true scales, and dark violet densely pubescent. They are

¹ *Seedling*.—Seeds sown early in the year at Colesborne produced two or three young plants, which showed the following characters in July:—Caulicle an inch or more in length, terete, green, glabrous, ending in a long whitish tap-root with numerous lateral fibres. Cotyledons oblong-spathulate, ⅝ inch long, entire, rounded at the apex, tapering at the base, sub-sessile, coriaceous, dark green and minutely pubescent above, pale green below. Stem white appressed pubescent, giving off alternately about six compound leaves; the lower three with five leaflets, the terminal leaflet being larger and broader in proportion to its length than the others; the upper three with 7 to 9 leaflets, uniform in size and shape; all the leaflets oval, entire, shortly-stalked, their under surface with a scattered appressed pubescence, dense on the midrib. Small ovoid densely pubescent buds are produced, one in the axil of each leaf, the shoot being terminated by an oblong white pubescent larger bud.

very small and lodged in the leaf-scar, which is oval, with the bud in the centre, and displays three crescentic small cicatrices left by the vascular bundles of the petiole. The leaf-scar is set obliquely on a projecting leaf-cushion. The branchlets in winter are the same as in summer, but they show more clearly their zig-zag nature, and at their apex will generally be seen a little stub which indicates the point where the end of the branchlet fell off in summer, no true terminal bud being developed. Occasionally a true terminal bud may be seen at the apex of the shoot, which is open and not concealed in the leaf-scar, minute, bearing two scales outwardly, and very pubescent.¹

VARIETIES

In addition to the pubescent form of Central China, not yet introduced, a few varieties occur, concerning the origin of which little is known.

Var. *variegata*.—Leaves dull yellowish white in patches. This form is neither robust in growth nor attractive in appearance.

Var. *pendula*² (Weeping Sophora).—One of the most formal of weeping trees. It is usually grafted by budding on seedlings of the common Sophora about 6 to 8 feet high; and from this elevation the branches hang down until on reaching the ground their tips spread out or turn up. It can be used as an arbour; and even in winter the light, smooth, green branches make it ornamental. The only trouble is in procuring smooth, straight stems of the ordinary Sophora of a sufficient height. F. L. Temple³ says: "In spring plant dormant Sophoras about $\frac{3}{4}$ inch in diameter in the fairly rich earth bottom of a greenhouse. Cut them back to the ground, and set them 1 foot apart each way; and by December first they will be out of the top of the house and as smooth as willows. Then lift and keep them protected in a cellar or frame, or heel them deep in a well-drained place till spring, when they can be planted in nursery rows, and grafted at the same time with the most gratifying results." With regard to the origin of the weeping Sophora nothing is known definitely; but Fortune⁴ states that at Shanghai in 1853 he saw "pretty specimens of *Sophora japonica pendula*, grafted high as we see the weeping ash in England." It is probable that this variety was imported early from China.

Var. *crispa*.—Leaves curled, the points of the shoots resembling as it were clusters of ringlets. We have never seen a specimen of this curious variety, which is not mentioned in the Kew Hand-list.

Var. *Korolkowii* (*Sophora Korolkowii*, Cornu).⁵—This has longer and narrower leaflets than the type, and the young shoots, leaf-stalk petiole, and under surface of the leaflets, are whitish pubescent. The flowers are said to be of a dirty white in colour. Köhne⁶ states that one of Dieck's introductions from Mongolia is identical with the plant cultivated at Segrez under this name, the origin of which is unknown. In the summer of 1904 I visited the Arboretum at Segrez, and saw this

¹ A Plate showing buds will appear in a later part.

² An excellent article upon different species of weeping trees was published in the *Gardeners' Chronicle*, 1900, xxviii. 477; and on p. 479 there is a good figure of a fine specimen of the weeping Sophora.

³ *Garden and Forest*, 1889, 164.

⁴ Fortune, *Residence among the Chinese*, 139.

⁵ Cornu's name is given on the authority of Zabel, in *Laubholz-benennung* (1903), p. 256. We have been unable to find Cornu's description of the species.

⁶ Köhne, *Dendrologie*, 1893, p. 323.

specimen, which is about 30 feet high with a stem a foot in diameter, bearing a large roundish crown like the common Sophora. In the absence of flowers or fruit, it is impossible to say whether it is a distinct species; but in foliage and other characters it differs so little from *Sophora japonica*, that probably Zabel¹ is correct in considering it to be only a form of that species. It seems to be well worth cultivation, judging from the vigorous growth and dense foliage of the fine specimen at Segrez.

Var. *violacea*.—This variety has also whitish pubescence on the shoots, petiole, and under surfaces of the leaflets, which are longish, with an acute or acuminate apex. The flowers are violet according to Dieck.² It does not appear to be in cultivation in England.

I incline to the belief that we have in these forms to deal with only two varieties of *Sophora japonica*, which is a widely spread species, and presents considerable variation in pubescence and in colour of the flowers in China.

Var. *oligophylla*, Franchet.³—This is a curious variety found by Père David at a tomb near Peking, where he observed two trees. The leaflets are very few in number, three or four, and the end one is trilobed; they are thicker in texture and more glaucous than is ordinarily the case. This variety would be well worth introduction.

DISTRIBUTION AND HISTORY

Sophora japonica, in spite of its name, does not appear to be really wild in Japan, although it is recorded from that country by Franchet⁴ and Matsumura.⁵ Shirasawa,⁶ the latest Japanese authority, says it is planted around habitations in both the sub-tropical and temperate regions of Japan, and that it was introduced from China. Sargent⁷ observes: "Even Rein (*The Industries of Japan*), usually a most careful observer, states that '*Sophora japonica* is scattered throughout the entire country, especially in the foliaceous forests of the north.' He had evidently confounded Sophora with Maackia,⁸ a common and widely spread tree, especially in Yezo. Sophora, which is only seen occasionally in gardens, does not appear to be a particularly popular tree with the Japanese." The Kew Herbarium specimens from Japan are from gardens near Nagasaki, no wild specimens having been ever received.

Sophora japonica is undoubtedly a native of China, and it is recorded from nearly all the provinces where Europeans have made botanical collections; but of its occurrence as a forest tree there is little information. It appears to be really wild in the province of Chihli. I have never seen it in the numerous mountain forests which I visited in Central China or Yunnan; and it is difficult to decide whether the trees seen at lower levels, where cultivation has been going on for centuries, are wild or planted. It has a wide range as a cultivated plant in China, as it flourishes from Peking to Hongkong and from Shanghai to Yunnan.

⁵ Matsumura, *Shokubutsu-me-i*, 279 (1895).

⁶ Shirasawa, *loc. cit.*, Text, i. 86. The tree is called *Enju* in Japan.

⁷ Sargent, *Forest Flora of Japan*, 1.

⁸ Maackia is another name for *Cladrastis amurensis*; but it is possible that the tree confused with *Sophora japonica* in Japan is *Sophora platycarpa*, Maxim, which is very similar to it in foliage. Dupont, *Les Essences Forestières du Japon*, p. 66, gives a very complete account of the wood and the uses of a forest tree in Japan, which he considered to be *Sophora japonica*; but as it is evidently not that species, and as it is uncertain whether he referred to *Sophora platycarpa* or *Cladrastis amurensis*, I have not quoted his description.

It has been known to the Chinese from the earliest times, and has been always named by them the *Huai* tree. In the *Chou Li*, a Chinese classical book, dating from several centuries before the Christian era, it is mentioned as having a place in official audiences. In front of the high officials were placed three *Sophora* trees, beside which stood the counsellors. It was also used as firewood, and was planted in cemeteries, being the tree prescribed by law to be planted beside the tumulus, 4 feet high, in which officials of low degree were buried. The tumulus of the emperor was 30 feet high, and around it pine trees were planted. Feudal princes were honoured with cypresses; and common people were only permitted to have willows around their tombs. The *Sophora* was also used medicinally from the earliest times in China, the flowers, fruit, bark, and root being all employed. In the *Erh-ya*, the oldest Chinese dictionary (twelfth century B.C.), the *Huai* tree is called the *guardian of the palace*; and it is said to open its leaves by night and close them by day. The text is probably corrupt, and the periods of expanding and folding of the leaves are reversed. This is perhaps the first reference in any literature to the phenomenon of the sleep of plants. The term *guardian of the palace* no doubt refers to its use in official audiences.

With regard to the uses of *Sophora* in China at the present day, in addition to its ornamental character as a tree planted frequently in the courtyards of temples, it is also of considerable economic importance. In commerce the flower-buds (*Huaimi*, *huai-hua*, *huai-tze*), and pods (*huai-chio*, *huai-shih*) are met with everywhere; but considerable confusion has arisen in books as to the exact uses of these products. Shirasawa (*l.c.*) is inaccurate in stating that the Chinese use the bark to dye paper and cloth of a yellow colour. Mouillefert¹ says the leaves are used for dyeing; but this is also an error. The facts are simple: the flower-buds are used as a dye, and the pods as a medicine.

The flower-buds, as seen for sale, are mixed with stalks, etc., and are evidently collected when quite young as they are only about $\frac{1}{8}$ to $\frac{1}{4}$ inch long. They are oval and pointed at the stalked end, dark greyish in colour, and tasteless. When immersed in water they impart to it a fine yellow colour. These flower-buds, packed in large sacks, are exported in considerable quantity from Shanghai and Tientsin. Consul Meadows in a letter to Kew gives an account of the process of dyeing, which is one for dyeing blue cloth a green colour rather than for obtaining a yellow colour.² Debeaux³ asserts that the buds are moistened with water, and a quantity of common salt is added; the mixture is then put in a press, which squeezes out a liquor with which cotton or silk may be dyed yellow. He adds that the leaves do not contain any yellow colouring matter.

Every part of the tree abounds in a purgative principle; and it has been asserted that it is dangerous to work with the wood when it is fresh, owing to the

¹ Mouillefert, *Traité des Arbres*, 629.

² The process, according to Meadows, is as follows:—"To dye a piece of cotton cloth of narrow width (1½ feet) a thousand feet long, a mixture is made of 42 lbs. of *Sophora* buds, 8 lbs. of alum, and 666 lbs. of water, which is boiled in a large pot for six hours. In Chekiang both cottons and silks are first dyed a light blue, and are then put in the mixture just described, and all is boiled over again for three or four hours; the cloth is then taken out and dried in the sun. It is afterwards boiled and sun-dried once or twice again, according as a lighter or darker tint of green is required."

³ Debeaux, *Note sur quelques matières tinctoriales des chinois* (1866).

distressing symptoms which ensue; and turners of the wood suffer especially. The active principle resembles the *cathartine* which occurs in senna leaves. In the botanical garden at Dijon there is a well beneath a *Sophora* tree, and when its leaves or flowers are about to fall the gardener covers the well, having found by experience that the water acquires laxative properties by the infusion in it of the *Sophora* leaves or flowers.¹

The wood, according to Shirasawa (*l.c.*), differs remarkably in the colour of the heart-wood and sap-wood; the specific gravity is in dry air 0.74. It is tough and durable, though light and coarse grained; and the annular layers are marked by broad bands of open cells. In Japan it is used for the pillars and frames of their wooden houses, but is not of sufficient importance to have been included in the Japanese Forestry exhibit at St. Louis, nor is it mentioned in Goto's *Handbook of the Forestry of Japan* as a valuable wood.

INTRODUCTION

Petiver² (1703 or a little earlier) speaks of "Hai-hoa, *Chinensibus, flore albo, siliquis gummosis articulatis*," evidently the *Sophora*, and it is probable that the specimen was collected in the island of Chusan by Cunningham in 1700.

Desfontaines,³ quoting Guerrapain,⁴ states that the tree was first raised in Europe from seeds sent by Père d'Incarville (a Jesuit stationed at Peking) in 1747, the first trees being planted at the Petit Trianon by B. de Jussieu. It was unknown to what genus the tree belonged, until it flowered near Paris in 1779. It was introduced in 1753 into England by James Gordon, a celebrated nurseryman at Mile End.⁵ Mr. Nicholson obtained from Mr. James Smith, former curator of Kew Gardens, some interesting details concerning the Kew trees. Five plants were early planted at Kew, all of which were still there in 1864, but two no longer exist. One of the three trees remaining is near the rockery; not far off is the famous specimen in chains, while the third tree is in the village at Kew beside the house once occupied by Mr. Aiton, the first director of the Kew Gardens. These three trees, according to Mr. Nicholson,⁶ are probably as old as any existing elsewhere in England. There is, however, another tree at Kew beyond the Pagoda of which there is no history.

CULTIVATION

Sophora japonica is an ornamental tree, the peculiarities of which make it interesting. The leaves are dark, glossy green, of an unusual tint, and the younger branchlets are of the same colour. The leaves fall very late in autumn, and keep on

¹ Loudon (ii. 564), quoting from Duhamel, states that the bark and green wood of this tree exhales a strong odour which produces on those who prune it a remarkable effect. A plank cut from a tree at Kew in Elwes' possession shows a hard, compact, yellowish brown wood.

² Petiver, *Musei Petiveriani Centurie decem rariora Naturæ continens*, No. 930 (1692-1703).

³ Desfontaines, *Histoire des Arbres*, ii. 258 (1809).

⁴ Guerrapain, *Notice sur la culture du Sophora*.

⁵ *Hort. Kew*, first edition (1789), ii. 45. In *Andrews Repository*, ix. 585, there is a figure of a specimen from a tree 40 feet high in the collection of John Ord at Purser's Cross, Fulham, which was planted by him forty years before. Ord is stated to have received his plants from Gordon, "who introduced the species from China in 1753." It is also stated that the *Sophora* first flowered in England at Syon in August 1797. Loudon, however (*loc. cit.*), states that "the oldest tree near London is at Purser's Cross, where it flowered for the first time in England in August 1807."

⁶ Nicholson in *Woods and Forests* (1884), p. 500.

42 The Trees of Great Britain and Ireland

the tree fresh and green long after most trees have lost their foliage. The time of flowering is also very late, and this is a point of interest, although the flowers are not conspicuous or remarkable for size or colour. It is a very hardy tree in England,¹ and seems to be free from all attacks of fungi and insects. Its roots do not sucker, which is a point in its favour when planted in towns or in gardens or parks. It has been freely used as a street tree in Italy, where its dense foliage is an advantage in the hot summers. It is remarkable how little the foliage is affected by the hottest and driest seasons, and on this account it might be tried in dry and hot situations. It thrives fairly well in all soils that are deep and not too compact, but it will only grow vigorously in deep rich soils, where seedlings will sometimes attain a height of 12 feet in four or five years.² It is propagated by seeds, which should be sown in spring.

REMARKABLE TREES

The trees in the Kew Gardens have been alluded to as regards their history. The one which occurs near the Pagoda, in 1903, was 68 feet high and 8 feet 3 inches in circumference. The old tree, with the branches held together by chains, now measures (1905) 50 feet high and 13 feet in girth at a foot from the ground, the narrowest part of the short bole, which branches immediately into three main limbs. A fourth limb, very large, was blown off some years ago. Not far off is a smaller tree about 6 feet in girth near the ground; it branches from the base, forming a wide-spreading low tree.

At Syon, two trees of considerable size are now living, each about 70 feet high; one measured in 1903 12½ feet in girth, the other 12 feet.³

The tree in the Oxford Botanic Garden was 65 feet high by 12 feet 3 inches in girth in 1903 when measured by Elwes.⁴

That in the old Botanic Garden at Cambridge is one of the finest trees in England, as it has a very symmetrical bole. It measured in 1904, 73 feet high by 11 feet in girth. It is figured in Plate 16.⁵

We are not acquainted with any large specimens of the *Sophora* now growing in Scotland, Ireland, or Wales, though Loudon mentions one at Tynninghame, Haddingtonshire, 42 feet high,⁶ one at Castletown near Dublin 35 feet high, and one at Oriel Temple, Co. Louth, of the same height.

In France and Germany there are probably larger specimens than in this country. (A. H.)

¹ The *Sophora* has withstood, without injury, the severest frosts in Perthshire. See pamphlet by Col. H. M. Drummond Hay, *The Comparative Hardihood of Hardwooded Plants, from Observations made at Seggieden, Perthshire* (1882).

² Nicholson, in an excellent article on the *Sophoras* in *Woods and Forests*, July 30, 1884.

³ One of these is mentioned by Loudon, ii. 565, as being the largest near London, and measured in 1838 57 feet high and about 9 feet in girth.

⁴ This is said by Loudon (*l.c.*) to have been twenty years planted in 1844, though probably this is an error, as it was then 35 feet high.

⁵ Loudon says there were two trees in the garden, both 50 feet high, which had flowered occasionally.

⁶ There is a splendid *Sophora* in the grounds at Cobham Park, Kent, which I measured in 1905, and found to be 85 feet by 10 feet. There is also one in the Tilt Yard at Arundel Castle, 62 feet by 9 feet 6 inches.—(H. J. E.)

ARAUCARIA

Araucaria, Jussieu, *Gen. Pl.* 413 (1789); Bentham et Hooker, *Gen. Pl.* iii. 437 (1880); Masters, *Journ. Linn. Soc. (Bot.)* xxx. 26 (1893).
Dombeya, Lamarck, *Dict.* ii. 301 (*non* Cavanilles) (1786).

TALL evergreen trees, with naked buds and coriaceous leaves, which are widest at their bases and spirally arranged on the shoots.¹ Usually dioecious. Male flowers in catkin-like masses, solitary or in fascicles at the ends of the branchlets; anthers numerous, with a prolonged connective, from which hang six to fifteen pollen sacs. Female flowers terminal, composed of many scales spirally arranged in a continuous series with the leaves, there being no obvious distinction between the seed-scale and the bract; each scale bears one ovule attached to the scale along its whole length. Cones globular, composed of imbricated wedge-shaped scales thickened at the apex. Seeds, one on each scale and adnate to it, flattened and without wings.

The genera *Araucaria* and *Agathis* constitute the tribe *Araucarineæ*, which are distinguished from the other *Coniferæ* by having a single ovule on a simple scale. In *Agathis* the ovule is free from the scale, while in *Araucaria* it is united with it. *Cunninghamia*, which was considered by Bentham and Hooker and by Masters to belong to this tribe, is now generally classed with the *Taxodineæ*; in it each scale bears three ovules.

There are about ten species of *Araucaria*, inhabitants of South America, Australia, New Guinea, New Hebrides, New Caledonia, and Norfolk Island. *Araucaria Cunninghami* has been reported several times as growing in the open air in England; but in some cases it is evident that *Cunninghamia sinensis* was the tree in question, while in other cases small plants were referred to which were speedily killed by the cold of our winters.² *Araucaria imbricata* is the only species which is hardy in this country. There are fine specimens of some of the other species in the Temperate House at Kew, viz. *Araucaria Bidwilli*, 48 feet high; *Araucaria excelsa*, 48 feet; *Araucaria Cunninghami*, 47 feet; and *Araucaria Cookii*, 30 feet.

¹ *Araucaria Bidwilli* has the leaves also spirally arranged, but by twisting on their bases they assume a pseudo-distichous appearance.

² In a letter in the *Gardeners' Chronicle*, May 1, 1869, Mr James Barnes, then gardener at Bicton, states, in reply to a suggestion that the tree there might be *Cunninghamia*, that it was really *Araucaria Cunninghami*, and that it had attained a height of 36 feet, with a diameter of branches of 28 feet, in a sheltered plantation in that favourable locality. But this tree was no longer living when I visited Bicton in 1902.—(H. J. E.)

ARAUCARIA IMBRICATA, CHILEAN ARAUCARIA

Araucaria imbricata, Pavon, in *Mem. Acad. Med. Madrid*, i. 199 (1797); Lambert, *Genus Pinus*, 106, t. 56, 57 (1832); Loudon, *Arb. et. Frut. Brit.* iv. 2432 (1844); Kent in *Veitch's Man. Coniferæ*, ed. 2, 297 (1900).

Araucaria Dombeyi, A. Rich. *Conif.* 86, t. 20 (1826).

Araucaria chilensis, Mirb., *Mem. Mus. Par.* xiii. 49 (1825).

Araucaria araucana, C. Koch, *Dendr.* ii. 206 (1873).

Pinus araucana, Molina, *Sagg. Storia Nat. Chile*, 182 (1782).

Dombeya chilensis, Lamarck, *Encycl.* ii. 301 (1786).

Araucaria imbricata is the oldest name under the correct genus *Araucaria*, and is, moreover, the one most generally used. *Piñon* is the Spanish name in Chile, *Pehuén* the Indian name.

Araucaria imbricata is a tree usually 50 to 100 feet high,¹ with a cylindrical stem, only slightly tapering in adult trees, and attaining 3 to 5 feet in diameter. The bark is very rough and divided into large thick irregularly pentagonal or hexagonal scales. The branches, in whorls of 6 or 7, are at first very spreading, and in young or isolated individuals persist for a long time, but in the forest generally fall off until a broad umbrella-shaped crown of very crowded branches remains. In certain cases,² secondary shoots appear on the trunk among the older branches as they die off.

Leaves: all of one kind, spirally crowded on the branches, sessile, coriaceous, rigid, ovate-lanceolate, with a sharp point at the apex, slightly concave on the upper surface, glabrous, bright shining green, marked with longitudinal lines, bearing stomata on both surfaces, margins cartilaginous; persistent for 10 or 15 years, withering during the later period of their life; their remains may be seen for a long time on the trunk and branches as narrow transverse ridges.

Male flowers: catkins almost cylindrical in shape, solitary or 2 to 6 in a cluster, terminal, sessile, erect, 3 to 5 inches long, yellow in colour, composed of densely packed anther scales, the tips of which are sharply pointed and recurved; pollen sacs 6 to 9. The male flowers frequently remain intact on the tree for several years; they generally in Europe appear early in spring, the pollen escaping in June or July.

Female flowers: ovoid, solitary, terminal, erect, about 3 inches long, composed of numerous wedge-shaped scales, terminating in long, narrow, brittle points.

Cones: globular, brown in colour, 4 to 6 inches in diameter, falling to pieces when the seeds are ripe (in England in late summer, in Chile in January or February). The cones take two years to ripen, fertilisation occurring in the second year in June or July, when the scales open and expose the ovule to the pollen blown from neighbouring staminate trees. Three months after fertilisation the seeds are fully matured.

Seeds: adnate to the scale and falling with it, 1 to 1½ inch long, wingless, covered by a thick brown coat. There are about 300 seeds in a cone.

¹ I have seen in Chile trees exceeding even 100 feet in height.—(H. J. E.)

² Such a case exists in a large tree at Tortworth Court.—(H. J. E.)

Seedling.—The cotyledons are two in number, and on germination remain below the soil enclosed in the seed (Plate 15F). The caulicle, to which is attached the cotyledons, is thick, fleshy, and carrot-shaped, serving as a store of nutriment for the plant after that of the cotyledons is exhausted; it is directed downward into the soil, and terminates in a long, slender, fibrous root, which gives off a few lateral rootlets. The plumule, the portion of the axis with its accompanying leaves, which is formed in the embryo prior to generation, protrudes between the stalks of the cotyledons, speedily becomes erect, and develops into the young stem, which bears leaves similar in shape to those of the adult plant. The cotyledons sometime after the stem has grown well above ground wither away, the ends of their stalks being visible on the upper part of the caulicle. At the end of the first season the stem is 4 or 5 inches long, and bears alternate leaves about ¾ inch long, gradually increasing in size from below upwards and forming a crowded tuft at the summit. The lower end or so of the stem is reddish, with leaves small and scale-like. The fusiform caulicle, about an inch in length, is continued below into a root 8 or 9 inches long.

Sexes.—The *Araucaria* is usually dioecious, the trees being either male or female. It was long supposed that there was a difference in the habit of the two sexes, due, doubtless, to Pavon's account of the matter. *Araucarias* differ, however, remarkably in habit, and no inference can be drawn as to sex from the habit or character of the growth of an individual. Monoecious trees (as is the case in nearly every dioecious species) are of exceptional and very rare occurrence. The most noted of these occurred at Bicton.¹ Other cases have been recorded from South Lytchett,² near Poole, and Pencarrow in Cornwall.³ (A. H.)

DISTRIBUTION

This remarkable tree was discovered in or about 1780 by a Spaniard, Don Francisco Dendariarena, who was employed by the Spanish Government to examine the trees in the country of the Araucanos, with the object of finding out those whose timber was best suited for shipbuilding. His account of its discovery, as quoted by Lambert, pp. 106-108, is as follows:—

“In September 1782 I left my companion, Don Hippolito Ruiz, and visited the mountains named Caramavida and Nahuelbuta belonging to the Llanista, Peguen, and Araucano Indians. Amongst many plants which were the result of my two months' excursion, I found in flower and fruit the tree I am about to describe.

“The chain or cordillera of the Andes offers to the view in general a rocky soil, in parts wet and boggy, on account of the abundance of rain and snow which fall in these regions, similar to many provinces in Spain. There are to be seen large forests of this tree which rises to the amazing height of 150 feet, its trunk quite straight and without knots, ending in a pyramid formed of horizontal branches which decrease in length gradually towards the top, and is covered with a double bark, the

¹ *Gard. Chron.* 1890, viii. 588, 593, Fig. 118.

² *L.c.* 753.

³ Specimens in the museum at Kew.

inner 5 or 6 inches thick, fungous, tenacious, porous, and light, from which as from almost all other parts flows resin in abundance; the outer is of nearly equal thickness, resembling cork cleft in various directions, and equally resinous with the inner."

I may say that the district spoken of is not really part of the Andes at all, but a coast range separated from the Andes by a wide tract of low country, mostly covered with forest. And as regards the bark, though I did not see any old trees felled in Chile, the bark of trees of 40-50 years old felled in England does not show bark at all approaching the thickness described. Neither have I seen in the districts I visited myself any trees as tall as he describes, or more than about 120 feet. He states that it is also found "juxta oppidum Conceptionis." There are no mountains near Concepcion high enough for the Araucaria, and I think this must be based on false information.

Don Dendariarena goes on to say that "the wood of this tree is of a yellowish white, fibrous, and full of very beautiful veins, capable of being polished and worked with facility. It is probably the best adapted for shipbuilding, as has been shown by the experiments made in the year 1780, in consequence of which orders were given to supply the squadron commanded by Don Antonio Bacaro, then at anchor in the port of Talcahuano."

"The resin abounding in all parts of the tree is white, its smell like that of frankincense, its taste not unpleasant. It is applied in plaster as a powerful remedy for contusions and putrid ulcers, it cicatrises recent wounds, mitigates headaches, and is used as a diuretic, in pills, to facilitate and cleanse venereal ulcers. The Indians make use of the fruit of this tree as a very nourishing food; they eat it raw as well as boiled and roasted, with it they form pastry, and distil from it a spirituous liquor."

Lambert says: "In a letter which I have lately received M. Pavon mentions an important particular, not noticed in the above description, namely, that the male tree is not above half the size of the female, and seldom exceeding 40 feet in height." I am not able to confirm this from personal observation either in Chile or England, and Dr. Masters¹ says that there is no reliable distinction between the male and female tree, whilst it is said in an account of the Araucarias in the Piltdown Nurseries² that the habit of the tree is no guide to the sex.

It was first described by the Abbé Molina, who called it *Pinus araucana*. Ruiz and Pavon who explored parts of Chile soon afterwards sent specimens to Europe to a Frenchman named Dombey, which were described by Lamarck under the name of *Dombeya chilensis*, but the generic name he gave cannot stand because it was previously used for a genus of Sterculiaceæ.

In 1795 Captain Vancouver visited the coast of Chile, accompanied by Archibald Menzies, who procured some seeds which he sowed on board ship,³ and succeeded in bringing home living plants, which he gave to Sir Joseph Banks, who planted one of them in his own garden at Spring Grove, and sent the remaining five plants to Kew. One of these, after being kept in the greenhouse till about 1806 or 1808,

¹ *Gard. Chron.* 1890, ii. 667.

² *Ibid.* 1891, i. 342.

³ Sir Joseph Hooker, who knew Menzies personally, tells me that he took these seeds from the dessert table of the Governor.

was planted out on what is now called Lawn L, and was at first protected during winter by a frame covered with mats. Here it grew for many years and attained the height of 12 feet in 1836 (*vide* Loudon), but eventually died in the autumn of 1892 at the age of nearly 100 years.¹ This is probably the tree figured by Lambert.

The first person who gives any account of the tree in its native forests, so far as I know, is Dr. Poeppig, whose account of the tree is printed in *Companion to Bot. Mag.* i. 351-355. It did not, however, become common in cultivation till the celebrated botanical traveller William Lobb, who was sent to South America by the firm of Veitch, sent home in 1844 a good supply of seeds which produced most of the finest trees now in England.

No account of his travels were, however, published, and on applying to Messrs Veitch before I went to Chile in 1901 I was informed that his journals, which I wished to consult, could not be found. The late Miss Marianne North was the first English traveller who published any account of the tree in its native forests, which she visited on her last journey in November 1884, mainly, as she says, for the purpose of painting this tree. But, owing to the difficulty and danger at that time of reaching the Andes, she went to the coast range of Araucania, called Nahuelbuta, which lies between the sea and the town of Angol, in the same district where the tree was probably first discovered. After describing her ride up from Angol to the mountains, which are here covered with a beautiful vegetation, among which Gunnera, Lapageria, Embotrium, Fuchsia, Buddleia, Alstroemeria, and many other favourite plants in English gardens are conspicuous, she says:²—

"The first Araucarias we reached were in a boggy valley, but they also grew to the very tops of the rocky hills, and seemed to drive all other trees away, covering many miles of hill and valley; but few specimens were to be found outside that forest. The ground underneath was gay with purple and pink everlasting peas, and some blue and white ones I had never seen in gardens, gorgeous orange orchids, and many tiny flowers whose names I did not know, which died as soon as they were picked, and could not be kept to paint. I saw none of the trees over 100 feet in height or 20 in circumference, and, strange to say, they seemed all to be very old or very young. I saw none of the noble specimens of middle age we have in English parks, with their lower branches resting on the ground. They did not become quite flat at the top, like those of Brazil, but were slightly domed like those in Queensland, and their shiny leaves glittered in the sunshine, while their trunks and branches were hung with white lichen, and the latter weighed down with cones as big as one's head. The smaller cones of the male trees were shaking off clouds of golden pollen, and were full of small grubs; these attracted flights of bronzy green parrakeets, which were busy over them. Those birds are said to be so clever that they can find a soft place in the great shell of the cone when ripe, into which they get the point of their sharp beak, and fidget with it until the whole cone cracks and the nuts fall to the ground. Men eat the nuts too, when properly cooked, like chestnuts. The most remarkable thing about the tree is its bark,

¹ *Cf. Kew Bull.* 1893, p. 24.

² Marianne North, *Recollections of a Happy Life*, 2nd ed. ii. 323, 324 (1892).

which is a perfect child's puzzle of slabs of different sizes, with 5 or 6 distinct sides to each, all fitted together with the neatness of a honeycomb. I tried in vain to find some system on which it was arranged. We had the good fortune to see a group of guanacos feeding quietly under the old trees. They looked strange enough to be in character with them, having the body of a sheep and the head of a camel; and they let us come quite near. On the other side of the mountains they are used as a beast of burden, though so weak that ten of them could not carry the load of an average donkey. After wandering about the lower lands, we climbed through the bogs and granite boulders to the top of one of the hills, and came suddenly to a most wonderful view, with seven snowy cones of the Cordillera piercing their way through the long line of mist which hid the nearer connecting mountains from sight, and glittering against the greenish blue sky. Each one looked perfectly separate and gigantic, though the highest was only 10,000 feet above the sea. Under the mist were hills of beech forest, and nearer still the Araucaria domes, while the foreground consisted of noble old specimens of the same trees grouped round a huge grey boulder covered with moss and enriched with sprays of embotrium of the brightest scarlet. No subject could have been finer, if I could only have painted it, but that 'if' has been plaguing me for years, and every year seems to take me farther from a satisfactory result."

Inspired by this charming description, and by a desire to see the magnificent forests of Southern Chile, whence I hoped to introduce new trees and plants to our gardens, I visited Chile in the winter of 1901-1902, and after various difficulties caused by the dispute about the frontier, which nearly led to a war between Chile and Argentina, I started from the hospitable home of my friends, Mr. George and Senora Bussey at San Ignacio, to see the Araucarias in the Sierra de Pemehue, a region where they attain their greatest perfection, and which, having only been recently conquered from the Indians, had been described by no scientific traveller; though Senor Moreno has written an excellent account of the Argentine side of the frontier, which I visited later.

The Sierra de Pemehue is a range of mountains lying on the west side of the upper course of the great Biobio river, and is not, strictly speaking, a part of the Cordillera of the Andes, from which it is separated by that river. The greater part of it is covered with splendid forests, principally composed of beeches, *Fagus obliqua* and *Fagus Dombeyi*, and it was near the head-waters of the Renaico river that I first saw what is to me the most striking of all trees hardy in England, and the only Chilean tree which as yet seems to have acclimatised itself thoroughly in this country.

They were growing in scattered groups on the cliffs far above us at an elevation of 3000-4000 feet, and we did not enter the Araucaria forest till we got near the top of the pass, which crossed over a mountain called Chilpa, between the Renaico and the Villacura valleys. Here the trees were growing scattered among Coigue trees (*Fagus Dombeyi*), and higher up in a forest mainly composed of Niere (*Fagus antarctica*), many of which were killed by forest fires, which had not, however, destroyed the thick-barked Araucarias, though I saw here but few young trees and no seedlings.

Their average height was 80-90 feet, and the diameter 2-3 feet, and the branches were mostly confined to the top of the tree, where they form a dense, flat-topped crown. On 27th January I saw much finer specimens in the valley above Lolco, on the road to Longuimay, and my companion, Mr. Bartlett Calvert, was successful in getting some excellent photographs which are here reproduced. Plate 17 shows the appearance of mature and young trees growing in an open grassy valley at about 4500 feet, with the high volcanoes of Longuimay and Tolhuaca in the background. The old tree on the right of the picture is about 90 feet, and the young one about 20 feet high, showing sixteen years of growth from a point 2-3 feet from the ground where the annual growths could no longer be distinguished. I therefore suppose this young tree to be twenty to twenty-five years old from seed.

Farther on in the same valley we came to much larger trees, which showed the curiously irregular slabs of bark of which Miss North speaks. The largest trees I saw had a girth of 24 feet at breast height, and were 90-100 feet high. The longest fallen stems I measured were little over 100 feet, and I should say 80-90 was the average height of full-grown ones. Plate 18 shows the habit which the trees assume when grown thickly at about 3500 feet elevation in the upper Villacura valley.

On the wind-swept ridges which we crossed higher up the pass, at an approximate elevation of 6500 feet, the Araucarias were much more stunted and had a very different habit of growth, but the high wind which prevailed, as it usually does at this season, made it impossible to photograph them. Two days later at Los Arcos, the frontier post of Argentina, I found scattered groves of Araucaria for about fifty miles south, as far as the valley of Quillen, but when we reached the country about the head-waters of the Pichelifeu river, about lat. 39° 30' S., I saw no more except a few isolated trees which appeared to have sprung up from seeds dropped by the Indians on their old camping grounds.

I had previously been told by Mr. Barton of Buenos Ayres, who is engaged in cutting timber on the north shore of the great lake Nahuelhuapi, about 100 miles to the south, that the Araucaria was found near this lake, and I had great hopes of discovering and introducing a new southern variety or species, which might prove hardier than *A. imbricata*.

But notwithstanding what Poeppig says as to the probability of its extension as far south as lat. 46°, I saw not a single tree on my journey from San Martin *via* Nahuelhuapi to Puerto Montt in lat. 41° 50', and none of the explorers who have been recently employed in surveying the frontier have, so far as I know, found it south of about lat. 41°. Sir T. Holdich is my authority for this statement.

Some of the trees here had much smoother bark covered with long tufts of grey lichen, and in this part of the forest there were plenty of young seedlings coming up, some of which I took up and unsuccessfully attempted to transplant to my friend's garden at San Ignacio.

The geographical range of the tree is therefore a very limited one, extending only from Antuco in about lat. 38° 40' to lat. 40° in the Cordillera, and on the coast range from about lat. 38° 30' to an unknown point probably not south of about lat. 41°. For, though Poeppig says it occurs on the Corcovado, he was speaking only from

hearsay, and the sudden change of the climate, which here becomes an extremely wet one, is probably the reason why the tree does not exist on the west coast in a much higher latitude, as do the majority of the trees and plants which are associated with it.

Another point in which I must differ from Poeppig is the bareness of the Araucaria forests of other vegetation. Though, of course, where the trees are closely crowded not many plants grow in their shade, yet the number of beautiful terrestrial orchids and other plants which I found in the more open parts of the Araucaria forest was very striking, and Miss North's observations in the Nahuelbuta range quite confirm my opinion that the moderate shade of the Araucaria is not prejudicial to herbaceous plants.

The soil on which it grows is mostly of volcanic origin, sometimes covered with deep vegetable mould, but more usually dry and rocky; and the climate, though warm and dry in the months of December, January, and February, is cold and wet in winter.

The only exact particulars I can give of the climatic variations were taken during the winter of 1901 at Rahue in the upper Biobio Valley, near Longuimay, at an elevation of 700 metres, which is lower and thus probably warmer than that of the Araucaria region. These observations I have condensed as follows:—

	MAXIMUM.	MINIMUM CENTIGRADE.	
Between April 21 and 30	+ 26 (on 25th)	- 3 (on 30th)	
„ May 1 „ 31	+ 19 (1st, 25th)	- 7 (on 13th)	snow on 7 days.
„ June 1 „ 30	+ 22 (on 27th)	- 6 (on 24th)	snow on 8 days.
„ July 1 „ 31	+ 12 (on 27th)	5 (on 10th)	snow on 6 days.
„ Aug. 1 „ 30	+ 12 (on 19th)	6 (on 17th)	{ snow on 5 days. rain on 7 days.
„ Sept. 1 „ 30	+ 24 (on 27th)	? 10 (on 2nd)	{ snow on 1 day. rain on 12 days.
„ Oct. 1 „ 31	+ 30 (on 17th)	? 6 (on 8th)	{ snow on 2 days. rain on 5 days.
„ Nov. 1 „ 23	+ 25 (on 21st)	? ?	{ snow on 2 days. rain on 7 days.

Reduced to Fahrenheit this register shows a very similar climate to that of some parts of England, very variable all the year round, but probably hotter and more sunny in winter.

As regards the summer climate I may say that in the months of January and February, which are the height of summer, it was never cold by day, and the sun and wind often unpleasantly warm, but at night the thermometer often fell to near freezing-point, and on one occasion, on 1st February, my sponge was frozen in camp just south of Lake Aluminé at about 5000 feet. We know that the Araucaria has borne in Great Britain temperatures below zero Fahr. without injury on dry and suitable soil, but it evidently will not endure the continuous wet of the southern coast region of Chile.

In the *Forstliche Naturwissenschaftliche Zeitschrift*, 1897, iv. 416-426, Dr. Neger, who was naturalist on the Chilean Boundary Survey in 1896-97, gives an

account of *Araucaria imbricata*, which does not add anything of great importance for English arboriculturists to what I have already stated. He says that there are two types of Araucaria forest, one of which is characteristic of the rainy coast mountain range of Nahuelbuta and the west side of the Andes on the Cordillera of Pemehue; and the other, which is peculiar to the drier plateaux of the Argentine territory, on the east side of the watershed. He refers to Reiche's account of the Nahuelbuta forest in *Engler's Bot. Jahrbuch*, xxii. 110, which gives a good account of the flora. He does not confirm the statement that the male trees are smaller in size than the female, and speaks of trees occurring in deep valleys 40-50 metres high, and 2-2½ metres in diameter at about 3 feet, but does not give any exact measurements, so that this height is probably an estimate by the eye. He says that the seeds do not ripen until May in the year after flowering, but I found them ripe in February and fit to eat in January. He gives some excellent illustrations of Araucaria forests on Nahuelbuta, one of which shows a wider and more unbroken extent than any that I saw; another shows the ability of the tree to take root and grow in the crevices of bare rock. Another shows a forest at the foot of the great volcanic peak of Lanin, where some of the trees have been almost buried by sand and still retain their upright position. Lastly, he gives a small map of the distribution which, however, is not sufficiently detailed to be very accurate; this makes Antuco the most northerly point, and a point somewhere north of lat. 40°, the southerly range of the tree. He says that in the museum of Santiago there are geological evidences of the existence at a former period of Araucaria as far north as the Puna of Atacama.

REMARKABLE TREES

The finest tree which until recently existed in England was at Dropmore, which, however, began to die about four years ago, and was dead when the photograph (Plate 19) was taken in June 1903. It is said¹ to have been purchased at a sale in the Royal Horticultural Gardens at Chiswick in 1829, and in 1893 to have been 69 feet high. When felled in 1905 Mr. Page found it to be 78 feet 6 inches high, and the butt was 27½ inches in diameter at the base under the bark, which was about 2 inches thick, the measurable timber in it being about 65 cubic feet.

There are many fine specimens at Beauport, Sussex, the seat of Sir Archibald Lamb, Bart., where a plantation was made about forty years ago, which gives a better idea of the Araucaria at home than any I have seen in England. It contains 27 trees on an area 102 paces round, and the inside trees are clearing themselves from branches naturally. Twenty of them Sir A. Lamb says are over 50 feet high, and in 1905 I estimated them to contain an average of 25 cubic feet (Plate 20). The largest tree at Beauport, as measured by Henry in 1904, was 74 feet high and 7 feet 9 inches in girth. The trees produce seeds freely, and a seedling growing in a chink of the garden steps was 4 feet high in 1903, and in 1905 had grown at least 2 feet more.

At Strathfieldsaye, Berks, the seat of the Duke of Wellington, the Araucaria has produced self-sown seedlings, a group of which is shown in Plate 15 E.

¹ *Gard. Chron.* 1893, i. 232; also *L.c.* 1872, p. 1324.

At the Piltdown Nurseries in Sussex there are many fine specimens,¹ one of which is said to have been 50 feet by 9½ feet in girth in 1854. Messrs. Dennett and Sons, the present tenants of this nursery, inform me that they believe this is one of the oldest trees in the country, and that in April 1903 it was about 70 feet high (perhaps more), with a girth of 7 feet at 5 feet, and 11 feet close to the ground. But a correspondent of the *Gardeners' Chronicle*² says that in 1891 it was 65 feet by 10½ feet at 4 feet, and that 3½ bushels of seed were collected in this nursery in 1889, which produced hardier plants than imported seed. He also states that one of the trees which was cut down in 1880 threw up in 1884 a sucker from the roots, which grew 15 feet high in five years, and showed in 1891 no signs of branching out in any way.³ He also states that it does not matter when Araucarias are pruned, as they grow steadily all the year. The soil at Piltdown is a deep loam with gravel subsoil, and though, as it is here stated, it is generally thought that a dry, well-drained subsoil is essential to the success of this tree, yet I have seen in the garden of Foss bridge Inn in the Cotswold Hills, in a low damp situation close to the banks of the Coln, two Araucarias, male and female, about 40 feet high, which produced ripe seed in 1903, from which Mr. Holyoake, gardener to the Earl of Eldon of Stowell Park, has raised plants.

At Bicton, Devonshire, the seat of the Honourable Mark Rolle, there is a fine avenue of Araucarias, which has been often mentioned in print; but the trees in it do not appear to be increasing in height so fast as the good soil and climate would lead one to expect. When I saw them in September 1902 the best which I measured was about 50 feet high by 8 feet 9 inches in girth. Ripe seeds were falling at the time, from which seedlings were raised.

There are also fine trees at Castlehill, North Devon, the seat of the Earl Fortescue, which have produced seed for many years past.

At Tortworth Court, Gloucestershire, the seat of the Earl of Ducie, who has one of the best collections of trees in England, and to whom I am indebted for very much assistance and advice in this work, there are many large Araucarias,⁴ the best of which I found to be 53 feet by 7 feet 6 inches in 1904. It is producing many young shoots among the dying branches of the trunk.

In Scotland the Araucaria grows well not only in the south-west where, at Castle Kennedy, the seat of the Earl of Stair, there is a fine avenue, 200 yards long, in which the largest tree is 50 feet by 6 feet 2 inches in girth, and from which self-sown seedlings have sprung, but also in Perthshire, where there are fair-sized trees, one of which on the banks of the Tay in the grounds of the Duke of Athole at Dunkeld, I found in 1904 to be 50 feet high, but only 3 feet 11 in girth. It grows well at Gordon Castle exposed to the full force of the north-east wind, and has ripened seeds as far north as Inverness.⁵ But some of the trees recorded in Perthshire and other places in Scotland have been killed during severe frosts, and as a rule the growth is not so rapid as in the south of England. Two

¹ *Gard. Chron.* 1885, xxiii. 342.

² *Ibid.* 1891, i. 342.

³ Sir Herbert Maxwell informs me that he saw at Cairnmore an old trunk of Araucaria which had died twenty years ago, still standing, with a young growth 3 feet high from the stool.

⁴ Cf. *Gard. Chron.* 1890, ii. 633.

⁵ *Ibid.* 1868, p. 464; 1872, p. 1323; 1894, xvi. 603.

trees at Redcastle, Ross-shire, planted in 1843, measured by Col. A. Thynne, are 47 feet by 7 feet 4 inches, and 40 feet by 6 feet; the latter, though exposed to the east wind, is branched to the ground.

At Ardkinglas there is a very healthy tree 50 feet by 6 feet, and at Inverary, Minard Castle, Poltalloch, and other places in Argyleshire, there are several thriving trees of good size. At Loch Corrie, near Glenquoich, there are two trees at 450 feet above sea-level, one of which in 1905 was 43 feet by 6 feet 2 inches.

In Ireland it seems at home almost everywhere. At Fota, in the extreme south, Henry measured one 62 feet by 5 feet; at Ballenetray, Co. Waterford, a tree was recorded¹ in 1884 as being 65 feet 6 inches by 6 feet; at Woodstock, Co. Kilkenny, there is a tree which in 1904 Henry found to be 65 feet by 9 feet 9 inches; and at Castlewellan, Co. Down, the seat of the Earl Annesley, and many other places, good trees occur.

In the milder parts of Western France the Araucaria thrives, but does not appear to have grown as large as in England. The best is reported by M. de Vilmorin as growing at Penandreff, near St. Renan, Finisterre, which in 1890 was 50 feet high by 7 feet 4 inches in girth. In the *Revue Horticole*, 1899, p. 460, this is confirmed. In Germany I have not heard of any fine examples.

CULTIVATION AND SOIL

The Araucaria should always be raised from seed, home-grown seed being preferable; for though plants have been raised from cuttings, which have grown to a considerable size, this mode of propagation is the cause of much disappointment, and of many ill-shaped and unsightly trees, not only in the Araucaria, but in many other conifers. The seed should be sown singly in pots, laying the seed on its side with the thick end in the centre, and will germinate best in a frame or cold greenhouse, where they can be protected from mice and frost. The young plants should not remain in pots more than one or at most two seasons, for though the tap-root does not become so long as in the case of pines, it wants room; and if the climate and soil are not very favourable, the young tree should not be permanently planted out till it is 1 or 2 feet high. The seedlings vary much in vigour, and on cold or calcareous soil many die young; but under better conditions the tree grows at least 1 foot a year when established.

It should be planted only in a well-drained situation, as severe frosts will often kill the trees when small; and though not so particular about the constituents of the soil as most Chilean trees, seems to thrive better on a sandy soil free from lime, especially on the red sandstone and greensand formations.

In the *Gardeners' Chronicle*, August 15, 1885, is an excellent note by Mr. Fowler, whose experience of this tree at Castle Kennedy was extensive, on the cultivation of the Araucaria; and another valuable note on the same subject will be found in the same journal, November 13, 1886, by Mr. C. E. Curtis. Both these authorities consider that the exudation of gum which often occurs in unhealthy trees

¹ *Woods and Forests*, Feb. 6, 1884.

54 The Trees of Great Britain and Ireland

is due to the roots of the tree having reached a cold wet subsoil, or from exposure to excessive cold. There seems to be no remedy for this disease, which usually kills the tree.

Araucarias do not thrive in the smoky atmosphere of a large town, and for this reason are not seen at their best in the immediate neighbourhood of London, nor do I know of any very fine ones in Wales or in the midland and northern counties of England.

USES

The gum which exudes from the bark is used in Chile as a salve for wounds and ulcers. It has a pleasant smell like that of turpentine, and sets hard when dry, but I am not aware that it contains any special intrinsic virtue.

The seeds are largely consumed by the Araucanos and other tribes of Indians, and are occasionally sent for sale to the markets of Valdivia and Concepcion. I have eaten them both roasted and boiled, and found them very palatable, with a nutty flavour somewhat like that of almonds.

The timber is said to have been formerly used in the dockyards of Chile, but is now considered inferior to that of the Alerce (*Fitzroya patagonica*), and perhaps owing to the remote positions in which the trees grow, is not now used except locally. Through the kindness of the Duke of Bedford I received two planks cut from a tree grown at Endsleigh, near Tavistock, of which the wood does not show any specially attractive quality. The Earl of Ducie describes it¹ as "not unlike good deal, but from the absence of turpentine and for some other reason it is smoother to the touch than the ordinary deals of commerce. In this respect its texture is not unlike that of redwood (*Sequoia sempervirens*). On testing a thin batten by breakage, it proved to be tough and strong for its size; but the fracture was abrupt, and showed little longitudinal fibre. The wood is somewhat heavier than ordinary deal." The timber is not mentioned in Stone's *Timbers of Commerce*. (H. J. E.)

GINKGO

Ginkgo, Linnæus, *Mantissa*, ii. 313 (1771); Bentham et Hooker, *Gen. Pl.* iii. 432, 1225 (1880); Masters, *Jour. Linn. Soc. (Bot.)*, xxx. 3 (1893).
Salisburia, Smith, *Trans. Linn. Soc.* iii. 330 (1797).

TREES, several extinct and one living species, bearing fan-shaped, fork-veined leaves on both long and short shoots. Flowers dioecious, arising from the apex of short shoots, which bear at the same time ordinary leaves. Male flowers: catkins, 3-6 on one shoot, each being a pendulous axis bearing numerous stamens loosely arranged. Stamen a short stalk ending in a knob, beneath which are 2-4 divergent anthers, dehiscing longitudinally. Female flowers, 1-3, more or less erect on the shoot, each consisting of a long stalk, which bears an ovule on either side below the apex. The ovule is sessile, straight, surrounded at its base by an aril or collar-like rim,¹ and naked (*i.e.* not enclosed in an ovary). Fruit: a drupe-like seed (sessile in the small bowl-shaped little developed aril) consisting of an orange fleshy covering enveloping a woody shell, within which, embedded in the albumen, lies an embryo with 2-3 cotyledons. The albumen is covered by a thin membrane which is only adherent to the woody shell in its lower part. Two embryos often occur in 1 seed, and of the 2 ovules only one is generally developed into a seed.

Ginkgo was formerly considered to belong to the Coniferæ, but recent investigations show that it is distinct from these, and is the type of a Natural order Ginkgoaceæ, which has affinities with Cycads and ferns. The seeds resemble closely those of Cycads, and at the end of the pollen tube are formed two ciliated antherozoids which are morphologically identical with the antherozoids occurring in ferns. Ginkgo, however, is a true flowering plant, as it produces seeds, and is a gymnosperm, since it bears ovules which are not enclosed in an ovary.

The extinct species have been found in the Jurassic and succeeding epochs. Gardner² considers the specimens which have been found in the white clay at Ardtun in the Isle of Mull to be specifically identical with *Ginkgo biloba*.

¹ Considered now to be a reduced carpel.

² J. S. Gardner, *British Eocene Flora* (1886), ii. 100.

GINKGO BILOBA, MAIDENHAIR TREE

Ginkgo biloba, Linnæus, *Mantissa*, ii. 313 (1771); Kent in *Veitch's Man. Coniferae*, 2nd ed. 107 (1900); Seward and Gowan, *Ann. Bot.* xiv. 109 (1900).

Salisburia adiantifolia, Smith, *Trans. Linn. Soc.* iii. 330 (1797); Loudon, *Arb. et Frut. Brit.* iv. 2094 (1838).

The Ginkgo when young is pyramidal in habit, with slender, upright branches: older, it becomes much more spreading and broader in the crown. It attains a height of 100 feet and upwards, with a girth of stem of about 30 feet. Bark: grey, somewhat rough, becoming fissured when old.

Leaves: deciduous, scattered on the long shoots, crowded at the apex of the short shoots, which grow slowly from year to year, their older portions being covered with the leaf-scars of former years. The short shoot may, after several years, elongate into a long shoot bearing scattered leaves. The leaves are stalked, and unique in shape amongst trees, recalling on a large scale the pinna of an adiantum fern; they show much variation in size (2-8 inches in breadth) and in margin, but generally are bilobed and irregularly crenate or cut in their upper part. There is no midrib, and the veins, repeatedly forking, are not connected by any cross veinlets. The stomata are scattered on the lower surface. In the bud the leaves are folded together and not rolled up, as in the crozier-like vernation of ferns.

Flowers and fruit: see description of the genus.

The drupe-like seeds have a fleshy outer covering of a bright orange colour when ripe, and when they fall upon the ground, this bursts and emits an odour of butyric acid which is very disagreeable.¹ They are imperfectly developed as they fall, though apparently ripe; and the fertilisation of the ovule and the subsequent development of the embryo occur while they are lying on the ground during winter. The kernels are edible, being known to the Chinese as *pai-kuo* (white fruits), and are sold in most market towns of China. They are supposed to promote digestion and diminish the effects of wine-drinking; and are eaten roasted at feasts and weddings, the shells being dyed red.

Fruit-bearing trees are now common in Southern Europe; but no fruit, so far as we know, has ever been produced in England. The well-known tree at Kew is a male, and produces flowers freely in exceptional years, *e.g.* in 1894, supposed to be due to the fact that the preceding summer was remarkably warm, with continual sunshine.

Extraordinary cases of abnormal formation of fruit have been observed in Japan. Shirai² described and figured in 1891 fruit which was produced on the surface of ordinary leaves of the tree. Fujii has studied since then the various stages of the development of ovules and of pollen sacs upon leaves. The so-called aril of the fruit is considered by him to represent a carpel, as he has observed transitional stages between the ordinarily shaped aril and a leafy blade bearing ovules.

¹ "The pulp surrounding the seed has a most abominable odour. Although warned not to touch it, I gathered the seeds with my own hands; but it took me two days' washing to get the odour off."—(W. Falconer in *Garden*, 1890, xxxviii. 602.)

² Shirai, in *Tokyo Bot. Mag.* 1891, p. 342.

Jacquin¹ grafted on the male tree at Vienna, when it was quite small, a bud of the female tree, from which a branch developed. This tree is now of large size; and numerous branches regularly bear male flowers, whilst one branch, now very stout, bears female flowers. This female branch puts forth its foliage about fourteen days later than the male branches, and retains them much later in autumn. In this case the shoot retains its individual characters, and the stock does not affect it even in regard to its annual development.

Seedling.—The germination in Ginkgo is not unlike that of the oak. We are indebted to Mr. Lyon² of Minneapolis for figures of the seedling, which are reproduced on Plate 15 C, D.

When the seeds are sown the hard shell is cracked at its micropylar end by the swelling of the embryo within. Through this opening the body of the embryo is thrust out by the elongation of the cotyledons, which remain attached to the caulicle by two arching petioles; between these the plumule or young stem ascends, while the root turns down into the soil. The cotyledons remain attached throughout the first season's growth. The first two or three leaves directly above the cotyledons remain small and scale-like. After reaching 4 or 5 inches in height the stem stops growing, having expanded into a rather close crown of ordinary leaves at its apex, which ends in a large terminal bud. The root attains in the first season about the same length as the stem, and develops numerous lateral fibres. This primary root, as is usually the case in Gymnosperms, persists as the tap-root of the plant.

Sexes.—Certain differences, besides those of the flowers, are observable in male and female trees.³ The male trees are pyramidal and upright in habit, the ascending branches being of free and vigorous growth. The female trees are closer and more compact in habit, more richly branched below, and the branches sometime become even pendent.⁴

Monsieur L. Henry⁵ states that in Paris the leaves of the female Ginkgo fell three or four weeks later than those of the male. Generally male trees are completely denuded of foliage by the beginning of November, while the female trees retain their leaves till the end of November or the beginning of December.

Burrs.—In Japan there often develops on old Ginkgo trees peculiar burrs, which are called *chi-chi* or nipples. These may be observed in an incipient stage on the large tree at Kew. They occur on the lower side of the larger branches of the tree, and vary in size from a few inches in length to 6 feet long by 1 foot in diameter. They occur singly or in clusters, and are generally elongated, conical in shape, with a rounded tip. If they reach the ground, as is sometimes the case, they take root, and then bear leaves. They are due to the abnormal development of dormant or adventitious buds. A description of this curious phenomenon and a photograph of a tree bearing a large number of these growths is given by Fujii in *Tokyo Bot. Mag.*

¹ Kerner, *Nat. Hist. of Plants* (Eng. trans.) ii. 572.

² See Lyon's paper in *Minnesota Botanical Studies*, 1904, p. 275.

³ Sargent denies this, and says it is impossible to distinguish the sexes till the trees flower; but observations on the Continent go to show that the sexual differences pointed out above really exist. See Sargent, *Garden and Forest*, 1890, p. 549.

⁴ See Schneider, *Dendrologische Winterstudien*, 127 (1903), and Max Leichtlin in *Woods and Forests*, Jan. 16, 1884.

⁵ *Bull. de l'Assoc. des anc. élèv. de l'école d'Hort. de Versailles*, 1898, p. 597, quoted in *Gard. Chron.* 1899, xxv. 201.

1895, p. 444. We are indebted to Mrs. Archibald Little for a photograph taken by her in Western China, of a tree 19½ feet round the base, and larger above, which very well shows these excrescences (Plate 23).

IDENTIFICATION

In summer the leaves are unmistakable. In winter the long and short shoots should be examined. The long shoot of one year's growth is round, smooth, brownish, and shining, the terminal buds being larger than the scattered lateral buds, which come off at a wide angle. The buds are conical, and composed of several imbricated brown dotted scales. The leaf-scars show 2 *small cicatrices*, and are *fringed above with white pubescence*. The short shoots are spurs of varying length, up to an inch or more, stout, ringed, and bearing at their apex a bud surrounded by several double-dotted leaf-scars. In *Pseudolarix* and the larches, which have somewhat similar spurs, the leaf-scars are much smaller, and show on their surface only one tiny cicatrice. In *Taxodium* there are no spurs, and the scars which are left where the *twigs* have fallen off show only one central cicatrice.

VARIETIES

The following forms are known in cultivation:—

Var. *variegata*. Leaves blotched and streaked with pale yellow.

Var. *pendula*. Branches more or less pendulous.

Var. *macrophylla laciniata*. Leaves much larger than in the ordinary form, 8 inches or more in width, and divided into 3 to 5 lobes, which are themselves subdivided.

Var. *triloba*. Scarce worthy of recognition, as the leaves in all Ginkgo trees are exceedingly variable in lobing.

Var. *fastigiata*. Columnar in shape, the branches being directed almost vertically upwards.¹

DISTRIBUTION AND HISTORY

The wild habitat of *Ginkgo biloba*, the only species now living, is not known for certain. The late Mrs. Bishop, in a letter to the *Standard*, Aug. 17, 1899, reported that she had observed it growing wild in Japan, in the great forest northward from Lebungé on Volcano Bay in Yezo, and also in the country at the sources of the great Gold and Min rivers in Western China. However, all scientific travellers in Japan and the leading Japanese botanists and foresters deny its being indigenous in any part of Japan; and botanical collectors have not observed it truly wild in China. Consul-General Hosie² says it is common in Szechuan, especially in the hills bounding the upper waters of the river Min; but he does not explicitly assert that it is wild there. Its native habitat has yet to be

¹ See *Garden*, 1890, xxxviii. 602. An interesting article by W. Falconer, who gives some curious details concerning the Ginkgo tree in the United States.

² *Parliamentary Papers, China*, No. 5, 1904; *Consul-General Hosie's Report*, 18. Mr. E. H. Wilson in all his explorations of Western China never saw any but cultivated trees.

discovered; and I would suggest the provinces of Hunan, Chekiang, and Anhwei in China as likely to contain it in their as yet unexplored mountain forests.

The earliest mention of the tree in Chinese literature occurs in the *Chung Shu Shu*, a work on agriculture, which dates from the 8th century, A.D. The author of the great Chinese herbal (*Pen-Tsao-Kang-Mu*, 1578 A.D.) does not cite any previous writers, but mentions that it occurs in Kiangnan (the territory south of the Yangtse), and is called *Ya-chio-tze*, "duck's foot," on account of the shape of the leaves. At the beginning of the Sung dynasty (1000 A.D.), the fruit was taken as tribute, and was then called *Yin-hsing*, "silver apricot," from its resemblance to a small apricot with a white kernel. In the *Chih-Wu-Ming*, xxxi. 27, there is a good figure of the foliage and fruit; and the statement is made that in order to obtain fruit the tree should be planted on the sides of ponds.

At present it occurs planted in the vicinity of temples in China, Japan, and Corea. It has always been the custom of the Chinese to preserve portions of the natural forest around their temples; and in this way many indigenous species have been preserved that otherwise would have perished with the spread of agriculture and the destruction of the forests for firewood and timber, in all districts traversed by waterways. Most of the curious conifers in China and Japan have a very limited distribution, and Ginkgo is probably no exception; though it is possible that it may still exist in the region indicated above.

I have never seen any remarkable specimens in China; but Bunge¹ says that he saw one at Peking, of prodigious height and 40 feet in circumference.

In Japan Elwes says that it is planted occasionally in temple courts, gardens, and parks. He did not see any very large specimen of the tree, the best being one in the court of the Nishi Hongagi temple at Kioto, which was of no great height, but had a bole about 15 feet in girth at 3 feet, where it divided into many wide-spreading branches which covered an area of 90 paces in circumference. This tree had green leaves and buds on the old wood of the trunk close to the ground, which he did not notice in other places.

Rein² says that the largest he knew of is at the temple of Kozenji near Tokyo, and this in 1884 was 7.55 metres in girth, and according to Lehman about 32 metres high. There is also one in the Shiba park, which in 1874 was 6.30 metres in girth. The tree is sometimes grown in a dwarf state in pots, but does not seem to be a favourite in Japan. The wood is somewhat like that of maple in grain, of a yellowish colour, fine grained, but not especially valued, though it is used for making chess boards and chessmen, chopping blocks, and as a groundwork for lacquer ware. The nuts are sometimes eaten boiled or roasted, but are not much thought of.

Ginkgo was first made known to Europeans by Kaempfer,³ who discovered it in Japan in 1690, and published in 1712 a description with a good figure of the foliage and fruit. Pallas⁴ visited the market town of Mai-mai-cheng, opposite Kiachta, in 1772, and saw there Ginkgo fruit for sale which had been brought from Peking.

¹ Bunge, in *Bull. Soc. d'Agric. du Depart. de l'Herault*, 1833.

² Rein, *Industries of Japan*.

³ Kaempfer, *Ameritates Exotice*, 811.

⁴ Pallas, *Reisen durch versch. Provinzen des Russischen Reiches*, 1768-1773, vol. iii.

Fortune¹ mentions that the tree grows to a very large size in the Shanghai district, and in the northern part of the Chekiang province. The Japanese name Ginkgo is their pronunciation of the Chinese *yin-kuo*, "silver fruit"; but the common name in Japan is *i-cho*.

INTRODUCTION

The tree was introduced into Europe about 1730, being first planted in the Botanic Garden at Utrecht. Jacquin brought it into the Botanic Garden at Vienna sometime after 1768. It was introduced into England about 1754; and into the United States in 1784, by W. Hamilton, who planted it in his garden at Woodlawn, near Philadelphia. It first flowered in Europe at Kew in 1795. Female flowers were first noticed by De Candolle in 1814 on a tree at Bourdigny near Geneva. Scions of this tree were grafted on a male tree in the Botanic Garden of Montpellier; and perfect fruit was produced by it for the first time in Europe in 1835.

CULTIVATION

Ginkgo is easily raised from seeds, which retain their vitality for some months. Female plants may be obtained by grafting. It is easily transplanted, even when of a large size. Trees of over 40 feet high have been successfully moved. It thrives in deep, well-drained, rich soil. It is useful for planting in towns, as it is free from the attacks of insects and fungi; and the hard leathery leaves resist the smoke of cities. It may also be freely pruned. It is of course best propagated by seed; but layers and cuttings may be employed in certain cases. Falconer (*loc. cit.*) says that it is not readily propagated by cuttings, and that it took two years to root a cutting in the gardens at Glen Core (U.S.A.). Pyramidal forms can be obtained by careful selection, and the broad-leaved variety by careful grafting. The Ginkgo is well adapted for cultivation in tubs or vases, and may then be trained either as a pyramid or a bush.

The tree has a formal appearance when young, and is not really beautiful till it attains a fair age. The peculiar form of the leaves renders it a striking object. The foliage, just before it falls in autumn, turns a bright yellow² colour, which makes it very effective in that season, but only for a few days, as the defoliation is very rapid.

REMARKABLE TREES

Ginkgo is perfectly hardy in England, and, as a lawn tree, is seen to great advantage. Many trees of considerable size occur in different parts of the country. The best known one is that at Kew, of which a photograph is given (Plate 21). In 1888 it was (measured by Mr. Nicholson) 56 feet in height, with a girth of 9 feet at

¹ See Fortune, *Wanderings in China*, 118, 251; *Residence among the Chinese*, 140, 348, 363; *Yedo and Peking*, 59.

² There is no trace of red in the autumnal tint, as is usual in other trees in their leaves before they fall. The tint in Ginkgo depends entirely on the yellow coloration of the disorganised chlorophyll corpuscles, and forms a beautiful object for the microscope.

a yard from the ground. It has a double stem, and in 1904 had increased to 62 feet high by 10 feet 4 inches in girth. Other remarkable trees near London¹ are:—

One at Chiswick House, which measured in 1889, 57 feet by 6½ feet, and in 1903, 62 feet by 6 feet 11 inches; and another at Cutbush's Nursery, Highgate, which was in 1903 56 feet high by 4½ feet in girth.

Ginkgo trees may be seen in the following places in London:—Victoria Park, Telegraph Hill, Lincoln's Inn Fields, Waterlow Park, Southwark Park.

At Grove Park, Herts, a tree measured in 1904 68 feet high by 8 feet 5 inches in girth.

At Bank House, Wisbech, the residence of Alexander Peckover, Esq., there is a tree which was 65 feet high and 7 feet in girth in 1904.

There is a very fine tree² at Frogmore, Windsor, which in 1904 measured 74 feet by 9 feet 3 inches, but divides into four stems (Plate 22).

At Barton, Suffolk, a tree planted in 1825 measured in 1904 50 feet by 2 feet 5 inches.

At Sherborne, Dorset, a tree 70 feet by 7 feet 7 inches in 1884.

At Melbury, Dorchester, the tallest tree in England is said to occur, being stated to be over 80 feet in height.³ The tree at Panshanger³ is reported to be 70 feet high by 10 feet at 1 foot above the ground. At Longleat³ there is a tree 71 feet by 9½ feet girth at 1 foot above the soil.

At Cobham Park, Kent, a tree 68 feet by 9 feet 4 inches.

At Badminton, Gloucestershire, a pair of symmetrical trees each about 50 feet by 5 feet.

At Blaize Castle, near Bristol, there is a good tree, of which Lord Ducie has kindly sent a photograph and a letter from Miss Harford, dated December 1903, which states:—"The Salisburia is, I am glad to say, in perfect condition, and a very fine graceful tree. Its height, measured last summer, was 72 feet. I have always heard that the one at Kew (which is not nearly so well grown) and the one in the Bishop's garden at Wells came over from Japan in the same ship as our tree."⁴

In Wales the finest tree that we know of is at Margam Park, Glamorganshire, the residence of Miss Talbot, which in 1904 was about 70 feet high and 6 feet in girth.

We have not heard of any fine specimens in Scotland or Ireland.

A curious form of the Ginkgo tree is reported⁵ to occur at Cookham Grove, Berkshire. This tree grows within 10 feet of the river wall, which surrounds the lawn, and when there is high water the roots are under water for several days at a time. The bole is only 2 feet in height, but measures 4½ feet in girth; at that point it breaks into many branches, some going upright to a distance of over 30 feet, while others grow almost horizontally, the spread of the branches being 45 feet.

¹ The well-known trees in the Chelsea Botanic Garden and in High Street, Brentford, are now mere wrecks.

² Figured in *Garden*, 1904, lxvi. 344.

³ *Flora and Sylva*, ii. (1904), p. 357.

⁴ Elwes has since seen and measured this tree, which he made to be 68 feet by 9 feet 3 inches, with a bole about 12 feet high.

⁵ *Gard. Chron.* 1886, xxv. 53.

62 The Trees of Great Britain and Ireland

Much finer trees occur on the Continent than those in England; and it is evident that while the tree is healthy and hardy in this country, it requires hotter summers and colder winters to attain its best development and ripen fruit. A fine pair, male and female, stand in the old Botanic Garden of Geneva, where they were planted in 1815. They were measured by Elwes in 1905, when the male tree was 86 feet by 4 feet 10 inches, with a straight upright habit, the female, which bears good seed, was considerably smaller. A famous specimen in the garden adjoining the palace of the Grand Duke of Baden at Karlsruhe measured, in 1884, 84 feet, with a diameter of 25 inches at 3 feet from the ground. Beissner¹ says trees occur in this garden of 25½ and 30 metres high, with stem diameters of 1.90 and 1.80 metres. The finest tree in Europe is probably one mentioned by Beissner,¹ which stands in the Botanic Garden at Milan, and measures 40 metres high and 1.20 metre in diameter. There is also a noble specimen in the gardens of the Villa Carlotta on Lake Como.

(A. H.)

¹ Beissner, *Nadelholzkunde*, 1891, pp. 191, 192. One of the trees at Karlsruhe is figured in *Gartenwelt*, iv. 44, p. 520.

LIRIODENDRON

Liriodendron,¹ Linnæus, *Sp. Pl.* 535 (1753); Bentham et Hooker, *Gen. Pl.* i. 19 (1862).

TREES, several extinct and two living species, belonging to the Natural order Magnoliaceæ, with deciduous, alternate, stalked, saddle-shaped, or lyrate leaves. Flowers: solitary, terminal, stalked, regular, enclosed in bud in a 2-valved spathe, which falls off when the flower opens. Floral receptacle: cylindro-conic, bearing from below upwards 3 imbricated petaloid sepals, 6 petals imbricated in two rows, numerous stamens, with anthers dehiscing outwardly by longitudinal slits, and a spindle-shaped column of numerous densely imbricated independent carpels. Each carpel is a 1-celled ovary, containing 2 ovules, and terminating in a style with stigmatic papillæ at its apex. Fruit: a cone of samaræ, falling off the receptacle when ripe, each containing 1 or 2 seeds.

Liriodendron appeared in the Cretaceous epoch, and numerous fossil species have been found in North America and Europe in the Tertiary period. Of the two now living, one occurs in the eastern half of the United States and Canada, the other is a native of Central China.

¹ *Liriodendrum* is the spelling used by Linnæus in his earlier descriptions of the genus in *Corollarium Gen. Pl.* 9 (1737), and *Hort. Cliff.* 223 (1737); but the form given above is the one now always adopted.

LIRIODENDRON CHINENSE, CHINESE TULIP TREE

Liriodendron chinense, Sargent, *Trees and Shrubs*, iii. 103, Pl. lii. (1903); Hemsley in Hook. *Ic. Pl. t.* 2785 (1905).

Liriodendron chinense, Hemsley, *Gard. Chron.* 1903, p. 370.

Liriodendron tulipifera, L., var. ? *chinensis*, Hemsley, *Jour. Linn. Soc.* xxiii. 25 (1886).

The Chinese tulip tree was discovered by Shearer¹ and Maries² in the Lushan mountains near Kiukiang, on the Yangtse, and was afterwards found by me growing plentifully in the mountain woods both north and south of Ichang, in Hupeh, at 3000 to 6000 feet altitude. Von Rosthorn³ found it farther west, at Nan-ch'uan in Szechuan. It does not occur on the lower levels, and is essentially a tree of the mountains bounding the valley of the Yangtse, from 107° to 116° E. longitude, and from 29° to 32° N. latitude. I never saw any large specimens, and it does not attain, so far as is known, the size of the American species. Von Rosthorn records it as about 50 feet in height. Maries notes it as a fine spreading tree occurring at a temple near Kiukiang. It was introduced in 1901 into cultivation from Hupeh by Wilson, who collected for Messrs. Veitch; and young trees may be seen in their nursery at Coombe Wood, and also at Kew. These seedlings in January 1905 were at Kew about 15 inches in height, and have stood without injury the cold of the last few winters; but it is too soon yet to decide whether this species will turn out to be hardy in this climate.

The Chinese tulip tree is almost indistinguishable in foliage from the American tree, but as a rule the leaves are more glaucous on the under surface, and the lobing is deeper and more obtuse. The flowers are greenish in colour and smaller in size than those of *Liriodendron tulipifera*. Moreover, the narrow petals spread out when fully open, and have not a tulip shape. The carpels are consolidated, so as to appear like a solid column, and are obtuse at the apex when ripe. In the American species the carpels are free from each other at an early stage, and have when ripe acute recurved tips.

In winter there is little to distinguish the two species, except that in *Liriodendron chinense* the twigs are grey (not shining brown), the buds come off at a very acute angle, and the leaf scars are oboval and not truly circular as they are in the common species.

The Chinese call the tree *Wo-ch'ang-ch'iu*, i.e. "goose-foot Catalpa," from the shape of the leaves, but the tree is of no economic importance with them. It apparently regenerates readily from the stool, as I found it, where the wood-cutters had been at work, as strong coppice shoots with enormous leaves, more than a foot across.

¹ In 1875. See L. M. Moore in *Jour. Bot.* 1875, p. 225.

² In 1878. See Hemsley in *Gard. Chron.* 1889, vi. 718.

³ Diels, *Flora von Central China*, 322 (1901).

LIRIODENDRON TULIPIFERA, TULIP TREE¹

Liriodendron tulipifera, Linnæus, *Sp. Pl.* 1st ed. 535 (1753); Loudon, *Arb. et Frut. Brit.* i. 284 (1838); Sargent, *Silva of N. America*, i. 19, tt. 13, 14 (1891).

A lofty tree, attaining in America in the most favourable conditions a height of 190 feet, and a stem diameter of 10 feet. Bark grey and smooth in young trees, becoming darker in colour and furrowed in old trees. Roots, fleshy with pale brown bark, having an aromatic odour and pungent taste.

Leaves extremely variable in shape, but generally saddle-shaped or lyrate in outline, with a rounded or cordate base, and a truncate emarginate apex,² the midrib being prolonged into a short bristle. Sometimes they are quite entire, but are more usually lobed, the lobes varying from 2-6 or even 8 in number, and often ending in a point. Venation pinnate. The leaves are 3-5 inches in length and in breadth, dark green and smooth above, lighter in colour and minutely pubescent underneath. Stalks about as long as the blades, angled and slender, so that the leaves quiver with any movement of the air. In autumn they turn bright yellow in colour, and give the tree a handsome appearance.

Two lateral stipules³ occur on the twigs, attached a little higher up than the insertion of the leaf-stalk. These are the scales which have formed the buds of the previous winter; and, as a rule, they shrivel up and fall off when the young leaves are fully matured; but some of them remain on vigorous shoots till late in summer.

The flowers resemble a tulip in shape, being 1½-2 inches long, with a width of 2 inches at the summit. The petals are greenish white, with an orange-coloured band at the base, which secretes nectar attractive to bees. These visit the trees in myriads in May, the flowering season in Illinois.

The fruit, light brown in colour, is a cone made up of a large number (about 70) of ripe carpels, which consist of a 4-ribbed pericarp surmounted by a flattened woody wing (the enlarged style). The wing may carry the seed by currents of air 300 or 400 feet from the parent tree. The carpels remain on the tree till thoroughly dry, some usually persisting throughout the winter on the receptacle, a few falling at a time as the wind dislodges them. The outer ones are nearly always sterile. The carpels will float in water for nearly a year without sinking; and this may explain the distribution of the tree along the banks of rivers. The seed has a fleshy albumen, in the summit of which is situated a minute embryo.

Seedling.—The seedling has two aerial short-stalked oval cotyledons about

¹ Usually called "Yellow Poplar" in the United States, "White-wood" also being a name in use amongst the western lumbermen.

² Lubbock, in *Trans. Linn. Soc. (Bot.)* xxiv. 84, ascribes the form of the leaves to the way in which they are packed in the bud.

³ Occasionally the stipules are attached as wings to the leaf-stalk either near its base or higher up; and in rare cases they even unite with the base of the leaf-blade, appearing then to be extra lower lobes of the leaf itself. For accounts of these peculiar stipules and remarkable forms of leaves occurring in tulip trees, see E. W. Bury in *Bull. Torrey Bot. Club*, 1901, p. 493, and in *Torreya*, 1901, p. 105, and 1902, p. 33.

$\frac{1}{2}$ inch in length. Above these on the stem follow the true leaves, the first and second orbicular in outline; the third and fourth showing lobes; all have long slender petioles. The first year's growth terminates in a bud just above the insertion of the fourth leaf. The primary root gives off a good many lateral fibres, which are delicate and brittle. Seedlings which germinated at Colesborne early in June were 3-4 $\frac{1}{2}$ inches high in August, with roots of about the same length or slightly shorter. According to Elwes there was no marked tendency to form a tap-root in any of the specimens which he examined.

VARIETIES

Several forms are in cultivation, which differ from the wild tree in habit, in form and colour of the leaves, and in colour of the flowers.

1. Var. *pyramidalis*, Lavallée.—Tree with erect branches, forming a narrow pyramid, like the fastigate oak.
2. Var. *integrifolia*, Kirch.—Leaves rounded at the base and without lobes. In this form, the shape of the leaves of seedling trees is preserved.
3. Var. *obtusiloba*, Pursh.—Leaves with only one rounded lobe on each side of the base.
4. Var. *heterophylla*.—Foliage variable; some leaves being entire, others with lobes, which are acute or obtuse.
5. Var. *crispa*.—Leaves with undulate margins.
6. Var. *variegata*.¹—Forms with variegated leaves, of which several sub-varieties have received names, as *argenteo-variegata*, *aureo-variegata*, *medio-picta*. That known as *aureo-marginata*² in which the edges of the leaves are yellow is the best.
7. Var. *aurea*.—Flowers yellow.

IDENTIFICATION

In summer, the shape of the leaves is unmistakable, resembling those of no other hardy tree: the variety *integrifolia*, though without lobes, preserves the truncate, slightly emarginate apex, in the centre of which may be seen the midrib prolonged as a short bristle.

In winter, the twigs and buds are very characteristic. Buds: terminal, larger than the lateral, which are alternate on the twigs, and arise from them at an angle of 45°. They are stalked, glaucous, glabrous, composed of 2 stipules joined together by their edges, forming a closed sac, in which is contained the young shoot;³ and on opening it a leaf will be seen embracing an interior bud. It is folded on its mid-rib with the stalk bent like a hook, bringing the apex of the leaf to the base of the bud. The twigs are glabrous, shining brown or slightly hoary, and marked by stipular rings just above the leaf-scars, which are circular, placed obliquely on prominent cushions, and dotted like a sieve with cicatrices of the fibrous bundles. The lenticels are few

¹ The variegated form in which the yellow marking occurs as irregular blotches in the central part of the leaves is well depicted in Lemaire, *Illust. Horticole*, xv. t. 571 (1868).

² A good figure of the variety is given in *Flore des Serres*, xix. 2025 (1873).

³ Within the outer bud or sac are contained several younger buds, one within the other, each with a folded leaf.

and minute. The pith is solid, but not continuous, being interrupted by woody cross-partitions. (A. H.)

DISTRIBUTION

In Canada the tulip tree occurs¹ in rich soil in the western peninsula of Ontario, from Hamilton to Huron Co. It forms a noble tree in the thick forest west of St. Thomas, and has been found in Nova Scotia.²

In New England it occurs in the valley of the Hoosac river, Mass., in the Connecticut river valley, and in Rhode Island, where it is frequent.³

It extends west to Southern Michigan as far north as Grand river, southward through all the States east of the Mississippi to Alabama, attaining its maximum size in the valleys of the Ohio river and its tributaries, and in the foot-hills and valleys of the Southern Alleghany mountains, in Tennessee, Kentucky, and North Carolina. West of the Mississippi it occurs commonly, though not in the south-eastern parts of Missouri and Arkansas. Its southern limit appears to be in Northern Florida, Southern Alabama, and Mississippi.

Sargent says of this tree that it is one of the largest and most beautiful trees of the American forest, only surpassed in the Eastern States by the occidental plane and the deciduous cypress.

It sometimes attains in the deep river bottoms and warm, damp, summer climate of Southern Indiana a height of 160-190 feet, with a straight trunk 8-10 feet in diameter clear of branches for 80-100 feet from the ground. Individuals 100-150 feet tall with trunks 5-6 feet in diameter are still common. The branches, which are small and short in proportion to the trunk, give this tree a pyramidal habit, except in the case of old or very large individuals, on which the head is spreading.

I have seen it growing in the neighbourhood of Boston, where, however, it did not seem to attain as large a size as in the south of England, and where seedlings do not come up freely so far as I saw. Near the gate of the Arnold Arboretum the largest tree, about 70 years old, was 85 feet high by 8 feet 6 in girth.

In Druidhill Park, Baltimore, it becomes a much finer tree, and surpassed in height any other species growing there. The tallest I saw was in a shady dingle, and measured 125 feet by 11 feet, with a straight clean stem. Older trees had rough bark coming off in scales.

In the mountains of North Carolina, at Biltmore, I saw much larger trees, and to give an idea of its development in this region I figure (Plate 24) a tree from a photograph⁴ kindly sent me by Mr. W. Ashe of the North Carolina Geological Survey, taken in the winter. This tree, which stood in Yancey Co., North Carolina, was a very characteristic specimen, more than 160 feet high and 6 feet in diameter at 5 feet from the ground. The smaller timber having been cut from around it only a few years previously, the form of the tree is perfectly typical, and shows the charac-

¹ Macoun, *Cat. Canadian Plants*, pt. i. 28 (1883).

³ Dame and Brookes, *Trees of New England*, 104 (1902).

⁴ Pinchot and Ashe, *Bull. No. 6, North Carolina Geol. Surv.* pt. ii. (1898).

teristic sharp angles made by the smaller erect branches with the larger horizontal limbs.

Another photograph sent me by Mr. Ashe shows a group of *Liriodendron*, in the forests of Transylvania Co., N.C., 120-140 feet high and 4-5 feet in diameter, associated with *Quercus rubra* and *Betula lutea* which are not so tall. This magnificent forest is, like most of those accessible to the lumbermen, rapidly decreasing in area and beauty, owing to the growing demand for timber.

For further details of the distribution in North Carolina refer to Pinchot and Ashe's admirable account, pp. 39-41, and to a paper by Overton Price on "Practical Forestry in the Southern Appalachians."¹

The largest trees of this species, however, have been recorded by Professor R. Ridgway² from Southern Indiana and Illinois, near Mount Carmel, Illinois, which I had the pleasure of visiting under the guidance of Dr. J. Schneck in September 1904. Though the largest trees recorded by him have now been cut, reliable measurements were taken of a tulip tree which reached the astonishing height of 190 feet, exceeding that of any non-coniferous tree recorded in the temperate regions of the northern hemisphere. Another tree cut "8 miles east of Vincennes, was 8 feet across the top of the stump, which was solid to the centre; the last cut was 63 feet from the first, and the trunk made 80,000 shingles." The soil here is an exceedingly rich, deep alluvium, and the climate in summer very hot and moist.

It is stated in *Garden and Forest*, 1897, p. 458, that at the Nashville Exhibition a log of this tree was shown by the Nashville, Chattanooga, and St. Louis Railroad Company, which measured 42 feet long, 10 feet 4 inches in diameter at the butt, and 7 feet at the smaller end, containing 1260 cubic feet of timber, and about 600 years old.

INTRODUCTION

The tulip tree was probably introduced, according to Evelyn,³ by John Tradescant about the middle of the seventeenth century, but this is somewhat uncertain, though it was grown by Bishop Compton at Fulham in 1688.

According to Hunter the tree which first flowered in England was in the gardens of the Earl of Peterborough at Parsons Green, Fulham, and this he describes in 1776 as "an old tree quite destroyed by others which overhang it." At that time there were also some trees of great bulk at Wilton, the seat of the Earl of Pembroke in Wilts.

CULTIVATION

Though the tree can be propagated by means of layers, and in the case of varieties by grafting, yet as seeds are easily procured from the United States it is much better to raise it from seed. Cobbett, who was a great admirer of the tulip tree, gives a long account of it, and of the best means of raising it,⁴ and says that if sown in May, which he thinks the best time, it will germinate in the following May,

¹ Yearbook U.S. Dept. of Agric. (1900).

² Notes on Trees of Lower Wabash, Proc. U.S. Nat. Hist. Mus. 1882, p. 49; 1894, p. 411.

³ Evelyn's *Silva*, 214. Ed. Hunter (1776).

⁴ Woodlands, par. 523 (1823).

but that if sown in autumn, part will come up in the next spring and part in the following year.

Dawson in an excellent paper on the Propagation of Trees from Seed,¹ says, "The tulip tree invariably takes two years, and as the proportion of good seed is as 1 to 10, it should be sown very thickly to ensure even an ordinary crop."

Probably this opinion was based on his experience with seeds grown in New England, where they do not ripen so well as they do in the south, for my own experience, gained by sowing seeds received from Meehan of Philadelphia, is different. In the spring of 1903 I sowed part of the seeds in a greenhouse, where they began to germinate six weeks later. Of those sown in the open ground, perhaps 10 per cent germinated in June. The following summer was cold and wet, and the seedlings in the open ground made slow progress, being only 2-3 inches high in the autumn, whilst those kept under glass were from 6-15 inches high at the same time. The young wood seems to ripen better than that of most North American trees and, as the spring of 1904 was favourable, they were not checked by frost. But the seedlings are difficult to transplant, owing to the fleshy and brittle nature of their roots, and are therefore best kept in a box or large pot till they are two years old, when the roots should be trimmed and planted out in deep sandy soil, and watered the first year; after this they should be transplanted frequently until large enough to put in their permanent situation, and if tall and straight grown trees are desired the young trees must be very carefully pruned, as like the Magnolia they do not thrive so well if large branches are cut off.

The tulip tree rarely ripens its seed in England, and that which I got from a tree at Westonbirt in Gloucestershire in 1901 did not germinate. But I am informed by Mr. A. C. Forbes, that a self-sown tulip tree is growing in the sand walk at Longleat, and Colonel Thynne confirms this in December 1904, when he tells me the young tree is 8 feet high. This, however, is the only instance I know of in England where natural reproduction has occurred.

SOIL AND SITUATION

The tree requires a deep, moist, rich soil to bring it to perfection, preferring heavy land to light, and apparently disliking lime in the soil. It probably prefers a moderate amount of shade when young, and would be more likely to grow tall and straight if surrounded by other trees. But isolated trees sometimes grow with a clean straight stem, as at Leonardslee in Sussex (see below) even on dry soil.

In the *Gardeners' Chronicle* for 1879 there was much correspondence on the merits of this tree for general cultivation in England, from which I extract the following particulars, which will be valuable to intending planters.

Most of the correspondents agree that it grows best on heavy soil, inclining to clay, or with a clay subsoil. Sir W. Thiselton Dyer says it does not do well on the light, dry soil of Kew Gardens.

¹ Trans. Mass. Hort. Soc. 1885, p. 152.

Mr. Bullen says that it grows well in heavy clay in the damp and smoky climate of Glasgow, and a tree is mentioned at the Grove, Stanmore, on damp, gravelly clay, which in 1879 was 77 feet high by $9\frac{1}{2}$ in girth.

The tulip tree has been much recommended for planting in towns, and specimens may be seen in London at Victoria Park, Manor House Gardens, Lincoln's Inn Fields, Waterloo Park, Clissold Park, etc.

Mr. Hovey says that in America it is not so much planted for ornament as it deserves to be, presumably because American planters desire a quick effect, and that it does not transplant well after it is 4-6 feet high; but that it grows on gravel, sand, peat, or clay, and is not very particular in that climate as to soil. He has known it grow 30 feet high and more in 20 years.

It is very liable to be attacked by rabbits, which eat the bark even of large trees, and I have seen several which have been killed or much injured in this way.

REMARKABLE TREES

Though this tree is one of the handsomest when in flower, stateliest in habit, and most beautiful in the autumn tints of its leaves, it is not now planted in England nearly as much as it was a hundred years and more ago, having, like so many other fine hard-wooded trees, been supplanted by conifers and flowering shrubs, which are easier to raise and more profitable to the nurserymen, who now appear to cater rather for the requirements of owners of villas and small gardens than for those of larger places. But though the tulip tree loves a hot summer, it endures the most severe winter frosts of our climate without injury, and in a suitable soil grows in some parts of the southern counties, after it is once established, to a great size.

The largest living specimen I know of in England is at Woolbeding, in Sussex, the seat of Colonel Lascelles, and measures 105 feet by 17. Though not so perfect in shape as some others, it is a very beautiful tree, and seemed, when I saw it in 1903, to be in good health. It grows on a deep, alluvial, sandy soil, which suits plane trees and rhododendrons very well (Plate 25).

There was even a larger one at Stowe near Buckingham, which when I saw it in 1905 was dead, apparently barked at the base by rabbits. It was at least 107 feet high, with a bole of about 30 feet, and a girth of 13 feet at 5 feet, and 21 feet 4 inches at the ground.

Another very fine tree is at Leonardslee, near Horsham, the seat of Sir Edmund Loder, Bart., also in Sussex, and is growing at an elevation of 400-500 feet on soil which, though very favourable to rhododendrons, is too poor to grow either oak, birch, or larch to the same size in the same time. Sir E. Loder tells me that the tree cannot be more than 90 years old, and it is now 97 feet high, with a perfectly clean, straight trunk 25-30 feet high, which towers above all the native trees of the district (Plate 27).

At Horsham Park, the residence of R. H. Hurst, Esq., is a very fine and symmetrical tree which I measured rather hastily, as over 100 feet in height by 15 in girth.

Another very remarkable tree (Plate 26) is the one at Killerton, in Devonshire, which I am sorry to hear has suffered severely in the gale of September 1903. This tree must be one of the oldest now living, as Sir C. T. D. Acland tells me that in a picture of his house, taken early in the last century, it seems nearly as tall as at present, and it is mentioned by Loudon as being 63 feet high in 1843. When I measured it in 1902 it was 80 by 15 feet, with a bole about 18 feet long, and must have contained nearly 300 feet of timber.

A very fine tulip tree, on heavier, damper soil at Strathfieldsaye, Berkshire, the seat of the Duke of Wellington, measures 105 feet by 12; and though not such a well-shaped tree as the one at Leonardslee is of the same type.

The tree which Loudon refers to as being the tallest known to him at Syon, was, in 1844, 76 feet high, at about 76 years of age, but this is now dead, as is the old tree at Fulham Palace mentioned by Loudon, which he estimated at 150 years of age.

At Bury House, Lower Edmonton, there is a magnificent tree which John W. Ford, Esq., informs us is thoroughly sound and in perfect health. He estimates it to be 70 to 75 feet in height, the girth 5 feet from the ground being 17 feet 4 inches. The bole at 13 feet divides into five limbs, of which the biggest are 5 feet round. The soil is splendid, being brick earth.

At Deepdene, Dorking, there is a fine tree on the lawn, which in February 1904 was 83 feet high by 14 feet in girth.

At Petworth, the seat of Lord Leconfield, there is a curious old tree which has an immense burry trunk 17 feet in girth.

A tree was recorded at Longleat in 1877 as being 106 feet high and 10 feet in girth, but this, as I learn from the Marquess of Bath, is now dead, though one or two other large specimens remain.

There is a very fine tree at Margam, in Pembrokeshire, which, as measured in 1904, is 92 feet high by 13 feet 6 inches at 6 feet from the ground, with a spread of branches 57 feet in diameter.

An immense tree at Esher Place, Surrey, is mentioned by Mr. Goldring as having a girth of 22 feet.

At Barton, Suffolk, two trees¹ were planted in 1832. They first flowered in 1843. In the year following the severe winter of 1860 no flowers were produced, but the foliage was as good as usual. In 1904 these two trees had both attained the same height—79 feet; one having a girth of 7 feet 2 inches at 5 feet above the ground; the other divided into two stems at a point 2 feet from the ground where the girth was 10 feet 4 inches. The soil at Barton is good, consisting of 2 or 3 feet of loam resting on boulder clay.

At Ashby St. Ledgers, Rugby, the seat of the Hon. Ivor Guest, there is a good tree² which measured 80 feet in height by $16\frac{1}{2}$ feet in girth in 1900. This tree breaks into three stems at a little above 4 feet from the ground, and the girth is taken below this point.

At Hampton Court, Herefordshire, a tree³ on the lawn in 1879 was 80 feet

¹ Bunbury, *Arboretum Notes*, 60.

² Letter to Curator at Kew.

³ *Garden*, 1890, xxxviii. 178. The measurements refer to 1879, according to a note in *Woods and Forests*, April 23, 1884.

high by 12 feet 7 inches in girth, with an estimated cubic contents of timber of 223 feet. When I measured it in 1905 it was 95 by 13 feet, but the top and trunk were decaying.

At Erlestoke Park, Wiltshire, a tree,¹ growing near the bank of a lake, was 80 feet high by 14 feet in girth at 4 feet from the ground in 1902.

The following records from Hampshire were reported in *Woods and Forests*:²—North Stoneham Churchyard, near Southampton, a tree 12 feet 10 inches in girth; Cranbury House, near Winchester, a tree 11 feet 9 inches in girth; at Gramwell's Meadow, east of East Tytherley Manorhouse, near Romsey, a tree 85 feet high by 10 feet 5 inches in girth, with a stem free from burrs, planted in 1780. These measurements were taken in 1884. At Hale Park, in 1879, there was a tree 75 feet high with a short bole of 4 feet, girthing 18 feet 3 inches.

The finest tree at Kew, 70 feet high in 1844, is gone, but there still exists a well-proportioned specimen³ which stands at the end of the rhododendron dell. It is now (1905) 79 feet high by 9 feet 9 inches in girth. It produces fruit freely every year, but the seeds are always poorly developed and infertile.

In Scotland a tree was mentioned by Loudon as growing at The Hirsell, Coldstream, the seat of the Earl of Home, which was at that time 100 years old and 20 feet in girth 3 feet from the ground. I was informed by Mr. Cairns, head gardener at the Hirsell, that in 1903 it was slowly decaying, some of the larger branches being gone, but that what remained carry a large amount of healthy foliage, and flowers more or less every year.

At Drummonie Castle, Perthshire, formerly a seat of the Lords Oliphant, Hunter⁴ mentions a tree 8 feet in girth at 5 feet, and another at Gorthy Castle,⁵ girthing 9 feet 7 inches at 3 feet, which had been a good deal injured by cattle grazing in the park. He also (p. 400) speaks of a large tree at Castle Menzies, 10 feet in girth, but I did not see it on either of my visits to this interesting old place.

The tulip tree is not mentioned in the *Old and Remarkable Trees of Scotland*, but it grows at Gordon Castle, and even as far north as Dunrobin Castle in Sutherlandshire.

In the south-west of Scotland there do not appear to be any large trees, the biggest mentioned by Messrs. Renwick and M'Kay⁶ being one at Auchendrane House, Ayrshire, which was, in September 1902, 53 feet by 5 feet 8 inches, and one at Doonside, Ayrshire, which was 46 feet 9 inches by 8 feet 1 inch.

At Jardine Hall, Lockerbie, a tree⁷ measured in 1900 60 feet in height by 9 feet in girth.

At St. Mary's Isle, Kirkcudbright, a tulip tree⁸ was, in 1892, 10 feet 9 inches in girth.

¹ *Gard. Chron.* 1902, xxxii. 61.

² Issues of April 16 and 23, 1884.

³ Figured in *Gard. Chron.* 1890, viii. 219, where it is stated in the text that the tulip tree bears pruning well, and that there is an avenue of clipped trees in one of the courts at Chatsworth.

⁴ Hunter, *Woods, Forests, and Estates of Perthshire*, 145 (1883). This is apparently the tree mentioned in *Gard. Chron.* 1890, viii. 388, as being 60 feet in height then, and having recently flowered.

⁵ *L.c.* p. 371.

⁷ *Garden*, 1890, xxxviii. 178.

⁸ M'Kay and Renwick, *Trans. Nat. Hist. Soc. Glasg.* Sept. 4, 1894, p. 17.

In Ireland large tulip trees are rare. There are two good specimens at Fota, which measured in 1903, one 87 feet high by 11 feet 7 inches in girth, the other 57 feet by 14 feet 7 inches.

In France the tulip tree, favoured by warmer summers, seems to thrive better, and attains a larger size than in England. Mouillefert¹ speaks of a tree at the Chateau de Frêne, near Chaulnes, in the department of Somme, which in 1899 was 38 metres in height by 5 in circumference. He also mentions having seen in 1902 at the Chateau de Cheverny, near Blois, tulip trees planted along the banks of a canal, which at 50-60 years of age measured 31 metres in height and 2 metres in girth at 5 feet from the ground, whilst plane trees of the same age close to them were only 24 metres high and 1.65 in girth.

He considers that in a suitable soil and situation such as the valleys in a granitic mountain range, or on damp, rich soils, in fact in such places as the ash, the poplar, and the plane thrive, this tree might be grown as a forest tree to produce valuable timber, or as copse wood, cut at 18 or 20 years of growth for turnery purposes.

Considering, however, the cost of raising this tree in the nursery, and its liability to suffer from autumn frost in a young state, I do not think the tree can be considered likely to become a forest tree in England, except possibly in a few choice situations in the south and south-west.

TIMBER

The timber of the tulip tree is now very much used in North America for many purposes, and is also largely imported to England under the name of white-wood, canary-wood, and yellow poplar. Stevenson says of it,² "Though classed among the light woods it is much heavier than that of the common poplar, its grain is equally fine but more compact, and the wood is easily wrought and polished. It is found strong and stiff enough for uses that require great solidity. The heart-wood, when separated from the sap and perfectly seasoned, long resists the influence of the air, and is said to be rarely attacked by insects. It is imported in the form of waney logs and in sawn planks of very fine dimensions, in which state it commands a price fully equal to that of the first quality of Quebec yellow pine.

Hough³ speaks of it as "light, rather strong, with close straight grain, compact, easily worked, and yielding a satiny finish. Sap-wood nearly white, heart-wood of a light lemon-yellow colour, or sometimes of a light brownish tint—whence its two seemingly contradictory names, white and yellow poplar, the former referring to the sap-wood, the latter to the heart."

Sargent says it is light and soft, brittle and not strong, is readily worked, and does not easily split or shrink. The heart-wood is light yellow or brown, weighing when absolutely dry 26-36 lbs. to the cubic foot. Large canoes were formerly made from it by the Indians, and it is now extensively used in construction, for the

³ *The American Woods*, pt. i. p. 40, t. 2 (1893).

74 The Trees of Great Britain and Ireland

interior finish of houses, and in boat-building, as well as for shingles, pumps, and wooden ware.

The only timber I know which it resembles closely in colour, texture, and grain, is that of *Magnolia acuminata*.¹

Neither Stevenson, Hough, nor Stone, however, speak of a form of this timber known as "blistered poplar," which is occasionally found, as I believe, only in old trees, and which is sometimes imported in small quantities to Europe. This seems akin to the figured maple wood known as bird's eye maple, but has the figure in oblong patches from 2 inches long downwards, of a dark olive colour on a paler olive-green ground, and is one of the most ornamental woods I know, fit to be used in the finest cabinet work. I saw large planks of this variety in the Exhibition at St. Louis, and have had some of it worked into the panels of a screen.

The wood of the tulip tree grown in England seems to be nearly as good in quality as the imported timber, though not quite so pure in colour. From a tree which was cut at Highclere a plank was sent me by the kindness of the Earl of Carnarvon, which has been used in the same screen, and I have a large book-case of which the back is made of the imported wood, selected by an experienced cabinet-maker as best for the purpose.

Mouillefert says that in Paris its use is increasing for all purposes for which the wood of the lime and poplar is suitable, and that it has when fresh cut a pleasant smell of orange, which, however, is soon lost as it dries. (H. J. E.)

¹ Mr. Weale tells me that the timber of this Magnolia, as well as that of *M. grandiflora* and *M. glauca*, come into the Liverpool market mixed with that of the tulip tree, and that though the two former may easily be distinguished by a person who knows them well, yet that *M. glauca* can only be identified with a lens, and that in consequence of this mixture, opinions differ as to the suitability of the wood for laying veneers upon. He thinks that if bone dry, the wood of the tulip tree is fit for this purpose, but not equal to that of American chestnut, American cherry, or Honduras mahogany, of which the latter is best. He also says that for pattern making Quebec yellow pine is distinctly superior, and worth from 1s. to 2s. a foot more.

PICEA

SPRUCE-FIRS

Picea, Link, *Abhandl. Akad. Wiss. Berlin*, 1827, 179 (1830); Bentham et Hooker, *Gen. Pl.* iii. 439 (1880); Masters, *Jour. Linn. Soc. (Bot.)* xxx. 28 (1893).

Abies, Linnæus, *Gen. Pl.* 294 (in part) (1737); D. Don in Lambert, *Pinus*, vol. iii. (1837), ex Loudon, *Arb. et Frut.* iv. 2293 (1838).

THIS genus includes the spruce-firs, which in England, following the practice of Don and Loudon, are still often called *Abies*. However, all botanists in England, on the Continent, and in America apply the term *Picea* to the spruces, and *Abies* to the silver firs.

Tall evergreen trees belonging to the tribe Abietinæ of the order Coniferae, with shoots of only one kind, bearing in spiral order peg-like projections ("pulvini"), from which the leaves arise singly. The needle-like leaves are either tetragonal or flattened in section, and persist for many years, rendering the foliage very dense. At the ends of the leading shoots there is a terminal bud, with 2-5 side buds directly under it; the buds are dry and not resinous.

Flowers monœcious. Male flowers solitary in the axils of the uppermost leaves, ovoid or cylindric, short-stalked, surrounded at the base with scale-like bracts, composed of numerous stamens spirally arranged, each with 2 pollen-sacs opening longitudinally, and a connective prolonged into a toothed crest. Pollen grains with 2 air-sacs. Female flowers solitary, terminal, erect, stalked, with a few empty scales at the base; composed of 2 series of scales, the bracts small and membranous, and the ovular scales bearing at their base 2 inverted ovules. Cones: generally becoming pendulous, but in certain species remaining erect or spreading; cylindrical or ovoid, with the bracts minute and concealed, and the scales enlarged and firm in texture, with entire or denticulate margins, and bearing on their inner surface 2 winged seeds. The cones are ripe in the first season, and after dispersal of the seed (the scales persisting on the axis) fall off in the following winter, or remain in some species much longer on the tree. The cotyledons are 5-15 in number, 3-sided, and serrate in margin.

Species of spruce occur in Europe, Asia Minor, the Caucasus, Siberia, Mongolia, China, Japan, the Himalayas, and in North America. The genus is marked out into two natural sections by the character of the leaves. These are defined by Willkomm as follows:—

1. *Eu-picea*.—True spruces. Needles 4-sided and 4-angled, with stomata on all their surfaces. The ripe cones are always pendulous.

2. *Omorica*.—Flat-leaved spruces. Leaves 2-sided, flattened from above downwards, stomata being only borne on their dorsal surface. Ripe cones pendent, horizontal, or erect.

Other divisions have been made, such as that of Link into two sections, *Genuine* and *Dehiscentes*; and that of Mayr into three sections, *Omorica* (not identical with Willkomm's section of the same name), *Morinda*, and *Casicta*; but it is most convenient to adopt Willkomm's divisions.

The arrangement of the leaves on *lateral branchlets* is different in the two sections. All spruces agree in the disposition of the leaves arising from the upper side of such branchlets, as these always point forwards and cover the shoot. But, in ordinary species, the leaves underneath, while they part into two lateral groups, alter little their direction, which is more or less forwards; and the under part of the stem is laid only partially bare. In almost all the flat-leaved spruces, the leaves below part into two sets, which are directed outwards at right angles to the shoot, which is laid quite bare. This arrangement differs from that of the yew and most silver firs, where the leaves are divided into two sets both above and below; and this distinction depends on the fact that in these spruces the stomata are on the dorsal surface of the leaf, whereas in the yew, etc., they are on the ventral surface; and in the effort to direct the stomata away from the light, a different arrangement results in the two cases.

The arrangement of the leaves on leader or upright branchlets is the same in all species of spruce, being radial, the leaves pointing outwards and slightly forwards. In certain species, as *P. Breweriana*, *P. Morinda*, the lateral branchlets are pendulous and not horizontal; and the leaves then are similarly arranged in both the lateral and the leader shoots.

The section *Eu-picea* will be dealt with in a later part.

KEY TO SECTION OMORICA.—The flat-leaved spruces are distinguished from the silver firs by the peg-like projections on the shoots, and from ordinary spruces by the flattened leaves with stomata only on their dorsal surface.

I. *Young shoots glabrous, yellow.*

1. *Picea hondoensis*. Central Japan.

Buds broadly conical, with scales rounded in the margin, opening red. Shoots of second year red. Leaves thin, slightly keeled on both surfaces, blunt or ending in a short point.

2. *Picea ajanensis*. Manchuria, Amurland, Saghalien, Yezo.

As in 1, but the buds open green, and shoots of the second year are yellow.

3. *Picea sitchensis*. Western North America.

Buds ovoid with ovate obtuse scales. Leaves deeply keeled on ventral green surface, almost convex on dorsal white surface, ending in very sharp, cartilaginous points.

4. *Picea morindoides*.¹ Native country unknown.

Buds and scales ovate-obtuse. Leaves linear, straight, slender, acuminate, terminating in a callous sharp tip, somewhat flattened and distinctly keeled on both sides, marked with two white lines on the upper surface, and dark bluish green on the under surface. Leaves radially spreading on the branchlets.

II. *Young shoots pubescent with short hairs.*

5. *Picea Omorika*. Servia and Bosnia.

Pubescence brown. Buds ovate, conical, with outer scales ending in long subulate points. Leaves flattened but thick, obtuse or ending in a short point.

6. *Picea Breweriana*. Oregon, California.

Pubescence grey. Buds ovoid, with outer scales ending in long points. Leaves scarcely flattened, but convex above and below, keeled on dorsal surface, with midrib prominent on ventral green surface, and ending in a short point. The leaves spread out in all directions on the shoot.

¹ A new species described by Rehder in Sargent, *Trees and Shrubs*, 95, t. 48 (1903). It is only known as a tree growing in the arboretum of G. Allard at Angers. I have seen no specimens and take the characters given above from Rehder. In habit it resembles *Picea Morinda*, the branches being pendulous. The cones resemble those of *Picea Alcockiana*.

PICEA OMORIKA, SERVIAN SPRUCE

Picea Omorika, Bolle, *Monatschrift des Vereines zur Beforderung des Gartenbaues*, 124 (1877); Masters, *Gard. Chron.* 1884, xxi. 308, 309, Figs. 56, 57, 58, and 1897, xxi. 153, Fig. 44; *Jour. Linn. Soc. (Bot.)* xxii. 203 (1886); Willkomm, *Forstliche Flora*, 99 (1897); Kent, in *Veitch's Man. Coniferae*, 442 (1900); Richardson, *Edin. Bot. Garden, Notes, No. 1* (1900); G. von Beck, *Die Vegetationsverhältnisse der Illyrischen Länder*, 286, 360, 440, 474 (1901).
Pinus Omorika, Pančić, *Eine Neue Conifere in den Oestlichen Alpen*, 4 (Belgrade, 1876); Masters, *Gard. Chron.* 1877, vii. 470, 620.

A tree with a tall, slender stem, said to attain 130 feet in height, with a girth of stem of only 4 feet, with short branches, forming a narrow pyramidal crown. The topmost branches are directed upwards, the middle ones are horizontally spreading, and the lower ones are pendulous, with their tips arching upwards. Bark brownish red, and scaling off in plates, the fragments often being heaped in quantity round the base of the tree. The leaves on vertical shoots stand out on all sides, but on horizontal shoots they point forwards on the upper side, being pseudo-distichous in three or four ranks on the lower side. They are flattened, 4-angled, straight, or curved to one side, $\frac{3}{4}$ -1 inch long, linear, acute or obtuse with an apiculus, convex, and shining green on the ventral surface, marked with stomatic lines on each side of the prominent midrib of the dorsal surface.¹ They persist for 4 or 5 years.

The buds, ovoid-conic with brown, membranous scales, the outermost of which end in long subulate points, are produced chiefly near the end of the shoot; and in unfolding, the uppermost scales are pushed off as a cap. The dark brown hairs, which are conspicuous on the young shoots, persist on the older branchlets of even 3 or 4 years' growth in wild specimens.

The male flowers, which are partly solitary and partly whorled, are stalked, ovoid-cylindric, bright red, $\frac{1}{2}$ - $\frac{3}{4}$ inch long, and are surrounded at the base by numerous membranous bracts.

Cones, shortly-stalked 2-2 $\frac{1}{2}$ inches long, bluish black when young, dark-brown when ripe, clustered, the upper ones being directed upwards, while the middle ones are horizontal, and the lower ones pendulous. Scales almost orbicular in outline, broad and convex, streaked on the outer surface, with the margin slightly bent inwards, undulate and denticulate. Bract obovate-cuneate, minute. Seeds small, $\frac{1}{10}$ - $\frac{1}{8}$ inch long, obovate, blackish brown, with a wing $\frac{1}{3}$ inch long, obovate in outline.

¹ On horizontal shoots, the leaves, by twisting movements on their bases, are inverted, so that the green surface is turned upwards and the stomatic surface downwards.

DISTRIBUTION

The Servian spruce was first made known to science by Pančić, who discovered it in south-western Servia, near the village of Zaovina, on 1st August 1875. Its area is a small one, occupying about 20 kilometres long by 15 kilometres wide on both sides of the Drina valley, the boundary between Servia and Bosnia. Here it occurs on limestone rocks at altitudes varying from 2700 to 5300 feet. It grows in small groves in the wetter places in the ravines, but it does not there reach such a height as it attains in the rockier parts of the mountains, where it forms part of the mixed forest of Austrian and common pines, common spruce, beech, and sycamore. Pure woods of Omorika occur at higher elevations, between 4700 and 5300 feet, where sub-alpine plants accompany it. Wettstein gives the following as the composition of the characteristic Omorika woods:—

Dominant Trees.—*Picea Omorika*, *Pinus sylvestris*, *Carpinus duinensis*, *Picea excelsa*, *Fagus sylvatica*, *Populus tremula*, *Abies pectinata*, *Ostrya carpinifolia*, *Salix sp.*, *Pinus austriaca*.

Underwood.—*Corylus avellana*, *Cotinus coggygria*, *Spiraea cana*, with *Rhamnus fallax* and *Lonicera alpigena* at high altitudes.

Ground-herbage.—*Aspidium Filix-mas*, *lobatum*, and *angulare*.

Wettstein¹ says that an Omorika forest has a peculiar and gloomy aspect, the slender stems with their short branches and columnar or spindle-shaped crowns looking quite different from any other type of European forest. In mixed forests, the straight single stems, arising out of the general mass of the other trees, are equally peculiar.

Omorika seedlings and young trees are only found in exposed rocky situations, and in the bottoms of wet shaded ravines. The tree in the wild state is strictly confined to limestone soil, and never grows on the slate formation which is found in parts of the Drina valley, yet when cultivated, it does very well, at least in youth, on soils which are not calcareous.

The largest tree² recorded is one felled by Pančić, which measured 42.2 metres in height, and 0.385 metres in diameter. It showed 137 rings, and the width of the rings gradually diminished from 0.28 cm. in the 3rd decade to 0.04 cm. in the 14th decade. Pančić says that the tree has an inclination to grow with a spiral stem, and that it loses its branches up to about half its height, the largest of the branches being only about 2 metres in length. The cones are borne, according to him, upright on the topmost branches only, but elsewhere they hang down with their tips directed slightly upwards.

Pančić, in his first account of the tree, reports that he had heard on good authority of its occurrence in the mountains of Montenegro; it has since been

¹ *Sitzungsber. kais. Akad. d. Wiss.*, xcix. 503; *Oesterr. Bot. Zeitschr.* 1890, p. 357.

² Letter of Pančić, quoted in Stein's article on "Omorika" in *Gartenflora*, 1887, p. 14.

reported to occur also at Bellova in the Rhodope mountains in Bulgaria; but, so far as we can discover, these statements have not been confirmed. A fossil species which has been identified with the existing tree by Webber has been found in the interglacial deposits at Höttingen near Innsbruck in the Tyrol. An allied species, *Picea omorikoides*, Webber,¹ has been found at Aue in Saxony in a preglacial deposit which is of the same age as the Cromer forest bed on the coast of Norfolk. Lokowitz has also found near Mulhouse in Alsace some remains of a spruce in the middle Oligocene beds which resembles *Picea Omorika*.

In the herbarium at Kew there are specimens collected by V. Crucic on the Drina, and others with good cones gathered by Elwes at 2000 to 3000 feet altitude.

(A. H.)

I visited the valley of the Drina in Bosnia in 1900 on purpose to see this tree, and after driving a long day east from Serajevo, reached Rogatica, from where Herr Gschwind, the obliging forest officer of the district, was good enough to accompany me to Han Semec, a Gendarmerie station on the road to Visegrad, about 15 miles from Rogatica. Han Semec is at an elevation of 3800 feet, and is surrounded by beautiful forests of Austrian and Scots pines, spruce, silver fir, and beech.

The climate of the district is very cold in winter and warm in summer. The minimum temperature being -33° Reaumur on 23rd December, $+30^{\circ}$, the maximum on 7th July 1897, the snow lying as long as 4-5 months.² The rainfall in summer is heavy, amounting to 116.2 centimetres, which fell on 124 days, and the weather was wet most of the time I was there.

After passing through some beautiful mountain meadows and primæval forest of large spruce and silver fir mixed in places with beech and aspen, as well as small oaks and large birch, we came to the edge of a deep rocky ravine running down to the Drina valley. On the steep limestone cliffs overhanging this ravine, which are a favourite haunt of chamois, *Picea Omorika* was growing in clumps, and isolated trees occurred among common spruce, Scots and Austrian pine.

The branches are short and drooping as compared with those of common spruce, and the cones being found only near the top of the tree, we had to cut one down in order to procure fruiting specimens; on this I found young cones of the year, cones of last year which had not yet opened, and which, according to the forester, contained good seed only when there was turpentine exuding from them, and old cones which hang two or three years on the tree after shedding their seed. In habit and appearance the tree resembles the American *Picea alba* more than any tree I know, though its nearest botanical affinities are with *P. sitchensis* and *P. ajanensis*. Plate 28, which is from two of several photographs kindly sent me by Herr Othmar Reiser of the Landesmuseum, Serajevo, Bosnia, gives an excellent idea of the forest and of individual trees.

The average size of the full-grown trees on these steep cliffs was not above 50-60 feet, with about 1 foot of diameter, but I found some measuring 80-90 feet high and 18 inches diameter. Young seedlings were scarce and difficult to find on the mossy rocks; but we collected 20 or 30 plants, of

¹ Engler's Bot. Jahrb. xxiv. 1898, Heft 4, 510, 504.

² Cf. Met. Beob. Land Stationen in Bosnien (1899).

which I brought the smallest home in a tin box alive, and planted the larger ones in the forester's garden at Han Semec. Those which I brought home have established themselves slowly, but a quantity of seed received in the autumn germinated well in boxes, and in November 1905 was much larger than common spruce of the same age. They were quite uninjured by the severe frost of May 21, 1905, which injured the common spruce very severely, and on my limy soil are growing faster and more vigorously than any other species of *Picea*.

The tree appears to have been first distributed by Messrs. Fröbel of Zurich about 1884, and has been found quite hardy in England, as might be expected from the climate of its native country.

The finest specimen I know of in England is in the garden of W. H. Griffiths, Esq., at Campden, Gloucestershire, where it was bearing a good crop of cones near the summit in August 1905, and measured about 25 feet in height; this seems to show that the tree prefers limestone. At Kew there are three fine trees which were raised from seed obtained from Belgrade in 1889. These trees are now (1905) 13 inches in girth at 5 feet from the ground, and the tallest one is 23 feet high, making a strong, vigorous leading shoot, and assuming the very narrow pyramidal form which is so remarkable in the wild trees. The other two are 18 and 20 feet in height.

At Tortworth Court it has attained about 15 feet in height, and produced cones containing in the year 1902 apparently good seed; but Lord Ducie tells me that no plants raised from them can now be found. Though the tree is a very ornamental one I do not expect it can have any value as a forest tree in Great Britain, its timber having, so far as known, no special use. Judging from the soil and climate of its native country it should succeed in the Highlands of Scotland, especially on limestone soil, as well as, or better than in England, and as seedlings can now be procured in small numbers it will no doubt be planted by all lovers of coniferæ.

(H. J. E.)

PICEA BREWERIANA, BREWER'S SPRUCE

Picea Breweriana, Watson, *Proc. Amer. Acad.* xx. 378 (1885); Sargent, in *Gardeners' Chronicle*, xxv. 498, f. 93 (1886), and *Silva N. America*, xii. 51, t. 601 (1898); Kent, in *Veitch's Man. Coniferæ*, 430 (1900).

A tree, attaining 100-120 feet in height, with a stem 2 to 3 feet in diameter above its enlarged base. Branches crowded to the ground, with slender, pendulous branchlets, which are often 7 to 8 feet in length and sparsely covered in their first and second seasons with greyish pubescence. Pulvini long and slender, directed forwards. Leaves often nearly an inch long, rounded on both surfaces, the dorsal surface keeled and bearing 10 to 12 rows of stomata, the ventral surface dark green, shining with a prominent midrib, apex obtuse or short pointed. The leaves, on account of the shoots being pendulous, are radially arranged (never pseudo-distichous), their apices pointing outwards and downwards.

Cones on short stalks ($\frac{1}{4}$ inch), oblong-cylindrical, gradually narrowed from the middle to each end, $2\frac{1}{2}$ to 5 inches long by $\frac{3}{4}$ to 1 inch wide; scales broadly obovate with entire rounded margins; bracts minute, concealed, oblong, with denticulate upper margin. Seed with long wing (three times the length of the seed itself). The cones are pendent, greenish, or purplish green when fully grown, becoming dull brown when ripe, and open to let out the seed in autumn, but generally remain on the branches till the winter of the following year. (A. H.)

This tree has a more limited range than any other spruce, being confined, so far as we know at present, to a few stations in northern California and southwestern Oregon, on the Siskiyou Mountains, where it was discovered at an elevation of about 7000 feet, in June 1884, by Mr. Thomas Howell, who directed me to the best place from which the locality can be approached, a settlement called Waldo, about 40 miles west of Grant's Pass station, on the Southern Pacific Railway.

I went to this station in August 1904 with the intention of visiting Waldo; but finding that Messrs. Jack and Rehder, of the Arnold Arboretum, had just returned, and hearing from them that there were no cones on the trees in that year, I did not feel inclined to spend three days on the trip. I am, however, much indebted to these able botanists for the following information, and especially to Mr. Rehder for a beautiful negative of the tree, which is here reproduced. (Plate 29.)

There seems to be only a small grove of the trees about 20 miles south of Waldo, over the Californian boundary, which is best reached by following the trail to Happy Camp, and turning west near the summit of the pass to a place called Big Meadows, which is four miles from the pass.

There is another place where it grows near Selma, which is more accessible

than Big Meadows, and other localities are mentioned by Sargent, who says that Professor Brewer, after whom the tree was named, had previously, in 1863, found a tree which was probably the same species, on Black Butte to the north of Strawberry Valley, at the western base of Mount Shasta, where, however, it cannot now be rediscovered.

Another locality for Brewer's spruce was found in 1898, by Mr. F. Anderson, on an unnamed but conspicuous peak at the headwaters of Elk Creek, about two or three miles west of Marble Mountain and eighty miles west of Mount Shasta. The elevation of the peak is about 8000 feet, and several hundred specimens were found growing near the summit; the trunks were 16 to 20 inches in diameter at 3 feet from the ground, and there were plenty of cones on the tops of the trees which were about 80 feet high.¹

It grows on the Siskiyou in company with *Pinus ponderosa*, *P. Lambertiana*, and *P. monticola*, but usually gregariously in groves by itself. The soil and climate are dry, but there seems to be no special reason why this tree has proved in the eastern States of North America so difficult to cultivate; and as some of the conifers of the Pacific Coast which will not grow, or are not hardy in the eastern States, as, for instance, *Abies bracteata* and *Picea sitchensis*, thrive in England, and the trees with which it is associated in America are hardy and produce good seed here, we need not despair of seeing this beautiful tree established in the south of England.

The late Mr. R. Douglas, of Waukegan, Ill., visited Oregon in 1891 on purpose to obtain the seeds, and collected a large quantity of cones, from which several hundred thousand seedlings were grown. But those sown in America perished in their first and second years from causes which are not known, and attempts to raise the tree in the Arnold Arboretum have also failed.

Some of the seed, however, was raised by the late Baron von St. Paul Illaire at Fischbach in Silesia, which were alive in 1895;² and small plants were reported in 1903 to be growing in the Royal Pomological Institute at Proskau in Silesia.³

The late Mr. Johnson, of Astoria, Oregon, transplanted a few small trees to his nursery, some of which are, I believe, growing near Portland. Brandagee found a few two-year-old seedlings among the old trees, and half a dozen of them reached the Arnold Arboretum alive.

One of these was sent from there to Kew in November 1897, and is growing near the Pagoda, being about $2\frac{1}{2}$ feet in height at the present time (March 1905). It is the only living specimen known to us in Britain.

The tree is said by Professor Sheldon to grow from 100 to 150 feet high, but Sargent gives 120 feet as the extreme height, and Messrs. Jack and Rehder did not see any higher than about 110 feet by about 9 feet in circumference. Douglas informed Baron von St. Paul that the largest tree measured by him was 121 feet high, and 2 feet 11 inches in diameter at $7\frac{1}{2}$ feet from the ground. As the region in which it grows is so limited, and forest fires are very prevalent and

¹ *Erythea*, vi. 12 (1898), and vii. 176 (1899).

² *Mitt. Deutsch. Dendr. Ges.* 1895, p. 42.

³ *Ibid.* 1903, p. 77.

destructive, it is to be feared that unless special measures are taken for its protection by the State of Oregon this very beautiful tree may become extinct.

The timber, which I only know from a specimen in the Jesup Collection of North American Woods, preserved in the American Museum of Natural History at New York, is said by Sargent to be considerably heavier than that of other American spruces, soft, close-grained, with a satiny surface, the sapwood hardly distinguishable. The specimen alluded to is $13\frac{1}{4}$ inches in diameter under the bark at 166 years old. (H. J. E.)

PICEA AJANENSIS, AJAN SPRUCE

- Picea ajanensis*, Fischer, ex Lindley and Gordon, *Trans. Hort. Soc.* v. 212 (1850), and in Middendorff, *Reise, Florula Ochotensis*, 87, tt. 22-24 (1856); Masters, *Jour. Linn. Soc. (Bot.)*, xviii. 508 (1880), and *Gard. Chron.* 1880, xiii. 115, and xiv. 427, with figures; Mayr, *Monograph der Abietineen des Jap. Reiches*, 53, 102, t. iv. (1890); Kent, in Veitch's *Man. Coniferae*, 425 (1900).
Picea ajanensis, var. *microsperma*, Masters, *Jour. Linn. Soc. (Bot.)*, xviii. 509 (1880).
Picea jezoensis, Carrière, *Traité Gén. Conif.* 255 (1855).
Abies ajanensis, Lindley and Gordon, *loc. cit.* (1850).
Abies jezoensis, Siebold et Zuccarini, *Flora Japonica*,¹ ii. 19, t. 110 (*ex parte*) (1844); Veitch, *Man. Coniferae*, ed. 1, p. 72 (1881).

A tree, attaining in Yezo 100-150 feet in height. Bark like that of the common European spruce, grey, and composed of irregularly quadrangular scales which do not fall off. Branchlets shining, glabrous, yellow, never becoming reddish. Free part of the pulvini long, directed backwards on branchlets of old trees, not widened or channelled at their bases on the upper surface of the branchlets, persistent on old branchlets. Buds broadly conic, with ovate scales rounded in margin, showing on opening the young leaves tinged with red. Leaves flattened, thin, blunt, or ending in a short point, slightly keeled on both surfaces; ventral surface green without stomata; dorsal surface silvery white with two broad bands of stomata. Cones purple when young, brownish when ripe, straight, oblong, tapering at each end, 2 to 3 inches long by nearly 1 inch wide; scales narrowly oblong-oval, coriaceous, erose, and denticulate in margin; bracts minute, concealed, broad-oblong, slightly narrowed below, their upper rounded denticulate edge giving off abruptly an apiculus. Seed with a wing, which is twice or thrice as long as the seed itself.

IDENTIFICATION. (See *Picea hondoensis*.)

DISTRIBUTION

Picea ajanensis appears to be confined to Manchuria, Amurland, that part of Eastern Siberia which faces the southern half of the Sea of Ochotsk, Saghalien, the three southern isles of the Kurile group, and Yezo. The spruce of Central China, which has been identified with it in *Index Florae Sinensis*, ii. 553, has pubescent shoots, and is probably identical with *Picea brachytila*, Masters. The accounts of the Ajan spruce on the continent of Asia are of ancient date, the only recent one being that in Russian by Komarov,² who states that it grows abundantly with species of *Abies* and *Pinus koraiensis* in mountain woods in all the provinces of Manchuria. It has not, however, been collected there by any British travellers.

¹ The figures given by Siebold represent (1) a flowering twig which came from a garden in Tokyo, and was probably, according to Mayr, *Picea hondoensis*; and (2) a branch with cones, copied from a Japanese drawing of *Picea ajanensis* from Yezo. The description applies to two species, and the name *jezoensis* cannot stand. The synonymy is very involved, but, accepting Mayr's view, the facts are clear enough. The Hondo spruce was first distinguished clearly by Mayr, and therefore receives his name *Picea hondoensis*. The Yezo and Amurland spruces are the same species, and receive the name *Picea ajanensis*, first given by Fischer.

² Komarov, *Flora Manshurica*, i. 200 (1901).

Farther north, according to Maximowicz,¹ it extends throughout the territory of the lower Amur and the coast province facing the Sea of Ochotsk, reaching its northern limit in the interior in the Stanovoi mountains about latitude 55° 50', and on the coast at Ajan, lat. 56° 27'. Schmidt² says that thick forests of *Picea ajanensis* occur in the lower Amur and in the coast territory. A mountain at 1000 feet in the Amgun valley was clothed with a thick mossy wood of this spruce, in the shadow of which snow still lay on the 30th May. On the crest of the Bureja range it occurs as a low prostrate shrub. It descends very seldom to the river banks. Middendorff also notes that it is confined to the hills on the coast of the Sea of Ochotsk. Occasionally it grows on swampy flats in Amurland.

Schmidt describes the bark as being moderately rough and divided into generally 6-angled plates, about an inch in diameter and $\frac{1}{2}$ to 1 line in thickness; and that the form and colour of the leaves are very variable, their points being either acute or obtuse.

In the island of Saghalien, in its south-western part, there is a coniferous forest composed of *Picea ajanensis* and *Abies sachalinensis*, which clothes the slopes of the mountains up to 800 feet on the coast, and higher in the interior, where even the lofty crests are covered with dark forests of these two species.

In the Kurile Isles³ this species is confined to the three islands north of Yezo, namely Kunashiri, Shikotan, and Etorofu, reaching its northern limit in the last named. In Shikotan it forms with *Abies sachalinensis* a dense mixed forest, which in habit and height and cover of the ground strikingly resembles the coniferous forests at moderate elevations in Germany. The cones borne by the tree in this island are, however, small in size, and the tree itself does not attain its maximum dimensions.

In Yezo, Mayr reports that he has seen trees 130 feet in height, and considers reliable the reports of the Japanese foresters that it occasionally attains even 160-200 feet. It occurs in all the mountains of Yezo, only reaching the coast in the west of the island, where it is found in cold, marshy localities immediately behind the dunes, being only separated from the sea by a growth of *Rosa rugosa* and shrubby *Quercus dentata*. The important forests of it lie in the western and central mountains of Yezo, and also in the high ranges of Kitami, Kushiro, and Nemoro, where it forms mixed woods with the Saghalien silver fir and *Picea Glehnii*.

INTRODUCTION

We do not know that any plants of the continental Ajan spruce have been grown in Europe.

John Gould Veitch visited Hakodate in 1860, and sent home specimens and seeds of a weakly form of the Yezo *Picea ajanensis*, which was described by Lindley⁴ as a

¹ Maximowicz, *Primitia Florae Amurensis*, 261, 392 (1859). See also Regel, *Tentamen Florae Ussuriensis*, 136 (1861).

² Schmidt, "Reisen in Amurland und Saghalien," in *Mém. Acad. Imp. Sc. St. Petersburg*, VII. series, xii. No. 2, pp. 15, 20, 63, 98 (1868).

³ Mayr, *loc. cit.* p. 102.

⁴ *Gard. Chron.* 1861, p. 22. This is *Picea ajanensis*, var. *microsperma*, Masters, *Gard. Chron.* 1880, i. 115.

distinct species, *Abies microsperma*. Plants raised from the seed "turned out to be unsuitable for the climate of this country."¹ This form, according to Mayr, and so far as I can judge myself, can hardly rank even as a variety, and is not in cultivation at the present time.

Maries² visited Yezo in 1879 and sent home specimens, now preserved in the Kew Herbarium, and seeds of the true *Picea ajanensis* from that island; and young trees should accordingly be in cultivation in this country. This plant was kept separate by Messrs. Veitch at first, under the name *Abies yezoensis*. Maries considered the Yezo spruce to be quite distinct in habit and aspect from the two spruces which he had seen on Fujiyama (*Alcockiana* and *hondoensis*).

Mayr informed me last year that the Yezo spruce was not introduced into Europe until 1891; and that most of the trees on the Continent passing under the name of *Picea ajanensis* belong to *Picea hondoensis*. The specimens which have been sent me from old trees of reputed *P. ajanensis* in England also belong to that species. (A. H.)

On account of the heavy floods which occurred in July 1904, I did not get far enough north in Hokkaido to see this tree at its best, but in the State forests of Shari, Kutami, and Kushiro, it occurs in great masses, and is one of the principal economic products of the island. I saw it thinly scattered in forests of deciduous trees between Sapporo and Asahigawa, where it was of no great size, and in the forest round the volcanic crater-lake of Shikotsu in the south-east of Hokkaido it formed, here and there, nearly pure forests of small extent, mixed more or less with *Picea Glehnii* and *Abies sachalinensis*, at an elevation of 1000 to 2000 feet. The vegetation in these forests was quite unlike anything that I saw in Central Japan, the ground being covered with a dense layer of humus, and in the more shady places two or three species of *Pyrola* were abundant. *Daphne*, *Gaultheria*, *Ledum*, and other plants not seen elsewhere occurred, with curious terrestrial orchids and many ferns. The trees rarely exceeded 80 feet in height by 4 to 6 feet in girth, but higher up near the lake I measured one as much as 100 by 9 feet.

The general appearance of the tree is very like that of *P. sitchensis*, though I did not notice that the roots became buttressed, which is probably only the case in wet soil. The natural reproduction is good, but the seedlings grow slowly at first and seemed to thrive best in shade. The Japanese name is *Eso-Matsu*.

TIMBER

The wood of this tree is soft, but probably as good as that of other spruces. I passed the night at a factory in the forest where it was being cut up into thin slices for export to Osaka, where large quantities are used for making matchboxes. It is also employed for boat masts and other purposes, and is worth in Tokyo about 10d. per cubic foot. On account of its softness, lightness, and fineness of grain,

¹ Kent, in Veitch's *Man. Coniferae*, *loc. cit.*

² See Veitch's *Man. Coniferae*, ed. i. p. 72 (1881).

it is largely used in Japan for chip-braid, a peculiar Japanese industry, which has lately attained considerable importance, the export for 1903 amounting to no less than 1,363,000 yen—equal to about £140,000. This braid is mainly used for making hats and bonnets, but it is also woven into floor-matting, and as shown at the St. Louis Exhibition is both ornamental and cheap.

There are many different varieties of chip-braid, some of which are dyed of different colours, and others are plaited with a mixture of silk. It is exported in bundles of 50 to 60 yards long and 1 to 1½ inches wide, and is valued according to quality at 1s. to 6s. per bundle. The best are made by mixing chips of *Populus tremula* and *Picea ajanensis*.
(H. J. E.)

PICEA HONDOENSIS, HONDO SPRUCE

Picea hondoensis, Mayr, *Monograph der Abietineen der Japanisches Reiches*, 51, t. iv. fig. 9 (1890); Shirasawa, *Iconographie des Essences Forestières du Japon*, text 20, tab. v. figs. 1-22 (1900).
Picea ajanensis, Hooker, *Bot. Mag.* t. 6743 (1884), and of most writers.
Abies ajanensis, Fisch., var. *japonica*, Maximowicz, *Iter secundum* (1862).

A tree, attaining 80 feet in height in Hondo, the main island of Japan. Bark dark grey, peeling off in small roundish scales and leaving light-coloured spots on the trunk. Branchlets shining, glabrous, yellow in the first year; but becoming reddish brown in the second year, and retaining the red colour in succeeding years till the scaly bark begins to form. The free portions of the pulvini are directed forwards, and on the upper side of the branchlets are enlarged transversely at their bases and show two channels where they become decurrent on the stem; they are shorter than in *Picea ajanensis*, and on older branchlets tend to disappear. Buds like those of *Picea ajanensis*, but opening with greenish leaves. Leaves as in that species, but slightly shorter. Cones, red when young, yellowish when ripe, slightly curved, oblong, tapering to each end, about 2 inches long by ¾ inch thick, erect on terminal younger branchlets; scales membranous, oval, broader proportionately to their length than in *P. ajanensis*, with denticulate erose margins; bracts minute, concealed, oval lanceolate, denticulate, gradually tapering to an acute apex. Seed with a short wing (less than twice the length of the seed).

The description just given enumerates the characters, chiefly those of the bark, shoot, and cones, on which Mayr relies to distinguish the Hondo spruce from the true *Picea ajanensis*.

Picea hondoensis, as grown in this country, where it is usually called *Picea ajanensis*, assumes a broadly pyramidal outline, the main branches being rigid and directed either upwards or horizontally. In sunshine the branchlets turn their tips upwards, exposing to view the pale surface of the leaves. The arrangement of the leaves on lateral branchlets is the one normal in flat-leaved spruces, *i.e.* the upper side of the branchlet is densely covered with leaves, which have their apices directed forwards, while on the lower side of the branchlet the leaves part into two sets, directed outwards at right angles and leaving the twig bare beneath. All the leaves direct their stomatic pale surfaces away from the light, so that these look towards the ground.

The young cones are bright crimson, and make the tree highly ornamental in spring.

IDENTIFICATION

Picea Alcockiana, in which the leaves are conspicuously white on the dorsal surface, is often confounded in gardens with *Picea hondoensis*; but these two species are readily distinguished as follows:—

Picea hondoensis.—Leaves flat, with bands of stomata confined to the dorsal surface. On the lower surface of lateral branchlets the twig is bare, with the leaves directed outwards at right angles.

Picea Alcockiana.—Leaves quadrangular in section, with lines of stomata on the ventral surface, in addition to the bands of stomata on the dorsal surface. On the lower surface of lateral branchlets the twig is not quite bare, and the leaves are directed forwards at an acute angle.

Picea hondoensis, *Picea ajanensis*, and *Picea sitchensis* have been distinguished, so far as leaves and branchlets are concerned, in the key to Section *Omorica*. The cones of these three species are much alike. Those of *Picea sitchensis*, however, have scales oblong in outline, with their upper edge scarcely emarginate or erose; the bracts are large and visible between the scales towards the base of the cone. In the other two species the scales of the cones are oval with erose margins, while the bracts are minute, concealed, and differently shaped.

The cones of *Picea Alcockiana* differ considerably from those of the three preceding species. Their scales are rounded, being nearly semicircular in outline, with the upper edge almost entire or only minutely denticulate; and their outer surface is markedly striated.

DISTRIBUTION

Picea hondoensis is confined to the central chain of mountains in the main island of Japan, occurring at altitudes above 4000 feet. Shirasawa (*loc. cit.*) mentions as localities, Fuji, Mitake, Novikura, Sirane to Nikko, Chokarsan to Ugo, etc.; and says that in the lower levels it is accompanied by *Tsuga diversifolia*, and ascends to 8000 feet in company with *Abies Veitchii*. Mayr states that on Fuji it is accompanied by *Picea bicolor* (*Alcockiana*), both occurring in mixed woods with *Larix leptolepis* and *Abies Veitchii*. Farther north, *Picea polita* joins the two spruces just named; and all three reach their northern limit in the high mountains of Iwashiro at 38° lat. Its southern limit is 35° lat.

Elwes saw very little of this tree in Japan, but near the top of the Wada-toge pass there were some small spruces growing at about 4500 feet elevation, which he believes to have been this species. *Tohi* is the Japanese name.

INTRODUCTION

Picea hondoensis was introduced in 1861 by John Gould Veitch. It was distributed as *Abies Alcockiana*, an unfortunate circumstance, due to the fact that the seeds of the two spruces growing on Fujiyama (*Picea hondoensis* and *Alcockiana*) were both collected for Mr. Veitch by natives and were mixed together. Dr. Masters cleared up the question as to the distinctness of these two species in an article in the *Gardeners' Chronicle*,¹ in which, however, he retained the name *Picea ajanensis* for the spruce, which Mayr afterwards separated as *Picea hondoensis*. If

¹ *Gard. Chron.* 1880, i. 115, and ii. 427.

Mayr's view of the specific distinctness of *Picea hondoensis* and *Picea ajanensis* be upheld, most of the specimens cultivated in this country under the latter name (and many also incorrectly labelled *Alcockiana*) must be renamed as *Picea hondoensis*.

The best specimen we have seen in England is a tree at Hemsted in Kent, which was planted by the Earl of Cranbrook in 1887, and, when measured by Elwes in 1905, was 44 feet high.

There is one at Benmore, near Dunoon, the property of H. S. Younger, Esq., which Henry measured in 1905 as 52 feet by 4 feet 4 inches, about twenty-five years planted.

At Fota, Co. Cork, there is a fine tree which, in 1904, Henry found to be 44 feet by 4 feet 3 inches. (A. H.)

PICEA SITCHENSIS, MENZIES' OR SITKA SPRUCE¹

Picea sitchensis, Carrière, *Traité Conifer.* 260 (1855); Trautvetter et Meyer, in Middendorff, *Reise Florula ochotensis*, 87 (1856);² Sargent, *Silva N. America*, xii. 55, t. 602 (1898); Kent, in Veitch's *Man. Coniferae*, 452 (1900).

Picea Menziesii, Carrière, *Traité Conifer.* 237 (1855); Masters, *Gard. Chron.* xxv. 728, figs. 161, 162 (1886).

Picea sitkaensis, Mayr, *Wald. N. Amerika*, 338 (1890).

Pinus sitchensis, Bongard, *Vég. Sitcha*, 46 (1832).

Abies Menziesii, Lindley, *Penny Cycl.* i. 32 (1833); Loudon, *Arb. et Frut. Brit.* iv. 2321 (1838).

Abies sitchensis, Lindley and Gordon, *Jour. Hort. Soc.* v. 212 (1850.)

A tree, sometimes exceeding 200 feet in height, with a trunk 4 to 20 feet in diameter, tapering above its enlarged and buttressed base; in Alaska dwindling to a low shrub. Bark with large, thin, red-brown scales. Branchlets yellow, shining, glabrous. Buds ovoid, acute at the apex, with ovate obtuse scales. Leaves arranged on lateral branchlets as in *Picea ajanensis*, ending in sharp cartilaginous points; deeply keeled on the ventral green surface, and almost convex on the dorsal surface, which has two white broad bands of stomata. The male catkins are solitary at or near the ends of the branchlets, and are of an orange reddish colour.

Cones: on short straight stalks, cylindrical-oval, blunt at the free end, $2\frac{1}{2}$ to 4 inches long by 1 to $1\frac{1}{2}$ inches wide, composed of oblong or oblong-oval scales, rounded towards the apex, denticulate and scarcely erose in margin; bracts lanceolate, denticulate, about half as long as the scales, and peeping out between them towards the base of the cone. The cones when ripe are yellow or brown, and generally fall off in the autumn and winter of the first year. Seeds, with a wing, three to four times as long as the seed itself.

The Sitka spruce seems to vary considerably over its wide area. There are specimens at Kew from the Columbia River, with pubescent young shoots, and bearing small cones which have oval, not oblong, scales, and minute almost orbicular bracts. Other specimens from Alaska have larger cones than usual, but with bracts shorter than usual, and the leaves are not so deeply keeled or so sharp-pointed as in the type.

Cultivated trees are generally broadly pyramidal in outline, and when old, often show the enlarged and buttressed base, so characteristic of wild trees; the roots sometimes extending superficially above the ground for several feet. The tree often produces on its lateral branches small erect shoots, on which the leaves spread radially in all directions.

(A. H.)

IDENTIFICATION. (See *Picea hondoensis*)

¹ Called also Tideland spruce on the Pacific coast.

² Trautvetter and Meyer are often cited as the authors of the name *Picea sitchensis*; but the correct date of their publication is later than that of Carrière's. See Trautvetter, *Flora Rossica Fontes*, 303 (1880).

VARIETIES

On the Continent, according both to Beissner¹ and to the late Prof. Carl Hansen, whose "Pinetum Danicum," published in the *Journal of the Royal Horticultural Society for 1892*, is a valuable contribution to our literature, a variety (*speciosa*) occurs in cultivation, which is light blue in colour and very decorative. It differs from the ordinary form in being slower in growth and in having leaves, which are shorter, stiffer, and more sharply pointed.

DISTRIBUTION

According to Sargent, this spruce extends farther north-west than any other North American conifer, being found in long. 151° west on the east end of Kadiak island, and all through the coast region of Alaska and British Columbia, west Washington and Oregon, and as far south as Caspar in Mendocino County, California.

In the north it is a small tree, sometimes only a bush, but on the coast of south-east Alaska is the largest and most abundant tree, and grows in company with the western hemlock. Here it attains over 100 feet in height, and ascends the mountains to about 3000 feet.

In the south of British Columbia it is larger in size, but in Vancouver's Island it did not seem common, and was not a conspicuous tree in the south-east parts of the island which I visited.

In Washington it grows to a very large size, and I measured one in swampy ground near a logging camp in the White River valley which was 23 feet in girth at 6 feet from the ground, and appeared to be 3 to 4 feet in diameter at the place where it was broken off at about 120 feet from the ground.

Prof. Sheldon, in a pamphlet on *The Forest Wealth of Oregon*, calls it the largest tree in the state, growing 200 to 300 feet high, and has figured as the frontispiece of this paper what he calls the largest Tideland spruce in the world. This tree grew on the coast in God's Valley, on the North Nehalem River, Clatsop County, Oregon, and measured 30 feet $11\frac{1}{2}$ inches in diameter at 2 feet from the ground, and 20 feet $4\frac{1}{2}$ inches at 6 feet from the ground.

He states that it is distinctly a moisture-loving tree, and in the extensive coast belt forest which it forms is an ideal lumber tree, free from limbs for a great part of its height.

It is not mentioned as growing in the great forest reserve of the Cascade Range, and, according to Sheldon, extends southwards along the coast as far as Curry County. In northern California it grows on rich alluvial plains at the mouths of rivers, or in low valleys facing the ocean, where it is associated with *Sequoia sempervirens* and *Abies grandis*, and thus may be said to be almost strictly confined to a region where there is perennial moisture in the air, and an annual rainfall of 50 inches and upwards.

¹ *Nadelholzkunde*, 392 (1901).

Sargent says its growth is very rapid, the leading shoots of young trees on Puget Sound being often 3 to 4 feet long.

John Muir measured a tree in Washington 180 feet high, at 240 years old, with a trunk 4 feet 6 inches diameter. Another near Vancouver, B.C., only 48 years old, had a trunk 3 feet in diameter.

In Alaska, Gorman measured two trees—one grown in a dense wood, well protected from wind, was 160 feet high, at 267 years old, with a diameter of 3 feet 11 inches; and the other on a hillside exposed to fierce north-east gales, was 4½ feet in diameter at 14 feet from the ground, and 434 years old. The heart of this tree was 32 inches from the south-west side, and only 16½ inches from the north-east side, showing the effect of prevalent winds on the production of branches and wood.

A tree measured by Muir at Wrangel, Alaska, was no less than 764 years old, with a trunk 5 feet in diameter, and this, I think, is the greatest age to which any recorded spruce has attained.

INTRODUCTION

Though discovered in Puget Sound in May 1792 by Archibald Menzies, who was surgeon and naturalist to Vancouver's expedition, it was not introduced to cultivation until 1831 by David Douglas, and was described by Lindley under the name of *Abies Menziesi* one year after Bongard had made it known to science under the specific name which we adopt. It is, however, still commonly known in Great Britain as Menzies' spruce, and his name it may well bear. According to Loudon, only a very few plants were raised in the Horticultural Society's Garden in the year 1832, of which some still survive.

The Oregon Association, which was formed a little later by a few Scottish arboriculturists for the purpose of introducing the conifers of the Pacific coast, and who sent out John Jeffrey as a collector about 1850, were fortunate in procuring a large quantity of seed, from which the pineta of Scotland and England have been stocked, and it has now become a common tree.

CULTIVATION

Though Menzies' spruce loves a wet climate, it loves a wet soil even more, and soon becomes unsightly and loses its foliage in dry localities. No conifer, except perhaps the Douglas fir, grows so rapidly where it has a suitable situation, and in some parts of Scotland it is now being planted experimentally as a forest tree.

It is easily raised, either from home-grown or imported seed, and is, like all spruces, slow of growth for the first few years, and requires at least five or six in the nursery before it is large enough to plant out.

At Durris, in Aberdeenshire, on the property of Mr. H. R. Baird, there is a plantation of Sitka spruce about 15 acres in extent, of which Mr. John Crozier, the forester in charge of the estate, gives us the following particulars in a letter dated 12th September 1904:—

"The plantation occurs at an altitude of 700 to 800 feet, the aspect being northerly, soil a sandy peat over boulder clay. The age of the plantation is twenty-five years; but there is no record either as to the number of the plants put out or the age when planted. They were, however, notched in, and their age would most probably be four years. They were planted rather irregularly, the distance varying from 6 to 9 feet, and both common spruce and Scots fir have been used to fill up between, to 3 feet between each plant. The average height of the Sitka trees is about 33 feet; and the girth at 5 feet taken at random is (where they had been planted 9 feet apart), 24 in., 22 in., 20 in., 25 in., 22 in., 22 in., 28 in., 22 in., 26 in., 25 in. The *largest* common spruces I could find on the same ground measured 9 in., 8 in., 11 in., 9 in., 11 in., 12 in., 16 in., 9 in., 10 in., 12 in., and their height was about 26 feet. I took the measurement of a hundred Sitkas over a track 20 feet broad, just as they came, and they averaged 22¾ in. Where the Sitkas had been planted at 6 feet apart, the common spruce and Scots fir are dominated, and the greater part of them quite dead. I drained some very wet parts a year ago, where both the Scots fir and common spruce had been killed through excess of moisture, but the Sitka had been very little harmed by it. Judging by what I have seen of the tree here and elsewhere, it will stand a greater degree of moisture than any other conifer I know. The plantation is altogether in a very healthy state."

A few hundred Menzies' spruces were planted out in 1879 on the mountain at Bronydd, on the property of Lord Penrhyn in North Wales, at 900 feet elevation; according to Mr. Richards, the forester, only half a dozen trees now survive, in a wretched condition. He states, however, that as the young growths come out late in the spring the tree is never touched by frost in North Wales. At Penrhyn there is a good specimen of the tree measuring 10 feet 6 inches in girth in 1904.

Menzies' spruce,¹ on account of its sharp needles, has been supposed to be free from the attacks of deer, rabbits, and hares; but recent observations made in the royal domain of Freyr in Belgium show that out of 10,000 plants introduced some years ago only 2000 remain, and these are not expected to survive long. This is much to be regretted, as they had grown splendidly.

REMARKABLE TREES

One of the largest trees we know of in the south of England is at Highclere, Berks, the seat of the Earl of Carnarvon, where we measured a tree in August 1903 which was 96 feet by 12 feet. The tree, having lost its lower branches owing to a heavy snow-storm, has put out new branches down the trunk, a somewhat rare occurrence in large conifers. Another very fine tree is growing at Barton, Suffolk, which was planted in 1847, and when measured by Henry in 1904 was 99 feet by 9 feet 3 inches. Both of these are in a dry climate but in a good soil.

At Bicton, Devonshire, I measured a tree in 1902 which was 85 feet by 11 feet

¹ Bull. Soc. Cent. Forest. Belgique, April 1901.

6 inches; and at Boconnoc, Cornwall, the seat of J. B. Fortescue, Esq., a tree was recorded in 1891 as being 85 feet high by 12 feet in girth at the age of 48 years.¹ In 1905 Elwes measured this and found it to be 86 by 15 feet.

At the same time¹ a tree growing at Howick Hall, Northumberland, the seat of Earl Grey, was 90 feet high at the age of 58 years.

At Beauport, Sussex, a tree measured in 1904 95 feet by 12 feet 10 inches. It has very wide-spreading superficial roots, one extending over the ground 16 feet in length. According to Sir Archibald Lamb, the tree five years ago was 12 feet 3 inches at 3 feet up, its present girth (1904) at that height being 13 feet 4 inches. (Plate 30.)

In Scotland the largest tree we know of, and probably the largest in Great Britain, is at Castle Menzies, said to have been 46 years old in October 1892, when its exact measurement was given by Mr. J. Ewing as 96½ feet high by 11 feet in girth. I measured it carefully in April 1904, and found it to be 110 feet high by 13 feet 2 inches. This tree is growing on the banks of a pond in good and damp soil, and has produced a greater amount of timber in a short time than any conifer I know in Scotland, except, perhaps, the Douglas fir, though *Sequoia sempervirens* may run it close in England. But spruce timber grown so fast is very soft, coarse, and knotty, close planting being essential to give the tree any economic value.

At Abercairney, Perthshire, there is a tree which was measured by Henry in August 1904, as 99 feet in height by 9 feet 9 inches in girth. This was 76 feet by 7 feet 5 inches in 1891.²

At the Keillour Pinetum,³ in the same county, on boggy ground on a hillside, there is a remarkable Menzies' spruce, 86 feet in height by 15 feet 9 inches in girth. It has wide-spreading buttressed roots, and is branched to the ground. According to a MS. account in the possession of Col. Smythe of Methven Castle this tree was planted in 1834 or 1835. In this pinetum many species of conifers were planted in these two years, and owing to the wet, boggy nature of the soil some kinds have grown slowly, such as *Picea nigra*, *Pinus Cembra*, *Abies balsamea*, and *Abies Pinsapo*. *Abies grandis* has perhaps succeeded best, next to *Picea sitchensis*, which has produced an amount of timber far in excess of the other species. *Abies grandis* here is 90 feet by 7 feet 3 inches. A *Picea alba*, planted presumably at the same time, is only 52 feet by 5½ feet.

Mr. Crozier reports that there is a Menzies' spruce 13 or 14 feet in girth at Dunrobin in Sutherland.

At Murraythwaite, in Dumfriesshire, the seat of W. Murray, Esq., a tree 78 feet by 8 feet 10 inches, planted about the year 1855, is growing near a pond, and is a fine healthy specimen, broadly pyramidal, and feathered to the ground.

A tree⁴ at Keir, near Dunblane, measured, in 1905, 82 feet by 9 feet 10 inches. At Smeaton Hepburn, Haddington, the seat of Sir Archibald Buchan Hepburn, Bart., where there is a remarkably varied collection of trees, a fine Menzies' spruce

¹ *Jour. Roy. Hort. Soc.* 1892, xiv. 486, 493.

² *Ibid.* 1892, xiv. 527.

³ Visited by Henry in August 1904.

⁴ This tree was reported in 1891 to be 61 feet by 7 feet 3 inches, and was then forty years old, *Jour. Roy. Hort. Soc.* (1892) xiv. 531.

measured, in 1905, 88 feet by 10 feet 7 inches. A very large tree is reported to be growing in the grounds of Major Ross at Killoch, Nairnshire.

In Ireland the finest example that we know is at Curraghmore, Waterford, the seat of the Marquess of Waterford. Mr. Crombie writes that it is now (March 1905) 106 feet in height, with a girth of 12 feet at 5 feet from the ground. This tree was reported¹ in 1891 to be 110 feet high (evidently an estimate) with a girth of 10 feet.

At Mount Shannon, Co. Limerick, there is growing a very vigorous tree, with branches to the ground, which in 1905 was 79 feet by 12 feet.

A tree at Clonbrock, Co. Galway, planted in 1881 and growing in boggy soil, was in 1904 56 feet high by 4 feet 8 inches in girth.

TIMBER

The wood is said by Sargent to be light, soft, and straight grained, not strong, with a satiny surface, and thick, nearly white, sapwood.

It is largely used on Puget Sound for purposes where cheap lumber is required, but I did not see it in the timber yards that I visited in Tacoma.

Laslett does not mention it in his work, but Stone, quoting Macoun, says that it is elastic, bends with the grain without splitting, and is much used in boat-building, for light oars, staves, doors, and window-sashes, resists decay for a long time, and is not attacked by insects.

I am informed by Mr. Rogers, one of the principal timber buyers for the Admiralty, that no other spruce makes such good light oars, and that in consequence it is now imported annually for that purpose. (H. J. E.)

¹ *Jour. Roy. Hort. Soc.* (1892), xiv. 562.

TAXUS

Taxus, Linnæus, *Gen. Pl.* 312 (1737); Bentham et Hooker, *Gen. Pl.* iii. 431 (1880); Masters, *Jour. Linn. Soc. (Bot.)* xxx. 7 (1893); Pilger, in Engler, *Pflanzenreich*, iv. 5, *Taxaceæ*, 110 (1903).

EVERGREEN trees or shrubs belonging to the division *Taxaceæ* of the order *Coniferæ*. Bark reddish or reddish brown, thin and scaly. Branches spreading, giving off branchlets, of one kind only, irregularly alternate, surrounded at their bases by brownish scales. Buds globular or ovoid, of imbricated scales. Leaves inserted on the branchlets in a spiral order, on upright shoots spreading radially, on horizontal shoots disposed by twisting on their petioles in one plane in a pectinate arrangement, the upper and lower leaves being of the same length, with their dorsal surfaces turned upwards and their ventral surfaces downwards. In fastigiata varieties all, or most, of the branchlets assume an erect position, and the leaves in consequence are arranged radially. The leaves are linear, flat, with recurved margins, dark green above, paler green below; the lower surface only bearing stomata, which never form conspicuous white bands; narrowed at the base into a short petiole, arising from a linear cushion on the twig; mucronate or acute at the apex and without a resin-canal.

Flowers dicecious, or in rare individuals monœcious, on the under surface of the branchlets of the preceding year, in the axils of the leaves, the female flowers being less numerous than the male flowers. Male flowers composed of a stalk, girt at its base by imbricated scales, and bearing above a globose head of 6-14 stamens with short filaments. The stamen is expanded above into a peltate connective, which bears on its lower surface 5 to 9 pollen sacs, united with each other and with the filament. The female flowering shoot, arising out of the axil of the leaf, is composed of a number of imbricated scales, in the axil of the uppermost one of which is borne an ovule, placed so close to the apex of the shoot as to appear terminal; in the scale next below a bud occurs, which occasionally develops into a second ovule. The ovule, which has a small membranous disc at its base, projects out of the scales by its micropyle. Seed sessile in a fleshy, juicy cup, forming an aril (the enlarged disc), open at the top and free from the seed in its upper part. The seed variable in form, 2, 3, or 4-angled, is generally ellipsoid and has a ligneous testa, containing oily white albumen, in the upper part of which is an axile straight cylindrical minute embryo with two cotyledons.

Yews differ from all other *Coniferæ* in the character of the fruit. They

resemble in foliage certain other genera of *Taxaceæ*, but are readily distinguishable as follows:—

Taxus.—Branchlets standing irregularly alternate on the branches. Leaves stalked, greenish underneath with no definite bands of stomata. Buds composed of imbricated scales.

Pruminopitys.—Branchlets and leaves as in *Taxus*, but with valvate bud-scales.

Cephalotaxus.—Branchlets opposite. Leaves like the yew in consistence, but with white bands beneath showing definite lines of stomata.

Torreya.—Branchlets sub-opposite. Leaves rigid and spine-pointed with white bands beneath, showing definite lines of stomata.

Saxegothæa.—Branchlets in whorls, ascending at an angle. Leaves with bases decurrent on the shoots, and with white bands beneath which are narrow and close to the median line.

The genus is widely distributed over large parts of North America, Europe, Algeria, and Asia, and occurs sporadically in the mountains of Sumatra, Celebes, and the Philippines. Seven distinct species have been described, each confined to a definite territory. These species are, however, rather geographical forms, only differing from one another in trivial characters of foliage and habit. The view taken by Sir Joseph Hooker¹ and by Pilger, the latest monographer of the genus, that they only constitute one species is probably correct. Many of the supposed specific distinctions, such as the density of the foliage on the branchlets, the size and form of the leaf, etc., are due in most instances to the influence of soil, shade, and climate. Moreover, in the varieties of the common yew, which are known to have arisen as sports in the wild state or in cultivation, greater differences occur in the characters of habit, foliage, and fruit, than are observable in the so-called species. In the account which follows, the geographical forms will be treated as varieties.

TAXUS BACCATA, YEW

Taxus baccata, Linnæus, *Sp. Pl.* 1040 (1753); Loudon, *Arb. et Frut. Brit.* iv. 2066 (1838); Lowe, *Yew Trees of Great Britain and Ireland* (1897); Kent, in Veitch's *Man. Coniferae*, 126 (1900); Kirchner, Loew, and Schröter, *Lebensgesch. Blütenpfl. Mitteleuropas*, i. 61 (1904).

The chief characters of the species have been given in the generic description. The different geographical forms are distinguished as follows:—

1. *Var. typica*, Common Yew.—A tree or shrub. Leaves falcate, acute, or acuminate, the apex diminishing gradually into a cartilaginous mucro; median nerve only slightly prominent above. Buds ovoid or globose, of closely imbricated brownish, rounded scales, usually not keeled on the back.

In certain Himalayan specimens the leaves are long and narrow, with a long acuminate apex, and the buds have keeled scales. Intermediate forms occur; and all Indian botanists and foresters seem to be agreed that the Himalayan yew cannot be separated from the European form even as a variety.¹

2. *Var. cuspidata* (*Taxus cuspidata*, S. et Z.²), Japanese Yew.—A tree or shrub. Leaves straight, scarcely falcate, median nerve prominent above, apex giving off abruptly a short mucro. Buds oblong, composed of somewhat loosely imbricated scales, which are ovate, very acute and keeled. In cultivated specimens the under surface of the leaves is yellow in colour, the buds being bright chestnut brown.

3. *Var. sinensis*,³ Chinese Yew.—A tree. Leaves short, rigid, median nerve not prominent above, apex rounded and giving off abruptly a short mucro. Buds ovoid, brownish, composed of densely imbricated scales, which are ovate, obtuse, and not keeled.

4. *Var. brevifolia* (*Taxus brevifolia*, Nutt.⁴), Pacific Coast Yew.—A tree. Leaves falcate, short, median nerve slightly prominent above, apex abruptly mucronate. Buds large, with loosely imbricated yellowish green scales, which are lanceolate, mucronate, and keeled.

5. *Var. canadensis* (*Taxus canadensis*, Marshall⁵), Canadian Yew.—A low, prostrate shrub. Leaves narrow, falcate; median nerve slightly prominent above, apex abruptly mucronate. Buds globose, small, with somewhat loosely imbricated, greenish, ovate, obtuse, keeled scales.

6. *Var. floridana* (*Taxus floridana*, Chapman⁶), Florida Yew.—A shrub or

¹ It has been described as a distinct species, *Taxus Wallichiana*, Zuccarini, in *Abhand. K. Bayr. Akad. Wissensch.* iii. 803, t. 5 (1843). Pilger, who ranks the different geographical forms as sub-species, keeps it separate from the European yew as sub-species *Wallichiana*.

² *Flora Jap. Fam. Nat.* ii. 108 (1846); Shirasawa, *Icon. Ess. Forest. Japon.* i. 33, t. 15 (1899).

³ *Taxus baccata*, L., Masters, *Index Floræ Sinensis*, ii. 546 (1902).

⁴ Nuttall, *Sylv.* iii. 86, t. 108 (1849); Sargent, *Silva N. America*, x. 65, t. 514 (1896).

⁵ Marshall, *Arb. Amer.* 151 (1785); Sargent, *Silva N. America*, x. 63 (1896). The plant cultivated at Kew as *Taxus canadensis*, var. *aurea*, a strong-growing, erect shrub, is apparently a variety of the common yew.

⁶ Chapman, *Flora South United States*, 436 (1860); Sargent, *Silva N. America*, x. 67, t. 515 (1896).

very small tree. Leaves very narrow, median nerve scarcely prominent, apex acute and gradually passing into the mucro. Buds small, with loosely imbricated, ovate, obtuse scales.

7. *Var. globosa* (*Taxus globosa*, Schl.¹), Mexican Yew.—A small tree. Leaves variable, narrow, straight, acuminate, mucronate. Buds of numerous ovate, rounded, obtuse, keeled scales.

DISTRIBUTION

I. COMMON YEW.—All authorities are agreed that the yew was formerly much more widely spread in Europe than is the case to-day. Conwentz² relies on three points to prove the ancient wider distribution:—(1) fossil remains; (2) prehistoric and historic antiquities; (3) place-names. He considers that nearly all the fossil remains of the Tertiary age, which have been described as species of *Taxus*, are not really yew. In more recent geographical strata, however, numerous fossil remains of yew have been found. Clement Reid³ gives the following list of deposits in which yew occurs in England:—

Neolithic.—Common in peat below the sea-level in the Thames valley and Fenland; Portobello, near Edinburgh.

Interglacial.—Hoxne, Suffolk.

Preglacial (Cromer Forest-bed).—Mundesley, Bacton, Happisburgh (in Norfolk), Pakefield (in Suffolk).

Conwentz has found fossil remains in numerous localities in England and Ireland; but his promised paper on the subject has not yet been published. Guided by place-names in Germany, he dug up fossil yew in many localities in that country.

He⁴ found under pure peat, 3 feet thick, in the Steller Moss not far from Hanover, some hundreds of stems of yews. He says that it is never found in the ramparts of prehistoric forts, but that it was often planted on fortifications by the knights of the Middle Ages.

He has prepared a list of some hundreds of English, Scottish, and especially Irish names of places taken from the yew. The Gaelic name for the yew is *iubhar*; and in Irish and Scottish place-names this generally appears Anglicised as *ure*, being sometimes corrupted into *o* or *u* simply. Youghal means yew-wood. Dromanure and Knockanure signify yew-hill. Glenure is the yew-glen. Gortinure and Mayo mean yew-field.

Conwentz examined prehistoric wooden boxes, buckets, and other vessels in the British Museum and in the Dublin Science and Art Museum, and identified the wood of some thirty articles as that of yew.

Yew is occasionally found in peat-mosses in Ireland, but is exceedingly rare as compared with pine and oak. Mr. R. D. Cole, who has kindly sent me a

⁴ *Bot. Centralblatt*, 1896, lxxi. 105; and 1900, Beihefte, ix. 223.

specimen of bog-yew, drew attention in 1903 to the occurrence of yew in Ballyfin bog in Queen's County. It was so plentiful there in former times that the farmers in the neighbourhood used it for gate-posts and in roofing houses. Mr. J. Adams has published a short account¹ of Mr. Cole's discovery, from which it appears that the cross-section of one trunk, 2 feet in diameter, showed no less than 395 annual rings. Another specimen showed 123 rings, only occupying a width of $1\frac{1}{2}$ inches. Mr. Cole informs me that in no case where the root was vertical did he find more than 18 inches deep of peat beneath; in other parts of the bog where the yews were found more deeply buried, their roots were twisted and out of their natural position, and were probably carried there by floods. Apparently then, the yew, unlike the common pine, never grew in any great depth of peat.

Large trunks of yew were formerly dug up on the shore of Magilligan in Co. Derry, between the rocks and the sea.² On the east side of Glenveigh, in Co. Donegal, thick logs are reported to be often found in the peat.³

In the Kew Museum there is a specimen of fossil yew, which was dug up in Hatfield Chase, near Thorne, Yorkshire, from under a bed of clay 6 feet in thickness; and another specimen is labelled, "Submarine Forest, Stogursey, Somersetshire."

Professor Seeley, F.R.S., in a very interesting letter, dated January 1904, says that he has seen "the broken stumps of yew trees standing as they grew by scores, possibly by hundreds, in Mildenhall Fen, about 1865, when the peat was entirely removed so as to prepare the land for corn. One tree sketched by Mr. Marshall, at that time Coroner for the Isle of Ely, from a section between Ely and Downham Market, showed the yew growing in sandy gravel with black flints. The roots were entirely in the gravel. Above the gravel is the 'Buttery Clay,' 2 feet 6 inches thick, into which the trunk of the tree extended vertically, rising about 1 foot into the Upper Peat, which was 4 feet 6 inches thick. This clay is marine, and is the delta mud of the Cam and the Ouse deposited on the Lower Peat and beyond it, where a depression of land admitted the sea over the Isle of Ely and killed the forests. A little part of the Scrobicularia Clay is 6 feet thick, and the peat above it 18 feet thick. The common trees in the peat there are pines and oaks. I have never seen the beech, and never heard of the lime. About the pine there is no doubt. It occurred in the forests of the Forest Bed of Norfolk, and at several localities in the peat of the fens, almost always on clay covered by peat."

In the present day the common yew is met with growing wild in most parts of Europe, from Scandinavia to the Mediterranean, and from the Atlantic to the western provinces of Russia. It has only recently become extinct in the Azores. It also occurs in Algeria, Asia Minor, the Caucasus, North Persia, the Himalayas, and Burma. The yew also extends into the mountains of Sumatra, South Celebes, and the Philippines.⁴

¹ *Irish Naturalist*, xiv. 1905, p. 34, with plate showing yew trunk and transverse section.

² Mackay, *Flora Hibernica*, 260 (1836).

³ Hart, *Flora County Donegal*, 237 (1898).

⁴ Specimens from these localities have been identified by Pilger as the Himalayan yew.

In England the yew is indigenous on all the chalky Downs of Sussex, Hampshire, and Wilts. According to Bromfield,¹ the yew is one of the few natural ornaments of our South Downs, over the bare sides and summits of which it is scattered abundantly as single trees, frequently of great size and antiquity; sometimes in groups; more rarely forming groves in the bottoms or valleys between these rounded hills, or in the steep woods which clothe their sheltered slopes. He mentions as one of the most remarkable of these yew groves, that at Kingsley Bottom, near Chichester. The yew is remarkably plentiful on the banks of the Wye, about Chepstow and Tintern, and grows in the most inaccessible positions on the limestone cliffs there, as it does also on the rocks of Matlock. The rocks at Borrodale and on Conzie Scar, near Kendal, are also truly natural stations of the yew.² The yew is frequent in the woods of Monmouthshire, and in the ancient forest of Cranbourne Chase in Dorsetshire.³ In the Wyre Forest it is certainly wild, occurring now as isolated trees amidst the beech and oak. In Seckley Wood, on the Severn, there are indigenous yew trees, one of which is remarkable for its curious pendulous habit.⁴ It ascends to 1500 feet in Northumberland.⁵

Concerning the occurrence of the yew as a wild plant in Scotland our information is scanty. Hooker⁶ states that it is indigenous as far north as Aberdeen and Argyll. White⁷ records it from Breadalbane in Perthshire. Lightfoot,⁷ writing in 1777, says it was found here and there in the Highlands in a truly wild state, and that there were the remains of an old wood of yew at Glenure in Upper Lorn, Argyllshire.

It is now of rare occurrence in the wild state in Ireland. According to Praeger,⁸ it is found on rocks, cliffs, in old woods, and on lake shores, now almost confined to the west. It is recorded from various localities from Kerry to Donegal, and Praeger considers that some of these instances may represent the last remnants of aboriginal stock; but it is impossible now to say definitely, as introduced trees grow around the supposed wild ones. The yews in the rough wood at Avondale, in Wicklow, may be wild. Many years ago Moore⁹ found the yew growing at Benyvena, in Co. Derry, in the crevices of the rocks, at an elevation of 1200 feet, when it assumed the appearance of a low shrub. In Smith's *Kerry* (1756), it is stated that "the yew grew in prodigious quantities in all our southern baronies until it was destroyed for making coals for the iron-works."¹⁰

In Norway the yew is called "Barlind," and, according to Schubeler,¹¹ grows wild only in the south, especially along the coast, the farthest point north known to him being near Sondmore, in lat. $62^{\circ} 30'$ N., where it attains the height of 32 feet. In the east it does not extend farther north than Hurdalen, lat. $60^{\circ} 35'$, where it attains a height of 8-10 feet. Schubeler mentions as the largest yews known

to him in Norway some at Tufte, on the Christiana fjord, which are 42-43 feet high, with a girth of 3 feet 4 inches to 3 feet 9 inches. The thickest one was, however, 4 feet 10 inches at 2 feet from the ground. He figures (p. 458, fig. 84) what is very rarely seen in England, a self-layered yew, and says that he found in a wood at Hallangen a tree 24 feet in length with a diameter of only 6 inches.

In Sweden the yew grows as far north as lat. 63° 10', and thrives so well that a tree at Maltesholm, in Scania, is said to have had a diameter of 89 centimetres when only 75 years old. It occurs on the Swedish Island of Åland (lat. 60°), but only as a small shrub.

Its northerly limit in Russia appears to be Esthonia, its eastern limit also passing through that province, and continuing southwards through Livonia, Courland, Lithuania, Volhynia, Podolia, and the Crimea. It occurs also in Denmark,¹ but only in one place wild, viz., at Munkehjerg, the beautifully situated hotel near the town of Veile, in Jutland. Formerly the yew was much more widely spread in Denmark, but owing to the value of the wood the wild trees have been destroyed in most parts of the country.

In Belgium, where the yew is often planted, its occurrence in the wild state has been denied by some authors. Wildeman and Durand,² however, consider that it is probably wild in the neighbourhood of Huy and in Hainault.

In France³ it occurs chiefly in mountainous regions, as in the Vosges (where it is rare), Jura, Cevennes, Pyrenees, and Corsica. In the Pyrenees it ascends to 5400 feet, and, according to Bubani,⁴ is always rare (due to destruction by human agency), and only occurs on limestone and in cool and shaded situations. In France generally, it is most common on precipices and rocky spots, and nearly always on limestone. It never forms pure woods; but is, however, remarkably abundant in the forest of Sainte Baume (Department of Var), where the oldest and largest wild yew trees in France occur, some attaining a girth of 11½ feet. In Normandy, according to Gadeau de Kerville,⁵ it is not indigenous, being probably introduced at a very early period before the conquest of Gaul by Julius Cæsar. It is usually planted in churchyards and cemeteries as in England, and nowhere exceeds 19 metres (about 60 feet) in height. The largest in girth, about 33 feet, at 3 feet from the ground, stands in the churchyard of Estry (Calvados). There are also two very fine trees at the church of La Lande Patny (Orne). Several others are figured by this author, of which the one at La Haye de Routot (Eure) is remarkable, on account of having in the interior of its hollow trunk a chapel about 6 feet in diameter and 10 feet high, which was built in 1806, and dedicated to Saint Anne des Ifs by the Bishop of Evreux.

In Germany, according to Willkomm,⁶ the yew is most abundant in Pomerania, Hanover, and Thuringia, and he instances localities where it forms small pure woods. In the Darmbach forest district in the Eisenach Oberland there are, in

addition to many young plants, 311 yew trees of 1 foot or more in girth of stem. On the Veronica mountain at Angelroda in Thuringia, there are about 150 yew trees, of which the largest are possibly 600 years old. Apparently there were anciently two zones of distribution of the yew in Central Europe—a northern one which extended from the Netherlands through the coast provinces of Germany to the eastern shore of the Gulf of Riga, and a southern area comprising the mountainous regions of the Vosges, Jura, Black Forest, the whole of the Alps to Croatia, and the Carpathians. The yew also occurred in the hilly land of central Germany, where, at the present time, according to Drude,¹ it is indifferent to soil, as it grows on the muschelkalk near Göttingen, on the dolomite of Süntel in the Weser mountain district, and on primitive rock on the southern slope of the Rachel (up to 3300 feet altitude). On the dolomite it occurs as isolated trees, while in the ravines and rocky parts of Süntel it forms thick underwood. In the Bavarian Alps it ascends to 3800 feet, not being met with below 1240 feet.

In Switzerland the yew ascends in the Alps to 4660 feet. The largest and finest yew is at Geistler, near Burgdorf, at an elevation of 2400 feet above the sea. This tree is well figured in *Les Arbres de la Suisse*, t. xii., and is said to be 50 feet high by 12 feet in girth at 4 feet above the ground; it divides into several stems at about 10 feet up.

In Austria-Hungary the yew occurs in the Carpathians and the Alps, ascending in Transylvania to 5400 feet; and it is reported to occur in Roumania and Bulgaria.

The yew is generally distributed throughout the mountains of the Iberian Peninsula. In Spain, according to Laguna,² it almost always occurs as isolated trees, and is found in all the Cordilleras from the Sierra Nevada to the Pyrenees and the mountains of Asturias, also in the Balearic Isles. He has only seen it forming pure forest in the Sierra Mariola, near to Alcoy (Valencia). In the high part of that chain on its northern slope there exist what are called the *Teixeras de Agres*, groups of yews belonging to the town of Agres. Here, in 1870, there were still living some hundreds of ancient yews, with some young trees.

Gadow³ says, "There are numerous large and small trees forming a scattered forest, between Riano and Cistierna at about 3600 feet elevation, the terrain belonging to the reddish Permian rubble. The yew tree is widely distributed throughout the Spanish mountains and on the Serra da Estrella (in Portugal), but is rare everywhere. Most of the trees are solitary and old, with decaying tops. Younger trees are ruthlessly destroyed by their branches being lopped off, to be used in the cattlefolds partly instead of straw, and partly for repairing the fences and roofs. The vernacular name is *Tejo*."

Willkomm⁴ states that in the high mountains of Spain it occurs as isolated stunted trees, and says that on the Sierra de la Nieve there was an old yew tree which measured only 17 feet in height, although it had a girth of 17½ feet. In the south of Spain it ascends to 6500 feet.

³ *Flore Forestal Española*, i. 114 (1883).

⁴ *Pflanzenverbreitung auf der Iberischen Halbinsel*, 251 (1896).

In Italy, according to Piccioli,¹ the yew is found on the hills and in woods of the mountain regions of the Apennines and the Alps. It is only found in the maritime region in Liguria; but is common in Sardinia, where it ascends to 5660 feet. In Sicily it is found in the region of the olive, and occurs on Mount Etna, mixed with beech, to a height of 6000 feet. The yew, however, is not mentioned in Tornabene's *Flora Aetna*.

In Greece² isolated trees occur in mountain woods up to the sub-alpine region. It is recorded from near Kastania, in Pindus, Mount Olympus, and Oeta (Thessaly); Mount Parnassus, Mount Malero (Laconia), and other places.

The yew³ formerly occurred in the Azores, attaining timber size on Corvo and Flores, whence it was exported as a source of royal revenue. It is now apparently exterminated.

It occurs sporadically in the high mountains of Algeria,⁴ in the Atlas of Blidah, Djurdjura, and Aures. A photograph of a venerable tree in Algeria, taken by M. de Vilmorin, is reproduced in *Garden and Forest*, 1896, p. 265.

In the Caucasus⁵ it occurs throughout the whole territory, including Talysch, at altitudes varying from sea-level to 5660 feet.

In Asia Minor it occurs in Anatolia and Mysia, according to Boissier. Kotschy found it common in the Cilician Taurus from 6160 to 7600 feet altitude. Szovitch collected it in Armenia. It also occurs in North Persia.

Some wood⁶ found in the palaces of Nineveh, and recorded on a tablet as having been brought as "cedar" from Lebanon, proved on microscopical examination to be yew. (A. H.)

The yew, according to Gamble,⁷ is a conspicuous tree in the Himalayan forests, at 6000 to 11,000 feet altitude from Afghanistan to Bhutan. It occurs in the Khasia Hills at 5000 feet, and in Upper Burmah at 5000 to 6000 feet. Sound trees are very scarce, but a very large one cut in Sikkim in 1876 was quite sound. Gamble has measured trees 20 feet in girth; one, 16 feet in girth, had a cylindrical bole 30 feet high. Madden records a tree at Gangutri, near the source of the Ganges, 100 feet high and 15 feet in girth, which surpasses anything I know of elsewhere. I have seen fine yews at 9000-10,000 feet on the Tonglo ridge, which divides Nepal and Sikkim, and have found many orchids upon them, one of which, *Cælogyne ochracea*, has lived for 24 years in my collection. The growth in India varies from 23 to 55 rings per inch of radius. The timber weighs 46 to 59 lbs. per cubic foot, and is used for bows, carrying-poles, and native furniture, and if more common would be more extensively used, as it is very strong and elastic, and works and polishes beautifully. It requires, however, long seasoning.

Sir Joseph Hooker⁸ noted that at 9500-10,000 feet on Tonglo the yew is an

immense tall tree with long sparse branches and slender drooping twigs, while at Choongtam (5000-6000 feet altitude) it is small and rigid, much resembling in appearance our churchyard yew. The red bark is used as a dye and for staining the foreheads of Brahmans in Nepal.

There is a specimen at Kew, collected by Sir George Watt in Manipur, which bore yellow berries.

In the United States¹ there are a number of large European yew trees in New York, Philadelphia, and Baltimore, showing that the tree must have been brought to the eastern United States more than a century ago. Sargent says that everywhere south of Cape Cod it appears to be perfectly hardy. Farther east it suffers from the cold in severe winters, and cannot be considered a desirable tree for general planting in eastern New England. T. D. Hatfield,² writing from Wellesley in Massachusetts, states that the variegated form of the common yew is hardy in places where the green type perishes.

II. JAPANESE YEW, var. *cuspidata*.—*Ichii* in Japan, *Onko* of the Ainos in Hokkaido. Though Sargent says³ that, judging from his observations, it is confined to the island of Yezo, it is stated in the *Forestry of Japan*, p. 88, that it is found also in Kiso and Nikko, and it was included in the list of trees growing wild in the royal forest of Kiso, though I did not see it myself. In Nikko it is planted in the temple gardens; a fine specimen, of which I give an illustration taken at this place (Plate 53), shows how much it resembles our yew in habit and appearance. This tree was about 40 feet high by 12 in girth. In the Hokkaido it grows scattered through the lowland and hill forests, among deciduous trees and conifers, but nowhere, so far as I saw, gregariously, and attains a large size, trees of 50-60 feet high with clear trunks 2-3 feet in diameter being not very rare. It sometimes produces beautifully veined burrs, and when old is often rotten inside.

It is a favourite in gardens in Hokkaido, as trees of considerable size can be moved without killing them. The wood, which seems milder, sounder, and more free from holes and flaws than in England, is much used by the Japanese for water-tanks, pails, and baths, and is cut into handsome trays, sometimes carved, which I bought quite cheaply in Sapporo. I also procured large planks and slabs of it, measuring as much as 26 inches wide, and quite sound, such as I have never been able to get from English yews. Chopsticks, clogs, and the Aino bows are also made of yew wood, and when cut into thin shavings very pretty braid is made from it.

I was informed by Mr. N. Masaki of the Imperial Art School in Tokyo, that the semifossil wood known at Sendai as *Gindai-boku* is dug from the bed of the Natonigawa river, near which deposits of lignite are found. This wood was believed by the carvers at Nikko to be fossil *Cryptomeria* wood, but is so like the bog yew found in Great Britain in grain and colour that I have little doubt that it is yew. This wood is only procured in small pieces of irregular shape, the largest that I saw being made into a tray about 20 inches square. It is very hard, of

¹ *Garden and Forest*, 1897, p. 400. Large trees also occur at Washington, *loc. cit.* 1896, p. 261.

² *Ibid.* p. 405.

³ *Forest Flora of Japan*, p. 76.

a rich reddish brown colour, and when polished or carved is extremely handsome.

The Japanese yew also occurs in Saghalien, the Kurile Isles,¹ Amurland, and Manchuria. Apparently it is very variable in habit, as Maximowicz² regarded the Amurland plant as a mere shrub, though in one place in the mountains he saw a tree a foot in diameter. Trautvetter² saw no difference between the yew in Amurland and in Europe, except that the seed of the former was smaller and more pointed.

The Japanese yew was introduced into England between the years 1854 and 1856 by Fortune,³ who states that he received it from Mr. Beale in Shanghai, to whom it had been sent from Japan. It was first cultivated and propagated by Mr. Glendinning of the Chiswick Nursery. It has not grown to be a tree in England so far as we know, as it assumes rather the form of a large branching shrub with two or three stems. It is usually distinguished from the other yews, as seen in cultivation, by the peculiar yellow colour of the under-surface of the leaves, which are broad, somewhat leathery in texture, and abruptly pointed. This yellow colour is not, however, confined to the Japanese yew, as it occurs in the Chinese yew, and also apparently in some Pyrenean specimens, and is perhaps due to climatic influences.

According to Sargent⁴ the Japanese yew was introduced into the eastern United States in 1862, and has proved to be perfectly hardy as far north as Boston. It grows rapidly in cultivation, and promises to become a large long-lived tree. Sargent speaks of a dwarf compact form of this plant with short dark green leaves in cultivation in the United States, which probably originated in Japanese gardens. It often appears under the name of *Taxus brevifolia*, but must not be confounded with the true *Taxus brevifolia* of the Pacific coast. This is doubtless the *Taxus cuspidata*, var. *compacta*, of the Kew Hand List, of which we have seen no specimen. Sargent has also seen in California a yew with fastigate, somewhat spreading branches, which had been imported from Japan, evidently another garden variety of *Taxus cuspidata*.

III. CHINESE YEW, var. *sinensis*.—The yew has only been found in China, in the provinces of Hupeh and Szechuan, where it is a very rare tree in the mountains at 6000 to 8000 feet, occurring on wooded cliffs. The largest tree seen by Henry was about 20 feet in height, but with a girth of 7 or 8 feet. The bark is almost a bright red in colour. Franchet⁵ considered the Chinese yew to resemble *Taxus cuspidata*, S. et Z., which in his opinion does not seem to differ from the European yew in any positive character. The Chinese mountaineers reported the timber to be red, strong, and of fine quality, and called the tree *Kuan-yin-sha*, "the fir of the Goddess of Mercy."

IV. PACIFIC COAST YEW, var. *brevifolia*.—Though this tree was introduced by William Lobb in 1854,⁶ it is still very rare, and we know no specimens of any size in

¹ Miyabe, "Flora of Kurile Isles," in *Mem. Boston Soc. Nat. Hist.* iv. 261 (1890).

⁶ Veitch's *Man. Conifera*, ed. 1, 305 (1881).

England, though it might be so easily mistaken for the common yew, that we have possibly overlooked it. It would no doubt grow well in England, as it is a native of the colder and damper parts of the north-west coast of America, from Queen Charlotte Islands along the coast ranges of British Columbia, western Washington, and Oregon; in California on the Sierra Nevada at 5000 to 8000 feet, and as far south as Monterey; and extends eastward to the western slopes of the Rocky Mountains in Montana, where it becomes shrubby in habit. I have seen it in Washington on the slopes of Mount Tacoma, where it grew isolated in the dense forest, and attained no great size, though it occasionally reaches a height of 70 to 80 feet. In Vancouver's Island it is not uncommon in the rich, low meadows of the east coast, but the largest I saw were not over 30 to 40 feet high. The wood seemed indistinguishable from that of the European species, and was, like it, rotten at heart in old trees and full of holes. Sargent says that the Indians use it for bows, paddles, spear handles, and fish-hooks, but except for fencing posts it does not seem to be used by settlers.

V. CANADIAN YEW, var. *canadensis*.—This is only a creeping shrub with a stem occasionally a foot or two in height, and though it is said by Loudon to have been introduced in 1800, it has never obtained a place in English gardens. I have seen it common in Canada in thick forest, where it produced red berries very like those of our yew. Sargent gives its distribution as from Newfoundland to the northern shores of Lakes Superior and Winnipeg, southwards through the Northern States to New Jersey and Minnesota.

VI. FLORIDA YEW, var. *floridana*.—This is one of the rarest of North American trees, confined to a few localities in Western Florida, and, except by its habit, not easily distinguished from *T. canadensis*. It is usually shrubby, rarely attaining 25 feet high. It has never been introduced to cultivation in England, and is probably not hardy.

VII. MEXICAN YEW, var. *globosa*.—A tree about 20 feet in height, discovered in 1837 by Ehrenberg in Southern Mexico. There are also specimens at Kew of yews collected in Mexico by Hartweg, F. Müller, and W. Saunders, which vary considerably in foliage. This variety is scarcely known, as recent collectors have failed to rediscover the tree. It is very like the common yew.

(H. J. E.)

VARIETIES OF THE COMMON YEW IN CULTIVATION

These have in some cases originated as individual sports in the wild state; in other cases they are due to the art of the gardener, who has greatly increased the number of varieties by selection. They differ from the type in various ways:—(1) in habit (fastigate, prostrate, pendulous, and dwarf forms); (2) in the colour, shape, size, and disposition on the branchlets of the leaves; (3) in the colour of the fruit. André,¹ in an interesting article, illustrated by figures, has drawn attention to the remarkable differences which occur in the shape of the seed and of the aril in the different cultivated varieties; but it is probable that these are not so constant as he believed.

¹ *Revue Horticole*, 1886, p. 105, translated in *Garden*, 1889, xxxv. 36.

A. *Fastigate Forms*.—In these the branches take an upward direction (vertical or ascending), and the leaves tend to spread out radially from the branchlets.

1. Var. *fastigiata*, Irish Yew, Florencecourt Yew.

Taxus baccata fastigiata, Loudon, *Arb. et Frut. Brit.* iv. 2066 (1838).

Taxus fastigiata, Lindley, *Syn. Brit. Flora*, 241 (1829).

Taxus hibernica, Hook. ex Loudon, *loc. cit.*

Columnar and compact in habit, all the branches and branchlets being directed vertically upwards. Branches stout, branchlets few and short. Leaves, always spreading radially in all directions around the branchlets, dark green and shining, with the apex usually more obtuse than in the common yew. Dr. Masters considers the Irish yew to be a juvenile form,¹ in which the characters of the seedling (the radial disposition of the leaves and the upright habit) are preserved throughout the life of the plant. As the original tree was a female, and the variety is propagated by cuttings, all Irish yews are of the same sex. When they bear flowers they are generally fertilised by the pollen of common yews growing in their neighbourhood, and the seed resulting, when planted, generally produces plants indistinguishable from the common yew.² Dr. Masters¹ received from Mr. Tillett of Sprowston, near Norwich, sprays of an Irish yew which bore male flowers. This was apparently an instance of a monoecious tree, a phenomenon which occurs though rarely in the common yew. No true male Irish yew has ever been met with. The aril of the Irish yew differs usually from that of the common form in being more oblong in shape.

The Irish yew was discovered³ in the mountains of Fermanagh above Florencecourt by a farmer named Willis about the year 1780. He found two plants, one of which he planted in his own garden, and is now no longer living. The other was planted at Florencecourt, the seat of the Earl of Enniskillen; and from it cuttings were distributed, which are the source of all the Irish yews in cultivation. The original tree is still living, and a figure of it is given in Veitch's *Manual*, p. 141, as it appeared about thirty years ago. Kent says that in 1900 it had an open straggling appearance.

One of the finest Irish yews known to us is that at Seaforde, near Clough, Co. Down, the seat of Major W. G. Forde. This tree was reported to be 33 feet high in 1888,⁴ and 35½ feet in 1903.⁵ A plate of it is given (Plate 58), reproduced from a photograph kindly sent us by the owner, who reports the present measurements (1905) to be:—Height, 37 feet; girth at the ground, 9 feet; circumference of branches at 20 feet from the ground, 91 feet.

Two large trees exist at Comber, Co. Down, of which Mr. Justice Andrews gives the following particulars in a letter:—

“The Irish upright yew trees at Comber, mentioned in Mackay's *Flora Hibernica* (1836), p. 260, are the two large yews⁶ in the garden beside ‘Araghmore,’ the residence of Mrs. John Andrews. My earliest recollection of them goes back

¹ *Gard. Chron.* 1891, x. 68.

² Sir C. Strickland writes in *Gard. Chron.* 1877, vii. 151: “All the plants I have raised from Irish yew berries are exactly like the common yew.” But Elwes saw at Orton Hall three seedlings from the Irish yew of which one was fastigate in habit.

³ *Gard. Chron.* 1873, p. 1336.

⁴ *Ibid.* 1888, iv. 484.

⁵ *Ibid.* 1903, xxxiii. 60.

⁶ London figures one of these on p. 2067.

60 or 70 years, and they were then apparently as tall as they are now, but not so much spread out. I cannot accurately estimate their height and girth, but they are the two largest upright yews I have seen.”

At Brockhill,¹ Worcester, there are two large Irish yews, estimated by Mr. Lees to have been at least 100 years old. Very handsome specimens are also growing at Montacute House, Somerset.

The Irish yew is very effective as a garden tree, but requires pruning and wiring every two or three years in order to keep it in good shape. There is at Colesborne a terrace planted on both sides with Irish yews about 50 years ago, which are kept in shape by wire, and when so treated are of very uniform growth and habit.

Taxus fastigiata aurea is a form of the Irish yew, in which the young shoots are golden yellow. In *Taxus fastigiata argentea* the tips of the branchlets are white.

2. Var. *Chesthuntensis*.

Taxus baccata Chesthuntensis, Gordon, *Pinet. Suppl.* 98 (1862).

This was raised by William Paul of the Cheshunt Nursery from a seed of the Irish yew, which it resembles. The branches, however, are ascending, but not so erect as in the parent form. The leaves have an acute apex, and resemble in colour those of the Irish yew, being dark green and shining on the upper surface; they are broader and shorter than those of the common yew. It is less formal than the Irish yew, and is said to grow twice as fast.

3. Var. *elegantissima*.—This was raised, according to Barron,² by Fox of the Wetley Rock Nurseries, who had an Irish and a golden yew growing together, from which this came as a seedling. It is generally a dense compact shrub, but forms occur which are more open in habit. The leaves are usually radially spreading, but are often two-ranked on some of the branchlets; they are long, and terminate gradually in a long, fine cartilaginous point. Young leaves are golden yellow; adult leaves have white margins.

4. Var. *erecta*.

Taxus baccata erecta, Loudon, *loc. cit.* 2068 (1838).

Taxus baccata Crowderi, Gordon, *Pin. Suppl.* 98 (1862).

Taxus baccata stricta, Hort.

A dense broad shrub with erect and ascending branches. The leaves are dark green, shining, short, and acute; and are usually radially arranged, but often on the lower branchlets are disposed in two ranks.

The Nidpath Yew³ resembles this variety, but is more columnar in habit, with a tendency to spread at the top. The leaves, as seen on a shrub at Kew, are bluish green, and usually are all radially arranged.

A variety named *imperialis* is described as being a slender, tall form with ascending branches and dark green leaves.

¹ *Trans. Worcester Nat. Hist. Club*, 1847-1896, p. 211.

² *Gard. Chron.* 1868, p. 921. Veitch's *Manual*, 1st ed. 302, states that it was introduced by Messrs. Fisher, Son, and Sibray of the Handsworth Nurseries, near Sheffield.

³ Nicholson, *Dict. of Gardening*, iv. 12.

B. *Dwarf forms with leaves radially arranged on the branchlets.*

5. Var. *ericoides*.

Taxus baccata ericoides, Carrière, *Conif.* 519 (1855).

Taxus baccata empetrifolia, Hort.

A low shrub with ascending branches. Leaves generally radially arranged, but occasionally two-ranked, uniform in size, falcate, short, acute, tapering to a fine cartilaginous point.

6. Var. *nana*.

Taxus baccata nana, Knight, *Syn. Conif.* 52.

Taxus Foxii, Hort.

A dwarf shrub. Leaves generally radially arranged, some being two-ranked; very variable in length, but always short, straight or falcate, often twisted or curved.

C. *Varieties with leaves distichously arranged, assuming pendulous, prostrate, and other non-fastigiate habits.*

7. Var. *Dovastoni*, Dovaston Yew.

Taxus baccata Dovastoni, Loudon, *loc. cit.*, 2082 (1838).

A tree or large shrub, with spreading branches, arising in verticils, and becoming very pendulous at their extremities. Leaves dark green with an abruptly mucronate apex.

An account of the original tree, from which this variety has been propagated, is given in Loudon and in Leighton's *Flora of Shropshire*.¹ This tree was planted as a seedling about the year 1777 at Westfelton, near Shrewsbury. It was in vigorous health in 1900, and measured then 8 feet 10 inches in girth at 4½ feet from the ground. Nineteen years previously its girth was 7 feet 11 inches. It is described as having a single leader, with branches pendulous to the ground. The original tree is monoecious; one branch only producing fertile berries, from which seedlings were raised, which reproduced the habit of the parent.¹ Barron² states that all his Dovaston yews are female trees. Carrière³ sowed seeds of this form on many occasions, and the offspring was always like the common yew, doubtless due to his Dovaston yews being fertilised by the pollen of ordinary yew trees in the vicinity.

Carrière further states that MM. Thibaut and Keteleer obtained in 1865, from seeds of this variety, plants which were in the proportion of three-fourths variegated in foliage and one-fourth green; but in no case was the pendulous habit observed. The variegated plants passed into commerce as *Dovastoni variegata*; but these were simply ordinary variegated yews. A sub-variety, however, occurs in which the leaves of the Dovaston yew are variegated with yellow; and this is known as var. *Dovastoni aureo-variegata*.

8. Var. *pendula*.—Growing at Kew, this is an irregularly branching wide, low,

¹ *Gard. Chron.* 1900, xxvii. p. 146, where a figure and full details of the Dovaston yew are given.

² *Ibid.* 1868, p. 992. He gives the dimensions of the Westfelton tree in 1876 as 34 feet high by 7½ feet in girth. *Garden*, ix. 341.

³ *Traité gén. des Conifères*, ii. 763 (1867).

dense shrub, making no definite leader, with the tips of the branchlets pendulous. Var. *gracilis pendula* is said to have the branches and branchlets more elongated, and to attain a larger size than var. *pendula*.

9. Var. *horizontalis*.

Taxus baccata horizontalis, Knight, *Syn. Conif.* 52 (1850).

This resembles the Dovaston yew in the verticillate arrangement of the spreading branches. The branchlets, however, instead of being pendulous, are turned slightly upwards at the ends of the branches.

10. Var. *recurvata*.

Taxus baccata recurvata, Carrière, *Conif.* 520 (1855).

A large shrub, with branches somewhat ascending and elongated, and pendulous branchlets, which bear the leaves so arranged as to be all directed upwards, each leaf being recurved. The leaves resemble those of the Dovaston yew.

11. Var. *procumbens*.

Taxus baccata procumbens, Loudon, *loc. cit.* 2067 (1838).

A low prostrate shrub, keeping close to the ground, with branches long and ramified. This is distinct from *Taxus canadensis* in characters of leaves and buds.

D. *Varieties with leaves distichously arranged, in which the leaves are variously coloured.*

12. Var. *aurea*, Golden Yew.

Taxus baccata aurea, Carrière, *Conif.* 518 (1855).

A golden yew is mentioned in Plot's *History of Staffordshire* as occurring in that county in 1686. There are many kinds of golden yew, which are of different origin. The form generally known as *aurea* is a dense shrub or low tree, with narrow falcate leaves which are variegated with yellow. Golden yews of this kind are said to be all male trees. The original was reared by Lee of Hammersmith, and was afterwards planted at Elvaston Castle. It was monoecious,¹ and from it Barron reared several varieties. The variety known as var. *Barroni* has the leaves more decidedly yellow than those of the common golden yew; and one form of it is female and bears berries.

A great number of variegated yews of different kinds have been raised at Knap Hill, at the Chester Nurseries, and elsewhere. These have been obtained as seedlings in various ways; some were obtained by planting Irish yew amongst common golden yew; in other cases the seed-plants used were varieties like *elegantissima*, *erecta*, *adpressa*, etc.

13. Var. *Washingtoni*.—A low dense shrub, in which the leaves on the young shoots are golden yellow in colour.

¹ According to Barron the tree was a male; but he discovered on it a single branch bearing female flowers. See *Gard. Chron.* 1868, p. 921; also 1882, ii. 238.

14. Var. *glauca*.

Taxus baccata glauca, Carrière, *Conif.* 519 (1855).

A vigorous shrub, with leaves, which are shining and dark green on the upper surface, and glaucous blue beneath.

E. *Variety with differently coloured fruit.*15. Var. *fructu luteo*.

Taxus baccata fructu luteo; Loudon, *loc. cit.* iv. 2068 (1838).

This variety only differs from the common yew in the aril of the fruit being yellow. A tree of this kind was discovered about the year 1817 at Glasnevin, near Dublin, growing on the property of the Bishop of Kildare.

Cuttings, however, were first distributed from a tree noticed in the grounds of Clontarf Castle in 1838. This tree¹ was about 50 feet high in 1888. At Ardsallagh, Co. Meath, the residence of Mrs. M'Cann, there is a tree 30 feet high and 7 feet in girth, with yellow fruit, occurring in an avenue of old yews. There are several trees of this kind at Powerscourt,² the best one of which was about 40 feet high in 1888. Bushes raised from the seeds of these trees are reported to be bearing yellow berries, from which it would appear that this variety comes true from seed. It is remarkable that all the yellow-berried yews known, except the one mentioned above as collected at Manipur, should occur in the neighbourhood of Dublin.

F. *Variety with small leaves.*16. Var. *adpressa*.

Taxus baccata adpressa, Carrière, *Rev. Horticole*, 1855, p. 93; *Taxus adpressa*, Gordon, *Pinetum*, 310.

Taxus tardiva, Lawson, *ex* Henkel and Hochstetter, *Syn. Nadelh.* 361.

Taxus sinensis tardiva, Knight, *Syn. Conif.* 52 (1850).

A large spreading shrub with densely crowded branchlets, bearing remarkably small broad leaves, arranged on the shoots, as in the common yew. The leaves are dark green above, $\frac{1}{4}$ - $\frac{1}{2}$ inch long, elliptic linear in outline, with a rounded apex, from which is given off a short mucro. The aril is broad and shallow, not covering the seed, which is 3-angled and often depressed at the summit.

This is by far the most distinct of all the forms, geographical and horticultural, not only in foliage, but also in fruit. It has been considered by many botanists to be a distinct species, conjecturally of Japanese or Chinese origin. It is not known in Japan,³ except as a plant introduced from Europe; and there is no reason for doubting the positive information⁴ as to its origin given by Messrs. James Dickson and Sons and by the late Mr. F. T. Dickson of Chester, though there is a slight discrepancy in their two accounts. The latter states that it was found as a seedling by his father amidst some yew seedlings about 1838, while the former give

¹ *Gard. Chron.* 1888, iv. 576.

³ Matsumura, *Shokubutsu Mei-I.* 290 (1895).

² *Ibid.* 707.

⁴ *Gard. Chron.* 1886, xxix. 221, 268.

the date as 1828, and the locality as a bed of thorn seedlings in the Bache Nurseries, Chester.

Only female plants of this variety are known, and it is reproduced by grafting. Its flowers are doubtless fertilised by the pollen of common yew trees near at hand, and as a rule it produces a great crop of berries. Messrs. Dickson and Sons have frequently sown seeds which invariably produced the common yew.

Var. *adpressa stricta* is a form of this variety in which the branches are erect or ascending. It is not known whether it originated as a seedling or as a sport fixed by grafting. It was raised by Mr. Standish.

Var. *adpressa aurea* is a form with golden leaves.

Var. *adpressa variegata* is a form with the young shoots suffused with a silvery yellow colour. This was exhibited at the Royal Horticultural Society on August 27, 1889.

There are fine examples of var. *adpressa* in Kew Gardens.

SEEDLING¹

The two cotyledons, together with the seed-case which envelops them as a cap, are carried above ground by the lengthening caulicle; and speedily casting off the remains of the seed-case, act as if they were true leaves. They differ from the latter in bearing stomata on the upper and not on the lower surface, and in having their apices rounded and not acute. The young stem, angled by the decurrent bases of the leaves, gives off at first three or four opposite pairs of true leaves, which are succeeded in vigorous plants by a few alternate leaves, crowded at the summit around a terminal bud, which in all cases closes the first season's growth, when the young plant is 1 to 3 inches high. The caulicle, 1 to 2 inches in length, ends in a strong tap-root, which descends several inches into the soil, and gives off a few lateral fibres.

The growth of the seedling during the next four or five years is very slow, often scarcely an inch annually. Afterwards the growth becomes more rapid.

SEXES, FLOWERS, FRUIT, BUDS

The yew is normally dioecious; but exceptions occur, and in our account of the cultivated varieties two or three instances of monoecious trees have been mentioned. The celebrated yew at Buckland,² Kent, is monoecious. As a rule it is only a single twig or branch which bears flowers of a different sex from those on the rest of the tree. A yew³ at Hohenheimer, near Stuttgart, is reported, however, to bear male and female flowers irregularly over the whole tree, each kind, however, on separate twigs. There is a specimen at Kew of a branch, sent in 1885 by the Rev. T. J. C. Valpy of Elsing, Norfolk, which bears both male flowers and fruit.

¹ Figured in Lubbock, *Seedlings*, ii. 553, fig. 677 (1892).

² *Gard. Chron.* 1880, xiii. 556. There are specimens of this yew in the Kew herbarium.

³ Kirchner, *loc. cit.* 74.

Gilbert White thought that male trees are more robust in growth than female trees; but we are unaware of any accurate observations on this subject. Kirchner,¹ however, states that there is a slight distinction in the habit of the two sexes, male trees being taller with longer internodes and shorter leaves.

In early spring drops of mucilage may be observed glistening on the ovules of female trees in flower. The mucilage is secreted by the micropyle, and seems to entangle the grains of pollen which have been wafted on the ovules by the wind. The clouds of pollen which fly forth from the male flowers are well known. The pollen is liberated from the stamens by a very elaborate mechanism, which serves to protect the pollen grains in rainy weather. A good account of this is given by Kerner.²

A large quantity of fruit of the yew falls to the ground in autumn; but the seeds in this case do not as a rule germinate. Natural reproduction seems to be effected by birds like the thrush and blackbird, which, attracted by the fleshy aril, devour the whole fruit. The seeds, protected by their hard testa, escape digestion and are voided at a distance. They rarely germinate in the first year after ripening; seedlings come up as a rule in the year following, a few even appearing in the third year.

The buds of the different geographical forms appear to differ more than the leaves themselves. The terminal bud is invested closely by the uppermost and youngest leaves and continues the growth of the shoot. The bud scales on unfolding remain at the base of the growing shoot, and on older branchlets persist as dry brownish scales, forming an involucre at the bases of the branchlets. Lateral buds are developed on the twigs at irregular intervals. Many of these remain dormant, retaining the power to take on growth at any moment. This explains the readiness with which the yew submits to pruning, and the facility with which it produces coppice shoots when the stem is cut. Spray or epicormic branches are frequently produced on the upper side of the branches or on the stem; and these also originate in dormant buds.

True root-suckers are never formed; but layering occurs, though very rarely, in branches which have come in contact with the ground. (A. H.)

AGE, HARDINESS

With regard to the supposed great age of yew trees, which has been much exaggerated by authors—especially by the great Swiss botanist, De Candolle—we must refer our readers to Lowe, who has discussed the subject very thoroughly in chapter iii. of his work. He proves that the average rate of growth is about 1 foot of diameter in 60-70 years in both young and old trees. There is, however, abundant evidence to show that though old trees grow at intervals much more rapidly than young ones, they do not grow uniformly, but have periods of comparative rest, and that the increase of girth is fastest when old trees have lost their heads and the stem is covered with young shoots.

¹ Kirchner, *loc. cit.* 74.

² *Nat. Hist. Plants*, Eng. translation, ii. 145, 146 (1898).

No tree has such a remarkable faculty of covering up wounds or injuries by the growth of fresh wood from the outside; and even after the main stem is completely dead, fresh and entirely new stems may grow up around it and form a new tree around the dead one. For this reason most of the yews of very large size are mere shells, and even when no hollow can be seen from the outside, decay—which is often indicated by moisture running from holes in the trunk—has set in.

Three very curious sections showing the way in which these trunks grow are given by Lowe, pp. 78 and 79.

The yew, though occurring wild far north, as in Norway, is not perfectly hardy, and many instances are on record in which it has been injured or killed during severe winters. It was affected in Cambridgeshire¹ and severely injured at Glasgow by the severe frost of 1837-1838. In the winter of 1859-1860 the young shoots of many trees were killed at Burton-on-Trent.²

Many cultivated yews³ were killed by the frost of 1879-1880 in Switzerland, Rhineland, Hessa, Thuringia, etc. though in the same localities other native conifers were not injured by the severe cold. Duhamel⁴ states that in France the yew suffered much damage from the great frosts of 1709; and Malesherbes found several killed by the frost of 1789.

POISONOUS PROPERTIES OF THE YEW

The poisonous properties of the yew have been well known from the earliest times, and the subject has been so carefully investigated in the *Journal of the Royal Agricultural Society of England*, 1892, p. 698, by Messrs. E. P. Squarey, Charles Whitehead, W. Carruthers, F.R.S., and Dr. Munro, and summarised by Low in chapter x. of his work, that we need not do more than give a brief résumé of the present state of our knowledge. Through the kindness of Sir W. Thiselton Dyer, we have been able to peruse a file of the Board of Agriculture entitled "Yew Poisoning," in which the subject has been further discussed by that gentleman with whose opinions we are in complete accordance.

The conclusions drawn by Dr. Munro, after careful study from a medical point of view, are as follows:—

"Both male and female yew leaves contain an alkaloid.

"This alkaloid in both cases appears to agree with the taxine of Hilger and Brande. Taxine is probably the poison of the yew, but it is doubtful whether it has ever been obtained in a pure state, and its physiological effects have not been sufficiently studied. Other alkaloids are probably present in yew.

"Taxine is present in fresh yew leaves as well as in those withered or air-dried. It is also present in the seeds, but not in the fleshy part of the fruit.

"The yew poison may be one of moderate virulence only, and may occur in greater percentage in male than in female trees, or the percentage may vary from tree to tree without distinction of sex, and this may explain the capricious

¹ Lindley, *Trans. Hort. Soc.* 1842, ii. 225.

³ Kirchner, *loc. cit.* 62.

² *Gard. Chron.* 1860, p. 578.

⁴ *Traité de Arbres*, i. 302 (1755).

occurrence of poisoning. Also the half-dried leaves would be, *ceteris paribus*, more potent than the fresh.

"Further and extended chemical researches, in conjunction with physiological experiments, are necessary to clear up the matter.

"The principle having a specific uterine action is possibly not the same as that which causes death."

This poison, if taken in sufficient quantity, is deadly to man, horses, asses, sheep, cattle, pigs, pheasants, and possibly other animals, but under ordinary circumstances small quantities of the leaves may be and are habitually eaten by live-stock without apparent injury, whilst it seems proved that the wood of the yew may be used for water vessels and for baths, as in Japan, without any deleterious effects.

Sargent, *Silva of North America*, vol. x., 63, says "no cases of poisoning by *Taxus* in North America appear to be recorded"; and Brandis, *Forest Flora of British India*, p. 541, says that "in India domestic animals are said to browse upon *T. baccata* without experiencing any bad effects."

With regard to the danger of allowing this tree to grow in hedges and fields where stock are pastured, there seems to be abundant evidence, which is well summarised by Mr. E. P. Squarey, and which my own experience entirely confirms, that though animals which have been bred and fed in places where they have access to yew are more or less immune, probably because they never eat it in sufficient quantity to do harm, yet that animals freshly turned into such places when hungry, or in winter and spring when there is little grass, are liable to die from eating it, and that fatal effects most commonly ensue when loppings or partially withered branches and leaves are eaten.

It has been held in more than one case that landowners, and others responsible for keeping up fences, who allow yew trees to remain insufficiently fenced, are liable to an action for damages if another person's cattle from adjoining land eat the branches and die.

With regard to the danger of yew trees in game coverts we have little exact knowledge, but in certain cases there seems to be evidence of its being poisonous to pheasants, and the following passage, which was communicated by Sir William ffolkes, Bart., of Hillington Hall, Norfolk, to the editor of the *Journal of the Royal Agricultural Society*, 1892, p. 698, is worth quoting in full.

"Some years ago, when shooting through the coverts here the second time, we found about fifteen carcasses of pheasants under some yew trees. These could not have been overlooked the first time in picking up, as there was no stand anywhere near this place where so many pheasants could have been shot. My keeper informs me that it is after the pheasants have been disturbed by shooting that they take to perching in the yew trees. This may or may not be so, but at any rate it appears that, when they take to perching in these trees, they are apt to eat a few of the leaves. We now always drive them off the yew trees when they go to perch at night. I enclose some of the yew which poisoned the pheasants, and would like to add that never before this year have

we picked up a dead pheasant anywhere near these yew trees till the coverts had been shot."

We have no record of any case of deer being poisoned by yew, though no doubt in a heavy snow they might be tempted to eat it, and Mr. Squarey states that in the "Great and Little Yews" of which I write later, hares and rabbits, which are very numerous, have never been found dead from poisoning.

I may add that I have frequently seen yews of a few inches in girth barked and killed by rabbits where they are very numerous and hungry, but it is one of the last trees to be attacked.

CULTIVATION

The yew is best raised from seed, except in the case of varieties which are propagated by cuttings, which are taken off in April or August and put into sandy soil in a shady border, or, better, under a handlight, as they will then root more quickly.

Seed, if sown when ripe, will sometimes come up in the following spring, but usually lies over the first year, and is therefore treated like haws. The seedlings grow very slowly at first, and require several years of nursery cultivation before they are large enough to plant out.

They are easy to transplant in early autumn or in spring, and may be safely moved at almost any time of the year even when of large size, if care is taken to prepare the roots and keep them watered until new ones are formed.

The yew in Buckland Churchyard, about a mile from Dover, may be mentioned as an instance of the great age at which this tree may be transplanted with safety, if proper care and appliances are used. This tree was a very old and large one, divided into two stems, one of which, almost horizontal, was 10 feet 10 inches, and the entire trunk no less than 22 feet in girth. It was removed by the late Mr. W. Barron on March 1, 1880, to a position 60 yards off, where Mr. John Barron of Elvaston Nurseries tells me it is now in a vigorous state of health. An account of this tree is given by Lowe; and the manner in which it was transplanted, with pictures of its appearance before and after removal, is described fully in *Gard. Chron.* 1880, p. 556-7.

By sowing seeds there is some chance of obtaining variegated forms, which are among the most ornamental shrubs we have.

The Hon. Vicary Gibbs has found that at Aldenham the use of nitrate of soda increases in a marked degree the growth of young yew trees. Some yews planted by him in 1897 and treated with liberal quantities of this manure had attained in 1905 an average height of 12 feet, with a girth of stem of 16 inches at a foot above the base.

SOIL AND SITUATION

Though the yew grows naturally most commonly on limestone formations in England, it will grow on almost any soil except perhaps pure peat and wet clay,

and attains its largest dimensions on deep sandy loam. It grows better under dense shade than any tree we have, and may therefore be used for under-planting beech-woods where bare ground is objected to, and where the soil is too poor and dry or too limy for silver fir. In such situations, however, it grows very slowly and produces little or no fruit.

REMARKABLE TREES

No tree, except perhaps the oak, has a larger literature in English than the yew; and though a monograph on the *Yew Trees of Great Britain and Ireland* by the late John Lowe, M.D., was published by Macmillan so lately as 1897, I am able to add many records of trees not known to him, and shall not allude to most of the trees which he has described and figured.

It is strange that neither Loudon, Lowe, nor any other writer has, so far as I know, described the yews in the close walks at Midhurst, which, on account of their extraordinary height, form what I believe to be the most remarkable yew-grove in Great Britain or elsewhere.

The age and history of these wonderful trees is lost in obscurity, but it is said in Wm. Roundell's very interesting book on Cowdray¹ that Queen Elizabeth was entertained at a banquet in these walks, so they must have been of considerable age and size 300 years ago.

The close walks are situated close to the town on the other side of the river, and consist of four avenues of yew trees forming a square of about 150 yards, together with a grove of yews at the upper end which average, as nearly as I could measure them, about 75 feet in height, but some probably exceed 80. These trees are for the most part sound and healthy, though little care has been taken of them, and some have fallen. They are remarkable not only for their great height, which exceeds that of any other yews on record in Europe, but on account of their freedom from large branches, many having clean boles of 20-30 feet with a girth of 8-9 feet. They stand so thick together that on an area of about half an acre or less—I made 213 paces in going round it—I counted about 100 trees and saw the stumps of 10 or 12 more, which would probably average over 30 cubic feet to each tree without reckoning the branches.

The ground below is absolutely bare of vegetation, and though I found some small seedlings among the grass and briars on the outside of this area, I do not think the yew grows from seed under its own shade.

The photographs (Plates 54, 55) will give a fair idea of the appearance of this wonderful grove, and of the walks which lead to it. Some of the trees have a remarkable spiral twist in them like fluted columns, which I have not seen so well developed elsewhere.

The soil on which they stand seems to be of a light sandy nature, but deep enough to grow large fine timber of other species, and is, I believe, on the Lower Greensand formation.

¹ Cf. *Guide to Midhurst*, p. 41 (Midhurst: G. Roydon (1903)).

Another and perhaps the largest pure yew-wood in England is on the downs three miles west of Downton, Wilts, on the property of the Earl of Radnor. It is known as "The Great Yews," and contains about 80 acres. The trees are not remarkable for their size, and appear to have been partly planted, as the largest are at regular intervals and of about the same age. Probably at a time when yew-wood was wanted for bow-making an existing wood was filled up with planted trees, and no doubt these yews could tell some striking tales. Mr. E. P. Squarey, who took me to see them, and who has seen little change in them during the last 60 years, pointed out one under which some tramps had been caught in the act of roasting a sheep they had stolen, and related various tragedies which had occurred in this wild district in bygone times.

"The Little Yews" is the name of another wood about half a mile from the "Great Yews," which, though not of such large extent, contains much finer trees, many being from 8 feet to 10 feet in girth and 50 feet high. As in other yew woods (at any rate where rabbits exist) I found few or no young trees coming up, and the mixture of beech, ash, oak, thorn, whitebeam, and holly trees which are found in the more open spaces all appear to be self-sown. Several of the largest trees have been recently blown down.

After the Midhurst and the Great and Little Yews, I think the Cherkley Court Yew Wood is the best in England; and, thanks to the kindness of A. Dixon, Esq., the owner, I am able to give some particulars of this interesting place, which Lowe thought to be the finest collection of yews in existence.

The wood covers an area of 50 to 60 acres in a shallow valley forming part of the old Ashurst estate, about three miles from Leatherhead in Surrey, on the east side of the old pilgrims' road to Canterbury. It was formerly a rabbit warren, but is now carefully preserved by Mr. Dixon. It is said that 500 yew trees were once sold out of this wood by Mr. Boxall for 10 guineas each, and these two facts will probably account for the fact that there are now scarcely any young trees coming up, and but few trees with straight, tall trunks. Their average height does not exceed about 40 feet, and the majority of them are not well-grown trees, but there are some of great girth, of which the best is called the Queen Yew, and measures 14 feet 6 inches at 1 foot from the ground; then swelling out in a peculiar way and measuring 20 feet 4 inches at about 4 feet. At this height it begins to branch, and though the main stem goes up some way, the whole tree is certainly under 50 feet in height.

One of the most curious trees in this grove, called the Cauliflower Yew, was figured in the *Gardeners' Chronicle*, and copied in Veitch's *Coniferae*, ed. ii. p. 128. This tree has now lost much of its beauty, owing to a heavy snowstorm which occurred in 1884 and which did serious damage to the Cherkley Yew Wood.

Another place of great interest to naturalists, where the yew is in great abundance, is Castle Eden Dene, in Durham, the property of Rowland Burdon, Esq. This locality is renowned among botanists as the last in England where the ladies' slipper orchid (*Cypripedium Calceolus*) still exists. It is a deep valley about 3 to 4 miles long, running down to the sea, and, in some places, has steep cliffs of a

peculiar magnesian limestone formation, which decomposes into a red loamy soil, on which yews grow very freely, though they do not attain anything like the size that they do in the south of England. The largest which I measured was only 8 feet in girth. What makes them so picturesque is the way in which their roots spread over the bare rocks, and the mixture of curiously gnarled wych elms which accompany them. All the foot-bridges are here made of yew wood, but it is not cut except for home use, and is not increasing by seed—again, I think, on account of the rabbits.

There is a remarkably fine yew walk at Hatherop Castle, Gloucestershire, the seat of G. Bazley, Esq., which is supposed to be about 300 years old, in which the trees average about 60 feet in height with a girth of 9 to 12 feet.

The yew in Harlington Churchyard, near Hounslow, Middlesex, was considered by Kirchner (*loc. cit.* 60) to be the tallest yew tree in Europe, viz., 17.4 metres (57 feet). Lowe, page 85, gives the height in 1895 as 80 feet, on the authority of the Rev. E. J. Haddon. Henry saw this yew in October 1895, and measured the height as 50 feet only, and this is correct, within a margin of error of less than 2 feet. This tree is 17 feet 3 inches in girth at the base, where the bole is narrowest; above this it swells and is very gnarled, and at 10 feet up it divides into two great limbs.

A celebrated yew stands in the churchyard at Crowhurst, in Surrey, and has been described by Lowe (p. 201) and figured by Clayton.¹

Crowhurst, in Sussex, has another great old tree of which much has been written, and which Low figures (p. 38).

One of the finest yews in England is the Darley yew, growing in the churchyard at Darley Dale, Derbyshire. From a work on Derbyshire Churches, by the Rev. J. C. Cox, M.A., which has been sent me by Messrs. Smith, the well-known nurserymen of Darley Dale, I abridge the following particulars of it:—The churchyard is celebrated for what is claimed to be the finest existing yew tree in England, or even in the United Kingdom. Rhodes, writing of it in 1817, says that the trunk for about 4 yards from the ground measures upwards of 34 feet in girth; but Lowe gives (p. 207) measurements taken by four different persons between 1836 and 1888, of which the largest is 34 feet 6 inches by Mr. Smith in 1879, and the most recent and exact by Mr. Paget Bowman in 1888, which gives 32 feet 3 inches at 4 feet from the ground. This gentleman cut from it with a trephine nine cylinders of wood on one horizontal line which show 33 to 66 rings per inch of radius, showing an average growth of an inch in 46 years. There is a cavity in the tree about half-way up one of the trunks which will hold seven or eight men standing upright. At the ground the girth is 27 feet, and at this point no increase has taken place for 52 years. The height is not given, but a photograph by Mr. Statham shows it as about 50 feet.

I have chosen the tree at Tisbury for illustration as a specimen of the churchyard yew, for though figured by Lowe, his plate gives a poor idea of its symmetry, and it is one of the largest healthy yews in England. Though difficult to measure on account of the young spray which its trunk throws out, I made it in 1903 to be

¹ *Trans. Bot. Soc. Edinburgh*, 1903, p. 408.

about 45 feet high by 35 in girth. The trunk is hollow, and has inside it a good-sized younger stem, probably formed by a root descending inside the hollow trunk from one of the limbs. It is a female tree, and of its age it is impossible to form a correct estimate. (Plate 35.)

At Kyre Park, Worcestershire, the residence of Mrs. Baldwyn Childe, is a very fine yew tree growing near the wonderful grove of oaks which I have described elsewhere; it measures 55 feet high by 20 in girth. Under it the Court Leet of the Manor was formerly held.

The most widespreading yew I have seen is a tree at Whittinghame, the seat of Mr. Arthur Balfour, which I measured in February 1905. It grows near the old tower, formerly the property of Sir Archibald Douglas, one of the conspirators of Darnley's murder, and, according to a local tradition, this was plotted under its shade. The tree is not remarkable for height or girth, the bole being only about 12 feet high and 10½ feet in girth, but spreads out into an immense drooping head, the branches descending to the ground and forming a complete circular cage or bower about 10 yards in diameter, inside which, Mr. Garrett, the gardener, told me that 300 school children had stood at once. The branches lie on the ground without rooting, so far as I could see, and spread so widely that I made the total circumference about 110 paces. Mr. Garrett, with a tape, made it 125 yards. The appearance of the tree from outside is fairly well shown in Plate 36.

Another tree of this character, but not so large, grows at Crom Castle, on upper Lough Erne, and is described in the *Ulster Journal of Archaeology* by Lord Erne.¹ It is said to resemble an enormous green mushroom in contour, and has evidently been a trained tree, its horizontal branches being supported on timber supports upheld by about 60 stout props. Its total height is given as 25 feet, with a bole of 6 feet and a girth of 12 feet, the branches being 250 feet in circumference.

Yew trees in a wild state do not, as a rule, grow so large as those which are planted, probably because they are usually in poor rocky soil and crowded by other trees; but Lord Moreton tells me of a remarkably fine one which was shown him by Mr. Roderick Mackenzie, son of the owner of Fawley Court, in a wood on the Greenlands property on the Chiltern Hills. He described the tree as of the most symmetrical growth, and he guessed it to be nearer 70 feet than 60 feet high, with a girth of about 12 feet.

YEW HEDGES AND TOPIARY WORK

The yew, owing to the readiness with which it submits to pruning, forms an admirable hedge, and an excellent account of the conditions necessary to success in the making and keeping up of yew hedges is given by Mr. J. Clark in recent issues of the *Garden*,² to which we refer our readers.

One of the oldest and finest yew hedges in Great Britain is that at Wrest Park,³

¹ *Cf. Loudon, loc. cit.* 2081.

² *Garden*, 1905, lxxvii. 54 and 136.

³ *Gard. Chron.* 1900, xxvii. 375.

which is said to be 350 years old. There is a very high one of semicircular form enclosing the approach to the front door of Earl Bathurst's house at Cirencester.

Others¹ occur at Pewsey in Wiltshire, Melbourne in Derbyshire, Holme Lacy near Hereford, Hadham in Hertford, Albury Park near Guildford, etc.

An interesting account of the use of yew in topiary work is given by Kent,¹ who gives two illustrations of the remarkable effects produced by this art at Elvaston Castle. Leven's Hall,² Westmoreland, is also noted for the extraordinary forms into which the yew has been forced to grow. In a recent work³ by Elgood and Jekyll pictures are given of several remarkable effects produced by the yew, notably the Yew Alley at Rockingham, the Yew Walk at Crathes, and the Yew Arbour at Lyde.

There are some remarkable clipped yews in the garden at Gwydyr Castle, in the valley of the Conway, a beautiful old place now belonging to Lord Carrington, which have been the subject of careful attention from Mr. Evans, the gardener, for forty years. The largest is in the form of an immense round-topped mushroom, 36 yards round and about 36 feet high, with a perfectly smooth, close, regular surface. In the west garden at the same place there is a double row of yews, eleven on each side, of the same form, but very much smaller.

TIMBER

Since foreign timber has almost entirely superseded home-grown wood, the remarkable qualities of this most durable and beautiful timber have been almost forgotten, though, if we may believe what Evelyn, Loudon, Walker, and other old authors tell us, it was formerly highly valued, not only for bow-making, but for all purposes where strength and durability, when exposed to wet, were required.

At the present time, though I have made many inquiries, I cannot find a cabinetmaker in London who knows or uses the wood; it is rarely to be found in timber yards, and I was told by one of the principal timber merchants in York that I was, in his forty years' experience, the first person who had ever asked for it. It has little or no selling value, and may be bought occasionally for about half the price of oak.

In various old houses, however, examples may be found of its use for furniture, panelling, and inlaying, which show what the wood is worth, when well selected and thoroughly seasoned, to people who do not mind a little trouble.

Evelyn says that for posts to be set in the ground and for everlasting axle-trees there is none to be compared to it, and that cabinetmakers and inlayers most gladly employ it.

Loudon quotes Varennes de Feuilles, who states that the wood, before it has been seasoned and when cut into veneers and immersed some months in pond water, will take a purple-violet colour.

¹ Veitch's *Man. Coniferae*, 137 (1900).

² *Gard. Chron.* 1874, p. 264.

³ *Some English Gardens*, pp. 34, 42, 107 (1904).

Dr. Walker¹ speaks of the yew as a tree which grows well in the shade of rocks and precipices, especially near the sea-shore. "No timber is planted in Scotland that gives so high a price as that of yew and laburnum." He mentions a yew that grew on a sea-cliff, in the small stormy island of Bernera near the Sound of Mull, which, when cut into logs, loaded a large six-oared boat, and afforded timber to form a fine staircase in the house of Lochnell.

Sir Charles Strickland tells me that yew wood which is occasionally dug up in the bogs and fens of East Yorkshire is of a pinkish grey colour, and the most beautiful English wood he knows, but the samples of it which Henry has procured in Ireland are much darker in colour.

Miss Edwards states that in the Pyrenees water vessels are made of yew wood, which have the property of keeping the water cool in hot weather, and that there is a flourishing manufacture of such vessels bound with brass hoops at Osse.

Marshall is quoted by Loudon to the effect that about 1796 yew trees at Boxhill were cut down and sold to cabinetmakers at high prices for inlaying, one tree being valued at £100, and half of it actually sold for £50. Boucher says that, from his own experience, bedsteads made of yew wood will not be approached by bugs. Mathieu² states that in France the wood is sought for by turners, sculptors, and makers of instruments and toys.

The thin straight shoots of the yew which are cut by gipsies in the south of England make most excellent whip sticks, lighter than, and quite as tough as holly. I believe that yew would also make first-rate handles for polo sticks and golf clubs, though makers of these articles do not as yet seem to have used it.

Boulger³ says that in the library of the India Office there is a Persian illuminated manuscript on thin sheets of yew, and it also makes very ornamental boards for bookbinding.

As an example of what can be done with yew wood, I may refer to Macquoid's *History of English Furniture*, where a coloured illustration (plate iv.) is given of an extremely handsome armchair in Hornby Castle, the property of the Duke of Leeds. Macquoid says:—"The date is about 1550. It is made of yew, which adds to its rarity, for up to this time it was practically penal to employ yew wood for any other purpose than the manufacture of the national weapon; in this instance the wood has become close, as hard as steel, and of a beautiful dark amber colour."

At Hatfield House, the historic mansion of the Marquess of Salisbury, the small drawing-room is panelled entirely with yew wood, the doors being also made of fine burry pieces, but the workmanship in this case is not perfect, and the colour of the wood has been spoilt by varnish.

At Dallam Tower, Westmoreland, the seat of Sir Maurice Bromley-Wilson, the staircase is made of yew wood grown on the property.

Trees are occasionally found in which the whole body of the log consists of small burry growths something like that of maple, and when this is mixed with contorted grain of various shades of pink the effect is very good. But such trees

¹ *Economical History of the Hebrides*, vol. ii. pp. 205, 240 (1812).

² *Flore Forestière*, 511 (1897).

³ *Wood*, 346 (1902).

126 The Trees of Great Britain and Ireland

are even now so valuable that they are cut into veneer, and I have a magnificent specimen of such in a sheet 8 feet long by 18 to 20 inches wide which has been mounted for me as a table by Messrs. Marsh, Cribb, and Co. of Leeds.

The reason why it is neglected for all these purposes is apparently as follows:— The tree is usually grown in the form of a bush, and does not often become tall and straight enough to form clean timber. It is not usually planted close enough to become drawn up into clean poles, and is rarely felled except when in the way, or when it has become decayed and unsightly.

No tree is so deceptive in appearance as an old yew tree. Not only is it usually full of holes and shakes, but the heartwood is generally more or less unsound when over a foot in diameter. Some defects are usually present in an old yew tree, and even when clean and sound, the heartwood is not so good in colour as the younger wood or the slabs; and as the bark grows over and covers all these defects it is generally impossible to say how much, if any, of the timber of a large yew will be useful until it is sawn through the middle.

It seems to be soundest and best in colour when of moderate age and not over 12 to 18 inches in diameter, though the slabs from old trees of which the heartwood is pale, shaky, or faulty often show the finest and most twisted grain.

(H. J. E.)

CRYPTOMERIA

Cryptomeria, D. Don, *Trans. Linn. Soc.* xviii. 166 (1839); Bentham et Hooker, *Gen. Pl.* iii. 428 (1880); Masters, *Jour. Linn. Soc. (Bot.)* xxx. 23 (1893).

A GENUS with one very variable living species, in Eastern Asia, belonging to the tribe Taxodineæ of the order Coniferae.

A tree with evergreen leaves spirally arranged and decurrent on the shoots, which are only of one kind. Flowers monœcious. Male flowers: spike-like, sessile in the axils of the uppermost leaves of the branchlets, composed of numerous imbricated stamens, which have a pointed connective, and 3 to 5 pollen sacs. Female flowers: globular cones solitary and sessile on the tips of branchlets near to those on which the staminate flowers occur, composed of numerous bracts with free recurved pointed ends spirally imbricated in a continuous series with the leaves. Ovular scales, each bearing 3 to 5 ovules, united with the bracts for three-fourths of their length and dilated into roundish crenately-lobed extremities. Fruit: a globular brownish cone, ripening in the first year, but persisting on the tree after the escape of the seeds by the gaping apart of the scales till the next year or longer; scales about 20 to 30 in number, peltate, stalked with a disc dilated externally, which shows on its outer surface the recurved point of the bract (incorporated with the scale in its greater part), and on its upper margin 3 to 5 sharp-pointed rigid processes. The stalk-like portion of the scale bears on its inner side 2 to 5 seeds, which are ovate-oblong, somewhat triquetrous in section, and narrowly winged, with a mucro near the apex.

CRYPTOMERIA JAPONICA

Cryptomeria japonica, Don, *Trans. Linn. Soc. (Bot.)*, xviii. 167, tab. xiii. 1 (1839); Hooker, *Icon. Plant.* vii. 668 (1844); Siebold, *Flora Japonica*, ii. 43, tab. 124, 124b (1870); Kent in *Veitch's Man. Coniferæ*, 263 (1900); Shirasawa, *Iconographie des Essences Forestières du Japon*, text 24, tab. ix. 25-42 (1900); Mayr, *Fremdländische Wald- und Parkbäume*, 278 (1906).

A tall tree, attaining in Japan a height of 150 feet or more, and a girth of 20 to 25 feet, the trunk tapering from a broad base. Bark reddish brown, and peeling off in long, ribbon-like shreds. Leaves persistent for 4 or 5 years, arranged spirally on the shoots in five ranks, curving inwards and directed forwards, awl-shaped, tapering to a point, compressed laterally, keeled on front and back, bearing stomata on both sides, with the base decurrent on the branchlet to the insertion of the next leaf. The buds are minute, and composed of three minute leaves, which are free at the base, and not decurrent.

The male flowers are clustered at the ends of the branchlets in false racemes, the leaves in the axils of which they arise being reduced in size, and fulfilling the function of bracts. They appear on the tree in autumn and shed their pollen in early spring, remaining for some time afterwards in a withered state.

The buds of the female flowers are also to be seen in autumn terminating some of the branchlets, and covered externally with small, awl-shaped leaves.

The shoot¹ is frequently continued in the leafy state throughout the cone ("proliferation"), and the extended portion often grows to several inches in length beyond the cone, and even in some cases bears male catkins.

Woody excrescences² of a conical shape often develop on the stem, to which they are loosely connected. They correspond to the "wood-balls" which are found on beeches and cedars, and like these are due to abnormal development of dormant buds.

Seedling: the cotyledons, which are generally 3 in number, the occurrence of 2 only being rare, are carried above ground by an erect caulicle, about $\frac{1}{2}$ inch long, ending below in a primary root, which is reddish, flexuous, and about 3 inches long, giving off a few lateral fibres. The cotyledons are linear, flattened, obtuse, and about $\frac{1}{4}$ inch long; two, narrowed at the base, are prolonged on the caulicle as ribs; the other, sessile on a broad base, is not decurrent; all bear stomata on their upper surface. The first leaves on the stem are in a whorl of 3, similar in shape to the cotyledons, but longer and with slightly decurrent bases. The leaves following are inserted spirally on the stem, and are longer, sharper-pointed, and more decurrent. All are spreading, with stomata and a prominent median nerve on their lower surface. The stem, roughened by the leaf-bases, terminates above in a cluster of 5 to 6 leaves, crowded at their insertion and directed upwards.

¹ Remarkable instances of proliferous cones and other abnormalities are described and figured in *Rev. Horticole*, 1887, 392.

² Figured in *Gard. Chron.*, May 30, 1903, p. 352.

VARIETIES

There are at least two well-marked geographical forms, var. *japonica* and var. *Fortunei*, which will perhaps be ranked as distinct species, when the trees are studied in the wild state. Other varieties, which have probably arisen in cultivation, are distinguished by peculiarities of the foliage.

1. Var. *japonica*, the type described by Don from Japanese specimens collected by Thunberg.—This is the form which occurs wild in Japan. The tree is pyramidal in habit, with straight, spreading branches and short, stout, dark green leaves. The cones are composed of numerous scales, bearing long acuminate processes, and showing long points to the bracts, making the outer surface of the cone very spiny, especially towards the summit. There are generally 5 seeds to each scale.

2. Var. *Lobbii*.¹—Tree narrow, pyramidal in habit, with short branches densely ramified. The leaves are long and light green in colour. The cones are like those of the preceding variety, but with the processes and tips of the bracts even longer and more slender. This is perhaps a geographical form, occurring in Japan, where it was collected by Wright. It has certainly proved hardier than the Chinese variety both in this country and on the Continent.

3. Var. *Fortunei*² or *sinensis*.³—A tree diffuse in habit, with deflexed branches and long, slender branchlets. Leaves long and slender. Cones with fewer scales (about 20), which end in short processes, the tips of the bracts being of no great length, so that the whole cone looks much less spiny than that of the Japanese forms. Seeds fewer, often only 2 on a scale, but apparently indistinguishable from those of the Japanese trees. This is the form which occurs wild in China, and which was first introduced into this country. It was described by Sir W. J. Hooker⁴ from specimens gathered by Sir Everard Home in Chusan. The Chinese form ripens its seeds three weeks sooner at Dropmore than the var. *Lobbii*.

4. Var. *araucarioides*.⁵—Branches deflexed, with the branchlets long, pendulous, and very distantly placed. Leaves small, stout, stiff, and curving inwards at the top, dark green in colour. Cones as in var. *japonica*, of which this is only a slight variety. It is described as a shrub or low tree; but this may arise from its being propagated from cuttings. Large trees occur, of a similar habit, which seem, however, to be sports from var. *Fortunei*.

5. Var. *pungens*.⁶—Leaves straight, stiff, spreading, darker green, and more sharply pointed than in common forms. I have not seen cones; and the origin of this variety is not clearly known.

¹ Gordon, *Pinctum* (1858), p. 54.

² *Cryptomeria Fortunei*, Hooibrenk, *Wien. Jour. für Pflanzenkunde*, 1853, p. 22.

³ *Cryptomeria japonica*, var. *sinensis*, Siebold, *l.c.* 49.

⁴ Hooker, *loc. cit.* He points out the difference in the cones of the Chinese and Japanese trees, but says that they are undoubtedly one species. Bunbury, *Arboretum Notes*, 172, remarks that the cones of the Barton tree, from Chinese seed, are very different from Don's figure of Japanese cones.

⁵ Carrière, *Traité Gén. Conif.* (1867), p. 193.

⁶ *Hort.* A sub-variety of this, *pungens rubiginosa*, is mentioned in *Garden*, iii. 1873, p. 322. The leaves are said to assume a coppery or tawny red colour from August until April.

6. Var. *spiralis*.¹—A slender shrub, with leaves strongly falcate and twisted spirally by their free ends around the branchlets, which assume in consequence a corkscrew-like appearance. A specimen of this at Kew also bears some branchlets with normal leaves.

7. Var. *dacrydioides*.²—Leaves very closely set and very short (about $\frac{1}{4}$ inch long) There is a specimen at Kew of this form, gathered by Maries and said to be wild. It is probably a depauperate form, originating in rocky, barren, exposed ground.

8. Var. *nana*.³—A dwarf, procumbent, dense, spreading shrub, with short acicular needles, closely set on the rigid branchlets and directed outwards. This form attains only 3 or 4 feet in height, and very often bears monstrous fasciated twigs.

9. Some slightly variegated forms of *Cryptomeria* have appeared in cultivation; in one the tips of the branchlets are whitish; in another the leaves are yellowish in colour.

10. Var. *elegans*, Masters, *Jour. Linn. Soc. (Bot.)* xviii. 497 (1881); *Cryptomeria elegans*, Veitch, ex Henkel und Hochstetter, *Synopsis der Nadelhölzer*, 269 (1865).—A fixed seedling form. The juvenile foliage is retained throughout the life of the tree, which bears the same relation to the type as *Retinospora squarrosa* does to *Cupressus pisifera*. It agrees in cones and in the anatomical structure of the leaves with the typical form.

In habit this is rather a large bush than a tree. The leaves, while spirally arranged on the shoot as in the ordinary form, spread outwards and are not directed upwards. They are decurrent on the branchlets, linear, flattened, curving downwards, sharp-pointed, grooved on the middle on both surfaces, and are light green in colour, changing in late autumn and winter to a reddish bronze colour, which gives the tree a remarkable and handsome appearance. There is a dwarf form of this variety, *Cryptomeria elegans nana*, which is a low, dense bush with crowded leaves, changing in colour in the autumn like the ordinary variety, except that the pendulous tips of the branchlets remain green.

The origin of this remarkable form is obscure. In Japan, according to Siebold, it is known as *to-sugi*, i.e. "Chinese *Cryptomeria*," and is said to have been introduced from China. Kaempfer mentions a *nankin-sugi*, introduced into Japan from China, cultivated on account of its beauty, which is possibly this variety.

Cryptomeria elegans was introduced from Japan to England in 1861 by John Gould Veitch.⁴ The largest specimen we know occurs at Fota; it is 42 feet high by 4 feet 9 inches in girth. In Cornwall this variety grows to a great size, the tops of the trees often bending down under the weight of their branches and foliage; and the outer lower branches commonly take root and grow into independent trees, which form a colony round the parent stem.⁵

At Tregothnan there is a very fine example (Plate 37) which measures 35 feet by 4 feet 6 inches, and at Killerton there is another almost equal in size. In the

pinetum at Cowdray this form also grows very well, and it is perfectly hardy at Colesborne and in Yorkshire. At Poltalloch in Argyllshire it also attains large dimensions.

IDENTIFICATION

Cryptomeria resembles *Sequoia* and *Araucaria Cunninghami* in having leaves which are spirally arranged and markedly decurrent on the shoots. The awl-shaped leaves of *Araucaria Cunninghami* strongly resemble those of the ordinary forms of *Cryptomeria*; but in the former they always end in bristle-like points, whereas in the latter they taper to a blunt point. The subulate leaves of *Sequoia gigantea* are closely appressed to the shoots in three ranks, with only their upper half free; whereas in *Cryptomeria* they are in five ranks, and are free from the shoots for the greater part of their length.

INTRODUCTION

The tree is said by Siebold¹ to have been introduced into St. Petersburg by the overland route through Siberia, several years before Fortune sent it to England. The credit of the introduction into England is, however, due to Captain Sir Everard Home,² who sent seeds to Kew from Chusan in 1842. Several seedlings were raised at Kew, which were kept in a greenhouse till 1847, and were then planted out; but they never did well. One planted near the rockery was living in 1880, when it measured 26 feet high by 2 feet 3 inches in girth; and another stood for some years near the main entrance. Both these trees have been cut down, and there do not appear to be any survivors of the first importation now at Kew or elsewhere. Fortune introduced the tree in quantity in 1844, when he sent seeds, apparently gathered in Chekiang, from Shanghai to the Horticultural Society. The first tree planted in France was at Chaverney in 1844, and the second at Angers in 1847. All the old trees in this country and on the Continent are from Fortune's seeds, and belong consequently to the Chinese form.

The variety *Lobbii* was introduced by Thomas Lobb in 1853 from the Botanic Garden of Buitzenborg in Java, where it had been sent from Japan in 1825 by Siebold.³ It differs only slightly from the ordinary Japanese form. Siebold⁴ states that he introduced the typical Japanese form into Leyden in 1861. John Gould Veitch introduced several kinds of *Cryptomeria*, as the result of his visit to Japan in 1860; but I have not been able to identify these, and according to H. J. Veitch,⁵ the typical Japanese form was first introduced by Maries in 1879. Probably there are no trees of this kind in England older than this date. The introduction of variety *elegans* has been already given above. (A. H.)

DISTRIBUTION IN CHINA

Cryptomeria was discovered in China in 1701 by J. Cunningham, who found it in

¹ Siebold, *loc. cit.* 48.

the island of Chusan, off the coast of Chekiang. His specimens, three in number, are preserved in the British Museum, and a branch with cones was figured both by Petiver¹ and Plukenet.² A few years previously, probably in 1692, it had been found in Japan by Kaempfer,³ whose specimen also is kept in the British Museum; and Thunberg⁴ obtained specimens in Japan, the material on which Don founded his description of the genus. It was collected in China at different times by Sonnerat,⁵ Millett,⁶ and Sir Everard Home;⁷ but we owe to Fortune the only account of importance of the tree in the wild state in China.

Fortune⁸ saw the tree for the first time in the plain of Shanghai in 1843, where it is planted in cemeteries and temple-grounds, and grows to a great size, the poles which are set up in front of temples and mandarins' offices being often of *Cryptomeria*. In 1844 he found it growing wild in the mountains south-west of Ningpo, where it forms dense woods with *Cunninghamia* and other trees. It is met with in the Chekiang mountains even at high elevations—the finest specimens seen by Fortune occurring in the Bohea hills, which he crossed in 1849. He was particularly struck with a fine solitary tree, at least 120 feet in height, which stood near the gate in the pass of the high range which separates the Chekiang and the Fukien provinces. At Ningpo the junks are mostly built of the timber of this tree.

Cryptomeria was also collected by Swinhoe⁹ in the country inland from Amoy, and by Père David in the interior of Fukien, where, he says,¹⁰ it is a beautiful tree, becoming rare in the wild state, but existing still in the mountains at moderate elevations.

Specimens¹¹ have been collected in other parts of China, but always, I believe, from planted trees. In Yunnan I only met with two trees, one (18 feet in girth) near a temple, and the other near a village. *Cryptomeria* apparently only occurs wild in China in the mountains of the Chekiang and Fokien provinces, between 25° and 29° N. lat., but may be found elsewhere when the interior of the country is better explored. In its native home in China the tree is subject to severe cold in winter, but the spring arrives suddenly with no late frosts, and the summer is much warmer than in England. In China the tree is called *kuan-yin-sha* ("goddess of mercy fir") in Yunnan, *kung-ch'io-sung* ("peacock-pine") in Szechuan, and *sha* ("fir") simply in Chekiang, where it shares the name with *Cunninghamia*, the timber of both trees being much used in the construction of houses and boats.

CRYPTOMERIA IN JAPAN

Both from an ornamental and economic point of view this is the most important

tree of Japan, as it is also the largest, and though it is now difficult to say how far its natural distribution extends, it has been planted everywhere from such a remote period, and grows so rapidly that it is now the most conspicuous tree in all those parts of Japan which I visited except in the island of Hokkaido.¹

I saw it wild in the primeval forests which cover the mountains on the frontier of the provinces of Akita and Aomori in the extreme north, near a station called Jimba, at an elevation of about 1000 feet, where the lower edge of the forests and more accessible valleys have already been denuded of their best timber. The Japanese Government have lately made a good road up one of the valleys, which enabled me to see the forest at its best under the guidance of their obliging foresters. The hills are here very steep, often with a slope of 30° to 40°, and covered on the north-east aspects with an almost pure growth of *Cryptomeria*, and though on the south-west aspects a few deciduous trees, such as maple, magnolia, oak, chestnut, and *Æsculus* were mixed with it, I saw no other conifer. This forest is not truly virgin, because from time to time trees have been cut for shingles and tub staves, which are made in the forest and carried out on men's backs as usual in the remoter parts of Japan. But in many places it was quite dense, and the undergrowth consisted largely of ferns, *Aucuba*, *Skimmia*, *Hydrangea*, and a variety of other shrubs, and tall, rank-growing herbaceous plants such as *Spiræa* and *Rodgersia podophylla*.

The trees average in size 100 to 110 feet high by 2 to 3 feet in diameter, and are clean for half their length or more, in the denser parts of the forest. The largest trees which have been felled here do not exceed about 100 feet in timber length and about 4 feet diameter. The rings of one of 5 feet in girth which I measured showed 116 years' growth, of which about 87 were red heart-wood. Another close by was very flat-sided, measuring 3 feet 9 inches in diameter one way, and only 2 feet 9 inches the other, the centre on that side being only 1 foot from the nearest point of the bark. This tree was about 136 years old, over 100 years growth being red heart-wood.

Many trees were more or less curved at the butt, and many others forked low down into two, three, or more stems. There were plenty of cones on the trees which had sufficient light, but a careful search did not discover a single self-sown seedling, all the young trees which were coming up—and those not numerous—being evidently suckers or growths from the stool. The dense layer of coarse, sour humus and half-decayed leaves and branches form a bed in which the seedling after germination cannot take root, but on the railway banks and other exposed surfaces not overgrown by dense grass young seedlings appeared and grew freely. Many of these trees had large climbers, such as *Vitis Coignetæ*, *Schizophragma*, and *Wistaria*, growing nearly to their tops. Plate 38, taken from a negative kindly given me by the Japanese Imperial Forest Department, shows the appearance of this forest. Plate 39 A, from the same source, shows a mature forest of *Cryptomeria* in the island of Shikoku. Plate 39 B shows the trunk of the tree and the manner of felling still adopted in Japan, *cf.* p. 137.

The forester told me that the system adopted in this forest, now that it is

¹ Mayr quotes Dr. Honda for the fact that the most southern locality where it grows wild is in the island of Yakushima, the northernmost of the Riu-Kiu islands, where in a dense forest at a high elevation it forms immense trunks.

accessible, would be clean felling, followed by replanting as soon as possible, in the same manner as is generally adopted in the south of Japan.

I could not learn the exact range of *Cryptomeria* as a wild tree,¹ but in the north, where the winter is long and hard, and the snow lies deep for months, it prefers the shady aspect, though it does not attain the same gigantic proportions as it does farther south.

Nikko is approached by a magnificent avenue of *Cryptomerias* on both sides of the road, 20 miles long, known more or less imperfectly by every visitor to that place, but which can only be properly appreciated by going some way east of Imaichi station, to the point where the trees in good soil attain their greatest dimensions. I took a photographer here specially to take the picture reproduced, and measured the finest trees I could find, of which the tallest was about 145 feet high, and the average 110 to 120 feet, with a girth of 12 to 20 feet on the better soils. Many of the trees have been planted so close together that they have now grown into one tree. The one which I figure (Plate 40) is composed of six stems, which measure 21 feet in greatest diameter, and about 60 in girth. Cf. Sargent, *Forest Flora of Japan*, p. 75.

The age of these trees, of which many have been blown down by recent gales and some felled, is, as near as I could count the rings of wood, 260 to 270 years, of which over 200 is red wood. The bark is not over $\frac{1}{2}$ to $\frac{3}{4}$ inch thick, and though some of the trees were beginning to decay at the heart, others were quite sound. The soil is generally a rich black humus overlying a yellow tufaceous volcanic gravel, and the influence of bad soil on the trees is seen very clearly at a point about three miles east of Imaichi, where the road crosses a low ridge of dry and sandy soil, and where they are not more than 80 to 90 feet high by 6 to 8 feet girth.

At the celebrated temples of Nikko there are larger trees than any that I saw in the avenue. The best—shown in Plate 41—is about 150 feet high by 23 feet in girth, but I could not measure the height exactly on account of its position. They are said to be about 300 years old, being probably older than those in the avenue, and seem mostly in perfect health on a slope facing south where the soil is evidently deep and good.

But these magnificent trees are quite eclipsed by those which I saw later at the celebrated monastery town of Koyasan, in the province of Kishu, not nearly so well known to European tourists as it should be. The magnificent cemetery at this place is over a mile long, and planted as an irregular avenue with many lateral annexes—each of which was in the past the private burying ground of great families—with *Cryptomeria* trees which are said to be 400 years old, and which, I believe, surpass in grandeur any other trees planted by man in the world. They grow at an elevation of about 2800 feet, in a climate which is much milder, and gives evidence of a much heavier rainfall than that at Nikko; for many of the trees had shrubs growing on them as epiphytes on their trunks. In one case a tree of *Cupressus obtusa* has its stem, 6 to 8 inches thick, completely embedded in the trunk of a sound and

¹ In *Forestry of Japan*, p. 18, it is only said that splendid natural pure woods of it occur in the Nagakizawa State forests in Akita, and in Yakujima in the island of Kyushu, which I had not time to visit, but whether there is any notable difference between the trees in these distinct areas, separated by nearly ten degrees of latitude, is not stated, so far as I can find. According to Shirasawa (*loc. cit.*) fossil *Cryptomeria* trees of great dimensions have been found in nearly all parts of Japan.

healthy *Cryptomeria*, from whose sap alone it must now be deriving its sole nourishment, as no decaying wood is visible, and it is about 20 feet from the ground. The shape of the trees here is more picturesque and less regular than at Nikko, some having spreading branches quite near the ground; the best of these measured 133 feet by 19 feet 3 inches, with a spread of 25 yards.

The finest trees in the cemetery, and probably the finest in existence, stand on the right at its extreme end, close to an enclosure, just before reaching the large barn-like temple called "Mandoro," or hall of ten thousand lamps, which is itself surrounded and backed up by a grove of superb trees standing very thickly together. Of the trees on the right just before reaching the temple one had previously been measured by Prof. Honda of Tokyo University, who made it 58 metres high. I made it 180 feet with a girth of 24 feet. But though this may be the tallest it is not so fine a timber tree as the one standing just beyond it, which does not swell so much at the ground, but carries its girth higher up and is cleaner. This tree is broken off at about 150 feet, but seems quite vigorous, and certainly contains 2000 feet or more of sound timber.¹

So far I have spoken only of the *Cryptomeria* in a wild state and as an ornamental tree, but it is also planted very largely in many parts of Japan for timber, and forms a most profitable source of revenue to many of the smaller landowners and farmers as well as to the State. Its cultivation has attained a maximum in the district of Yoshino in the province of Yamato, and from *The Forestry and Forest Products of Japan*, published at Tokyo in 1904, we learn that this cultivation dates back 400 years, and covers as much as 38 per cent of the whole area of the district, of which no less than 93 per cent is forest land. The inhabitants have probably brought the art of profitable timber growing to a higher point of perfection than any other people in the world, no less than 85 per cent of the local male population consisting of woodmen, sawyers, timber carriers, and foresters. The quantity of *Cryptomeria* timber alone exported from Yoshino amounted in the year 1902 to 8,857,000 cubic feet, valued (I presume locally) at 1,695,000 yen, equal to about £175,000 sterling.

The trees are planted out at three years old after being twice transplanted in the nursery, where they are raised from seed and kept shaded during the first year. This, at least, is the rule in the Kisogawa district, though I was told that in the south *Cryptomerias* are more cheaply and quickly raised from cuttings, and that these produce as good trees as seedlings.

About 4000 per acre are usually planted, and weeded once or twice a year for three years, when they suppress the weeds by their shade. The plantations grow very fast, and are pruned from the eighth to the twenty-third year after planting out. Thinning is done at the earliest at twelve years, and the thinnings form such a profitable source of revenue that income is probably returned quicker by such a *Cryptomeria* plantation than by any other tree. The final felling takes place at about 120 years old, when as many as 180 trees, containing 15,000 cubic feet, may be found on an acre. The previous thinnings are estimated at 16,000 cubic feet, making the total product per acre in 120 years over 30,000 feet. This result, which

¹ Mayr, however, states that he measured a tree at Takaosan which attained 68 metres (over 200 feet) in height by 2 in diameter.

appears astonishing, is perhaps exceptional, but all the plantations I saw gave evidence of extremely rapid growth, and showed a larger proportion of clean useful poles and timber than any plantations which I have seen in other countries.¹

TIMBER

The wood is used for almost every purpose in Japan, but especially for tubs, staves, and building. Though not as valuable as the best wood of *Cupressus obtusa* for high-class buildings and internal work, it is, when properly selected, sawn, and planed, highly ornamental both in colour and grain, easy to work, durable, and strong enough for most purposes. It has also a most agreeable odour due to the presence of a volatile oil called *sugiol* by Kimoto,² who gives an analysis of it, and states that the wood on this account is used for making *saké* casks, the *saké* acquiring a peculiar pleasant aroma.

It varies very much in colour and figure, the most valuable being the wide planks—sometimes 3 to 4 feet wide and over—which are used for doors, ceilings, and partitions in the best houses. The darkest in colour comes from the southern island of Kiusiu, and is known as *Satsuma sugi*. When it shows a very fine red grain in old gnarled butts it is known as *Ozura-moko*, the best of this colour being very valuable. There is also a grey-coloured variety known as *Gindai sugi*, which appears to be taken from trees which have died before felling, but I could not get very definite information on this point.

The finest example I know of the ornamental use of *Cryptomeria* wood is the ceiling of the large dining-room in Kanaya's Hotel at Nikko, which is composed of panels about 30 inches square, cut from the butts of trees which show very curly and intricate graining, and without polish have a natural lustrous gloss. The Japanese never paint or varnish the wood in their houses inside or out, and attach more importance than European builders do to its quality, colour, and figuring. It seems very strange that none of the numerous travellers and writers on Japan have, so far as I can learn, as yet paid any attention to the beauty of the Japanese timbers. As a rule *Cryptomeria* is spoken of by English-speaking Japanese and Europeans as cedar, but *sugi* is the native name.

The bark of the tree is also largely used, when taken off in large sheets, for covering outbuildings of secondary importance, but does not appear to be so much valued or so durable as the bark of *Cupressus obtusa*, *Thujaopsis dolabrata*, or *Sciadopitys verticillata*. An ounce of the seed contains about 50,000 seeds. For raising trees to plant in the colder parts of Europe I should certainly prefer seed from the natural forests of the north to what is grown in the subtropical climate of South and Central Japan, and I should therefore warn anyone wishing to plant this tree largely to be very careful about the origin of the seed or plants.

The value of this wood varies considerably in Japan according to locality and

¹ Tables of Production and Rate of Growth in Japan are given by Honda in *Bull. Coll. Agric. Tokyo Imp. Univ.* ii. 335 (1894-1899).

² *Bull. Coll. Agric. Tokyo Imp. Univ.* iv. 403 (1900-1902).

quality, but about 80 yen per 100 cubic feet, equal to about 1s. 8d. per foot, is the price in Tokyo, and selected half-inch boards for ceilings and panellings cost from 2s. to 4s. each.

Rein, in *Industries of Japan*, p. 226, speaks of a *Cryptomeria* which he measured in 1874 having at $1\frac{1}{2}$ metres high a girth of 9.41 metres, equal to about 30 feet. This grew on the Sasa-no-yama-toge, between Tokyo and Kofu, at about 750 metres above sea level.

Weston, in *The Alps of Japan*, mentions trees high up on the eastern side of the pass between Nakatsugawa and the Ina-kaido, called the Misaka-tōge, on the northern slope of Ena-San, which measured at 3 feet from the ground no less than 26 feet in girth. It would not be supposed possible that in a country where neither machinery nor horse-power is used for the removal of timber such large trees could be utilised, but the Japanese are very ingenious in the handling of large logs in their mountain forests.

I was presented by Baron Kiyoura, Minister of Agriculture, with a most curious and interesting series of sketches, which I found in the Imperial Bureau of Forestry, showing the means adopted for felling and transporting large timber growing in rocky gorges and the most inaccessible situations. These I exhibited at a meeting of the Scottish Arboricultural Society at Edinburgh on 10th February 1905.

The *modus operandi* is as follows:—First men climb up the trees and lop off all the large branches, so that the tree may not lodge among its standing neighbours when felled. Ropes are then attached to the trunk and carried round a windlass, so that it may be pulled over in the right direction.

When the tree is felled it is cut into suitable lengths, often 20 to 30 feet long, and a hole cut in the end, to which a stout rope is attached. By this it is sometimes dragged, sometimes lowered, to the nearest slide, which is built up of smaller timber. Or, if the locality is too distant from a slide or from a stream large enough to float it, a platform is built on the mountain-side, on which it is sawn into boards, which are carried out of the forest on men's backs, or on sledges on the snow.

A most ingenious plan, which I have seen in no other country, is adopted where the slope of the mountain is too steep to let a log slide at its own pace.

The slide is built in a zig-zag form, and at each angle a bank is made and covered with earth and bark to check the impetus of the log, whose upper end when so checked is reversed by means of a strong pole laid across the slide, and then goes downwards till it reaches the next angle, where it is again checked and reversed by its own weight.

To see a large gang of men, all singing in chorus at their work, moving timber in a mountain forest under the direction of their foremen, is one of the most interesting sights I beheld in Japan, and I could not sufficiently admire the pluck, activity, and ingenuity they showed in the very dangerous and difficult work which is necessary when logs get jammed, as they often do in these rapid mountain torrents; and when men, standing on small rafts fastened to boulders in a roaring rapid, or let down from above by ropes, have to dislodge the logs from where they have stuck fast.

Cryptomeria japonica yields in Japan a turpentine or semi-solid resin, named *sugi-no-janai*, which was shown at the Edinburgh Forestry Exhibition. This resin, which is very aromatic, is used as incense in Buddhist temples, and as a plaster for wounds and ulcers.

CULTIVATION

The tree ripens seeds in good summers in the south of England, which are easy to raise, and the seedlings grow rapidly after the first year. Seeds which I gathered in 1900 from a tree at Stratton Park, Hants, the seat of the Earl of Northbrook, and sowed in the open ground, germinated at the end of April, whilst others sown in a pot on Christmas Day and kept in a greenhouse, germinated on 17th April, and grew much better than those sown in the open. Some of the young trees planted out at two years old are now (January 1905) 3 to 4 feet high, and have not suffered at all from the spring frosts.¹

The seedlings are easy to transplant, and might be raised in nurseries at a lower rate than many trees, though they should have some protection for the first two or three years, and if kept in pots the roots should not be allowed to become cramped, and if twisted round the bottom of the pot should be carefully spread when planted out. The tree may also be propagated from cuttings, and this plan is sometimes adopted in Japan, as being cheaper and quicker than raising seedlings, but except in the case of varieties, should not be adopted if tall, straight trees are desired. I have seen in the garden of Mr. Chambers at Grayswood, near Hazlemere, Sussex, a self-sown *Cryptomeria* which had germinated in a chink of the garden steps, and which is now growing at Colesborne, and I have no doubt that others might be found in suitable situations, as Mr. Bartlett has lately found a seedling at Pencarrow, Cornwall, growing at the base of the parent tree. *Cryptomeria* seems to be more adaptable to various kinds of soil than many exotic trees, and does not mind a moderate amount of lime, but loves a situation well sheltered from cold winds, and a soil deep enough and light enough to keep its roots moist during summer. I have not seen it grow well on heavy clay, where it suffers from spring frost. If timber and not ornament is the object, I should plant it about 10 feet apart, alternate with some fast-growing conifer, such as common larch or spruce, which might be cut out when the trees became too crowded.

Mayr² considers that in warm, damp parts of Europe the *Cryptomeria* may probably be planted profitably as a timber tree in sheltered valleys and in good soil, but recommends the mixture of other trees as nurses wherever the winter temperature is low, and says that alders are preferred by the Japanese for this purpose. He says that a plantation of this tree in East Friesland had attained 12 metres in height and 23 centimetres in diameter; and on the island of Mainau, on Lake Constance, he measured, in 1897, a tree which was 18 metres high and 40 centimetres in diameter.

¹ But the severe frosts of May and October 1905 have injured several and killed some of the weakest of these seedlings.

² *Fremdländische Wald- und Parkbäume*, p. 285.

REMARKABLE TREES

The finest specimens of *Cryptomeria* known to us in England are at Hempsted, the seat of the Earl of Cranbrook, in Kent, which Lord Medway thinks were planted before 1850. They grow in a sheltered situation on a greensand formation, and the largest exceeds *Sequoia sempervirens*, planted near it, in height. I made it 80 feet by 8 feet, and another tree 72 feet by 8 feet 2 inches. Both are symmetrical, and seem to be growing fast (Plate 42).

At Pencarrow, in Cornwall, a number of trees were planted by Sir W. Molesworth in 1848-9, and have thriven very well, though the soil is not very favourable. Mr. Bartlett informs us that the tallest of them, which grows on a dry, steep, stony bank, crowded by other trees, is now 68 feet by 5 feet 6 inches. The largest, on moister soil, is 62 feet by 8 feet. Six other trees, planted in 1875, vary from 48 feet by 5 feet down to 33 feet by 4 feet 3 inches. At this elevation, 450 feet, there is often snow, and the thermometer sometimes falls to 12° and 14°.

At Castlehill, in North Devon, the late Earl Fortescue planted many *Cryptomerias*, but though they have grown well, they are mostly rather bushy than tall trees, and may have been raised from cuttings. One of them, which was 8 feet in girth and only 40 feet high, was covered with burr-like excrescences as much as 8 inches long.

At St. George's Hill, near Byfleet, growing on Bagshot sand on the highest part of the hill, surrounded by pines, is a tree 64 feet by 5 feet 5 inches.

At Kitlands,¹ near Leith Hill, Surrey, there is a large *Cryptomeria*, planted by the late D. D. Heath, Esq., the branches of which have taken root and formed a grove, whose branches in turn root outside.

There is a fine tree at Killerton, which in 1902 was about 75 feet high, by 6 feet 5 inches in girth, though owing to its situation it was difficult to photograph or to measure exactly. A tree at Bicton is nearly equal to it in height and girth. At Eastnor Castle, Worcestershire, the property of Lady Henry Somerset, there is a tree 65 feet high by 5 feet 10 inches in girth.

At Fonthill Abbey, Wilts, the seat of Lady Octavia Shaw-Stewart, there is a beautiful tree 67 feet high by 9 feet 3 inches in girth. At the entrance gate of Rufford Abbey, Notts, the seat of Lord Savile, there is a fine tree about 62 feet high.

At Dropmore a large tree, planted in 1847, was cut down in 1904,² and measured 68 feet 6 inches by 5 feet 9 inches. Though it seemed in perfect health, Mr. Page informed me that the heart was partly decayed. There are still three good specimens at Dropmore—two of the Chinese kind, planted in 1847, which measure (February 1905) 64 feet by 5 feet 6 inches, and 62 feet by 6 feet 7 inches; the third, var. *Lobbii*, planted in 1853, is 74 feet high by 4 feet 7 inches in girth. These measurements were kindly sent by Mr. Page.

At Barton, Suffolk, one, planted in 1848, was found by Henry in 1904 to be

¹ Nisbet in *Victorian Surrey County History*, ii. 575 (1905).

² *Gard. Chron.* Jan. 21, 1905, p. 44. This tree was reported to be 41 feet high in 1868 (*l.c.* 1868, p. 464).

140 The Trees of Great Britain and Ireland

63 feet by 5 feet 3 inches, and proves that the tree will thrive on good soil even in the east of England.

At Williamstrip Park, Gloucestershire, the seat of Lord St. Aldwyn, there is a tree 45 feet by 5 feet, probably one of the first introduced.

At Penrhyn, North Wales, there is a fine tree, 64 feet by 5 feet 5 inches.

The best example I know of the growth of *Cryptomeria* as a forest tree is at Tan-y-bwlch, in Merionethshire, the property of W. E. Oakeley, Esq., where a large number of seedlings were raised about 40 years ago from a tree which is now 62 by 6 feet, and has apparently not grown much lately.

The best of its progeny, growing on a slate formation where rhododendrons flourish exceedingly, near sea level, is already 53 by 4½ feet, and many others average about 40 by 3½ feet. Some are growing among beech and oak, others in a plantation of larch and Corsican pine facing north. In the latter the average girth of 8 trees was 3½ feet, whilst larch of the same age was little over 2 feet, and Corsican pine about the same. Mr. Richards, forester to Lord Penrhyn, who saw this plantation shortly after it was made, agreed with me that its success would amply justify planting *Cryptomeria* on a large scale in North and West Wales in sheltered places on good land up to about 300 feet above the sea. But, judging from a large board sent me by Sir John Llewellyn, grown in South Wales, the timber is much lighter and softer than it is in Japan, and perhaps will not be equal for outside work to that of Douglas fir grown on similar land.

At Dynevor Park, in Caermarthenshire, the seat of Lord Dynevor, there are some well-grown trees, the tallest of which is 56 feet by 6 feet 10 inches.

At Belshill, Northumberland, the property of Sir W. Church, there is a tree 50 feet by 4 feet 8 inches, which is about 50 years old and quite healthy.

In Scotland the tree seems quite hardy, and at Keir, the seat of A. Stirling, Esq., a tree planted in 1851 has increased from 42½ feet in 1892 to 52 feet by 8 feet girth in 1905. It has the trunk covered with burrs. At Castle Kennedy, the seat of the Earl of Stair, there is a tree 56 feet by 6 feet 1 inch.

In Ireland there are several fine trees. At Coollattin, Wicklow, the property of Earl Fitzwilliam, a tree measured 63 feet high by 6 feet in girth in 1906. At Woodstock, Kilkenny, a tree of the variety *Lobbii*, which was planted by Miss Tighe in 1857, is now (1904) 67 feet high by 6 feet 7 inches in girth. Close by this tree is a wonderful group of *Cryptomerias*, which have been produced by natural layering. The parent tree in the centre is about 50 feet high, and around it are over 20 trees, with straight stems, which are themselves layering, so that in course of time a grove may be produced.

At Fota there are many examples of *Cryptomeria* and its varieties. The form *spiralis* is about 15 feet high. The variety *araucarioides* is 31 feet by 3 feet 8 inches in girth, very compact in habit. *Elegans* is 42 feet by 4 feet 9 inches. The variety *Fortunei* measures 72 feet high, with a girth of 8 feet, a beautiful pyramidal tree, displaying the stem below with its characteristic stringy bark. This tree was planted in 1847.

(H. J. E.)

PYRUS

Pyrus, Linnæus, *Gen. Pl.* 145 (1737); Bentham et Hooker, *Gen. Pl.* i. 626 (1865).

Malus, Ruppert, *Fl. Jen.* ed. 3, 141 (1745); and Medicus, *Phil. Bot.* i. 138 (1789).

Sorbus, Linnæus, *Gen. Pl.* 144 (1737).

TREES and shrubs belonging to the sub-order Pomaceæ of the order Rosaceæ. Branchlets of two kinds, long and short shoots, the flowers in certain species being borne on the latter only. Leaves deciduous, alternate, stalked, simple or pinnate; stipules deciduous. Flowers in cymes or corymbs, regular, perigynous or epigynous, calyx-lobes 5, petals 5. The receptacle (the end of the axis) is hollowed out, the ovary being attached to its interior. A disc is present, either annular or coating the receptacle. Ovary with 2 to 5 cells, each cell containing 2 ovules. Fruit, a pome, the external fleshy part being formed of the receptacle, while the interior or core is the developed ovary; cells 2 to 5, with a membranous or cartilaginous endocarp, each containing 1 or 2 seeds, though occasionally some are empty.

The genus *Pyrus* has been divided variously into sections, which some botanists treat as distinct genera. The following arrangement is perhaps the simplest:—

A. Leaf in the bud rolled inwards towards the midrib.

1. **Pyrophorum.** Flowers in corymbs on spur-like branchlets, ovary with 5 cells, styles free. Fruit pyriform or hollowed out at the base, flesh granular. Leaves simple. Pears: confined to Asia and Europe.
2. **Malus.** Flowers fascicled or umbellate on spurs, ovary with 3 to 5 cells, styles united at the base. Fruit with a cavity at the base, flesh homogeneous. Leaves simple. Apples: species in North America as well as in Europe and Asia.
3. **Aronia.** Flowers in terminal corymbs, ovary with 4 to 5 cells, styles free or united at the base. Fruit small, not hollowed at the base, endocarp very thin, flesh almost homogeneous. Leaves simple, crenate, with the midrib glandular on its upper side. Two North American shrubs.

B. Leaf folded in the bud. Flowers in terminal corymbs.

4. **Hahnia.** Ovary with 2 to 3 cells, styles united below. Fruit crowned by the calyx, and having a hard, almost bony endocarp, flesh granular. Leaves simple, lobed. *Pyrus torminalis*, the only species.

5. **Sorbus.** Ovary with 3 or 5 cells, styles free. Fruit crowned by the calyx, endocarp membranous or coriaceous. Leaves pinnate. Includes two subsections:—

Aucuparia, with 3-celled ovary and small globular fruit, and
Cormus, with 5-celled ovary and large pear- or apple-shaped fruit.

6. **Aria.** Ovary with 2 to 5 cells, styles free. Fruit crowned by the calyx, endocarp membranous, flesh granular. Leaves simple. Includes the whitebeam and its allies.
7. **Micromeles.** Ovary with 2 to 3 cells. Fruit small, globose, umbilicate, endocarp membranous or coriaceous, calyx-lobes deciduous. Leaves simple. Includes several Asiatic species.

SYNOPSIS OF THE PRINCIPAL SPECIES IN CULTIVATION EXCLUSIVE OF
PEARS AND APPLES.

(Cf. Plates 43-45, where leaves of most of the species are shown.)

- I. *Leaves regularly pinnate, the leaflets being separate and never decurrent by their bases on the rhachis.*

A. **Aucuparia.** Mountain ashes. Leaflets unequal-sided at the base. Fruit small, not exceeding $\frac{1}{3}$ inch.

(1-3) *Winter buds white-tomentose.*

1. **Pyrus Aucuparia**, Gaertner. Europe, Northern Asia, Japan. Young branchlets and leaves pubescent, adult leaves glabrous or only slightly pubescent beneath. The common mountain ash.
2. **Pyrus lanuginosa**, DC. South-eastern Europe. Only differs from the preceding in the adult leaves being densely woolly beneath.
3. **Pyrus thianschanica**, Regel. Chinese Turkestan. Young branchlets and leaves glabrous; adult leaves quite glabrous beneath and conspicuously veined on the upper surface.

(4-5) *Winter buds shining, glutinous, glabrous or sparingly pubescent, the pubescence appressed and of a rusty colour.*

4. **Pyrus americana**, Torrey and Gray. North America. Leaflets long, narrow, acuminate, glabrous beneath.
5. **Pyrus sambucifolia**, Chamisso and Schlechtendal. Manchuria, North-East Asia, Japan, North America. Leaflets broader than in No. 4, obtuse or acute (not acuminate), more or less pubescent beneath.

B. **Cormus.** True Service. Leaflets nearly equal sided at the base. Fruit large, $\frac{1}{2}$ inch diameter or more.

6. **Pyrus Sorbus**, Gaertner. Central and Southern Europe. Winter buds greenish, viscid, pubescent only at the tip; under surface of the leaves slightly pubescent in spring, soon becoming glabrous.

II. *Leaves pinnate, but upper 3 or 5 leaflets coalesced or decurrent by their bases on the rhachis.*¹

7. **Pyrus Aucuparia**, Gaertner, var. **satureifolia**, Koch. A hybrid. Differs from the common form in the coalescence into one large segment of the 3 upper leaflets; leaflets glabrous beneath.

8. **Pyrus Aucuparia**, Gaertner, var. **decurrens**, Koehne (*Pyrus lanuginosa*, Hort. non DC.) A hybrid. Upper leaflets decurrent on the rhachis by broad bases, often the upper 3 or 5 coalescing into one segment; leaflets tomentose beneath.

III. *Leaflets pinnate or deeply cut at the base, with 1-4 pairs of segments, the upper part of the leaf lobed or serrate; leaves very variable in shape.*¹

9. **Pyrus hybrida**, Moench. A shrub of hybrid origin. Main axis of the leaf glandular above, under surface of the leaf sparingly pubescent, the parents being *Pyrus aucuparia* and *Pyrus arbutifolia*.

10. **Pyrus pinnatifida**, Ehrhart. A hybrid. Axis of the leaf without glands, under surface densely grey tomentose.

IV. *Leaves simple, lobed.*

A. *Under surface of the leaf glabrous, or nearly so, light green in colour.*

11. **Pyrus torminalis**, Ehrhart. Europe, Algeria, Asia Minor, and the Caucasus.

B. *Under surface of the leaf grey tomentose.*

12. **Pyrus cratægifolia**, Savi. Italy. Leaves small, resembling those of a hawthorn, on each side 4-6 triangular-ovate toothed lobes.

13. **Pyrus latifolia**, Boswell Syme. Britain, France, Spain, Central Europe. Leaves broad-oval with a wide base; lobes decreasing from below upwards, small triangular, separated by sinuses, which form a right angle and are not narrowed. In some forms the lobes are mucronate, in others cuspidate; and, in var. *decipiens*, the outline of the leaf is like *intermedia*, but the lobing is different.

14. **Pyrus intermedia**, Ehrhart. Europe. Leaves elliptic, with a usually narrow base, lobes decreasing from below upwards, rounded, mucronate, separated by narrow sinuses, which are very acute or almost closed at their bases. This includes several forms:—

Mougeoti. Leaves with 9-12 pairs of nerves, lobes shallow.

¹ These two sections comprise hybrids, the leaves of which vary in shape, not only on different individual trees, but often also on a branch. Hybrid origin may always be suspected when such variation is observed, or when the lobing or cutting is irregular and not symmetrical.

Scandica. Leaves with 7-9 pairs of nerves, lobes deep, with sharp teeth.

Minima. Leaves with 5-7 pairs of nerves, smaller and narrower than in the preceding varieties.

Certain forms of *Pyrus pinnatifida* closely resemble *scandica*, but the lobing in these will be found always irregular and often very deep.

15. ***Pyrus lanata***, D. Don. Himalayas. Leaves large, broad oblong, woolly underneath, nerves 12-15 pairs, lobes regularly serrate.

C. *Under surface of the leaves, which are orbicular in outline, snowy-white tomentose.*

16. ***Pyrus Aria***, Ehrhart, var. *flabellifolia*. Greece. Leaves with 3-5 pairs of nerves.

17. ***Pyrus Aria***, Ehrhart, var. *græca*. Greece, Asia Minor. Leaves with 6-10 pairs of nerves.

V. *Leaves simple, not lobed, and only occasionally obscurely lobulate.*

A. **Aronia.** *Leaves finely serrate in margin, with glands on the upper surface of the midrib.* This section comprises 2 North American species and a hybrid of garden origin, small shrubs, only referred to here to prevent their being confused with other species of *Pyrus*.

18. ***Pyrus arbutifolia***, Linnæus fil. North America. Leaves beneath whitish grey tomentose, with about 6 pairs of nerves directed forwards at a very acute angle.

19. ***Pyrus alpina***, Willdenow. A hybrid between *Pyrus Aria* and the preceding species. Leaves densely grey tomentose beneath, with 9-10 pairs of nerves directed outwards at an angle of 45°.

20. ***Pyrus nigra***, Sargent. North America. Leaves glabrous beneath or very slightly pubescent.

B. *Leaves without glands on the midrib.*

(21-22) *Leaves glabrous beneath.* These 2 species, of which the first is a shrub and the other a small tree, are only referred to here to distinguish them from other species.

21. ***Pyrus Chamæmespilus***, Linnæus. Vosges, Jura, Alps, Pyrenees. Leaves sessile or nearly so, elliptic, with 6-8 pairs of nerves.

22. ***Pyrus alnifolia***, Franchet and Savatier. Japan and China. Leaves stalked, broadly ovate, with 9-12 pairs of nerves.

(23-26) *Leaves white pubescent beneath.*

23. ***Pyrus Aria***, Ehrhart. Europe, Caucasus, Siberia, Central China. Leaves oval or elliptic with very slight lobules or only doubly-toothed, the teeth or lobules diminishing in size from above downwards; nerves 7-12 pairs, very prominent on the lower surface, pubescence snowy white.

24. ***Pyrus Aria***, Ehrhart, var. *rupicola*. British Isles (Europe?) Leaves obovate-oblong (broadest above the middle), lobulate above, the lobules and teeth acute, nerves 5-9 pairs, pubescence at first as white as in the type, but ultimately becoming greyer.

25. ***Pyrus Aria***, Ehrhart, var. *Decaisneana*. Origin unknown. Leaves large, elliptic, or oblong, with margin serrated almost uniformly, nerves 12-15 pairs.

26. ***Pyrus Hostii***, Hort. A hybrid. Leaves like 23, but with very sharp, irregular teeth and tomentum *thin*, white to greyish white.

(27) *Leaves grey, densely-woolly pubescent beneath.*

27. ***Pyrus vestita***, Wallich. Himalayas. Leaves very large, elliptic, serrate, and occasionally obscurely lobulate in margin; nerves 15-18 pairs.

As many of the species mentioned above are merely shrubs or very small trees, they do not fall within the scope of our work. For this reason, *Pyrus hybrida*, *cratægifolia*, *Chamæmespilus*, *alnifolia*, and the three species of the section Aronia, will not be further referred to. *Pyrus Hostii*, a hybrid of inconstant origin, will be briefly mentioned in connection with *Pyrus Aria*.

Pyrus Aucuparia and its allies will be dealt with in a subsequent part.

The two following species are not known to us to attain timber size in cultivation in the British Isles; but Mr. H. C. Baker tells us that at Chilternhouse, near Thame, there is a specimen of *P. vestita* 50 feet by 6 feet 5 inches.

PYRUS LANATA, DON.¹

Known in gardens as *Sorbus majestica*. A tree of the eastern temperate Himalayas; leaves large, oval, oboval, or broadly oblong, with serrate lobes, glabrous above when adult except for some pubescence along the midrib, greyish woolly beneath. Flowers white in densely woolly corymbs; petals glabrous within; styles 2 to 5, free, densely tomentose. Fruit large, about an inch in diameter ($\frac{1}{2}$ to $1\frac{1}{2}$ in.), narrowed to the base, red, edible. Judging from wild specimens the foliage is very variable; and the cultivated specimen at Kew bears leaves (figured in Plate 43), which differ from those of wild trees in being less deeply lobed.

PYRUS VESTITA, WALL.²

Often known in gardens as *Sorbus nepalensis* or *Sorbus magnifica*. A tree of the temperate Himalayas from Garwhal to Sikkim. Leaves (*cf.* Plate 43) very large, ovate-acute or elliptic, lobulate-serrate, densely covered with white wool when they first appear, but later in the season becoming shining green and glabrous above, remaining densely woolly beneath. Flowers in very woolly corymbs; petals woolly within; styles 3-5, tomentose only at the base. Fruit large, about $\frac{3}{4}$ inch in diameter, globose.

PYRUS SORBUS, TRUE SERVICE¹

Pyrus Sorbus, Gaertner,² *De Fruct.* ii. 43, t. 87 (1791), Loudon, *Arb. et Frut. Brit.* ii. 921 (1838).

Pyrus domestica, Ehrhart,² "Plantag," 20, ex *Beiträge zur Naturkunde*, vi. 95 (1791); Smith, *Eng. Bot.* t. 550 (1796).

Sorbus domestica, Linnæus, *Sp. Pl.* 477 (1753).

Cormus domestica, Spach, *Hist. Vég. Phan.* ii. 97 (1834).

A tree, attaining a height of 60 to 80 feet. Bark, like that of the common pear, dark brown, fissuring longitudinally, and scaling off in narrow, rectangular plates. Leaves pinnate: 6 to 9 pairs of sessile leaflets and a terminal stalked leaflet. Leaflets linear oblong, almost equal-sided at the base, and acute at the apex, serrate with acuminate teeth, except towards the base where they are entire; dull green above, paler below, glabrous on both surfaces when mature, some pubescence often, however, remaining underneath. Flowers white, in short pubescent corymbs; styles 5, united at the base and woolly in their whole length. Fruit either pear- or apple-shaped, generally green, tinted with red on one side, 5-celled, about an inch in diameter.

The fruit apparently varies much in flavour, but in good varieties is agreeable though astringent. The French proverb, *Ils ne mangent que les cormes*, applied to destitute persons, would indicate that the fruit was poor; and this is doubtless often the case. In parts of France a perry is made from them, and they are also preserved dry like prunes. At Vevay³ in Switzerland there are avenues planted, consisting of service trees of various kinds; and the brilliancy of the fruit and of the hues of the foliage in October give a very fine effect.

VARIETIES

Two well-marked forms occur, one *maliformis*,⁴ with apple-shaped fruit, the other *pyriformis*,⁴ with pear-shaped fruit. There would seem, however, to be in France, though little known to planters in general, varieties which produce fruit of a superior kind. Two of these are strongly recommended by a writer in the Journal of the French National Horticultural Society: ⁵ one discovered on the estate of M. Dufresne, near Bordeaux, which has large pyriform fruits of a carmine yellow, produced in large bunches and excellent in flavour, as soon as they commence to mellow; the other was also found growing wild in woods belonging to M. Lafitte at Agen, which has fruit of a bright pink colour.

¹ *Service* is commonly derived from the Latin *cerevisia*, a drink said to have been formerly made of berries of the different species of Sorbus, or to have been flavoured with their leaves. C. Woolley Dod controverts this view in *Gard. Chron.* 1890, vii. 87, and holds that *service* is simply a corruption of *sorbus*, and that *cerevisia*, a drink, according to Pliny, made of cereal grain in Gaul, was ordinary malt ale.

² Gaertner's and Ehrhart's names were both published in the same year. Gaertner's preface antedates that of Ehrhart by a few days. Nothing is known for certain of the pamphlet "Plantag" cited by Ehrhart. Which name has priority of publication is uncertain.

³ *Woods and Forests*, July 16, 1884.

⁴ Loddiges, *Catalogue*, ex Loudon, *loc. cit.*

⁵ Quoted in *Garden*, 1886, xxx. 89.

IDENTIFICATION

In summer the tree is only liable to be confused with the mountain ash and its allies. The bark is, however, different, being rough, scaly, and dark-coloured in the true service tree, smooth and grey in *Pyrus Aucuparia*, etc. In *Pyrus Sorbus* the leaflets at the base are practically symmetrical, and their serration is very acute. Buds if present are the best distinction, as explained below.¹ In winter *Pyrus Sorbus* is distinguished by the following characters, shown in Plate 45:—

Twigs: long shoots glabrous, round; leaf-scars, crescentic with 5 bundle dots, set parallel to the twig on projecting cushions. Terminal buds larger, side buds coming off at an acute angle; all ovoid, densely viscid, shining, generally pubescent at the tip. Bud scales few in number, greenish, sometimes reddened, viscid, quite glabrous, the margin without cilia. Short shoots ringed, glabrous, ending in a terminal bud. The viscid greenish buds, 5-dotted leaf-scars, and rough scaly bark, distinguish this species from other kinds of Pyrus.

DISTRIBUTION

The Service tree is largely cultivated in central and southern Europe; and in many places, where it is recorded as wild, is really only an escape from cultivation. It is met with in the forests of France which rest upon limestone; but in the north and east it does not produce fruit every year, and is doubtfully wild except in the south and west. Willkomm considers it to be wild in the southern parts of the Austrian empire (Dalmatia, Croatia, Banat, Carniola, and South Tyrol), in the valley of the Moselle, in the Jura and Switzerland; also in southern Europe and Algeria. In France it is occasionally met with as a standard in coppiced woods.

Mouillefert says that the tree may live to be 500 or 600 years old, and that it was uninjured by the severe frost of 1879-80, when the thermometer fell to -25° Reaumur. He says, also, that it prefers a rich calcareous soil, but will grow on sand if not too dry. (A. H.)

REMARKABLE TREES

Pyrus Sorbus is not a native of Britain, though a single specimen which grew in a remote part of Wyre Forest in Worcestershire was long considered to give it a claim to be introduced into the British flora. This tree was mentioned in the *Philosophical Transactions*² as long ago as 1678 by Mr. Pitt, who says that he found it in the preceding year as a rarity growing wild in a forest of Worcester, and identifies it with the *Sorbus pyriformis* of L'Obelius, a tree not noticed by any preceding writer as a native of England. Pitt says nothing about the size of the tree, merely observing: "It resembles the Ornus or quicken tree, only the Ornus bears the flower

¹ The stipules of the various species of the section Sorbus differ considerably in shape, as shown in Plate 43; but they are usually quickly deciduous, and can only assist identification in spring.

² *Phil. Trans.*, abridged edition, ii. 434 (1809).

and fruit at the end, this on the sides of the branch. Next the sun, the fruit has a dark red flush, and is about the size of a small jeneting pear. In September, so rough as to be ready to strangle one. But being then gathered and kept till October, they eat as well as any medlar."

Ray's account¹ in 1724 is as follows: "The true Service or Sorb. It hath been observed to grow wild in many places in the mountainous part of Cornwall by that ingenious young gentleman, Walter Moyle, Esq., in company with Mr. Stevens of that county. I suspect this to be the tree called *Sorbus pyriformis*, found by Mr. Pitt, alderman of Worcester, in a forest of that county, and said to grow wild in many places of the morelands in Staffordshire by Dr. Plot, *Hist. Nat. Stafford*, 208." In modern times the tree has, however, never been found wild in any part of Cornwall or Stafford, and probably it was confused with *Pyrus latifolia*.²

Nash,³ in 1781, refers to the tree in the Wyre forest as occurring "in the eastern part of Aka or Rock parish, about a mile from Mopson's Cross, between that and Dowles Brook, in the middle of a thick wood belonging to Mr. Baldwyn, which I suppose to be the *Sorbus sativa pyriformis*, mentioned by Mr. Pitt in the *Philosophical Transactions for 1678*, called by the common people the Quicken pear tree." This tree was figured by Loudon,⁴ t. 644, from a drawing sent him by the Earl of Mountmorris. The Rev. Josiah Lee, rector of the Far Forest, told Mrs. Woodward that the old inhabitants of the district, where it was called the "Whitty Pear tree," used to hang pieces of the bark round their necks as a charm to cure a sore throat. Lee's *Botany of Worcestershire*, 4, gives a good figure of this tree "from a sketch taken many years ago," and another as it appeared in 1856; and says that in 1853 it was in a very decrepit state, producing a little fruit at its very summit. It was burnt down in 1862, by a fire kindled at its base by a vagrant. In a note Lees says that he thinks the tree must have been brought from Aquitaine and planted beside a hermitage in the forest, of which no trace is left but a mound of stones overgrown by brambles. He found the privet and *Prunus domestica* occurring near it, and nowhere else in the forest.

A seedling (Plate 46) from the Wyre forest tree is growing on the lawn at Arley Castle, near Bewdley, formerly the property of Lord Mountmorris, now the residence of Mr. R. Woodward. I measured it in 1903, when it was 55 feet high by 7 feet 4 inches in girth, and quite healthy, though a large hole in the trunk has been filled with cement. A few seedlings have been raised from it at Arley, but grow very slowly.

There is a large healthy tree in the park at Ribston Hall, Wetherby, the seat of Major Dent, of the pyriform variety, which in 1906 I found to be about 65 feet high by 9 feet in girth, and bearing fruit. This tree was probably brought from France by the same Sir. H. Goodricke who sowed the original Ribston pippin in 1709.

¹ Ray, *Synopsis Methodica*, ed. 3, p. 542.

² Miller, *Gard. Dict.* iii. ed. (1737), under *Sorbus sativa*, says, "The manured service was formerly said to be growing wild in England; but this I believe to be a mistake, for several curious persons have strictly searched those places where it was mentioned to grow, and could not find it; nor could they learn from the inhabitants of those countries that any such tree had ever grown there."

³ *History of Worcestershire*, i. 11.

⁴ Loudon gives the measurements in 1838 as 45 feet high, with a diameter of trunk at a foot from the ground of 1 foot 9 inches, and states that it was in a state of decay at that time.

At Croome Court, the seat of the Earl of Coventry, there are two good-sized trees in the shrubbery, one of which is 59 feet high and 6 feet 2 inches in girth. The other, with a clean stem, about 50 feet by 7, is beginning to decay.¹ Lady Coventry told me that the fruit, which is only produced in good seasons, makes excellent jam when fully ripe, but some seeds which she was good enough to send me did not germinate.

Loudon mentions a tree at Melbury Court, Dorsetshire, estimated to be 200 years old, and 82 feet high, with a diameter of 3 feet 4 inches, growing in dry loam on sand. If this was really a true sorb, it must have been the largest on record, but I learn from the gardener at Melbury that it has long been dead.

There are two good-sized trees at Painshill, and another at Syon which Henry found to be 44 feet high and 6 feet 9 inches in girth, but on this heavy soil the tree does not seem to be so long lived, and is dying at the top.

In the Botanic Gardens at Oxford are two well-shaped trees of this species, which were laden with fruit in 1905, and supposed to have been planted by Dr. John Sibthorp, who was Professor of Botany in 1784-95. The largest measures about 50 feet by 5 feet, and is of the maliform variety. Its fruit, which ripens and falls about the middle of October, is very sweet and pleasant to eat, much better than medlars, whilst the fruit of the other, which is the pyriform variety, does not turn red, is smaller, and ripens later. I have raised seedlings from both of these trees.

In the Cambridge Botanic Garden there is a tree with very upright branches, which measured, in 1906, 42 feet by 3 feet 4 inches.

At Tortworth there is a healthy, well-shaped tree, not more than 40 years planted, which is about 40 feet by 5 feet 11 inches. This is in a rather exposed situation, and it had no fruit in 1905.

At Woodstock, Co. Kilkenny, Ireland, there is a tree which seems to be the largest now living in this country. Henry measured it in 1904 and found it 77 feet high by 10 feet 8 inches in girth, with a bole dividing into three stems at 10 feet from the ground and bearing fruit.

TIMBER

A large tree was blown down at Claremont Park, Surrey, the seat of H.R.H. the Duchess of Connaught, in 1902, which I am assured by Mr. Burrell, the gardener there, was a sorb.² Its trunk was sent to Mr. Snell of Esher, to whom I am indebted for two fine planks of its wood. These show a very hard, heavy, compact surface of a pinkish brown colour with a fine wavy grain, which takes an excellent polish, and this wood has been used with beautiful effect in the framing

¹ Loudon speaks of a tree at Croome 45 years planted, and 80 feet high, which is possibly the same, but his measurements are very unreliable.

² "Among interesting trees to be found at Claremont is a good specimen of the pear-shaped service, carrying a heavy crop of fruit. It is rather over 60 feet high and 7 feet 6 inches in girth at 2 feet from the ground." Note by E. B. in *Garden*, 1883, xxiv. 422. Mr. E. Burrell gives a fuller account of the Claremont trees in the same journal, 1888, xxxiii. 154, in which he states that he thinks the variety *maliformis* does not increase in height after it gets to be about 30 feet high, whereas *pyriformis* at Claremont is close on 70 feet high.

of a brown oak chest, made for me by Messrs. Marsh, Cribb, and Co., of Leeds. Mouillefert says it is one of the hardest and most valuable woods grown in France, and is especially sought for by engravers, carvers, turners, and gun-makers. It seems to be difficult both to propagate and to grow, at least in its youth, and Loudon says that though it may be grafted on the pear or the mountain ash, it is one of the most difficult trees to graft, and that it will not layer successfully, and that it grows very slowly from seed, not attaining more than 1 foot high in four years. Seeds¹ sown in autumn germinate in the following spring. The young seedling has two oval entire-margined cotyledons, and attains about 4 inches in height in the first year's growth. Plants may be had from the French nurserymen. Mr. Weale, of Liverpool, reports as follows on a sample of this wood which I sent him:—"The wood is close and homogeneous in texture, tough, but inclined to be brittle. Rays on transverse section invisible, and rings only to be distinguished by the difference in colour of the spring and autumn wood. Harder than whitebeam, seasons well, without warping or splitting, and with little shrinkage. A reliable wood when thoroughly dry."

(H. J. E.)

PYRUS TORMINALIS, WILD SERVICE

Pyrus torminalis, Ehrhart, "Plantag." xxii. ex *Beit. zur Naturkunde*, vi. 92 (1791); Loudon, *Arb. et Frut. Brit.* ii. 913 (1838); Conwentz, *Beob. über Seltene Waldbäume in West Preussen*, 3 (1895).
Crataegus torminalis, Linnæus, *Sp. Pl.* 476 (1753).
Sorbus torminalis, Crantz, *Stirp. Austr.*, ed. 2, fasc. ii. 85 (1767).
Torminaria Clusii, Roemer, *Synopsis*, iii. 130 (1847).

A tree, attaining exceptionally a height of 80 feet, but more generally only reaching 40 or 50 feet. Bark smooth and grey at first, but after fifteen or twenty years of age scaling off in thin plates, and ultimately becoming fissured. Leaves long-stalked, broadly oval, nearly as broad as long, with a cordate or truncate base and an acute apex; with 6-10 triangular acuminate serrate lobes; shining and glabrous above, obscurely pubescent beneath; nerves pinnate, 5-8 pairs. Flowers white in corymbs. Styles 2, glabrous, united for the greater part of their length. Fruit ovoid, brownish when ripe, with warty lenticels, vinous in taste when in a state of incipient decay; cut across transversely it shows a ring of white hardened tissue, forming a mesocarp around the core.

The leaves are generally described as glabrous on the under surface, but in all specimens traces of pubescence may be observed, which is much more marked on coppice shoots and epicormic branches.

VARIETIES

None have been obtained in cultivation so far as we know, and wild trees vary very little in any of their characters. A variety, *pinnatifida*, with the lobing of the leaves very deep, is described by Boissier,¹ from specimens occurring in Asia Minor and Roumelia.

IDENTIFICATION

The leaves in summer are unmistakable (see Plate 44), and can only be confounded with certain forms of *Pyrus latifolia*; but in the latter species the under surface of the leaf is always plainly grey tomentose, and the lobes are much shorter than in *P. torminalis*. In winter the following characters, shown in Plate 45, are available.

Twigs: long shoots, glabrous, shining, somewhat angled, with numerous lenticels; leaf-scar semicircular with 3 bundle traces, set parallel to the twig on a greenish cushion. Buds almost globular, terminal larger, side-buds nearly appressed to the twig; scales green with a narrow brown margin, glabrous, with the apex double-notched. Short shoots slightly ringed, glabrous, ending in a terminal bud.

(A. H.)

¹ *Flora Orientalis*, ii. 659 (1872.)

DISTRIBUTION

The most complete and recent account of the tree is a monograph cited above with maps by Prof. H. Conwentz, who describes at great length the various places where the tree is found and the conditions under which it grows. It is widely distributed throughout most of the woods and forests of Europe, but does not occur in Scandinavia, Holland, or the greater part of Russia, where it is only met with in the southern provinces. It also occurs in the Caucasus, Asia Minor, Syria, and in Algeria. It is found on most geological formations, including granite in the Vosges, gneiss in Siberia, and basalt in Austria; and it prefers a soil rich in humus. Willkomm says that on mountains it is commoner on limestone than on other soils, but the French foresters say that it is practically met with on all soils that are not very dry or very wet. It is a tree of the lowlands and hills, attaining 700 metres altitude near Zurich, 1200 in Herzegovina, and 1900 in the Caucasus. It occurs more or less rarely over all parts of Germany, especially in the north-east, and it attains its maximum size in the royal forest of Osche in West Prussia. The largest tree known to Conwentz was "25 metres high, with a clean stem of 12 metres, and a girth at 1 metre from the ground of 2 metres." The age of this tree was estimated from the rings in the broken trunk of another tree at 235 years.

The scarcity of the tree, as a rule, cannot be accounted for by any deficiency in reproductive powers, for the fruit is produced in some abundance in good years; and being eaten by many birds and animals, among which the waxwing chatterer, the nutcracker, and the fieldfare are mentioned, the seeds must be widely dispersed, while the freedom with which the roots produced suckers is remarked upon.

The timber seems to be much more highly valued in Germany than here, from 18 to 52 marks per cubic metre being given for it, according to quality, in places where hornbeam is only worth 11 marks. It is very hard and durable, and takes a fine polish like that of maple.

In the Hartz mountains and Thuringia it is known as "Atlasholz," and is much used and valued for furniture making.

The fruit is not so much valued as formerly, when it was sold in Prague and Vienna in the winter at the market, and also in Wurtemberg, under the names of Häspele, Arlesbeere, or Adlsbeere.

Conwentz says that the Latin name *torminalis* was derived from the Latin word *tormina*, and given on account of the properties of the fruit, to which one of its names in England, "gripping service tree," also has reference.

In Upper Alsace a spirit is distilled from the fruit, which tastes something like Kirschwasser.

DISTRIBUTION AND REMARKABLE TREES IN ENGLAND

Pyrus torminalis does not occur as a wild tree, and is rarely planted in Ireland, Scotland, or the North of England. Its range is from Anglesea and Nottingham southwards. It is known as the service or gripping service tree; and in Kent and

Sussex the fruit is called chequers. It is found in woods, copses, and hedgerows, usually on loam or clay, but does not seem to grow on sandy soils. It attains its greatest size in the Midland counties, where it reaches a height of from 50 to 70 feet. It never seems to be gregarious, and though it reproduces itself by seed or suckers, yet being usually looked on as underwood and not allowed to grow up to its full size, does not attract notice, and is unknown except to the most observant woodmen, even in districts where it occurs. In the vale of Gloucester, on the Earl of Ducie's property, there are probably thirty or forty trees of it scattered over a considerable area. The tallest of these, though not the thickest, is in Daniel's Wood, and is figured (Plate 47). This tree was 62 feet by 5 feet 1 inch in 1904, and is still growing vigorously among other trees and underwood. Not far off is another which may grow to as fine a tree.

In the Cotswold Hills the tree is very rare. I only know a single decaying specimen of moderate size in Chedworth Wood, close to the road leading from Withington to Chedworth Downs.

On Ashampstead Common, in Berks, I found one about 65 feet high and 8 feet in girth, crowded among other trees, which had produced a few suckers. At Rickmansworth Park, Herts, are two fine trees growing together by a pond, which are probably planted (Plate 48), and which Henry measured in 1904, when they were 65 feet by 8 feet 3 inches, and 63 feet by 9 feet 1 inch respectively. The largest specimen known to me is at Walcot, Shropshire, growing on a bank in good soil with a wych elm crowding it on one side, but probably planted. It measures as nearly as I could estimate about 80 feet high, and is no less than 8 feet 9 inches in girth.

At Cobham Hall, Kent, a tree planted beside a pond measured 55 feet high by 4½ feet in 1906.

In the woods in Worcestershire, as I am informed by Mr. Woodward, it is not uncommon, but is not looked upon as of any value. There is a tree at Arley 5 feet 1 inch in girth. In Wychwood Forest, Oxon, now nearly all destroyed, I am informed by Mr. R. Claridge Druce, of Oxford, the tree was formerly common enough for its fruit to be collected and sold in Witney market under the name of service berries.

In Cornbury Park, and in the remains of the forest outside it, there are at least six good-sized trees surviving. Of these the largest, just outside the park wall on the south side, is 65 to 70 feet high by 6 feet 6 inches in girth, a well-shaped, vigorous tree, which on 16th October 1905 was covered with unripe fruit. Another, also outside the park, is about 50 feet by 6 feet 10 inches, with a fine clean bole 12 to 14 feet long. I saw no suckers or seedlings near these trees.

In the woods and coppices north and north-east of London, and in Herts, the tree is not unfrequent on clay soil, and Pryor¹ gives several localities for it.

In Epping Forest, Mr. E. N. Buxton tells me that he does not know of more than thirty trees on an area of 3000 acres, growing on heavy gravelly clay. The largest in his grounds is 40 to 50 feet high.

¹ *Flora of Hertfordshire*, 154 (1887).

In Sussex, Sir E. Loder knows it as an uncommon hedgerow tree of no great size, and Mr. Stephenson Clarke, of Borde Hill, also tells me that it occurs there, and more commonly in the Isle of Wight, where, in Bridlesford Copse, Woolton, a wood of about 200 acres, are perhaps two dozen old trees, which differ in appearance from the Sussex ones in assuming a somewhat pendulous habit of branching when well grown. I find no mention of the occurrence of the tree in the New Forest, and the Hon. G. W. Lascelles does not know it there.

We have no record of *Pyrus torminalis* as a planted tree in Scotland, except that the Rev. Dr. Landsborough¹ notes a tree in vigorous health in Bellfield Avenue, Kilmarnock, which was 2 feet 9 inches in girth in 1893. He calls it the English service tree or table rowan, and adds that, in spite of its Latin name, the fruit is pleasant. In Ireland the tree is very rare. Henry saw, however, a fine specimen in 1903, at Adare, Limerick, which measured 53 feet by 5 feet 10 inches.

The fruit is ripe late in October, when it falls, if not previously eaten by birds, and the seeds, which only seem to mature in warm summers, should be sown at once, or kept in sand exposed to the weather and sown in spring, when they will germinate the next year. Seedlings raised by me from seed gathered at Les Barres, France, which were sown 7th July 1902, germinated 9th March 1903, and were on 14th October 1904 1 to 2 feet high. The leaves turn a reddish yellow in autumn, when the tree is decidedly ornamental, though, on account of its slow growth, it does not seem to have any value as a forest tree, and is rarely procurable from nurserymen in this country.

TIMBER

Pyrus torminalis is unknown as a timber tree in the trade owing to its scarcity, and is mentioned by Boulger² only as "a small tree, sometimes 30 feet high, with wood practically identical in character and uses with that of the rowan." Stone does not mention it at all, and Marshall Ward, in his edition of Laslett, says nothing worth quoting.

I am indebted to Mr. Stephenson Clarke for a log of the timber, which resembles that of the whitebeam tree, being hard, heavy, and, according to Loudon, weighing, when dry, 48 lbs. per cubic foot.

Mr. Weale, of Liverpool, reports as follows on a sample of this wood which I sent him:—"Of a hardness between true service tree and whitebeam. Rays on transverse section just visible, a little narrower than sycamore, but wood generally exhibits similar characters. Takes a good finish, but this is not lasting, the ring boundaries rising after exposure. Seasons fairly well, shrinks a little, and rather inclined to twist."

Evelyn says that "the timber of the sorb is useful to the joiner, of which I have seen a room curiously wainscotted; also to the engraver of woodcuts, and for most that the wild pear tree serves." (H. J. E.)

PYRUS LATIFOLIA, SERVICE TREE OF FONTAINEBLEAU

Pyrus latifolia, Boswell Syme, *Bot. Exchange Club Report*, 1872-1874, p. 19 (1875).

Pyrus rotundifolia, Bechstein, N. E. Brown in *Eng. Bot.* iii. ed. Suppl. 164 (1892).

Crataegus latifolia, Lamarck, *Flore Française*, ed. i. 486 (1778).

Sorbus latifolia, Persoon, *Syn. Pl.* ii. 38 (1807).

A tree, attaining a height of 60 feet in France, with smooth, grey bark, which becomes fissured at the base in old trees. Leaves broadly oval, with a broad, rounded, or truncate base and an acute apex; margin with small triangular lobes, decreasing in size from the base of the leaf upwards, dentate and mucronate, the sinuses opening between the lobes almost at a right angle. The leaves are firm in texture, shining and glabrous above, tomentose and greyish green beneath, with 6 to 10 pairs of lateral nerves prominent underneath. Flowers in moderate-sized corymbs, never long peduncled. Fruit globular, $\frac{1}{2}$ inch diameter, smooth, reddish, marked with brown dots, flesh edible; containing two cells, one seed in each cell, or more often one cell with one seed, the other cell containing two aborted ovules.

The description just given is drawn up from Fontainebleau specimens; and trees absolutely identical are said to occur in various forests in Seine-et-Oise, Seine-et-Marne, Marne, Aube, and Yonne.

A series of forms,¹ however, occur in the forests of the east of France, in Alsace-Lorraine, Spain, Switzerland, Austria-Hungary, and Bosnia, which differ slightly in the general outline of the leaf and in the colour and marking of the fruit; and these are supposed to be hybrids between *Pyrus Aria* and *Pyrus torminalis*, between which species they oscillate in the characters of the foliage and fruit; whereas, according to French botanists, the tree of Fontainebleau is a true species, as it reproduces itself naturally by seed; and, moreover, one of the supposed parents, *Pyrus Aria*, is not, according to Fliche, wild in the forest of Fontainebleau.² However, the differences are trifling; and it is convenient, in the present state of our knowledge, to treat these supposed hybrids as varieties of *Pyrus latifolia*.

VARIETIES

Var. *rotundifolia* (Bechstein).³ Leaves broadly oval or suborbicular, sometimes even broader than long, truncate or rounded at the base, sub-obtuse at the apex; lobes obtusely cuspidate.

Var. *decipiens* (Bechstein).⁴ Leaves elongated with acute bases, much resembling

¹ These may be called, if their hybridity is considered to be established, *Pyrus Ario-torminalis*, Garcke, *Flora von Deutschland*, ed. 17, 207 (1895). Fliche, in Mathieu, *Flore Forestière*, 177 (1897), sums up the question thus:—Fontainebleau tree not a hybrid, near to *Pyrus Aria*, a true species, seed germinating readily and producing natural seedlings; Lorraine tree nearer to *Pyrus torminalis* than to *Pyrus Aria*, a true hybrid, seeds rarely perfect. Rouy et Fourcaud, *Flore de France*, vii. 22 (1901), suggest that the Fontainebleau tree is a hybrid fixed and behaving as a true species. See also Irmisch in *Bot. Zeitung*, 1859, p. 277.

² Cf., however, p. 156, note 2.

³ *Pyrus rotundifolia*, Bechstein, *Forstbotanik*, 152 and 316, t. 5, 1843.

⁴ *Pyrus decipiens*, Bechstein, *loc. cit.* 152 and 321, t. 7.

those of *Pyrus intermedia*, except that the lobes are triangular pointed, and not rounded as in that species, the sinuses never being acute at their bases.

Var. *semilobata* (Bechstein).¹ Leaves oval or elliptic oval, acute at the apex, narrowed at the base, lobes sharply cuspidate.

IDENTIFICATION

In summer the leaves are distinguishable from those of *Pyrus intermedia* by the characters of the lobes and sinuses; while broad-leaved forms differ from *Pyrus torminalis* in being tomentose beneath, the lobes never being so long as in that species. The tomentum wears off the under surface of the leaf towards the end of the season, and is never so dense or so persistent as in *intermedia*. On Plate 44 figures are given of leaves from wild trees occurring at Symond's Yat (Fig. 9) and Minehead (Fig. 11), and from a cultivated tree at Kew (Fig. 12). In winter a tree cultivated at Kew showed the following characters, represented in Plate 45.

Twigs: long shoots, shining, round, glabrous, except for a little pubescence near the tip; lenticels numerous as oval prominent warts; leaf-scars set somewhat obliquely on prominent, often greenish cushions; crescentic with three bundle dots, of which the central one is the largest. Terminal bud oval, much larger than the side buds, which come off the twigs at a very acute angle, with their apices bent inwards. All the buds are viscid, pubescent at the tip, and composed of oval scales, which are keeled on the back, ciliate in margin, and short-pointed at the tip. Short shoots ringed, slightly pubescent, ending in a terminal bud. In the specimens examined the leaf-scar at the base of the terminal bud had acute lateral lobes not observed in other species of *Pyrus*; but these are probably not always present.

DISTRIBUTION

The tree was first discovered in the forest of Fontainebleau,² and was described by Valliant³ as "*Cratægus folio subrotundo, serrato, et laciniato.*" Duhamel du Monceau gave a figure of the leaf in his classic work.⁴ The distribution on the Continent of the type, and of the forms allied to it, has been given above.

In England a small tree, of somewhat rare occurrence, grows wild in woods

¹ *Pyrus semilobata*, Bechstein, *loc. cit.* 152 and 317, t. 6.

² I visited Fontainebleau in 1905 on purpose to see this tree at home, and found only small trees of it in full flower on 14th May. I was informed by M. Reuss, Inspector of Forests at Fontainebleau, that the tree grows scattered only in the part which is called Montenflamé and Mont Merle, where the sand is covered by the calcareous strata of Beaune, so that the tree is evidently peculiar to calcareous formations. Formerly the trees were cut with the underwood, but are now reserved on account of their rarity, as well as the whitebeam and *P. torminalis*, which M. Reuss considers to be indigenous at Fontainebleau, and therefore admits the possibility of their hybridising. The largest tree known to him is on Mont Merle, at the corner of the roads d'Anvers et de l'Echo in the 16th série, and is 40 centimetres in diameter, or about 4 feet in girth at 5 feet from the ground. It is known to the peasants at Fontainebleau as *baguenaudier* or *elorsier*, but is generally termed by French botanists *alisier de Fontainebleau*.—(H. J. E.)

³ *Botanicon Parisiense*, ed. 3, p. 63 (1727).

⁴ *Traité des Arbres*, i. 194, t. 80, fig. 2 (1755).

in Cornwall, South Devon, and Gloucestershire,¹ which is very near to, if not absolutely identical with, the Fontainebleau tree, as some of the specimens have leaves which resemble rather those of the varieties *rotundifolia* and *semilobata*. The South Devon tree produces fertile seed,² which has been planted, and the offspring differs in no respect from the wild trees. In English trees the flowers are reported to have a disagreeable odour,³ and the fruit ripens in the end of October or November. When fully grown, but still hard, it is olivaceous brown in colour, with numerous scattered small brown or grey dots; but when quite mature it becomes reddish. At Minehead in Somerset, the Nightingale Valley and Leigh Woods near Bristol, and at Castle Dinas Bran, Denbigh, the variety *decipiens* occurs.⁴ Mr. E. S. Marshall observed a remarkably fine specimen with good fruit on the Conan river in East Ross-shire; but as no other specimen was seen this tree is probably not wild in that locality. The tree in Earl Bathurst's woods near Cirencester has given rise to some difference of opinion. It was identified at Kew as *Pyrus intermedia*; but in the specimens which I have seen the leaves have the triangular lobing and tomentum of *Pyrus latifolia*, and I have no doubt that it is this species.⁵ Its foliage is very variable, some leaves being broad, with rounded bases like the type, whilst others have narrowed bases, and approximate in outline to the *decipiens* variety.

REMARKABLE TREES

Pyrus latifolia is seldom planted except in botanical gardens, as at Kew, Edinburgh, and Glasnevin. There are several fine trees at Edinburgh, one of which was figured in the *Gardeners' Chronicle*⁶ for 1882, when it was 45 feet high by 5 feet 3 inches in girth. Professor Balfour had the tree measured again in January 1904, when it was 45 feet high by 6 feet 6 inches in girth. A year or two before it was considerably pruned on the top branches, and this probably accounts for it not being higher in 1904 than it was in 1882. Professor Balfour kindly sent me specimens of the Edinburgh trees, which, though they differ slightly, are all referable to *Pyrus latifolia*. He informed me that while the birds eat the fruit off one tree as soon as it is ripe, in another the fruit remains on the tree untouched. The variability of the fruit in this species is remarkable, and points undoubtedly to hybrid origin.

A tree exists at Oakleigh House,⁷ near Keynsham in Somerset, which was planted many years ago. (A. H.)

¹ "Occurs at Bicknor, Coldwell, and Symond's Yat, which form a single range of wooded limestone rock in West Gloucestershire, about $\frac{3}{4}$ mile in length."—Rev. A. Ley, *Bot. Exchg. Club Report*, 1893, p. 415. "French Hales" is the name given to this species in Devon, according to Britten and Holland, *Dict. Eng. Plant Names*, p. 194 (1886). They state that the fruits are sold in Barnstaple market. These authors call the tree *Pyrus scandica*, as, at the time they were writing, its identity with the Fontainebleau tree was not established.

² Briggs, *Jour. Bot.* 1887, p. 209, and 1888, p. 236.

³ Briggs, *Flora of Plymouth*, 144 (1880); and Boswell, *Bot. Exchg. Club Report*, 1872-74, p. 20.

⁴ Cf. N. E. Brown, *loc. cit.* 165. Mr. J. White reports a tree 30 feet high in Leigh Wood (*Bot. Exchg. Club Report*, 1902, p. 45).

⁵ Mr. Hickel, Inspecteur des eaux et forêts, who knows the Fontainebleau tree well, and to whom I sent specimens, is of my opinion.

⁶ Vol. xviii. 749.

⁷ *Jour. Bot.* 1899, p. 488.

My attention was called by Mr. R. Anderson of Cirencester to a very remarkable tree growing in a part of Earl Bathurst's woods about two miles from Cirencester, known as the Dear Bit. The tree, though it has lost some of its principal branches, is still, as our illustration shows (Plate 49), a very handsome one, and in size exceeds any other of the kind of which we have a record, either in this country or on the Continent. It is, as nearly as I can measure it, about 75 feet high by 11 feet in girth. It grows on dry shallow soil of the Oolite formation, and is close to a ride, which leads me to suppose that it was planted perhaps at the time when the park was laid out. It is near the north-east edge of the wood, and open to the south-west. I have never seen the flowers of this tree, which bears fruit only in favourable seasons near the ends of its uppermost branches, and as the birds are fond of it, and even in good years many of the seeds are immature, I have not until 1904 been able to procure any. A few of these have now produced small plants.

I have been unable to find any self-sown seedlings near this tree, and though there are one or two good-sized *P. torminalis* in another part of the park, probably planted, none of them approach it in size. As to the possible age of this tree, I can only say that the drive on the edge of which it grows has, as I am told by Mr. Anderson, certainly been in existence over 100 years, and the bank was covered with old beech, which were cut in 1892. The tree has become one-sided from the pressure of a beech which until then closed it in on the south-west side, where it is now open. As these beeches were 150 years old or more, the tree may be now from 150 to 200 years old, and it seems very probable that the person who designed this park had seen the tree at Fontainebleau, and introduced it when Oakley Park was planted by the ancestor of the present Earl Bathurst in Queen Anne's reign.

(H. J. E.)

PYRUS INTERMEDIA, SWEDISH WHITEBEAM

- Pyrus intermedia*, Ehrhart, *Beiträge zur Naturkunde*, iv. 20 (1789); Loudon, *Arb. et Frut. Brit.* ii. 915 (1838).
Pyrus scandica, Ascherson, *Fl. des Prov. Brandenburg*, i. 207 (1864).
Pyrus suecica, Garcke, *Fl. Deutschland*, ed. ix. 140 (1869); Conwentz, *Beob. über Seltene Wald-bäume in West Preussen*, 81 (1895).
Sorbus scandica, Fries, *Flora Hollandica*, 83 (1818).
Sorbus intermedia, Persoon, *Syn. Pl.* ii. 38 (1807).
Sorbus Mougeoti, Soyer-Willemet et Godron, *Bull. Soc. Bot. de France*, v. 447 (1858).
Cratægus Aria scandica, Linnæus, *Amœn. Acad.* 190 (1751).
Cratægus Aria suecica, Linnæus, *Sp. Pl.* 476 (1753).

A shrub or small tree attaining a height of 20 to 50 feet. Leaves stalked, oval or elliptic, rounded or cuneate at the base, pointed at the apex; margin lobed, lobes diminishing in size from the base upwards, rounded, toothed, shortly acuminate, separated by sinuses which are very acute or almost closed at their bases; upper surface green, shining, glabrous when adult, lower surface greyish tomentose. Flowers in branching corymbs, with pleasant odour; petals spreading, tomentose; styles 2, free, tomentose at the base. Fruit oval, red, sweet-flavoured, smooth or slightly dotted.

VARIETIES

1. *Scandica*.¹ Leaves less narrowed and almost rounded at the base, deeply lobed, with numerous sharp teeth; 6-8 pairs of nerves. Fruits large, surmounted by the curved and outwardly-reflected calyx teeth.
2. *Mougeoti*.² Leaves narrowed at the base, slightly lobed, with few short teeth; nerves 9-12 pairs. Fruit very small, surmounted by erect and inwardly-curved calyx teeth.
3. *Minima*.³ Leaves linear-oblong, with 3-4 pairs of lobes, variable in size, but generally deepest at the middle part of the leaf; nerves 6-8 pairs. Flowers—early in June—in loose corymbs, not flat-topped, small, and resembling those of *Pyrus Aucuparia*. Fruit small, globose, bright red, surmounted by erect calyx lobes.

In Plate 44 figures are given of the leaves of var. *scandica* from Bergen (Fig. 19), of the variety from Great Doward in Hereford (Fig. 10), and of var. *minima* from Breconshire (Fig. 17).

IDENTIFICATION

In summer the greyish tomentum of the leaves underneath, and the rounded lobes, with sharp sinuses which are almost closed at their bases, will distinguish the

¹ *Sorbus scandica*, Fries, *loc. cit.*

² *Sorbus Mougeoti*, Soy.-Will. et God. *loc. cit.*

³ *Pyrus minima*, Ley, *Jour. of Bot.* 1895, p. 84, and 1897, p. 289, t. 372; *Sorbus minima*, Hedlund, *Kon. Sv. Vetén. Akad. Handl.* (1901-2) 60.

tree from *Pyrus Aria* and *Pyrus latifolia*, the species nearly allied. In winter the following characters are available, as shown in Plate 45:—

Twigs: long shoots, round, glabrous, often with waxy patches; lenticels long, numerous. Leaf-scars: crescentic, with 3 equal-sized bundle dots, obliquely set on a brownish projecting cushion. Buds glistening, pubescent at the tip; terminal much the largest; side-buds arising at an acute angle with their apices directed inwards. The bud-scales have a dark-coloured rim to the ciliate margin, and their apex is scalloped with a central projection ending in a tuft of long hairs. The short shoots are ringed, pubescent, with a terminal bud.

DISTRIBUTION

The variety *minima* occurs only in Breconshire, on the limestone mountain cliff Craig Cille, near Crickhowell, and at Blaen Onnen, two miles to the west of Craig Cille, and is a small shrub clothing the cliffs up to 2000 feet altitude. The flowers and fruit are very similar to those of the mountain ash; and Koehne supposes it to be a hybrid between *Pyrus intermedia* and *Pyrus Aucuparia*, which occur in the same locality.

The form *Mougeoti*, which is considered by many botanists to be a distinct species, occurs in Lorraine, the Vosges, Jura, Suabian and Western Alps, and in the Carpathians. It never attains a great size, being either a low bush or a small tree 15 to 30 feet in height. In Piercefield Park, Monmouth, Great Doward in Hereford, and a few other localities in the west of England, a shrub or small tree has been found which is near this form.¹

Var. *scandica* has been found in Britain, in a few localities in Denbighshire and Breconshire,² and also at Chepstow³ in Monmouthshire, always growing on limestone rocks. It was supposed to grow also in Arran, but Koehne,⁴ as will be seen in our account of the peculiar forms of that island under *Pyrus pinnatifida*, denies its occurrence there.

(A. H.)

This variety is widely spread in Northern Europe. The best account we know of this tree is by Conwentz, who calls it "*Pirus Suecica*." He says that most authors speak of it as a small tree or shrub—Koehne only gives it as 7 metres high. It grows on granite, gneiss, chalk, and alluvium, and extends from the island of Åland, South-east Sweden, South Norway, and Denmark, to North-east Germany, where, however, it seems to be quite a rare tree and only recently discovered.

It is represented in France, Switzerland, Austria, and Bosnia by *P. Mougeoti*, which many botanical authors have mistaken for it, and which, according to Conwentz, can only be distinguished in some varieties by the fruit.

In the island of Oesel, in the Baltic, it is much planted, and often attains 2 metres in girth. Conwentz, however, found wild specimens at Soëginina near Karral, at Pajumois near Keilkond, at Wita Jahn, and in other places—mostly small trees, but

¹ It is called *Pyrus intermedia*, Ehrh., by the Rev. Augustin Ley. Briggs and Boswell think it is perhaps a form of *Aria* or *rupicola*. See *Jour. Bot.* 1884, p. 216. It is certainly quite distinct, in my opinion, from *scandica* or *latifolia*.

² *Jour. Bot.* 1903, p. 215.

³ Specimen at Kew.

⁴ *Jour. Bot.* 1897, p. 99.

in some places attaining 10 metres in height. In the Finnish islands of Åland it is found truly wild, in a few places only, sometimes in company with an allied species, *P. fennica*. Conwentz identified it at Bergö, Skarpnåtö, Labnäs, and elsewhere. The finest specimen he saw at Östergeta, being 12 metres high and 2 metres in girth.

In south-eastern Sweden it is more abundant, but does not occur in any of the provinces north of Wermland, about lat. 60° N. In the neighbourhood of Stockholm it grows at Stockby to 12 metres in height. In Södermanland and the island of Gothland it is more common.

In Denmark the tree has been found in many places, and is undoubtedly wild near Aarhus in Jutland, in the forests of Adslev, Kolden, and Jexen. I believe that I also saw it in the forest of Roldskov near Aalborg, though I did not at that time distinguish it from *Pyrus Aria*. In the island of Bornholm it is known under the name of "Axelbar."

In Germany it is confined to a limited area on the coasts of West Prussia and Pomerania, where Conwentz has found it living in six places only—Koliebken, Hoch Redlau, Oxhöft, Karthaus, Gr. Podel, and Markuhle near Kolberg. He gives maps showing the position of the trees in these places, and says that whilst *P. torminalis* grows in the interior, where the hornbeam is predominant, *P. intermedia* grows in the country along the coast, where the beech is the prevailing tree. It occurs most commonly in a shrubby condition, the tallest wild one being only 13 metres high by 1 metre in girth, but one tree at Gross Podel in Pomerania is 1.90 metre in girth, and at Wernigerode, in the Harz, a cultivated tree has attained 17 by 3.17 metres, which is the largest known to Conwentz. He thinks that the scarcity of the tree in Germany arises from its not being indigenous, as no geological evidence exists of its having been formerly commoner, and suggests that it has been introduced from Sweden by birds of passage, such as the waxwing or thrushes, which are fond of the fruit, and may have voided the seeds after migration from the north.

The Swedish name is *Oxel*, and this name being found in many place and family names in Sweden, shows that the tree was probably more common formerly than at present.

In Norway, Schübeler¹ says that it is wild only in the most southern parts, as at Porsgrund, Grimstad, and Dalen in Eidsborg, in lat. 59° 42' N. There are large trees at Lunde in Stavanger district growing near the church. In the Botanic Gardens at Christiania I have seen a tree which is about 12 metres high and over 2 in girth. It has been planted and grows well at Stenkjær, at the north end of the Trondhjem Fjord. The Norsk name is *Maave*.

Dr. Brunchorst, Director of the Bergen Museum, informed the Earl of Ducie that *Pyrus intermedia*, as well as *P. pinnatifida* (*P. fennica*), were found on the south-west coast of Norway, and that a hybrid which he calls *Pyrus Meinickii*, *P. fennica* × *Aucuparia*, has also been recently discovered in the "Mosterö Bommel Fjord." Dr. Brunchorst, who has paid much attention to this genus, says that three species which he cultivates at Bergen vary much, and perhaps pass into one another.

¹ Schübeler, *Viridarium norvegicum*, vol. ii. 477 (1888).

Lord Ducie has brought plants of these to Tortworth, where he grows them under the name of *Pyrus hybrida*.

REMARKABLE TREES

This species appears to be now rarely planted, except in botanical gardens. The best specimen which we have seen occurs at Syon (var. *scandica*). In 1904 it measured 48 feet in height by 7 feet 10 inches in girth, with a bole of 7 feet, dividing into 8 large branches, and forming a wide-spreading crown of foliage, about 50 yards in circumference (Plate 50). Another fine tree is growing at Livermere Park, Bury St. Edmunds, Suffolk, specimens and particulars of which have been kindly sent to us by Mr. Stiling. It is now (1905) 45 feet high by 8 feet 5 inches in girth, with a bole of 8 feet dividing into 12 main branches, the diameter of the spread of foliage being 45 feet. This tree was reported¹ in 1889 to have been 42 feet high by 8 feet 3 inches in girth. In August 1905 it was covered with fruit. (H. J. E.)

There is a fine specimen at Stowe, near Buckingham, growing near the bridge over the lake in sandy soil, which measures about 45 feet high by 7 feet 9 in. in girth, with a 7 feet bole. It was loaded with fruit in August 1905.

At Wykeham Abbey, the Yorkshire seat of Viscount Downe, there is a fine tree on the lawn, about 40 feet high, spreading from the ground, where it measures 10 feet 8 inches in girth, into a large and well-shaped head.

This tree is planted in some of the parks and gardens in London, and grows well at the Botanic Gardens in Regent's Park. I am informed by Mr. A. Stratford, Superintendent of the Corporation Park of Blackburn, that it makes a good shade tree in that smoky town.

¹ *Garden*, 1889, xxxvi. 342. Note by J. C. Tallack, who named the tree *Pyrus pinnatifida*.

PYRUS PINNATIFIDA, BASTARD MOUNTAIN ASH

Pyrus pinnatifida, Ehrhart, "Plantag." 22, ex *Beiträge zur Naturkunde*, vi. 93 (1791); Loudon, *Arb. et Frut. Brit.* ii. 915 (1838); N. E. Brown, in *Eng. Bot.* iii. cd. Suppl. 168 (1892); *Gard. Chron.* xx. 493, fig. 78 (1883).

Pyrus semipinnata, Roth, *En. Pl. Phæn. in Germ.* i. sect. post. 438 (1827).

Pyrus fennica, Babington, *Man. Eng. Bot.* ed. 3, p. 111 (1851).

Sorbus hybrida, Linnæus, *Sp. Pl.* 684 (1762); Schübel, *Viridarium norvegicum*, ii. p. 476.

Sorbus fennica, Fries, *Summa Veg. Scand.* 42 (1846).

A species of hybrid origin, occurring as a small tree, which may attain 50 feet in height, with smooth, grey bark. Leaves variable in shape, mostly pinnate or deeply cut at the base, with 1-4 pairs of segments more or less separate; the upper part cut into deep sharp-toothed lobes; green and glabrous above, grey tomentose below. Flowers white in loose corymbs; styles 3, woolly at the base; fruit small, globular, coral red, and resembling that of *Pyrus Aucuparia*.

VARIETIES

This form, the parents of which are *P. Aucuparia* and *P. intermedia*, must be carefully distinguished (see p. 143) from *Pyrus hybrida*, Moench, a shrub of different origin.

Pyrus Thuringiaca, Ilse,¹ a cross between *P. Aucuparia* and *P. Aria*, is generally included under *P. pinnatifida*, from which it differs only in the leaf, whiter beneath, having its upper part lobulate or dentate and not deeply lobed.

Sorbus arranensis, Hedlund,² is the name given to a form occurring in the Isle of Arran, which is intermediate between *P. pinnatifida* and *P. intermedia*, and closely resembles the latter, differing only in the deeper and more irregular lobing of the leaf.

The hybrid forms, which are intermediate between *P. pinnatifida* and *P. Aucuparia*, are generally regarded as varieties (var. *satureifolia*³ and var. *decurrens*⁴) of the latter species, and will be mentioned in our account of the mountain ash.

IDENTIFICATION

Pyrus pinnatifida and the intermediate hybrids are variable and inconstant in the shape of the leaf. There is no difficulty, however, in their identification, if it be noted that hybridity may be suspected in all cases where the leaves vary on the one hand from the regularly pinnate separate leaflets of *Pyrus Aucuparia*, and on the other from the regular uniform lobing or serration of *Pyrus intermedia* or *Pyrus*

¹ In *Jahresh. Bot. Gart. u. Mus. Berlin*, i. 232 (1881).

³ Koch, *Dendrologie*, i. 189 (1869).

⁴ Koehne, *Deutsche Dendrologie*, 248 (1893). This variety is commonly known as *Pyrus lanuginosa*, Hort.

Aria. In winter, specimens of cultivated *Sorbus fennica* show the following characters represented in Plate 45 :—

Twigs: long shoots glabrous, shining, dark brown, with a few scattered lenticels. Leaf-scar crescentic, very narrow, set obliquely on a reddish brown, slightly projecting cushion; it shows a varying number of bundle traces,¹ 3, 4, or 5, and may thus be distinguished from other species of *Sorbus*, as *Pyrus Aucuparia* has 5 dots on the scar, while *Pyrus Aria*, *intermedia*, and *latifolia* have only 3. Terminal bud large, conic, tomentose, especially at the apex. Lateral buds small, either appressed to the stem or diverging from it at an acute angle. Bud-scales few, densely pubescent on the outer surface, and ciliate in margin. Short shoots ringed, pubescent, bearing a terminal bud.²

DISTRIBUTION

The form *fennica* occurs plentifully in Scandinavia, where it grows wild, reproducing itself naturally by seed, and behaving as a true species. It extends in Norway, according to Schübeler, up to lat. 66° 14' on the west coast as a wild plant, and in Sweden up to 60° wild and 62° planted; it also occurs in Finland, but is not recorded from other parts of Russian territory. In Central Europe it only occurs sporadically, and apparently always in company with the parent species; it is recorded from various mountain stations in France, Switzerland, Germany, and Austria.

The hybrids which occur in the Isle of Arran have attracted much attention and discussion. Formerly it was believed that *Pyrus Aucuparia*, *Pyrus intermedia* (var. *scandica*), and *Pyrus fennica*, all occurred in a wild state. Koehne,³ however, considers that (excepting *Aucuparia*) all the plants in question on the island are hybrids, there being two sets, one typical *fennica*, while the other set comprises forms between that and *scandica*. This view, which excludes one of the parents (viz. *scandica*), implies that these hybrids, once established, may under favourable conditions reproduce themselves naturally and behave generally as true species.

N. E. Brown says of this species that it is "rare and perhaps not indigenous except in Scotland"; but he has seen specimens from Kent, Sussex, Hants, Somerset, Gloucester, Leicester, Stafford, Cumberland, Roxburgh, Arran, and Dumbarton. He thinks that Arran seems to be the only truly native locality for this tree in the British Isles, and believes that the Arran plant placed under *intermedia* is a form of it. Watson, however, states in his *Compendium*, p. 510, that Borrer held it to be wild in North Hants between Farnham and Farnborough, where it was observed sparingly along with *Aria* and *Aucuparia*, both more plentifully. A specimen picked by James M'Nab in Darent Wood, Kent, is, according to Watson, identical with Arran specimens.

There is a fine tree on the edge of a shrubbery close to Wilton House, Wilts, the seat of the Earl of Pembroke, about 50 feet by 5.

¹ If the dots are not plainly visible externally, they can be seen clearly on paring off the epidermis of the scar.

² The twigs in winter described above clearly show the hybrid origin of this species; the varying number of dots on the scar, the pubescence and shape of the scales, etc. show the influence of *Pyrus Aucuparia*.

³ Koehne, *Jour. of Bot.* 1897, p. 99. See also Rev. Dr. Landsborough's account of the Arran hybrids in *Trans. Bot. Soc. Edin.* xxi. 56 (1897).

There is a tree at Williamstrip Park, Fairford, the seat of Lord St. Aldwyn, which is in a decaying condition. It consists of a large stool measuring 8 feet at the ground, with four stems about a foot in diameter by about 60 feet high. There is also a tree at Arley Castle 50 feet high by 3 feet 5 inches in girth in 1905. One at Bayfordbury is 40 feet by 5 feet 2 inches, branching at 4 feet into four stems, with numerous ascending branches. At Aldenham Cottage, Letchmore Heath, Herts, is a fine tree 44 feet by 6 feet 2 inches, with a bole of 6 feet. At Danson Park, Welling, Kent, the residence of Mr. Bean, there is said to be a tree about 30 feet high, with a girth of 12 feet 4 inches at 1½ feet above the ground, described to be like a large bush with seven main branches. (A. H.)

PYRUS ARIA, WHITEBEAM

Pyrus Aria, Ehrhart, *Beiträge zur Naturkunde*, iv. 20 (1789); Loudon, *Arb. et Frut. Brit.* ii. 910 (1838).

Crataegus Aria, Linnæus, *Sp. Pl.* 475 (1753).

Sorbus Aria, Crantz, *Stirp. Aust.* ii. t. 2, f. 2 (1762).

Aria nivea, Host, *Fl. Aust.* ii. 8 (1813).

A tree in woods and on good soil attaining a height of 40 to 50 feet, and rarely 70 feet in height; but in rocky and mountainous situations usually remaining shrubby. Bark smooth and grey, becoming slightly fissured in old trees. Leaves stalked, oval or obovate, rounded, cordate, or cuneate at the base, sharp or obtuse at the apex, biserrate or slightly lobulate with teeth, the lobules largest towards the apex of the leaf; green and glabrous when adult above, but always snowy-white tomentose beneath; nerves, 8-12 pairs, very prominent on both surfaces. Flowers with an unpleasant odour, white, in loose corymbs; the peduncle, receptacle, calyx, and corolla, white tomentose; styles 2, free, pubescent at the base. Fruit globose or ovoid, $\frac{1}{2}$ inch in diameter, shining red with a few brown dots, tomentose at the base and apex; flesh scanty, sweetish acid in flavour.

IDENTIFICATION

In summer the leaves, snowy white underneath and with prominent nerves, are a sure guide. The leaves of *Aria* from a wild specimen growing at Gosford, Kent (Fig. 18); of var. *rupicola* from a wild specimen from north-west Lancashire (Fig. 13); of var. *salicifolia* (Fig. 16) and var. *Decaisneana* (Fig. 8), both from specimens cultivated at Kew, are shown on Plates 43 and 44. In winter the following characters are available, as shown in Plate 45:—

Twigs: long shoots round, shining brown, glabrous except for a little pubescence near the tip, marked with scattered wart-like lenticels. Leaf-scars set obliquely on prominent leaf-cushions, crescentic, with three bundle traces. Buds ovoid, conical-pointed, shining, and somewhat viscid; terminal larger, side-buds coming off at an acute angle. Bud-scales glued together, strongly keeled, glabrous on the surface, densely long ciliate in margin. Short shoots ringed, generally glabrous, and ending in a terminal bud. Viscid buds occur also in *Pyrus Sorbus*, which is, however, very distinct in its five-dotted scars and glabrous scales.

VARIETIES

Some authors take *Pyrus Aria* in a wide sense, and under it group *Aria* proper, *rupicola*, *latifolia*, *scandica*, etc. as sub-species. Most of these, as being readily distinguishable by many characters, have been considered by us as distinct species. Taking *Pyrus Aria* in a narrow sense, as comprising forms with leaves

snowy white beneath, it exhibits a great variety of forms in the wild state, explained by its wide geographical distribution and its occurrence on different soils and in different situations. Moreover, various horticultural varieties have been produced. The type has been described above; the following is a list of the most important varieties:—

1. Var. *rupicola*.¹ Differs from the type in the leaves having fewer nerves, generally 7 (5-9) pairs, less prominent; obovate-oblong in shape, widest above the middle, lobulate above, with the tomentum ultimately becoming slightly grey. Fruit smaller, $\frac{3}{8}$ inch diameter, carmine-scarlet. This variety occurs always on limestone rocks, and is recorded from many stations in the British Isles. It is probably a form due to poor soil and exposure to wind, and other uncongenial conditions.

2. Var. *græca*, Boissier.² A shrub occurring in Spain, Albania, Greece, Syria, and Asia Minor. Leaves round, thick, almost leathery in consistence, nerves 6-10 pairs, broad, cuneate at the base, lobulate, with large teeth in the upper two-thirds. This form is also known as *Sorbus cretica*, Fritsch, and *Aria græca*, Decaisne.

3. Var. *flabellifolia*.³ Leaves orbicular, cuneate, or rounder at the base, margin with large incisions, sharply toothed, nerves 3-5 pairs. South-eastern Europe and Asia Minor.

4. Var. *Decaisneana*, Rehder.⁴ Leaves large, 4-6 inches long by 2-3 $\frac{1}{2}$ broad, elliptic or oblong, narrow or acuminate at the apex, rounded or subcordate at the base, serrate in almost the whole margin with sharp teeth; nerves 12-14 pairs; petiole channelled above, nearly an inch long. Flowers first white, then becoming pinkish; styles glabrous. Fruit purplish, ellipsoid, crowned by the persistent hairy sepals. This tree is of unknown origin; it has been said to be Himalayan, but I am not aware on what authority. It closely resembles *Pyrus lanata* from that region.

5. Var. *sinensis*. Leaves narrow, lanceolate or ovate, with acuminate apex and cuneate base; crenately serrate. A series of forms occur in the mountains of Hupeh in China, where the trees are common at high elevations, and vary in size from 10 to 40 feet in height. Seeds were sent home by Wilson to Messrs. Veitch in 1901, and seedlings, very beautiful in foliage and vigorous in growth, are now growing at Coombe Wood.

6. Var. *salicifolia*. Leaves narrow, ovate-lanceolate, doubly serrate in margin, with long petioles. Origin unknown.

7. Certain horticultural varieties occur in which the leaves are variously coloured, as *lutescens*, *chrysophylla*, *sulphurea*.

8. Var. *quercooides*. Leaves regularly lobed with their edges bent upwards.

PYRUS HOSTII,⁵ Hort., may here be mentioned, as it occurs in cultivation and

¹ *Pyrus rupicola*, Boswell Syme, *Eng. Bot.* ed. 3, t. 483.

² *Flora Orientalis*, ii. 658. There is a form in south-east Europe called *meridionalis*, which differs only slightly from this variety.

³ *Crataegus flabellifolia*, Spach, *Hist. Vég. Phan.* ii. 103.

⁴ Rehder in *Cyclop. Am. Hort.* iv. 1689 (1902). *Aria Decaisneana*, Lavallée, *Arbor. Segrez.* p. 51, t. 18. *Pyrus Decaisneana*, Nicholson, *Kew Hand-list of Trees and Shrubs*, 187 (1894). *Sorbus Decaisneana*, Zabel, *Handbuch Laubholz-Benennung*, 199 (1903).

⁵ Figured in *Garden*, 1881, xx. 376.

resembles *Pyrus Aria*. It is of hybrid origin, one parent being either that species or *Pyrus intermedia*, while the other is *Pyrus Chamæespilus*. It is distinguished from *Pyrus Aria* by the larger and more irregular teeth of the leaves (*cf.* Plate 44), and its flowers are pinkish white, borne in loose corymbs. Various intermediate forms have been distinguished, as—

Sorbus ambigua, Michalet. Exactly intermediate between *Pyrus Aria* and *Pyrus Chamæespilus*, with the leaves larger than in the second, and smaller than in the first, and the margins having a tendency to lobing. Tomentum whitish.

Sorbus arioides, Michalet. A form intermediate between *ambigua* and *Aria*.

Chamæespilus × *Mougeoti*. Leaf large, with lobes well marked and rounded; tomentum greyish. These hybrids are common in the Jura and the Alps.

DISTRIBUTION

The whitebeam is a wide-spread species. It occurs throughout Europe generally, reaching in Norway as far north as lat. 63° 52', and in Sweden to lat. 59°. It is met with also in Algeria, Asia Minor, the Caucasus, Armenia, Siberia, and Central China, assuming in some of these regions remarkable varietal forms. It is replaced in the Himalayas and Japan by *Pyrus lanata*, Don, an allied species.

While it occurs on all soils except those which are wet, it has a decided preference for limestone. In woods and hedges it grows to be a small tree; but in exposed situations on rocky mountains, etc. it dwindles to a mere bush. On the Alps it ascends to 4800 feet.

In the British Isles its distribution has not been accurately made out, as many supposed records refer rather to *intermedia* or *latifolia*. Apparently, however, as a wild tree, the typical form is almost entirely confined to the southern and midland counties of England and to south Wales. Variety *rupicola* is recorded from nearly every county from Devon to Sutherland, and is widely spread on the littoral range between Lancaster and Humphrey Head, ascending in Banffshire to 1200 or 1400 feet, where it has been found by Dr. Shoolbred of Chepstow on limestone cliffs near Inchroy in upper Banffshire. In Ireland the whitebeam is rare and local, and both the type and *rupicola* occur. (A. H.)

REMARKABLE TREES

By far the finest specimen that we know of in England or elsewhere grows on the edge of Camp Wood, near Henley on Thames, on Sir Walter Phillimore's property, where Henry saw it in 1905. It measures 75 feet high by 4 feet 9 inches in girth, with a bole about 35 feet long, and has very smooth beech-like bark (Plate 51).

There is a large and very well shaped tree at Walcot, Shropshire, which in 1906 Elwes found to be 56 feet high and 6½ feet in girth, with a clean bole about 20 feet long.

There is a handsome tree on the lawn at Belton Park, which measures 41 feet by 6 feet 7 inches.

A very spreading, ill-shaped tree in a thicket at Mount Meadow, near Cobham, Kent, is 9 feet 3 inches in girth.

At Stowe, near Buckingham, there are several fine trees near the Queen's Temple, which are about 50 feet high, but the tree when growing wild on the Cotswold Hills, where it is common, rarely exceeds 30 feet with a stem 2 to 3 feet in girth, and is more usually seen as a bush with many stems.

The whitebeam, like the mountain ash, is occasionally found as an epiphyte growing on other trees, where its seeds have been dropped by birds. Though this is more common in the damp climate of the west of England, yet we know of two cases which are remarkable on account of their situation. One is in the Yew Tree Vale in Surrey, where a whitebeam is growing near the top of a yew tree;¹ the other is near Colesborne in the Cotswold Hills. In this case a large limb has been torn by the wind from a Scots pine, and in the crevice on the east side of the tree, where but very little vegetable matter has yet had time to form, a healthy young whitebeam, now about 3 feet high, grew for seven or eight years, when it began to lose vigour.

Though it is well known that the decaying mossy trunk of a fallen tree is one of the most favourable situations for the seeds of many conifers to germinate and grow, yet in this case the roots of the whitebeam must derive their nourishment almost entirely from the air, the case being very different from those so often seen in the Himalayas and other countries, where a large quantity of moss, ferns, and decaying vegetable matter accumulate in the forks of large old trees.

The whitebeam is easily propagated by seed, which, if sown in autumn, will germinate partly in the following spring and partly in the second year after sowing. The seedlings grow slowly at first, and require five or six years in the nursery before they are large enough to plant out. When planted on good soil the whitebeam is a very ornamental tree, both on account of its leaves and fruit, which is larger and more abundant than when wild. It is, however, so much liked by birds that it is soon eaten up.

TIMBER

The wood is hard, heavy, and even in the grain, and is white in colour, with some dark spots, and in old trees becomes occasionally tinged with red. It is used on the Continent in turnery and in making tools.

Loudon says that it was used for the axletrees, naves, and felloes of wheels, carpenters' tools, and walking-sticks, but that the greatest use of its wood, until iron superseded it, was for the cogs of small wheels. I have felled a tree 18 inches in diameter, which when cut through was perfectly sound at heart, and was considered to be well suited for chair-making.

¹ *Garden*, 1882, xxii. 164.

170 The Trees of Great Britain and Ireland

In Hampshire¹ the wood is used for making whip-handles, and the tree is known there on that account as "whip-crop."

Mr. Weale, of Liverpool, reports as follows on a sample of this wood which I sent him:—"The wood is of a medium hardness, good length of fibre, and takes a clean finish. Not tough. Rays invisible on transverse section. Grain moderately close and even. Warps badly in drying, and is liable to split."

In a little book on English timber by "Acorn" (Rider and Son, London, 1904), I find the following note on the whitebeam, though the author does not notice either of the service trees:—"In a green state whitebeam has a strong smell, and even after seasoning this is retained to a certain extent. A great many handles for cutlery are made from it, and its hardness is admirably adapted for these, as it is capable of taking a very high polish from the extreme closeness of its grain. It is also used in the manufacture of musical instruments, and the tops and small pieces are always appreciated by the turner." As it is usually available only in small pieces, these would probably, when thoroughly seasoned, be very useful to introduce as blocks in parquet flooring. (H. J. E.)

¹ Townsend, *Flora of Hampshire*, 125 (1883).

TAXODIUM

Taxodium, Richard, *Ann. Mus. Par.* xvi. 298 (1810); Bentham et Hooker, *Gen. Pl.* iii. 429 (1880); Masters, *Jour. Linn. Soc. (Bot.)* xxx. 24 (1893).
Schubertia, Mirbel, *Nouv. Bull. Soc. Philom.* iii. 123 (1812).
Glyptostrobus, Endlicher, *Syn. Conif.* 30 (1847).

DECIDUOUS or subevergreen trees, several extinct species and a series of living forms, which have been variously considered to constitute one, two, or three species, belonging to the tribe Taxodineæ of the order Coniferæ.

Branchlets of two kinds, those at the apex of the shoot persistent, and bearing axillary buds, those lower down on the shoot deciduous and without buds. Buds of two kinds: those near the apex of the shoot, two in number, sub-terminal, globose, composed of imbricated, ovate, acute, keeled scales; these buds continue the growth of the persistent shoot. The lateral buds, situated lower on the shoot, are minute globose swellings, enclosed in two transverse, broadly oval, concave, membranous scales, which do not meet. These buds produce the deciduous branchlets, and are developed both on older and current year's shoots, in the latter case arising in the axils of primary leaves.

Leaves inserted spirally on the branchlets; on the persistent shoots, spreading more or less radially; on the deciduous shoots, in the usual forms of the species, thrown by a twisting of their bases into two lateral ranks, thus assuming a pseudo-distichous arrangement; linear, acute, channelled along the median line above, keeled and bearing stomata below. In var. *imbricaria* the leaves are not pseudo-distichously arranged, but are appressed around the twig and spreading at their free apex; they are narrow, long-pointed, concave above.

Flowers monœcious. Male flowers in panicles, 3 to 5 inches long, arising at the end of the preceding year's shoot. Each flower is minute, sub-sessile, and consists of a stalk surrounded at its base by ovate scales, and bearing 6 to 8 distichously opposite stamens. Female flowers, scattered near the ends of branchlets of the preceding year, solitary, globular, consisting of numerous imbricated pointed bracts, adnate below to the thickened fleshy scales, each of which bears two ovules.

Fruit, a globular or ellipsoidal, short-stalked, woody cone, an inch or more in diameter, ripening in the first year, composed of thick coriaceous peltate scales, the stipes of which are slender and spring off at right angles from the axis of the cone; the discs, rhomboidal in shape, show a triangular scar at the base, above which they are irregularly crenulate and rugose. The bract having almost entirely coalesced

with the scale, its apex appears on the upper part of the scar as a minute reflexed point. Some of the scales are sterile; the others bear each two erect unequally three-angled seeds.

Taxodium is readily distinguishable in winter from other deciduous trees by the peculiar buds and branchlet scars which mark the twigs. The latter are very slender, terete, glabrous, and brown in colour, and bear at their apex the two pseudo-terminal buds described above, one of which, however, is often aborted in trees growing in England. Scattered over the twigs appear the branchlet scars and the lateral buds. The former are small circular depressions, surrounded by a slightly raised rim, and having a single dot or a minute protuberance in their centre. The lateral buds, also previously described, are smaller than the branchlet scars, and on twigs of one year arise just above the minute scars left by the primary leaves, in which a single dot may be made out with difficulty. Single-dotted leaf-scars occur in *Larix* and *Pseudolarix*; but in these genera branchlet scars are absent, and the twigs show spurs or short shoots, which are wanting in *Taxodium*.

The genus *Taxodium* was once common and widely distributed over the Holarctic region. During Miocene and Pliocene times it was spread over the interior of North America, throughout Europe, and in north-eastern Siberia. In the present day it is restricted to the Southern United States and Mexico.

The genus can only be confounded with *Glyptostrobus*, now represented by one living species, *G. heterophyllus*, Endlicher,¹ a native of the province of Canton, in Southern China, where it occurs as a small tree along the banks of rivers and streams. Like *Taxodium*, it has deciduous foliage and branchlets. The leaves assume two forms—on ordinary branchlets long and linear and arranged in three rows, on fruiting branchlets closely imbricated, scale-like, concave internally and carinate externally. The cone, pyriform in shape, is composed of scales, which are not peltate, but elongated and arising from its base. The bract coalesces with the scale below; but above the middle is free and recurved, leaving bare the 5 to 7 lobed summit of the scale. The seeds, oblong or obovate, often short-spurred at the base, are narrowly winged on the sides and prolonged at the base into a flat, lancet-shaped wing. *Glyptostrobus heterophyllus* is not hardy at Kew, where specimens may be seen in the temperate house. A plant of it is reported to be growing in the open air at Castlewellan.

¹ *Glyptostrobus heterophyllus*, Endlicher, *Syn. Conif.* 70 (1847); Masters, *Jour. Bot.* 1900, p. 37, and *Gard. Chron.* xxvi. 489 (1899); *Thuja pensilis*, Staunton, *Embassy to China*, ii. 436 (1798); Lambert, *Pinus*, ed. 2, ii. 115, f. 51.

TAXODIUM DISTICHUM, DECIDUOUS CYPRESS

Taxodium distichum, Richard, *Ann. Mus. Par.* xvi. 298 (1810); Loudon, *Arb. et Frut. Brit.* iv. 2481 (1838); Sargent, *Silva N. America*, x. 151, t. 537 (1896); Kent, in Veitch's *Man. Conifera*, 281 (1900).

Cupressus disticha, Linnæus, *Sp. Pl.* 1003 (1753).

Schubertia disticha, Mirbel, *Mém. Mus. Par.* xiii. 75 (1825).

Three well-marked forms of *Taxodium* occur in the wild state, which differ in certain characters, such as the form of the foliage, its partial persistence or complete deciduousness, and the time of flowering; and in the present state of our knowledge these may be considered as constituting one species, the peculiarities mentioned appearing to depend on conditions of soil and climate, and to be by no means constant.

1. Var. *typica*. A tall tree, with a gradually tapering stem, which has an enlarged base, usually hollow internally and buttressed externally. When young it is strictly pyramidal in form; but in older trees the crown becomes wide and flattened, often 100 feet across, according to Sargent. The bark is dull reddish brown, 1 to 2 inches thick, fissured and separating into long fibrous scales. The leaves in this form are arranged pseudo-distichously on horizontally spreading branchlets, and are linear in shape (see generic description). This form is the one which occurs generally in the alluvial swamps of the south-eastern United States.

2. Var. *imbricaria*.

Taxodium distichum, var. *imbricaria*, Sargent, *l.c.* 152.

Taxodium distichum pendulum, Carrière, *Conif.* 182 (1867).

Taxodium imbricarium, Harper, *Bull. Torrey Bot. Club*, xxix. 383 (1902), and xxxii. 105 (1905).

Taxodium sinense, Gordon, *Pinetum*, 309 (1858).

Cupressus disticha, β *imbricaria*, Nuttall, *Gen.* ii. 224 (1818).

Glyptostrobus pendulus, Endlicher, *Syn. Conif.* 71 (1847); Hooker fil., *Bot. Mag.* t. 5603 (1886).

A tree, generally smaller in size than the type, with branchlets normally erect, but occasionally somewhat spreading and very rarely pendulous. Leaves appressed on the branchlets and acicular-acuminate (see generic description).

According to Mohr,¹ this is the "upland Cypress" which occurs on the shallow ponds of the pine-barrens and in semi-swampy woods on poor sandy soil. He considers it to be greatly inferior to the typical cypress of the alluvial swamps in regard to the size and quality of the wood; and states that in the earlier stages of its growth and on vigorous adventitious shoots it produces leaves of the ordinary form. It passes readily, according to his observations, into the type, where the soil conditions are favourable. He considers the peculiarity of the foliage to be an adaptation to check excessive transpiration during the time of drought when the sandy soil is laid bare to the sun and the supply of water diminishes.

¹ *Contrib. U.S. Nat. Herbarium*, vi, 117 and 325 (1901).

Harper considers this variety to be a distinct species, and in support of this opinion alleges that certain differences which he has observed in the two forms are constant. The bark in var. *imbricaria*, both in cultivated and wild specimens, is considerably thicker and more coarsely ridged than in the typical form. The enlargement of the base of the trunk is abrupt in the former, conical in the latter. Knees are formed more abundantly in trees of the type, and are usually slender and acute, sometimes reaching a height of 6 feet. In var. *imbricaria* the knees are short and rounded, often almost hemispherical in shape. The type is a lover of limestone, the variety just the opposite. The distribution of the two forms is different, dependent upon the geological nature of the soil, var. *imbricaria* always growing on the Lafayette formation, which is a deposit of sandy clay, while the type always occurs on other formations. Harper admits the occurrence of intermediate forms, but states that they are rare. He has records of 300 to 400 stations in Georgia for var. *imbricaria*, at each of which there may be from ten to several thousand trees, while he has only seen intermediate forms about twenty times, and never more than 100 trees at one station. In the intermediate forms branchlets with distichous leaves occur on young shoots. Harper has seen in Georgia specimens of var. *imbricaria* as large as the ordinary form; but it is generally admitted to be a smaller tree. The two forms often grow close together, but in different situations. On the Savilla river in Camden County, Georgia, he noticed the type growing along the water's edge below the Lafayette formation, while a hundred yards or so away var. *imbricaria* was flourishing in moist pine-barrens.

Var. *imbricaria* is possibly a juvenile form, analogous to *Cryptomeria elegans*. The generally smaller size of the trees and the various differences noted by Harper are probably the result of poor soil, and do not, in my opinion, entitle this form to rank as a distinct species.

This variety was early introduced into England, as it was in cultivation, according to Aiton,¹ at Kew in 1789. The original tree at Kew, now dead, was living in 1886, when it was described by Sir Joseph Hooker² as 40 feet in height and of remarkable habit, on account of its slender twisted stem with decurved branches and pectinately-disposed branchlets. A small tree, 20 feet in height, is now growing in Kew Gardens.

A tree of the Mexican kind was reported³ to be growing at Penrhyn Castle, North Wales; but Elwes saw it in 1906, and confirms the opinion I had formed from specimens sent by Mr. Richards, that it is var. *imbricaria*. It is 44 feet high and 4 in girth, and comes into leaf later than the ordinary form growing near it.

At Pencarrow,⁴ Cornwall, there is a fine specimen, which was planted about 1841 by Sir W. Molesworth. It had attained in 1899 a height of over 30 feet, with a girth of stem of 2 feet 9½ inches at 5 feet from the ground.

¹ *Hortus Kewensis*, iii. 372. Described as "Cupressus disticha, var. nutans; foliis remotioribus subsparis: long-leaved deciduous cypress." This varietal name was kept up by Loudon, *loc. cit.* 2481, who considered it to be identical with the *Taxodium sinense* of cultivators of his time.

² *Bot. Mag.* t. 5603 (1886), where it is described as *Glyptostrobus pendulus*, Endlicher.

³ A. D. Webster, *Hardy Coniferous Trees*, 115 (1896). This tree is described in *Garden*, 1887, xxxi. 480.

⁴ Figured in *Gard. Chron.* 1899, xxvi. 489, fig. 161.

As ordinarily seen in cultivation it is a small tree of slow growth, and is quite distinct from the Chinese *Glyptostrobus heterophyllus*, with which it has been occasionally confused.

3. Var. *mucronatum*.

Taxodium mucronatum, Tenore, *Ann. Sc. Nat. sér.* 3, xix. 355 (1853).

Taxodium mucronulatum, Sargent, *Silva N. Am.* x. 150, note 2 (1896).

Taxodium Montezumæ, Decaisne, *Bull. Soc. Bot. de France*, i. 71 (1854).

Taxodium mexicanum, Carrière, *Traité Conif.* 147 (1855).

Taxodium distichum mexicanum, Gordon, *Pinetum*, 307 (1858).

This differs from the type in the foliage being more persistent, generally lasting two years on the tree, and in the time of flowering, which is in autumn. The panicles of male flowers are generally more elongated than those of the United States tree. The leaves are usually shorter, lighter green in colour, and blunter at the apex.

These differences scarcely entitle this form, which occurs in Mexico, to separate specific rank. Specimens¹ of the type, occurring at high elevations (1600 to 2000 feet) in Texas, approach it in character of the foliage; and in some Florida specimens the panicles of flowers are as large as any occurring on Mexican trees. The cones vary greatly in size and form in trees of *Taxodium*, occurring both in Mexico and the United States. Sargent, who has seen the tree in Mexico, was unable to distinguish it, by either foliage or habit, from the type.

It is evidently a geographical form in which certain differences of foliage have been brought about by climatic influence. One is led by a study of the specimens from many different regions to see in *Taxodium* a single species very variable in the wild state, rather than a number of distinct species.

Taxodium does not produce knees, so far as we can learn, in Mexico, where trees generally stand upon dry ground. According to Seeman,² the tree is known in Mexico as *Sabino*, and is diffused over the whole tableland of that country. There are reported to be extensive forests of it at altitudes varying from 4500 to 7500 feet. Concerning, however, the character and distribution of these forests our information is very scanty. Much more is known about the remarkable isolated examples of very old and enormous trees, which have always attracted the attention of travellers in Mexico. The most noted of these is the tree of Santa Maria del Tule, about eighteen miles south-east of the city of Oaxaca, which was measured by Baron Thielmann³ in 1886, when its height was between 160 and 170 feet. Its

¹ Specimens collected by Hillier in Keir County, Texas, are in the Kew Herbarium.

² *Botany of Voyage of H.M.S. "Herald"* (1852-1857), p. 335.

³ *Garden and Forest*, 1897, p. 123; figured on p. 125. The tree is also depicted in *Gard. Chron.* 1892, xii. 646, fig. 100. According to a correspondent, the girth was 139 feet in 1886; 25 years previously it had been 136½ feet. Various and conflicting measurements of this tree, taken by Exter, Baron von Karwinski, and Galeotti, in the early part of the nineteenth century, are given by Zuccarini in *Ray Society, Reports on Botany* (1846), p. 19. The latest measurements of this tree I know of are on a very fine photograph given me by the late Hon. Charles Ellis, as follows:—

TAXODIUM DISTICHUM AT MITLA, NEAR OAXACA.—Reported dimensions—

Girth at 4 feet from ground,	132 feet.
" " 6 " " "	154 "
" higher up . . .	198 "
Height, 100 to 120 feet.	

(H. J. E.)

actual girth at 5 feet from the ground, following all sinuosities, was 146 feet, the longest diameter being 42 feet. The cypress of Montezuma, which is the largest of the great trees in the gardens of Chapultepec, near Mexico, is about 48 feet in girth, according to Elwes, who saw it in 1888. Its height is about 170 feet.¹

Taxodium mucronatum was first described² from a specimen growing in the Botanic Garden at Naples, said to have been introduced into Europe in 1838. Elwes saw this tree in April 1903, when the old leaves were partly persistent. A tree at Palermo has borne fruit. There are specimens at Kew labelled "Hort. Cusinati," collected by J. Ball, which bear very large cones, $1\frac{1}{2}$ inches long by an inch in breadth.

Two seedlings were raised by Elwes from seeds brought by Mr. Marlborough Pryor from Oaxaca in 1904, one of which is to be planted out in a sheltered dell at Tregothnan in Cornwall, the other in the Temperate House at Kew. The larger of these, which grew slowly in a greenhouse through the winter of 1904-5, was about 18 inches high at one year old.

The typical form is the one commonly cultivated in England. In summer the foliage is decidedly ornamental, being of a delicate green colour. In autumn the leaves, before they fall, become reddish brown in colour.

Sub-varieties.—About a dozen sub-varieties are enumerated by Beissner,³ pyramidal, pendulous, fastigiate, dwarf forms, etc. The tree is very variable in habit.

Taxodium distichum rarely produces flowers or fruit in England. It first bore fruit about the year 1752. A tree⁴ at Ryton-on-Dunsmore, which was forty years old, produced flowers, apparently all males and in great abundance, in 1868. Fruiting specimens were sent to Dr. Masters⁵ from Menabilly in Cornwall in 1893; the cones were smaller than native-grown ones. One of these was prolific, the cone terminating in a branch bearing leaves and male flowers; and from the sides of the cone leaf-bearing branches also emerged, which on examination proved to form no part of either bract or scale, but were separate outgrowths from the axis of the cone. On a tree at Gwydyr Castle, North Wales, fruit is borne about every third year, but Mr. Macintyre informed me that it never was fully matured, and no seedlings were ever raised. According to Webster,⁶ this tree was profusely covered with cones in 1884, but had none when Elwes saw it in 1906. Bunbury⁷ states that at Abergwynant, in Wales, a tree produced oval cones.

Gay⁸ says that though often cultivated in wet places in several old parks at Paris, he has only seen fruit at the Trianon on a tree growing in very dry ground.

¹ *Garden and Forest*, 1890, p. 150, fig. 28.

² Carrière, *Traité Conif.* 147 (1855).

³ *Nadelholzkunde*, 152 (1891).

⁴ *Gard. Chron.* 1868, p. 1016.

⁵ *Ibid.* 1893, xiv. 659, fig. 105, showing fruiting branch, scales, and seeds. In the same journal, 1886, xxvi. 148, fig. 28, are represented abnormal flowers of this species, from a tree growing in England; also, in *Gard. Chron.* 1888, iii. 565, fig. 77, is depicted a remarkable gnaw on a *Taxodium*.

⁶ *Woods and Forests*, 1885, p. 25.

⁷ *Arboretum Notes*, 161.

⁸ Note in Kew Herbarium.

Seedling.—There are 5 or 6 cotyledons, borne in a whorl at the summit of a purplish brown caulicle, about 2 inches long, ending in a tiny curved rootlet, which subsequently develops a few lateral fibres. The cotyledons are linear, 1 to $1\frac{1}{4}$ inch long, $\frac{1}{16}$ inch broad, sessile on a broad base, gradually diminishing to an acute apex, upper surface dark green, bearing stomata in lines with a raised midrib; lower surface pale green and uniform. On the stem above the cotyledons are borne about 3 false whorls of leaves, $\frac{1}{2}$ inch long, those below resembling the cotyledons, but bearing stomata on both surfaces; those above having decurrent bases. In the axils of the uppermost leaves lateral branchlets are given off, bearing needles in two rows and forming short shoots, which fall off in autumn.

The preceding description is taken from seedlings raised at Colesborne from cones gathered by Elwes in September 1904 at Mt. Carmel, Illinois. (A. H.)

DISTRIBUTION

This remarkable tree occurs in North America from southern Delaware, where, according to Sargent, it formerly attained almost its largest size, all along the coast region as far as the Devil's River in Texas, and up the Mississippi valley as far as southern Illinois and south-western Indiana. In these regions it inhabits river bottoms usually submerged during several months, and swampy places. On the Edwards Plateau of Texas,¹ several hundred miles west of the great cypress swamps of eastern Texas, it occurs at 1000 to 1750 feet above sea-level, and attains an enormous size at the edges of the deeper holes near the heads of the permanent water of the Pedernales and other streams. This highland form in certain respects resembles the Mexican variety. In some parts of Louisiana, Texas, and the Gulf States, it occurs as pure forest, and in places so continuously flooded that the seed cannot germinate. I have passed on the railway, built on trestles for miles, through cypress swamps where the soil was submerged to a depth of 5 or 6 feet, and where few other trees could live. In drier places, such as the Wabash valley in southern Indiana, near Mount Carmel, where the cypress is evidently not so happy, it was associated with ash, liquidambar, and maple. In this locality also, although the trees were covered with fruit, I could find no seedlings; and as the accessible trees are in most places being rapidly cut for their timber, they seem likely to become scarcer unless protected. As far as I know it does not grow from the stool or from suckers.²

In Arkansas and Missouri there are swamps³ in which both *Taxodium* and *Nyssa uniflora* grow together, the latter with a peculiar dome-shaped base,

¹ *Ann. Report U.S. Geol. Survey*, xviii. 210, 211 (1898). There are specimens from this locality at Kew.

² R. Ridgway describes this locality as being in 1873 heavily timbered with cypress over an area of about 20,000 acres, in which the best trees had even then been cut and floated out into the river. The largest stump he measured was 38 feet in girth at the ground and 22 feet at 8 feet high. The largest standing tree measured was 27 feet in girth above the swollen base, and the tallest 146 and 147 feet high. Their average height, however, was not above 100 feet, and even the finest of them would not compare for symmetry and length with the sweet gums (liquidambar) and ashes (*Fraxinus americana*) with which they were associated.—*Proc. U.S. Nat. Mus.* 1882, p. 87. An excellent photograph taken here is published in *Garden and Forest*, iii. p. 7, and shows the knees remarkably well.

³ Coulter, *Missouri Bot. Garden Report*, 1903, p. 58.

analogous to the cone-shaped base of the former; and from Coulter's observations it would appear that seedlings of *Taxodium* are also rare here, and that it is being beaten in the struggle by the *Nyssa*, the seedlings of which are very abundant.

A disease¹ due to a fungus has attacked many of the trees in the Mississippi valley; the heartwood is found when the trees are cut down to be full of holes $\frac{1}{4}$ to $\frac{3}{4}$ inch in diameter.

Taxodium is one of the most striking and characteristic trees in the Gulf States, having its branches often covered with *Tillandsia usneoides*, the "Spanish moss" of the inhabitants, the long grey masses of which wave in the wind and give it a strange appearance. The trunk takes many curious forms, which seem to be induced by the nature of the soil and the depth of the water, sometimes branching low and surrounded by buttresses, sometimes growing straight up to a considerable height (Plates 52-53).² From the stout wide-spreading roots arise woody cylindrical projections, sometimes above a foot in diameter and 5 to 7 feet high, which are called "cypress knees." The growth and functions of these have been the source of much discussion.³ Berkeley⁴ supposed that they serve to aerate the submerged roots; others have thought that they help to anchor the roots in soft muddy soil. As the knees, however, occur to some extent even on ground which is never flooded, as in the trees at Syon, these suppositions, though highly probable, must remain somewhat doubtful.

The knees are hollow inside, and smooth externally, being covered with a reddish, soft, and spongy bark. They never show any sign of vegetation, and will not put forth shoots, even if wounded and covered with earth.

CULTIVATION

In England the *Taxodium* grows much better than might be expected considering how much colder and shorter are our summers than those of its native country. It was introduced by John Tradescant about 1640, and described by Parkinson⁵ as *Cupressus americana*.

For some unexplained reason it has lost the popularity it once enjoyed, and is now seldom planted, though it grows well in the southern and western counties. I have raised it from American seed, which, however, must be soaked in warm water for some time, and placed in a warm house to get good results. It grows rapidly at first, but as the young wood is not ripened, and no terminal bud formed (which

¹ Coulter, *Missouri Bot. Garden Report*, 1899, p. 23.

² For the negatives of the first of these photographs I am indebted to Miss E. Cummings of Brookline, Mass., a lady who is second to none in her love of and knowledge of trees. The second, which was sent by Mr. W. Ashe, represents a typical cypress swamp on the Roanoke river, North Carolina, which has never been cut for timber.

³ Sargent, *loc. cit.* 152, note 1; Coulter, *loc. cit.* The best review I know of the literature on this subject is in a letter by R. H. Lamborn in *Garden and Forest*, iii. p. 21, which should be consulted by those interested, and which is illustrated by a very curious photograph, taken at Lake Monroe in Central Florida, of the denuded roots of the tree, showing that in some cases, at least, the anchor theory is proved.

⁴ *Gard. Chron.* 1857, p. 549.

⁵ Parkinson, *Theatr.* 1477, fig. In *Catalogue of Trees*, London, 1730, p. 25, it is stated that the first tree, raised in Tradescant's garden near Lambeth, was then still living, being 40 feet high by 2 fathoms in girth.

Sargent says is also the case in America), the young plant must be kept under glass for the first two or three winters in order to develop a straight leader.

Many of the old trees which are to be found in England have evidently suffered from spring and autumn frosts when young, and have become stunted in consequence, but when the wood is ripe the tree will stand as much as 30° to 40° of frost, and I have seen it existing in the open air as far north as Copenhagen.

It should be planted in deep, moist loam, and the most sheltered situation that can be found, and may then be expected in the south and south-west to grow into a very fine and ornamental tree.

REMARKABLE TREES

The trees at Syon have been frequently described and figured. They are planted in damp soil by the side of a sheet of water, and one of them has produced knees of 1 to 2 feet high. This tree, which is shown in Plate 54, measured, in 1903, 90 feet by 12, but there is a much taller one on the other side of the water, which, when we saw it last in 1905, was 110 feet high, and is the tallest we know of in Europe. Another in the Duke's walk is 85 feet by 10 feet 3 inches.

But those at Whitton, near Hounslow, are even more remarkable, and are believed to have been planted by the Duke of Argyll between 1720 and 1762. They grow on gravelly soil, which, though apparently dry, is probably underlaid by damp alluvium. There are five trees standing in a group, of which the largest, carefully measured by us both in 1905, was 98 to 100 feet high by 13 feet 6 inches in girth; the others are all large, healthy, and growing trees (Plate 55).

At Pain's Hill, Surrey, there are two good trees: one,¹ measured by Henry in 1904, is 90 feet by 10 feet 9 inches, the other is 80 feet by 8 feet 6 inches.

At Parkside Gardens, Wimbledon, a tree is growing which is remarkably like the Ginkgo at Kew in habit. The bole at 7 feet divides into two stems, which give off seven or eight ascending branches. In 1904, measured by Henry, it was 65 feet by 11 feet 2 inches.

At Gothic Lodge, Wimbledon, the residence of Sir William Preece, there is a tree with a fine bole of 20 feet, dividing into several upright stems. In 1904, measured by Henry, it was 90 feet by 11 feet. This is perhaps the tree mentioned by Miller,² who says that a "tree at Wimbledon in the garden of Sir A. Janssen, Bart., bore cones for some years past and seeds which have been as good as those brought from America."

At White Knights, Reading, there are several trees, but none of large size, the biggest measuring, in 1904, 67 feet by 7 feet 10 inches. They are remarkable, however, for variety of habit. One is a tall, narrow tree with upright branches, almost fastigiate. In another tree the stem is twisted, as often occurs in the chestnut, and most of the branches are twisted also in the direction against the sun. Loudon mentions these as young trees of peculiar habits.

¹ This is probably the tree, reported in *Woods and Forests*, February 4, 1885, to be 83 feet in height by 10 feet in girth at 3 feet above the ground.

² Miller, *Gard. Dict.*, ed. 8, sub *Cupressus disticha* (1768).

At Barton, Suffolk, there are three trees, which measured in 1903, (*a*) in the Arboretum, 50 feet by 5 feet 5 inches, dying; (*b*) a smaller tree beside it, in a worse condition; (*c*) on the lawn, 56 feet by 4 feet 3 inches. The latter tree¹ was planted in 1826, the other two in 1831. It is evident that the dry though deep soil at Barton is not favourable to the growth of this species.

At Frogmore, Windsor, there are two specimens very different in habit. One, a clean-stemmed tree, growing near water, but without knees, is 80 feet by 8 feet 6 inches. The other, not so large, has a weeping habit, and is branched to the ground.

At Strathfieldsaye there is a tree, mentioned by Loudon as being 46 feet in height by 3 feet 4 inches in diameter, which I found in 1903 to be 63 feet high by 9 feet in girth. It is growing in stiff clay soil and has no knees; the stem is deeply furrowed.

At Dropmore there is a tree beside a pond, planted in 1843, and now measuring 60 feet by 5 feet 9 inches.

At South Lodge, Enfield, a tree is growing near water, with small knees, which, measured by Henry in 1904, was 77 feet by 11 feet 10 inches.

At Combe Abbey, Warwickshire, Mr. W. Miller² reports that a tree, mentioned by Loudon as 47 feet by 2 feet 3 inches in 1843, had attained, in 1887, 75 feet by 11 feet 6 inches at 3 feet from the ground.

At Longford Castle,³ Salisbury, there are two trees, growing within a few yards of the river Avon. One, very tall, has a straight trunk free from branches for about 30 feet, and a girth of 8 feet 10 inches at 4 feet from the ground. The other is 6 feet in girth, and branches at 7 feet up.

At Brockett's Park, near Hatfield, the residence of Lord Mountstephen, there are many trees planted along a walk on the banks of the Lee, and forming an irregular line in which the trees vary very much in size. In the sheltered part of the valley, where the soil and situation are very favourable, they average 70 to 80 feet high, the best I measured being 80 feet by 10 feet and 86 feet by 9 feet. But lower down the stream, where the valley is more exposed to the wind, they are stunted, and not more than half the height of those above. There are knees on some of the trees overgrown with moss and meadowsweet, but not so large as those at Syon.

At Upper Nutwell, near Exeter, there is a tree which Mr. G. H. Hodgkinson informed me in June 1904 was 84 feet high by 11 feet 9 inches in girth.

Large trees have been reported at many other places, especially in the south of England, viz. :—

Connington Castle,⁴ Huntingdonshire, a tree 70 feet by 7 feet in 1877; Watford,⁵ Herts, 85 feet by 14 feet in 1884; Stanwell,⁶ Surrey, a tree 13 feet in girth in 1904; Embley,⁷ near Romsey, Hampshire, a tree 8½ feet in girth in 1872, standing on the top of a hill.

¹ Bunbury, *Arboretum Notes*, 161.

² *Gard. Chron.* 1905, xxxvii. 12.

³ *Garden*, 1890, xxxvii. 538.

⁴ *Ibid.* 1877, xii. 405.

⁵ *Woods and Forests*, 1884, p. 546.

⁶ Reported by Sir Hugh Beevor.

⁷ Bunbury, *Arboretum Notes*, 161.

I have seen no trees in Scotland of any size, and Henry has heard of none in Ireland, but there is one in the Edinburgh Botanic Gardens 31 feet by 3 feet in 1905.

TIMBER

According to Sargent the timber is light and soft, close, straight grained, not strong, easily worked, and very durable in contact with the soil. It is largely used for building, most of the houses in Louisiana and the Gulf States being built from it, and large quantities are also now exported to the North, where it is found a most valuable wood for doors, sashes, balustrades, and greenhouses.

The Stearns Lumber Company of Boston, U.S.A., are making a speciality of it, and from a pamphlet published by this firm I take the following particulars :—

The timber varies considerably in different localities, and they consider, after long experience, that the so-called Gulf Cypress, grown in Florida, is better than the Louisiana Red Cypress, or that from the Atlantic coast of Georgia. Farther north it is apt to be more shaly and of coarser grain; and it is claimed that the seasoning is better done in the South than in the Northern States, from one to five years being required to do this properly, according to the dimensions of the timber, and that the longer in reason that it is kept in the pile before using the better.

It is said to be more durable, and to shrink and swell less than spruce or pine, to take paint well, and, as it contains no pitch, to resist fire longer than other coniferous woods.

It is quoted from the *Richmond Despatch* that a house, built by Michael Braun in 1776, and still owned and occupied by his descendants, was covered with cypress shingles, which were only removed in 1880.

Such shingles are now made by machinery at a very low price, and would be well worth trying for roofing houses in England, as they are very light in weight and inexpensive, and though I have no evidence that they are better than shingles made from English oak, their much greater size makes them easier to lay, and they can be cut to fancy patterns, which makes them very ornamental for roofing.

This wood is also highly recommended for doors, sashes, tanks, and other purposes where a great power of enduring damp is required.

It occasionally produces very ornamental wood, which is mottled and grained with red and brown, and some doors made of this wood, two of which I now possess, are extremely handsome.

Whether the wood grown in England will prove equally good I cannot say, as large trees are so seldom cut down in England that I have been unable to try it, but would certainly advise anyone who may have the opportunity to do so.

(H. J. E.)

THUYA

Thuya,¹ Linnæus, *Gen. Pl.* 378 (1737); R. Brown, *Trans. Edin. Bot. Soc.* ix. 358 (1868); Bentham et Hooker, *Gen. Pl.* iii. 426 (*ex parte*) (1880); Masters, *Jour. Linn. Soc. (Bot.)* xxx. 19 (1893). *Biota*, Endlicher, *Syn. Conif.* 47 (1847).

EVERGREEN trees of pyramidal habit and aromatic odour, belonging to the tribe Cupressineæ of the order Coniferae. Branches spreading and much ramified, terminating in so-called "branch-systems," which are flattened in one plane and are 2-, 3-, or 4- pinnately divided, their primary and other axes being densely clothed with scale-like leaves. These branch-systems² when they fall are cast off as a whole, the leaves not falling separately. The leaves, which are minute, are more or less coalesced with the axes, on which they stand in 4 ranks in 2 decussate pairs, those of the lateral ranks being conduplicate or boat-shaped, those placed dorsally and ventrally being flattened. In the seedling stage and certain horticultural varieties,³ the foliage is different, the leaves being acicular, spreading, and uniform; all 4 ranks in this case are alike.

Flowers monœcious, all solitary and terminal on the ultimate short branchlets of the preceding year, the male and female flowers on different branchlets, the former on the branchlets near the base of the shoot, the latter on those near its summit. Male flowers cylindrical or globular, consisting of 3 to 6 pairs of stamens placed decussately on an axis, each with an orbicular connective bearing 2 to 4 pollen sacs. Female flowers minute cones, composed of opposite scales in which no distinction of ovular scale and bract is visible, continuous in series with the leaves at the end of the branchlet, 2 to 4 pairs in *Biota*, 4 to 6 pairs in *Euthuya*, mucronate at the apex, some sterile, the others fertile and bearing 2 to 3 ovules.

Cones solitary, ultimately deflected, except in *Biota*, in which they retain the erect position, oblong, ovoid, or almost globose, composed of 3 to 6 pairs of decussate scales, which are not peltate, some fertile, the others sterile, the uppermost often united together. Seeds 2 to 3 on each fertile scale. Cotyledons 2.

The genus *Thuya*, as understood here, does not include *Chamaecyparis* and

¹ *Thuya* has been written *Thuja* in Linnæus, *Hort. Cliff.* 449 (1737), and *Sp. Pl.* 1002 (1753); and *Thuia* in Scopoli, *Introd.* 353 (1777).

² The branchlets become brown in colour before they fall. See Masters, *Gard. Chron.* 1883, xx. 596.

³ In addition to the varieties, in which the foliage retains permanently the seedling character, other forms occur in cultivation, in which the leaves are intermediate in shape between those of the seedling and of the adult plant. These varieties resemble the so-called *Retinospora* forms of the genus *Cupressus*, and were formerly considered, like them, to belong to a distinct genus.

Thujopsis, which were united with it by Bentham and Hooker. So limited, it comprises 5 species, and is divided into the two following sections:—

I. *Euthuya*. Cones with thin, coriaceous mucronulate scales, those of the 2 or 3 middle ranks being fertile. Seed thin, with lateral wings and a minute hilum. This section comprises 4 species, *Thuya occidentalis* and *Thuya plicata* of North America, *Thuya sutchuenensis* of central China, and *Thuya japonica* of Japan.

II. *Biota*. Cones with thickened, conspicuously umbonate scales, which are fleshy when young, almost ligneous when ripe; those of the lowest two ranks fertile. Seed thick, without wings, the hilum being large and oblong. This section includes one species, *Thuya orientalis* of north China.

The Thuyas resemble considerably in foliage and habit the flat-leaved cypresses. The latter are best distinguished by their fruit, which consists of peltate scales fitting closely by their edges. In a subsequent part, the peculiarities, as regards the branch systems and leaves, of these cypresses (*Cupressus Lawsoniana*, *nootkatensis*, *thyoides*, *obtusa*, and *pisifera*) will be described, and may then be compared with those now given below for the four species of *Thuya* in cultivation.

In the discrimination of the Thuyas, in addition to the characters shown by the bark, mode of branching, and fruit, the primary and secondary axes of the branch-systems give good marks of distinction. These axes are markedly flattened in *Thuya occidentalis*, terete in the other species. In *Thuya orientalis* the branch-systems stand in vertical planes, the inner edges of which are directed towards the stem of the tree. In ordinary forms of the other three species they are arranged in horizontal planes. The leaves on the main axes in each species differ as follows:—

1. *Thuya plicata*:¹ widely spaced, long, ending in long, fine, free points, which are parallel to the axis; glands inconspicuous or absent. Under surface of the foliage usually marked with white streaks.

2. *Thuya japonica*: placed closely together, shoots ending in short, rigid, thick, triangular points, directed outwards at an acute angle; glands absent. Under surface of the foliage conspicuously marked with broad white streaks.

3. *Thuya occidentalis*: widely spaced, ending in long, fine points, which are parallel to the axis; glands raised, large and conspicuous on the flat leaves. Under surface of the foliage pale green; white streaks inconspicuous or absent.

4. *Thuya orientalis*: widely spaced, ending in short triangular free points, which are not rigid, and are directed slightly outwards at an acute angle: flat leaves marked by longitudinal glandular depressions. Under surface of the foliage pale green, without white streaks.

Thuya sutchuenensis, Franchet,² is a small tree occurring in north-east Szechuan in central China, where it was discovered by Père Farges growing at an altitude of 1400 feet. The branchlets are much flattened, thin in texture, and practically glandless. Cones composed of 8 obovate scales, the apices of which are slightly thickened. This species has not been introduced into cultivation.

¹ This species exhales a peculiar aromatic odour, which is different from that of the other Thuyas.

THUYA PLICATA, GIANT THUYA

Thuja plicata, D. Don in Lambert, *Pinus*, ed. 1, ii. 19 (1824); Masters, *Gard. Chron.* xxi. 214; figs. 69, 70, 71 (1897); Sudworth, *Check List Forest Trees U.S.* 31 (1898); Sargent, *Manual Trees N. America*, 75 (1905).

Thuja gigantea, Nuttall, *Jour. Philad. Acad.* vii. 52 (1834); Sargent, *Silva N. America*, x. 129, t. 533 (1896); Kent, in Veitch's *Man. Coniferae*, 239 (1900).

Thuja Menziesii, Douglas, ex Carrière, *Traité Gén. Conif.* 107 (1867).

Thuja Lobbi, Hort.

Thuja Craigiana, Hort. [*non* A. Murray, *Bot. Exped. Oregon*, 2 (1853)].

A lofty tree, attaining a height of 200 feet, with a trunk remarkably conical, the base being broad and buttressed, sometimes girthing as much as 40 to 50 feet near the ground.

Bark of the trunk fissuring longitudinally in narrow thick plates, which scale off, leaving exposed the reddish brown cortex beneath. On the branches, the bark only begins to scale when they become old and thick. Branches horizontal, ascending towards their ends, forming in England a dense, narrow, pyramidal tree, usually clothed to the base.

The 3-4 pinnate branch-systems, disposed in horizontal planes, have their main axes terete and covered with long leaves ending in acute points which keep parallel to the axes. The glands on these leaves are inconspicuous or absent. On the ultimate axes the leaves are smaller, the flat ones scarcely glandular, and ending in mucronate points; the lateral ones keeled on the back, slightly curved, and ending in sharp cartilaginous points. On the lower surface of most branchlets the foliage is streaked with white, some branchlets usually remaining uniformly green.

The male flowers are dark red in colour, cylindrical, and composed of about 6 decussate pairs of stamens.

The cones when ripe do not remain erect, but are deflected out of the plane of the branchlets. They are oblong, light brown in colour, and composed of 5 to 6 pairs of scales, of which the 2nd, 3rd, and 4th pairs are larger than the others, and fertile. The scales are oval or spatulate, with a rounded apex, from immediately below which externally a small deltoid process is given off. The seeds, 2 or 3 on each fertile scale, are brown in colour, two-thirds the length of the scale, and surrounded laterally by a scarious wing, which is deeply notched at its summit.

Seedling.¹—The 2 cotyledons are linear, flat, acute at the apex, and slightly tapering towards the base, supported on a terete caulicle, about $\frac{3}{8}$ inch long, which ends in a long brown flexuose primary root giving off a few fibres. The stem, terete and smooth near the base, becomes ridged above by the decurrent leaf-bases. The first 4 true leaves are in opposite pairs, decussate with the cotyledons. Above these the stem gives off a number of whorls or pseudo-whorls of longer ($\frac{1}{2}$ inch) sharply pointed leaves, dark green above and pale beneath, with markedly decurrent

¹ Figured in Lubbock, *Seedlings*, ii. 551, fig. 676 (1892), and Sargent, *loc. cit.* t. 533, fig. 12.

bases. After a few of these whorls lateral branches are given off, which sometimes bear a few acicular leaves at their bases. The lateral branches ramify and approach in character those of the adult plant, as the leaves are arranged decussately in 4 ranks. These leaves are variable, being acicular and loosely imbricated, or scale-like and closely imbricate. The branches are ascending, horizontal, or drooping, and are more or less flattened from above downwards.

HISTORY¹

This tree was discovered by Née, who accompanied Malaspina in his voyage round the world during the years 1789 to 1794; and his specimen, gathered at Nootka Sound, is preserved in the Natural History Museum at South Kensington. It was referred to by James Donn, in *Hortus Cantab.* ed. 4 (1807), as *Thuja plicata*, without any description; and subsequently D. Don drew up from it the oldest description of the species under the same name. The *Thuja plicata* of gardens, which was early in cultivation, is a variety of *Thuja occidentalis*, and has no connection with the plant of Née.

Archibald Menzies, who accompanied Vancouver's expedition as botanist, gathered specimens also at Nootka Sound in 1795. Nuttall received specimens later from the Flathead river, on which he founded his description of the species as *Thuja gigantea*. It was introduced into cultivation² in 1853 by W. Lobb, and distributed from Veitch's nursery at Exeter as *Thuja Lobbi*, as at that time Nuttall's name *Thuja gigantea* was wrongly applied to *Libocedrus decurrens*, and Don's name, *Thuja plicata*, in a similar erroneous way, had gone into common use for a variety of *Thuja occidentalis*. Afterwards the tree became generally known in England as *Thuja gigantea*; and it is unfortunate that Don's name, *Thuja plicata*, must, following the law of priority, be substituted for a name so well known and so established as *gigantea*. This change of name has, however, been adopted in the *Kew Hand List of Conifers*, and by Sudworth and Sargent in North America, and on the whole it is now most convenient to adopt the name *Thuja plicata*.

(A. H.)

DISTRIBUTION

This tree is, next to the Douglas fir, the most important from an economic point of view in northern Oregon, Washington, and British Columbia.

It extends in the north as far as southern Alaska, in the east to the Cœur d'Alène Mountains in Idaho and to north-western Montana, and in the south to Mendocino County in northern California. It is known as Cedar, or Red Cedar, and is found most abundantly on wet soils and in wet climates, ascending from sea level to an elevation, according to Sargent, of 6000 feet, where it becomes a low shrub.

¹ See Masters, in *Gard. Chron. loc. cit.*

² At the Royal Botanic Gardens, Edinburgh, there were in 1884 five trees of supposed *Thuja gigantea*, which were raised, it was said, from seed sent to Edinburgh by Jeffrey in 1851, while collecting for the Oregon Association. Three of these trees, according to Nicholson, were true *gigantea*, the other two being what is now known as *Thuja occidentalis*, var. *plicata*. See *Woods and Forests*, Feb. 27, and Mar. 19, 1884. These trees cannot now be identified.

It is scarce in the dry belt of country east of the Cascade Mountains, but common in the Selkirk and Gold ranges, though, so far as I know, it never extends to the eastern side of the Rocky Mountains.

On the coast and in Vancouver Island it attains an immense size. I have never measured trees more than 200 to 220 feet high, but Prof. Sheldon says that it attains 250 feet in Oregon, though no actual measurements are given.¹ As regards their girth, I have measured two trees which may have grown from the same root, so close do they stand together, one of which was 39, the other 25 feet at 5 feet from the ground. These stand on Mr. Barkley's farm in Vancouver Island, in swampy land near sea level, and are figured in Plate 56.² At over 2000 feet elevation in Oregon I measured another, also a twin tree, which was 30 feet in girth. Mr. Anderson states that he has seen Indian canoes 6 feet and more from the level of the gunwale to the bottom, hewn out of a log of this tree, such canoes being often 50 feet and more long. A hewn plank 5 feet wide by 15 feet long is in the museum at Victoria, B.C., and split boards, quite straight, 12 feet long and 15 inches wide, are made from it without difficulty.

The natural reproduction by seed was, wherever I saw it, very good, though in the densest shade the western hemlock seemed to have the advantage.

CULTIVATION

Wherever I have seen this tree growing in England and Scotland it is a vigorous, healthy tree of great beauty and promise, and one that I think is likely in fifty years or so to become a more valuable timber tree than the silver fir or spruce.

It has been stated in a report by Herr Bohm, in the March number of the *Zeitschrift für Forst. u. Jagdwesen* for 1896,³ that the parasitic fungus *Pestalozzia funerea* has done serious damage to the tree in North Germany, and statements to the same effect have been made elsewhere; but I can say that out of the thousands of this tree that I have raised from English seed and planted out in a bad soil and climate, I have never had any die from any disease whatever, and have found it an easier tree both to raise and to transplant than any other conifer. It will grow on almost any soil at the rate of at least one foot per annum, as in damp, cold bottoms where the spruce will hardly thrive, on the poor dry oolite soil of the Cotswold hills, and seems equally indifferent to wind, damp, and spring frosts.⁴ It seldom loses its leader, is rarely blown down, endures heavy shade, and transplants both in

¹ In the Canadian Court of the Colonial Exhibition of 1886, there was shown a portion of a bole of this species, which was taken from a tree girthing 21 feet, and having a length of 250 feet. It came from British Columbia.—*Gard. Chron.* 1886, xxvi. 207.

² An illustration of a tree growing near Snoqualmie Falls on the Seattle and International Railway, Washington, was given in *The Pacific Rural Press* in 1897. This is said to have been 107 feet 7 inches round at the base, and was supposed to have been over 1000 years old, but we know of no good evidence that it ever attains so great an age as this.

³ Cf. A. C. Forbes, *Gard. Chron.* 1896, xix. 554.

⁴ The very severe frost on May 20-21, 1905, when 10°-15° of frost were registered in many places, which killed many young beech trees in low situations at Colesborne, and checked the young growth considerably, killed none except a few of the weakest Thuyas which were freshly transplanted; but the autumn frost of the following October, when the trees were still in growth, seems to have done more harm, though the young trees did not die till the following spring.

early autumn and late spring with great readiness. It has, therefore, every good quality a forest tree can have, except the as yet unproved one of cleaning its trunk from branches without pruning.

And as this has not yet been properly tested by thick planting, I venture to say that there is no conifer better worthy of an extensive trial as a timber tree for such purposes as the larch is now used, and especially for fencing posts, for which its remarkable durability in the ground seems to make it most valuable.¹

I should therefore recommend that this tree should be planted at distances of 6 to 8 feet apart in situations where larch will not thrive, and not thinned as long as the trees keep healthy.

In the New England states it is not hardy enough to live in many places, but Professor Sargent tells me that a variety raised from seed from the Coeur d'Alène mountains in northern Idaho is hardy at Boston, where the form from the Pacific coast is tender, just as in the case of the Douglas fir.

No reliable tests, so far as I know, have yet been made in England or America as to the breaking strain and strength of this wood, but Sheldon states that it is used for telegraph posts in Oregon, and though its branches die off so slowly that the home-grown timber may probably be knotty, it is certainly not worse in this respect than spruce, to which I should consider it in every respect a superior forest tree.

The seed usually ripens about the end of October, and is very freely produced in most seasons. It soon sheds when ripe, and should be sown in boxes or in the open ground in early spring. I have tried both plans with great success, and find it best to plant the seedlings at two years old in nursery lines, and plant out the trees finally either in the early autumn or spring, when the deaths will be very small if the roots are not allowed to dry before planting.

There is very little variation among the seedlings, which grow rapidly in moist soil, and are less liable to suffer from spring frost than most trees, though if planted in mid-winter the tops are liable to die back.

There is no reason why this tree should not be sold in nurseries at the price of spruce except the absence of a regular demand, as it can be got up to a proper size for planting in two years less time.

The tree seeds itself very rapidly on sandy soil in many parts of the west and south of England, though liable to be thrown out of the ground by frost during the first year, and often destroyed by rabbits. On the lower greensand at Blackmoor, Hants, self-sown seedlings were quite numerous, both of this tree and of many other conifers, but rabbits are not allowed here, and both Lord and Lady Selborne take great interest in self-sown seedlings.

REMARKABLE TREES

The giant Thuya has not been long enough in cultivation to show whether it

¹ I have recently been shown by Mr. Molyneux a plantation of *Thuya gigantea* and larch called Mays hill, made by him in 1888 on poor, heavy wheat land overlying chalk at Swanmore Park, Hants, the seat of W. H. Myers, Esq., M.P. Here the Thuyas have completely outgrown the larch, and in many cases suppressed them, and are 15 to 20 feet high, and quite healthy; whereas where the larch were planted alone in the same place they are diseased and sickly.

will attain the same dimensions that it does in America, but there are many trees which are already 60 to 70 feet in height at less than fifty years from seed.

By far the finest that I have seen or heard of are at Fonthill Abbey, Wilts, the residence of Lady Octavia Shaw-Stewart, which were raised in the late Duke of Westminster's gardens at Eaton Hall from seeds collected for Lord Stalbridge in 1860. Here, on a bed of greensand at an elevation of 400 to 500 feet, well sheltered from wind, are growing some of the finest and best grown conifers in Great Britain. In a group of three *Thuyas*, the middle one measured in 1906, as nearly as I could ascertain, not less than 90 and probably 95 feet in height by 10 feet in girth, and already began to show the buttressed trunk which is so characteristic in its native country. The other two trees were not much less in size, and all were a picture of health and symmetry (Plate 57).

The next tallest that we know of is a tree at Albury Park, the Surrey seat of the Duke of Northumberland. This was measured by Henry in 1904, and by myself in 1905, but owing to the way in which it is shut in by other trees it is difficult to measure accurately, and though the late Mr. Leach, the head gardener at Albury, and Dr. Henry both considered it about 90 feet high, I should not like to say that it is over 80, with a girth of 7 feet 6 inches. It is, however, a very healthy and vigorous tree, and growing fast, and the Duke's agent and gardener both hold a very high opinion of the probable value of the tree for timber, and are planting it largely on the estate. See *Gard. Chron.* Jan. 30, 1892, where an account is given of the trees at Albury in which Mr. Leach is quoted as saying: "If I had 1000 acres to plant with trees that would give the most remunerative return in a given time, the above would be my mainstay."

Sir Charles Strickland, one of the oldest and most experienced planters in England, also has a high opinion of this tree, and is quoted as follows by Mr. A. D. Webster in an article on this tree in *Trans. Scottish Arb. Soc.* vol. xii. p. 343:—"There is a hillside here (Hildenley, Yorkshire), with a thin soil upon limestone rock, which I planted two or three times over with very small success—chiefly, I believe, on account of the extreme dryness of the site. The *Thuya* grows there with great vigour, and I have scarcely lost one of those planted. Among the other merits of this *Thuya* is the ease with which it may be transplanted, owing to its having bushy, fibrous roots, instead of the long tangles which larch and many other conifers have." I saw this plantation in 1905, and though the situation is too dry for *Thuya* to grow to any size, it bears out Sir Charles's good opinion. He has continued to raise the tree largely from his own seed, and is planting them largely at 5 feet apart, without mixture.

At Castlehill, North Devon, the seat of Earl Fortescue, there are also very fine specimens of *Thuya plicata*. The best is growing in a quarry in a well-sheltered place, but on dry, rocky ground. It measured in April 1905 about 74 feet high by 5 feet 11 inches in girth, and bids fair to become a noble tree.

At Fulmodestone, Norfolk, there are two trees, planted in 1863, which measured in 1905, 67 feet by 7 feet, and 61 feet by 6 feet 8 inches, and have natural seedlings around them.

At Coolhurst, near Horsham, Mr. C. Scrace Dickens showed me a very fine and symmetrical tree 75½ feet high by 5½ in girth, and only 8 yards in the spread of its branches.

At many places in the south-west of England trees of from 65 to 70 feet are growing of which the following are the best we have measured ourselves:—Linton Park, Kent, 70 feet by 7 feet 1 inch in 1902; Dropmore, Bucks, 68 feet by 6 feet 10 inches in 1905; Killerton, Devonshire, 68 feet by 7 feet 10 inches in 1905; Bicton, Devonshire, 70 feet by 8 feet 2 inches in 1902; Blackmoor, Hants, 60 feet by 6 feet.

In Wales a tree at Hafodunos measured 65 feet 6 inches by 9 feet 7 inches in 1904, with natural seedlings a few feet from its base on the stump of an old tree; at Welfield, near Builth, the seat of E. D. Thomas, Esq., a tree 68 feet high and 6½ feet in girth was flourishing on the Llandilo slate formation; and at Penrhyn Castle Mr. Richards showed me a well-shaped and healthy young tree about 50 feet high, one of fifty which had been transplanted when about 18 feet high, only one of which died after being moved.

In Scotland *Thuya plicata* flourishes in the south and west, as well as in England. At Inverary Castle a tree only 25 feet high in 1892 is now over 60. At Poltalloch there are many, of which one in 1905 was 65 feet by 7 feet 2 inches. As far north as Gordon Castle it grows well, and at most of the places from which reports were sent to the Conifer conference in 1892 it is spoken of as healthy and vigorous. At Murthly, Scone, and Castle Menzies, I have seen fine trees, but have not measured any of remarkable size.

At Monreith, Dumfriesshire, the seat of Sir Herbert Maxwell, Bart., who has a high opinion of this tree, a large number have been raised from seed and planted out, but are as yet too young to measure.

At Benmore, near Dunoon in Argyllshire, the property of H. J. Younger, Esq., where there are very interesting plantations of several kinds of exotic conifers made in the winter of 1878-79, *Thuya*, when mixed with the common larch and Douglas fir on a steep hillside at 250 to 500 feet above sea-level, is now being suppressed by these species, which grow more vigorously. However, in one part of the plantation, near Ardbeg, at only 50 feet above sea-level and in fairly good soil, the *Thuya* was holding its own fairly well with the Douglas, and had attained, at twenty-four years old, 50 feet in height with clean stems varying from 25 to 38 inches in girth at 5 feet from the ground. Near Kilmun, on the same property, there is now, according to the forester, about 1½ acres of *Thuya*, which has been planted mixed with larch. The larch has been cut out, and the whole area is now pure *Thuya*, with clean stems larger in size than in the other parts of the plantations where it occurs mixed with Douglas fir.¹

In Ireland the best trees we know of are at Castlewella, co. Down, 65 feet in 1903; Hamwood, co. Meath, 71 feet by 6 feet 3 inches in 1904; Churchill, co. Armagh, 68 feet by 5 feet 10 inches in 1904; Adare, co. Limerick, 71 feet by 7 feet 7 inches in 1903.

¹ We are indebted to Mr. Angus Cameron, factor for the property, and to Mr. J. M. Stewart, forester, for further particulars of these plantations, for which we cannot now find space.

At Dartrey, in co. Monaghan, the Earl of Dartrey planted in 1882 a considerable area of slightly hilly ground with a mixture of larch, spruce, Douglas fir, and Thuya. In 1904, twenty-two years after planting, of the four species, all grown densely under the same conditions, the Thuya had made the most timber, the trees averaging 40 to 50 feet in height by $4\frac{1}{2}$ feet in girth. The Douglas fir was slightly taller, but not so stout in the stem, averaging about $3\frac{1}{2}$ feet in girth. The Earl of Dartrey speaks very highly of the timber of Thuya, which he considers to be superior to that of the best larch.

At Brockley Park, Queen's Co., the residence of Mr. Wm. Young, there are trees growing on light soil on limestone, which have made 40 cubic feet of timber in 30 years, and 50 feet in 35 years. The tallest tree, 30 years old, was in 1906 64 feet high by 7 feet 9 inches at a foot from the ground, and $3\frac{1}{2}$ feet girth at 24 feet up; and its branches were 105 feet in circumference.

TIMBER

Sargent says, *Garden and Forest*, iv. p. 109: "The wood is very valuable; it is light, soft, and easily worked, and so durable in contact with the ground, or when exposed to the elements, that no one has ever known it long enough to see it decay."

The great value of the cedar for shingle-making has long been known, and several instances were mentioned by reliable people in Vancouver Island of hand-made shingles, or "shakes" as they are called, remaining good 40 to 50 years on roofs without decaying in the wet climate of this island.

They are now manufactured on a very large scale by machinery in all the Puget Sound mills, and exported largely to the middle and eastern states in neat bundles, and I have no doubt that, if carefully selected and laid, such shingles would be very suitable for roofing in England. Sargent says, *Garden and Forest*, iv. p. 242, "that nearly 100 mills were in 1891 exclusively devoted to making Red Cedar shingles, and that the combined output of half of these operated by one company was 3,500,000 per diem. They are now supplanting the Pine shingle of Michigan, the Cypress shingle of the south, and the Redwood shingle of California."

As a rule in the American forests, they begin to decay at the heart long before they attain their full growth, and the trunk seems to continue growing round the hollow centre for an almost indefinite time, as in the case of the yew. On drier land it keeps sound longer, and if cut when 2 to 3 feet in diameter the wood is probably at its best. It resists decay for an immense time when fallen.

For inside finish the wood is excellent, though not hard enough for flooring and wainscot, or strong enough for joists. For ceiling and panelling it is most ornamental when well cut, as I saw in the Hotel at Duncan's, Vancouver Island.

Mr. Stewart has found at Benmore that it is very suitable for all estate purposes, and prefers it to larch for planking and fencing, as he finds it less liable to warp and crack.

(H. J. E.)

THUYA OCCIDENTALIS, WESTERN ARBOR VITÆ

Thuya occidentalis, Linnæus, *Sp. Pl.* 1002 (1753); Loudon, *Arb. et Frut. Brit.* iv. 2454 (1838); Sargent, *Silva N. America*, x. 126, t. 532 (1896), and *Manual Trees N. America*, 74 (1905); Masters, *Gard. Chron.* xxi. 213, figs. 67, 68, and 258, fig. 86 (1897); Kent, in Veitch's *Man. Conif.* 244 (1900).
Thuya plicata, Hort. (*non* Don).

A tree, attaining a height of 50 to 60 feet, with a stout and buttressed trunk, sometimes 6 feet in diameter. It often divides near the base into two or three stems. In England the branches, short and spreading, form a tree pyramidal in outline, which is not so dense in foliage as *Thuya plicata*. Bark of the trunk scaling off in thin papery rolls, but not so freely or so finely as in *Thuya japonica*. The branches when of no great size begin to show scaly bark.

The branch systems are disposed in horizontal planes, resembling those of *Thuya plicata*; but their main axes are flattened, being compressed from below upwards, while the leaves are shorter than in that species, ending in similar long points. The flat leaves on the main axes are studded with conspicuous large circular elevated glands. The smaller leaves on the ultimate branchlets vary as regards the presence or absence of glands; the lateral pairs are shorter than and not so acutely pointed as in *Thuya plicata*. The foliage is dark green above, pale green and not marked with white streaks below.

The male flowers, minute and globose, are composed of three decussate pairs of stamens. The female flowers are yellow.

The cones become deflected when ripe, as in *Thuya plicata*. They are oblong, light brown, and composed of 4 to 5 pairs of scales, of which the 2nd and 3rd pairs are larger than the others, and fertile. The scales are ovate or spatulate, ending in a rounded or acute apex, with a minute external process, which is generally much less developed than is the case in *Thuya plicata*. The seeds, usually two on each fertile scale, are scarcely distinguishable from those of the last-named species.

Seedling.¹—Cotyledons as in *Thuya plicata*. The caulicle and stem are quadrangular. The first two true leaves are opposite, spreading, and similar to the cotyledons, though smaller. These are followed by 5 or more whorls or pseudo-whorls, each of three similar leaves, linear, acute, and sessile. The ultimate leaves are opposite, decussate, and adnate for the greater part of their length to branchlets, which are flattened from above downwards.

VARIETIES

Few trees, except *Cupressus Lawsoniana*, show a greater tendency to variation in the seed-bed. Sargent says that if anyone will sow a quantity of seed he will be sure to find forms among the seedlings as novel and as interesting

¹ See Lubbock, *Seedlings*, ii. 548, 560 (1892).

as any now in cultivation. Many of the varieties only show their distinctive characteristics when young, and soon grow up into the normal form. Beissner gives as many as forty varieties; but it is doubtful if all these are recognisable. Those commonly met with in cultivation in this country are enumerated below:—

1. Var. *ericoides*.¹

Retinospora dubia, Carrière, *Conif.* ed. 2, p. 141.

A form in which the seedling foliage is fixed and preserved. It is a dwarf, compact, rounded, or somewhat pyramidal shrub, with slender branchlets, on which the leaves, heath-like in appearance, are borne in distant decussate pairs. They are spreading, linear, and soft in texture, becoming brown in winter. This shrub resembles *Cupressus pisifera*, var. *squarrosa*; but in the latter the leaves are much whiter on both surfaces, and do not brown in winter. The latter also attains a much larger size, and often becomes a large shrub or small tree.

2. Var. *Ellwangeriana*.

Retinospora Ellwangeriana, Carrière, *Rev. Hort.* 1869, p. 349.

This is a transition form, in which both kinds of foliage, seedling and adult, appear on the shrub, which may attain a considerable size. There is no regularity in the distribution of the two kinds of leaves; but in shrubs at Kew of this variety the juvenile foliage persists on branchlets in the interior shaded parts, the external branchlets having adult foliage.

It was probably this form which M'Nab² mentions as having seen in 1866 in quantity in the nursery of Messrs. P. Lawson and Sons, who had received it from Messrs. Ellwanger and Barry of America under the name of Tom-Thumb Arbor Vitæ. M'Nab states that the heath-like leaves have a slight smell of juniper, while the other foliage has the odour of ordinary *Thuya occidentalis*.

3. Var. *plicata*, Masters, *Gard. Chron.* xxi. 258, fig. 86 (1897).

Thuya plicata, Parlatores, *D.C. Prod.* xvi. 457.

A tree differing from the type in the branch-systems tending to assume the vertical plane, being curved so that the ultimate branchlets lie in different planes. The foliage is conspicuously glandular, the lateral leaves being flattened, so that they become almost like the median ones in appearance. According to Kent the foliage shows a brownish tint.

This variety was long considered to be a distinct species; but it is only a seedling of *Thuya occidentalis*, with which it agrees in cones and in general character of the leaves.

4. Var. *Wareana*. This only differs from the last in the colour of the foliage, which is a deep green without any brown tinge. It was raised by Mr. Ware of Coventry.³ According to Masters⁴ it has larger leaves than var. *plicata*, and corresponds very closely with native specimens of *Thuya occidentalis* gathered at Niagara.

¹ A plant of this variety growing into the mature form at Meehan's nursery, Germantown, U.S., showed that it was only a juvenile state of *Thuya occidentalis*.—*Garden and Forest*, 1893, p. 378.

² *Trans. Edin. Bot. Soc.* ix. 61, fig. (1868).

³ Gordon, *Pinetum*, ed. 2, p. 409.

⁴ *Gard. Chron.* xxi. 258 (1897).

5. Var. *dumosa*. A dwarf shrub, with the foliage and branchlets of var. *plicata*.

6. Var. *pendula*. A shrub with pendulous branches and branchlets.

7. Var. *erecta*. Branches slender and erect. In var. *erecta viridis* the foliage is dark green and shining on the upper surface. It originated in Messrs. Paul's nurseries at Cheshunt.¹

8. Var. *Späthi*. A monstrous form, with seedling foliage on the younger branchlets, older branchlets being tetragonal, and clothed with sharp-pointed adult leaves.

9. Various forms occur with coloured foliage, as *lutea*, *aurea*, *vervæneana*, etc.

Thuya occidentalis was probably the first American tree cultivated in Europe. Belon² describes it as occurring in a garden at Paris about the middle of the sixteenth century. It was introduced into England prior to 1597, as it is mentioned by Gerard in his *Herball* published in that year. (A. H.)

DISTRIBUTION, ETC.

According to Sargent, *Thuya occidentalis* frequently forms nearly impenetrable forests on swampy ground, or occupies the rocky banks of streams from Nova Scotia and New Brunswick, north-westward to Cedar Lake at the mouth of the Saskatchewan, and southward through the northern states to southern New Hampshire, central Massachusetts and New York, northern Pennsylvania, central Michigan, northern Illinois, and central Minnesota, and along the high Alleghany mountains to southern Virginia and north-eastern Tennessee; very common in the north, less abundant and of smaller size southward; on the southern Alleghany mountains only at high elevations.

Mr. James M. Macoun says of this tree in his excellent pamphlet, *The Forest Wealth of Canada* (Ottawa, 1904), that the white cedar, as it is there usually called—though in New England this name is always given to *Cupressus thyoides*—is very rare in Nova Scotia, but abundant throughout New Brunswick and Ontario. It grows to a considerable height, but seldom exceeds 2 feet in diameter. The wood is soft and not strong, and has never been much used for timber, but is unexcelled for shingles. It is chiefly used for fence rails and posts, railway ties, and telegraph posts. No other wood is used in any quantity for telegraph poles in Ontario and Quebec. It is very durable in contact with the soil or when exposed to the weather.

I saw the tree abundantly in wet swamps and also on dry ground near Ottawa, where, in Rockcliff Park, good though not large trees of it may be seen, the best having all been cut out for telegraph poles. On dry, rocky ground the tree grows freely from the stool, and in wet places in the woods reproduces abundantly from seed, which was ripe at the end of September, and, as usual in the forests of Canada, germinates and grows best when it falls on a rotten log.

¹ *Gard. Chron.* xiv. 213 (1880).

² Belon, *De Arboribus Coniferis*, p. 13 (1553).

REMARKABLE TREES

Thuja occidentalis never attains to a considerable size when planted in this country. There is a specimen at White Knights, near Reading, of great age, which is now dying at the top. According to the gardener there it has not made any growth for the last thirty-five years. It measured in 1904, 41 feet in height by 4 feet in girth. At Stratton Strawless, Norfolk, there is also a specimen of considerable age, remarkable for the pendulous habit of the branches, which is 35 feet in height. There are more large specimens at Belton Park than at any other place I know in England, the largest I have measured being 41 feet by 3 feet 9 inches. Henry, however, in 1904 measured one at Arley Castle as tall, which divides into three stems near the ground, where it measures 7 feet 6 inches in girth. At Auchendrane, Ayrshire, Renwick measured a tree in 1902—which, according to a specimen procured by him in 1906, was *Thuja occidentalis*—as 42 feet high by 6 feet 8 inches in girth, with a bole of 12 feet.

It seems to be one of the best conifers for making shelter hedges in gardens, as it stands clipping well, and for this purpose may be relied on to attain 15 to 20 feet in height in any fair soil. As it grows slowly at first when raised from seed, it is usually propagated by cuttings. (H. J. E.)

THUYA JAPONICA, JAPANESE THUYA

Thuja japonica, Maximowicz, *Mél. Biol.* i. 26 (1866); Masters, *Jour. Linn. Soc. (Bot.)* xviii. 486 (1881), and *Gard. Chron.* xxi. 258, fig. 87 (1897); *Revue Horticole*, 1896, p. 160; Kent, in Veitch's *Man. Coniferae*, 244 (1900); Shirasawa, *Icon. des Essences forestières du Japon*, 28, t. xi. 18-34 (1900).

Thuja Standishii, Carrière, *Traité Gén. Conif.* 108 (1867).

Thuja gigantea, var. *japonica*, Franchet et Savatier, *Enum. Pl. Jap.* i. 469 (1875).

Thujopsis Standishii, Gordon, *Pin. Suppl.* 100 (1862).

A tree attaining, according to Shirasawa, a height of 90 feet in Japan, with a tapering stem, open in habit as cultivated in England, and not forming such a dense pyramid as *Thuja plicata*. Bark of the trunk scaling off in very narrow longitudinal papery strips. The bark commences to scale on young branches of less than a half inch in diameter. The branches curve upwards towards their extremities.

The branch-systems, 3-4 pinnate, are disposed in horizontal planes, which droop at their outer extremities. Primary axes terete, with leaves densely crowded, all the four sets ending in short, rigid, thick, free points, glands being absent. The leaves on the ultimate branchlets are obtuse, and not acutely pointed as in *Thuja plicata*; and glands may be present or absent on the flat leaves. The foliage is light green above, while on the under surface there are whitish streaks, somewhat triangular in outline, which exceed in area the greener parts.

Male flowers cylindrical, with 6 decussate pairs of stamens. The cones are deflected, ovoid, and composed of 5 to 6 pairs of scales, of which the second and third pairs are larger than the others and fertile. The scales are broadly oval, with a rounded apex, from below which externally is given off a short, broad, triangular process, projecting from the scale at right angles or nearly so. The seeds, three to each fertile scale, and nearly equal to it in length, differ considerably from those of *Thuja plicata* and *Thuja occidentalis*, the wing being narrow, not so scarious in texture, entire, and not notched at the summit.

Fortune discovered *Thuja japonica* in cultivation around Tokyo in 1860, and sent home seeds of it to the nursery of Mr. Standish at Ascot, who distributed plants under the name of *Thujopsis Standishii*. Maximowicz, who had also seen it cultivated at Tokyo, gave the species its first authoritative name in 1861. Maries found it growing wild on the mountains of Nikko, in central Japan, in 1877. Sargent,¹ who, in company with James H. Veitch, met with a few solitary specimens on the shores of Lake Yumoto in these mountains, at 4000 feet altitude, describes it as a small pyramidal tree of 20 to 30 feet high, of open and graceful habit, with pale green foliage and bright red bark. Shirasawa, however, states that it attains a height of 90 feet, with a diameter of stem of nearly 6 feet; and that it grows in the central chain of Hondo, in the mountains of Kaga, Hida, and Shinano, at elevations of 2000 to 6600 feet. The stem, according to Shirasawa, is often twisted, and gives off great wide-spreading branches. (A. H.)

¹ *Garden and Forest*, 1893, p. 442, and 1897, p. 441.

According to Komaror, *Flora Manchurica*, i. 206 (1901), *Thuya japonica* grows wild abundantly in northern Corea in the Samsu district, but was not observed by him in Manchuria or elsewhere on the mainland.

This tree is not, so far as I saw, as common in Japan, where it is called Nezuko, as *Cupressus obtusa* or *C. pisifera*, though it is said by Goto¹ to be found in the provinces of Yamato, Bungo, Satsuma, Omi, Iwashiro, Shimotsuke, and Uzen, at an elevation of from about 3000 to 6000 feet.

The only place where I saw it wild was at Yumoto, above Nikko, where it was scattered in mixed forest with Tsuga, Thujopsis, birches, and other deciduous trees, and it is said to be never found in unmixed woods. At Koyasan I found small trees of it, perhaps planted, and brought away a seedling, which is now living at Colesborne.

At Atera, in the Kisogawa district, the forester told me that it grows best as a young tree in shade, and that where *Cupressus obtusa* has been felled it often comes up from seed. It does not attain very large dimensions, so far as I could learn, and is not considered a tree of much economic importance.

The timber is light and used for carpentry. It sometimes has a very pretty figure, and in old trees is of a pale grey colour, though perhaps this is only assumed by trees which were dead before cutting. It is cut into thin boards, and used for ceilings and other inside work, and is said to cost about 2d. per square foot in the board at Tokyo, and to make very durable shingles.

In Great Britain the tree seems to grow slowly, and is not common in gardens. The largest I have seen is a grafted and very spreading tree in Mr. W. H. Griffiths' garden at Campden, Gloucestershire, which is about 25 feet by 2½ feet, and probably one of the oldest in England. It has produced fertile seeds from which plants have been raised. The largest recorded at the Conifer Conference was at Dalkeith Palace, where it was 15 feet high in 1891. A tree at Kilmacurragh, co. Wicklow, Ireland, was 24 feet by 2 feet 4 inches in 1906, and bears fruit. Another at Castlewellan measured 25 feet high in the same year. (H. J. E.)

¹ *Forestry of Japan* (1904).

THUYA ORIENTALIS, CHINESE ARBOR VITÆ

Thuya orientalis, Linnæus, *Sp. Pl.* 1002 (1753); Loudon, *Arb. et Frut. Brit.* iv. 2459 (1838); Masters, *Jour. Linn. Soc. (Bot.)* xviii. 488; Kent, in Veitch's *Man. Coniferae*, 248 (1900).
Biota orientalis, Endlicher, *Syn. Conif.* 47 (1847).

A tree or dense shrub, with the trunk often branching into several stems from near the base. Bark of trunk thin, reddish brown, and separating in longitudinal papery scales. The bark begins to scale on branches which are about a half inch in thickness. The branches are ascending, becoming tortuose at their extremities, and giving off more or less equal-sided branch-systems, which are disposed in vertical planes, with their inner edge directed towards the stem of the tree. These are finer and more closely ramified than in the preceding species. Their main axes are terete; bearing median leaves, marked by a glandular longitudinal depression, and ending in triangular free points (not appressed to the axis); and lateral leaves, ending in similar but longer free points, which are thickened at the part where they become free and reflected away from the axis. The leaves on the ultimate branchlets are closely imbricated, appressed to the stem, and marked with longitudinal depressions.

The male flowers are globose and composed of 4 decussate pairs of stamens.

The cones¹ are erect and ovoid, fleshy and bluish before ripening, but ultimately becoming dry and woody, the scales gaping widely. Scales, usually 3 pairs (occasionally a fourth pair, sterile and much reduced, appears at the base), the two lowest fertile, the uppermost pair aborted and sterile: ovate, obtuse, thick, and ligneous, bearing externally below the apex a hooked process. The seeds, 2 on each scale, are large, ovoid, without wings, brown in colour, with a white, large, oblong hilum.

The seedling² resembles that of the other species of *Thuya*, except that the cotyledons are much larger, about an inch in length.

VARIETIES

A great number of varieties of this species have been obtained. The most remarkable of these are:—

1. Var. *pendula*, Masters, *Jour. R. Hort. Soc.* xiv. 252.

Thuya pendula, Lambert, *Genus Pinus*, ed. 2, ii. 115 t. 52; Siebold et Zuccarini, *Fl. Jap.* ii. 30 t. 117.

Thuya filiformis, Lindley, *Bot. Reg.* xxviii. t. 20 (1842).

Biota pendula, Endlicher, *Syn. Conif.* 49.

Cupressus pendula, Thunberg, *Fl. Jap.* 265.

¹ The cones ripen in one year, but frequently in England retain their seed till the spring of the following year.

² Tubeuf, *Samen, Früchte, u. Keimlinge*, 104, fig. 144 (1891).

A shrub, with a straight trunk, bare of branches below. The branchlets, numerous, long, flexile, cord-like, unbranched or only slightly branched, are produced in irregular fascicles of 5 to 20 or more at irregular intervals along the branches. They are slender and pendent, and bear leaves distantly placed in 4 rows in decussate pairs. The leaves, broadly decurrent at the base and long acuminate at the apex, spread out from the branchlets at an acute angle. Cones are occasionally borne, which are like those of the type.¹ There is a specimen at Kew of a plant raised from seed of this variety, which is ordinary *Thuya orientalis*. It was sent from the Botanic Garden at Turin by Mr. Hanbury in 1860.

There are several forms of this variety, differing in habit and length of leaves; in one the branchlets are tetragonal.

This shrub was first observed by Thunberg in Japan, and specimens were collected near Yokohama by Maximowicz. It was also met with by Fortune in China, and has been raised in Europe.

2. *Var. decussata.*

Retinospora juniperoides, Carrière, *Conif.* ed. 2, p. 140.

A low shrub, with erect stems and branches, bearing foliage like that of the seedling. The leaves are in 4 rows in decussate pairs, spreading, and resembling those of a juniper, except that the points are not prickly. They are greyish green in summer, changing to brown in winter.

3. *Var. Meldensis.*

Biota Meldensis, Lawson, in Gordon, *Pinetum*, 37.

A small tree with ascending flexible branches. It is a transition form, bearing acute acicular spreading leaves like that of the seedling, and occasionally leaves of the adult character. The leaves are bluish green, changing to brown in the winter. This plant was raised from seeds of *Thuya orientalis* gathered in the cemetery of Trilbardoux near Meaux in France; and for a long time was supposed to be a cross between *Thuya orientalis* and *Juniperus virginiana*.

4. *Var. intermedia.*

Biota orientalis intermedia, Carrière, *Man. des Pl.* iv. 322.

This is also a transition form. It is a shrub with elongated pendent branchlets, the ramifications of which arise from all sides of the axis, not remaining in one plane. There are two kinds of leaves, those towards the ends of the branchlets resembling the adult foliage of *Thuya orientalis*, while those on older parts are spreading, arranged in decussate pairs, oval-lanceolate, decurrent at the base, and acute at the apex. In *Var. funiculata*, if it is in reality distinguishable, there appears to be a larger proportion of adult foliage.

Many other varieties have been described: some of peculiar habit, as *gracilis* and *pyramidalis*, which are fastigate; others with coloured or variegated foliage, as *aurea*, *argenteo-variegata*, *aureo-variegata*. *Var. ericoides* of this species closely

¹ At Barton, a shrub of this variety produced cones, which had very long hooked processes on the scales (Bunbury, *Arboretum Notes*, 153).

resembles the variety of the same name belonging to *Thuya occidentalis*; the latter is slightly whiter on both surfaces of the leaves.

DISTRIBUTION, ETC.

Thuya orientalis occurs wild in the mountains of north China. It is common in the hills west of Peking, where Fortune¹ observed trees of a large size, 50 or 60 feet in height. Elsewhere in China it is only met with planted in cemeteries and temple grounds. It has been known to the Chinese from the earliest times as the *Poh* or *Peh* tree, and is mentioned in their classical books; it was planted around the graves of feudal princes, and its wood was used for making the coffins of great officials. The tree was introduced into Japan from China at an early period, probably like so many other Chinese plants, by the Buddhist missionaries. Japanese botanists are all agreed that it is not indigenous in Japan. Various other regions have been mentioned as being the home of *Thuya orientalis*, as Siberia, Turkestan, Himalayas, etc.; but specimens collected in these countries are undoubtedly from cultivated trees. The tree is mentioned by Gmelin in his *Flora Siberica*, i. 182 (1747); but only as occurring between Kiachta and Peking. Ledebour² denies its existence in any part of Siberia.

Thuya orientalis was first grown in Europe at Leyden, some time before 1737, when Linnæus³ described the plant as *Thuya strobilis uncinatis squamis reflexa acuminatis*. Royen, who sent a specimen to Linnæus, mentions the species with considerable details in his account⁴ of the plants that were cultivated at that time in the Botanic Garden at Leyden; but his promised account of the history of its introduction apparently never was published. It is possible that it was raised from seed sent home by the Dutch from Japan, as Kaempfer, who travelled in that country from 1690 to 1692, collected specimens of *Thuya orientalis* which are still preserved in the Natural History Museum at South Kensington.⁵ Seeds were also soon afterwards sent to Paris by the missionaries in north China.⁶ The earliest account of it in England occurs in a letter dated February 1, 1743, from the Duke of Richmond to Collinson, as follows:—"I am sorry to find by Miller that I am not likely to have the Chinese Thuya. I own, if it belonged to anybody that would sell it, I should be foolish enough to offer ten guineas for it, because it is the only one in England that can match that which I have already." It was cultivated early by Miller⁷ in the Physic Garden at Chelsea.

Thuya orientalis never attains in this country any considerable dimensions. It ripens good seed; and at Kew, on a wall near the Director's office, may be seen a

¹ *Yedo and Peking*, 307, 382 (1863). Fortune supposed that the wild tree in north China was distinct from that cultivated near Shanghai; but there is no doubt that the trees, which attain a great size in the hills west of Peking, are ordinary *Thuya orientalis*.

² *Comment. in Gmelini Fl. Sibericam*, 60 (1841).

³ *Hort. Cliff.* 449 (1737).

⁴ *Flora Leydensis Prodrromus*, 87 (1740).

⁵ I have seen these specimens. See Salisbury, *Coniferous Plants of Kaempfer*, in *Jour. Science and Arts*, ii. 313 (1817). Kaempfer does not mention the plant in his *Amenitates Exotica*.

⁶ See Miller, *Gard. Dict.* ed. 6 (1752), and ed. 8 (1768), sub "Thuya."

⁷ Cf. Aiton, *Hort. Kew.* iii. 371 (1789).

200 The Trees of Great Britain and Ireland

young tree which originated from a seed probably carried there by a bird from a tree in the gardens.

In the garden at Hampton Court, Herefordshire, there are a pair of fine specimens about 40 feet high, and about 7 feet round at the base, where they divide into several stems which have been formed into an arch over the path, and in most old gardens trees of 25 to 35 feet may be found, but, like *T. japonica* and *T. occidentalis*, it must be looked on as an ornamental shrub rather than a timber tree.

Plate 58 represents the trunk of what I believe to be the finest beech in Gloucestershire, which is known as "The Gladstone Beech," having been specially admired by the late Mr. Gladstone when staying at Cirencester House. It grows near Pinbury Park, formerly the seat of Sir Robert Atkyns, author of *The History of Gloucestershire*, and now the summer residence of Earl Bathurst. It measures about 110 feet high by 19 feet 9 inches in girth at the smallest part of the trunk, and though a very old tree, past its prime, is still a magnificent object. I am indebted for the negative to Mr. T. A. Gerald Strickland.

THUJOPSIS

Thujaopsis, Siebold et Zuccarini, *Fl. Jap.* ii. 32 (1842).

Thuja, Bentham et Hooker, *Gen. Pl.* iii. 427 (1880).

Cupressus, Masters, *Journ. Linn. Soc. (Bot.)*, xxx. 19 (1893) and xxxi. 363 (1896).

THIS genus is considered by many authorities to be merely a section of *Cupressus* or of *Thuja*. The foliage and cones, however, are remarkably distinct, and justify its retention as a separate genus.

Evergreen trees, belonging to the tribe Cupressineæ of the order Coniferae, with reddish bark scaling off in longitudinal shreds. Branches in false whorls or scattered, giving off secondary branches, which terminate in very flattened branch-systems, disposed in horizontal planes. These resemble in their general arrangement those of *Thuja* and *Chamæcyparis*, and are mostly tripinnate, all the axes being covered with small coriaceous leaves, adnate in part of their length, and arranged in four ranks in decussate pairs. The leaves on the main and ultimate axes differ only in size.

The ventral and dorsal leaves are flattened and ovate or spatulate, with rounded apices; the lateral leaves are carinate, more or less spreading, with a slightly acute apex, which is bent inwards. The dorsal flat leaves are shining green, and marked with a central ridge, which is often hollowed in the middle line. The ventral flat leaves have a central green ridge, with a concavity white with stomata on each side. The lateral leaves, green on the dorsal side, exhibit a single stomatic concavity on their ventral side.

Flowers monœcious, solitary, and terminal, the male and female flowers borne on separate lateral branchlets as in *Thuja*. Male flowers cylindric, $\frac{1}{4}$ inch long, with six decussate pairs of stamens. Female flowers with five ovules on each scale. Cones globular, almost erect, with eight clavate, woody scales, in decussate pairs from a central axis, the upper pair abortive. Seeds three to five on a scale, laterally winged, the wing not notched at the summit.

The seedling¹ resembles that of *Thuja plicata*, but has broader and very blunt cotyledons, with shorter and broader primary leaves.

¹ See Tubeuf, *Samen, Früchte, u. Keimlinge*, 103, fig. 143 (1891).

THUJOPSIS DOLABRATA

Thujopsis dolabrata, Siebold et Zuccarini, *Fl. Jap.* ii. 34, tt. 119, 120 (1842); Franchet et Savatier, *Enum. Pl. Jap.* i. 469 (1875); Shirasawa, *Icon. Essences Forest. Jap.*, text 27, t. xi. 18-34 (1900).

Thuya dolabrata, Linnæus, *Suppl. Pl. System*, 420 (1781); Masters, *Jour. Linn. Soc. (Bot.)*, xviii. 486 (1881), and *Gard. Chron.* xviii. 556, fig. 95 (1882); Kent, in Veitch's *Man. Conif.* 236 (1900).

The species has been described in detail above.

Two well-marked geographical forms occur, both confined to the main island of Japan:—

1. Var. *australis* (var. *nova*). A small tree 40 to 50 feet in height, or a shrub growing as underwood in the dense shade of forests. As a tree it has a slender trunk, with drooping branches and a narrow pyramidal top. Branchlets very flat and only slightly overlapping, the lateral leaves ending in acute points bent inwards. Cones broadly ovoid, with scales thickened at the apex, which is prolonged externally into a blunt triangular process. This is the form which is known in cultivation in Europe, and described and figured in the works cited above.

2. Var. *Hondai*, Makino.¹ A larger tree, attaining 100 feet in height, with a stem of over 3 feet in diameter. The branch-systems are more densely ramified, the branchlets being placed close together and overlapping one another by their edges more than is the case in the preceding variety. The leaves also are smaller, whiter underneath, and crowded more closely on the shoots; those of the lateral ranks being usually blunt and not curved inwards at the apex. The cones are globular, with scales not thickened at the apex, which is devoid of the process so conspicuous in the other form, or merely shows it as an obsolete transverse minute mucro. The seeds appear to be more broadly winged, the wings being more scarious in texture.

This form has not yet been introduced. Elwes has brought home excellent specimens of it in fruit from the Uchimappe Forest, near Aomori, in the extreme north of Hondo. These differ in the characters given above from specimens of the ordinary form obtained by him in the forest of Atera, Kisogawa, and Yumoto (4000 to 5000 feet altitude) in Central Hondo. The smaller leaves, set more closely on densely ramified branchlets in this variety, may be due to the influence of dense shade. The difference in the cone is paralleled by what occurs in the fruit of the different geographical forms of *Cryptomeria japonica*. I am inclined to think that var. *Hondai* is not a distinct species; but as it is very different, from the point of view of cultivators, it may conveniently bear the name *Thujopsis Hondai*.

¹ *Tokyo Botanical Magazine*, 1901, xv. 104.

Several horticultural varieties have been introduced, viz. :—

3. Var. *latevirens*, Masters, *Jour. Linn. Soc. (Bot.)*, xviii. 486.

Thujopsis latevirens, Lindley, *Gard. Chron.* 1862, p. 428.

Thujopsis dolabrata nana, Gordon, *Pinetum*, ed. 2, p. 399.

A dwarf shrub having no definite leader, with slender and much-ramified branchlets, and very small and bright green leaves. This variety often shows acicular leaves, spreading all round the shoot, and is apparently a fixed seedling form. It was introduced in 1861 from Japan by J. Gould Veitch.

4. Var. *variegata*. This only differs from the ordinary cultivated form in having the tips of many of the branchlets pale yellow or cream colour. It was introduced by Fortune in 1861.

DISTRIBUTION

Thujopsis dolabrata was discovered by Kaempfer,¹ who mentions it in his *Amœnitates Exoticæ*, p. 884, as "a kind of Finoki." His specimen is still preserved in the Natural History Museum at South Kensington, and was figured by Lambert² in his account of the species. Thunberg long afterwards (about 1776) sent specimens to Linnæus, who first gave a scientific description of the tree. Thunberg³ cites the locality as follows:—"Crescit in regionibus Oygarwæ et Fakonicæ, inter Miaco et Iedo."
(A. H.)

Thujopsis dolabrata in Japan is known under the name of *Hiba*, and is found in a wild state north of about lat. 35°, and in the southern part of this area is a mountain tree only, occurring in the forest of the Kisogawa district from about 3000 to 5000 feet. In the vicinity of Nikko it is common between about 4000 and 6000 feet according to Sargent, but I only saw it here near Lake Yumoto where it did not appear to attain such large dimensions as farther north. The variety found in the forests of Atera is distinct in its fruit from the northern form. The excellent figure on Plate xi. in Shirasawa's *Essences Forestières* appears to be taken from the southern variety.

The northern form has been described by Makino as var. *Hondai*, but the latter is not mentioned either by Goto or Shirasawa, nor is it recognised as specifically distinct in any of the Japanese collections which I saw. Though the tree usually occurs in mixture with *Tsuga* at Nikko, and with *Sciadopitys* at Atera, yet in the extreme north of Japan, on the hills north of Aomori, it is found in pure forest on hills of volcanic formation from near sea-level up to about 3000 feet. An excellent account of the forest of Uchimappe is given in *Forestry and Forest-Products of Japan*, where it is stated that the mountains are of Tertiary formation, and the under-lying rock composed of tufa, sandstone, and slate. Pieces of this rock which I brought home have been examined by Mr. Prior of the British Museum of Natural History, who considers that in all probability they represent a rather basic andesite or basalt, but owing to the weathered and decomposed state of the specimens, satisfactory sections could not be made. I visited this forest in the

¹ See Salisbury, *Jour. Science and Arts*, 1817, ii. 313.

² *Genus Pinus*, ed. 2, ii. tab. 68 (1842).

³ *Flora Japonica*, 266 (1784), sub *Thuya dolabrata*, Linn.

company of Mr. Shirasawa in June, and after passing through the flat rice-fields which extend from the sea to the foot of the hills, entered the forest, which consists mainly of *Thujopsis* naturally reproduced, though here and there, trees of *Quercus glandulifera*, *Magnolia hypoleuca*, and other species occur, whilst *Cryptomeria* and *Cupressus obtusa* are planted in the valleys, and *Larix leptolepis* on those parts of the hills where the natural forest has been destroyed by fire. From observations taken at the meteorological observatory of Aomori, it appears that the climate of this part of Japan is cold in winter and the snowfall heavy, the thermometer falling in February to -15° Centigrade, and rising in September to 32.5° Centigrade; the average temperature for the whole year being 9° , and the average moisture 78 per cent. The average height of the trees here is about 70 to 80 feet, attaining in deep shady valleys 100 feet or perhaps more, and about 2 feet in diameter when closely grown, at the age of 150 to 180 years when it is considered ripe for felling.

The stems are often much curved at the butt from the pressure of the snow on the young seedlings, which require eight to ten years to get above its surface in winter, and these butts are usually cut separately and used for special purposes. The tree does not seem to have the power of reproducing itself from the stool, but produces abundant seed, which in dense shade germinates freely, though the growth of the seedlings is very slow at first.

The undergrowth of the forest is very different from what I saw in other parts of Japan, bamboo-grass (*Arundinaria Veitchii*) being much less prevalent, but in the damp places tall herbaceous plants were numerous, with *Aucuba*, *Skimmia*, and *Ilex*, and other evergreen shrubs on the drier ground, and many pretty liliaceous plants and orchids in places.

Goto says of this tree,¹ that it formed under the old regime, together with *Cupressus pisifera*, *C. obtusa*, *Thuja japonica*, and *Sciadopitys*, the so-called "Goboku" or Five Trees, which enjoyed careful protection at the hands of the feudal authorities; he also says that it is rarely planted, being regenerated naturally by seed, and that it forms extensive forests in a mixture with other conifers such as *Thuja japonica* and *Pinus parviflora*, in the mountains on the northern frontier of the province of Rikuchu, in Goyosan, and in the mountains of the Tone districts, Kozuké. It has lately come to be in great demand for railway sleepers.

Plate 60 (in Vol. I.) represents a dense growth of trees of this species in the forest of Uchimappe very similar to what I saw in the Kisogawa district at about 3000 feet. I am indebted to the Japanese Forest Department for the negative from which it was made.

The wood of *Thujopsis* is highly valued in those parts of Japan where it grows, on account of its great durability. This is proved by specimens shown at the St. Louis Exhibition, one of which had been used as a gate-post for eighty-three years, another as a plank in a fishing-boat for eighty-four years, others as railway sleepers in use for fourteen years. The wood has an aromatic smell, takes a fine lustrous polish when planed, and is yellowish white in colour, showing a fine grain, which makes selected planks from the butt length very ornamental. Exceptional

¹ *Forestry of Japan*, 18 (1900).

cases occur in which the wood is curiously mottled and freckled. A ceiling and a screen made of such wood, which I saw in the Forestry Bureau at Aomori, were very beautiful.

The wood weighs about 30 lbs. per cubic foot, and is worth at Aomori from 40 to 50 yen per 100 cubic feet, or about 1s. per cubic foot. It is much valued not only for joinery and building purposes, but for foundations, ship and boat building, as it is stronger and more resinous than other woods of the same character.

The bark also, which is thin, tough, and durable, is much used for roofing and for partitions and walls of out-houses, fences, etc.

CULTIVATION

T. Lobb sent a plant from the Botanical Garden at Buitenzorg in Java, to Exeter in 1853, which died; and soon after, Capt. Fortescue, a cousin of Earl Fortescue, brought a plant from Japan which was planted at Castlehill in 1859. But this tree, as I learn from Mr. Pearson, the head gardener, has been dead for some time, though plants raised from its cuttings are still growing at Castlehill and elsewhere.

In 1861 Mr. J. G. Veitch and R. Fortune sent seeds from Japan to the Chelsea and Ascot Nurseries, from which plants were raised and generally distributed, so that the tree is now common in England.

From what I have said of its habitat in Japan it is clear that though this tree is hardy as regards frost in winter, it requires conditions which are rarely found in England to bring it to any size, and, as a matter of fact, it has not yet become a tree anywhere except in Devonshire and Cornwall, though perhaps if seeds from North Japan are obtained the results might be better.

Though no doubt it has ripened seeds elsewhere, I have never obtained any which germinated, except from a tree planted about 1881 by Queen Alexandra in the Earl of Northbrook's grounds at Stratton Park, Hants, which I gathered in October 1900. One of these grew, and is now a healthy plant about 9 inches high. It seems to suffer less from spring frost than many Japanese and Himalayan conifers.

The finest tree that I have seen in England is at Killerton, which in 1902 measured 35 feet 6 inches in height and 2 feet 4 inches in girth. It is growing on a slope facing south-west in a peculiar soil, which Sir C. T. D. Acland describes as "Trap, soft below the surface, but hard after exposure. This trap overlies red sandstone, but is rather darker and more porous." This soil evidently suits most conifers admirably, as I have seen no other collection which contains so many fine specimens as this.

At Boconnoc, at Carclew, and at other places in Cornwall there are trees approaching this in height, but we have not seen any specimen above 15 to 20 feet in other parts of England, though as a bushy shrub 12 feet high it exists in most modern gardens. In Scotland it seems hardy in the west and in Perthshire, whilst at Castlewella in Ireland it has attained 30 feet in height. At Powerscourt and Kilmacurragh, Wicklow, there are trees with the lower branches layering and forming numerous independent stems.

(H. J. E.)

ÆSCULUS

Æsculus, Linnæus, *Gen. Pl.* 109 (1737); Bentham et Hooker, *Gen. Pl.* i. 398 (1862).
Pavia, Boerhave, ex Miller, *Gard. Dict.* ed. 6 (1752).

DECIDUOUS trees and shrubs, belonging to the natural order Sapindaceæ, some authorities, however, making the genus the type of a distinct order Hippocastaneæ. Leaves in opposite decussate pairs, without stipules, stalked, digitately compound; leaflets five to nine, serrate in margin, pinnately veined. Branchlets stout, terete, with large triangular leaf-scars. Buds large, of numerous decussately opposite scales which are homologous with leaf-bases, the outer deciduous, dry or resinous, the inner accrescent and often brightly coloured.

Flowers in large terminal racemes or panicles, appearing later than the leaves, of two kinds, hermaphrodite and staminate, on the same plant; placed in the axils of minute caducous bracts on stout jointed pedicels. Calyx imbricate in bud, five- or two-lobed, the lobes unequal, united with an hypogynous annular disc in the hermaphrodite flowers. Petals four to five, imbricate in bud, alternate with the calyx lobes and inserted on the disc. Stamens five to eight, usually seven, inserted on the inner margin of the disc, unequal in length; filaments filiform; anthers two-celled, sometimes glandular at the apex. Ovary three-celled, rudimentary in the staminate flowers, each cell containing two ovules. Style slender, elongated, generally curved. Fruit a capsule; prickly, roughened, or smooth; coriaceous; three-celled, three-seeded, and three-valved, or by abortion one- to two-celled and one- to two-seeded, the remains of the abortive cells and seeds usually remaining visible. Seeds without albumen, rounded or flattened by mutual pressure; seed-coat brown and coriaceous, marked by a large whitish hilum. Cotyledons thick and fleshy, unequal, cohering together by their contiguous faces, remaining in the seed-coat during germination.

About twelve species of *Æsculus*¹ are known to occur in the wild state. They are natives of North America, Europe, and Asia. The genus was formerly divided into two sections, *Pavia*, with smooth fruit, and *Hippocastanum*, with spiny fruit; but this division is not a natural one. The following synopsis groups the species under sections, which are more natural, being dependent on the characters of the flowers and buds:—

I. HIPPOCASTANUM. Buds viscid. Calyx irregularly campanulate, four- to five-

¹ The two Mexican species, which have tri-foliolate leaves, are now separated as a distinct genus, *Billia*.

lobed. Petals four or five, claws not longer than the calyx; stamens exerted. This section includes all the old-world species.

1. *Æsculus Hippocastanum*, Linnæus. Greece.
2. *Æsculus indica*, Colebrooke. Afghanistan, north-western Himalaya.
3. *Æsculus punduana*, Wallich, *List* 1189 (1828). Sikkim, western Duars, Khasia Hills, Upper Burma, Tenasserim, Siam, Tonking. Large tree. Leaflets six to seven, very large, thinly coriaceous, stalked, acuminate, serrate. Panicles 12 to 15 inches or more, flowers white or yellow. Fruit brown, smooth.

Not introduced and not likely to be hardy.

4. *Æsculus chinensis*, Bunge, *Enum. Pl. Chin. Bor.* 10 (1835). Northern and Central China. A tree, 40 to 50 feet high. Leaflets five to seven, large, stalked, obovate-oblong, rounded at the base, abruptly acuminate at the apex, finely serrate, shining above, glabrescent below except for pubescence along the nerves, petioles pubescent. Panicles, 8 inches long, pubescent. Flowers small, white; sepals shortly and unequally five-lobed, pubescent. Petals four, minute. Filaments glabrous. Fruit¹ pear-shaped or globular, small ($\frac{3}{4}$ inch diameter), one-celled, three-valved, brown, covered with warts, not spiny.

This species has been much confused with the next, from which it differs in every way. The flowers, though small, are numerous in the large panicle, and the foliage is very handsome. It is common enough in the mountains of central China, in Shansi, and in the hills to the west of Peking; and when introduced is likely to prove hardy in England.

5. *Æsculus turbinata*, Blume. Japan.

II. PAVIA. Buds not resinous. Calyx tubular, five-toothed. Petals four, yellow or scarlet.

6. *Æsculus glabra*, Willdenow. North America.
7. *Æsculus octandra*, Marshall. North America.
8. *Æsculus Pavia*, Linnæus, *Sp. Pl.* 344 (1753); *Bot. Reg.* t. 993 (1826). Middle United States. A shrub. Leaves with slender grooved petioles, the edges of the grooves jagged. Leaflets five, obovate, acute at the base, acuminate at the apex, finely serrate without cilia, slightly pubescent beneath. Flowers in loose panicles, 4 to 7 inches long. Petals red, meeting at the tips; upper pair longer, with claws about three times as long as the small spatulate limb; lateral pair shorter, with claws as long as the calyx, and rounded limb equalling the claw in length; margin of petals beset with minute dark glands. Stamens as long as the upper pair of petals. Fruit brown, without spines.

This species, though only a shrub, is mentioned here at some length, as it closely resembles *Æsculus octandra*, and moreover enters into such important hybrids as *Æsculus carnea*, *versicolor*, etc. All its hybrids may be recognised by the red colour of the flowers and the glandular margin of the petals. It is readily distinguished from *Æsculus octandra* by its smaller leaves and peculiar petioles. In winter it shows the following characters:—Twigs slender, glabrous, shining, with numerous lenticels.

¹ Cf. Hance in *Journ. Bot.* viii. 312 (1870).

Leaf-scars obovate or crescentic on slightly prominent cushions, with three groups of bundle-dots; opposite scars joined by a linear ridge. Terminal buds long oval or fusiform, pointed; scales numerous, the upper rounded, the lower pointed at the apex and keeled on the back, minutely ciliate in margin. Pith wide, circular, green.

9. *Æsculus austrina*, Small, *Bull. Torrey Bot. Club*, 1901, xxviii. 359; Sargent, *Man. Trees N. America*, 647 (1905); *Æsculus Pavia*, β *discolor*, Torrey and Gray, *Fl. N. Amer.* i. 252 (1838), in part. A small tree, attaining 30 feet in height, occurring in Tennessee, S. Missouri, E. Texas, and north-western Alabama. This resembles the last species. The leaflets, however, are usually more irregularly but finely serrate, and pale tomentose beneath. Panicles pubescent, 6 to 8 inches long. Petals bright red, meeting at the tips, unequal, oblong-obovate, rounded at the apex, glandular, those of the upper pair about half as wide as those of the lateral pair, with claws much longer than the calyx. Stamens longer than the petals. Fruit brown, slightly pitted. Not introduced.

III. MACROTHYRSUS. Buds not viscid. Calyx five-toothed. Petals four to five, white, claws longer than the calyx. Stamens exerted, very long.

10. *Æsculus parviflora*, Walter, *Flora Caroliniana*, 128 (1788). South-eastern North America. A shrub. Leaflets five to seven, elliptical or oblong-ovate, densely grey-tomentose beneath, finely serrate. Panicles erect, 8 to 10 inches long, slender, narrow. Flowers white, faintly tinged with pink. The long and thread-like stamens are pinkish white and very conspicuous.

This is a valuable shrub, as it flowers late, in July or August, some five or six weeks later than any of the other species except *californica*. Occasionally it forms a short single trunk, but generally it sends up a crowd of stems from the ground. It is figured in *Gard. Chron.* 1877, viii. fig. 129; and is often known in gardens as *Pavia macrostachya*, Loiseleur, or *Æsculus macrostachya*, Michaux. See *Bot. Mag.* t. 2118 (1820), where it is stated that the species was introduced by Mr. John Fraser in 1785. Canon Ellacombe reported in 1877¹ that he had at Bitton a specimen, which was at least forty years old, but that it remained a bush, not exceeding 8 or 10 feet in height.

IV. CALOTHYRSUS. Buds viscid. Calyx two-lipped or five-lobed. Petals four, pink or white, claws not longer than the calyx. Stamens exerted.

11. *Æsculus californica*, Nuttall. California.

12. *Æsculus Parryi*, A. Gray, *Proc. Amer. Acad.* xvii. 200 (1881); Sargent, *Garden and Forest*, 1890, p. 356, fig. 47. Lower California. A small shrub, resembling the preceding species; but differing in the five-lobed calyx, and in the leaflets, which are small, obovate and hoary pubescent beneath. It has not been introduced.

V. HYBRIDS. The most important is *Æsculus carnea*, Hayne, which is a cross between the common horse-chestnut and *A. Pavia*. This is described fully below.

¹ *Gard. Chron.* 1877, viii. 691.

Æsculus plantierensis, André, a supposed hybrid between *Æsculus carnea* and *Æsculus Hippocastanum*, will be mentioned under the former species. *Æsculus versicolor*, Dippel, a hybrid between *Æsculus Pavia* and *Æsculus octandra*, will be treated under the latter species.

The following key to the species in cultivation is based on the characters of the leaves and buds. In Plate 61 the leaves of all these species are shown; and in Plate 62 are represented the twigs and buds of six species, viz., *Hippocastanum*, *carnea*, *indica*, *glabra*, *octandra*, and *californica*:—

A. Leaflets sessile or nearly so; buds very viscid.

1. *Æsculus Hippocastanum*.

Petioles glabrescent. Leaflets obtusely and irregularly serrate.

2. *Æsculus turbinata*.

Petioles pubescent, especially towards their tips. Leaflets regularly and crenately serrate.

B. Leaflets stalked.

*Buds viscid.

3. *Æsculus indica*.

Leaflets finely and sharply serrate, pale beneath. Buds very viscid.

4. *Æsculus carnea*.

Leaflets obtusely and irregularly serrate. Buds only slightly viscid, the brown scales having a dark-coloured margin.

5. *Æsculus californica*.

Leaflets shallowly and crenately serrate, pale beneath. Buds viscid, glistening with white resin.

**Buds not viscid.

6. *Æsculus parviflora*.

Leaflets densely grey-tomentose beneath, finely serrate in margin. Buds minutely pubescent.

7. *Æsculus octandra*.

Leaflets pubescent beneath, broadly lanceolate, shortly acuminate, with twenty or more pairs of nerves in the terminal leaflet; margin finely serrate but not usually ciliate. Petioles without jagged marginal ridges.

8. *Æsculus glabra*.

Leaflets glabrous beneath, except for a slight pubescence along the midrib and tufts in the axils, long-acuminate, with about fifteen pairs of nerves in the terminal leaflet, finely serrate with ciliate tufts in the bases of the serrations. Petioles with smooth marginal ridges.

9. *Æsculus Pavia*.

Leaflets slightly pubescent beneath, narrowly lanceolate, finely serrate but not ciliate in margin. Petioles flattened on the upper side, with marginal sharp ridges, usually jagged.

ÆSCULUS HIPPOCASTANUM, COMMON HORSE-CHESTNUT

Æsculus Hippocastanum, Linnæus, *Sp. Pl.* 344 (1753); Loudon, *Arb. et Frut. Brit.* i. 462, iv. 2543 (1838); *Gard. Chron.* 1881, xvi. 556, figs. 103, 104.

A large tree, attaining in England a height of over 100 feet and a girth of 15 or even 20 feet. Bark smooth and dark brown in young trees, becoming greyish and fissured longitudinally in old trees, at the same time scaling off in thin plates. Leaves palmately compound, digitate, on a long stalk widened at its insertion. Leaflets five to seven, sessile, obovate, cuneate at the base, abruptly acuminate at the apex, unequally and coarsely serrate; green above; beneath pale, tomentose at first, but ultimately glabrous, except for small tufts of hairs in the axils of the veins and a few scattered hairs over the surface; middle leaflet the largest, with twenty-four or more pairs of nerves, lower pair smallest; venation pinnate; petiole glabrous. The leaflets as they emerge from the bud are at first erect, but soon bend downwards on their stalks. When nearly full grown they rise up and become horizontal. In autumn they turn yellow or brownish and fall early, each leaflet disarticulating separately from the petiole.

Flowers in large upright pyramidal panicles, the primary branches of which are racemose, the lateral branches cymose. Upper flowers staminate and opening first; lower flowers hermaphrodite. Calyx greenish, five-toothed. Petals four to five, crumpled at the edge, white, with yellow spots at the base, which ultimately become pink. Stamens seven, longer than the petals, the filaments bent down when the flower opens and the stigma protrudes, later moving up on a level with the style. Fruits few on each panicle, large, globular, green, with stout, thick conical spines, three-valved, usually one-seeded, occasionally two- to three-seeded. Seed large, shining-brown, with a broad whitish hilum. Cotyledons two, large, fleshy, distinct below, blended into one mass above.

SEEDLING¹

The cotyledons are large and fleshy and remain in the seed, which frequently germinates on the surface of the soil or only slightly buried beneath it. The cotyledons have long petioles ($\frac{3}{4}$ -1 inch), which are broad and flattened, with a concavity on their inner surface. The caulicle, very variable in length (1 to 4 inches), is stout, brownish, pubescent, and ends in a stout tap-root, which gives off numerous branching fibres. The young stem is stout, terete, brownish, striated and marked with numerous lenticels, puberulent or glabrous; it has no scale-leaves, differing in this respect from the young stem of the oak. In other respects the germination of the oak and of the horse-chestnut are almost identical. At a varying height

¹ Cf. Lubbock, *Seedlings*, i. 356 (1892), where it is stated that the seed is carried a considerable height above ground during germination owing to the great length of the caulicle. So far as I have observed, the seed does not change its position during germination.

above the cotyledons the first pair of true leaves are produced, which are opposite, compound, digitately five-foliolate, and closely resemble the adult foliage except that they are smaller in size. Successive pairs of similar leaves follow on the stem, each pair being placed decussately with reference to the pair immediately below it.

ABNORMAL FLOWERING

The horse-chestnut sometimes produces a second crop of flowers in autumn, which appear in much smaller panicles than those of spring. This is due to the premature fall of the leaves in July or August, usually following an excessively dry season. The buds are stimulated to premature energy and put forth young leaf-shoots, which are terminated by flowers. This phenomenon, which is equivalent to an anticipation of the opening of the buds by several months, as they would normally open in the following spring, is frequently observed in the trees planted in the boulevards of Paris.¹ In the dry season of 1884, a single tree at Kew produced small panicles of flowers in September, after previously shedding nearly all its leaves. In the following year it produced a few panicles of the ordinary size. At Hythe,² near Southampton, a horse-chestnut is reported to have bloomed and fruited three times in 1868, once in spring, again after the rain which succeeded the long drought, and a third time in September.

IDENTIFICATION

In summer the common horse-chestnut is unmistakable. The only other species with large sessile leaflets, *Æsculus turbinata*, is easily distinguished by their regular crenate serration. In winter the twigs and buds show the following characters:—Twigs stout, brown, glabrous or minutely pubescent towards the tip; lenticels numerous. The large opposite leaf scars, flat on the twigs with no prominent cushion, are joined by a linear ridge, and vary in shape, the larger being obovate with seven bundle-dots, the smaller semicircular or crescentic with usually only five dots. Buds very viscid, larger than in the other cultivated species; the terminal much exceeding the lateral buds in size, occasionally absent, and replaced by the saddle-shaped scar of the previous year's inflorescence; scales imbricate, the external ones in four vertical ranks, rounded at the apex, glabrous, not ciliate, dark red-brown. The buds contain the next year's shoot in an advanced state of development, flowers being visible in them in October. The scales are morphologically equivalent to leaf-bases. In the interior of the bud, scales are observable with traces of leaf-blades, which gradually pass into the true leaves, visible in the upper part of the bud.

VARIETIES

1. Var. *flore pleno*, Lemaire, *Illust. Horticole*, 1855, ii. t. 50. A variety with double flowers, the pistil even in some cases becoming petaloid. Mr. A. M.

¹ See article by Roze, translated in *Gard. Chron.* 1898, xxiii. 228.

² *Gard. Chron.* 1868, p. 1116.

Baumann discovered in 1822, near Geneva, a horse-chestnut tree, of which a single branch bore double flowers; and from this branch the variety was propagated at the Bollweiler nursery in Alsace.¹ The flowers last longer than those of the single kind,² and no fruits are formed, which renders it useful as a tree in streets, where the fall of fruits is an inconvenience. This variety is very hardy, and resisted well the severe winter of 1879-80 in France.³

2. Var. *laciniata* (var. *asplenifolia*, var. *incisa*). Leaflets cut up into narrow lobes. According to Beissner⁴ this variety has been in cultivation for over forty years; and a form of it was found by Herr Henkel of Darmstadt, which keeps its foliage much longer than the typical form; but this is not the case in some localities.

3. Var. *crispa*. Leaves short-stalked, with broad leaflets. Tree compact in habit.

4. Var. *pyramidalis*. Upright in habit.

5. Var. *umbraculifera*. Crown densely branched, and globular in outline.

6. Var. *tortuosa*. Branches bent and twisted.

7. Var. *Memmingeri*. Leaves yellowish in colour, looking as if powdered with sulphur.

8. Var. *aureo-variegata*. Leaves variegated with yellow.

Several other varieties of slight interest, which do not seem to be in cultivation in this country, are mentioned by Schelle.⁵

DISTRIBUTION AND HISTORY

The horse-chestnut occurs wild in the mountains of northern Greece. Halácsy,⁶ the latest authority, gives many localities in Phthiotis, Eurytania, Thessaly, and Epirus; but states that it is not found wild on Mount Pelion or in Crete. Baldacci,⁷ in 1897, found the tree growing wild on almost inaccessible precipices below the lower limit of the coniferous belt near Syrakou in the district of Janina in Albania.

The native country of the tree was long a matter of doubt; but the whole question was satisfactorily elucidated by Heldreich⁸ in a paper, from which we extract most of the following account. Linnæus considered the habitat of the tree to be northern Asia, and De Candolle thought that it came from northern India. The tree is, however, not known wild in India, where it is replaced by *Æsculus indica*. Boissier⁹ states that it is recorded from Greece by Sibthorp, from Imeritia (Caucasus), by Eichwald, and from Persia by various authors. It is, however, unknown in the wild state in Persia; and Radde¹⁰ mentions it only as a planted tree

¹ *Rev. Belgique Horticole*, 1854, iv. 216.

² See *Garden*, 1890, xxxviii. 601, where some observations are recorded on the periods of flowering of the single and double horse-chestnuts, and of *Æsculus carnea*.

¹⁰ *Consp. Fl. Græca*, i. 291 (1900).

in the Caucasus. All the evidence goes to show that it is confined to northern Greece and Albania.

Heldreich states that the horse-chestnut was first found wild in Greece by Dr. Hawkins.¹ In his own travels in Greece in 1897 he observed it in many stations, all lying in the lower fir region, between 3000 and 4000 feet altitude, where it grows in shaded moist gulleys, in company with alder, walnut, plane, ash, several oaks, *Ostrya carpinifolia* and *Abies Apollinis*. These stations, situated in remote uninhabited spots, establish the fact that the tree is really wild. Plants introduced into Greece by the Turks are always found in the neighbourhood of towns. Whether the tree was known to the ancient Greeks is doubtful.

The horse-chestnut was first mentioned² by the Flemish doctor Quakleben, who was attached to the embassy of Archduke Ferdinand I. at Constantinople,—in a letter to Matthiolus in 1557. The latter received a fruit-bearing branch, and published the first description³ of the tree as *Castanea equina*, because the fruits were known to the Turks as *At-Kastane* (horse-chestnut), being useful as a drug for horses suffering from broken wind or a cough.

The tree was introduced into western Europe from Constantinople, the first tree being raised by Clusius at Vienna from seeds sent by the Imperial Ambassador, D. Von Ungnad, in 1576. This tree quickly grew, and was mentioned by Clusius⁴ in 1601.

The horse-chestnut was introduced into France⁵ in 1615 by Bachelier, who brought the seeds from Constantinople. Gerard mentions it in his *Herbal* of 1579, p. 1254, as a tree growing "in Italy and sundry places of the eastern countries"; and in Johnson's edition of this work, published in 1633, the tree was stated to be growing in Tradescant's garden at South Lambeth. It was probably introduced into England about the same time as into France. (A. H.)

CULTIVATION

No tree is easier to raise from seed than the horse-chestnut. Its large fleshy fruit are so little hurt by frost and damp that they germinate freely where they fall, and do not seem to be eaten by mice like acorns and beech-mast.

Seeds which have been exposed all winter germinate more readily in spring than those which have been kept dry, and should be sown early and covered with about two inches of soil.

Though it is advised by French writers that the extremity of the radicle should be pinched off before sowing in order to prevent a strong tap-root from forming, as is done in the case of walnuts and chestnuts, I have not observed that they suffer from removal if this is not done; and if transplanted at one or at latest two years after sowing there are abundance of fibrous roots which make the tree an easy one

¹ Sibthorp et Smith, *Fl. Græca Prodrömus*, i. 252 (1806). Hawkins' observation has been disputed, as he records it from Pelion, where the tree does not, so far as we know now, occur wild. Orphanides was the first to establish beyond doubt that the tree is indigenous to the mountains of northern Greece. Cf. Grisebach, *Vegetation der Erde*, French ed. i. 521.

⁴ Clusius, *Rar. Plant. Hist.* 7 (1601).

⁵ Toumefort, *Relation d'un Voyage au Levant*, i. 530 (1717).

to move, even when five or six feet high. As the tree is liable to form large side branches, the buds should be rubbed off the stem early in order to form a clean trunk, though it bears pruning well as a young tree.

Though somewhat liable to suffer from cold winds and spring frost, which injure the foliage and flowers, the tree is hardier in this respect than many of our native trees, though coming from a warm southern country.

As regards the chemical nature of the soil it is quite indifferent, for though it grows faster on a good loam and does not come to perfection on sandy soil, it attains a large size on dry, rocky, calcareous soils, and even at an elevation of 800 feet and upwards resists wind better than many trees. I have seldom seen horse-chestnuts blown down, though large heavy branches are often torn off by violent winds.

As an ornamental flowering tree for parks, lawns, and avenues it has no superior, though on account of its branching habit it requires considerable attention in order to form tall shapely trees. Its principal defect is the tendency of the leaves to become brown and ragged early in the autumn, but they fall quickly, and being easily removed make less litter than the leaves of the beech, oak, or sycamore.

The large branches when allowed to rest on the ground in damp situations frequently take root and become naturally layered, the best instance of this that I have seen being at Mottisfont Abbey, Hants.

For town planting, on account of its beautiful flowers and dense shade during the hottest months, the horse-chestnut is perhaps, next to the plane, one of the best trees we have, and does not seem to suffer much from smoke. In parks it is valuable for its fruit, which are so much liked by deer that they are eaten as fast as they fall, and would perhaps be worth collecting for winter food.

The extraordinary hardiness of this southern tree is proved by the fact that it will grow to a large size as far north as Trondhjem in Norway, lat. $63^{\circ} 26'$, a tree figured by Schubeler near this place being 37 feet by 8 feet 9 inches. Another in the Botanic Garden at Christiania, which is considered the largest in Norway, measured in 1861, 16.62 metres by 2.45 metres, and when I saw it in 1903 had increased to no less than 28 metres high by 3 in girth, though it has been exposed to as low a temperature as -18° to -20° Réaumur.

As regards the age which the horse-chestnut attains we have few exact records, but it does not seem a very long-lived tree. J. Smith states¹ that an avenue running south-east from the front of Broadlands House, near Romsey, Hants, was planted in 1735; but in 1887 only two trees remained, which were 11 feet and 12 feet 4 inches in girth.

REMARKABLE TREES

There are so many fine trees in almost every part of Great Britain that I need not go into great detail as to their dimensions, but though it is possible that in Bushy Park, or other places near London, taller trees exist, I have only at

¹ *Trans. Scot. Arb. Soc.* xi. 540 (1887).

Petworth measured one which exceeds in height the group of three which grow near my own house at Colesborne, of which I give an illustration (Plate 63). The height of these as measured in 1902 by Sir Hugh Beevor and myself was 105 feet, and the girth of the largest 11 feet. They grow in a sheltered situation, on damp, cold soil. One of these trees being inclined to split at the base, owing to the great weight and length of one of its principal limbs, was chained up many years ago, and though the iron band which was put round it has become buried in the wood the limb has not broken off.

At Dynevor Castle, Carmarthenshire, the seat of Lord Dynevor, where the park contains a greater number of fine trees than any I have seen in South Wales, there is a very large tree which the Hon. W. Rice measured in 1906 and found to be 109 feet by 17 feet 9 inches. For height and girth combined this seems to be the largest tree in Great Britain.

The tallest tree I have seen is in a grove of beech, chestnut, oak, and silver fir, which grows near the house at Petworth Park, the seat of Lord Leconfield in Sussex, on a deep greensand formation. This tree, though forked at six feet from the ground, has been drawn up to a great height by the trees surrounding it, and though difficult to measure exactly, probably exceeds 115, and may be 120 feet. The two stems are 9 feet 8 inches and 8 feet respectively in girth.

In Bushy Park most of the horse-chestnuts are past their prime; many of the old trees are dead and have been replaced by young ones. The largest, seen in 1906, was growing near the gate; it had a bole of 20 feet giving off four great stems, and measured 100 feet high by 16 feet 5 inches in girth. Another near the pond was 101 feet by 16 feet 1 inch.

At Birchanger Place, near Bishop Stortford, the seat of T. Harrison, Esq., there is one of the largest and finest trees in England, which measures about 80 feet by 20 feet, with a bole about 15 feet high and a spread of 32 yards; a beautiful photograph was taken in 1864 when the tree was in flower, but it is now partially decayed on the north side, and has lost some large branches.

At West Dean Park, Sussex, the seat of W. D. James, Esq., there is a large tree about 70 feet by 16 feet, with branches spreading over an area no less than 36 yards in diameter.

At Hampton Court, Herefordshire, the seat of John Arkwright, Esq., there is a very fine tree growing on deep alluvial soil in the big meadow south of the house. Measured by T. Hogg in 1881¹ it was 93 feet by 16 feet 6 inches. When I saw it in 1905 it had increased about three feet in height and was 18 feet 7 inches in girth, and still handsome and vigorous.

The largest trees I have seen as regards girth and spread of branches are in Ashridge Park, on a bank near the lodge on the Berkhamstead road. The largest of these is about 80 feet high and 20 feet in girth, with extremely wide-spreading branches, and there are several others of 16 to 17 feet girth in the row. These trees are growing on a dry, flinty, calcareous loam.

¹ *Trans. Scot. Arb. Soc.* ix. p. 151 (1886).

There is a fine tree at Syon, which in 1905 was 93 feet high by 15 feet 4 inches in girth; and at Broom House, Fulham, there is a tree 95 feet high.

In the courtyard at Burleigh, near Stamford, the seat of the Marquess of Exeter, there is a large and very beautiful tree, figured by Strutt, plate 37, which was in 1822 60 feet high by 10 feet in girth, with a spread of 61 feet diameter. When I saw it in 1903 it was still in perfect health, and was about 80 feet by 12 feet 6 inches. It had remarkably spiny fruit, and its trunk was covered with small twigs.

At Trebartha Hall, near Launceston in Cornwall, Mr. Enys reports in 1904 a tree 15 feet 6 inches in girth, with an estimated height of 70 feet.

In Scotland the horse-chestnut seems as much at home as in England, and thrives in most places as far north as Gordon Castle, where there is a tree, measured in 1881 by Mr. Webster, 65 feet high by 13 feet 4 inches in girth, and 274 feet in circumference of its branches.

At Newton Don, Kelso, the seat of Mr. C. B. Balfour, there is a tree which was in 1906, 13½ feet in girth with a spread of branches of 165 feet in circumference.

In Perthshire there is a very beautiful tree, remarkable for its weeping habit, in the park at Dunkeld, which measures 80 feet in height by 17 feet 6 inches in girth (Plate 64). At Kilkerran, Ayrshire, Mr. J. Renwick has measured a fine tree 84 feet high by 14 feet in girth, with a bole 22 feet high. At Pollok, near Glasgow, a tree measured, in 1904, 63 feet high by 13 feet 6 inches girth at 2½ feet from the ground, with a bole of 5 feet, giving off four great stems.

None of these are equal to a tree in a group of seven standing at the west end of Moncreiffe House in Perthshire, which Hunter¹ describes as the largest in Scotland, and which then measured 19 feet in girth at five feet from the ground. At ten feet it divides into three great limbs, one of which has become firmly rooted in the ground, and extends so far from the trunk that the total spread of the tree is 90 feet in diameter.

The remarkable hardness of this tree is shown by the existence of one, reported by Mr. Farquharson of Invercauld, as growing at an elevation of 1110 feet, which was supposed to be 177 years old in 1864, when it was 8 feet 7 inches in girth.²

In Ireland the horse-chestnut attains a great size, the largest we know of occurring at Woodstock in Co. Kilkenny, on an island in the River Nore. One tree measured in 1904, 93 feet in height by 18 feet 1 inch in girth, and according to the careful records which have been kept of the growth of the many fine trees on this property, measured in 1825, 10 feet 2 inches in girth; in 1846, 13 feet 2 inches; in 1901, 17 feet 9 inches. Another about the same height, in a meadow near the river, measured in 1825, 11 feet in girth; in 1834, 12 feet; in 1846, 12 feet 11 inches; in 1901, 14 feet 4 inches.

¹ *Woods and Forests of Perthshire*, 1883.

² *Old and Remarkable Trees of Scotland*, p. 115.

TIMBER

The wood of the horse-chestnut is one of the poorest and least valuable we have, on account of its softness and want of strength and durability. Though it has a fine close and even grain, white or yellowish-white colour, and is not liable to twist or warp so much as most woods, it does not cut cleanly, decays rapidly, and is only used as a rule for such purposes as cheap packing-cases and linings.

It burns so badly that it is of little use as firewood, and though occasionally cut into veneers or used as a cheap substitute for sycamore, poplar, and lime, in making dairy utensils, platters, and brush backs, it cannot be said to have a regular market. From 4d. to 8d. a foot is about the usual value in most parts of England, though Webster says that it was worth a shilling in Banffshire some years ago.

Holtzapffel says that it is one of the white woods of the Tunbridge turner, a useful wood for brush backs and turnery, preferable to holly for large varnished and painted works on account of its great size.

I am not aware whether it has been tried for pulp-making, but it would seem to be a suitable wood for that purpose on account of its softness, and could, if required, be produced in quantity at a low price. (H. J. E.)

ÆSCULUS CARNEA, RED HORSE-CHESTNUT

Æsculus carnea, Hayne, *Dendrol. Flora*, 43 (1822).

Æsculus rubicunda, Loiseleur, *Herb. Amat.* vi. t. 357 (1822); Loudon, *Arb. et Frut. Brit.* i. 467 (1838); Carrière, *Rev. Horticole*, 1878, p. 370, coloured figure of var. *Briotii*.

Æsculus Hippocastanum, L. × *Æsculus Pavia*, L., Koch, *Dendrologie*, i. 507 (1869).

A small tree, occasionally 50 feet, but rarely exceeding 30 feet in height. Leaves resembling those of the common horse-chestnut, but darker green with an uneven surface, the leaflets being shortly stalked and more or less curved and twisted. Flowers red, showing as they open an orange-coloured blotch at the base of the petals, which afterwards becomes deep red. Petals five, standing nearly erect, their limbs not spreading horizontally at right angles to the claws, as occurs in the common horse-chestnut; edges of the petals furnished with minute glands, like those present in *Æsculus Pavia*. Fruits with slender prickles.

IDENTIFICATION

In winter, the species is distinguished as follows:—Twigs rather stout, grey, shortly pubescent; leaf-scars as in *Æsculus Hippocastanum*. Buds slightly viscid and smaller than in that species; scales brown, edged with a dry membranous dark-coloured rim. Lateral buds small, oval, pointed, arising from the twig at an acute angle.

VARIETIES

1. Var. *Briotii*. Flowers in larger panicles and more brilliantly coloured, the filaments, calyx, and style being red. Fruits never developing fully, falling soon after the flowers. This variety¹ was obtained in 1858, by M. Briot at the State Nurseries of the Trianon, Versailles, as a seedling of *Æsculus carnea*.

2. Several variegated forms are known, as var. *aureo-maculata* and *aureo-marginata*. Var. *alba* is a form with white flowers. Var. *pendula* is pendulous in habit.

3. *Æsculus plantierensis*, André, *Rev. Horticole*, 1894, p. 246, is supposed to be a cross between *A. carnea* and the common horse-chestnut, as it is intermediate in character. This variety arose in the nursery of Messrs. Simon-Louis Frères at Plantières-lès-Metz, from a seed of *Æsculus Hippocastanum*. Other intermediate forms, named by André *Æsculus intermedia* and *Æsculus balgiana*, were derived from seeds of *Æsculus carnea*.

HISTORY

Nothing is known for certain concerning the origin of *Æsculus carnea*. Loiseleur received the plant from Germany in 1818, and there are no earlier accounts of it. Its parentage, however, is undoubted: it possesses characters of both the supposed parents. The leaves and slightly spiny fruit are derived from the common horse-chestnut. The colour of the petals and the glands on their margins come from *Æsculus Pavia*. According to André² the seeds when sown usually produce plants which bear whitish flowers and are of no horticultural value. The species is accordingly always propagated by grafting. Koch,³ however, reports that while some seedlings are like those of the common horse-chestnut, others produce smooth fruits. At Kew, according to Mr. Bean, it has come true from seed.

The largest specimen of this tree that we have seen occurs at Barton in Suffolk. It was 50 feet high in 1904, with a bole, however, of only 2 feet, girthing 7 feet 9 inches at a foot above the ground, and dividing into three stems.

It does not seem to live long or to attain any great size in England, and is often supposed to be a red-flowered form of the common horse-chestnut. (A. H.)

ÆSCULUS INDICA, INDIAN HORSE-CHESTNUT

Æsculus indica, Colebrooke, Wallich, *List* 1188 (1828); *Bot. Mag.* t. 5117 (1859); Hiern, in *Flora British India*, i. 675 (1875); Bean, in *Gard. Chron.* 1897, xxii. 155 and 1903, xxxiii. 139, *Suppl. Illust.*; Collett, *Flora Simla*, 97 (1902); Gamble, *Man. Indian Timbers*, 193 (1902); Brandis, *Indian Trees*, 185, 705 (1906).

Pavia indica, Wallich, ex Jacquemont, *Voyage dans l'Inde*, iv. 31, t. 35 (1844).

A large tree, attaining in India 150 feet in height and 40 feet in girth of stem. Bark in old trees peeling off in long strips. Leaves large, glabrous, dark green above, pale, almost glaucous beneath; leaflets five to nine, stalked, obovate-lanceolate, acuminate, finely and sharply serrate, with about twenty pairs of nerves in the terminal leaflet. Panicles 12 to 15 inches long, loose, narrow, erect. Flowers large, about 1 inch long; calyx $\frac{1}{3}$ inch long, irregularly lobed, often splitting so as to appear two-lipped. Petals four, white, of two unequal pairs; the upper pair narrow and long with a red and yellow blotch at the base, the lower pair flushed with pink. Stamens seven or eight, scarcely longer than the petals, spreading. Fruit brown, rough, without spines, irregularly ovoid, one to two inches long, containing one to three dark brown shining seeds.

IDENTIFICATION

In summer the viscid buds and the large stalked leaflets with finely serrate margins distinguish it from the other species in cultivation. In winter the twigs show the following characters:—Branchlets coarse, shortly pubescent; lenticels like brown raised warts, numerous; pith circular, white; leaf-scars on slightly prominent cushions, each pair wide apart and joined by a raised linear ridge, obovate or semicircular with a raised rim and three groups of bundle-dots. Buds viscid, greenish, the lower scales only being brown; terminal buds ovoid, pointed, the two lowest scales having projecting beaks; scales not ciliate, the outermost four pubescent; lateral buds small, arising at an acute angle.

DISTRIBUTION

It is a common tree in the north-west Himalayas from the Indus to Nepal, occurring at elevations of from 4000 to 10,000 feet, and also occurs in Afghanistan. Sir George Watt informs me that he has measured many trees 150 feet in height with trunks of enormous size, a girth of 40 feet not being uncommon. The wood is used in building and for making water-troughs, platters, vases, cups, packing-cases, and tea-boxes. The twigs and leaves are lopped for use as fodder. The fruit is given as food to cattle and goats; ground and mixed with ordinary flour, it is part of the dietary of the hill tribes. The bark of old trees is very remarkable in appearance, exfoliating in long flakes, which remain attached at their upper ends and hang downwards and outwards. (A. H.)

CULTIVATION

Colonel Henry Bunbury brought seeds from India in 1851, from which plants were raised by Sir Charles J. F. Bunbury¹ at Barton in Suffolk. The large tree² now flourishing on the lawn at Barton (Plate 65) is one of the original seedlings, and measured, in 1904, 66 feet high by 7 feet 9 inches in girth. Another tree in the arboretum at Barton measured 65 feet high by 7 feet 2 inches in girth; and divides into two main stems at 7 feet above the ground. This tree flowered for the first time in 1858, producing twelve panicles, being then only seven years old from seed, and 16 feet in height. It did not suffer in the least from the terrible winter of 1860, and flowered as usual in the summer following. In 1868 it ripened fruit, and four thriving plants were raised from its seed. There are no records of the tree on the lawn, which is now the finer of the two. Other trees were planted apparently at Mildenhall,³ which is about fifteen miles distant from Barton; but these never thrived, and none remain. The soil at Mildenhall is a light loam on chalk, and probably did not suit the tree.

I saw the beautiful tree at Barton in full flower on June 24, 1905, when it did not seem to have received the least injury from the severe frosts and cold north-east winds which had occurred a month previously, and which ruined the flowers and destroyed the fruit of the common horse-chestnut in many places.

It seems incredible that this species should be so rare and have remained so little known in England, where it ought to be planted generally in the south and west. Mr. Bean says that the seeds soon lose their vitality if kept dry, and that of some scores received in ordinary paper packets from India in recent years, not one has germinated at Kew. He recommends that the seeds should be gathered as soon as ripe, and be sent packed in fairly moist soil. Mr. Walker, the gardener at Barton, informed me that it ripens seed in good years, and showed me several seedlings raised from them which appeared to grow as well as the common horse-chestnut.

The only other place except Kew, however, where we have seen it, is at Tortworth, where the Earl of Ducie planted in 1890 a few seeds which were sent to him by the late Duke of Bedford. The seedlings were planted at first in sunny places in the open, but did not thrive until moved to a sheltered dell in 1900, where they are now growing well, the best being about 12 feet high.

At Kew there are two or three small trees which have flowered a few times. It seems, therefore, that it only requires a good deep soil and a sheltered situation to succeed as well as it has done at Barton. The late Lord Morley informed me that there was a tree recently planted, but growing very well at Saltram, his place in Devonshire.

According to Jouin,⁴ this tree is quite hardy at Metz. (H. J. E.)

ÆSCULUS TURBINATA, JAPANESE HORSE-CHESTNUT

Æsculus turbinata, Blume, *Rumphia*, iii. 195 (1847); André, *Revue Horticole*, 1888, p. 496, figs. 120-124; Bean, *Gard. Chron.* 1897, xxii. 156, and 1902, xxxi. 187, fig. 58; Shirasawa, *Icon. Essences Forestières du Japon*, text 113, t. 71, ff. 16-28.
Æsculus chinensis, Masters (*non* Bunge), *Gard. Chron.* 1889, v. 716, fig. 116.

A tree attaining in Japan, according to Shirasawa, 100 feet in height and 20 feet in girth of stem. Bark thick and scaly. Leaves resembling those of the common horse-chestnut, but much larger, mainly differing in the serration, which is finely crenate. Leaflets five to seven, sessile, obovate-cuneate, occasionally as much as 15 inches long, abruptly acuminate, pubescent beneath. The terminal leaflet has fifteen to twenty-two pairs of nerves. Petiole remaining pubescent towards the tip. Panicles 6 to 10 inches long, dense, somewhat narrow. Flowers yellowish-white, smaller than those of *Æsculus Hippocastanum*. Fruit slightly pear-shaped, 1½ to 2 inches in diameter, four to five on a verrucose rhachis, brown, warty, without spines; valves three, thick; seeds usually two.

IDENTIFICATION

In summer only liable to be confused with the European species, from which it is distinguished by the character of the serration of the leaflets. In winter the twigs closely resemble those of that species, but are not so stout; they are similarly pubescent towards the tip, and are marked with smaller but similar five to seven dotted leaf-scars. Buds smaller, equally viscid, the scales, however, not being uniform in colour, but partly light chestnut brown and partly dark brown. Pith large, irregularly circular in cross-section, and yellowish in tint.

DISTRIBUTION

The tree is known in Japan as *Tochinoki*, and is common in the forests at 1500 to 5500 feet elevation in the mountains of the main island, descending to lower levels in Yezo. It is recorded by Debeaux, *Fl. Shanghai*, 22, from the provinces of Kiangsu and Chekiang; but no one else has seen the tree in China, and Debeaux's identification is probably incorrect.

The exact date of the introduction of the tree into Europe is uncertain, but it is supposed to be about thirty years ago. It has often passed under the name of *Æsculus chinensis*, an entirely different species. It first produced fruit in 1888 in the arboretum at Segrez in France. It flowered in 1901 at Coombe Wood. As only small trees are known to exist in England, the hardiness of the tree and its suitability for garden decoration are as yet unproved; but at Tortworth it is growing vigorously, and has ripened its buds well whilst still quite small;

and the great size of the leaves on the young trees give it a striking and distinctive appearance. (A. H.)

In Japan I saw this tree planted in gardens and parks near Tokyo, where it does not seem to grow so large as in its native forests and in higher, colder situations. Sargent says¹ that in the forests of the interior of Hondo, at 2000 to 3000 feet, it attains 80 to 100 feet high, with trunks 3 to 4 feet in diameter, and that these were perhaps the largest deciduous trees that he saw growing wild in the forest. It reaches its most northern point of distribution near Mororan in Hokkaido at sea-level, and I did not see it near Sapporo, in the Aomori district, or near Nikko. At a tea-house called Hideshira, near the village of Sooga on the Nakasendo road, Central Japan, I saw the largest trees of this species growing in a dense grove with *Zelkova acuminata*. They attained over 80 feet high, with clean trunks 40 to 50 feet long, and a girth of 14 feet.

On the Torii-toge Pass, between Wada and Yabuhara, at about 3300 feet, there were many fine trees growing by the side of the road, of one of which I give an illustration from a photograph taken for me by Masuhara of Tokyo in November (Plate 66).

TIMBER

The timber of this tree, though not highly valued in Japan on account of its softness and want of strength, is used for boat and bridge building; furniture making, house-fittings, and for the groundwork of lacquer. It often shows a wavy figure, and when old assumes a pale reddish-brown colour, which makes it very ornamental. Such wood, which I procured at Aomori, has been used with good effect in my Japanese wardrobe, and takes a good polish. It is also much used for trays, and from the large burrs and swellings near the root very handsome trays, as much as 18 or 20 inches square, are carved by the Japanese and sold in the villages at a low price. Its value in Tokyo is given at 60 to 100 yen per 100 cubic feet. I saw a plank of this wood in a timber merchant's shop in Osaka measuring 15 feet long and 58 inches wide, showing wavy figure all through. For this plank 90 yen, equal to about £9, was asked, these immense planks being much valued by Japanese connoisseurs for house decoration. (H. J. E.)

ÆSCULUS GLABRA, OHIO BUCKEYE

Æsculus glabra, Willdenow, *Enum. Pl. Hort. Berol.* 405 (1809); Loudon, *Arb. et Frut. Brit.* i. 467 (1838), Sargent, *Silva N. America*, ii. 55, tt. 67, 68 (1892), *Man. Trees N. America*, 644 (1905).

Æsculus pallida, Willdenow, *loc. cit.* 406 (1809).

A tree attaining 70 feet in height and 6 feet in girth in America. Bark dark brown and scaly, becoming in old trees $\frac{3}{4}$ inch thick, ashy-grey, densely furrowed and broken into thick plates roughened on the surface by numerous small scales. Leaves with long slender stalks; leaflets five, oval or obovate-cuneate, long-acuminate, finely serrate in margin, with tufts of hairs in the bases of the serrations, glabrous underneath except for a few hairs along the midrib and tufts in the axils; petiolules short. Terminal leaflet with about fifteen pairs of nerves. Flowers in pubescent panicles, 5 to 6 inches long; calyx campanulate; petals four, pale yellow; claws shorter than the calyx; limbs twice as long as the claws, broadly ovate or oblong in the lateral pair, oblong-spathulate, much narrower and sometimes red-striped in the upper pair. Stamens usually seven, long, exerted, pubescent. Ovary pubescent. Fruit ovate or obovate, brown, 1 to 2 inches long, roughened by prickles.

The species is distinguished in summer by the glabrous leaves, which always show some cilia in the bases of the serrations. In winter the following characters of the twigs and buds may be recognised:—Twigs glabrous, shining, with orange-coloured lenticels. Leaf-scars slightly oblique on obscure leaf-cushions, crescentic or semicircular, with three groups of bundle-dots, the opposite scars wide apart and often not joined by any linear ridge. Pith large, circular, greenish. Buds not viscid; terminal much larger than the lateral, the latter arising from the twig at an angle of 45°; ovoid, acuminate; scales keeled on the back, ciliate in margin, acuminate, the pointed tips being raised outwardly, dark brown.

Var. *Buckleyi*, Sargent (*Æsculus arguta*, Buckley, *Proc. Acad. Phil.* 1860, p. 448), is a geographical form, occurring in Iowa, Missouri, Kansas, and Texas, and characterised by six to seven leaflets, which are sharply and unequally serrate.

No well-marked horticultural varieties are known.

The type occurs in alluvial soil in Atlantic North America, from Pennsylvania to N. Alabama, and westward to S. Iowa, Central Kansas, Indian Territory, and S. Nebraska. Sargent says that it is nowhere very common and from an ornamental point of view very inferior to *Æsculus octandra*.

This species was introduced, according to Loudon, in 1812, but appears to be very rare in this country. At Devonshurst, Chiswick, a tree cut down in 1905 was 60 feet in height by 6 feet in girth, but though the tree probably exists in some nurseries and old gardens, where it is mistaken for *Æsculus octandra*, more commonly than is supposed, we cannot mention any which are remarkable.

(A. H.)

ÆSCULUS OCTANDRA, SWEET BUCKEY

Æsculus octandra, Marshall, *Arbust. Am.* 4 (1785); Sargent, *Silva N. America*, ii. 59, tt. 69, 70 (1892), and *Man. Trees N. America*, 646 (1905).

Æsculus lutea, Wangenheim, *Schrift. Gesell. Nat. Fr. Berlin*, viii. 133, t. 6 (1788).

Æsculus flava, Aiton, *Hort. Kew*, i. 403 (1789).

Æsculus neglecta, Lindley, *Bot. Reg.* xii. t. 1009 (1826).

Pavia flava, Moench, *Method.* 66 (1794); Loudon, *Arb. et Frut. Brit.* i. 471 (1838).

A tree attaining in America 90 feet in height and 9 feet in girth of stem. Bark of trunk $\frac{3}{4}$ inch thick, dark brown, slightly fissured, separating on the surface into thin small scales. Leaves with long slender petioles. Leaflets five, occasionally seven, elliptical or obovate-oblong, cuneate at the base, acuminate, finely serrate, pubescent beneath; petiolules short. Terminal leaflet with twenty or more pairs of nerves. Flowers in pubescent panicles, 4 to 6 inches long; calyx campanulate; petals four, yellow, coming into contact at the tips, very unequal, the upper pair much longer than the lateral pair, claws villose within and much exceeding the calyx, limb of lateral pair obovate or round with a subcordate base, limb of upper pair spatulate, minute. Stamens usually seven, shorter than the petals, villose. Ovary pubescent. Fruit 2 to 3 inches long, brown, smooth or slightly pitted.

IDENTIFICATION

In summer distinguished from *Æsculus glabra* by the leaflets being pubescent beneath and devoid of cilia in the serrations; from *Æsculus Pavia*, by the larger leaves, which have petioles with smooth ridges on their upper surface. In winter the twigs show the following characters:—Branchlets glabrous, shining, with a few scattered lenticels. Leaf-scars flat on the twigs (there being no cushion), obovate, with usually three groups of bundle-dots; opposite scars joined by a linear ridge. Pith large, circular, green or white. Buds not viscid, terminal much larger than the lateral, the latter arising at an angle of 45° , long-oval, pointed at the apex; scales brown, the cilia on the exposed margins minute or absent, upper scales rounded at the apex and on the back, lower pair pointed at the apex and keeled on the back.

VARIETIES

1. Var. *hybrida*, Sargent (Var. *purpurascens*, A. Gray; *Æsculus discolor*,¹ Pursh). This is a form occurring wild in the Alleghany mountains. The flowers are purple or red in colour, and the under surfaces of the leaves, as well as the petioles and panicles, are clothed with a dense pale pubescence.

2. *Æsculus versicolor*, Dippel. This is a hybrid between *Æsculus octandra* and *Æsculus Pavia*, and is intermediate in character, the flowers varying in

¹ Figured in *Bot. Reg.* iv. 310 (1818).

colour from yellowish to pink. The edges of the petals show a few glands and are tufted ciliate.

A considerable number of forms of this variety are known in cultivation in which slight differences occur in the length and shape of the petals. *Æsculus Lyoni* and *Æsculus Whitleyi* are apparently sub-varieties of this hybrid. The forms with red flowers are often known in gardens as *Pavia rubra*, a name which belongs properly to *Æsculus Pavia*.

DISTRIBUTION

This tree occurs in alluvial soil of river valleys and on moist mountain slopes, from Pennsylvania southward to Georgia and N. Alabama; and westward to S. Iowa, Indian Territory, and W. Texas. Sargent says that when at its best on the slopes of the Tennessee and Carolina mountains, it sends up a straight shaft sometimes free of branches for 60 to 70 feet, and reaches a total height of 90 feet.

(A. H.)

CULTIVATION

According to Loudon this species was introduced into England in 1764, but though more common in cultivation than any *Æsculus* except *A. Hippocastanum*, and apparently not particular about soil, it does not attain any great size. It is perfectly hardy at Colesborne, and ripens fruit in most years, from which I have raised seedlings, which, however, do not grow so fast or well as those of the common horse-chestnut. A seedling raised from a tree at Tortworth in 1905 was 6 inches high in the first year, and some raised from seed which I gathered in the Arnold arboretum, which germinated earlier, were much injured by the frost of May 21-22.

At Syon there are two trees, probably of a great age, both grafted on the common horse-chestnut. One is 65 feet high by 4 feet 4 inches in girth; the other is 56 feet high by 6 feet 4 inches in girth, with a bole of 7 feet, dividing into three stems, which form a wide-spreading crown. A tree at Belton Park, Lincolnshire, was, in 1904, 50 feet high by 3 feet 4 inches in girth, with a fine straight stem, drawn up in a wood. Another, crowded by other trees near the Broad Water at Fairford Park, Gloucestershire, measures about 60 feet by 4 feet 5 inches. A self-sown seedling was growing near it in 1903. There is also a tree, measuring about 50 feet by 5 feet 6 inches, at Charlton Kings, near Cheltenham.

(H. J. E.)

ÆSCULUS CALIFORNICA, CALIFORNIAN BUCKEYE

Æsculus californica, Nuttall, in Torrey and Gray, *Fl. N. America*, i. 251 (1839); *Bot. Mag.* t. 5077 (1858); Sargent, *Silva N. America*, ii. 61, tt. 71, 72, and *Man. Trees. N. America*, 648 (1905); Bean, in *Gard. Chron.* 1902, xxxi. 187, fig. 57.

A tree, attaining in America 40 feet in height, with a short trunk occasionally 9 feet in girth. Bark smooth, grey or white. Leaves with slender grooved petioles. Leaflets five to seven, stalked, oblong lanceolate, acuminate at the apex, cuneate or obtuse at the base, shallowly and crenately serrate, pale glabrescent beneath. Terminal leaflet, with ten to twelve pairs of nerves. Flowers in dense pubescent panicles, 3 to 8 inches long. Calyx two-lipped, upper lip with three teeth, lower lip with two teeth much shorter than the four narrow oblong petals, which are white or pale rose in colour. Stamens five to seven, long, erect, exserted. Ovary pubescent. Fruit pear-shaped, two to three inches long, smooth, pale brown.

In summer it is readily distinguished from the other species with viscid buds by the small leaves, pale beneath. In winter the twigs are slender, grey, glabrous, with numerous lenticels. Leaf-scars wide apart, joined by a linear ridge, flat on the twig, without a leaf-cushion, crescentic or semicircular, with a row of five to seven bundle-dots. Pith large, circular, white. Terminal buds, larger than the lateral buds, which arise at an acute angle, oval, pointed, glistening with white resin; scales gaping at the apex of the bud, broadly ridged on the back, ciliate in margin, with a tuft of hairs at the apex.

The species is a native of California, where it grows on the banks of streams. A very striking picture of a tree, at San Mateo, California, is given in *Garden and Forest*, iv. 523. It shows a very short forked bole, nearly 20 feet in girth at 2 feet from the ground, and an immense umbrella-shaped head only 32 feet high and 60 feet in diameter, densely covered all over with flowers.

It was introduced in 1855 by Messrs. Veitch, and flowered in their nursery at Exeter in 1858. It fruited¹ at the Bath Botanic Gardens in 1901, and again in 1905, though it remains a shrub. It is perfectly hardy in the south of England, and is remarkable for the beauty of its flowers, which appear in June and July. The best specimen we know of in the country is one which Elwes found growing in a shrubbery at Hutley Towers near Ryde, Isle of Wight. It is about 30 feet high, and was in flower on June 22, 1906.

(A. H.)

¹ *Gard. Chron.* 1902, xxxi. 187.

TSUGA

Tsuga, Carrière, *Traité Conif.* 185 (1855); Bentham et Hooker, *Gen. Pl.* iii. 440 (1880); Masters, *Journ. Linn. Soc. (Bot.)* xxx. 28 (1893).
Hesperopeuce, Lemmon, *Rep. Calif. State Board Forestry*, iii. 111 (1890).

EVERGREEN trees belonging to the natural order Coniferæ. Branches horizontal or pendulous, pinnately and irregularly ramified. Buds, one terminal and a few lateral, arising irregularly in the axils of some of the leaves of the current year's shoot, most of the leaves being without buds in their axils. Leaves linear, arising from the branchlets in spiral order, and usually thrown by a twisting of their petioles into a pectinate arrangement, or in one species spreading radially. Petioles short, arising from prominent leaf-bases on the branchlets, appressed against the twigs, a sharp angle being formed by the leaf with the stalk at the point of junction. The leaf has one resin-canal, lying in the middle line between the vascular bundle and the epidermis of the lower surface. The leaves persist for several years; and all the species have in consequence of this and their numerous and fine branchlets very dense foliage.

Flowers monœcious. Male flowers in the axils of the leaves of the previous year's shoot near its apex, composed of numerous spirally arranged, short-stalked, two-celled anthers, with glandular-tipped connectives. Female flowers terminal on lateral shoots of the previous year, short-stalked or sub-sessile, erect, composed of spirally arranged, nearly circular scales, and membranous, usually shorter bracts. Ovules, two on each scale. Cones solitary, small, composed of concave woody imbricated scales, which persist on the axis of the cone after the escape of the seeds, and of inconspicuous bracts, which, except in one species, are concealed between the scales. The cones, ripening in one season, allow the seeds to fall out in the first autumn or winter, but remain on the tree until the summer or autumn of the second year. The seeds, two on each scale, are minute, furnished with resin vesicles and winged. The seedling has three to six cotyledons, which bear stomata on their upper surface.

Tsuga is confined to temperate North America, Japan, China, and the Himalayas. The genus consists of nine species, and is divided into two sections:—

I. *Hesperopeuce*, Engelmann, in Brewer and Watson, *Bot. California*, ii. 121 (1880).

Leaves rounded or keeled above, bearing stomata on both surfaces, and radially arranged; the shorter and lateral branchlets standing in a plane at right angles

to the longer and terminal ones. Cones oblong-cylindrical, large, composed of numerous (about seventy) scales.

This section includes one species:—

1. *Tsuga Pattoniana*, Sénéclauze. Western North America.

II. *Micropeuce*, Spach, *Hist. Vég.* xi. 424 (1842), identical with *Eutsuga*, Engelmann, *loc. cit.* 120 (1880).

Leaves flat, grooved above, bearing stomata on the lower surface only, pectinately arranged on the branchlets, which are all in one plane. Cones ovoid, small, composed of few scales, rarely more than twenty-five.

This section comprises the remaining species, of which six are in cultivation in this country. These may be conveniently arranged as follows:—

A. *Leaves serrulate in margin. Shoots pubescent.*

2. *Tsuga Canadensis*, Carrière. Eastern North America.

Leaves, $\frac{1}{3}$ to $\frac{2}{3}$ inch long, usually tapering from the base to the acute or rounded apex; lower surface marked with two narrow well-defined white stomatic bands, the part of the leaf external to them being pure green in colour. Buds brown, ovoid, pointed, composed of pubescent, keeled acute scales.

3. *Tsuga Albertiana*, Sénéclauze. Western North America.

Leaves, $\frac{1}{4}$ to $\frac{3}{4}$ inch long, usually rounded at the apex and uniform in breadth; lower surface with two ill-defined broad white stomatic bands, which are indistinctly continued to the margins, there being no distinct bands of pure green. Buds greyish, ovoid, apex obtuse and flattened; scales keeled, pubescent.

4. *Tsuga Brunoniana*, Carrière. Himalayas.

Leaves, 1 to $1\frac{1}{4}$ inch long, gradually tapering from the base to the acute apex; lower surface silvery white, stomatic bands well-defined and extending almost to the margins. Buds globose, flattened on the top, surrounded at the base by a ring of modified leafy scales, the other scales ovate, acute, pubescent.

B. *Leaves entire in margin. Shoots glabrous.*

5. *Tsuga Sieboldii*, Carrière. Japan.

Leaves, $\frac{1}{4}$ to 1 inch long, oblong, rounded and notched at the apex, shining above; lower surface with two narrow well-defined white stomatic bands. Buds red, ovoid, slightly acute at the apex; scales glabrous and ciliate.

C. *Leaves entire in margin. Shoots pubescent.*

6. *Tsuga diversifolia*, Maximowicz. Japan.

Shoots pubescent, both on the leaf-bases and in the furrows between them. Leaves, $\frac{1}{4}$ to $\frac{1}{2}$ inch long, oblong, rounded and notched at the apex; lower surface with two narrow well-defined white stomatic bands. Buds red, pyriform, flattened above; scales obtuse, minutely pubescent.

7. *Tsuga Caroliniana*, Engelmann. Southern Alleghany Mountains.

Shoots pubescent in the furrows between the leaf-bases, which are glabrous.

Leaves, $\frac{1}{4}$ to $\frac{3}{4}$ inch long, oblong, rounded at the apex, which is entire, minutely notched or mucronate; lower surface with two narrow well-defined white stomatic bands. Buds reddish, ovoid, sharp-pointed; scales indistinctly keeled.

In addition to the preceding, two species of *Tsuga*, belonging to this section, occur in China. They are as yet imperfectly known. *Tsuga chinensis*, Masters,¹ a native of the high mountains of Szechuan, is closely allied to *Tsuga diversifolia*, and, like it, has pubescent young shoots. It differs in the cones, which are quite sessile, and have very lustrous scales. The leaves are described as being green beneath; but this is probably an inconstant character.

Tsuga yunnanensis, Masters,² which was discovered by Père Delavay in the mountains near Likiang in Yunnan, is unknown to me. Franchet considers it to be closely allied to *T. Sieboldii*.

TSUGA PATTONIANA, HOOKER'S HEMLOCK

Tsuga Pattoniana, Sénéclauze, *Conif.* 21 (1867); Engelmann, in Brewer and Watson, *Bot. California*, ii. 121 (1880); Masters, *Gard. Chron.* xii. 10, fig. 1 (1892).

Tsuga Hookeriana, Carrière, *Traité Conif.* 252 (1867); and Lemmon, *Erythea*, vi. 78 (1898).

Tsuga Mertensiana, Sargent, *Silva N. Amer.* xii. 77, t. 606 (1898), and *Trees N. Amer.* 51 (1905); Kent, *Veitch's Man. Conifera*, 468 (1900).

Pinus Mertensiana, Bongard, *Végét. de Sitcha*, 54 (1832).

Pinus Pattoniana, Parlatores, *D. C. Prod.* xvi. 2, p. 429 (1864).

Abies Pattoniana, Balfour, *Rep. Oregon Assoc.* 1 (1853); Murray in Lawson, *Pin. Brit.* ii. 157 (1884).

Abies Hookeriana, Murray, *Edin. New Phil. Journ.* 289 (1855); and in Lawson, *loc. cit.* 153.

Abies Williamsonii, Newberry, *Pacific R. R. Report*, vi. pt. iii. 53, t. 7, fig. 19 (1857).

Hesperopeuce Pattoniana, Lemmon, *Rep. Calif. State Board Forestry*, iii. 128 (1890).

A tree, occasionally attaining in America 150 feet in height, with a girth of 15 feet. Bark dark cinnamon in colour, deeply divided into rounded connected scaly ridges. Shoots brownish-grey, and densely pubescent. Branchlets in different planes, the shorter and lateral ones usually arising on the upper side of the longer and terminal ones, and disposed at right angles to them, giving a tufted appearance to the branch. Leaves radially arranged on the branchlets, not markedly different in size, $\frac{3}{4}$ to 1 inch long, curved, linear; apex usually rounded and obtuse, rarely acute; upper surface convex and keeled towards the apex; lower surface rounded with a median groove; both surfaces with about eight lines of stomata, which are sparse and do not form conspicuous white bands; margin entire. Buds brownish, ovoid, acute at the apex, composed of a few closely imbricated, strongly keeled scales.

Cones sessile, about two inches long, oblong cylindrical, tapering at the apex and slightly narrowed at the base, composed of five series of scales, each series with

¹ *Journ. Linn. Soc. (Bot.)* xxvi. 556 (1902); *Abies chinensis*, Franchet, *Journ. de Bot.* 1899, p. 259.

² *Journ. Linn. Soc. (Bot.)* loc. cit.; *Abies yunnanensis*, Franchet, *loc. cit.* p. 258; and cf. also Masters, *Journ. Linn. Soc. (Bot.)* xxxvii. 421 (1906), who identifies the specimens from Szechuan with this species; but judging from Franchet's description, they are the other species.

fourteen to fifteen scales. Scales thin, broader than long, semicircular with a wedge-shaped base, convex, margin irregularly denticulate, pubescent on both surfaces. Bract oblong, abruptly tapering at the apex, which is visible between the scales. Seed with terminal asymmetrical wing, and two resin-vesicles on the side next the scale.

The name *Pattoniana* is adopted as being the first published under the correct genus *Tsuga*. The tree is known to American botanists as *Tsuga Mertensiana*, which is unfortunate, as this name was for many years in use for the western hemlock. There is no confusion possible if *Pattoniana* be selected, as no other hemlock has been known at any time by this name.

VARIETIES

The preceding description is drawn up from living specimens of the form with bluish entire leaves, cultivated in this country, and applies, in all essential characters, to dried specimens from trees growing wild in America. I have examined the material in the Kew herbarium and also specimens collected by Elwes on Mount Shasta at 7500 feet elevation; and there do not appear to be two distinct varieties of the tree in the wild state, as the presumed alpine form is only a stunted shrub which agrees in botanical characters with the trees from lower levels.

In England, however, there is a form in cultivation, distinguished by its green serrulate leaves, which differs in many respects from the other form. Concerning its origin, we only know, on the authority of Murray,¹ that it was raised at Edinburgh from seeds collected by Jeffrey in 1851 on the Mount Baker range in British Columbia. Jeffrey found trees growing there from 5000 feet elevation to the snow line, varying in size from 150 feet in height and 13½ feet in girth at lower levels to a stunted shrub not more than 4 feet high close to the timber line. Specimens at Kew from Mount Baker gathered by Jeffrey all have entire leaves and belong to the ordinary wild form.

Engelmann,² who visited the Mount Baker range, states that the trees growing there are the ordinary forms of *Tsuga Pattoniana* and *Tsuga Albertiana*. He suggests that the plants raised from Jeffrey's seed may be a mountain form of the latter species; but this cannot be admitted, as they do not resemble that species in botanical characters (buds, leaves, etc.). It is possible that these plants are only a seedling variation of *Tsuga Pattoniana*, and do not correspond with any distinct species or geographical form in the wild state.

Murray,³ believing that he had two species to deal with, named the bluish form *Abies Hookeriana*, and assigned the name *Abies Pattoniana*, Balfour, to the other form. The original figure of Balfour's species represents, however, the same plant as *Abies Hookeriana* of Murray; and much confusion has resulted in consequence in the use of the two names *Hookeriana* and *Pattoniana*. It is most convenient to

¹ *Edin. New. Phil. Jour.* 289 (1855) and *Proc. Hort. Soc.* ii. 202 (1863).

² *Gard. Chron.* xvii. 145 (1882).

³ The distinctions relied on by Murray in the cones are trifling; and in the Kew Herbarium there are wild specimens showing these differences, but all belonging to the form with blue entire leaves. I have not seen cones belonging to the other form.

apply the name *Pattoniana* to the bluish form, as it is the earliest name of the wild plant, and to consider the green-foliaged plant to be a variety of it, which may be called var. *Jeffreyi*.

The two forms are distinguished as follows:—

1. Var. *typica*. The form distinguished in cultivation by its bluish foliage. Introduced in 1854 by William Murray, who found the tree on Scots Mountain, in California.

Leaves, though radially arranged, tending on the lower side of the shoot to be in the plane of the branch and not spreading; those on the upper side of the shoot curved and directed outwards and forwards. They are long and narrow, ½ to ⅞ inch long, and ⅓ inch wide, entire in margin, convex on both surfaces, the groove in the median line above being very short or absent and never continued to the apex of the leaf, which is rounded or acute; both surfaces marked with conspicuous lines of stomata extending from the base to the apex of the leaf.

2. Var. *Jeffreyi*. Only known in cultivation, distinguished by its greenish foliage.

Leaves spreading radially and directed outwards (never forwards) on all sides of the shoot; straight, short, and broad, less than ½ inch long and about ⅓ inch in width, serrulate in margin; upper surface flattened and distinctly grooved, the groove continued to the rounded apex; lower surface convex, with lines of stomata the whole length of the leaf. On the upper surface the stomata only occur in four to six broken lines towards the apex.

This form agrees with the typical form in the character of the buds and pubescence of the branchlets; the shoots, however, are not so slender.

(A. H.)

Mr. Gorman gives the following account¹ of the supposed Alpine form, alluded to above:—"Among the hardy alpine trees Hooker's hemlock stands pre-eminent, having a northern range far beyond that of even the white-barked pine. It is a small, dwarfed and stunted tree compared with the type, and seldom exceeds 12 inches diameter or 30 feet in height. It usually ranges in altitude from 5500 to 6400 feet, but is occasionally found up to and beyond 7000 feet where it can find sufficient moisture. Though generally favouring the heads of moist valleys it is sometimes to be found on the leeward side of peaks and slopes, where snowbanks of sufficient size have formed in winter to maintain an adequate supply of moisture during the rest of the year. It is in the latter situations where the tree reaches its highest altitude. In addition to its smaller size and more alpine habit it further differs from its nearest congener in having thinner bark and *small erect* cones, all the other hemlocks having pendent cones. The tree is too small and inaccessible to have any economic value."

This seems to be distinguished principally by its erect cones. Sargent,² who alludes to Gorman's account, does not consider this variation to be worthy of distinc-

¹ *Survey E. Part Washington Forest Reserve*, p. 336 (19th Ann. Report of the Survey, Part v. 1899).

² *Silva N. Amer.* xii. 78, note 1.

tion, and explains it by saying that the position of the cones "is evidently due to the thickness of the short lateral branchlets, on which they are terminal and which are sometimes so rigid that the weight of the cones does not make them pendent."

DISTRIBUTION

This tree is only found at high elevations, where it has much the same geographical range as the western hemlock, but it extends farther south in California and reaches its southern limit at 9000 to 10,000 feet on the south fork of King River in the Sierra Nevada.

In the north it descends to sea level on Baranoff Island, and on the shores of Yes Bay in Alaska, lat. 55° 54' N., where Mr. Martin Gorman collected it. As a rule it is a tree of high altitudes, growing on exposed ridges and slopes near the upper limit of the forest, in company with *Abies lasiocarpa*, *Picea Engelmanni*, and *Pinus albicaulis*. In the Rocky Mountains of British Columbia Mrs. Nicholl found it as a good-sized tree near Glacier up to 7000 feet, though Wilcox,¹ in his excellent account of the trees of that region, pp. 61-65, does not mention it.

Though usually a more or less stunted and ragged tree, it attains a large size on the Cascade Mountains, where I saw it in perfection on the road from Longmire Springs to Paradise Valley, on the south side of Mount Tacoma,² in August 1904, first at about 4000 feet, where it was only a scattered tree, and higher up it mixed with the western hemlock in a splendid forest. I was not able to distinguish the two species by their bark, though when not crowded, the habit of Hooker's hemlock is very distinct; but they could be identified by the fallen cones under the trees. The largest that I measured here was about 150 feet by 13 feet 8 inches. Higher up, where the forest³ opened out into glades at the bottom of the Paradise Valley, which is, in Professor Sargent's opinion, one of the most interesting in America for its alpine flora, it assumed a different and more flat-topped habit; the largest here that I measured was 108 feet by 13 feet 3 inches. It grew in company with *Abies lasiocarpa*, and seedlings of both were numerous on rotten logs on the shady sides of the clumps in which they always grew.

The tree in a very stunted state reaches the timber line—about 7500 feet—in company with *Abies lasiocarpa* and *Cupressus nootkatensis*; but in California, J. Muir⁴ measured a specimen at 9500 feet, near the margin of Lake Hollow, which was 19 feet 7 inches in girth at 4 feet from the ground.

Mr. Gorman gives an excellent account of the tree in his *Survey of the Eastern Part of the Washington Forest Reserve*, pp. 335-336, from which I quote as follows:—

"This hemlock is confined to the moist valleys and vicinity of the passes. It is the prevailing tree in Cascade Pass, 5421 feet, and is quite common about the

¹ *The Rockies of Canada*, 61-65 (1900).

² The local name is Mount Tacoma, but in maps and writings it is usually called Mount Rainier.

³ An account of this forest, with two beautiful illustrations of "Patton's spruce," is given in *Garden and Forest*, x. 1, figs. 1, 2 (1897).

⁴ *Mountains of California*, p. 20.

sources of the Stehekin, where it attains a very fair size for this region, ranging from 50 to 90 feet in height and from 12 to 27 inches in diameter. The altitudinal range is greater than was expected, from 3100 feet to 5800 feet, and a tree supposed to be of this species was found as low as 2100 feet in the Stehekin Valley.

"The tree is sometimes taken for the western hemlock, but may be distinguished by the erect top of the sapling, the cones long, purple, and more or less massed about the top of the tree; and the mature tree has an unusually thick, roughly corrugated bark: while in the western hemlock the top is generally drooping, the cones small, oval, and brown, and well distributed over the branches, and the mature tree has a comparatively thin bark. The wood is close grained and of fine texture, and is quite suitable for lumber or fuel, but is not much used on account of its growing usually in inaccessible situations."

Near Crater Lake in Southern Oregon, Mr. Leiberg (*Cascade Forest Reserve Report*, pp. 245, 259), says:—"A few scattered groves of Patton hemlock occur in the southern tracts, some of which are of large size, occasional individuals reaching six to seven feet in diameter. Occasional stands of Patton hemlock 200 to 300 years old exhibit fine proportions at this elevation, 6000 feet; the species usually grows in close groups, composed of ten or twenty individuals, collected together on what appears to be a common root; such close growth develops clear trunks, though not commonly of large diameter. Stands of this character sometimes run as high as 25,000 feet per acre."

REMARKABLE TREES

Though now introduced for about fifty-five years this tree has made but little show in our gardens, as the climate of most parts of England is probably too warm for it. I have seen flourishing specimens of no great size in several places, the best, perhaps, being one at Tyberton Court, Herefordshire, the seat of Chandos Lee Warner, Esq., where there is a tree of the typical form 43 feet high by about 3½ feet in girth, said to be fifty years old, and perhaps one of those introduced by William Murray, and sent out by Lawson.

In Scotland it seems to thrive even better, especially at Murthly Castle, where there is a fine group of trees on a lawn (Plate 67). When measured for the Conifer Conference in 1892 the best of these was 35 feet by 3 feet 10 inches, another 30 feet by 4 feet. When I last saw them in September 1906 the tallest tree on the left of the row was 47 feet by 3 feet 8 inches, the tree in the middle with weeping branches 43 feet by 4 feet 2 inches, and the thickest between these two was 6 feet 7 inches in girth. The difference in the habit of these three is well shown in the plate. They produced seed in 1887, from which a number were raised and planted at Murthly. These have grown slowly, and the tallest in 1906 were six or seven feet high, though quite healthy; and the growth of seedlings which I raised from seed gathered on Mount Rainier is extremely slow.

At Keillour, Henry measured, in 1904, a specimen which was 40 feet by 3 feet 9 inches; and at the Cairnies, near Perth, the seat of Major R. M. Patton, there were in 1892 two specimens little inferior to those at Murthly. (H. J. E.)

TSUGA ALBERTIANA, WESTERN HEMLOCK

Tsuga Albertiana, Sénéclauze, *Conif.* 18 (1867); Kent, Veitch's *Man. Coniferae*, 459 (1900).

Tsuga Mertensiana, Carrière, *Traité Conif.* 250 (1867); Masters, *Gard. Chron.* xxiii. 179, fig. 35 (1885).

Tsuga heterophylla, Sargent, *Silva N. Amer.* xii. 73, t. 605 (1898), and *Trees N. Amer.* 50 (1905).

Abies heterophylla, Rafinesque, *Atlant. Jour.* i. 119 (1832).

Abies Mertensiana, Gordon, *Pinetum*, 18 (1858).

Abies Albertiana, A. Murray, *Proc. Roy. Hort. Soc.* iii. 149 (1863).

A large tree, attaining in America 200 to 250 feet in height and 20 feet or more in girth, narrowly pyramidal in habit. Bark of old trees reddish brown, and deeply divided into broad, flat, connected scaly ridges. Young shoots whitish grey, and covered with short pubescence, intermixed with scattered long straggling hairs. Leaves pectinately arranged, the shorter leaves on the upper side of the branchlets, those in the median line above often parallel to the twig and directed forwards, exposing their stomatic surfaces. The leaves are $\frac{1}{4}$ to $\frac{3}{4}$ inch long, linear-oblong, uniform in width, serrulate in margin, dark green above, with a median groove continued up to the rounded apex; under surface with inconspicuous midrib and two broad white stomatic bands, which are ill defined on the outer side, there being no distinct marginal green bands. Buds greyish brown, ovoid, with an obtuse and flattened apex; scales keeled and pubescent.

Cones sessile, about one inch long, ovoid, composed of five series of scales, each series with six to seven scales. Scales spatulate, nearly twice as long as broad, wider in the upper half, abruptly narrowed below, rounded with a slightly acute apex, entire and slightly bevelled in margin, striate and slightly pubescent on the outer surface. Bract small, concealed, lozenge-shaped, pubescent and keeled. Seed with a very long wing, decurrent on the outer side of the seed to the base; seed with wing about three-fourths the length of the scale.

The young seedling has three to four cotyledons, which are a little more than $\frac{1}{4}$ inch in length, gradually tapering to an acute apex, sessile, flattened beneath, the upper surface two-sided and bearing stomata, margin entire. The young stem is pubescent and bears first two to three whorls of true leaves (three in each whorl), which are serrulate, shortly stalked, and bearing stomata on their upper surface. These are succeeded by leaves borne spirally. The cotyledons are supported by a caulicle, reddish and glabrous, about an inch in length, which terminates in a very slender flexuose tap-root.

The name *Albertiana* has been chosen, as it appears to have been published as early as that of *Mertensiana* under the correct genus *Tsuga*. *Tsuga Mertensiana* is now the name given by American botanists to *Tsuga Pattoniana*, and its adoption would cause considerable confusion. *Albertiana*, never having been applied to any other species, is correct on the grounds of common sense as well as of priority.

(A. H.)

DISTRIBUTION

On the west coast of North America it extends southwards from south-eastern Alaska, where it forms the greater part of the great coast forest, which reaches from sea-level up to about 2000 feet, and is associated with Menzies's spruce.

In British Columbia it is very abundant on the coast, and extends as far inland as the heavy rainfall reaches up the valley of the Frazer, on the Gold and Selkirk ranges, and east of the Columbia valley nearly up to the continental divide.¹ In Vancouver's Island it forms with the Douglas fir and red cedar a large though not economically important part of the forest. In Washington and Oregon it is also one of the principal elements of the forest, of which, in the Cascade Forest Reserve, it forms about nine per cent of the timber,² and extends up to 5000 feet, crossing the watershed of the coast range in lat. 45°.

In the drier parts of southern Oregon it becomes rare, and though it occurs in the redwood forests of northern California as far south as Cape Mendocino, I did not see it on the Siskyou mountains or on Mount Shasta. In the interior it is found in the wetter parts of northern Montana, Idaho, and in southern British Columbia, where, in company with Douglas spruce, *Picea Engelmanni*, *Abies grandis*, and *Larix occidentalis*, it sometimes forms a considerable part of the forest, and reaches up to 6000 feet in the Cœur d'Alène mountains, though I did not see it in the valley of the Blackfoot river, near Missoula, where the climate is drier.

It attains its finest development on the coasts of Washington and Oregon, where Sargent says that it attains 200 feet in height, with a stem 20 to 30 feet in girth. Plummer, in his Report on the Mount Rainier Forest Reserve,³ says (p. 101) that it attains an extreme diameter of 6 feet, with a height of 250 feet, of which half to two-thirds is crown. The largest that I actually measured, however, on my visit to Mount Rainier in August 1904, were under 200 feet, with a girth of 12 to 14 feet, and these were growing mixed with *Tsuga Pattoniana* at an elevation of 4000 to 5000 feet.

In the Cascade Reserve Forest of northern Oregon, near Bridal Veil, at about 3500 feet elevation, I measured and Mr. Kiser photographed a tree 175 feet high and 16 feet 6 inches in girth, with a clean bole of about 60 feet, but I am unable to reproduce this, as the negative has not arrived.

The growth of seedlings in all the forests that I saw was exceptionally good. Mr. H. D. Langille says,⁴ p. 36:—

“Certain cone-bearers are better adapted for restocking than others, though the reasons are not apparent. For example, young lovely firs (*A. amabilis*) are abundant everywhere within the zone of that species, whilst noble fir (*A. nobilis*), having a cone and seed of very similar size and nature, seldom germinates, and a seedling of that species is rarely seen.

¹ Mrs. Nicholl, who explored the Rocky Mountains in 1904 and 1905, tells me that it is a large tree at Glacier, on the Canadian Pacific Railway, and grows up to about 5000 feet.

² *Forest Conditions of Cascade Reserve*, p. 25, Washington, 1903.

³ *Twenty-first Annual Report of the U.S. Geological Survey*, part v. Washington, 1900.

⁴ *Forest Conditions in Cascade Reserve*, U.S. Geological Survey, Washington, 1903.

"From many observations made in the zone of the hemlock and lovely fir, it is apparent that these trees, from their ability to thrive under the most adverse conditions, are rapidly superseding the others, and will, under natural conditions, be the sole components of the alpine forests. It is a striking fact that, upon many areas where from 50 to 100 per cent of the present forest is red fir (Douglas), the reproduction is entirely hemlock and lovely fir. Should these forests be destroyed by fire it is probable that red fir would rival these species in restocking the burn; but under natural conditions it is evident that the red fir will be displaced, and the limits of the alpine trees become much lower than at present.

"The yellow pine (*P. ponderosa*), in some instances, does good work in stocking open spots in the timber, but seldom extends far beyond the parent tree. In the yellow pine forests most of the young growth is red or white fir (*A. grandis*), which, taking advantage of the shade and moisture afforded by the yellow pine cover, is growing rapidly, and will in time form a larger percentage of the forest than it has in the past."

I can confirm this from my own observation both in the Cascade Forest and in Vancouver's Island. The seedlings germinate most freely when they fall on the moss-covered rotting trunk of a fallen tree, along which a complete row of young trees often grows; and Plate 59, vol. i. shows a tree of this species, probably 150 years old, whose roots had completely enclosed the still sound trunk of a red cedar (*Thuja plicata*). A valuable paper¹ by Mr. E. T. Allen, dealing with the western hemlock from a forestry point of view, has been published by the U.S. Bureau of Forestry.

CULTIVATION

It was introduced in 1851 by Jeffrey, and named in 1863 by Murray, at the request of Queen Victoria, in memory of the late Prince Consort, who was a patron of the Oregon Association, and President of the Royal Horticultural Society.²

In grace, freedom of growth, and adaptability to varied conditions of culture, in England this, as an ornamental tree, is second to none, and much superior to any other hemlock. Though it has been in cultivation little over fifty years it has already attained a height of about 90 feet in such widely distant counties as Kent, Devonshire, and Perthshire.

The only soils on which it will not thrive are chalk, limestone, and heavy clay, and though it enjoys all the moisture that the wettest parts of England afford, it wants, like all its congeners, a well-drained soil and a sheltered situation.

It ripens seed abundantly in England, and has sown itself in several localities, especially at Blackmoor, the seat of the Earl of Selborne, where there are several self-sown trees, of which the best, growing on the lower greensand formation, is, at about fifteen years old, 10 to 12 feet high, though the parent trees do not exceed about 65 feet.

In Fulmodestone Wood, on Lord Leicester's estate in Norfolk, I have also seen self-sown seedlings; and though they are very slow in growth for the first four or five

¹ "The Western Hemlock," U.S. Dept. Agric. Forestry Bulletin, No. 33 (1902).

² Hunter, *Woods of Perthshire*, p. 359.

years, yet if kept moist and shaded in a mixture of sand and leaf-mould they may be planted out at five to six years old, with every hope of success.

So far as my experience goes, trees grown from cuttings are not so satisfactory, and there is no excuse for this practice except the saving of trouble, as seedlings are raised in quantity at a very low cost from home-grown seed in Scotland, as I have seen in the nursery at Murthly Castle.

REMARKABLE TREES

Among so many fine trees of this species, all of about the same age, it is hard to choose, but perhaps the largest¹ which we have measured is at Hafodunos, in Denbighshire, which in 1904 was found by Henry to be 94 feet 6 inches by 8 feet 5 inches, and this tree has also produced self-sown seedlings.

At Dropmore there is a very beautiful tree of the spreading type (Plate 68), about 70 feet by 6 feet. At Hemsted, in Kent, I was shown by Lord Cranbrook, in 1905, a tree which is perhaps as tall as any in England, but which, growing in a hole and surrounded by other trees, it was not possible to measure accurately. It is, however, about 90 feet by 4 feet 11 inches, well shaped and growing fast.

At Penllergare, near Swansea, the seat of Sir J. T. D. Llewellyn, Bt., are several fine trees growing in a sheltered valley, which were planted about fifty years ago in company with *Tsuga canadensis*. They are now from 70 to 80 feet high, whilst the best of the eastern hemlock is only 50 feet, and the difference in habit of the two trees is very well shown.

A very large tree, reported² to be 110 feet high, is growing at Singleton Abbey, near Swansea, the residence of Lord Swansea, but I have been unable as yet to get confirmation of the height stated. At Castlehill, N. Devon, are several fine trees, the best of which, on a steep bank above a waterfall, where it is somewhat drawn up by beeches, is 90 feet by 6 feet 7 inches. At Cardlew, Cornwall, is a fine tree, which in 1902 was 80 feet by 6 feet 3 inches, and in 1905, 82 feet by 6 feet 6 inches, both measurements taken by myself.

At Barton, Suffolk, a young and very thriving tree, shut in by tall beeches and conifers, in 1905 was 80 feet by 4 feet 3 inches, a remarkable instance of height as compared with girth.

In Scotland the tree flourishes exceedingly, and has been planted in many places. Perhaps the tallest is one at Castle Menzies, which in 1904 I made about 90 feet by 7 feet 8 inches, though the gardener thinks it is taller; but one of the most beautiful for its shape, graceful habit, and situation, grows by a deep shady burn on the road from Dunkeld to Murthly Castle, and is about 70 feet by 5 feet (Plate 69), and there are many other fine trees in the grounds there. A tree at Riccarton, near Edinburgh, planted in 1855, measured in 1905, 73 feet by 7 feet 1 inch. A very large tree, measuring in 1907, 10 feet in girth, is reported by Major P. J. Waldron, to be growing at Hallyburton, Coupar-Angus, the seat of Mr. W. Graham Menzies.

¹ This tree was in 1868, 28½ feet high by 2 feet 3 inches in girth at the base. In 1883 it measured 65 feet by 4 feet 11 inches at 3 feet from the ground (*Gard. Chron.* 1868, p. 657, and 1885, xxiii. 179). According to the owner, Colonel Sandbach, it was planted probably in 1856.

² *Gard. Chron.* xxxvii. 136 (1905).

The only place where the tree is reported to have been killed by frost is in the plantations at the Cairnies, Perthshire, where Hunter says (p. 364) that in the severe winter of 1880-81 many were injured and some killed. Two of the finest specimens in Scotland are, however, growing in the grounds at this place.¹

In Ireland the best specimen we know of is one at Glenstal, Co. Limerick, which measured in 1903, 78 feet high by 7½ feet in girth. One of exactly the same height by 6 feet in girth is growing at Kilmacurragh, Co. Wicklow; and around it are several self-sown seedlings. At Mount Usher, in the same county, there is a fine specimen, 28 years old, from seed, which was 57 feet high by 4 feet 5 inches in 1903.

TIMBER

The timber of the western hemlock has not until recently been much valued, or cut for lumber, on account of its supposed inferiority to that of the Douglas spruce, and is often left standing by loggers, but the increasing scarcity of lumber in some districts has led to its being converted into boards, and it is now largely used for the construction of buildings. Sargent says that it is light, hard, and tough, stronger, more durable, and more easily worked than the other American hemlocks. Allen² says that in strength it cannot be classed with oak, red fir, or longleaf pine, nor is it suitable for heavy construction, especially where exposed to the weather; but it possesses all the strength requisite for ordinary building material. It is largely used in Washington for mill frames.

At Mr. Bradley's sawmill at Bridal Veil, Oregon, I saw it being manufactured, and brought away a sample which quite bears out Sargent's high opinion of it. If such timber existed in Japan or in Europe, I am sure it would be highly valued for joinery, but so far as I can learn none has yet been shipped to Europe. Hemlock timber³ has been exported to Manila, and is likely to prove of considerable value in the tropics for housebuilding and indoor finish, as it appears to be free from the attacks of white ants. The wood is distasteful to rodents, and is used on that account by farmers for the construction of oat-bins.

The bark, according to Sargent, forms the most valuable tanning material produced on the west coast of North America, and the inner bark is eaten by the Indians of Alaska.

James M. Macoun³ says of it—"The abundance of other wood of better quality has prevented the hemlock from coming into general use, and the same prejudice exists in British Columbia against the western tree that prevailed until very recently against hemlock in eastern Canada. Though its grain is coarse, western hemlock is for many purposes just as serviceable as other woods which cost more. The bark is rich in tannin, but is too thin to be extensively used while there is such an abundance of Douglas fir in the same region." (H. J. E.)

¹ These are trees growing in peat soil at 635 feet altitude. The seeds were sown in 1853, and in 1868 one tree was 29 feet by 1 ft. 11 in., and the other 26 feet by 2 feet at three feet from the ground (*Gard. Chron.* 1868, p. 518).

³ *Forest Wealth of Canada*, 82 (1904).

TSUGA CANADENSIS, HEMLOCK OR HEMLOCK SPRUCE

Tsuga canadensis, Carrière, *Traité Conif.* 189 (1855); Sargent, *Silva N. Amer.* xii. 63, t. 603 (1898), and *Trees N. Amer.* 48 (1905); Kent, *Veitch's Man. Conifera*, 463 (1900).
Pinus canadensis, Linnæus, *Sp. Pl.* 1421 (1763); Lambert, *Genus Pinus*, i. t. 32 (1803).
Abies canadensis, Michaux, *Fl. Bor. Am.* ii. 206 (1803), and *Hist. Arb. Amer.* i. 137, t. 13 (1810); Loudon, *Arb. et Frut. Brit.* iv. 2322 (1838).
Picea canadensis, Link, *Linnaea*, xv. 523 (1841).

A tree attaining in America over 100 feet in height, but usually only 60 to 70 feet, with a girth of 12 feet as a maximum. Bark of old trees brownish and deeply divided into narrow rounded ridges, covered with appressed scales.

Young shoots greyish in colour and covered with short stiff pubescence. Leaves pectinately arranged, the shorter ones on the upper side of the shoot; those on the median line above pointing forwards, appressed to the twig, and displaying their white under surfaces. They are ½ to ⅔ inch long, linear, usually broadest towards the base and tapering to the apex, which is rounded or acute; distinctly and sharply serrulate in margin; dark green above with a median groove often not continued to the apex; lower surface with distinct midrib and two narrow well-defined white stomatic bands, the edges being pure green in colour. Buds brown, ovoid, pointed; scales ciliate, pubescent, keeled, acute.

Cones, ½ to ¾ inch long, ovoid, on slender puberulous stalks nearly ¼ inch long, composed of five series of scales, with about five scales in each series. Scales orbicular oblong, nearly as broad as long, entire and slightly bevelled in margin, striate, glabrescent in the exposed part. Bract small, concealed, lozenge-shaped. Seed with an oblong wing, decurrent half-way on its outer side. The seed with wing about two-thirds the length of the scale.

VARIETIES

A considerable number of horticultural varieties are known, no less than fourteen being described by Beissner. Some of these are variegated forms, as var. *argentea* or *albo-spica*, in which the tips of the young shoots are whitish. Others differ in habit and stature, as var. *pendula*, with pendulous branches, and var. *Sargentii*,¹ a flat-topped bushy form of compact habit with short pendulous branches. The latter was found about forty years ago on the Fishkill Mountains in New York, and was first cultivated and made known by Mr. H. W. Sargent. One of the original plants, growing on the Howland estate, in Matteawan, New York, is now about 25 feet across. Grafted plants of this variety form in a few years an erect stem, and lose the dense low habit which is the charm of the original seedlings.¹

Var. *parvifolia*, as cultivated at Kew, is a shrub, with stout branchlets, and very short leaves, about ¼ inch long, which spread radially outwards from the shoot.

(A. H.)

¹ Sargent, *Garden and Forest*, x. 490 (1897).

DISTRIBUTION

In the colder parts of New England and Canada the hemlock is one of the most characteristic trees of the virgin forest, and extends, according to Sargent, from Nova Scotia and New Brunswick westward through Ontario to eastern Minnesota, southwards through Delaware, southern Michigan, and central Wisconsin, and along the Appalachian Mountains to north-western Alabama. He says that it attains its largest size in the south, in the mountain valleys of North Carolina and Tennessee, and gives its size as usually 60 or 70 and occasionally 100 feet in height, with a trunk 2 to 4 feet in diameter; but Pinchot and Ashe (*loc. cit.* p. 134) give 110 feet with a diameter of 6 feet as its extreme size, with a beautiful picture of it (pl. xix.). When, however, I was at Ottawa in September 1904 I visited, in company with Mr. James M. Macoun of the Geological Survey, a forest near Chelsea, in the Gatineau valley, where several hemlocks of nearly 100 feet were standing, mixed with birches, maples, and other hardwoods, and found a fallen tree which must have been at least 125 feet, and perhaps 135 feet long, though the top was too rotten to follow it out to the end. Mr. Macoun, however, said he had never seen one so large before.

It often grows on rocky ridges, where it forms dense groves on the north side, and loves the steep banks of river gorges. Henry visited in 1906 Pisgah Mountain, near Hinsdale, in New Hampshire, where there remain on the estate of Mr. Ansell Dickinson about 700 acres of virgin forest. This mainly consists of a mixture of hemlock and hardwoods, with white pine occurring here and there singly and in small groups; though on one or two areas of a few acres the white pine and hemlock form a pure coniferous stand. The largest hemlock seen measured 113 feet by 7 feet 10 inches, with a clean stem of only 30 feet, being much branched though densely crowded by other trees. A great many small hemlocks throughout the forest formed an undergrowth, and had been suppressed in growth, one which was $\frac{3}{4}$ inch in diameter and 10 feet high showing 65 annual rings.

In the Arnold Arboretum, near Boston, is a fine natural grove of this tree, called Hemlock Hill, which gives a very good idea of its normal growth in New England. The average height here is 60 to 70 feet by 3 to 4 feet, and the best that I measured at the bottom of the hill was 80 feet by 4 feet 6 inches. These trees were rather crowded, and had clean boles for 15 to 30 feet up.

The growth of the tree is very slow, and Sargent says that the specimen of its timber in the Jessup Collection in the American Museum of Natural History at New York (which is the most complete that has ever been formed of the woods of any country) is only $13\frac{1}{2}$ inches in diameter inside the bark, though it shows 164 annual rings, of which the sapwood, 2 inches thick, has twenty-nine.

It seeds freely, but the seedlings do not germinate well in the open or on land which has been recently burned over, and seem to succeed best on a mossy stump or fallen log, where they must often remain eight to ten years before their roots reach the earth. According to Sargent they are only three or four inches high at four years old, under favourable conditions, and are easily destroyed.

CULTIVATION

Though introduced by Peter Collinson about 1736,¹ and at one time planted in almost every garden as an ornamental tree, the hemlock is rarely seen in Europe in a condition to remind the American of it as he knows it at home. Of late years it has been superseded by more modern and faster growing introductions.

I cannot exactly say what are the conditions which suit it best in this country, because I have not seen it planted in the shady, damp, and rocky gorges which it likes at home; but a deep light soil, free from lime and well drained, and a northern aspect, seem to suit it best in gardens. Its graceful habit and perfect hardiness should recommend it to all lovers of trees. It has a general tendency to fork near the ground, and this can only be checked by crowding it when young, or perhaps to some extent by careful pruning, as Loudon says that it bears the knife well, and is used for hedges in American nurseries; though I should consider either common spruce or arbor vitæ much better suited for the purpose here.

It ripens seed freely, but the plants I have raised were so small that frost and March winds destroyed them before I learned the necessity of protecting them; and in future I would imitate nature, and sow them on a mossy piece of half-rotten wood, or in a mixture of sand and leaf mould in a shaded frame.

REMARKABLE TREES

By far the most remarkable specimens of this tree which exist in England, or, as I believe, in Europe, are at Foxley, Herefordshire, the seat of the Rev. G. H. Davenport, which are believed to have been planted by Sir Uvedale Price, who was once the owner of this place. He was born in 1747, and died in 1828. In Nash wood, about half a mile from the house, on a rich soil of old red sandstone formation, in a dell facing south-west, a number of these trees are growing, which, though not quite so large as the tree at Studley, average about 55 feet high by 8 to 10 in girth, and although their trunks are not so straight and clean as in an American forest, are nearly all sound and healthy. I measured twenty of these trees in July 1906 and found the largest, the only one which was forked near the ground, to be 10 feet in girth. Another was 9 ft. 10 in., and had a trunk which would contain from 120 to 130 cubic feet. The others ranged from 7 to $9\frac{1}{2}$ feet at 5 feet from the ground, averaging over 8 feet, and were mostly clear of branches, or nearly so, for 15 to 30 feet from the ground. The dense shade of these trees keeps the soil quite free from vegetation below them, but I saw no seedlings in the grove. Though Mr. Davenport was good enough to have a considerable clearing made in order to get a better view of the trees, and Mr. Foster went to Foxley on purpose to photograph them, the difficulty of the subject was so great that the prints taken (Plate 70) do not show them as well as I could wish.

The largest tree which I have seen in England is at Studley Royal, not far below

¹ A tree said to be the original one planted by him at Mill Hill still survives, but was, when I saw it in 1906, in poor condition, the soil being too dry for it.

Fountains Abbey, and close to two very tall spruce. This, though hard to measure correctly owing to its crowded position, which makes a satisfactory illustration impossible, is over 80 feet high and 11 feet in girth, but is forked at about 7 feet from the ground.

The next best is at Strathfieldsaye, a very spreading tree in damp soil, also forking near the ground. The two stems measure 9 feet 6 inches and 8 feet 3 inches, and the height in 1903 was about 75 feet, the branches weeping to the ground on all sides (Plate 71). At Althorp there is a fine old specimen on the lawn, of a more upright type, which in 1903 was 63 feet by 8 feet 10 inches. At Walcot, in Shropshire, the seat of the Earl of Powis, is one of the best grown trees I have seen, with a bole about 25 feet high, and measuring 60 feet by 8 feet 8 inches. At Mr. Heelas' residence, near Reading, part of the old White Knights estate, is a tree, probably planted 150 years ago, which Henry in 1904 found to be 67 feet by 8 feet. At Arley Castle there is a fine tree dividing into three stems, of which the largest is 6 feet 7 inches in girth and nearly 70 feet high.

At Hardwick, Bury St. Edmunds, there is a tree, forked at 30 feet up, 60 feet by 5 feet 10 inches. At Beauport, Sussex, a tree measured in 1904, 65 feet by 7 feet. At Osberton, Notts, the seat of Mr. F. Savile Foljambe, there is a remarkably spreading old tree about 42 feet high, and dividing near the ground into three stems, each about 6 feet in girth. It has some layered branches which are over 20 feet high, and the total circumference is no less than 80 paces. Bunbury, *Arboretum Notes*, p. 140, mentions as the largest hemlock in the country one growing at Bowood, Wiltshire, the seat of the Marquess of Lansdowne, which, however, cannot now be found.

In Scotland, where the tree should succeed well, I have seen none of great size, except the tree at Dunkeld, which is growing in a thick wood of conifers mixed with beech on rocky ground, close to the Hermitage bridge. This is mentioned by Hunter as being 80 feet high by 10 feet in girth. Mr. D. Keir twenty years later made it 85 feet by 11 feet, and when he showed it to me in 1906 I found that, though the top is not easy to see, it is probably as much as 90 feet, and looks as if it would grow taller. It divides at about 12 feet into several stems, and is believed to be 140 to 150 years old.

At Dalkeith there was in 1891 a tree 42 feet high by 10 feet 6 inches in girth; and at Buchanan Castle, Stirlingshire, the seat of the Duke of Montrose, one measuring 45 feet by 6 feet 10 inches.¹

In Ireland the largest known to us is one at Carton, the seat of the Duke of Leinster, which in 1903 was 45 feet by 6½ feet.

TIMBER

Opinions as to the value of this wood differ a good deal, and I have no personal experience in the matter. Sargent says that it is light, soft, not strong, brittle, coarse, crooked-grained, difficult to work, liable to wind-shake and splinter, and not

¹ *Journ. R. Hort. Soc.* xiv. 520, 544 (1892).

durable when exposed to the air; but that it is now largely manufactured into coarse lumber for the outside finish of buildings, and is also used for railway ties and water-pipes. James M. Macoun, in *The Forest Wealth of Canada*, p. 82, says: "Though little inferior to white pine as rough lumber, a prejudice has for a long time existed against this wood, which is only now dying out. As a coarse lumber it to-day commands almost as high a price as pine. It is one of our best woods for wharves and docks, and great quantities are used annually for piles." It is not, so far as I can learn, imported into Europe. The value of its bark, however, for tanning heavy leather has long been known, and it is used more largely than any other in Canada and the Eastern States of America, often mixed with oak bark in order to modify the red colour of the leather tanned with it alone.¹

Canada pitch, made from the resin of this tree, and oil of hemlock, distilled from its twigs, were formerly used to some extent in medicine, but are not now of any commercial importance. (H. J. E.)

TSUGA CAROLINIANA, CAROLINA HEMLOCK

Tsuga Caroliniana, Engelmann, Coulter's *Bot. Gazette*, vi. 223 (1881); Sargent, *Gard. Chron.* xxvi. 780, fig. 153 (1886), *Silva N. Amer.* xii. 69, t. 604 (1898), and *Trees N. Amer.* 49 (1905); Kent, Veitch's *Man. Coniferae*, 466 (1900).

A tree attaining in America 70 feet in height with a girth of 6 feet. Bark reddish brown, and deeply divided into broad, flat, connected scaly ridges. Young shoots shining grey, with scattered short pubescence in the furrows between the glabrous leaf-bases. Leaves pectinately arranged, those on the upper side of the branchlet shorter than the others, ¼ to ¾ inch long, linear-oblong, uniform in breadth or slightly narrowed towards the rounded apex, which is occasionally minutely emarginate; dark green and shining above, with a median groove either continued up to the apex or falling short of it; lower surface with distinct midrib and two narrow, well-defined white stomatic bands, the edges being green; margin entire. Buds reddish brown, ovoid, sharp-pointed; scales indistinctly keeled and pubescent.

Cones on short stout stalks, pendulous or deflected, cylindrical-oblong, 1 to 1½ inch long, consisting of five series of scales, five scales in each series. Scales oblong-orbicular, rounded and slightly narrowed at the apex, pubescent externally, edge thin and bevelled. Bract concealed, wedge-shaped at the base, rounded at the apex. Seed with a long wing, which is decurrent half-way down its outer side.

Tsuga Caroliniana appears to be the American representative of *Tsuga*

¹ Prof. H. R. Procter of the Leather Industries Department of Leeds University, tells me that though the bark is still the principal tanning material of North America, it has been cut so recklessly that in many districts the supply is now insufficient, and is supplemented by extracts of other materials, especially that of Quebracho wood (*Loxopterygium*). In England its use was at one time considerable, but it is no longer a specially cheap material, and its colour has now to a large extent prevented its employment. The bark appears to contain from 8 to 12 per cent of a catechol tannin, yielding large quantities of insoluble "reds," and in this respect it is very inferior to the bark of the common spruce fir, which is largely employed in Austria, though it does not seem to be used in England.

diversifolia, and is remarkable for its limited distribution. It occurs at elevations of 2500 to 3000 feet, usually on dry rocky banks of mountain streams along the Blue Ridge, extending from south-western Virginia through South Carolina to northern Georgia. Sargent states that it occurs either in small groves or mingled with other species, and describes it as a beautiful tree of compact pyramidal habit, with dense dark-green lustrous foliage. Elwes saw it on the Blue Ridge in 1893, and brought home young plants, which, however, died in a year or two.

This tree was discovered in 1850 by Professor L. R. Gibbes. It was first raised in the Arnold Arboretum in 1881, and has proved there quite hardy. It was introduced from thence to England in 1886. There are two or three small specimens in the collection at Kew which are three or four feet in height and have a bushy, spreading habit. This species, judging from the slow rate of growth at Kew, is not likely to attain to timber size in England, and we know of no trees of any size living in this country. (A. H.)

TSUGA BRUNONIANA, HIMALAYAN HEMLOCK

Tsuga Brunoniana, Carrière, *Traité Conif.* 188 (1855); Hook. f., *Gard. Chron.* xxvi. 72, fig. 14 (1886), and *Flora Brit. India*, v. 654 (1888); Masters, *Gard. Chron.* xxvi. 500, fig. 101 (1886); Kent, Veitch's *Man. Coniferae*, 462 (1900); Gamble, *Man. Indian Timbers*, 718 (1902); Brandis, *Indian Trees*, 693 (1906).

Tsuga dumosa, Sargent, *Silva N. Amer.* xii. 60 (1898).

Pinus dumosa, D. Don, *Prod. Fl. Nepal.* 55 (1825).

Pinus Brunoniana, Wallich, *Pl. Asiat. Rar.* iii. 24, t. 247 (1832).

Abies Brunoniana, Lindley, *Penny Cyclop.* i. 31 (1833).

Abies dumosa, Loudon, *Arb. et Frut. Brit.* iv. 2325 (1838), and Brandis, *Forest Flor. N.W. India*, 527 (1874).

A tree forming in the Himalayas, according to Hooker, a stately blunt pyramid, with branches spreading like the cedar, but not so stiff, and drooping gracefully on all sides, attaining 120 feet in height and 28 feet in girth. In cultivation in England it assumes a bushy habit, and never makes a clean stem, the trunk being concealed by the dense pendulous branches.

Bark thick and rough. Branchlets light brown in colour with a short and not very dense pubescence. Leaves long, 1 to 1½ inch, narrow linear, gradually tapering towards the acute and recurved apex, serrulate in margin; upper surface dark green and deeply grooved; lower surface silvery white, the bands of stomata extending almost to the margins. Buds globose, flattened on the top; scales ovate, acute, pubescent.

Cones sessile, ovoid, an inch long, composed of about twenty-five woody scales, which are nearly orbicular, vertically striate, shining, showing externally a thickened ridge a little distance from and parallel to the thin entire margin; bract concealed. Seed two-thirds the length of the scale, with an oblong-ovate wing, which is decurrent on the outer side of the seed to its base.

Tsuga Brunoniana occurs in the Himalayas, from Kumaon to Bhotan, at altitudes varying from 8000 to 10,500 feet. Franchet considers that certain Chinese specimens constitute a distinct variety of the species, which he has named var. *chinensis*.¹ These were collected in N.E. Szechuan by Père Farges, and in the mountains of western Yunnan at 9000 feet altitude by Père Delavay. Diels² also identifies with this variety specimens collected by Von Rosthorn in Szechuan. I have seen no Chinese examples, and Mr. E. H. Wilson considers that there is only one species of *Tsuga* in the mountains of Szechuan, which is *Tsuga chinensis*, Masters. Small plants of the Chinese *Tsuga* are now in cultivation at Coombe Wood; and are as yet too young to entitle us to speak definitely concerning its affinities. (A. H.)

In the interior of Sikkim I saw this beautiful tree in great perfection in the same forests where Sir Joseph Hooker so well describes it,³ during my journey with the late W. E. Blanford to the Tibetan frontier in 1870. It occurs first in the Lachen valley at about 8000 feet in an extremely moist summer climate, where snow lies for two or three months in winter, growing in company with *Picea Morindoides*, *Abies Webbiana*, and, higher up, with *Larix Griffithii*, in a forest unrivalled in the temperate region for its botanical and zoological wealth; where it commonly attains a height of 100 to 120 feet. Afterwards, on the path from Lachoong to the Tunkralah, I saw even grander specimens, one of which, as measured by Sir J. Hooker, was over 120 feet high by 28 feet in girth. In these almost pathless forests it is covered with ferns and lichens and forms a graceful pyramidal tree with very drooping branches, and reaches an elevation of about 10,000 feet. On the outer ranges it is not so large, but extends into Bhotan, where Griffith found it from 6500 to 9500 feet. It probably occurs throughout Nepal and in the N.W. Himalaya, as far west as Kumaon, where it is a smaller tree and of little economic value, though in Sikkim the bark is used for roofing huts.

The Himalayan hemlock was introduced into England in 1838, according to Loudon,⁴ but is rarely seen, except in a stunted state, with several branching stems, and suffering from the absence of sufficient moisture. Like most of the Himalayan conifers, it grows too early and is injured by spring frosts; but in a few favoured districts of Cornwall and Ireland it seems more at home and has attained considerable size and beauty.

The best specimen that I have seen is at Boconnoc in Cornwall, the seat of J. B. Fortescue, Esq. (Plate 72). This tree measures about 53 feet high by 12 feet in girth near the ground, where it branches into several stems, which spread to about 70 feet in diameter. When I saw it in April 1905 it was covered with cones, from which I have raised many young plants.

There is a rather fine tree at Dropmore, planted in 1847, but not so large or healthy as the one described above; and at Beauport, near Battle, Sussex, there is also a fair specimen.

¹ *Jour. de Bot.* 1899, p. 258.

³ *Himalayan Journals*, i. 209, ii. 108, etc.

² *Flora von Central China*, 217 (1901).

⁴ *Encycl. Trees and Shrubs*, 1036 (1842).

At Southampton,¹ in the Red Lodge nursery belonging to Mr. W. H. Rogers, there was a tree twenty-five years old in 1884, about 20 feet high, which bore cones in profusion. At Kew a specimen planted in a sheltered position lived for many years, but ultimately succumbed. Sir Joseph Hooker² knew of no good specimen nearer London than one on a south slope near Leith Hill in a very sheltered and well-watered valley.

At Fota, in the S.W. of Ireland, the seat of Lord Barrymore, Henry measured a tree about 40 feet by 4 feet 10 inches in 1904; and there are trees at Kilmacurragh and Powerscourt, in Co. Wicklow, which are about 30 feet high, all of very branching bushy habit, and with several main stems.

Sargent³ has never seen a specimen in the United States. (H. J. E.)

TSUGA SIEBOLDII, SIEBOLD'S HEMLOCK

Tsuga Sieboldii, Carrière, *Traité Conif.* 186 (1855); Masters, *Jour. Linn. Soc. (Bot.)*, xviii. 512 (1881); Mayr, *Abiet. des Jap. Reiches*, 59, t. iv. fig. 12 (1890); Kent, *Veitch's Man. Coniferae*, 472 (1900).

Tsuga Tsuja, A. Murray, *Proc. R. Hort. Soc.* ii. 508, ff. 141-153 (1862).

Tsuga Araragi, Koehne, *Deutsche Dendrologie*, 10 (1893), and Sargent, *Garden and Forest*, x. 491, fig. 62 (1897).

Pinus Araragi, Siebold, *Verhandl. Batav. Genoot. Konst. Wet.* xii. 12 (1830).

Abies Tsuga, Siebold et Zuccarini, *Fl. Jap.* ii. 14, t. 106 (1842).

Abies Araragi, Loudon, *Trees and Shrubs*, 1036 (1842).

A tree attaining in Japan about 100 feet in height and 12 feet in girth, forming in England a small tree with a short bole and a dense crown of foliage, with numerous branches and pendulous branchlets.

Young shoots greyish in colour and quite glabrous. Leaves pectinately arranged, variable in size, the smaller on the upper side of the shoot, some of these being directed outwards at right angles to the general plane of the foliage. They are oblong, uniform in width, $\frac{1}{4}$ to 1 inch long, shining and dark green above with a median furrow continued to the rounded and emarginate apex; lower surface with green midrib and two narrow well-defined white bands of stomata; margin quite entire. Buds reddish, ovoid, slightly acute at the apex: scales glabrous on the surface, ciliate in margin.

Cones elongated ovoid, on a stalk about $\frac{1}{4}$ inch long, pendulous or deflected, composed of five series of orbicular scales, which are rounded at the apex and at the base and have a slightly bevelled margin. Bract included, very short and bifid. Seed with a long wing decurrent half-way along its outer side.

This tree has been much confused with the other Japanese species, from which it is very distinct in botanical characters. Koehne's proposed name, *Tsuga Araragi*, is not adopted by us, the name *Sieboldii* being the first one under the correct genus *Tsuga*. (A. H.)

¹ Note in Kew herbarium, and Nicholson in *Woods and Forests*, 1884, p. 243.

² *Gard. Chron.* xxvi. 72 (1886).

³ *Garden and Forest*, x. 491 (1897).

TSUGA DIVERSIFOLIA, JAPANESE HEMLOCK

Tsuga diversifolia, Masters, *Jour. Linn. Soc. (Bot.)* xviii. 514 (1881); Mayr, *Abiet. des Jap. Reiches* 61, t. xiv. fig. 13 (1890); Sargent, *Garden and Forest*, vi. 495, fig. 73 (1893), and x. 491, fig. 63 (1897); Kent, *Veitch's Man. Coniferae*, 467 (1900).

Abies diversifolia, Maximowicz, *Mél. Biol.* vi. 373 (1867).

A smaller tree than Siebold's hemlock, which it resembles in habit.

Young shoots pubescent, the pubescence occurring on both the leaf-bases and the intervening furrows. Leaves arranged as in *Tsuga Sieboldii*, but considerably shorter, scarcely exceeding $\frac{1}{2}$ inch in length, oblong, uniform in breadth, shining and dark green above with a median furrow continued to the rounded and emarginate apex; lower surface with green midrib and two narrow well-defined white bands of stomata; margin entire. Buds red, pyriform, flattened above; scales rounded at the apex, minutely pubescent and ciliate.

Cones subsessile, pendent or deflected, ovoid; scales shining, orbicular-oblong, truncate at the base, with edge slightly bevelled and thickened. Bract minute, concealed, rhomboid. Seed with a short terminal wing, which is not decurrent along its side. (A. H.)

DISTRIBUTION OF THE JAPANESE TSUGAS

In Japan I saw both species in their native forests; but so far as I could learn they are not distinguished by the foresters and are both called *Tsuga* (pronounced *tsunga*). By the Japanese botanists *Tsuga Sieboldii* is termed *Tsuga*, the other species being named *Kuro-tsuga* or *Kome-tsuga*. Of the two, the latter apparently has a more northern range than *Tsuga Sieboldii*. I saw it in the forest round Lake Yumoto at 4000 to 5000 feet elevation, where it is a picturesque and graceful tree of no great size. Both species, however, according to Shirasawa, are found in this district. *Tsuga diversifolia* also occurred high up in the Atera valley. Further south in the Kisogawa valley and at Koyasan I saw *Tsuga Sieboldii*, which at 2000 to 3000 feet attains a large size, growing scattered in mixed forests and not gregariously, like the other species at Lake Yumoto. I measured a tree at Koyasan, which had been felled; it was over 100 feet in height, of which half was free from branches, the butt being about 3 feet in diameter. I estimated it as 250 to 300 years old, though the growth had been so slow that I could not count the rings beyond 150. The wood of this tree, as I was told by the chief priest of the Gemyo-in temple, who was my host at Koyasan, is even better than that of Hinoki (*Cupressus obtusa*); and much of the wood used in building the temple had been *Tsuga*. Old trees, however, are now so scarce that the timber cannot be obtained in quantity. I bought some beautiful boards cut from it at Osaka, which have a pale yellow colour and very fine wavy figure. The wood is also made into shingles, which are said to last about forty years, and it has lately been used for paper-making. The bark is used for tanning fishing-nets, and the timber sells in Tokyo at thirty-five to forty yen

248 The Trees of Great Britain and Ireland

per 100 cubic feet.¹ The growth of the tree from seed is very slow at first as in the allied species.

HISTORY AND CULTIVATION

Tsuga Sieboldii was introduced into Europe by Siebold in 1850. Cones both of this species and of *Tsuga diversifolia* were brought from Japan by John Gould Vetch in 1861, and the latter species was sent out under the name *Abies Tsuga*, var. *nana*. Specimens cultivated at Kew as *Tsuga Sieboldii*, var. *nana*, belong to *Tsuga diversifolia*.

Though both species have been introduced long enough to prove their hardiness in favoured parts of the South of England, we have never seen even a moderately large tree, and doubt much if either species will attain timber size in this country. The Japanese hemlocks seem to prefer a light moist rich soil, free from lime, with shade and shelter from cold winds. They will not grow at all on the limestone soil of Colesborne. The best specimen we know is in the garden of Mr. W. H. Griffiths at Campden, Gloucestershire, and is about 15 feet high. It bore cones in 1905.

Sargent² says that *Tsuga Sieboldii* is one of the most graceful and satisfactory of the exotic conifers cultivated in American gardens, where it promises to grow to a large size; but in the garden of Mr. Hunnewell at Wellesley, Massachusetts, which I visited in May 1904, I noted that it had been almost killed to the snow line by the exceptionally severe winter of 1903-1904, though it had produced cones in the preceding year.³

(H. J. E.)

¹ In *Industries of Japan*, 236 (1889), Rein, who did not distinguish between the two species, probably speaking of *Tsuga Sieboldii*, says that the finest specimens seen by him were in the forests of Kin-shima-yama in Southern Kiu-siu, where it grows with *Picea polita*, and equals it in size, attaining 4 to 5 metres in girth. This goes to show that the tree enjoys a warm moist climate.

² *Silva North America*, xii. 60.

³ Beissner states in *Mitt. D. D. Ges.* 1905, pp. 165, 167, that *T. diversifolia* is hardier than *T. Sieboldii*, but both of them grow well in East Friesland, and Mayr says that *T. diversifolia* is hardy at Munich.

JUGLANS

Juglans, Linnæus, *Gen. Pl.* 291 (1737); Bentham et Hooker, *Gen. Pl.* iii. 398 (1880).

DECIDUOUS trees with furrowed bark. Twigs with chambered pith. Buds scaly, the lateral buds often extra-axillary or accompanied by superposed accessory buds. Leaf-scars large with three groups of bundle-traces. Leaves large, alternate, compound, imparipinnate; leaflets opposite, entire or serrate. Stipules absent.

Flowers monœcious. Male flowers numerous in pendulous catkins, which arise singly or in pairs above the leaf-scars of the preceding year's shoot, appearing in autumn and then visible as short cones covered by imbricated scales. Stamens eight to forty, in several series on the axis of a scale, which is five- to seven-lobed, the lobes representing a bract, two bracteoles and two to four perianth-lobes. Connective of the anthers clavate or dilated. Pistillate flowers few, in an erect spike terminating the current year's shoot; each flower with a three- to five-lobed or toothed involucre, composed of a bract and two bracteoles, adnate to the ovary. Inside the involucre is an epigynous and adherent four-lobed or toothed perianth. Ovary one-celled with one basal straight ovule. Style divided into two linear or lanceolate recurved spreading fimbriated plumose stigmas.

Fruit a large ovoid, globose, or pear-shaped drupe, with a fleshy, irregularly splitting husk, formed by the accrescent involucre and perianth. Nut ovoid or globose, thick-walled, longitudinally and irregularly wrinkled, two- to four-celled at the base, indehiscent or separating at last into two valves. Seed two- to four-lobed at the base, with fleshy cotyledons, which remain within the shell in germination.

About thirteen species of *Juglans* have been described; and there are two or three unnamed and little-known species in tropical South America. Of the described species three¹ confined to Mexico, one² a native of the Antilles, and the Californian walnut³ have not yet been introduced, and will not be dealt with in the following account.⁴

Plate 73 illustrates the leaves, branchlets, and leaf-scars of the species in cultivation.

¹ *Juglans mollis*, Engelmann; *J. pyriformis*, Liebmann; and *J. mexicana*, Watson.

² *Juglans insularis*, Grisebach. Concerning the walnut reputed to occur in Jamaica, *J. jamaicensis*, C. DC., cf. *Kew. Bull.* 1894, p. 371.

³ *Juglans californica*, Watson.

⁴ Since the above was written, Mr. Dode has published a paper containing descriptions of several new species in *Bull. Soc. Dendr. France*, i. 67 (1906); but these seem to us to be founded on variable characters, and to be rather forms due to cultivation.

KEY TO THE SPECIES OF JUGLANS IN CULTIVATION

I. Leaflets not serrate; usually entire or sinuate (Plate 73).

1. *Juglans regia*, Linnæus. Bosnia and Greece, through W. Asia and Himalayas to N. China.

Leaf-scars deeply notched without a pubescent band on their upper edge.
Leaflets 7 to 9, glabrous beneath except for inconspicuous axil tufts.

II. Leaflets serrate. Leaf-scars without a pubescent band on their upper edge.

* Leaflets glabrous beneath, except for the axil tufts.

2. *Juglans regia* × *nigra*. Two forms: *Juglans Vilmoriniana*, Carrière, and *Juglans pyriformis*, Carrière.

Leaflets 11 to 13, with fine shallow serrations.

** Leaflets pubescent beneath.

3. *Juglans rupestris*, Engelmann. Arizona, Texas, New Mexico, Mexico.

Leaflets small, 7 to 15, ovate or lanceolate, never oblong, green beneath.
Young shoots glandular-pubescent.

4. *Juglans nigra*, Linnæus. Canada and United States, east of the Rocky Mountains.

Leaflets large, 15 to 19, ovate-oblong with long-acuminate apex, pale beneath.
Young shoots glandular-pubescent.

5. *Juglans stenocarpa*, Maximowicz. Manchuria.

Leaflets large, 11 to 13; all oblong, except the terminal one which is broadly obovate, pale beneath. Young shoots glabrous.

III. Leaflets serrate. Leaf-scars with a transverse pubescent band on their upper edge.

6. *Juglans cinerea*, Linnæus. Canada and United States, east of the Rocky Mountains.

Leaf-scars semicircular, the upper edge straight and scarcely notched. Leaflets, 11 to 13, oblong; serrations fine and directed outwards.

7. *Juglans Sieboldiana*,¹ Maximowicz. Japan, Saghalien.

Leaf-scars obcordate, 3-lobed, notched above. Leaflets, 13 to 15, oblong; serrations shallow, irregular, directed forwards; base rounded and unequal.

8. *Juglans mandshurica*,¹ Maximowicz. Manchuria, Korea, China.

Leaflets and leaf-scars practically indistinguishable from those of the last species, though the leaflets are usually longer-acuminate. Fruit, however, remarkably distinct. See detailed description.

9. *Juglans cordiformis*,¹ Maximowicz. Japan.

Leaf-scars and leaflets closely resembling those of *J. Sieboldiana*, the leaflets, however, fewer (11 to 13) and with a cordate base.

¹ These three species, though differing remarkably in fruit, are very similar in leaves and shoots.

JUGLANS REGIA, COMMON WALNUT

Juglans regia, Linnæus, *Sp. Pl.* 997 (1753); Loudon, *Arb. et Frut. Brit.* iii. 1421 (1838).

A deciduous tree, attaining 100 feet in height and 15 to 18 feet in girth. Bark smooth and silvery grey in young trees, becoming ultimately more or less deeply fissured.

Leaves large, up to 10 inches long, coriaceous, of five to nine (rarely as many as thirteen) leaflets, sub-opposite or opposite, the terminal leaflet stalked, the others sessile; elliptic, long-ovate or obovate, shortly acuminate at the apex, tapering and unequal at the base, glabrous on both surfaces, except for inconspicuous tufts of pubescence in the axils of the nerves on the lower surface; dark green above, paler beneath, entire or slightly sinuate in margin; exhaling an aromatic odour. Venation pinnate, with ten to fourteen pairs of lateral nerves, which run nearly straight to near the margin, where they curve forwards and join with the next vein. The leaflets diminish in size from the apex to the base of the leaf. Rachis glabrous, terminal leaflet not articulated. Young shoots glabrous, with yellow sessile glands and white inconspicuous lenticels.

Male catkins arising singly or in pairs (one above the other) above the leaf-scars of the previous year's shoots, green, two to five inches long, sessile, pendulous, thickly cylindrical and densely flowered; flowers with stalked bracts, two to five perianth leaves and two bracteoles; stamens ten to twenty; anthers oblong, apiculate. Female flowers, one to four, at the apex of the young shoots, green, with usually purple stigmas; involucre minute, indistinctly four-toothed; perianth green, with four linear-lanceolate divisions.

Fruit globular, about two inches in diameter; pericarp green, smooth, glandular-dotted, coriaceous, and very aromatic, splitting irregularly when mature. Nut very variable in shape, wrinkled and irregularly furrowed, thin- or thick-shelled; divided interiorly by two thin dissepiments into four incomplete cells; one dissepiment separating the two cotyledons, the other dissepiment dividing them into two lobes. The structure of the fruit of the walnut is very complicated, and the reader is referred for further details to Lubbock's paper¹ on the fruit and seed of the Juglandæ.

The common walnut, according to Kerner,² is truly monœcious, the stigmas, however, ripening several days before the pollen is shed from the anthers.³ The unripe male catkins have the flowers crowded together in a short thick spike directed upwards. As soon as the pollen develops the spike elongates to three or four times its former length and becomes loose and pendulous, the flowers

¹ *Jour. Linn. Soc. (Bot.)*, xxviii. 247 (1890). Cf. also Lubbock, *Seedlings*, ii. 506 seq. (1902). Malformed walnuts are occasionally produced, which are very curious. Cf. *Gard. Chron.* 1858, p. 5, and 1890, viii. 758, fig. 154.

² Cf. Kerner, *Nat. Hist. Plants*, Eng. trans. i. 742, fig. 184 (1898).

³ This is not invariable. Delpino observed that while certain trees of the common walnut were protogynous, *i.e.* the stigmas ripening first, other trees were protandrous, the stigmas ripening after the anthers. In such cases the trees behave as if they were dioecious. Cf. Darwin, *Diff. Forms of Flowers*, 10 (1877), and Trelease, *Missouri Bot. Garden Report*, vii. 27 (1896).

separating from one another. The pollen then falls into a depression on the side of the neighbouring flower below, from which it is shaken out by the wind and carried to neighbouring branches of the tree, where it alights on the stigmas of the female flowers.

SEEDLING¹

The cotyledons are large, fleshy, obovate, bi-lobed and crumpled, filling the cavity of the seed, from which they do not emerge on germination, but remain underground. The primary root makes its exit by the apex of the nut, and becomes stout and flexuose, giving off a few lateral fibres. The caulicle is very short, stout, and woody. Young stem, erect, compressed, glabrous, greenish, and covered with lenticels. The first four pairs of leaves are mere scales, opposite or sub-opposite on the stem. The ninth leaf is foliaceous, and consists of three leaflets, the terminal one large, obovate or elliptical, and cuspidate, the lateral ones small, oblong and alternate. The next leaf is five-foliolate; the terminal leaflet, oblong-obovate; the middle pair ovate, acuminate, oblique at the base, unequal, and sub-opposite; the basal pair small, ovate, oblique, and unequal. The last leaf is like it, or bears only four leaflets. All these primary leaflets are serrate in margin, and more acuminate than those of the adult plant, which are entire. In these respects they resemble the adult leaves of *Carya* or other species of *Juglans*.²

IDENTIFICATION

The common walnut is distinguishable in summer from all the other species by its glabrous, entire, few leaflets. In winter the following characters are available:—Twigs stout, glabrous,³ shining, greenish or grey, with scattered longitudinal lenticels. Leaf-scars on prominent pulvini, broadly obcordate, the upper margin deeply notched in the centre and not surmounted by a band of pubescence; bundle-dots in three groups. Pith large, white or buff in colour, with wide chambers. Terminal bud ovoid, obtuse at the apex, with four external grey tomentose scales in two valvate pairs, the scales not lobed at their apex and merely representing leaf-bases. In many cases, as in slow-growing old trees, the true terminal bud is aborted on most of the branchlets, and its scar marks the end of the twigs. Lateral buds small, arising at an angle of 45°, globose, the two outer scales usually concealing the inner ones, pubescent at first, but ultimately becoming glabrous. Superposed lateral buds occur only rarely.

VARIETIES

Two distinct geographical forms are known:—

(a) *typica*, in Europe, Asia Minor, Persia, and the Himalayas. Leaves elliptic; nuts ovoid-globose with thin septa.

(b) *sinensis*, C. DC. in *Ann. Sc. Nat.* 4 Sér. xviii. 33, figs. 38, 39. North

¹ Cf. Lubbock, *Seedlings*, ii. 516, fig. 661 (1902).

² Cf. Fliche, *Bull. Soc. des Sciences*, Nancy (1886).

³ Some varieties of cultivated walnuts have the twigs covered with a minute pubescence.

China and Japan. Leaves oval or ovate. Nut globose, scarcely apiculate at the apex, sparingly wrinkled; septa thick and bony.

A large number of varieties have arisen in cultivation.

1. Var. *pendula*. Tree, pendulous in habit.
2. Var. *præparturiens*. A bushy shrub, producing fruit at an early period, sometimes when only two or three years old. According to Carrière¹ it was obtained from seed by Louis Chatenay, a nurseryman at Doué-la-Fontaine, about the year 1830, the first mention of it being in *Ann. Soc. d'Hort. Paris*, 1840, p. 741. M. Chatenay found in the midst of a number of seedlings of walnuts three years old a single individual which bore fruit. This variety was put into commerce by M. Janin of Paris. According to Carrière, when the seeds of it are sown, different forms are produced, from young plants which bear fruit in their second year up to others which only produce fruit at an advanced age. The plants are also variable in size. The nuts are generally thin-shelled and small, but good in quality.

3. Var. *præcox*. Comes into flower and fruit a fortnight earlier than the common kind.

4. Var. *serotina*, Desfontaines. This variety flowers very late, and is recommended in localities liable to spring frosts. It is said² that of this variety, when sown, only three per cent came true, and flowered late in the season.

5. Var. *monophylla*. Leaves simple or trifoliolate. A small tree of this kind, which bears both simple and trifoliolate leaves, the basal pair of leaflets being very small, is growing at Bayfordbury, the residence of Mr. H. Clinton Baker.

6. Var. *rotundifolia*. Leaflets oval.

7. Var. *serratifolia*.³ Leaves serrate. There is a specimen in the Kew herbarium from a tree in Germany, all the leaves of which were distantly serrate in margin. The leaves of young seedlings are always serrate; and this juvenile character is often retained in some walnut trees up to a considerable age.

8. Var. *laciniata*, Loudon. Leaves very deeply cut. The foliage of this variety is light and feathery, much more so than that of the common walnut, and is retained till late in the autumn. A fine specimen was reported in 1884 to be growing at Bicton.⁴ Elwes has seen only three trees of this form, of which the largest, growing on a lawn at Westonbirt, was 30 to 40 feet high. Another was at Melbury, and a third, of no great size, at Poltalloch in Argyllshire.

9. Var. *heterophylla*. Leaflets variable, some of the ordinary form, others irregularly cut.

10. Var. *variegata*.⁵ Leaflets with white margins.

11. A tree was growing in 1890 at Chawton Park, Alton, Hampshire, of which specimens with extremely narrow leaflets were sent to Kew.

The number of varieties of the walnut in cultivation, as regards the shape,

¹ *Rev. Hort.* 1882, p. 419.

² *Gard. Chron.* 1883, xx. 114. See *Rev. Hort.* 1861, p. 430, fig. 108. Called St. John's Walnut, as it does not put forth leaves till Midsummer or St. John's Day, in Parkinson's *Theatrum Botanicum*, 1414 (1640).

³ The serrate-leaved walnut is mentioned by Parkinson, *loc. cit.* 1413.

⁴ *Woods and Forests*, 1884, pp. 164 and 512. See also concerning this variety *L'Horticulteur Français*, 1862, p. 47.

⁵ *Rev. Hort.* 1861, p. 429, fig. 104.

colour, and other qualities of the fruit, is very great; but a detailed description of these does not come within the scope of our work. The most remarkable is the huskless walnut¹ of North China, which is cultivated in the mountains to the north-west of Peking. In this curious form the husk is almost wanting, being very thin and irregular. In var. *racemosa* the fruits are numerous, fifteen to twenty-four, and are set close together on the peduncle. In var. *maxima*, Loudon (var. *macrocarpa*), the fruits are very large. The nuts are elongated and very narrow in var. *elongata* (var. *Bartheriana*²); very sharp-pointed at both ends in var. *rostrata*; and have very thin shells in var. *tenera*,³ Loudon (var. *fragilis*). The kernel of the nut is bright red in var. *rubra* (var. *rubrocarpa*).⁴

HYBRIDS

I. *Juglans regia* × *nigra*. Two forms of this are well known in cultivation; they differ mainly in the character of the fruit.

1. *Juglans Vilmoriniana*, Carrière, *Rev. Hort.* 1863, p. 30. Young shoots glabrous. Leaf-scars obcordate, three-lobed, deeply notched above. Leaflets eleven to thirteen, ovate-lanceolate, sub-sessile, apex acuminate, base rounded or tapering; serrations fine and shallow, directed forwards; lower surface green and glabrous, except for conspicuous tufts of pubescence in the axils of the main veins. Rachis glabrous in the upper leaves of the shoot, pubescent towards its base in the lower leaves. Fruit with the thick husk of *J. nigra*. Nut smooth, globose, thicker shelled and more deeply furrowed than that of the common walnut.

In *Garden and Forest*, iv. 51 (1891), M. M. de Vilmorin gives particulars of the original tree in his garden at Verrières les Buisson, near Paris, and an excellent illustration of it in winter. He says that it was planted about 86 years previously as a young seedling by his grandfather as a memorial of the birth of his eldest son. Nothing certain is known of its origin, though it was supposed by Dr. Engelmann to be a hybrid, between the European and the black walnut. The characters of the bark, branchlets, and buds are intermediate; the leaves resemble those of *J. regia* more than those of *J. nigra*. The fruit, which is not produced every year, and never in quantity, is figured, and resembles most that of the black walnut. Of the few seedlings which have been raised from it one is growing beautifully in the Arboretum at Segrez, and produces fertile nuts. All the seedlings have grown well when planted in deep sandy soil mixed with clay. The tree at Verrières was seen by Elwes in 1905, and measured 95 feet high by 10 feet in girth, with a bole about 16 feet long. The habit of the tree was considered by him to resemble the black walnut rather than the common species.

There are young trees of *J. Vilmoriniana* growing at Kew, and one has been recently sent to Colesborne by M. de Vilmorin.

2. *Juglans pyriformis*, Carrière, *loc. cit.* 28, figs. 4 to 9. *Garden*, L. 478, fig. (1896).

¹ See Hance, in *Journ. Bot.* 1876, p. 50.

² Figured in *Garden*, L. 478 (1896); and *Rev. Hort.* 1859, p. 147, and 1861, p. 427.

³ The thin-shelled walnut is mentioned in Parkinson, *Theatrum Botanicum*, 1413 (1640).

⁴ See *Gard. Chron.* xxiii. 346 (1898). This variety is figured in *Wien. Illust. Gart. Zeitung*, 1898, p. 165.

Carrière states that this tree arose from a cross between *J. regia* and *J. nigra*. The leaves are identical with those of *J. Vilmoriniana*. The young shoots differ in having a glandular pubescence. The fruits are long-stalked and pear-shaped, but otherwise closely resemble those of *J. nigra*. Young trees of this kind are in cultivation at Kew.

3. Other hybrids between these species have been described. One mentioned by Sargent was an immense tree, found in 1888 by Prof. Rothrock on the Rowe Farm on the north bank of the Lower James River, Virginia. It is described as having the habit, foliage, and general appearance of *J. regia*, but producing a nut not unlike that of the black walnut, though longer and less deeply sculptured. The nut is exactly like that of *Juglans regia gibbosa*, Carrière,¹ which was raised by a nurseryman at Fontenay-aux-Roses in 1848.

De Candolle also described,² as *Juglans regia intermedia*, a tree which was found at the Trianon, and supposed to be a cross between the common and black walnuts. M. C. de Candolle informed Elwes that a similar hybrid exists at Geneva, and that its seedlings have characters intermediate between the two parents.

There are specimens at Kew, which were sent by Mr. E. Lyon in 1901 from Hurley, Marlow, where there is a fine old tree of *Juglans nigra*, from the seed of which plants were raised, which are apparently intermediate between that species and the common walnut.

II. *Juglans regia* × *cinerea*. *Juglans alata*, Carrière,³ *Rev. Hort.* 1865, p. 447. This is described as having young shoots pubescent: leaflets seven to nine, with the end leaflet stalked, the others subsessile; all oval or elliptic-lanceolate, abruptly acuminate, obscurely and remotely serrate, pubescent on both surfaces: rachis shortly pubescent. Three trees, presumably of this hybrid, have been observed near Boston in the United States; and a description and figure of them are given in *Garden and Forest*, 1894, p. 435, fig. 69.

III. *Juglans regia* × *californica*. A remarkable hybrid between the common walnut and the Californian wild species, has been obtained by Luther Burbank, who names it "paradox."⁴

DISTRIBUTION

The common walnut has a very wide distribution, occurring wild in Europe in Greece, Bosnia, Servia, Herzegovina, Albania, and Bulgaria; and extending eastward through Asia Minor, the Caucasus, Persia, and the Himalayas to Burma and North China and Japan. Its occurrence as an indigenous plant in Greece was first demonstrated by Heldreich,⁵ who found it growing wild in Ætolia at Korax, in Phthiotis on the Cæta and Kukkos mountains, and in Eurytania on Veluchi, Chelidoni, etc. It grows wild in Greece in mixture with oaks and chestnuts in great quantity, especially

¹ *Rev. Hort.* 1860, p. 99, figs. 21-23, and 1861, p. 428, figs. 101-103. Rehder considers this hybrid to be the same as *J. Vilmoriniana*.

² *Ann. Sc. Nat. Sér. iv.* xviii. t. 4.

³ This is probably the same as *Juglans intermedia quadrangulata*, Carrière, *Rev. Hort.* 1870, p. 493, figs. 66-68.

⁴ *Garden and Forest*, 1894, p. 436.

⁵ *Verhand. Bot. Vereins Prov. Brandenburg*, 150 (1879).

in the moister valleys and ravines up to the region of the silver fir, at altitudes varying between 2200 and 4300 feet. Small woods of walnut, undoubtedly wild,¹ occur in Bosnia and Servia, especially on the north slopes of mountains rich in springs. It ascends in Herzegovina to 2400 feet, in southern Servia to 1400 feet, and in Albania to 2200 feet. Velenovsky² considers it to be truly wild in the Rhodope mountains. According to Radde³ it occurs in the Caucasus, from the sea-level to 4500 feet altitude; also in Ghilan in North Persia. According to Meakin,⁴ it is met with wild in the mountains not far from Bokhara. There are wild specimens at Kew from Armenia. According to Aitchison it is wild in Afghanistan, at 7000 to 9000 feet, and also in the Kuram valley. It occurs in the temperate Himalayas and Ladak, at altitudes of 3000 to 10,000 feet from Kashmir and Nubra eastward. Kurz met with it in the Shan Hills in Burma. It is cultivated throughout China, and appears to be indigenous in North China and Japan;⁵ but other species of *Juglans* are much commoner in the wild state throughout China and Japan.

We are indebted to Sir W. Thiselton Dyer for the following:—

“The walnut found its western natural limit in Greece, but early made its way into Italy. Its classical name *Juglans* is *Jovis glans*, but in poetry it is always *Nux*. Virgil's *ramos curvabit olentes* hits off the acrid smell of the foliage. The nuts were thrown at weddings, as Virgil tells us, *sparge marite nuces*, because, amongst other reasons, Pliny says, they made the maximum of noise.

“*Relinquere nuces* was to put away childish things: so Catullus, *da nuces pueris iners*. The green rind enclosing the nut contains a dye used to darken the hair, the *viridi tincta cortice nucis* of Tibullus, in modern times more often the skin.”

The walnut is extensively cultivated in France, Germany (except in the north where it ripens fruit rarely), and throughout southern Europe. It is cultivated chiefly in the region of the beech, as in Hungary up to 2160 feet, on the southern slopes of the Alps up to 3800 feet, in the Vosges up to 2200 feet. In Norway it is grown on the west coast as far north as Trondhjem, where it has reached a height of 30 feet, and in very favourable summers ripens fruit. Many other localities are mentioned by Schubeler, vol. ii. pp. 429-431. In Sweden it exists near Stockholm, and in Scania, at Cimbrishamn (55° 30'), Linnæus measured, in 1749, a tree 60 feet high.
(A. H.)

PROPAGATION AND CULTIVATION

If the walnut is wanted as a fruit-bearing tree it is better to procure from a nurseryman grafted or budded trees of some of the large-fruited, thin-shelled sorts, which have been raised in France; and which grow best in the south and east of

¹ Beck von Mannagetta, *Vegetationsverhält. Illyrischen Ländern*, 219 (1901).

² *Flora Bulgarica*, 512 (1891).

³ *Pflanzenverbreitung in Kaukasusländern*, 170, 182.

⁴ *Russian Turkestan*, 23 (1903).

⁵ It is included as a wild plant in Japan by Matsumura in *Shokubutsu Mei-I*, 155 (1895); but Sargent in his *Forest Flora of Japan*, p. 60, says, “It is occasionally cultivated in the neighbourhood of temples and as a fruit tree; but we saw no evidence of its being anywhere indigenous, and it is probable that it was introduced from Northern China, where one form of this tree apparently grows naturally.”

England. The process of budding or grafting them is fully described by Loudon, p. 1431, and need not be repeated here.

If, however, walnuts are to be planted for timber or ornament, it is far better to raise them from nuts, which may be sown as soon as they are ripe, if they can be protected from mice and vermin; or kept in sand until February, when they should be sown two to three inches deep in rich light soil, which will encourage the production of fibrous roots at an early period. As the large strong tap-root makes the tree difficult to transplant, it should be undercut with a spade about six inches below the soil in the first year, or the nut may be allowed to germinate before sowing and the end of the root pinched off. If this is not done they must be carefully transplanted in March, and protected from late spring frost as much as possible until they have made stems four to six feet high. For though the walnut is one of the latest trees to come into leaf, none is more tender as regards spring frost, and as it does not bear pruning well and has a natural tendency to form branches rather than a clean stem, it is important that the trees should be carefully trained when young.

It is now much less planted than formerly, and the wood is not so much valued by country timber merchants as it ought to be, but there is no reason why it should not be treated as a forest tree on suitable soils, and drawn up among other trees with the object of growing clean timber; though I consider it inferior to the black walnut in this respect. It is evidently a lover of a warm soil and climate, and though on good limestone soil or deep loam resting on chalk it grows fast and to a great size, it should not be planted on heavy clay, on poor sand, or in exposed windy situations.

The walnut is very seldom blown down on account of its strong roots, and I have never seen one struck by lightning. It does not reach a very great age; so far as I know, 200 years is about the limit of its life, and many trees become hollow or decayed before attaining as much as this.

The only place where I have seen walnuts self-sown in England is at Holkham, where, in the Triangle plantation, are several trees, one 17 feet high, in a fairly thick plantation of larch and Scots pine on light sandy soil. They are 100 to 150 yards distant from the parent tree, the nuts having probably been carried by squirrels or rooks. On the sandhills at the same place I saw a self-sown tree five to six feet high, and on the roadside near Colesborne a young tree has sprung up from a nut dropped by a passer-by.

Mr. E. Kay Robinson¹ mentions the occurrence of young walnut trees amidst clumps of other large trees, due to the carrying away by rooks of the fruit from an old walnut tree in a garden near by. He has kindly sent us a photograph of a walnut tree growing in a field at Warham, near Wells, Norfolk, which had evidently been deposited by a rook, as the young tree in its growth had thrust up the roots of an old willow tree, amongst which it had grown.

¹ *Garden*, lxxi. 412 (1904).

REMARKABLE TREES

Though there are many very fine walnuts scattered through the southern half of England I cannot say where the largest tree actually is. Nothing that I know of now living equals a tree recorded by Mr. W. Forbes,¹ which grew on the estate of Sir Charles Isham at Lamport Hall, Northamptonshire, and was sold to Messrs. Westley Richards, gunmakers of Birmingham. According to the measurements given, this tree contained 816 cubic feet of sound wood, of which the butt, measuring 12 feet by 18 feet in girth, contained 243 feet and one limb 108 feet.

A magnificent tree, said to have been the largest in England, grew at Cothelstone, near Bishops Lydeard, Somersetshire, which Loudon records as being 64 feet high and 6½ feet in diameter,² but I am informed by Mr. E. V. Treplin, agent to Viscount Portman, that it was blown down some years ago.

No tree mentioned by Loudon equals the one of which I give a figure (Plate 74), which grows in front of the house at Barrington Park, near Burford, Oxfordshire, the property of Mr. E. C. Wingfield, on an oolite formation. This tree measured in 1903, 80 to 85 feet in height by 17 feet in girth, and has a fine bole and a very burry trunk. There are two other splendid walnuts in this park nearly as tall and over 15 feet in girth, and others have been cut down of which the timber, when cut up in London, was considered by Mr. A. Howard equal in colour and figure to Italian walnut. At the Moot, Downton, Wilts, the residence of my old friend Mr. Elias P. Squarey, are four fine walnut trees, one of which was said by Mr. D. Watney to be the largest he had seen during his long experience as a valuer, and estimated to contain over 400 feet. It measures 17 feet 2 inches in girth, with a short butt dividing into four big limbs which run up to about 80 feet in height. Another is the tallest walnut I have ever seen or heard of, and measured in 1903 about 100 (perhaps more) feet high by 13 feet in girth.

In the village street of Bossington, Somersetshire, I was shown by Mr. S. F. Luttrell of Dunster Castle, a very picturesque old gnarled walnut tree which at 5 feet is 17 feet in girth, but the roots are so spreading that the trunk, measured close to the ground and following the sinuosities, is 35 feet round. A walnut of apparently no great age in a field at Cobham village in Kent measured in 1905 about 70 feet by 13 feet, and the branches spread over a circumference of 99 paces.

An avenue of walnuts is seldom planted in England, but at Moor Court, Herefordshire, there is a short one which from an illustration in the *Gardeners' Chronicle* of February 6, 1875, seems very effective. They are 60 to 70 feet high and 10 to 12 in girth.

At Sudeley, Gloucestershire, the seat of Mr. H. Dent Brocklehurst, there are in a line before the Castle four beautiful trees of great age, the largest measuring 90 feet by 14 feet, and in Rendcombe Park near the Temple there is a fine old tree about 80 feet by 15 feet whose branches cover an area 105 paces in circumference.

¹ *Trans. Eng. Arb. Soc.* v. 155.

² In *Trans. Eng. Arb. Soc.* ii. 225, measurements of this tree made in 1888 by Dr. Prior are given as follows:—height, 94 feet 6 inches; girth, 18 feet; spread, 22 yards by 27.

At Laverstoke Park, Whitchurch, Hants, the residence of Mr. W. W. Portal, there is a fine well-shaped walnut, which was measured by Henry in August 1905, as 80 feet high by 13 feet 8 inches in girth, with a bole of 12 feet, dividing into two stems above.

In the eastern counties there must be many fine walnuts, but the only one of which I have any exact record is a tree which was figured by Grigor¹ at Ketteringham Park, Wymondham, Norfolk, the seat of Sir M. Boileau, Bart., and is said to have been planted at the restoration of Charles II. This tree was one of the best shaped as regards its branches that has been figured, and measured in 1841 68 feet high with a girth of 12 feet.

At Rickmansworth, Herts, Sir Hugh Beevor measured in 1901 a tree 98 feet high by 11 feet 9 inches in girth, the first limb coming off at 18 feet up, the second limb at 36 feet from the ground. At Gayhurst, near Newport Pagnell, Mr. W. W. Carlile showed me a tree growing on a clayey limestone, which, though of great age, is absolutely sound and has lost hardly a branch. It measures no less than 80 feet by 17 feet, and is very perfect in shape. At Ware Park, Herts, Mr. Baker tells us of a tree 16 feet 4 inches in girth, and this seems to be a district where the walnut comes to great perfection. He showed me another of the thin-shelled French variety growing close to the bank of the Lea at Roxford, which, though much cut by frost, was 16 feet in girth.

At Castle Howard, Yorkshire, there is a large tree in the park near the stables, growing among beech and oak which have drawn it up to a height of 80 or 90 feet, though it leans very much to one side. It has a clean bole about 20 feet long by 11 feet 8 inches, dividing into two long straight clean stems, a very unusual form in this tree.

In Scotland the walnut is not so much at home as in England, but in the warmer parts of the east and in Perthshire it attains considerable dimensions. The best that I have seen myself is a tree at Gordon Castle (Plate 75) which in 1904 measured 60 feet by 10 feet, and is, considering the exposed position and latitude, a remarkable tree. But there must have been a still finer one here in 1881, when Mr. J. Webster, father of the present gardener, recorded in the *Trans. Scot. Arb. Soc.* ix. 63, a tree of equal height and 13 feet 4 inches in girth at 5 feet. Col. Thynne has given me a photograph of a fine tree at Cawdor Castle, Nairnshire, which measures 65 feet by 15 feet 7 inches.

Hunter records several very fine trees in Perthshire as follows: "At Gask the largest tree in the policies is a walnut, a little west of 'The Auld House.' It measures 17 feet 5 inches at 5 feet and then swells to a girth of 21 feet at 8 feet from the ground, and at Blair Drummond there is a fine tree," which Mr. A. Morton, the gardener, informs me is now about 80 feet by 13.

Though the walnut is not uncommonly planted in Ireland, we have seen none remarkable for size. The largest one is reported to be growing at Kilkea Castle in Kildare.

¹ *Eastern Arboretum*, 279 (1841).

TIMBER

Until mahogany became common in England about the middle of the eighteenth century, walnut was considered the most valuable wood for furniture, carving, and inside work, and on the Continent most of the best old furniture was made from it. Later it became very valuable for gun-stocks, and is still almost the only wood used, for all except cheap guns. Loudon states that during the long wars at the beginning of the last century in France no less than 12,000 trees were cut annually for gun-stocks, which caused it to become very scarce, and in England as much as £600 was paid for the wood of one tree.

Sir W. Thiselton Dyer informs me that when for political reasons the War Office thought it no longer desirable to depend on walnut, which was mostly imported from the Black Sea, he was consulted as to what other wood might be found as a substitute; but though some twenty sorts of colonial woods were sent for trial from the Museum at Kew to the Small Arms Factory at Enfield, none except the black walnut was found to be at all suitable.

The reason for this is that walnut wood does not warp, and can be cut cleanly in any direction to fit the locks and mechanism of the magazine rifle, and is not liable to swell and bind the lock when wet. But it requires a good deal of care in selection and in cutting out the stocks, so that they are not liable to break at the grip; and the best gunmakers in England obtain their stocks ready cut to specified sizes from French merchants who make a *spécialité* of this trade.

Maple wood has been found suitable in Japan, for when I was there during the late war, I saw numbers of roughly shaped gun-stocks of that wood being cut in the forest near Koyasan, and carried out on men's backs to supply the immense demand of the arsenal. But in England it was found to make a rifle stock 4 ounces heavier than walnut, and is also liable to warp.

The late Mr. J. East told me that, in the year 1838, at Missenden in Bucks, four walnut trees were sold in one lot for £200, and about the same time two other trees were sold for £100 each, but the demand is now so much lessened by foreign importations, and by the substitution of other woods, such as mahogany and American walnut, that its average price now is not more than from 1s. 6d. to 3s. per foot.

The wood requires a long time to season thoroughly, and should not be used for good work until three to six years after felling, as it is liable to shrink considerably. It is also liable to be ring shaken, and has another great defect in the fact that the sapwood, which forms a large proportion of most trees, is pale in colour and very liable to be attacked by wood-eating beetles. Almost all the old Italian furniture which I have seen is more or less damaged in this way, and though the sapwood is often stained so as to look like the heartwood, it is better in first-class work only to use the latter.

As a rule English walnut does not show so much of the dark markings as is found in the logs imported from Italy and the Black Sea, and Italian walnut is usually specified by English architects. But I have seen such fine panelling made from English wood alone that I have no hesitation in saying that with careful

selection and seasoning, the best effect can be obtained from old trees grown on dry soil in this country; and in a small work on English timber by "Acorn"¹ it is stated that the home-grown timber is harder and more durable than the foreign.

The finest wood as regards colour and pattern comes from near the root, and from the forks in the tree, which, however, are liable to twist if used in the solid, and in order to obtain as much as possible of these figured pieces the tree, if old, should be grubbed, and great care taken in cutting it up into suitable thicknesses for the purpose for which it is wanted. The forked parts should be cut into thin veneers and matched as well as possible. For panelling, walnut comes only second to oak, and is found in some of the best houses in England. As a fine example of Italian walnut panelling I may mention the billiard room at Edgworth, near Cirencester, which was designed for my friend Mr. Arthur James, by Mr. Ernest George. Of modern English walnut panelling I have seen a good example put up in Mr. Franklin's beautiful old house, Yarnton Manor, near Oxford, which he has recently restored, and in which the panelling both of oak and walnut is admirable. The late Mr. Holford of Westonbirt, Tetbury, had his large music-room entirely fitted with walnut cut on his own estate.

A newer system of using walnut wood in large knife-cut unpolished veneers is now adopted by modern decorators, of which a fine example may be seen in the board room of the Royal Insurance Company at Liverpool.

One of the most valuable woods in the world is produced by the burrs or excrescences which are produced on the walnut tree, rarely in England, but more commonly in its native country, and which are sought for by agents travelling for French firms at Marseilles, who seem to have a monopoly of this wood. Sometimes they are very large, measuring two to three feet in diameter, but more usually smaller, and are sold at very high prices, as much as £50 to £60 per ton, according to Laslett. They are called *loupes* in France, and are cut into very thin sheets to cover the very finest pianoforte cases, and much used for cabinet-making. These burrs are said to grow on trees in mountainous and inaccessible regions in Circassia, Georgia, North Persia, and Afghanistan; and I am told by Mr. C. W. Collard that those now imported are not so fine as they used to be some years ago.

I can find no records or measurements of walnuts abroad which show that it ever exceeds in warmer climates the size it attains here; but the largest foreign log which I have ever seen was shown by Messrs. Riva and Massara of Milan at the Exhibition held there in 1906. This log measured about 28 feet long by 15 feet in girth, and was said to contain about 16 cubic metres of timber, equal to about 560 feet. Its weight was 14,800 kilogrammes, and I was informed by the owners that they paid 5800 francs (about £232) for it in Switzerland. But Correvon² quotes *La Patrie Suisse* to the effect that a walnut was cut at Bois-de-Vaux, near Lausanne, which required twenty-four horses to haul it. The lower part of its trunk measured about 24 feet, the diameter was 6 feet 4 inches, and the total contents about 700 cubic feet. This butt was sold for £150 to make gun-stocks.

JUGLANS NIGRA, BLACK WALNUT

Juglans nigra, Linnæus, *Sp. Pl.* 997 (1753); Loudon, *Arb. et Frut. Brit.* iii. 1435 (1838); Sargent, *Silva N. America*, vii. 121, tt. 333, 334 (1895), and *Manual Trees N. America*, 128 (1905).

A tree attaining 150 feet in height, with a girth of about 15 to 20 feet, forming in the forest a narrow round-topped head, but with spreading branches when isolated. Bark of old trees dark brown, deeply furrowed with broad ridges, which are scaly on the surface.

Leaves up to 3 feet in length, of fifteen to twenty-three leaflets, which are ovate or ovate-lanceolate, long-acuminate at the apex, rounded at the base, sub-sessile, with coarse sharp irregular serrations; upper surface with a very minute and very scattered pubescence; lower surface with numerous glandular and simple hairs. Rachis with yellow glands and scattered glandular hairs. Young shoots with sessile yellow glands and numerous glandular hairs; older shoots pubescent. Leaf-scars obcordate, deeply notched at the apex, without any band of pubescence on their upper edge.

Staminate catkins three to five inches long; scales with six orbicular concave pubescent lobes, and a bract $\frac{1}{4}$ inch long, which is triangular and tomentose; stamens twenty to thirty. Pistillate flowers, two to five in a spike; involucre lacinate in margin or reduced to an obscure ring below the apex of the ovary; perianth lobes ovate, acute.

Fruit solitary or in pairs,¹ globose or slightly pear-shaped, pubescent, not viscid, yellowish green, $1\frac{1}{2}$ to 2 inches in diameter; nut oval or oblong, $1\frac{1}{8}$ to $1\frac{1}{2}$ inch, deeply ridged irregularly, four-celled interiorly at the base, and slightly two-celled at the apex.²

IDENTIFICATION

In summer it is readily distinguishable from *J. cinerea* and the Eastern Asiatic species, which have serrate leaflets, by the character of the leaf-scar, which is deeply notched at the apex and without the transverse band above its upper margin, which characterises those species. The long acuminate pubescent leaflets distinguish it from the hybrids *pyriformis* and *Vilmoriniana*. It has much larger leaflets than *J. rupestris*, and cannot be confused with *J. stenocarpa*, which has a broadly obovate terminal leaflet.

In winter the following characters are available:—Twigs stout, reddish brown, glandular-pubescent; lenticels small. Leaf-scars on prominent pulvini, obcordate, deeply notched above, without pubescent band, with three groups of bundle-dots. Pith large, buff-coloured, with wide open chambers. Terminal bud ovoid or conical, grey-

¹ A tree at Albury, Surrey, has, however, borne fruit in clusters of three, four, and six, of which specimens are preserved at Kew.

² For a detailed account of the fruit, seed, and cotyledons of the species, see Lühbock, *Seedlings*, ii. 517 (1902).

tomentose, usually with four external scales visible in two valvate pairs, the scales not lobed at the apex. Lateral buds, arising at an angle of 45°, small, globose, pubescent, with two to three scales visible externally; there are often two buds superposed, the lower one minute and embedded in the notch of the leaf-scar. The reddish-brown pubescent twigs and superposed pubescent lateral buds will distinguish this species from the common walnut.

VARIETIES AND HYBRIDS

No varieties are known. The Black Walnut forms hybrids with the common walnut, which have been dealt with under the latter species. Burbank has raised a hybrid, which he calls "Royal," between *J. nigra* and *J. californica*.¹

Juglans nigra × *cinerea*. A tree supposed to be this hybrid grew in the Botanic Garden at Marburg, and was described by Wender as *Juglans cinerea-nigra* in *Linnaea*, xxix. 728 (1857). (A. H.)

DISTRIBUTION

According to Sargent the black walnut occurs in rich bottom lands and fertile hillsides, from western Massachusetts to southern Ontario, southern Michigan and Minnesota, central and northern Nebraska, eastern Kansas, and southward to western Florida, central Alabama, and Mississippi, and the valley of the San Antonio River, Texas; most abundant in the region west of the Alleghany Mountains, and of its largest size on the western slopes of the mountains of North Carolina and Tennessee, and on the fertile bottom lands of southern Illinois and Indiana, south-western Arkansas, and the Indian Territory.

The black walnut is not only one of the largest deciduous trees throughout a great part of the Middle States, but also one which, until it became too scarce, furnished a great part of the most valuable hardwood. It reached its maximum of size and abundance in the western foothills of the Southern Alleghany Mountains and in the rich, fertile alluvial river bottoms through which the great rivers of Ohio, Indiana, Tennessee, and Kentucky flow, and which were the first homes of the settlers who crossed the mountains towards the end of the eighteenth century, and for a quarter of a century carried on an unceasing warfare with the Indians. These pioneers also waged war against the forest whenever they could spare time, and for many years used the black walnut for fencing and for house-building, because it was an easy wood to split and to work; but they did not foresee that the trees which they destroyed would become one of the most valuable products of their farms, and would in a century be almost extinct as timber trees in many places where they were formerly the commonest.²

When I was travelling in the mountains of North Carolina in 1895, I saw but

¹ *Garden and Forest*, 1894, p. 436.

² An interesting account of the war waged against the black walnut by pioneers in Indiana in 1834 is given in *Woods and Forests*, 1884, p. 633.

few black walnuts of large size, and met with men who were travelling about purposely to find and buy them in all accessible places. In the North Carolina forestry exhibit at the St. Louis Exhibition in 1904, I saw a walnut log from a tree in Jackson County, Kentucky, over 12 feet long and 52 inches in diameter which had evidently been lying long in the forest, and had been repeatedly burnt over, which produced over 800 cubic feet of timber, and was sold, as I was told, for \$800. I heard of another still standing in Kentucky which was valued at \$1000.

These great trees are now hardly to be seen except in remote regions where it is impossible to get them out, and when I visited the Lower Wabash Valley in southern Illinois, where Prof. R. Ridgway¹ found the largest deciduous trees in the United States, I did not see one of great size. Dr. J. Schneck, who was my guide and who knows the flora of this region better than anyone, gives in his *Catalogue of the Flora of the Lower Wabash*, the measurements of a tree taken by himself as follows:—Circumference, at 3 feet above the swell of the root, 22 feet; height of trunk to first branch, 74 feet; total height, 155 feet. Prof. Ridgway measured another 15 feet in girth at 3 feet, and 71 feet to the first branch, where the trunk was 3 feet in diameter. Assuming such trees to have measured 12 feet in girth in the middle they would contain 600 to 700 feet of clean timber in the first length alone, and now be worth as much as many acres of the land they grew on would fetch when cleared for agriculture.

But in regions which have colder summers and poorer soil, the black walnut does not attain anything like these dimensions, and I have seen none in New England which equal the best trees in Britain. Emerson² speaks of one in the Botanic Garden at Cambridge, Mass., as measuring 6 feet 3 inches at 3 feet from the ground, and the tree which he figures growing near Roslyn was a poor specimen of small size.

In Canada it was once abundant in the rich forests of Southern Ontario, but almost all the old trees have been cut down, and plantations are now being made in various parts of Ontario and Western Quebec, and in Alberta and British Columbia, as well as in many parts of the United States from Kansas to California.

Black walnuts of great size are indeed now so rare that I have been unable to procure a really good photograph of the tree in its native forest, and there is none in Pinchot and Ashe's *Timber Trees of N. Carolina*. These authors say that it bears seed abundantly only every three or four years, and that young seedlings are not common except in low fertile, rather open lands, or in meadows which border streams. The growth is very rapid until the tree has reached a large size; only small trees send up shoots from the stump.

The tree, however, has been so largely planted in many parts of the States and in Canada, and succeeds so well, even so far west as British Columbia, that it may again become generally useful as a timber tree.

¹ *Proc. U.S. Nat. Museum*, 1882, p. 49.

² *Trees of Massachusetts*, i. 213.

CULTIVATION

The black walnut was first described by Parkinson,¹ and was introduced into England by the younger Tradescant before 1656, as it is mentioned in the list² of the plants growing in his garden at that time. A tree was growing in Bishop Compton's garden at Fulham in 1688, according to Ray.³

The black walnut is easy to grow from seed, but, except the hickories, none is more difficult to transplant, on account of the long fleshy tap-roots which it forms at an early age, and which, when grown in the good deep soil which it likes, are at a year old often three or four times as long as the seedling itself. For this reason, unless special care is given to its treatment, it is not likely to become so fine a tree as when sown *in situ*, and, though I have successfully transplanted many at one or two years old, I would much prefer the other method.

Though the nuts ripen in England in hot summers, they are not so large, and do not, I think, produce such strong plants as those imported from North America, and, if possible, I should prefer to get them from trees growing in Canada or New England than from farther south.⁴ The nuts are best sown when ripe, as if kept dry for some time, they either lose their germinating power or come up so late that they make weak plants. In any locality which is subject to late frosts it would be better to sow them in boxes at least two feet deep and plant them out when a year old, as like many exotic trees they do not ripen their young wood well, and are liable to be frozen back in winter or spring, which induces a bushy instead of a straight habit of growth.

As this tree requires to be well sheltered and drawn up by surrounding trees in order to form a tall and valuable trunk, it should be sown or planted in small deeply-dug patches in a rich wood, kept free from weeds and protected from mice, rabbits, and boys, until the trees are six to eight feet in height, which they should be under favourable circumstances at four to six years after sowing.

All these difficulties have made the tree unpopular with nurserymen, who rarely care to grow trees for which there is little regular demand. But the great value of the timber, its rapid growth on suitable places, and its perfect hardiness when once established, give it, in my opinion, so much importance, that, however troublesome it may be in its early stages, it should be tried at least on a small scale as a timber tree in the warmest and best soils of the southern, eastern, and west midland counties. For further particulars of the nursery treatment of this tree see Cobbett's *Woodlands*, Art. 553; or *Arboriculture*,⁵ iv. 7, July 1905. Cobbett,

¹ *Theatrum Botanicum*, 1414 (1640).

² *Museum Tradescantianum*, 147 (1656).

³ *Historia Plantarum*, ii. 1798 (1688)—no doubt the tree mentioned by Loudon as existing in 1835 (see p. 268).

⁴ But the question as to whether the seeds of trees grown in a comparatively cold climate produce hardier plants than seed from a warm one, is as yet unsolved; and Prof. H. Mayr of Munich, than whom there is no better authority, is inclined to believe that the differences which are observed in the comparative resistance to frost depend on the variable constitution of the individual plant rather than on inherited power.—Cf. H. Mayr, *Fremdl. Wald. u. Park-bäume* (Berlin, 1906).

⁵ A magazine of the International Society of Arboriculture; J. P. Brown, Connorsville, Ind., U.S.A.

who knew the tree well, considered as I do that it was a hardier and better timber tree than the common walnut.

The black walnut cannot be expected to attain great size except on deep soil in a warm situation. A tree grown from a nut, brought by my father from America over 60 years ago, is now only about 60 feet high and 3 feet in girth, on the dry oolite of the Cotswolds; whilst in Kent, on good loam, it has attained 100 feet by 12 feet in about 100 years, and probably contains as much timber, and that of twice the value, as any oak of its age in Great Britain. It seems indifferent to the chemical nature of the soil, if it is deep, light, and well drained, and should have a southern or western aspect.

It is stated in *Woods and Forests* that the tree is almost if not entirely rabbit-proof, for when nearly everything else is barked it is left untouched, even in a young state.

I have no certain knowledge as to the age which this tree attains, but from the fact that the old ones at Fulham Palace and Syon are dead or dying, I should suppose that, like the common walnut, it is not a very long-lived tree.

CULTIVATION IN GERMANY AND FRANCE

The high value of the timber of the black walnut has led to experiments with the tree in Continental forests. These trials have, however, hitherto been only on a small scale.

In the State forests of Prussia the black walnut has been planted in twenty-two different stations, the whole area under cultivation being thirty-one acres, the separate plots varying in size from seven acres to a rood. Schwappach¹ draws the following conclusions from the results obtained in these experimental plots:— Of all the exotic species which have been tried in Prussia, *Juglans nigra* is the most exacting as regards soil and climate. It only thrives on deep moist rich soils, such as loamy sand rich in humus or pure loam, and never succeeds on shallow soils of any kind, or on wet clay or sand. It requires for its good development a considerable amount of warmth and a long season of vegetation. It has only succeeded on the best oak soils, such as the alluvial lands by the rivers Oder, Mulde, and Elster, and in certain restricted areas of the hilly land of central and western Germany.

Schwappach gives a description of the long tap-root of the seedling, and the consequent difficulty in transplanting; but he lays stress upon the fact that in Germany the seedlings normally make their appearance very late, and believes that this is one of the main causes of failure, as the young plants do not then ripen their wood, and are destroyed by late frosts. He advocates the early germination of the seeds by artificial means, such as by placing them in pits covered with straw, soil, and horse-dung. These speedily germinate, and are then planted in the forest in gaps of about a rood in extent, which are the result of clear felling, or under

¹ *Ergebnisse Anbauversuche Fremländischen Holzarten*, 37 (1901).

the existing canopy of an old wood where the trees will soon be removed. The black walnut requires strong sunlight for its successful growth, yet lateral protection is necessary during the first few years. Heavy shade is hurtful, as it hinders the ripening of the wood of the shoots. The black walnut, after it has successfully passed the dangerous period of youth, becomes perfectly hardy; and older plants resist both spring and winter frosts. Schwappach advocates close planting, with beech or hornbeam as nurses, and recommends thinning at 15 to 20 years old, to remove badly-shaped trees, and to give more light to those which are destined to remain.¹

In France Henry has seen a small plantation of black walnut near Annecy; but the results obtained were unsatisfactory, as the young plants had suffered much from frost. M. Pardé,² however, strongly recommends its cultivation, and points out that, unlike the common walnut, it can be grown as a forest tree; and states that at Les Barres it sows itself regularly and abundantly.

REMARKABLE TREES

The largest tree which we know of in England is growing in the London County Council public park of Marble Hill, Twickenham, in rich alluvial soil close to the Thames. It was measured by Sir Hugh Beevor and Dr. Henry in August 1905, and the height was found to be 98 feet, the stem girthing at 5 feet up 14 feet 3 inches. The bole is about 18 feet long, dividing into two great limbs, with large spreading branches, forming a beautifully symmetrical crown. The diameter of the greatest spread of the branches was 93 feet (Plate 76).

Perhaps the next finest tree now standing in England is the one which I figure (Plate 77), and which grows on a bank at The Mote, near Maidstone, the property of Sir Marcus Samuel, Bart. I have twice measured this tree, first in 1902, when I made it 103 feet by 12 feet in girth, and again in 1905, when I made it 101 feet by 12 feet 6 inches. I am informed by Mr. Bunyard of Maidstone that it was probably planted about 100 years ago by his grandfather. The tree is so healthy, and apparently growing so fast, that it may become very much larger than it now is. At Gatton Park, Surrey, the seat of J. Colman, Esq., there was, in 1904, a tree about 100 feet by 9 feet 6 inches in girth, with a very tall, handsome trunk. Another at the same place, which, when I saw it, was lying on the ground, was about 95 feet by 9 feet, with a bole 10 feet long, and, according to the measurement given me by the late Mr. Cragg, agent for the estate, contained 315 cubic feet of timber.

At Highclere, Berks, there is a fine tree 90 feet by 9 feet 6 inches; and at Bute House, Petersham, Henry measured one 78 feet by 11 feet 10 inches in 1903. At Burwood House, Surrey, Col. Thynne has measured a tree, which I have not seen,

¹ Mr. John Booth of Berlin, who has for many years been one of the best advocates for the planting of exotic trees for timber, tells me that the black walnut has been largely planted near Strassburg under the direction of Forstmeister Rebmann, and the results are extremely successful.

² *Les Principaux Végétaux Ligneux Exotiques*, p. 21.

79 feet by 12 feet. At Syon House there was a fine tree mentioned by Loudon, as then 79 feet high and 2 feet 11 inches in diameter. In 1849, according to the manuscript catalogue of trees at Syon, it was 90 feet by 7 feet 3 inches; when I saw it in 1903 its top was gone, the tree fast decaying, and the girth about 10 feet.

At Youngsbury, near Ware, Herts, there are two fine trees which Mr. H. Clinton Baker measured in March 1906. The larger was 90 feet high by 11 feet 10 inches in girth; the smaller 80 feet by 11 feet 3 inches. At Albury, Surrey, near the gardener's cottage, there is a tree which measured in 1904, 90 feet by 9 feet 2 inches. At Arley Castle a black walnut is bearing mistletoe. At Barton, near Bury St. Edmunds, there is one which is about 75 feet by 7 feet, which cannot be more than about 60 years old.

Sir Hugh Beever reports a fine tree, 80 feet high by 12 feet girth, at Spixworth Hall, Norfolk. In the rooms of the Hall there is some flooring made of locally-grown black walnut. At Wimpole, he measured another tree 78 feet by 12 feet 8 inches.

At Strathfieldsaye there is a plantation of eighteen young black walnuts in a group on the lawn, which, though about eighteen years old when I saw them in 1903, were only 8 to 10 feet high. Three others raised at the same time but planted out younger are twice as high. This seems to me to prove the importance of not keeping this tree long in the nursery. A fine tree on the other side of the house at the same place is about 80 feet by 7 feet, and had a few nuts on it even in the wet season of 1903.

At Fulham Palace there was a tree, which, according to Loudon, was 150 years old in 1835, being then about 70 feet high and 5 feet in diameter. In 1879¹ this tree was 16 feet in girth breast-high, and had passed its prime; and has been quite dead for ten years. This is the largest girth of any black walnut recorded in England.

At Bisham Abbey, near Marlow, the property of Sir H. J. Vansittart Neale, growing in a grove near the garden, where they have been drawn up by other trees, are four fine black walnuts, of the age of which there is no record. The tallest is nearly if not quite 100 feet high, with a clean bole about half as long, and a girth of 8 feet 2 inches; the others have shorter trunks, the biggest being 10 feet 3 inches in girth, and another 8 feet 6 inches, but are nearly as tall.

At Corsham Court, Wilts, the seat of Lord Methuen, is one of the finest specimens in England, with a clean trunk about 35 feet without a branch and 11 feet 5 inches in girth. It is 75 to 80 feet high, and has a very spreading crown of drooping branches, which cover a space 30 yards across. At Lacock Abbey, near Corsham, the seat of Mr. C. H. Talbot, are some good trees planted by the grandfather of the present owner between 1780 and 1800, of which the largest is about 100 feet by 11 feet 5 inches, with a bole of 8 feet, but this has ceased to bear nuts. The others were planted subsequent to 1828, and the best of them is 60 to 70 feet high by 7 feet girth, and bears nuts profusely.

¹ Figured in *Gard. Chron.* 1879, xi. 372, t. 52. Cf. p. 265.

At Walsingham Abbey, Norfolk, the seat of H. Lee Warner, Esq., there was a specimen figured in Grigor's *Eastern Arboretum*, p. 300, as a tree clothed to the ground with foliage, and of which the spreading branches were propped up. In 1840 it was 8 feet in girth, with a spread of branches 165 feet in circumference, but is now much decayed.

At Brightwell Park, Oxon, the property of R. Lowndes Norton, Esq., there are three or four well-grown trees about 50 years old, the largest of which measures 68 feet by 5 feet 10 inches, and bears fruit abundantly. The leaves of these trees were conspicuous by their yellow colour in the first week of October.

At all the four last-named places these trees have been known as hickories, and it is probable that others of the so-called hickories in England are really black walnuts.

Two trees¹ growing close together at The Firs, Manor Lane, London, S.E., both measured, in 1886, 10 feet 9 inches at 4 feet above the ground, and were estimated to be 90 feet high. They were then in excellent health, and bore good crops of nuts, which, however, were rarely perfectly developed.

Many other trees no doubt exist in old places south of the Thames; but we have never seen or heard of any large ones in the midland or western counties. Sir Charles Strickland, however, tells us that the black walnut is quite hardy in Yorkshire; and that he has trees at Hildenley, 15 to 20 feet high and ripening seed, whilst at Housham, another place of his in the same county, they thrive even better in the woods, where they look like becoming fine timber trees.

In Ireland, the largest tree seen by Henry is at Ballykilcavan, Queen's County: it measured in 1907, 68 feet high by 9½ feet in girth. We know of no trees of any size in Scotland.

The largest which we have heard of in Europe is a tree growing at Schloss Dyck, the seat of Fürst Salm-Dyck in Germany, which was planted in 1809, and in 1904 measured 35 metres high by 3.58 metres in girth, with a crown diameter of 35 metres.

TIMBER

It is very strange that though this timber has been imported on a large scale from North America for many years, both to England and the Continent, where it commands a very high price, its value is quite unknown to the English country timber merchant, and none of the writers on wood seem to know much about it. Even Marshall Ward, in his edition of Laslett (1894), says (p. 181) that it will not bear comparison with the quality of either Black Sea or Italian walnut wood. Boulger, in *Wood* (p. 339), says that it is "more uniform in colour, darker, less liable to insect attack, and thus more durable than European walnut." Stone says (p. 211), "This wood is readily confused with *J. regia*."

I can only say that I have seen four different trees felled in England, of which the wood was perfectly distinct by its purplish colour from that of any European walnut; and though I have not been able to get any definite proof of the truth of

¹ *Gard. Chron.* 1886, xxvi. 616, fig. 120.

Boulger's statement as to its freedom from insect attack, yet the furniture which I have had made from three of the trees in question is distinctly superior to that of common walnut, and as good as imported black walnut, in colour; and when properly seasoned, for which three or four years should be allowed, as good cabinet-maker's wood as the best Circassian or Italian walnut: and Unwin,¹ quoting Nordlinger and Mayr, says that the timber of trees grown in Germany has the same specific gravity and the same beautifully coloured heartwood as in America. I am informed by experienced cabinetmakers and timber merchants that the colour and quality of the wood now imported is, either on account of its being younger or grown in different localities, inferior to what it used to be when first introduced to this market, and Mr. A. Howard told me that he could not buy American timber of better quality than that of a tree blown down at Albury which was given me by the Duke of Northumberland. It takes a beautiful polish either with oil or French polish, has not warped in the least degree, and has in many cases a beautifully variegated figure. The sapwood is thick and of a paler colour, and should not be used in first-class work any more than that of the common walnut, which is always attacked sooner or later by the larvæ of a woodboring beetle.

From what I saw of it in America, I believe it to be extremely durable when exposed to the weather, as it lasts long in fences, and large canoes were made from it, whilst it was the favourite wood for furniture until its increasing scarcity and price caused it to be superseded by oak and mahogany.

Old trees often show a beautiful wavy grain, as well as a variety of markings, and from the forks and burrs veneers are cut, which, though of a different colour, are equal in beauty and pattern to mahogany or satinwood.

Cobbett² states, though he does not appear to have seen it himself, that there was at New York part of a black walnut trunk, which measured 36 feet round at the base, and had been scooped out and used as a bar-room, and afterwards as a grocer's shop, and that this tree, if it had been sawed into inch boards, would have yielded 50,000 feet, worth at that time \$1500, but this seems exaggerated; though Loudon states (p. 1438) that a tree, perhaps the same as the one Cobbett speaks of, and grown on the south side of Lake Erie, was exhibited in London in 1827, which was 12 feet in diameter, hollowed out and furnished as a sitting-room.

(H. J. E.)

JUGLANS CINEREA, BUTTERNUT

Juglans cinerea, Linnæus, *Sp. Pl.* 1415 (1763); Loudon, *Arb. et Frut. Brit.* iii. 1439 (1838); Bentley and Trimen, *Medicinal Plants*, iv. t. 247 (1880); Sargent, *Silva N. America*, vii. 118, tt. 331, 332 (1895); and *Manual Trees N. America*, 126 (1905).

A tree attaining in America occasionally 100 feet in height, with a girth of 9 feet, but usually smaller in size, dividing at 20 or 30 feet above the ground into many stout horizontal limbs, and forming a broad, low, round-topped head. Bark of young trees smooth and light grey, becoming in older trees deeply fissured, with broad scaly ridges.

Leaves with eleven to seventeen leaflets, which are sub-opposite, sessile, oblong, unequal-sided, rounded, and slightly unequal at the base, acuminate at the apex; margin finely serrate, the tips of the serrations being directed outwards, ciliate; upper surface finely pubescent with stellate and long simple hairs; lower surface pale, with numerous fine stellate hairs, there being some glandular hairs on the midrib towards its base. Rachis with numerous short glandular hairs. Young shoots with white sessile glands and numerous short white glandular hairs; old shoots pubescent. The leaf-scars are semicircular or triangular, with the upper edge a straight line, and furnished with a transverse band of pubescence.

Flowers: staminate catkins 2 to 3 inches long; scales with six puberulous lobes; bract rusty-pubescent with acute apex; stamens eight to twelve. Pistillate flowers in six- to eight-flowered spikes; involucre with viscid glandular hairs, and slightly shorter than the linear-lanceolate perianth lobes.

Fruit: in drooping clusters of three to five, ovate oblong with two or rarely four obscure ridges, coated with rusty clammy hairs, 1½ to 2½ inches in diameter. Nut ovate, abruptly acuminate and contracted at the apex, with eight ribs, internally two-celled at the base and one-celled above the middle with a narrow pointed apical cavity.

VARIETIES AND HYBRIDS

No varieties are known. A hybrid between it and *Juglans nigra* has been observed. See *Juglans nigra*.

IDENTIFICATION

The best mark of distinction of this species at all seasons is the leaf-scar, which has a transverse raised band of pubescence above its upper margin, which is never notched, and is straight or slightly convex. In winter the following characters are observable in the twigs and buds. Twigs stout, reddish brown, covered with dense glandular pubescence. Leaf-scars, as described above, obovate, on prominent pulvini, with three groups of bundle-dots. Terminal buds oblong, greyish, densely pubescent, the two outer scales conspicuously lobed at the apex, the two inner scales scarcely

lobed. Lateral buds, directed outwards at an angle of 45°, small, ovoid, pubescent; frequently two superposed. Pith dark brown, with narrow chambers. (A. H.)

DISTRIBUTION

According to Sargent, it occurs in rich moist soil near the banks of streams and on low rocky hills from southern New Brunswick and the valley of the Saint Lawrence in Ontario to eastern Dakota, south-eastern Nebraska, central Kansas, and northern Arkansas, and on the Appalachian Mountains to northern Georgia and northern Alabama; most abundant and of its largest size northward. The grey walnut or butternut, as it is commonly called, is a common tree over the same region as that which produces the black walnut, but never attains the same size, and, as a rule, unless drawn up in the forest is a much more spreading and less valuable tree. It does not in New England usually exceed 30 to 50 feet in height, with a trunk 1 to 4 feet in diameter, but sometimes in the rich forests of the Wabash valley attains greater dimensions. Ridgway says, *loc. cit.* 76, that two trees felled in the "Timber Settlement," Wabash county, measured 97 feet and 117 feet in length, with clear trunks 50 feet and 32 feet long, and 1 foot 10 inches in diameter. Pinchot and Ashe, *loc. cit.* 82, say that in North Carolina it is nowhere common, but in cool rich mountain valleys it attains 70 feet high with a diameter of 3 feet. In New England Emerson, *loc. cit.* 210, mentions a tree in Richmond, Mass., which was 13 feet 3 inches in girth at the smallest place below the branches. I never saw any such trees as these; and near Ottawa, where the tree is approaching its northern limit of distribution, it was a small branchy tree bearing little fruit.

INTRODUCTION

The butternut was first described by Parkinson,¹ and was apparently introduced into England at the same time as the black walnut, *i.e.* sometime before 1656, as it is probably one of the species mentioned by Tradescant² as growing in his garden. Loudon states that it was introduced into cultivation by the Duchess of Bedford in 1699; but the tree referred to by him was *Carya alba*.³

CULTIVATION

Though it must have been planted in many places in this country the butternut seems to be now a very scarce tree. The only one I have seen of any size grows in the grounds of Mr. C. S. Dickens at Coolhurst, near Horsham, and was in 1902 52 feet high and 4 feet 2 inches in girth. This produced fruit in 1900 from which I raised two seedlings, one of which is now growing at Colesborne. I noticed that the roots of these seedlings instead of being long, fusiform, and free from rootlets, as in *J. regia* and *J. nigra*, formed a thick, fibrous mass, which made the tree

¹ *Theatrum Botanicum*, 1414 (1640).

² *Museum Tradescantianum*, 146, 147 (1656).

³ Aiton, *Hort. Kew*, iii. 360 (1789), *ex Brit. Museum Sloane MSS.* 525 and 3349.

very easy to transplant. I have since then raised numerous seedlings from imported seed, by sowing them both in pots and in the open ground. If allowed to become dry they sometimes lie over a year, and should therefore be sown as soon as ripe. The young trees are distinguishable from those of *J. nigra* by having fewer pairs of leaflets, but they grow quite as fast, and are quite as hardy as the latter. Both *nigra* and *cinerea*, though liable to injury from late spring frosts, are much hardier as regards winter frost when old enough to ripen their wood, but as, like other walnuts, they do not bear pruning well, they require careful attention when young in order to become shapely trees. Sir Charles Strickland has raised from seed plants at Boynton in Yorkshire which grew to five or six feet high, but all ultimately died.

Mr. J. H. Bonny, Ratcliffe Cottage, Forton, Garstang, sent specimens to Kew in 1900 from a tree 60 years old, which fruited for the first time in that year. It had only attained 22 feet high by 2½ feet in girth at 5 feet from the ground. There is a tree at Bayfordbury which produced a few nuts in 1905. It is 35 feet high by 3 feet 2 inches in girth, and is as large as a black walnut planted beside it. At Tredethy in Cornwall, the seat of F. T. Hext, Esq., I am told by Mr. Bartlett, that there was in 1905 a tree 35 feet by 2 feet 2 inches.

At Riccarton near Edinburgh, the seat of Sir James Gibson Craig, Bart., there is a butternut growing in a sheltered spot which Henry measured in 1905, and though its position makes it difficult to measure accurately, he believes it to be about 50 feet by 3 feet 3 inches.

In Ireland Henry measured in 1904 at Kilmacurragh, Co. Wicklow, a tree 32 feet high by 3 feet 4 inches; while at Charleville in the same county, the seat of Lord Monck, a tree, planted probably in 1869, was 25 feet high by 2 feet in girth.

TIMBER

The timber of this tree, though it resembles that of other walnuts in texture and grain, is much inferior in colour to that of the black walnut, but Hough¹ says that though not so high-priced it is nevertheless of great value for interior finish and wainscoting. In Prof. Sargent's house at Brookline, near Boston, I saw a very handsome mantelpiece and some panelling made from it, and it is occasionally used for furniture. It is pale brown in colour, with whitish-grey sapwood, and the burrs are sometimes cut into handsome veneers. Mr. John Booth² states that he cut down some exotic trees planted by his father at the celebrated Flottbeck nurseries near Hamburg when about 50 years old; and from the wood of a butternut wainscoted a room; "the polish was even finer than that of *J. nigra*, with a splendid glossy hue."

Emerson says, *loc. cit.* 209, that from the bark a mild purgative is made, and that the Shakers at Lebanon obtain a rich purple dye from it. The common dye used by the early settlers for their homespun cloth was from the husk of the

¹ *American Woods*, p. 61.

² *Gard. Chron.* xxx. 407 (1901).

butternut, which gives a fawn colour. The young half-grown nuts make excellent pickles if gathered early in June, but the ripe nuts, though eaten by boys and Indians, are oily and soon become acrid.

According to L. B. Case, who wrote an interesting article¹ on this tree, if an incision is made in the trunk early in spring before the unfolding of the leaves, it yields a rich saccharine sap, nearly if not quite equal to that obtained from the sugar maple. The medicinal uses of the bark are fully explained in Bentley and Trimen's work cited above. (H. J. E.)

JUGLANS RUPESTRIS, TEXAN WALNUT

Juglans rupestris,² Engelmann, *Sitgreave's Report*, 171, t. 15 (1853); Sargent, *Silva N. America*, vii. 125, tt. 335, 336 (1895), and *Manual Trees N. America*, 129 (1905).

The typical form, with small leaflets, which has been introduced into cultivation in Europe, is a shrub or small tree; bark of young trunks smooth, pale, whitish, becoming in older trees deeply furrowed and scaly. Leaflets, seven to fifteen or more, small, one to three inches long, sub-sessile, ovate or lanceolate, never oblong, apex acuminate, base rounded and unequal-sided, crenulate-serrate and non-ciliate in margin; upper surface with scattered minute pubescence; lower surface green with scattered minute brown hairs and axil tufts. Rachis with numerous sessile yellow glands and glandular hairs. Young shoots with numerous sessile yellow glands, interspersed with glandular hairs and obcordate leaf-scars, which are notched above. Older shoots shortly pubescent.

Flowers: staminate, catkins slender, two to four inches long, scales three- to five-lobed, with ovate-lanceolate tomentose bracts; stamens twenty. Pistillate flowers few in a spike, tomentose, involucre irregularly divided into a lacinate border, slightly shorter than the ovate acute calyx-lobes.

Fruit: globose or rarely oblong, very variable in size, $\frac{1}{2}$ to $1\frac{1}{2}$ inch in diameter; husk glabrate or coated with rufous hairs; nut globose without ridges, often compressed at the ends, dark brown or black, grooved with longitudinal simple or forked grooves, four-celled at the base, two-celled at the apex.

Var. *major*, Torrey, *Sitgreave's Report*, 171, t. 16 (1853): usually a tree, attaining 50 feet in height with a trunk 15 feet in girth. In this form the leaflets are large, reaching 6 inches in length; the fruit is also larger. It would appear that this variety is the western form, the typical form being characteristic of the eastern part of the area of distribution of the species.

¹ *Woods and Forests*, 1884, p. 200.

² It is probable, as Rehder points out in *Cycl. Am. Hort.* ii. 846, that *Juglans longirostris*, Carrière, in *Rev. Horticole*, 1878, p. 53, fig. 10, belongs to this species.

IDENTIFICATION

The form of this species usually cultivated in England is distinguished in summer by its small leaves, bushy habit, and the other characters given above. In winter the following characters are available:—Twigs very slender, olive-green or brown, densely pubescent. Leaf-scars set obliquely on prominent pulvini, small, obcordate, notched above, without pubescent band above the upper margin; bundle-dots in three groups. Terminal bud elongated, slender, densely and minutely pubescent, the tips of the two outer scales slightly lobed. Lateral buds, arising at an angle of 45°, minute, ovoid, pubescent, usually solitary. Pith small, brownish, with wide chambers.

DISTRIBUTION

According to Sargent this species occurs on the limestone banks of the streams of central and western Texas, shrubby or rarely more than 30 feet high (var. *typica*); common and of larger size in the cañons of the mountains of New Mexico and Arizona south of the Colorado plateau. It is also met with in northern Mexico,¹ where it frequently leaves the mountain cañons, following the water-courses which are dry throughout most of the year. In such situations its average diameter is 12 to 18 inches, and its height 20 to 30 feet; the nuts, less than an inch in diameter, are scarcely edible.

CULTIVATION

This species was discovered in western Texas in 1835 by Berlandier. It was growing in 1868 in the Botanic Garden at Berlin, according to a note in Engelmann's Herbarium.² It does not seem to have been known in England till 1894, when seeds from Fort Huancha in Arizona were sent to Kew by Sargent. A tree grown from this seed has attained now (1905) about 12 feet in height. There is one nearly as large at Tortworth, and a seedling from Kew is planted at Colesborne, where it seems at least as hardy as the common species and ripens its wood earlier. A tree planted at Mount Edgcumbe, near Plymouth, in 1898 is 9 feet 4 inches high, with a spread of 10 feet. It has been cut back twice, and looks better as a bush than as a tree. (A. H.)

JUGLANS MANDSHURICA, MANCHURIAN WALNUT

Juglans mandshurica, Maximowicz, *Prim. Fl. Amur.* 76 (1859); and *Mél. Biol.* viii. 630, fig. (1872); C. De Candolle, in *D.C. Prod.* xvi. 2, 138 (1864); *Gard. Chron.* 1888, iv. 384, fig. 53.
Juglans regia octagona, in *Revue Horticole*, 1861, p. 429, fig. 106.
Juglans regia cordata, in *Garden*, 1896, p. 478, fig.

A tree attaining 60 feet in height and 5 feet in girth. Bark dark ashy in colour, furrowed in old trees. Judging from herbarium specimens, as I have not been able to examine living trees in England, this species differs little in character of leaves and branchlets from *Juglans Sieboldiana*. Maximowicz, who observed both species growing wild, states that he was unable to find any good distinctions between the two species except in the characters of the nut.

The fruit occurs in short racemes, six to thirteen in a cluster, and is globular-ovate to oblong, viscid, and stellate pubescent. The nut resembles that of *Juglans cinerea*, but is less sharply ridged, globose or ovate, rounded at the base, abruptly and shortly acuminate at the apex, eight-ribbed, with the intervals much wrinkled.

This species occurs in mountain woods in eastern Manchuria, between the Bureia range and the Sea of Japan, from lat. 50° to the Korean frontier. It is frequent along the river Amur in its lower part and on its tributaries. This species is also widely spread throughout Northern and Western China, where it is common in mountain woods at low altitudes, from Chihli through Hupeh and Szechwan to Yunnan. So far as I have seen it, both in Hupeh and Yunnan, it never makes a large tree, and rarely exceeds 40 feet in height, but Komarov informed us that in Mandshuria it attains 80 feet high by 19 to 20 in girth.

This plant was introduced¹ into the Botanic Garden of St. Petersburg by Maximowicz from seeds sent from the Amur. A tree² from seed planted in 1879 in the Arnold Arboretum bore fruit in 1883, which was large, more nearly spherical and less rough than the butternut, and of good flavour. The tree is described as being compact and handsome in habit, and likely to become of value as a fruit tree in the northern parts of the United States, where the common walnut cannot be grown successfully.

Specimens were sent to Dr. Masters³ in 1888 from a tree which had fruited in the nursery of Mr. J. van Volxem at Brussels, where the fruit ripens some weeks before that of the common walnut, and the tree seems less injured by spring frosts.

JUGLANS CORDIFORMIS, CORDATE WALNUT

Juglans cordiformis, Maximowicz, *Mél. Biol.* viii. 635, cum fig. (1872); Shirasawa, *Icon. Ess. Forest Jap.*, text 35, t. 17 (1899); Rehder, *Mittheil. Deut. Dendrol. Gesell.* 1903, p. 117; *Gardeners' Chronicle*, 1901, xxx. 292, Supplementary Illustration.
Juglans Sieboldiana, var. *cordiformis*, Makino, in *Tokyo Bot. Mag.* 1895, p. 313.

A tree attaining 50 feet in height and 6 feet in girth. Bark, according to Shirasawa, remaining smooth for a long time, becoming fissured with age.

Leaves with eleven to thirteen leaflets, which are sub-opposite, oblong with unequal sides, acute or acuminate at the apex, cordate at the base, sessile or subsessile, the petiole not exceeding $\frac{1}{16}$ inch, the base of the leaflet extending over the rachis so that the leaflet appears to be more sessile than is the case in *J. Sieboldiana*; serrations fine, shallow, irregular, directed forwards and ciliate; upper surface finely pubescent, with only tufted hairs; lower surface pale in colour, pubescent, with numerous stellate hairs, dense along the midrib on which the hairs are glandular; rachis with densely glandular long reddish hairs, sessile glands being absent. Young shoots covered with long white hairs, which are tipped with red glands and are much denser than in *J. Sieboldiana*; no sessile glands visible. Leaf-scar as in that species.

Flowers: male catkins twelve inches long or more; female catkins about five inches long, bearing seven to twelve flowers.

Fruit globose; nut heart-shaped, much flattened, sharply two-edged, with a shallow longitudinal groove in the middle of each flattened side, smooth over the surface, rather thin-shelled.

IDENTIFICATION

Readily distinguished in summer by the cordate leaflets and the young shoots densely covered with long white hairs, which bear red glands at the tips. See under *Juglans Sieboldiana*.

In winter the following characters are available:—Twigs stout, brown, covered with long glandular hairs, which tend, however, to fall off from the lower part of the shoot. Leaf-scar large, set slightly obliquely on pulvini which are scarcely elevated, obovate with two lateral lobes and notched above; the upper margin with a transverse raised band of pubescence; bundle-dots in three groups. Terminal bud conical, but compressed laterally, brown, densely pubescent, the two outer scales lobed at the apex. Lateral buds often two superposed, small, brown, ovoid, arising from the twigs at an angle of 60°, densely pubescent. Pith large, brown, with wide chambers.

DISTRIBUTION

According to Maximowicz, this species occurs in Nippon. Shirasawa says that it is spread along the banks of rivers in the temperate regions of Japan, being rare in

the mountains. The wood, according to this author, is light, with little difference between the sapwood and heartwood, and when well seasoned does not warp or split, and on this account it is much esteemed for making gun-stocks. Sargent¹ did not find this tree in Japan, and says that its peculiar nuts are considered by Japanese botanists to be merely extreme varieties of *Juglans Sieboldiana*. However, the species is kept up as distinct by Matsumura,² and cultivated specimens at Kew of the two species can be readily distinguished.

Rehder states in 1903 that a tree in the Arnold Arboretum raised from seed of true *Juglans cordiformis* fruited some years ago. The fruits, however, did not show the characteristic form of this species, and he doubted whether the tree in question was true *cordiformis*, or only a variety of *Sieboldiana* with aberrant fruit.

Nuts were obtained in 1862 by Albrecht,³ physician to the Russian Consulate at Hakodate, which were sown in the Botanic Garden at St. Petersburg, and produced healthy plants, which were about four feet high, in 1872. Maximowicz also found the nuts in the market at Yokohama. Sargent, who found them offered for sale by the Nurserymen's Association of Yokohama, was informed that they were collected on the slopes of Fujisan.

The tree has been recently sent out by Continental nurserymen, and is hardy in this country. A specimen at Kew, which was raised in 1899 from seed procured from Harvard, is now about twenty feet high. The male catkins, which are produced freely and expand in May, give the tree a striking appearance, but the fruit has not yet matured. (A. H.)

¹ *Forest Flora of Japan*, 60 (1894).

² *Shokubutsu Mei-I*, 155 (1895).

³ See Maximowicz, *loc. cit.*, and Bretschneider, *European Bot. Discoveries in China*, i. 622 (1898).

JUGLANS STENOCARPA, NARROW-FRUITED WALNUT

Juglans stenocarpa, Maximowicz, *Prim. Fl. Amurensis*, 78 (1859); and *Mé. Biol.* viii. 632, *cum fig.* (1872); Rehder, *Mittheil. Deut. Dendrol. Gesell.* 1903, p. 117.

A tree of which only the fruits are known in the wild state. The following description of the foliage is taken from a specimen cultivated at Kew.

Leaves with eleven to thirteen leaflets, of which the terminal one in well-developed specimens is much broader than the others, being obovate with a short acuminate apex (4 inches broad by 6 inches long). The lateral leaflets (2½ inches broad by 6 inches long) are oblong, acuminate at the apex, rounded and unequal at the base, subsessile, the petiolule being less than 1/8 inch; upper surface with scattered stellate pubescence; lower surface pale in colour, with similar pubescence; all the leaflets coarsely and almost crenately (not sharply) serrate and ciliate in margin. Rachis with very scattered stellate hairs and white sessile glands, there being no glandular hairs. Young shoots glabrous with numerous yellow glands, there being, however, a slight pubescence towards the base of the shoot. Older shoots glabrous, grey, shining, smooth. Leaf-scar broadly obcordate, notched at the summit, three-lobed, and without any band of pubescence on the upper margin.

The nuts, on which Maximowicz founded the species, are described by him as being shining, cylindrical or oblong-oval, slightly narrowed at the base, acuminate at the apex, eight-ribbed, with the intervals between the ribs deeply and obtusely wrinkled. The nuts are cinnamon brown in colour and are two-celled.

This species, having serrate pubescent leaflets and non-bearded leaf-scars, can only be confused with *Juglans nigra* and *J. rupestris*. It is readily distinguished in summer from these and all other species of walnut in cultivation by the broad terminal leaflet, which is always well marked in fully developed leaves.

In winter the following characters are available:—Twigs stout, yellowish brown, shining, minutely pubescent towards the apex, glabrous elsewhere. Leaf-scars large, on pulvini which are only slightly elevated, broadly obcordate, notched above and without any pubescent band along their upper margin; bundle dots in three groups. Terminal bud conical, brown, tomentose, the two outer scales slightly lobed at the apex. Lateral buds small, ovoid, tomentose, arising at an angle of 45°. Pith large, buff in colour, with narrow chambers.

The nuts of the tree were found in Russian Manchuria by Maximowicz. Nothing is known about the tree itself.

Specimens are cultivated in the Arnold Arboretum which were obtained from Regel and Keiseling's nursery at St. Petersburg. There are two small plants at Kew which were obtained under the name *Juglans mandshurica* from a Continental nursery. (A. H.)

JUGLANS SIEBOLDIANA, SIEBOLD'S WALNUT

Juglans Sieboldiana, Maximowicz, *Mél. Biol.* viii. 633 fig. (1872); Lavallée, *Arbor. Segrezianum*, p. 1, tab. I. et II. (1885); *Garden*, 1895, xlvii. 442.

Juglans ailantifolia, Hort. Sieb. ex Lavallée, *loc. cit.*; and Carrière in *Revue Horticole*, 1878, p. 414, figs. 85 and 86.

A tree attaining 50 feet in height and 5 feet in girth.

Leaves with thirteen to fifteen leaflets, which are sub-opposite, oblong, acuminate at the apex, with base rounded and unequal, sub-sessile, the petiolule being less than $\frac{1}{16}$ inch; serrations fine, shallow, and irregular, directed forwards, ciliate between the teeth; upper surface finely pubescent, with both single and tufted hairs; lower surface pale in colour, covered with numerous stellate hairs, denser close to the midrib on which there are glandular hairs; rachis with long brown glandular hairs and a few small glands near its base. Young shoots green, with long white glandular hairs and white sessile glands; lenticels at first white, becoming brown, conspicuous. Leaf-scars obcordate, three-lobed, deeply notched above, and with a transverse band of pubescence along the upper edge.

Flowers: staminate catkins very long, up to 12 inches, with bracts obtuse at the apex and very villous, scale five-lobed. Pistillate spikes, five to twenty flowered, the rachis and flowers covered with rufous tomentum.

Fruit in long racemes which are ten to twenty inches long; globose to ovate-oblong, shortly acuminate at the apex, viscid and covered with stellate hairs. Nuts ovoid or globose, rounded at the base and acuminate at the apex, with thick wing-like sutures, very slightly wrinkled and pitted, not ribbed, rather thick-shelled.

IDENTIFICATION

This species seems to be practically identical in leaves and shoots with *Juglans mandshurica*, and differs little in these respects from *Juglans cordiformis*, except that the leaflets of the latter are distinctly cordate at the base. All three species differ, however, remarkably in fruit, and must be kept distinct on that account. They belong to the section of walnuts with bearded leaf-scars, and are readily distinguished from *Juglans cinerea*, the other species of this group, by having the leaf-scars deeply notched above.

In winter the following characters are available:—Twigs stout, brown, glabrous except near the tip, where the pubescence of summer is retained. Leaf-scars large, on very slightly raised pulvini, obovate, two-lobed above; upper margin convex, with a central notch, and surmounted by a raised band of pubescence; bundle-dots in three groups. Terminal bud brownish, elongated, covered with a dense minute pubescence; outer pair of scales lobed at the apex. Lateral buds arising at an

acute angle, small, ovoid, pubescent; frequently two superposed. Pith large, brown, with narrow chambers and thick plates.

DISTRIBUTION

According to Maximowicz it occurs throughout the whole of Japan, there being large trees around temples at Hakodate. At Miadzi, in Kiusiu, it is wild on the sides of mountain streams, being a tree of about eighteen inches in diameter. It is also supposed to occur in the island of Saghalien, as nuts cast up by the sea were found there by F. Schmidt.

Sargent¹ says that *Juglans Sieboldiana* is a common forest tree in Yezo and the mountainous regions of the other islands of Japan. Specimens more than 50 feet high are uncommon. It is a wide-branched tree, resembling the butternut in habit and in the colour of its pale furrowed bark. The walnuts of this species are an important article of food in Japan, as the nuts are exposed for sale in great quantities in the markets of all the northern towns.

Elwes collected specimens at Asahigawa in central Yezo, and noted that it was always a small tree, 20 to 30 feet in height by a foot in girth. He also saw it near Nikko, but never of any size. It is called *Kurumi*. The wood, though used to some extent in Japan for gun-stocks and ornamental work, does not take a high place among the valuable timbers of the country. It was not included in the collection of woods exhibited at St. Louis.

CULTIVATION

Juglans Sieboldiana was introduced from Japan into Leyden about the year 1860 by Siebold, and was sent from there to Segrez in 1866, under the name of *Juglans ailantifolia*. At Segrez it passed unscathed through the severe winter of 1879-1880, which proved fatal there to the common walnut.

According to Sargent this species is perfectly hardy in New England, where it ripens its fruit. It is not worth growing there as an ornamental tree; but it will produce fruit in regions of greater winter cold than the common walnut can support, and may find some place in planting as a fruit tree.

The largest specimen we know of in these islands is at Belgrove, Queenstown, Ireland, the residence of W. E. Gumbleton, Esq. It was, in 1903, 24 feet in height by 2 feet 9 inches in girth. There are specimens at Kew about 12 feet high, which were grown from seed received in 1894. There is also a small plant at Gunnersbury House, Middlesex, which has borne fruit.

(A. H.)

¹ *Forest Flora of Japan*, 60 (1894).

COMMON OAK

THE following is an account of the three species into which the *Quercus Robur* of Linnæus has been divided:—*Quercus pedunculata*, *Quercus sessiliflora*, and *Quercus lanuginosa*. Brief notes are given also of certain Mediterranean and Oriental forms which are in cultivation. The generic character will be given in another part, with our description of the exotic oaks in cultivation in these islands. Plates 78 and 79 show the twigs and buds of the pedunculate and sessile oaks, as well as those of some other species which will be described in a later volume, and the leaves of the three species now treated and of some of their varieties.

Those wishing to have the latest information on the oak from a physiological point of view are referred to the late Prof. Marshall Ward's work,¹ which contains many details on points with which we do not propose to deal.

Loudon's account of the oak, covering over 100 closely printed pages, is also well worth study, especially with regard to the numerous historical trees, the quality of the timber, and the fungi, galls, and insects which live on or attack the tree.

QUERCUS PEDUNCULATA, COMMON OR STALKED-CUPPED OAK

Quercus pedunculata, Ehrhart, *Beiträge*, v. 161 (1790); Loudon, *Arb. et Frut. Brit.* iii. 1731 (1838),

Boswell Syme, *Eng. Bot.* viii. 145, tab. 1288 (1868).

Quercus Robur, Linnæus, *Sp. Pl.* 996 (*ex parte*) (1753).

Quercus Robur, L., sub-species *pedunculata*, DC. *Prod.* xvi. 2, p. 4 (1864).

Quercus Robur, L., var. *pedunculata*, Hooker, *Student's Flora of the British Isles*, ed. 2, 364 (1878).

A large tree, attaining a height of over 100 feet and a girth of stem of 20 to 30 feet, with the main branches large, long, and irregularly bent.

Bark, when old, irregularly fissured, and gradually increasing to a thickness of two inches or more. Branchlets in winter stout, glabrous, angled, grey, with a five-angled pith and small semicircular leaf-scars, which are set obliquely on prominent leaf-cushions and show three irregular groups of leaf-traces. Buds brown, clustered at the ends of the twigs, and arranged alternately (in 2/5 order) lower on the twigs, arising at an acute angle; blunt-oval, five-angled, with numerous imbricated scales (in five rows), which are glabrous on the surface and

¹ *The Oak*, by H. Marshall Ward, F.R.S. (1892).

shortly ciliate on the margin. The bud-scales are stipules, which fall off as soon as the leaves expand.

Leaves deciduous, sessile or with very short stalks, extremely variable in shape and size, but never symmetrical, generally with four to five pairs of entire, irregular, rounded lobes; obovate-oblong, diminishing in size to the base, which has always *two small emarginate auricles*; slightly silky pubescent when young, quite glabrous when adult; coriaceous in texture; dark green above, bluish green beneath. *Some of the lateral nerves run to the sinuses between the lobes.* The leaves from suckers which are very rare are usually entire or only slightly lobed, and are not auricled at the base. The fall of the leaves is very slow, often continuing for weeks, and frequently a part of the leaves remain on the tree till the close of winter.

Flowers appearing with the leaves; the male catkins being pendulous spikes (each bearing about a dozen flowers) arising from the preceding year's shoot and the lower part of the current year's shoot; the female inflorescences being long, obliquely erect spikes (each bearing one to five flowers at the upper end) arising in the axils of the two or three uppermost leaves. Male flower: calyx five- to seven-lobed, enclosing five to twelve stamens. Female flower: calyx six-partite, surrounded by a scaly cupule and enclosing an inferior ovary, surmounted by a cylindrical style terminating in a trifid stigma. Ovary three-celled, each cell containing two pendulous ovules.

Fruits: one to five, sessile on an elongated glabrous peduncle (1 to 6 inches long). Cup hemispheric, composed of many appressed, triangular, obtuse, glabrous or slightly tomentose imbricating scales. Acorn: variable in size and shape, flattened at the base where attached to the cup, and bearing the remains of the style at the apex, smooth and shining, containing one seed in one cell, five ovules and two cells being aborted and only visible as shrivelled remains at the base.

SEEDLING

The cotyledons remain enclosed in the coats of the acorn, and are not lifted above ground. The caulicle, stout and dark-coloured, gives off a long woody primary root. The plumule arises between the petioles of the two cotyledons, and develops into the young shoot, which at first bears only a few scattered scales, the first green leaf, small and obovate-oblong, coming afterwards; those succeeding are larger, obovate, and lobed. By the end of the first season the seedling has a long primary root with spreading lateral rootlets and a glabrous stem, averaging 6 to 8 inches high, bearing five or six sub-sessile glabrous leaves spirally arranged and ending in an ovoid glabrous bud. Each of these leaves has a minute stalk, with a pair of tiny linear stipules.

Seedlings,¹ according to Brenner, who made many observations, vary considerably in appearance, according to the soil in which they are grown, those in dry ground having leaves with deeper lobes, ending in sharp points; those in moist earth having shallow undulating round lobes.

¹ Brenner, *Flora* (1902), Band 90, p. 122.

VARIETIES OF *QUERCUS PEDUNCULATA*1. Var. *fastigiata*, Spach, *Hist. Vég.* xi. 151 (1842), Fastigate or Cypress Oak.

Quercus fastigiata, Lamarck, *Encyc.* i. 725 (1783).
Quercus pyramidalis, Gmelin, *Fl. Bad.* iii. 699 (1808).
Quercus cupressoides, Hort.

The Cypress Oak has the branches pointing upwards, which gives the tree an irregular fastigate shape; but in foliage and fruit it does not differ from the common oak. It has been found wild in the south-west of France, in the Landes and Pyrenees, in the provinces of Galicia and Navarre in Spain, and in Calabria. A famous tree of this variety stood in 1876 near the village of Hareshausen, close to Babenhausen in Hesse, which was supposed to be 280 years old, and it then measured 100 feet high and 10 feet in girth.¹ It had been celebrated in Germany since the middle of the eighteenth century, and stood originally in the forest, now cleared away. From this tree nearly all the German trees, and possibly many English and French trees of this variety, have been derived. This variety comes true from seed to some extent; of thirty acorns sown at Nancy, twelve produced pyramidal oaks, the remainder reverting to the ordinary type. At White Knights, of several hundred acorns sown by the gardener, only five came true to the fastigate type. Elwes has raised plants from seed which in youth at least are more or less fastigate. The tree at White Knights is a remarkably good specimen, being 81 feet high and 8 feet in girth, and is beautifully symmetrical in shape. Sir Herbert Maxwell tells us that there are two trees at Dawick, Peeblesshire. Other fine specimens are at Knole Park, Kent, where Elwes measured one 66 feet by 5 feet; and at Hardwick, Suffolk, where he saw one 61 feet by 4 feet 10 inches. A very well shaped tree of this variety at Melbury Park (Plate 80) measures 65 feet by 3 feet 8 inches, and has the form of a well-grown Lombardy poplar. But none of these are equal to a tree growing at the Trianon at Versailles, which Elwes saw in 1905, and which measures about 90 feet by 10 feet.² Several sub-varieties have appeared in various nurseries, and have received names, but as we have seen none of these in cultivation we do not think them worth recording.

2. Var. *pendula*, Loudon, *Arb. et Frut. Brit.* iii. 1732 (1838), Weeping Oak.—In this variety the branches are pendulous. The most famous tree of this kind is at Moccas Court in Herefordshire; but it has now almost ceased to weep, and Elwes would not have been able to distinguish it if it had not been pointed out to him. The present owner, the Rev. Sir George Cornewall, writes that "weeping oaks are far from uncommon in Herefordshire," and showed

¹ Petzold, *Deutschen Reichsanzeiger*, quoted in *Gard. Chron.* v. 51 (1876). See also *Gard. Chron.* xix. 179, fig. 26 (1883), where Mr. Wissenbach states that the oldest and finest specimens in Germany occur in the royal park at Wilhelmshöhe, near Cassel, the best measuring 100 feet high and 8 feet 6 inches in girth. It is 100 years old, being a graft of the original tree in the forest near Babenhausen. An earlier account of the latter tree is given by a correspondent in *Gard. Chron.* 1842, p. 36.

² A group of fine trees of this variety, said to be more than 100 feet in height, is reported to be growing in the park of Verdais in Haute Garonne. *Woods and Forests*, 105 (1884).

him a very striking one on the road from Moccas to Bredwardine, from the acorns of which seedlings have been raised. In 1884 there was a weeping oak at the King's Acre nurseries, Hereford, grafted at 3 feet up, which was planted by Cranston in 1785.¹ It bears acorns every year; but none of the seedlings, it is said, show a tendency to droop. The top of this tree is not pendulous; the weeping only occurs on the outer parts of the lower branches.

3. Var. *filicifolia*, Lemaire, *Illust. Hort.* i. t. 32, verso (1854), Fern-leaved Oak, also known as *asplenifolia*, *pectinata*, *pinnata*, *taraxacifolia*, etc. The leaves are stalked and cuneate at the base, long and narrow in outline, deeply and irregularly pinnatifid. This was found wild in the mountains of southern Germany; and was sent out by Messrs. Booth and Sons, Hamburg.

4. Var. *heterophylla*, Loudon, *Arb. et Frut. Brit.* iii. 1732 (1844), Various-leaved Oak. This variety has leaves varying greatly in shape; some are lanceolate and entire, others are cut at the edges or deeply lacinate; but all are cuneate at the base. It has received a variety of names, as *comptonæfolia*, *incisa*, *dissecta*, *laciniata*, *salicifolia*, *Fennessi*, *Fenzleyi*, *diversifolia*, *cucullata*, etc. Loudon's figure represents a branch from an accidental seedling, raised in 1820 in the nursery of Messrs. Fennessey, Waterford. There is a free-growing tree of this variety at Smeaton-Hepburn, East Lothian, which measured in 1905, 56 feet by 4 feet 8 inches.

5. Var. *hyemalis*, Bechstein, *Forstbot.* 333 (1810). In this variety the fruit stalk is very long, at least as long as the leaf itself. This is also known as *Quercus longipes*, Steven, *Bull. Soc. Nat. Mosc.* i. 385 (1857).

6. Var. *scolopendrifolia*, Hort. This form has leaves with short stalks and cordate bases, somewhat variable in shape. Most of the leaves are long and narrow, with short lobes; but others more angular in form have swollen bladder-like projections on their upper surface. Certain sub-varieties are distinguished as *bullata*, *cochleata*, *crispa*, etc.; all having leaves variously deformed and presenting bladder- or blister-like projections on their surfaces.

7. Var. *Concordia*, Lemaire, *Illust. Hort.* xiv. t. 537 (1867). Leaves yellow, much more brightly coloured than in the variety commonly cultivated under the name *aurea*, the colour persisting during the summer. This beautiful form, the *Golden Oak*, originated in the nursery of Messrs. van Geert at Ghent in 1843. The late Mr. Charles Ellis wrote in 1894 to Kew that some golden oaks occur at Inglewood, Hungerford, Berkshire, as bright as the golden elder when seen in May. Mr. Clarke, gardener to H. J. Walmesley, Esq., the owner, informs me that the trees are now in vigorous health, and measure at 6 feet from the ground 45 feet by 6 feet 2 inches and 40 feet by 4 feet 9 inches respectively.

8. Var. *purpurascens*, A.DC., *Flore Française*, vi. 351 (1815), Purple Oak.—This was found wild near Le Mans by De Candolle; and another wild tree was subsequently found in Thuringia. The young leaves, petioles, and branchlets are purple, the colour fading away later in the season. This form

¹ *Woods and Forests*, 794 (1884), with a full-page engraving of the tree, which was reported to be 72 feet high and 8½ feet in girth.

has received many names, as var. *purpurea*, Loudon, and var. *sanguinea*, Spach. There are slight sub-varieties which are known as *atropurpurea*, *atrosanguinea*, *nigra*, *nigricans*, etc. The purple oak was first described by Bechstein (*Forst. Bot.* 333) in 1810 as *Quercus sanguinea*.

9. Var. *variegata*, Endlicher. Oaks with variegated leaves are not uncommon in the wild state. There is a specimen at Kew of a curious form sent by Mr. J. Lindsay Johnston from Eastlodge, Crondall, Hants, in 1882. The Rev. W. Wilks has sent leaves of an oak at Shirley, which were of a beautiful pink colour in November 1902. There are many forms of variegated oaks in catalogues; but it must be remembered that there is often a tendency in them to revert to the green form in a short space of time. Some of these sub-varieties may be distinguished as follows:—*argenteo-marginata*, margin of leaves white; *argenteo-picta*, leaves with white streaks; *aureo-variegata*, leaves with yellow streaks; *rubrinervia*, veins red in the young leaves; *aureo-bicolor* and *tricolor*, leaves variously coloured yellow, white, and green.

Elwes has seen a very fine variegated-leaved oak at Haldon near Exeter, the seat of J. F. G. Bannatyne, Esq., and I measured one 57 feet high and 7 feet in girth, at The Grove, Teddington, which, according to Loudon,¹ was 37 feet high in 1837. This tree bears leaves, which come out variegated green, white, and pink, changing in autumn to a pure pink colour. The present owner, Charles E. Howard, Esq., informed me that it fruited only once to his knowledge, in 1887.

An account is given in the *Gardeners' Chronicle* of 14th September 1861 of a common oak which became variegated, the result of having been struck by lightning. This tree grew near Mawley, the seat of Sir Edward Blount, and contained about thirty feet of timber. It was struck by lightning on 26th June 1838, and did not appear to suffer at the time; but shortly afterwards the foliage, which was previously green, became beautifully variegated, and continued to produce variegated leaves and remained healthy.

10. Var. *cuprea*, Hort. This variety has bronze-coloured leaves when young, and is said to be a very distinct and vigorous form.

11. Var. *tardissima*, Simonkai, *Le chêne de juin*.²—This variety has more regular branching and denser foliage than the common form; but is chiefly remarkable for the lateness of its leafing, which occurs five to eight weeks after the common oak. It was discovered in France in the valley of the Saône, from Pontailler to Saint-Amour; and has since been found at various places in the departments of Loir-et-Cher and Cher, and also in Hungary. It appears from experiments made at Nancy to come true from seed;³ and the delay in the putting forth of the leaf is as marked in seedlings as in old trees. It grows vigorously; and apparently, in spite of the short period each season that it

¹ Loudon, *Gard. Mag.* 1837, p. 10.

² For interesting accounts of this variety, the following papers may be consulted:—Gilardoni, *Le chêne de juin* (1875); Jolyet, *Bull. de la Soc. des Sciences*, 1899.

³ But seedlings raised by Elwes at Colesborne from acorns sent from France by M. L. Pardé do not seem to retain the late-leafing habit.

carries foliage, it produces as much timber as the common form.¹ The variety is considered of some importance in France, as owing to the lateness of leafing it is never affected by spring frosts; and it is recommended for cold, damp situations where the common oak is injured by this cause.

Many other varieties doubtless occur, both in cultivation and in the wild state. Specimens were sent to Kew from an old oak tree at Springfield, West Wickham, Kent, which bore extremely large leaves all over the tree, measuring as much as 8 inches long and 6 inches wide, and similar leaves occur on a tree at Colesborne. At Tortworth there is an oak about fifty years old, which bears fruit on very long peduncles, and has remarkably glossy coriaceous leaves² somewhat variable in shape, but generally obovate-lanceolate, with quite entire or only slightly lobed margin. This is almost identical with a specimen at Kew, gathered near Arcachon in France by Mdme. de Vilmorin. Specimens collected in Wistman's Wood, Dartmoor, are also remarkable for their irregularly shaped and very slightly lobed leaves, which have a cuneate base.

The variation in the size and shape of the leaves in natural wild seedlings growing side by side is often remarkable. Elwes gathered from three trees growing on the rocks above Minard Castle, Lochfyne,³ leaves varying from about 2 to 8 inches long. Meehan⁴ narrates that when he settled in Germantown, near Philadelphia, he found a single *Quercus Robur* on the grounds of Mr. J. Hacker, from the acorns of which he raised hundreds of young seedlings, and has from these a second generation. He found amongst the seedlings numerous varieties, e.g. trees with leaves quite sessile, others with a petiole $\frac{1}{4}$ inch long, others with leaves as entire as those of *Quercus Prinus*, others with pinnatifid lobes; while in some cases the acorns were only a little longer than broad, in other cases cylindrical and twice as long as broad. Evidently here there was no possibility of hybridisation, as there was only one tree. This experiment of Meehan's, however, only goes to show the extreme variability of *Q. pedunculata*; and there is no evidence brought forward that any of the varieties became in the least like *Q. sessiliflora*.

In all the preceding varieties we are treading on safe ground, as there is no doubt that they are all derived from *Q. pedunculata*; but the case is different with certain forms from the Orient and southern Europe, which were considered by De Candolle to be varieties of *Q. pedunculata*, but by other authorities are treated as distinct species. A brief account of such of these as are in cultivation in England follows:—

Quercus Haas, Kotschy, *Die Eiche. Eur. u. Or.* t. 2 (1862); *Q. Robur, pedunculata*, var. *Haas*, DC. *Prod.*—This oak occurs in Cilicia and the Taurus, and in habit and size resembles the common oak; it differs in the following respects:—Young shoots white pubescent, puberulous when adult. Buds finely pubescent. Leaves on very short pubescent stalks, obovate, with cordate base, and four or five

¹ Mathcy, *Exploitation Commerciale des Bois*, 95 (1906), speaks of its timber as being excellent, with very little sapwood, and scarcely any defects.

² Figured in Plate 79, fig. 2.

³ *Bull. of the Torrey Bot. Club*, ix. 55 (1882).

pairs of rounded lobes, the lateral nerves reaching to the sinuses as well as to the lobes; coriaceous; under surface bluish green, with a stellate pubescence, often discernible only with a lens. Fruit: 2 to 6 on a long stalk, very large, the acorns being $\frac{4}{5}$ inch in diameter. The cups look very distinct from those of the common oak.

This species is considered by Zabel¹ to be a hybrid between *Q. pedunculata* and *Q. lanuginosa*, but it seems rather to be a geographical form of *Quercus pedunculata*. Elwes saw two stunted trees which may be this at Orton Hall, Peterborough, said to have been raised from acorns sent by the late Sir H. Layard from Kurdistan.

The following three species or geographical forms were considered to be varieties of *Quercus pedunculata* by De Candolle.

Quercus Brutia, Tenore, *Sem. Ann. Hort. Neap.* (1825), p. 12.—Occurs in southern Italy. The difference between it and some northern forms of *Q. pedunculata* is very slight, as the leaves are glabrous. The fruit is large and somewhat peculiar.

Quercus Thomasii, Tenore, *loc. cit.* This also occurs in southern Italy, and is a form with large acorns, having leaves pubescent on the under surface, and standing on short pubescent petioles.²

Quercus apennina, Lamarck, *Encyc. i.* 725 (1783).—This is a small oak which occurs on dry situations in the south of France, and is said to form considerable forests in the Apennines in Italy. It has hoary, tomentose shoots and small leaves, with the under surface pale pubescent, and shorter stalks than *Quercus lanuginosa*, which it otherwise much resembles. The fruit is crowded on thick grey tomentose axes, and the cupules are greyish tomentose with appressed scales.

Hybrid or Intermediate Forms.—Hybrids between *Quercus sessiliflora* and *Q. pedunculata* occur; but they seem to be rare in the wild state in England, and I have only seen two or three specimens which could not at a glance be referred to one or other species without doubt. The best name for the hybrid is *Quercus intermedia*, Boenn, in *Rchb. Fl. Germ.* 177 (1830). The type specimen of *Q. intermedia*, Don, obtained by Leighton in Wyre Forest, Shropshire, is true *sessiliflora*. Another specimen in the British Museum labelled *intermedia*, gathered in 1843 in Surrey, is *pedunculata*; in this some of the peduncles are rather short, but there is one fully developed peduncle of the usual length, and the leaves in no way differ from ordinary *pedunculata*. What is often supposed to be *intermedia* is, however, the common oak, bearing leaves with stalks of a moderate length. The word *pedunculata* is apparently a trap to deceive all but the practised botanist. In *Q. pedunculata* the acorns are sessile on a long peduncle, which is distinct from a shoot, as it bears only acorns, never buds or leaves. I have received specimens from professional foresters, labelled "*sessiliflora*, intermediate form," in which the

¹ *Laubholz-Benennung*, 78 (1903).

² Elwes has received seedlings of both these forms from Herr Sprenger of Naples, and has sent some of them to Kew; but they do not at present show any appreciable difference, which was the case also in the oaks which he saw growing in the Sila mountains in Calabria.

peduncle bearing the acorns overtopped the end of the shoot, and was mistaken for it, and the acorns in consequence were considered to be sessile on the shoot. I think that the alleged occurrence of numerous intermediate forms is due to an imperfect appreciation of the real distinctions between the two species; and specimens to support the common occurrence of hybridity are not as yet forthcoming. The first writer who tried to break down the distinctions between the two species in England—Greville¹—was not at all sure that he had succeeded; and in view of the important sylvicultural differences between the two trees the subject is one of more than academic interest.

Certain cultivated forms may be hybrids, as, e.g. *Quercus falkenbergensis*; and *Q. armeniaca*, Kotschy, from Armenia, is an undoubted hybrid. (A. H.)

The question of the distinctness of the sessile and pedunculate oaks in England has been discussed at great length on many occasions, but is one on which opinions, even among careful observers, always have differed, and differ still. Perhaps the best account of their peculiarities and merits is given by Loudon, pp. 1737-46, and in the *Gardeners' Chronicle* (1900), when a discussion was opened by Prof. Fisher, and continued by other well-known authorities.

Prof. Fisher describes the physiological difference, and maintains the opinion, which, largely based on French experience, is confirmed in some parts of England, that the pedunculate oak is naturally adapted to a wet soil, while the sessile will thrive in comparatively dry situations, and says that these peculiarities are of great importance to planters in selecting seed. As nurserymen rarely distinguish them and are, as a rule, careless of the source from which their seed comes, provided it will produce good nursery plants, I should strongly advise all oak planters to select and grow their own oaks from the trees which thrive best on similar soil in their own district, or in places with similar soil and climate.

Mr. A. C. Forbes says that in many localities the sessile oak is quite rare, and in Wilts "probably the rarest indigenous tree that we have." He accounts for this by the fact quoted from a paper² by Mr. J. Smith of Romsey, that at the time when oak timber was in demand for the navy, the durmast oak was not considered fit for that purpose, being, as it was said by the purveyors for the navy, more liable to dry rot, and this tradition still lurks in the minds of the older woodmen, tales being told of how they deceived those worthy gentlemen into passing the durmast oak for the dockyards.

There is a great deal of very interesting information in this paper both on the rate of growth and effects of transplanting of oaks, on their insect enemies and fungoid diseases, and a list is given, with many particulars and measurements of many of the most celebrated oaks of England. No one who is interested in oaks should fail to read it, but it is too long to quote from as freely as I should wish.

Sir Herbert Maxwell, in *Gardeners' Chronicle*, Nov. 10, 1900, says: "The long correspondence in your columns relative to the merits of the durmast or sessile-flowered oak will probably leave most people of the same mind as they were when it

¹ *Trans. Bot. Soc. Edin.* i. 65, tt. 4, 5 (1841).

² *Trans. Scot. Arbor. Soc.* xiii. 21 (1891).

began"; and goes on to say, "What is important is the fact that the durmast will thrive and ripen its season's growth in moist northern and western latitudes, which are unfavourable to the development of the pedunculate kind. In our salt-laden atmosphere upon the western seaboard much of the growth made by the pedunculate oak during one season fails to ripen before it is nipped by frost, and the tree is much more subject than the durmast to galls—a sure sign of debility; and it never carries with it the wealth of glossy foliage that never fails to distinguish the latter."

He then speaks of the fine oaks at Merevale Park, which are described on p. 318, as being of the sessile variety, and says that at Knole Park, Kent, on the other hand, the general growth is pedunculate; but there is a magnificent avenue of durmast oaks, leading to the house from the direction of the Wilderness, and these tower far and straight above the gnarled and twisted veterans in the rest of the park.

Another peculiarity of the sessile oak is referred to in a letter from the Hon. Gerald Lascelles to Mr. Stafford Howard, in which he says: "I doubt whether there is much difference between the timber of the sessile and pedunculate oaks, but I think that the sessile is straighter and cleaner in growth, and one thing is certain—that it is almost immune from the attacks of the caterpillar (*Tortrix viridana*) which so often destroys every leaf on the pedunculate oak in early summer. Whether this does any real harm or not is a moot point, but I think it must be a check to growth, and that the trees would be better without it. I have seen a sessile oak standing out in brilliant foliage when every tree in the wood around was as bare of leaf as in winter."¹

Mr. J. Smith, in the paper above referred to, pp. 29-30, confirms Mr. Lascelles' observations, and says that in 1888, which was the worst year for these caterpillars that he remembered, he passed through a wood composed of *Q. sessiliflora* in which, though it had been attacked by the caterpillars, they had left off, evidently either poisoned or starved. He also quotes a resident in the Forest of Dean who, writing in 1881, says: "It was strikingly evident last summer that the *Q. Robur pedunculata*, or old English oak, was attacked by blight (? caterpillars) more severely than *Q. R. sessiliflora*"; and Mr. Baylis, who now has charge of Dean Forest, writes to me on the subject as follows:—"I can confirm the statement that the larva of the green oak moth defoliates *Q. pedunculata*, very much more than *Q. sessiliflora*, and I think the reason is this: the latter is the first to come into leaf, and the leaf has time to get fairly tough before the caterpillar has reached its most destructive stage, which is about the time that *Q. pedunculata* is coming into leaf."² I have very frequently noticed this fact that the oak with more decided pedunculate characters is almost invariably attacked rather than the other."

The only published exact observation that I know of with regard to the relative rate of growth of the two forms on the same soil is by Mr. H. Clinton Baker of Bayfordbury.³ Near his house are growing on sandy loam, close to each other, a pedunculate oak raised in 1811 from the celebrated tree at Panshanger, and a sessile

¹ Sir Herbert Maxwell remarks, *in litt.*, that though visitations of *Tortrix* are not common in Scotland, yet in June 1905 the oaks on the shore of Loch Awe and Loch Lomond, which are sessile, were stripped of their leaves by this pest.

² Usually *Q. pedunculata* is the first to come into leaf. Cf. p. 292.

³ *Gard. Chron.* xxxvii. 132 (1905).

oak raised in 1840 from a tree at Woburn Abbey. Measurements show that the former was 6 ft. 7 in. in girth in 1865, and is now 9 ft. 4 in.; whilst the latter, only 1 ft. 8 in. in 1865, is now 8 ft. 7 in. Mr. J. Hopkinson in *Trans. Hertfordshire Nat. Hist. Soc.* xii. pp. 249, 250, gives diagrams showing the comparative annual increase during two periods of these trees. I may add that the habit of the two trees differs but little, and the soil is more suitable to the sessile oak.

Mr. Sharpe,¹ forester at Monreith, where Sir Herbert Maxwell planted in 1898 a quantity of oaks of the two species, on a fairly deep loam soil, measured ten of each sort in 1905, and informs us that the sessile oak averaged 13½ feet in height, and the pedunculate oak only 10½ feet. (H. J. E.)

QUERCUS SESSILIFLORA, SESSILE OR DURMAST OAK

Quercus sessiliflora, Salisbury, *Prod. Stirp. Hort. Chap. Allerton*, 392 (1796); Loudon, *Arb. et Frut. Brit.* iii. 1736 (1838); Boswell Syme, *Eng. Bot.* viii. 157, tab. 1289 (1868).

Quercus sessilis, Ehrhart, *Beiträge*, v. 161 (1790).

Quercus Robur, Miller, *Gard. Dict.*, vii. 1 (1759).

Quercus Robur, Linnæus, var. β ; *Mantissa*, 496 (1771).

Quercus Robur, L., sub-species *sessiliflora*, DC. *Prod.* xvi. 2, p. 6 (1864).

Quercus Robur, L., var. *sessiliflora*, Hooker, *Stud. Flora Brit. Isles*, ed. 2, 364 (1878).

A tree resembling *Q. pedunculata*, but with more regular branching, resulting in a denser crown of foliage. It differs somewhat in the characters of the branchlets, buds, leaves, pistillate flowers, and fruit, as follows:—

Branchlets pubescent, especially near the top. Buds more sharply pointed, with scales pubescent on the outer surface, especially near the apex, and having long marginal cilia.

Leaves with a long petiole; symmetrical, obovate-oblong, widest at the middle and gradually diminishing to the base, which is cuneate and generally without auricles; firm, almost coriaceous in texture; sinuately lobed or pinnatifid, the lobes being oblong or triangular, entire, occasionally apiculate; upper surface glabrous and shining, dark green; lower surface brighter even glaucous green and always more or less pubescent. *Lateral nerves running to the sinuses are very seldom present.* Pistillate flowers with stigmas almost sessile. Fruit solitary or crowded, inserted on the branchlets, or borne sessile on an erect, stout, short pubescent peduncle. Cups pubescent, with scales more numerous and more closely crowded together than in *Q. pedunculata*.

This species is quite distinct from *Q. pedunculata*, and the characters given above are very constant. The pubescence, which is visible in this species throughout, on the top of the twigs, buds, stalks, peduncles, cups, and under surface of the leaves, is not so pronounced in specimens occurring in rainy districts; but it can always be made out by a lens. The physiological differences are well marked. The sessile

¹ Cf. Sir Herbert Maxwell's account in *Gard. Chron.* xxxvii. 82 (1905).

oak comes into flower and leaf later by some days than the other species, and it is less liable to attacks of the roller moth. It bears shade better, and on this account can be grown closer as a forest tree. It grows naturally on drier soils, and on the Continent ascends to higher altitudes than *Quercus pedunculata*. It is different in habit, the terminal bud being stronger than the others, so that the shoot is continued in the same direction, and the branches keep straight; whereas in *Q. pedunculata* the lateral buds at the apex often develop more vigorously and a crooked branch results, with the leaves much more tufted.

SEEDLING

At first the seedling differs little from that of *Q. pedunculata*, though the young leaves are more distinctly stalked; but towards the end of the first year, the characters shown in the adult stage are well marked, namely:—the stem, leaves, and terminal bud are pubescent, and the leaves have a cuneate base and short but distinct stalks.

VARIETIES OF *QUERCUS SESSILIFLORA*

1. Var. *longifolia*, Dippel, *Laubh.* ii. 67 (1892).—This is also known as *macrophylla*. The leaves are variable, but are as a rule very long, as much as eight inches, and narrow in proportion to their length, the lobing being never constant. The base of the leaf is always cuneate.

2. Var. *laciniata*, Koehne, *Dendrol.* 130 (1893).—Leaves small with deeply-cut segments, which are directed forwards; base cuneate.

3. Var. *mespilifolia*, Wallroth, *Sched. Crit.* 494 (1822).—Leaves, with a petiole of one inch, lanceolate, long, and narrowed at both ends, averaging five inches long by one inch broad at the widest part; quite entire in margin or very slightly lobed. This form has been found wild at Nordhausen in the Harz mountains, at Wolgast in Pomerania, and in various places in Austria and Hungary. Var. *Louetti*, is a somewhat pendulous sub-variety, which is considered by most authors to be identical with var. *mespilifolia*.

4. Var. *sublobata*, Koch, *Dendrol.* ii. 2, 32 (1873). *Quercus sublobata*, Kitaibel, in *Schult. Oest. Fl.* i. 619 (1814).—This is nearly the same as the last variety, but the leaves are slightly and regularly lobed. It came into commerce from the Royal nursery at Geltow near Potsdam, and hence is often known as var. *geltoviana*.

5. Var. *cochleata*, Petzold et Kirchner, *Arb. Musc.* 630 (1864).—This resembles the common form, except that the edges of the leaf are curved upwards, so that the centre of it is rendered concave. It is said to be a free-growing variety.

6. Var. *afghanistanensis*, Hort.—This variety, as cultivated at Kew, has obovate leaves very similar to the common form, except that the lobes of the leaf are more shallow and more numerous, and its bluish under surface is covered with a fine pubescence which extends to the petioles. It is considered by Zabel¹ to be a hybrid between *Q. lanuginosa* and *Q. sessiliflora*. It was sent out by Messrs. Booth of

¹ *Laubholz-Benennung*, 77 (1903).

Hamburg, who stated in their catalogue that it came from Afghanistan; but Petzold and Kirchner, *loc. cit.*, consider this origin to be improbable. What is sold under this name in some nurseries is *sessiliflora* or *Mirbeckii*.

7. Var. *iberica*, Hort.—This variety, as cultivated at Kew, has small oblong-ovate leaves, broad and cordate at the base, acute at the apex, with numerous small deltoid lobes, each terminating in a callous acute tip, the margins of the lobes being often turned downwards and inwards.

8. Var. *falkenbergensis*, Hort.—This has small dark-green leaves, broadest in diameter in their upper third, lobes few and broad, and the base generally cordate and auricled. The fruit is sessile or on short peduncles. It is very probably a hybrid between *Quercus pedunculata* and *Q. sessiliflora*.¹ This variety was found in 1832 in a wood at Falkenberg in Hanover, and was put into commerce by Messrs. T. Booth and Sons in 1837.

9. Var. *alnoides*, Hort.—This variety, as cultivated at Kew, has small leaves, not exceeding 2 inches in length, with about eight pairs of small lobes, the apex of the leaf being generally acute, the base cordate or cuneate.

10. Var. *pinnata*, Hort.—Leaves deeply pinnate, the sinuses extending almost to the midrib.

11. Var. *rubicunda*, Hort.—Leaves deep red, more especially in the early part of summer.

12. Var. *purpurea*, Hort.—Leaves purple, becoming green with reddish nerves in early autumn. This variety, according to Mr. Nicholson, is a thoroughly distinct and valuable ornamental tree.

13. Var. *variegata*, Hort.—Leaves variegated either with white or yellow tints.

14. Var. *aurea*, DC. *Prod.* xvi. 2, p. 9 (1864). *Quercus aurea*, Kitaibel, in *Reichb. Icon.* xii. 8, t. 645 (1850).—The leaf has generally six pairs of deeply cut lobes, rounded at the top. The young shoots bear yellowish leaves, and are themselves deep yellow. This occurs wild in Austria, and is considered by Zabel² to be a hybrid between *Q. conferta* and *Q. lanuginosa*; but a type specimen at Kew does not show evidence of *Q. conferta* parentage.

15. Var. *dschorochensis*, Hort.—The variety which is cultivated under this name does not seem to be the species³ found by Koch on the Dschoroch range of mountains near Trebizond in Asia Minor; and at Kew is apparently a form of *sessiliflora* with oblong-oval leaves, which have eight or nine pairs of very shallow sinuate lobes.

¹ Zabel, *loc. cit.* 79.

² *Ibid.* 77. It is *Quercus aurea*, Wierzbicki, of Kotsehy, *Eichen*, t. 4 (1862).

³ *Quercus dschorochensis*, C. Koch in *Linnaea*, xxii. 328 (1849); *Quercus sessiliflora*, var. *dschorochensis*, DC. *Prod.* xvi. 2, p. 9 (1864).

QUERCUS LANUGINOSA, PUBESCENT OAK

Quercus lanuginosa, Thuillier, *Flora Envir. Paris*, ed. 2, 502 (1799).

Quercus pubescens, Willd. *Sp. Pl.* iv. 450 (1805).

Quercus Robur sessiliflora, var. *lanuginosa*, DC. *Prod.* xvi. 2, p. 10 (1864).

Quercus sessiliflora, Salisbury, var. *pubescens*, Loudon, *Arb. et Frut. Brit.* iii. 1736 (1838).

A small tree, rarely attaining 60 feet in height, and often, in the wild state, a dense shrub with a twisted stem. Bark rather rougher and more scaly than that of the common oak. Twigs and buds densely pubescent, the scales of the latter being ciliate on the margin and pubescent all over their surface. Leaves small, about 3 inches long, variable in shape, wrinkled in margin, cuneate or cordate at the base, with four to eight pairs of rounded lobes variable in depth; always densely pubescent underneath; petiole tomentose, $\frac{1}{2}$ to 1 inch long. Axis of male flowers pubescent. Female flowers with sessile stigmas and tomentose ovary. Fruits, one to four, crowded on a short thick stalk, or sessile; cups tomentose and often tubercular.

This oak occurs on dry soils, especially those of limestone formation, in the south of France, Corsica, Spain, Portugal, Italy, Alsace, south Baden, Thuringia, Austria, Hungary, southern and western Switzerland, Turkey, Greece, Crimea, Caucasus, and Asia Minor. In Provence it forms dense, low thickets covering extensive areas of the very dry lower parts of the limestone mountains. In Corsica it appears to be the only deciduous species of oak; and was seen by me forming scattered groves in the mountains below the zone of *Pinus Laricio*, at about 2000 feet elevation. I observed no trees larger than a foot in diameter; and it is evident that it is very distinct from *Q. sessiliflora*, which, if it occurred, would grow to a large size in the Corsican humid climate. The tree is of no importance in Corsica as a source of timber; and Mr. Rotgès of the forest service considered that it should always be treated as coppice.

It produces hybrids with both *Q. sessiliflora* and *Q. pedunculata*, and differs markedly from both these species in its habit of producing root-suckers, and moreover the bark is different.

Loudon incorrectly states that it occurs in the New Forest, and Sussex. There is a tree of this form growing at Syon with a remarkably curved bole of about 18 feet long and 5 feet 10 inches in girth. If upright this tree might have been 50 feet high. Elwes has seen this species growing wild in the forest of Fontainebleau, which Hickel informed him was about its northern limit as a wild tree; here it is usually small and stunted, so far as he saw, and of no economic value.

VARIETIES OF *QUERCUS LANUGINOSA*

1. Var. *Hartwissiana*, Hort.¹ Leaves with six or seven pairs of lobes, which are mucronate at the tips.

¹ According to Schneider, *Laubholzkunde*, 194 (1904), the plant so named by Steven in *Bull. Soc. Nat. Mosc.* 1857,

2. Var. *dissecta*, Hort. Leaves deeply cut.

3. Var. *Dalechampii*, Koch, *Dendrol.* ii. 2, p. 38 (1873); *Quercus Dalechampii*, Tenore, *Ind. Sem. Hort. Neap.* 1850, p. 15; *Quercus sessiliflora*, var. *Tenorei*, DC. *Prod.* xvi. 2, p. 7 (1864).

This form, which is considered by some to be a distinct species, occurs in southern Italy. It is in cultivation at Kew, and has leaves 3 to 4 inches long on short stalks. The leaves are oblong-oval, with bases cuneate or truncate, often auricled, coriaceous in texture, shining green above, bluish and only slightly pubescent beneath, with six to eight pairs of acute shallow lobes, which have their margins curved inwards and backwards. The bark of the tree is very rough and scaly.

i. 387, is either a form of *Q. macranthera* or a hybrid of that species. The plant, however, usually cultivated as *Hartwissiana* is probably a variety of *Q. lanuginosa*, which Steven collected and described as *Q. crispata* (*Bull. Soc. Nat. Mosc.* 1857, i. 386).

DISTRIBUTION OF THE COMMON OAK

Owing to the general opinion of English botanists that there is only one indigenous species of oak, with two inconstant varieties, there are few accurate records of the distribution of the two species, and in the majority of cases it is impossible to say whether the specimens in our great herbaria are from wild or cultivated trees. Moreover, owing to the great changes caused by the spread of cultivation and the cutting down of most of the original woodland, the correct distribution of the two species can scarcely be made out. It is probable, however, that in ancient times the pedunculate oak occupied the alluvial lands and the better soils, now almost entirely devoted to agriculture and pasture. Hedgerow trees are invariably of this species. The sessile oak occupied the hilly land and the poorer soils; and in existing oak-woods occurring in such situations, which have never been touched by the plough, it is always the species met with, as in the Wyre Forest, the Forest of Dean, in the district about Burnham Beeches, in Lord Cowper's woods near Welwyn, Herts, which are on high-lying poor gravel soil, etc. In Scotland, judging from a specimen at Kew, the famous Birnam wood consisted of *Quercus sessiliflora*.¹ In Ireland, the ancient wood of Shillelagh, in Wicklow, of which a remnant still exists, was the same species. The Cratloe wood near Limerick is of pure sessile oak; and it is the only species in the wilder parts of Kerry. All the specimens of *Q. pedunculata* which I have received from Ireland, are from planted trees.

In England the oak ascends to 1200 feet in Yorkshire. In an interesting paper by H. B. Watt on the "Altitude of Forest Trees in the Cairngorm Mountains"² in Scotland, 700 to 800 feet is given as the highest level at which the oak was observed; but Mr. Watt says, in a MS. note, that he found in July 1903 a small oak at Corriemulzie at an elevation of 1200 feet. The same author gives many interesting particulars of the oak in Scotland, in a paper published in the *Annals of the Andersonian Naturalists' Society*, ii. 89 (1900). In Ireland the oak ascends in Derry to 1480 feet. There are remains of virgin forest in Donegal, on Sir Arthur Wallace's property near Lough Esk; and a very large oak wood, which is of great antiquity, occurs at Clonbrock, the seat of Lord Clonbrock, in Co. Galway, on the limestone formation. There are smaller woods in many of the mountain glens, and Mr. Welch of Belfast says that where these primitive bits of forest have never been touched by tillage, peculiar and local forms of land-shells occur, and the Clonbrock oak forest contains rare plants, moths, etc., unknown elsewhere. The oak was in early times much more widely spread; it has been found, *e.g.*, in a peat moss in the Orkneys. Mr. T. T. Armistead³ found a young oak growing in a sheltered ravine on the coast

¹ Mr. Stuart Fotheringham of Murthly confirms this by leaves from the large oak behind the Birnam Hotel at Dunkeld, which Hunter says is one of the few survivors of the Great Birnam Wood.

² *Cairngorm Club Journal*, iv. 111 (1903).

³ *Zoologist*, 1891, p. 19.

of Hoy, Orkney, and the acorn from which it sprang must have been brought from the mainland by a rock-dove or rook.

Remains of oak are found in all the later geological deposits; in the pre-glacial deposits in the Cromer forest-bed; in inter-glacial deposits in Hampshire, Sussex, Hertford, Middlesex, and Suffolk; in neolithic deposits; common in "submerged forests" everywhere; at the base of peat-mosses in many localities (ascending in them up to 1000 feet in Yorkshire).¹ Mr. S. B. J. Skertchley describes² the growth of five successive oak forests in the valley of the Ouse, and considers the oldest of them to be some 70,000 years old. These forests spread downwards towards the fen till checked by water and peat moss, the latter eventually burying and preserving them. The trees in thousands lie to the north-east, having been blown down by the south-west, which is still the prevailing wind. The word oak occurs in place-names both of Celtic and Saxon origin, the Saxon forms in names being ac, oak, wok, and auch. These forms are illustrated by names like Auchley, Auckland, Acworth, Wokingham, Oakingham, Oakham, Oakfield, Oakley, Martock, Holyoak, and Selly-oak. The Gaelic name is *dair*, as in Derry, Edenderry, Ballinderry, Kildare, Adare, Darnock, Kildarragh, Auchindarroch, Craigandaroch.

Quercus pedunculata, according to Willkomm, occurs throughout the greater part of Europe, Asia Minor, and the Caucasus. Its northern limit reaches, on the west coast of Norway, 62° 55', on the eastern side of Norway 60° 45', in Sweden 60°, in Finland 61° 30' at Björneborg and 60° at Helsingfors, then passes along the coast of Esthonia to St. Petersburg, and crosses Russia south of Jaroslav and Perm, then descends southwards, reaching the Ural river between Orenberg and Orsk, and descends along that river to Iletzkoi. Its distribution in the Caucasus and Asia Minor is not known with exactness, owing to the conflicting opinions about the oaks of these regions. In Europe it occurs as far south as Greece, Sicily, and in the Peninsula reaches its southern limit in the Sierra Morena range. The western limit, beginning at the western part of this range, includes the northern part of Portugal and Galicia, and continues up along the coast of France, ending in Ireland and Scotland. It is essentially a tree of the plains and low hills, but it ascends in Southern Scandinavia to 993 feet, in the Berne Oberland to 2530 feet, in the Tirol to 3160 feet, in the Jura to 2216 feet, and in the Pyrenees to 3300 feet.

It is, according to Max von Sivers,³ a much scarcer tree than it formerly was in the Baltic Provinces of Russia, and only exists in pure forests of any extent in Kurland, where it attains in river valleys and loamy soil very large dimensions, as much as 9 metres (about 30 feet) in girth. Some of the best trees produce logs free from branches over 60 feet long and 5 feet in girth at the top. He attributes its comparative scarcity at present to over-felling during the last two centuries, but states that replanting has been recently carried on to some extent.

Quercus sessiliflora occupies a more restricted area than the other species. Its northern limit is 60° 11' in Norway, 58° 30' in Sweden; it then passes through east Prussia, Lithuania, and crosses the central provinces of Russia, Minsk, Mohilev,

¹ C. Reid, *Origin of the British Flora*, 145 (1899).

² *Fenland, Past and Present*, chap. xv. (1878).

³ *Die Forstlichen Verhältnisse der Baltischen Provinzen*, 1903.

Tula, and Penza, to Sergievsk near the southern Ural, in lat. 54°. The eastern limit commencing here, extends southwards, taking in the Crimea and Cilicia in Asia Minor. The southern limit extends through Greece, southern Italy, Sardinia, Catalonia, and the northern provinces of Spain to Asturias.

As a wild tree it does not occur in low-lying plains and alluvial ground; but is met with on the hills and lower ranges of the great mountain chains of Europe. It ascends in Hanover to 1900 feet, in the Alps to 3900 feet, in the Carpathians to 3300 feet, and in the Pyrenees to 5300 feet. In all these localities it ascends considerably higher than the pedunculate oak, reaching, *e.g.*, in the Alps 1500 feet higher than that species. (A. H.)

PROPAGATION AND CULTURE

The oak produces acorns in great abundance in some seasons,¹ generally about one year in three; but this varies very much in different parts of the country; and, so far as I have noticed, fruit occurs oftener and more abundantly in the south and west of England. It begins to bear at a very early age in some cases; and I received, in 1906, a packet of acorns from Miss Woolward, which she assured me were taken from oaks only ten years old from seed. Mr. Emerton, the head gardener at Belton Park, Notts, where they grow, confirms this. In the same season I saw acorns on the Billy Wilkin's Oak, which must be 700 to 800 years old; and was told that the Cowthorpe Oak, which is possibly much older, still bore a few. Acorns are greedily eaten by all domestic animals, but are injurious to cattle if taken in very large quantities.² Pheasants and pigeons also consume a great many, and rooks are credited with dropping most of the acorns which so often spring up as seedlings in places far from their parent tree.

The raising of oaks from seed is so easy, and the plants obtained are, as a rule, so much superior to what one can buy, that no one who wishes to plant them should fail to try the experiment by selecting acorns from the best oaks in the neighbourhood. These ripen in October, and should be gathered from the ground as soon as they fall, as dry as possible. They will not keep if stored damp, and my own experience is that they make stronger growth the first year if sown as soon as gathered, because the radicle will then bury itself deep in the ground before winter, and the germination will take place earlier. But if it is desired to sow the acorns where the tree is to grow, they must be protected against mice, rooks, pheasants, and wood-pigeons, all of which are very fond of them. Red lead or paraffin is sometimes used, but the latter is liable to injure the acorn, and it is said that chopped furze placed over the acorn is the best means of protecting them against mice. They should be covered with at least an inch of soil, and, if dibbled, care must be taken that they do not fall in the hole end downwards, but lie on their side in their natural position.

In 1901 I made experiments on the growth of oaks from acorns produced by

¹ I saw a large oak on the lawn at Marks Hall, Essex, which produced no less than 31½ bushels of acorns in 1906.

² Mr. T. P. Price, of Marks Hall, told me that in 1904 ten bullocks died there from this cause.

many trees in different parts of England, in order to learn whether the size of the acorns and the vigour of the parent tree had much influence on their strength. I have now watched the growth of these young trees for six seasons, and have arrived at no definite conclusion, though I am much surprised by two facts which have become evident. Lord Ducie has an oak in his park which usually produces acorns of unusual size, some that he has weighed being only 36 to the pound. The plants from these were no stronger than those of normal acorns; and some of the very finest plants that I raised were produced by the small acorns of a very stunted grafted tree with variegated leaves, which I only sowed to see whether any variegation would appear in their leaves. I found, however, that on the average the acorns gathered on my own place on similar soil gave the best results, and that those from Hants and Kent did not produce such good seedlings as those from Nottinghamshire.

The shoot appears above ground about the time the oak comes into leaf, or rather sooner, and the first growth is completed in three weeks or a month. A second growth, corresponding to the summer shoots of the parent tree, is produced in July or August, and sometimes even a third shoot. If sown in a nursery-bed they will be 4 to 12 inches high at the end of the first season, and should be transplanted in the following spring before they are a year old. For if the tap root is not cut early it will become so long and strong in good soil that the transplantation is a severe check to the young tree.

When lined out in the nursery they must remain two years longer, in good soil kept clean, after which the best of them should be 2 to 3 feet high and fit to plant out permanently, except where the herbage is long and coarse. They are sometimes left three years, but this is too long, though, where the land they are to go to is good and not too heavy, liberties may be taken with oaks which could not be risked on poor soil. If not planted out at three years they should be transplanted once more in the nursery, and at five or six years old ought to be 4 or 5 feet high, whilst oaks sown *in situ* in land covered with herbage or weeds will at the same age often be not more than a foot high and much less strong. In the long run, however, those which have never been transplanted will probably pass the others when once they have established a good root system, which in poor soil is a very slow process. Transplanted oaks, if they do not come away with good straight leaders, are best cut down to the ground the second or third spring after they are planted, when their roots are sufficiently established to throw up a strong leader. Some say¹ that this should not be done until the beginning of June when the sap is running strongly, but experiments which I have made seem to prove that April or May is better. Mice are the worst enemies of young seedling oaks, and where they are numerous cause an immense deal of damage by barking and biting them off close to the ground.

¹ Hayes states, *Planting*, 160 (1794), that from long observation he can aver that the root of an oak never produces a growth of finer young wood than when the tree is felled about the first week in June, when the sap is flowing most freely, and refers to Marshall's *Minutes of Agriculture and Planting in the Midland Shires of England* for evidence in support of this opinion.

Billington's account of the immense losses which were caused by mice to the oaks sown in the Forest of Dean, which is quoted at length by Loudon, pp. 1805-7, shows that in places where mice are numerous it is more economical to plant than to sow; and I have on my own property failed to get anything like a good stand of young oaks by sowing, on account of the ravages of mice and rooks, though every precaution which experience could suggest was taken. I tried dibbling in wheat, and sowing in lines and patches, both on cultivated and uncultivated ground, and have only partial or complete failures to record. In better and lighter soils, and especially in woods of large size where rabbits are kept down, I have seen splendid results from self-sown acorns; and Mr. A. C. Forbes's prize essay on the natural reproduction of woods from seed, published in the *Transactions of the English Arboricultural Society*, v. 239, should be consulted, as well as Loudon's remarks on the same subject, pp. 1804-5.

Mr. Stafford Howard, C.B., who probably knows more about forestry and has done more to improve the management of the Royal Forests than any Commissioner who preceded him, except, perhaps, Lord Glenbervie, has sent me an excellent photograph of a grove of self-sown oaks on his property at Thornbury Castle, Gloucestershire, which has originated from acorns, self sown, in what used to be an osier bed, and which are now about thirty to forty years old. Plate 81 shows their present appearance. On December 29, 1904, Mr. Howard showed me this grove, of which about an acre, containing 139 trees, has been wired in and under-planted with beech at about 6 feet apart. Six trees have been measured and marked with the object of showing whether the future increase of the oaks will pay for the cost of under-planting. As I am not aware that this practice, which in Germany and France is considered good forestry, has ever been properly tested in England, I hope that the results of this experiment will be recorded.

The best illustration of the possibility of converting coppice with standards, into pure oak wood, was shown me in 1900 by Mr. A. C. Forbes in a wood called Derry Hill, on the property of the Marquess of Lansdowne, three miles from Chippenham. In this case the coppice was cut early in the winter, after a good crop of acorns, and completely cleared before the following May. The constant presence of workmen faggoting and cleaning the coppice, not only kept away pheasants and pigeons, but also buried a good many of the acorns; and the soil being suitable for oaks, their growth was so good in the next three years that by cutting away the shoots of the coppice wherever it crowded and overgrew the young oaks, a stand was obtained far thicker, cleaner, and more vigorous than I have ever seen from planted trees. If carefully attended to until the seedlings overtop and smother the remains of the underwood, and provided also the remaining standards are cut and removed before they damage the seedlings, I should expect this wood to become one of the best of its sort in England.¹

On the property of Dr. Watney, at Buckhold, Berks, I have also seen some

¹ On revisiting the place seven years later I found that the growth had not been so good as it promised to be, owing perhaps to the underwood being cut too hard, and the soil having become overgrown with grass.

admirable illustrations of the growth of young oaks from seed, and of the result of converting oak coppice wood into standards, by leaving all the best poles uncut, and carefully thinning out the weakest at intervals. This process, owing to the great fall in the value of oak bark, to the production of which large areas of oak coppice in the west and south-west of England were mainly devoted, has become very generally desirable; but if the stools are old, it is best to grub them, and replant the ground with seedlings mixed with other trees, as has been largely done on the estates of the Duke of Bedford near Tavistock.

With regard to the effect of transplanting oaks on their future growth and height, opinions differ as much as on any subject. The late Sir James Campbell, who managed Dean Forest for many years, often told me that the oftener you transplanted an oak the better it grew, and he communicated a paper with measurements of some trees in Dean Forest to the International Forestry Exhibition at Edinburgh in 1884 in proof of this; but Mr. Smith, who quotes and refers to these measurements in the paper on oaks above referred to, agrees with me that they do not prove the case; and Mr. Philip Baylis,¹ who succeeded Sir J. Campbell at Dean Forest, writes me as follows:—

“At one time I was of the opinion, founded on the above measurements, that trees were benefited by being transplanted, but have long ago given up that opinion. It is true that for a time after the tree has recovered from the shock of moving, you may, in consequence of the greater number of fibrous roots produced by the moving, get a stimulated growth; but I am convinced that the tree which eventually produces the finest timber tree is the one which is never moved from the place where the seed first germinated.”

In this opinion I entirely agree, and believe that though oaks, like other trees, may be drawn up to a considerable height when surrounded closely by other trees, especially the beech, yet that their straight upward growth largely depends on the depth to which the main roots can descend. I do not know that it has ever been proved at what age the tap root decays, and this no doubt depends very largely on the subsoil; but though one may see very large spreading oaks on a thin soil, I never saw a very tall and straight one except on deep land.

In an appendix to the First Report of the Commissioners of Woods and Forests, published as a blue-book in 1812, will be found (p. 143) some very interesting and valuable observations on the sowing and transplanting of oaks, in which instances are quoted from several places which go to show that oaks on some soils at least, as at Moccas Court, in Bere Forest, and in the Forest of Dean, will grow as fast or faster when transplanted at 8 to 10 feet high, or even more, than when sown *in situ*.

In another appendix to the same report, on page 141, are some further observations, made by men of great experience on the growth of oaks from the stool, which prove that when the stools are young and sound and the land good, sound oak trees of as much as 160 cubic feet may be so produced; but that when the stool has

¹ Mr. Baylis sends me a very interesting photograph showing the difference between the roots of transplanted and untransplanted oaks.

become old and partially decayed, or when the land is poor, such shoots are not likely to attain any size. The best example I know of an oak wood produced entirely from stools is one below the approach to Carclew in Cornwall, which the late Colonel Tremayne showed me in 1902. Here the trees average 15 to 20 feet apart, and have clean boles 25 to 30 feet high, and are about 4 feet in girth.

Marsham's opinion on the growth of oaks, taken from a paper printed in the *Philosophical Transactions*, are so much to the point, and his personal experience was spread over such a very long period (from 1719 to 1795) that I quote him as follows:¹—

“In 1719 I had about two acres sowed with acorns, and from 1729 to 1770 I planted oaks from this grove, always leaving the best plants standing for the future grove; but most of the transplanted trees are already larger than those that were not removed; the largest of which is now (1795) but 5 feet 6 inches 8 tenths in circumference; and the largest transplanted tree (which was planted in 1735) is 8 feet 8 inches 7 tenths, viz., near 38 inches gained by transplanting in 60 years. And in beeches from seed, in 1733, the largest is now (1795) but 6 feet 9 inches; and the largest transplanted beech is 7 feet 5 inches 1 tenth, viz., 8 inches larger, although the transplanted beech is eight years younger than that from the seed. This proves that it is better to plant a grove than to raise one from the seed. The expense of planting is inconsiderable, and the planted trees are full as good and handsome, and many years are saved, besides the extra growth of planted trees. But this extra growth will not prove near so great in groves as in single trees. The first grove I planted from these acorns of 1719, was in 1731. In 1732 I made another grove from them, and in 1735 I planted a third grove from them, and in 1753 the last considerable number of plants were taken from the grove, and these are very good trees: so thirty-four years may be saved. But I would by no means advise the planting trees so large, as the trouble and expense will be too much, unless where a shelter or screen is wanted.

“Whether a grove is to be raised from seeds or planted, it is advisable to shelter it round; if from the seed, with such sorts as will grow quicker; and if by planting, with larger and taller trees. The soil in Norfolk is unfavourable to elms; therefore in planting I will venture to recommend hornbeams, as they may be planted large trees. I planted some hornbeams (rather large) in 1757, and, disliking their situation, in 1792 I removed them when they were about three feet in circumference, and did not lose one tree; and they made shoots of near half a yard that year; but I ought to say I cut off their heads.

“Before I quit this subject, I will presume to recommend, if young oaks are unthriving, there is reason to hope they may be helped by cutting them down to a foot or six inches; for in 1750 I planted some oaks from my grove of 1719 into a poorer soil, and although they lived they were sickly; so in 1761 I cut most of them down to one foot, and then by cutting off the side shoots, in three or four years led them into a single stem, and most of them are now thriving and handsome trees, and you

¹ *Phil. Trans.* 1797, pp. 128-152.

can hardly see where they were cut off, and some are four feet round; and I have used the same method with unhealthy chestnuts, beech, hornbeam, and wych elm, and with the same success.”

RATE OF GROWTH

The rate of growth in the oak is principally governed by the soil and situation, and varies so much that any estimates of its possible increase are of little value unless based on local experience. We often read calculations of the profits of planting, drawn from Continental experience or from exceptionally favourable cases in England, which are very misleading and greatly in excess of reasonable expectations, and there is no tree to which these remarks apply more strongly than to the oak.

Few plantations give more ample proof of this than those made by the Government in the woods at Alice Holt, which were planted between 1810 and 1830, with the object of providing timber for the navy, and which were no doubt done by experienced planters. But the growth has been so poor that, when I visited them in 1905, in company with Mr. Stafford Howard and Mr. Lascelles, we saw but few oaks which looked as if they would ever be fine trees, and their average value was not much over 10s. per tree. In one place, called Willow Green, oaks of seventy years old were not over 30 or 40 feet high and not thick enough for gate-posts.¹

In many parts of the Forest of Dean the results are not much better, and are largely attributed to over-thinning, and to the fact of the ground being thrown open to grazing too soon; but the soil and spring frosts must also have had a good deal to do with it.

In the New Forest the results are better, but not at all equal to what might have been expected. I am indebted to Mr. Stafford Howard for the following information on some of these plantations and the way in which they were made:—

Planting in the New Forest.—In order to make provision for the future needs of the navy, in view of the fact that planting had been greatly neglected in the New Forest, an Act was passed, 9 & 10 Will. III., for that purpose. Under this Act it was provided that 2000 acres should forthwith be enclosed and planted with timber for the use of the navy only, underwood and all other produce being excluded; that 200 acres should be enclosed annually for twenty years following, and that as soon as any of the land thus enclosed was safe from damage from cattle, it should be thrown open and a like area enclosed in its stead. The plantations described were made under the powers of this Act.

The precise form of cultivation employed was as follows:—

“Pits or beds of three spits of ground each were dug a yard apart, and three acorns planted triangularly in each bed. Half a bushel of acorns was allotted for each person to plant in one day. Two regaders attended every day during

¹ Mr. Howard says that in the lower part of the Goose Green enclosure, and in the Straights, there is much better timber, and that in Dr. Schlich's report on these woods over 300 acres were classified as good, where the trees attain a mean height of 60 feet.

the time of planting to see that it was properly done; and after the ground was fully planted with acorns it was sown with haws, holly berries, sloes, and hazel nuts, drains were cut where necessary, and traps were set to catch mice, and persons attended daily to reset the traps and to keep off crows and other vermin."

Whether from subsequent neglect or not, the plantations thus formed were never thinned at all, but allowed to grow up like a nursery quarter. Although contrary to every theory of plantation management, it cannot be denied that they were in this bad soil successful in growing a heavy crop of oak timber on moderate land.

Denny Enclosure.—There are some very good examples of natural regeneration in places in this wood, which was reinclosed in 1870. A photograph was sent which contrasts the young growth inside the fence of the enclosure with the bareness of the outside where the cattle graze.

Salisbury Trench.—This plantation was made in or about the year 1700, and measures about 100 acres. It was thrown open under an order dated 20th August 1807. It is calculated that there are now left after frequent thinning about sixty trees to the acre. Two years ago it was reinclosed with a view to its gradual regeneration, and there is already a large number of young oak and beech coming up in the open spaces.

North and South Bentley.—These plantations were made about the same time, probably just before that of Salisbury Trench, and are of the same character, except that there is some beech here and there in North Bentley. During the past twenty years the trees felled in Salisbury Trench, being for the most part the poorest ones, have averaged $23\frac{1}{2}$ cubic feet; and there now remain about sixty to the acre. In North Bentley they have averaged about 25 cubic feet, in South Bentley 29 cubic feet, and about sixty trees to the acre remain standing.

One of the best private oak plantations of which the exact age is known is on the property of Lord Kesteven at Banthorpe, near Casewick, Lincolnshire. It was made by Sir John Trollope, grandfather of the present owner, in 1800, with acorns which had to be sown a second time, as they were eaten by mice in 1799. It is on good soil, and, as near as I could judge by the eye, contains about sixty trees to the acre, straight for the most part, and clean up to 30 to 40 feet. In 1905 twelve average trees in the plantation had an average timber length of 34 feet, an average quarter girth of 18 inches, and contained 903 cubic feet without tops or branches, which would make my rough estimate of 5000 feet to the acre very nearly correct, and if profit alone were considered I should say that these trees had now reached the proper age for felling.

The late Mr. John Clutton, who valued timber for the Crown for many years, gave,¹ in 1873, particulars of the size of oaks.

In the same volume Mr. Ralph Clutton, in an excellent paper on the self-sown oak woods of Sussex, gives many exact details of the growth of oak without underwood, with measurements and valuations, which should be consulted by all landowners in that part of England.

Under more favourable circumstances, however, oak plantations may yield a good profit, as shown by the following extract from the *Norfolk Chronicle*, sent me by Sir Hugh Beevor, and printed in Grigor's *Eastern Arboretum*, p. 360.

“Being enabled from old memoranda of undoubted authority, and from information received several years ago from different persons, who remembered or who assisted in the work, to give you, perhaps, an unusually accurate account of the produce of a piece of land measuring eight acres, planted with acorns in the year 1729, I take the liberty of so doing, and of requesting your insertion of it in your paper whenever you may have the best opportunity. The piece was under the plough at that time, cold and unprofitable, from the practice of underdraining not being then introduced; at Michaelmas 1729 it was sown with wheat, and acorns dibbled in; when reaped, the stubble was left very long, which is supposed to have caused the plants to run up very straight.

“ Besides a great many used on the ground, from 1729 to 1763, plants were drawn out and sold to the amount of . . . £100 0 0

In the year 1764 by 1500 poles sold	50 0 0

£1314 10 0

The underwood never came to perfection, but was stubbed up in the year 1767, and the feed of the ground let for 10s. an acre for thirty years . . . 120 0 0

Value of the feed at the same price to the present time 144 0 0

There are now 320 trees standing, worth if now felled 1200 0 0

£2778 10 0

“ The expenses of felling cannot be now correctly ascertained, but the topwood is not included in the above account of receipts, nor a great many trees which have been used on the premises from the year 1763 to the present time, and at a moderate estimate must have much more than paid for the expenses of the labour.—TIIOS. HOWES, Morningthorpe, April 22nd, 1834.”¹

The Earl of Darnley showed me an oak in “Mount Meadow,” near Cobham, planted by Lady Elizabeth Brownlow, who was born in the year 1800, which therefore could not be much over 100 years old. It has a straight clean bole measuring about 40 feet by 12 feet 10 inches, and a small spreading top.

The following extract from a letter of Robert Marsham to Gilbert White is worth quoting, though I could not identify the tree when I visited the place recently.

“Stratton, 24th July 1790.—I early began planting, and an oake which I

¹ Sir Hugh Bevor in 1902 measured eleven of the oaks remaining in this grove, which was nearly all felled in 1885, and found that they averaged 80 to 90 feet high by 8 feet 2 inches in girth at 6 feet, the cubic contents being about 145 feet each.

planted in 1720 is at one foot from the earth 12 feet 6 inches round, and at 14 feet (the half of the timber length) is 8 feet 2 inches. So measuring the bark as timber gives 116½ feet buyer’s measure. Perhaps you never heard of a larger oak, and the planter living. I flatter myself that I increased the growth by washing the stem, and digging a circle as far as I supposed the roots to extend, and spreading sawdust, etc., as related in the *Phil. Trans.* vol. lxvii. p. 12.”

Blenkam¹ mentions a remarkable instance of rapid growth:—“Three thriving oaks, growing on a hard gravelly and poor soil, were felled in Nottinghamshire, which on an average girthed 15 feet at three feet from the ground, and each tree contained about 430 cubic feet. The trees were planted in 1692 or 1693, and were about 149 years old when felled. They were perfectly sound and yearly increasing in size.”

In a paper by Mr. Clayton² a photograph is given of a section across the butt of an oak felled at Ravenfield Park between Doncaster and Sheffield in 1885, which had a butt 36 feet long without a branch, and an average diameter of 5 feet, and which showed only 212 annual rings on a radius of 27¾ inches. If the actual age of this tree was only 212 years, its growth must have been unusually rapid, and a comparison of this with the section of the oak from Wistman’s Wood (cf. p. 326) shows how remarkably the growth of trees depends on their situation.

As an illustration of the possible value of a hardwood plantation about forty acres in area in the Sherwood Forest district, I am able to give the following particulars, for which Mr. Doig, forester to Earl Manvers is my authority. In White’s *History of Sherwood Forest* the land in question is called “Robert Fitzorth’s land.” It now goes by the name of Osland. It had been in cultivation previous to 1730, about which time it was planted, or perhaps sown, with beech, oak, ash, chestnut, larch, and spruce. The conifers had mostly been cut previous to 1846, before which time there are no records of the value of the thinnings taken from it. Since then the following have been cut or blown down:—

	Number.	Cubic Contents.	Value.
Oak	1801	38,735	£3,732 2 9
Oak poles	1628	8,696	371 5 1
Beech	2054	74,213	3,756 0 8
Ash, elm, etc.	63	2,215	123 2 5
Chestnut	43	1,289	102 4 4
Larch and spruce	117	660	26 9 1
	5706	125,808	£8,111 4 4
Standing in 1903:—			
Oak	182	18,200	1,820 0 0
Beech	701	63,090	3,154 10 0
Chestnut	14	1,336	88 10 0
Larch	5	400	23 6 8
Total	6608	208,834	£13,197 11 0

¹ *British Timber Trees*, 42 (1862).

² *Trans. Bot. Soc. Edin.* xxii. 396.

This shows an average number of trees per acre (omitting the oak poles) of about 125, and a value of £320 per acre.

Perhaps the greatest increase of girth on record in the oak is cited by Gadeau de Kerville¹ of three oaks which were felled at Neauphe-sur-Dives (Orne) in Normandy in 1894. Their exact age was not possible to decide, as they were already trimmed and barked and part of the sapwood taken off, but the rings counted by M. de Kerville were 115 to 120, and the girths 6.16, 4.98, and 4.28 metres respectively. He thought that they might be from 150 to 200 years at most, and this would make the average annual increase of the largest, on the section measured, over 5 centimetres per annum.

REMARKABLE TREES

The mass of information on the oak which exists in English literature, is so great, so scattered, and often so impossible to verify, that I have had great difficulty in making a selection of what is really valuable and authentic, and have preferred rather to speak of trees and woods that we have seen ourselves, and to quote from the letters of living correspondents, than to repeat what has been written by Evelyn, Hunter, Strutt, Selby, Loudon, and other writers, whose works can always be consulted by those desirous of more detailed particulars than our space will allow.

Some of the most wonderful oaks of England, which we have seen and now figure, must be described more particularly, and among these I think the oaks of Powis Castle come first. Robert Marsham, in a letter communicated by Sir T. Beever to the *Bath and West of England Societies' Transactions*, i. 78 (1783), says:—"The handsomest oak I ever saw was in the Earl of Powis' noble park by Ludlow in 1757, though it was but 16 feet 3 inches. But it ran straight and clear of arms, I believe, near full 60 feet, and had a large and fine head."

In April 1904 the Earl of Powis showed me some trees growing in his ancient park at Powis Castle, near Welshpool, Montgomeryshire, which I believe to be actually the champion oaks of Great Britain at the present time. They grow on a Silurian formation at about 300 to 400 feet elevation, with an east aspect, and are, as far as one can judge, perfectly sound in the butt, though one of them lost several branches during the dry seasons between 1893 and 1903, and another has a large decayed limb which, if not taken off, may cause the butt to decay.

The measurements which I give were made most carefully by Mr. W. F. Addie, agent for the Powis estates, who used a long ladder and a man to climb nearly all over them and take the length and girth of the principal branches down to 6 inches quarter-girth. I checked the height and girth of the trunks myself as carefully as possible, and believe that the following is a very accurate estimate.

¹ *Les vieux arbres de la Normandie*, iii. 373 (1895).

	Girth at Ground.		Height of Bole.	Girth at 4 Feet 6 inches.		Height of Tree.	Cubic Contents.

Of the extraordinary size to which oaks have attained in this district we have a record which is without parallel in this or any country. My attention was called to it by the Earl of Powis, who, knowing the locality, believes it to be true. It is taken from a work called *Collections Relating to Montgomeryshire*, xiii. 424-425 (1880), published by the Powysland Club at Welshpool, and runs as follows:—

"In 1793 and 1796 a large fall of oak timber took place at Vaynor park in the parish of Berriew, when some trees of enormous dimensions were cut down. Major Corbett Winder has kindly favoured us with a copy of the following memorandum of the particulars of the contents of some of the largest trees:—

"Dimensions of twenty-six of the largest oaks cut down in Vaynor Park in 1793 and 1796.

No. of Tree.	Feet.	No. of Tree.	Feet.	No. of Tree.	Feet.
1.	1127	10.	1523	19.	1516
2.	1121	11.	1859	20.	1428
3.	2501	12.	1328	21.	1298
4.	2202	13.	1808	22.	1077
5.	1713	14.	1793	23.	1161
6.	1106	15.	1289	24.	1018
7.	1453	16.	1101	25.	1170
8.	1953	17.	1467	26.	1322
9.	1192	18.	1246		

Total: 37,772 cubic feet, averaging 1452½ cubic feet per tree."

The counties of Hereford, Worcester, Shropshire, and Stafford have produced and perhaps still contain the largest oaks in England, next to those I have just mentioned, but the long years of agricultural depression which have impoverished so many of the squires of England, have caused the felling of many of the finest. Among these the most celebrated was the Hereford Monarch which grew at Tyberton, near the house of Chandos Lee Warner, Esq., to whom I am indebted for two copies of a print taken from drawings which were made by G. L. Lewis, and published in a scarce work called *Portraits of British Forest Trees*.³ One of

¹ The photographs from which these plates are reproduced were taken in June 1904 by Mr. R. G. Foster of Burlord.

² This plate is from a photograph taken in 1906 by Lord Powis.

³ Vale, Hereford, 1837.

these shows the tree in summer, the other in winter, and prove it to have been a tree of faultless shape and beauty, if not quite equal in bulk to the Champion Oak at Powis Castle. I visited the site of this tree in 1905, but the stump was no longer visible, and the soil, though a good deep red loam, did not show in the other trees any striking evidence of unusual fertility.

Its measurements, as given me by Messrs. Openshaw of Woofferton Court, to whom I am indebted for many particulars about trees in their district, were as follows:—

Butt	30 feet by 55½ inches quarter-girth	}	923 feet.	
Second length .	60 " " 26 " "			
One branch .	18 " " 42 " "			220 "
Other branches more or less damaged by lightning, about .	400 "			
			<u>1543 feet.</u>	

A record of the tree was sent me by Messrs. Stooke and Sons of Palace Yard, Hereford, as follows:—"The Hereford Monarch.—An Oak tree, containing 1200 cubic feet, felled in Tyberton Park, ten miles from Hereford, April 1877. Length of tree, cut off at 18 inches diameter, 88 feet. Length of butt only 29½ feet. Height of tree when growing 130 feet. Circumference at 5 feet from the ground 22 feet 8 inches. Photograph taken of tree as felled, and showing the larger bough as shattered by lightning. Purchased by Messrs. R. and T. Groom and Sons, Wellington, Salop."

Mr. T. E. Groom of Hereford, whose firm bought it, informed me that though the tree would have been worth about £300 before it was struck, it did not actually cost them more than £200. It was felled in consequence of its having been disfigured by a stroke of lightning. Before this it was a perfectly sound tree with over 1500 feet of timber in it. It was still growing and might have become much larger. The butt was quartered and sold to a vat maker who cut it all into thin rims. At the end of the 30 feet of butt were two parallel spires each containing several hundred feet. The larger one was so much broken that it had but little useful timber left in it. The smaller was 60 feet long and about 2 feet in diameter at the top end. This was cut up into railway planking. The tree also made several thousand keys and trenails used on the railway.

Another immense tree was felled in Staffordshire on May 29, 1786, of which Messrs. Openshaw give me the following particulars:—"It grew in the middle of the Grove field on Bath farm, Chillington estate, and measured as follows:—

Butt, 30 feet by 60 inches = 750 feet at 5s.	£187 10 0
Limbs (22), 560 at 1s. 8d.	46 13 4
Thirteen cords of wood at 10s. 6d.	7 7 0
The root	2 10 0
2½ tons bark	8 8 0
	<u>£252 8 4</u>

"No branches under 9 inches quarter-girth were included in the above. Twelve men worked twelve hours each in felling this tree."

One of the tallest oaks which I have ever measured in England is a comparatively young tree in perfect health and vigour, which, though not shut in by other trees, appears to be still growing, and may even attain a greater height. It stands on the edge of a plantation at the bottom of a steep slope facing north-east in Whitfield Park, Herefordshire, the seat of Capt. Percy Clive, who showed it me in 1906. A careful measurement from both sides made it 130 feet high, or perhaps a little more, by 11 feet 10 inches in girth, with a straight bole of 55 feet free from branches, though two or three small ones had been cut off four years ago. For symmetry and height combined I have not seen its equal in England, and the photograph of it taken by Mr. Foster, though under the circumstances a very good one, fails to give a correct idea of its great height (Plate 85). The soil is old red sandstone, and the tree is of the sessile type.

At Foxley, near Hereford, the seat of the Rev. G. H. Davenport, are many fine oaks, all of which, so far as I saw, are sessile. The best is about 104 feet high by 20 feet girth, with a bole of 20 feet. In the Nash Wood there is a superb lot of young oaks with the tallest and cleanest stems in proportion to their thickness I have seen in England. They may average 90 feet high, and one which I measured was clean and straight to 62 feet and only 3 feet 4 inches in girth. Mr. Davenport believes them to be sixty to seventy years old, and if well taken care of they should in a hundred years be some of the finest of their type in England.

The largest oaks now standing in Herefordshire that I know of are at Holm Lacy, one of which, a short-boled spreading tree now much decayed, was in 1905 75 feet by 30 feet 2 inches, and 125 yards in circumference of the branches. The other, 90 to 95 feet high, with a bole 25 feet by 23 feet 9 inches, is vigorous and healthy, though perhaps not quite sound.

In Lord Leigh's park at Stoneleigh Abbey, Warwickshire, are many fine old oaks, relics of the Forest of Arden, which grow on a red sandstone soil, and are in many cases long past their prime. The largest stands near the Abbey, and is 28 feet 3 inches in girth; though the top is much broken and decayed, the butt seems sound. Another, just outside the Tantarra Lodge, is a vigorous tree of later date, and measures 22 feet 10 inches in girth, with a fine spreading crown; a third, near the river, is 27 feet 5 inches in girth. The most interesting, however—of which I hope to give an illustration later—is Shakespeare's Oak, so called from the tradition that Shakespeare used to sit and write under it. It grows on the top of a low sandstone cliff, over which at least half the thickness of its trunk projects, and is supported entirely by the roots on the other side to which it leans; it measures no less than 25 feet in girth, and though deeply cleft on one side and hollow, has vigorous branches.

The oak grove at Kyre Park, Worcestershire, the property of Mrs. Baldwin Childe, was first noticed by the Woolhope Club, who visited it in 1893, and described later by Sir Hugh Beevor, who published a short account of it.¹ I had the pleasure of visiting this wonderful grove in March 1904, when some

¹ *Trans. of the English Arboricultural Society*, v. 473.

photographs were taken (Plates 86 and 87), which give a good idea of the remarkable size and height of the trees. The soil is a good deep loam on the red sandstone formation. The grove is unfenced and has been open to cattle for many years, and there is no visible evidence of the trees having been drawn up by beech. The majority of them are of the sessile variety, though some are pedunculate oaks, as proved by specimens kindly sent me by Mrs. Baldwyn Childe and by the observation of her very obliging agent, Mr. J. W. Openshaw, who found six trees of the pedunculate to about twenty-four of the sessile form. Sir Hugh Beavor speaks of them as sessile, and at the time I was there it was difficult to distinguish one from the other. As to their age, Mr. Openshaw writes that he could not count the rings because they were so minute, but from the evidence of Habingdon's *History of Worcestershire*, written in the time of Queen Elizabeth, they must be very old. Habingdon says:—"The Parcke of Cure Wyard is not to be shutt up in silence, for it is adorned with so many tall and mightie oakes as scarce any ground in England within that quantity of akers can shoue so many." Most of these trees do not show decay in their tops like so many of our great park oaks, and may thrive for centuries to come.

Sir Hugh Beavor's measurements of their height agree very fairly with my own, but exact measurements of the heights of such trees are difficult to obtain, and they are not so remarkable for their girth as for the way in which they run up with clean stems to a great height. The two tallest are certainly over 130 feet by my own measurements in 1907. Sir Hugh Beavor gives 78 and 79 feet as the first length of two, and one which was blown down in 1897 was 82 feet to the first limb, though only 16 inches in quarter-girth, and with no measurable tops. These trees show very few burrs, but some have large buttresses at the base.¹ The largest, according to Mr. Openshaw, has a stem 83 feet long by 17 feet 8 inches in girth at 5 feet, and contains 1031 cubic feet of timber. Fourteen of them contain over 600 feet, and the smallest tree in the grove has 97 feet, which is considered a big oak in many districts. The tree I have figured (Plate 86), with Kyre House in the background, is on the outside of the grove, and of different type from most of them. It is the third largest tree in contents, having 694 cubic feet in the butt and 150 cubic feet in the tops. I made it 115 feet high by 18 feet 6 inches at 5 feet, and it looks vigorous and is growing fast. The other tree figured (Plate 87) is 85 feet to the first limb, 13 feet 6 inches in girth at 5 feet, and contains 604 feet in the butt, and 112 in the tops. The measurements given below, taken by Mr. Openshaw, may be thoroughly relied on. They were taken in the usual way by strap, and good allowance made for taper. The heights were taken with the help of a long pole; and both Mr. Openshaw and his father, who has probably as much experience in measuring big oaks for sale as anyone in England, are confident that the grove contains more than they have estimated, though no doubt a quantity of the timber would be broken in falling if cut. Of this, however, there is not the least risk in the lifetime of the present owner, who is much interested in, and very proud of her trees.

¹ One of these measures no less than 44 feet round the base, and at five feet from the ground is 20 feet in girth.

"*Kyre Park*.—Measure of oak trees in Woodpatch grove made by John W. Openshaw, November 1904. The tape girths are over bark taken at 5 feet. The quarter-girth is the middle of first length taken under bark. Eleven trees removed (1883, 1887, 1897) contained 2990 feet, average 272 feet. Ninety-seven trees now standing contain 38,365 feet, growing on 5 acres, 2 roods, 19 poles of land; an average of 395 $\frac{2}{3}$ feet per tree. A hundred and eight trees contained 41,365 cubic feet, an average of 383 feet per tree. There remain distinct traces of sixty and indistinct traces of ten trees having been removed, including the eleven referred to above."

There is an oak of remarkable size in another part of the Kyre estate called the Hannings, growing on high ground exposed to the north, in a rough pasture overgrown with trees, which no doubt have drawn it up in youth. It is 113 feet in total height, with a trunk nearly straight to about 90 feet high, where the head begins, and 15 feet 10 inches in girth. Mr. Openshaw and I estimated its contents as follows:—

1st length 18 feet by 48 inches = 288 feet.
 2nd ,, 20 ,, 40 ,, = 222 ,,
 3rd ,, 50 ,, 24 ,, = 200 ,,

710 feet.

£100 was refused for this tree a few years ago.

There is also in the deer park a circle with a diameter of fifty yards formed by ten (formerly twelve) oaks of great age and very spreading in habit, and a very

ancient oak near by, called the Gibbet Oak, on which tradition says that criminals were formerly hung in chains.

Of the difficulty and risk of removing some of these immense trees when steam traction engines were not in use by timber merchants, Mr. Openshaw gave me an excellent instance which he actually saw himself. A very large oak was felled in a field near Woofferton and sold to a naval timber buyer at Exeter. It was so long and heavy that two of the largest timber carriages were fastened together, and 28 horses brought to get it away. In rolling it up on to the carriage one of the chains got round a horse's leg, but they dared not stop to clear it, and the horse was killed. Mr. Openshaw saw the carriage coming down the road with the log on it, and, believing that it could not pass through the turnpike gate, warned the woman who kept it, to get out of the house, as if the log touched it the house would certainly come down. The man in charge of the team, however, ran on in front and steered the leaders so accurately through the gate that, with an inch to spare, it got past in safety.

It seems probable that many of the great oaks in England which are now decayed, owe their lives to the cost and risk of converting and removing them in the days when there were no railways, and good roads were scarce or absent.

The Nunupton Oak.—The remains of a very large fallen oak, not, however, so big as the one at Croft Castle, is described in the *Transactions of the Woolhope Naturalists' Field Club*, 1870, p. 307. It had long been hollow, and was large enough to contain forty-two sheep at once. It was alive and covered with leaves up till about 1851, when it was set on fire by accident, and was felled soon afterwards, with what object I do not know. In 1870 it was 60 feet long and 26 feet 8 inches in girth, and was still lying in much the same condition when I visited it in 1904.

According to the late Mr. Edwin Lees, whose knowledge of the botany of Worcestershire was very accurate, and whose sketches of old trees, some of which I have, through the kindness of his widow, been allowed to copy, the finest old oak in the county known to him in 1867 stood in a field near the Severn, below Holt, and was known as the Boar Stag Oak. It measured about 34 feet in girth at 3 feet from the base, and might be roughly calculated at 800 years old.

Other remarkable oaks in Worcestershire were described and figured by W. G. Smith, in the *Gardeners' Chronicle*, 1873, p. 1497. They grew in the Lug Meadows, near Moreton, and were known as Adam and Eve. When the Shrewsbury and Hereford Railway was made, Eve, which measured 25 feet in girth, and was quite hollow, was converted by the navvies into a residence: the top was thatched in, a brick fireplace built, and a door fitted, and for months after the line was opened this tree was the only residence of the stationmaster, and was afterwards converted into a lamp-room and so used for fourteen years.

The finest oaks that I know of in Somersetshire are at Nettlecombe Court, the seat of Sir Walter Trevelyan, Bart. When staying at Dunster Castle, in March 1904, Mr. Luttrell was good enough to give me an opportunity of seeing them. He told me that at a previous time, which, from the information received from the agents for the property, I gather to have been about 1847, but Mr. Luttrell thinks it was

earlier, £40,000 was offered for about forty acres of oak timber on this property; and an old man at Nettlecombe said that the tools were actually brought to the place ready to fell them, when the owner changed his mind and they were allowed to stand. A considerable part of these oaks have been since felled, but a magnificent grove still remains on the slopes of a combe, at an elevation of five to six hundred feet on the south-west side of Nettlecombe Park, facing to the north and east, and on a soil locally called "shiletty," which is a reddish rocky formation, overlaid by a thin layer of rubbly stone, probably old red sandstone, which would appear too thin and dry to produce big oak timber. The age of these trees, so far as I could judge by counting the rings of one which had been blown down, is not more than 200 to 250 years, but some may possibly be much older.¹ The majority are very clean and free from limbs to from 40 to 60 feet up, and average 10 to 12 feet in girth. One, about 210 years old and over 100 feet long, was 3 feet in diameter at the butt, and had fifty annual rings in a radius of 9 inches near the heart, but outside of this the growth had been much slower. I had not time to measure them carefully, or estimate the number now standing on an acre; but two of the finest trees on the steep banks of the combe were 116 by 14 feet, with a bole 65 feet long; another was 116 by 16 feet, with a bole of 50 feet by 36 inches quarter-girth. The thickest trees, which I did not measure, are on the outside of the grove. Assuming the price of £1000 per acre to have been based on 4s. per foot for the butts, which for trees of this size and character would, sixty years ago, have been about the value, and the trees to have averaged 200 cubic feet, there would have been perhaps forty trees to the acre, averaging £25 each, and though the cubic contents do not come up to what we are told is produced in some of the picked areas of oak forest in France and Germany, I have never heard of an actual sale of any timber in England at so high a price.

At Hazlegrove, Somersetshire, the property of the Rev. A. St. John Mildmay, is a remarkably fine oak, reported to be the largest in the county. It is about 75 feet high by 29 feet 9 inches at 5 feet from the ground, and at ground level spreads out to no less than about 18 yards in circumference. Though it seems sound, yet it has a rent on the north-east side, as though struck by lightning, and many of the largest limbs have been broken by wind, and are mended with lead. A drawing of it, made in 1833 when it seems to have been in full vigour, is in Hazlegrove House.

In Melbury Park, Dorsetshire, the seat of the Earl of Ilchester, there is an extraordinary oak, known as Billy Wilkin's Oak (Plate 88), which swells into an immense burry trunk, 38 feet in girth at the ground, and 35 feet at 5 feet up. Above this it falls away a good deal, and is only about 50 feet high. Like all the trees I have seen of this type, of which perhaps it is the largest in England, it is of the pedunculate variety, and bears acorns abundantly.

At Longleat, Wilts, which has a most beautifully timbered park, and is one of the finest places in England, there is an extremely fine tall oak growing in the

¹ The Rev. Mr. Hancock, who is a connection of the Trevelyans of Nettlecombe, says that he has always heard that they were planted about 1600, when part of the existing house was built.

grove of limes which I shall describe later, in a position which makes it difficult to photograph. This tree measures about 100 feet high by 23 feet in girth, and has a fine clean bole of 40 feet. It contains, according to Mr. A. C. Forbes's estimate, about 950 feet of timber.

The finest oak I have seen in Devonshire is in the park of the Hon. Mark Rolle at Bicton, a place long celebrated for its arboretum and for its avenue of Araucarias, which I have elsewhere described. It measures about 78 feet high by 24 feet 8 inches girth at 3 feet, and has a spread of branches of 103 feet in diameter. There are some fine but not extraordinary oaks at Powderham Castle and at Poltimore in the same county.

Near Mottisfont Abbey, Hants, there is a very thick but short pollard oak on the banks of the Test, of which a photograph, by Mr. J. Bailey, Southampton, has been kindly sent me by Mrs. Meinertzhagen, who long resided at Mottisfont. It measures 32 feet in girth and spreads considerably, and, though evidently of very great age, is full of healthy foliage. It must have been frequently flooded, as it stands close to the river.

Near Bramley, Hants, by the road leading to "The Vine," is an oak, which Henry measured in 1905, 100 feet by 22 feet, and which seems quite sound. There are, so far as I know, no oaks now living in the New Forest which are remarkable for their size as compared with the trees I have mentioned.

Of the historical parks of England I know none which contains so many fine oaks as Bagot's Park, near Rugeley, Staffordshire. This must be one of the oldest parks in England, for though Lord Bagot cannot tell me the exact date of its enclosure, he states that it belonged to his family long before 1367, and that in the "Peregrinations of Dr. Boarde, *temp.* Henry VIII.," printed at the end of Hearne's *Benedictus Abba*, p. 795, "Baggotte's Park" is mentioned in the list of Staffordshire parks. It is generally said to contain 1500 acres within the pale, but varies from time to time, as land has been added in some places and taken out in others for planting, to be again restored when the woods are grown.

This practice seems to be well worthy of more general adoption, for no one who is acquainted with the condition of the trees in many of our oldest parks can have failed to notice, that they are as a rule going back; and as trees cannot be successfully raised to a great height if deer are not excluded—unless enclosures of considerable size are made about once in a generation, in which trees can be properly drawn up to a sufficient height, before they are thinned and the deer admitted—the time must come, and in some cases already has come, when nothing but wrecks are left, and the singly planted trees, though protected by iron or wooden guards at great cost, are a mere mockery of their predecessors.

The soil in Bagot's Park is poor and cold, being a moist gravelly loam upon a clay or marl bottom, and Lord Bagot says it is not worth 10s. per acre at the present time. It affords, however, an excellent proof of the fact that land which is not valuable from an agricultural point of view, may often be of great value for planting. The woods extend over many hundred acres and consist almost wholly of oak, mostly, I believe, of the pedunculate variety. Many of the trees are of great age, being mentioned by Dr. Plot in 1686 as full-grown timber.

I visited it in March 1904, and, though the weather was dull, Mr. Foster was able to secure some excellent photographs, of which I reproduce the following:—

Plate 89 represents the Beggar's Oak, which has been well figured by Strutt in his plate No. 2, and though eighty years have elapsed since that picture was taken, a comparison with my plate shows that very little change has taken place in the tree—thanks to the care with which it has been treated by successive owners, who have worthily kept up the spirit described by Strutt in his account of this tree. It now measures, as nearly as I could estimate, 62 feet high, with a bole of about 33 feet long, and a girth of 24 feet. The roots measure 25 paces round, and the branches cover an area of 114 paces round (according to Lord Bagot's measurement 7850 square feet). It is one of the finest and best-preserved oaks of its type that I know, for though the Major Oak in Sherwood Forest (Plate 95) is bigger, it is not nearly so sound; and the Bourton Oak (Plate 93), which is taller and in better condition, is not so large in girth or so spreading at the base.

Another very fine tree in this park is the Squitch Bank Oak, also figured by Strutt (Plate 34), who gives its measurements as follows:—height, 61 feet; girth, 21 feet 9 inches; contents, 1012 feet. When I saw it in 1905 its top was dead, and the butt seemed to be decaying at the base internally. I measured it as about 60 feet by 24 feet 10 inches, so that it has increased three feet in girth in eighty years. The Beggar's Oak, in the same time, has increased rather more, but in measuring the girth of such trees as this a few inches higher or lower will often make a great difference, and therefore these rates of increase cannot be considered exact.

Other great trees in this park mentioned by Strutt were the Rakeswood Oak, the Long Coppice Oak, and the twisted oak on the Squitch Bank, which, though I did not see them, still survive. In the Horsepool grove are a number of younger but very tall and straight trees, which have been grown close together, and which Lord Bagot's old woodman, W. Jackson (now dead), said he "could remember so thick that you could hardly swing an axe amongst them." Of these, one, which was called Lord Bagot's Walking-Stick, is the straightest and cleanest oak I ever saw in England, though recently struck by lightning; another was 95 feet by 8 feet 6 inches, with a clean stem 65 feet high. On the other side of the park, at the west end of the grove called the Cliffs, are a number of splendid trees of great size. Two of them, standing near each other, are figured in Plate 90. Of these, the one in the foreground measures about 112 feet by 16 feet 8 inches, with a bole 35 feet high and four great erect limbs. The other, about the same height and a foot less in girth, has a clean bole 45 feet high. One hundred pounds was offered and refused for it. In the same grove, farther east, is an oak with a bole about 40 feet by 15 feet 3 inches, twisted from right to left, and another called the King Oak, which, though now partly hollow, has been perhaps the finest timber oak in the park (Plate 91). It is now about 100 feet high, but has been taller, as the topmost branches are dead, with a straight clean bole 21 feet 3 inches in girth, and must have contained over 1000 feet of timber. It is stated¹ that in 1812 £200 was offered for the first length of this tree, estimated at 12s. per foot, and £93 for the

¹ *Gard. Chron.* xvi. 230 (1881).

remainder, including the bark, estimated at £14 per ton. Near it is a tree of great height, leaning at an angle of about one in four to one side, though quite firm in the ground; and it seemed to me that all the trees in this grove owed their great height and clean stems to their having been drawn up by beech trees, many of which are now dead or dying. Close to the Park Lodge are three very curious and picturesque old trees, one of which is called the Venison Oak, because King John is supposed to have dined under it; another, which we christened the Beer-barrel, is an immense burry shell 10 or 12 feet high and 28 feet round, with hardly any branches; a third we called Gouty Toes, because of a huge swollen root, like a gouty foot, on one side of it.

Dr. Plot, in his *Natural History of Staffordshire*, p. 213, after speaking of different species of trees growing together, among which were an oak and an ash near Chartley, hollies and oaks at Bagot's Park, and an oak and thorn at Drayton Basset, goes on to speak of trees "that grow so conjoynd that they seem (after the manner of some sort of animals) to prey upon one another," and says: "But the most signal example of this kind is the large fair birch, about the bigness of one's thigh, that grows on the bole of an oak in the lane leading south from Adbaston Church, which has sent down its roots in six branches perpendicularly through the whole length of its trunk and fastened them in the ground, which might be seen in a hole cut in the bottom of the oak; having eaten out the bowells of the old tree (as all the rest will doe) that first gave it life and then support. All which are occasioned, no doubt, by the seeds of those trees dropt by birds in the mould on the boles of the others that lyes commonly there, and is made of the annual rottings of their own leaves."

He goes on to speak of another great oak, "lying near the Lodge house in Ellen Hall Park, of so vast a bulk that my man upon a horse of 15 hands high, standing on one side of it, and I also on horseback on the other could see no part of each other"; and also of an oak that "was felled about twenty years since in Wrottesley Park which, as the worthy Sir Walter Wrottesley (a man far from vanity of imposition) seriously told me, was 15 yards in girth."—"How much less in bigness and number of tuns the oak might be that grew in the New Park at Dudley, and made the table now lying in the old hall at Dudley Castle, is not remembered, but certainly it must be a tree of prodigious height and magnitude out of which a table all of one plank could be cut, 25 yards 3 inches long and wanting but 2 inches of a yard in breadth for the whole length, from which they were forced (it being so much too long for the hall at Dudley) to cut off 7 yards 9 inches, which is the table in the hall at Corbins Hall hard by, the ancient seat of the Corbins."

In the park at Merevale Hall, Warwickshire, the seat of W. F. S. Dugdale, Esq., are a quantity of very fine and tall oaks, which rival those at Bagot's Park, and are, according to Sir H. Maxwell, of the sessile variety, though when I saw them they were not in leaf. They stand at a considerable elevation, on a dry and seemingly rather shallow red sandstone. Many of them are 100 feet and more in height, with clean trunks of 40 to 60 feet long.

The best that I could find measured as follows:—112 feet by 13 feet, with a

straight bole 65 feet long; 107 feet by 15 feet, with a clean bole of 70 feet, and probably containing about 600 feet of timber; 107 feet by 17 feet 3 inches, with a bole 48 feet long, and about the same cubic contents as the last; 114 feet by 15½ feet, bole about 60. This last is, I believe, the same tree which Mr. Dugdale had measured some years ago, when it was thought to be 133 feet high; but I do not think it can be nearly so much, the sloping ground on which it stands making a base line difficult to get. He tells me that these trees are believed to have been planted by the monks who lived at Merevale Abbey at the foot of the hill, which would make them at least 370 years old, and that most of them have now passed their best. The timber being very straight in the grain is largely used for cleaving spokes.

Chirk Castle in Denbighshire, the seat of R. Myddleton, Esq., and one of the most ancient inhabited castles in England, is in a park full of oaks, most of which I believe to be of the sessile variety. They are not of great age, having been planted, as Mr. Parker, agent for the property, told me, after the Commonwealth, but are remarkable on account of their uniformly straight boles 30 to 60 feet high. They grow on millstone-grit, where the rock comes very near the surface, on land where the pedunculate variety would not, I think, make nearly such fine trees. I only measured two, one just below the castle which was 100 feet by 11 feet 8 inches, with a straight clean bole of 60 feet; another, probably of greater age, about 90 feet by 18 feet 2 inches, was beginning to decay at the base. A curious growth is seen on an oak in this drive, a branch having grown out of one stem into another, somewhat in the same style as the beech in Plate 4 of this work.

The trees in the Great Park of Windsor have been described by many writers, and especially by the late Mr. William Menzies in a rare folio published by Longmans in 1864,¹ which gives photographs of some of the finest trees, these being, so far as I know, the first large photographic plates of trees published, and, considering the imperfect development of the art forty years ago, wonderfully good.

They show Queen Victoria's Favourite Oak, which was chosen by her late Majesty shortly after her accession, and which stands with the three other royal trees between High Standing Hill and New Lodge. This is a very well shaped tree of fair size, 70 feet high and 11 feet in girth when Menzies measured it in 1864. Now, as I am informed by Mr. Simmonds, it has increased only 9 inches in girth. Queen Anne's Oak, a very handsome tree in shape, but past its prime, though supposed to be only 400 years old, measured 60 feet in height by 15 feet 3 inches in girth. Queen Charlotte's Oak, a tree of no special beauty, was 65 feet high by 17 feet 3 inches in girth. The great Pollard Oak at Forest Gate, known as William the Conqueror's Oak, and figured in the Supplement to *Gardeners' Chronicle*, 31st October 1874, supposed by Menzies to be 800 years old, though about 37 feet in girth, and the largest in the forest, is now a wreck; but there are near the Prince Consort's chapel, and in the Cowpond grove, many beautiful tall and straight-grown oaks, one of which, growing near the culvert of the pond, measured by me in March 1904, was from 114 to 118 feet high and 10 feet

¹ *History of Windsor Great Park and Windsor Forest.*

10 inches in girth. For this tree Mr. Simmons told me, £100 was offered to make the keel of a ship forty or fifty years ago. It should live for many years, and may perhaps become the finest timber oak in Windsor Forest.

Mr. Menzies gives¹ an excellent explanation of the old custom of pollarding oaks and beeches, which has produced the picturesque veterans which are so common in most of our really old parks. For the support of the deer in winter it was customary to lop off the boughs of the oak and beech. The law required that no bough should be cut larger than a buck could turn over with its horns, and after they had been stripped by the deer these branches became the perquisite of the keepers, under the name of "fireboote," or "houseboote." Any timber fit for the navy could not be cut without the sign manual of the King, a rule yet extant; but in times of civil war, and in royal forests which were granted to favourites in the times of the Stuarts, the keepers often cut and sold as timber or firewood a great deal more than the deer needed; and notwithstanding that these matters were investigated by James I. with his national and personal thriftiness, and that the surveyors whom he employed were spoken of by the country people as "shroade and terrible men,"² these abuses increased to such a point that the growing scarcity of naval timber was a common complaint for centuries.

There is no doubt that browse or lop, being the natural winter food of deer in hard weather, is more suitable for them than beans and maize, which is now given in so many places probably to save trouble. I find in my own park that ash and elm are the favourites, and beech the next best lop for deer, and only give hay when the ground is frozen or covered with snow; but many parks are so overstocked with deer and with cattle in summer that in February and March the former must have some extra food, or a heavy death-rate follows.

Gloucestershire is not famous for fine oaks, though the Boddington Oak, near Tewkesbury, now gone, must have been an exceptionally large tree. The Newland Oak, near Coleford, is an immense pollard, with a short burry trunk no less than 43 feet in girth. An excellent photograph of it has been published as a postcard by Mr. J. W. Porter of Coleford. There are some fine ones in the Winchcombe Valley, near Sudeley Castle, one of which is 25½ feet in girth; but in the Vale of Gloucester elms are commoner than oaks, and I know none of special note, though Mr. J. R. Yorke tells me of a large tree still standing near Forthampton Court.

The largest I have seen are in Witcombe Park, the seat of W. H. Hicks-Beach, Esq., a small but picturesque park lying under the steep Birdlip Hill. Here on fertile clay soil, facing north and west, are a number of very fine trees, which, judging from the rings counted on one of the largest which has recently been felled, are not so old as they appear to be. This tree, which measured about 90 feet by 17½ feet, and contained 400 to 500 cubic feet, was only about 210 years old, and beginning to fail in the upper branches, which were dying off. The largest tree, in a very exposed position, has lost some of its biggest limbs, and measures 25 feet in girth at about 5 feet from the ground, and 50 feet round the roots at the base. A very tall, well-shaped, handsome tree, with its bole clean and straight

¹ *Op. cit.* 7.

² Arthur Standish, *The Common Good*.

for 30 to 40 feet, stands on high ground in the centre of the park; and at the bottom of the hill near the house is a pollard which seems sound, and is 24½ feet in girth at the smallest part of its trunk.

In a grove near Campden, close to Norton House, which has been lately restored by the Earl of Harrowby, I was shown a remarkably tall and clean oak over 100 feet high with a straight bole clean for 60 feet, but only 7 feet 5 inches in girth.

Near Bourton-on-the-Water, on the east side of the road to Stow, stands a pedunculate oak which, of its type, is almost equal in size to any I have seen, and which is specially remarkable on account of the perfect condition of all its branches, which, as Plate 93 shows, are growing to the very tips, and which spread over an area of 115 paces in circumference, equal to that of the Beggar's Oak. This tree grows in a grass field on the property of Mrs. Butler of Wick Hill.¹ It measures about 85 feet high by 22½ in girth, and has the appearance of having been pollarded at about 12 feet up very early in life. There are some fine tall oaks at Wick Hill, not far off, measuring 85 feet by 14 feet and 80 feet by 13 feet, and there are still some big ones in the cow pastures at Sherborne Park in the same district. But the best of these were felled fifty years ago by the father of the present Lord Sherborne, who has never ceased to lament their loss.

There are many superb oaks in Earl Spencer's park at Althorp, Northants, which were carefully measured by the former forester, Mr. Mitchell, now at Woburn. Lord Spencer's ancestors were evidently great lovers of trees, and followed a practice which is much to be admired. In Althorp Park are several inscribed stones, giving the date of planting and the name of the planter. The earliest of these is in the Heronry, and is dated 1568.

Of the others one reads as follows—

This Wood was planted by
Robert Lord Spencer
In the year of our Lord,
1602-1603

Another has the legend—

This Wood was planted
by Sir William Spencer, Knight of the Bath
in the year of our Lord
1624
Up and be doing, and God will prosper

When one sees how small are the trees planted about 300 years ago, when compared with the older trees, one realises the immense time it takes for such oaks to grow. The finest at Althorp is shown on Plate 94. It grows near a farmyard, and is No. 8 in Mitchell's list.² It measures about 90 feet in height, and carries a thick straight stem up to about 45 feet high, and girths 19 feet 6 inches at 5 feet. It must contain at least 1000 feet of timber, and is apparently sound, healthy, and growing, with no signs of decay in the top.³

There are some very fine oaks in Burleigh Park, Stamford, the seat of the

¹ In 1906 I saw this tree again, and found that a large fungus had attacked its trunk, and that some of the branches were showing signs of decay at the ends. Steps are being taken to preserve it as far as possible.

² A description of some of the finest trees at this place is given in *Trans. Scottish Arb. Soc.* xiii. 83.

³ Sir Hugh Beevor measured fifteen oaks standing on one acre in a grove planted at Althorp in 1561-1568, and found them from 100 to 115 feet high, with an average girth of 11 feet 8 inches, and the average cubic contents of the first length of 54 feet was 330 feet. In another plantation, made in 1589 on stiffer soil than the last, there were more trees per acre, but their size was less, the average being 90 feet by 9 feet 7 inches.

Marquess of Exeter. The best, known as the King Oak, is 100 feet high by 16 feet 6 inches in girth. At Ashridge the oaks are not so fine as the beeches, but the King Oak in that park is a splendid tree, measuring 98 feet by 21 feet 8 inches.

Sherwood Forest, in Nottinghamshire, contains an immense number of very ancient, picturesque, and curious oaks, many of them now mere wrecks, but preserved with care by Earl Manvers, who is the owner of a large area of the unenclosed part of what was formerly a royal forest. I have seen no other place where so many of the trees are covered with immense burrs, and where they assume such extraordinary shapes, as in that part of Sherwood Forest between Edwinstowe and the Buck gate entrance to Thoresby Park. The soil in this district is mostly a poor-looking sand on which the birch thrives remarkably. About seventy years ago the open forest which up to that time had been grazed by sheep, came into the possession of Lord Manvers. An immense quantity of seedling birch then sprang up, and large quantities of acorns were sown to fill up the vacant spaces caused by the decay of the old oaks, most of which are now stag-headed, and dead at the top.

The finest oak now standing in Sherwood Forest is the Queen or Major Oak (Plate 95). This tree, though hollow, and having its branches partly supported by iron stays, is still healthy and vigorous. It measures about 60 feet in height by 30 feet 5 inches in girth, and the spreading roots are about 18 paces round at the ground. The spread of the branches is 30 yards in diameter. It is about three-quarters of a mile from Edwinstowe, and is not far from another tree known as Simon Foster's Oak, which is about 44 feet high and 25 feet in girth.

At Welbeck, the seat of the Duke of Portland, in the same beautiful and well-wooded district, known as the Dukeries, on heavier soil than that at Thoresby, are a number of magnificent oaks which were described and figured in 1790 in a scarce pamphlet by Major Rooke. Of these I saw the Porter Oaks, so called because they stand opposite each other on each side of a gate in the park. When measured by Rooke about 1779 they were as follows:—No. 1. 98 feet high, 23 feet girth at 6 feet; contents, 840 feet. In October 1903, 25½ feet; the top having been dead for many years it is now much less in height. No. 2. 88 feet high, 20 feet girth at 6 feet; contents, 744 feet. Now it is 23 feet and rapidly decaying.

Another tree, called by Rooke the "Duke's Walking Stick," of which there is a small figure in Loudon, p. 1766, was in 1779, 111 feet 6 inches high, and 70 feet 6 inches to the first branches; at 6 feet it measured 12 feet in girth, and was estimated to contain 440 cubic feet. A very celebrated oak at Welbeck is the Greendale Oak, which has often been figured and described. In my copy of Strutt there is a good plate of this tree, without number or description, bound at the end of the volume. Tradition says that a bet was made by a former Duke of Portland, that he had an oak so large, that a coach and four could be driven through its trunk, and the hole having been cut, he won his bet. When measured by Rooke it was, above the arch of the hole, 35 feet 3 inches in girth, the hole being 10 feet 3 inches high and 6 feet wide. Even at that time Rooke's figure shows it to have been a mutilated wreck, but the tree is still alive.

Near the Greendale Oak there is a magnificent though dead specimen of burr

oak, about 50 feet high and 28 feet 9 inches in girth, and though all the veterans are long past their prime, there are still healthy growing oaks at Welbeck on the south side of the road to Norton, of which I measured one with a butt 32 feet high and 19 feet in girth, which Mr. Michie, the forester, considered would contain 500 feet in the butt alone. Such oaks have actually been cut and sold here in recent times; and I have a photograph, given me by Mr. G. Miles of Stamford, of a tree which he bought at auction for £40, and whose trunk measured 38 feet 6 inches long by 43¼ inches quarter-girth—equal to 511 feet 8 inches. It was so heavy that the weight on the wheels of the timber carriage broke through the road, and when brought to the station after much risk and trouble, the railway company refused to take it to Peterborough except on a special train by itself.

In Rockingham Park, Northants, the seat of the Rev. Wentworth Watson, there are a number of wonderful oaks, many of which are brown, and I had the opportunity, through the kindness of Mr. C. Richardson of Stamford, of seeing several of these felled in September 1903. He told me that, in the whole course of his long experience, he had never seen so many fine brown oaks together as these. The park lies high, on land which looks like oolitic limestone, the rock in some places coming near the surface; but where these oaks grow there is a good depth of loamy soil. Some of the trees which I saw lying were more or less hollow, and required no saw to bring them down. I was anxious to photograph one in the act of falling, and as the fellers were at work on one of the best, I asked them to let me know how long it would take; the roots only being then cut all round the tree. I expected that some hours would be required, but before the camera was fixed to take the tree as it stood, they suddenly called out, "stand clear," and down it came.

Plate 96 shows what the roots of these brown oaks are usually like, but if there is a foot or two of sound wood in the lower part, and the brown colour extends a good way up the trunk, they are still very valuable. I asked the fellers if they could tell a brown oak standing without boring it, and they said they could make a good guess at the colour, though they could not be sure. Probably long experience in a district where brown oak seems to be commoner than elsewhere, is the only guide, if there is one; but stories are told of men going in the night to bore such trees with an auger before trying to buy them, in the hopes of getting a bargain. From a statement sent me by Mr. Richardson, it appears that twenty-six of these trees were sold for £1100, five of them for £100 each, and contained about 8030 feet, all measured over bark, and nothing allowed for defects.

The best of this lot were eventually sold to Messrs. J. T. Williams of New York, and afterwards bought by the Pullman Company at a very high price. Mr. Richard Dean, of that Company, informs me that he considered the wood superior to any that they had previously used, and was good enough to send me some samples of the veneer made from them, which has been used in decorating their palace railway cars. The largest of these specimens measures 6 feet 1 inch by 2 feet 8 inches without a flaw, and is throughout of a uniform chestnut-brown colour, mottled with silvery patches, formed by the medullary rays, showing that it has been cut from a quartered plank.

The sandy and gravelly tracts in Essex have extensive woodlands, in which the oak is the principal timber tree. Sound oak trees with boles measuring from 16 to 20 feet in girth are scattered through the county. Oak trees of larger dimensions, many in a more or less decayed condition, have been measured and described by Mr. J. C. Shenstone.¹ Some of these I visited under his guidance in March 1907, and I think the following are worthy of notice:—At Thorrington are four trees from 27 to 31 feet in girth, decayed; at Danbury Park two trees of 31 feet in girth, decayed; at Hatfield Broad Oak the Doodle Oak, 42 feet in girth, decayed; at Havering-atte-Bower Bedford's Oak, 27 feet in girth, decayed; in Easton Park the finest tree is 80 feet by 23 feet, sound and vigorous, and there are many old pollards of great size. One of these, covered with burry growths, is 29 feet in girth; and another, on which the burr is very peculiar from its kidney-shaped lobes, is 33½ feet, of which the burr takes up 14 feet. At Marks Hall, near Coggleshall, the property of T. P. Price, Esq., there are very large sound oaks, as well as some relics of the ancient forest; the largest, which is perhaps the finest tree of its kind now standing in the county, is 90 feet by 24 feet 3 inches, and though some large branches are gone on one side it seems sound and vigorous. The only very large oak now left in Epping Forest is the Fairmead Oak, 30 feet in girth, and much decayed. At Thorndon Park, the ancient seat of Lord Petre, are many picturesque relics of the ancient forest; and at Wealside House, Brentwood, is an oak 27 feet in circumference of bole.

Mr. E. R. Pratt of Ryston Hall kindly sends me the following account of—

Kett's Oak at Ryston, Norfolk.—In the year 1547 this tree was the trysting-place of the West Norfolk rebels under the brothers Robert and William Kett. The former and the other "Governors" selected large oak trees under which their Courts sat to administer justice and regulate disorders. The Court in this case did not seem to look upon sheep-stealing as other than a necessary evil, since they left on the tree the following inscription:—

Mr. Prat, your shepe are very fat
and we thank you for that
we have left you the skinnes
to buy your ladye pinnes
and you must thank us for that.

Dimensions in 1840.		In 1906.	
On the ground level,	46 feet 6 inches.	49 feet	6 inches.
Three feet from the ground,	27 " 4 "	26 "	6 "
Five feet do.	24 " 3 "	23 "	11 "

From the photograph which accompanied this account it seems that the old tree is still fairly sound and vigorous. In an old map of the seventeenth century Kett's Oak is marked, showing that it was then known as a landmark.

Other remarkable oaks in Norfolk which I have seen are at Merton Hall, the

¹ *Essex Naturalist*, June 1904.

seat of Lord Walsingham, where the largest, now much decayed, is about 27 feet in girth; at Blickling, where an oak in the kitchen garden 95 feet high, said by Grigor to have been planted by the Earl of Buckinghamshire, has a straight clean trunk 32 feet high and 15½ in girth; and at Stratton Strawless, where there is a beautiful straight-stemmed oak close to the house clean to 40 feet high and over 10 in girth.

Cowthorpe Oak.—No oak in England has probably been the subject of so much writing as the Cowthorpe Oak, near Wetherby, which perhaps never was such a great tree as has been supposed, and is now a mere wreck. It has been figured several times, so that I need only refer those who wish to know more of it to a paper with illustrations by Mr. John Clayton, published in the *Transactions of the Botanical Society of Edinburgh*, 1903, p. 396. A comparison of the various measurements taken at different times shows great discrepancies. Mr. Clayton attempts to prove by a diagram that the decay of its roots have allowed it to settle into the ground, and thus explains the diminution in its girth, but the discrepancy between measurements taken by different people is considerable. The girth at 5 feet given by Marsham as 36½ feet in 1768, when no hollow or cavity is mentioned as existing in the tree, and the girth given by Mr. Clayton of 36 feet 10½ inches, at 5 feet 3 inches in 1893, are so nearly identical that I do not think Mr. Clayton proves his argument. Whether trees ever subside owing to the decay of their roots is to me a very doubtful point, and I have certainly seen oaks felled which, though of great age and completely hollow, were supported in their original position by a mere shell. I visited the Cowthorpe Oak in July 1906, and found that in its present condition no accurate measurement of it could be taken, a large part of one side having fallen in. I could see no evidence to support Mr. Clayton's idea that the base of the tree had sunk into the ground. The few living branches still bear acorns, from which some seedlings were raised in 1905 by Messrs. Kent and Brydon, nurserymen of Darlington.

The finest oaks in Yorkshire that I have seen or heard of are in the park at Studley Royal, which were described and figured by Loudon from drawings which I have seen in the Marquess of Ripon's library. Though I could not identify the drawings with trees now standing, Loudon gives the dimensions of the largest pedunculate tree as 80 feet by 24 feet 4 inches, and the largest sessile oak, which he says was then the largest in England, as 118 feet by 33½ feet. The best that were shown me were a pedunculate oak 80 feet by 23 feet, a good deal past its prime, and a sessile oak which I made 114 feet by 12 feet 2 inches, a vigorous and healthy tree.

One of the most remarkable oaks in England on account of its shape is the Umbrella Oak at Castlehill, North Devon (Plate 97). This tree had not altered materially during the recollection of the late Earl Fortescue, who lived to be over eighty, though it does not give the impression of very great age. It grows on a slope called Eggesford Bank, near the house, and has a clean bole about 8 feet by 6 feet 8 inches. The branches spread horizontally from one point, and form a close flat surface, of which the twigs are interlaced, and spread to a diameter of about 25 yards. Seedlings have been raised from its acorns, which do not produce this very curious habit, and attempts to reproduce it by grafts have not succeeded.

Another freak of nature is the Marriage Oak in Eridge Park, Kent, which Lord H. Nevill was good enough to show me. Here a yew and an oak have grown up together, though the two trunks, which measure 16 feet 3 inches in girth, have not combined, the yew having spread its branches widely over the top of the bole of the oak. A similar case is recorded by Mr. A. D. Webster¹ in the South Park at Holwood, Kent. Here the two trees have combined their stems into a normally shaped trunk, which girths 7 feet 10 inches at 5 feet, the yew being only 15 feet high, and spreading 36 feet, while the oak is 35 feet high with a spread of 54 feet.

Pollard oaks, when they are hollow at the top, sometimes support other trees of considerable size, which originate from seeds dropped by birds or brought by the wind. The best living instance of this that I know, is on an oak of no great size at Orwell Park, the seat of E. G. Pretyman, Esq., in Suffolk. This grows in a wood near the Decoy Pond, which is full of large self-sown hollies mixed with oaks, and looks as if it might be part of an original forest. Here a birch about 30 feet high, 20 inches in girth, is growing on the top of the oak, and has formed inside its hollow trunk what on one side seems to be a woody stem, whilst on the other side the roots are still in process of formation within the bole of the oak, which on that side is dead, but on the other has living branches.² Henry has seen a similar example on the road between Byfleet and Cobham, on Lady Buxton's property, where the birch, growing out of a stout oak bole, is 49 feet high and 8 inches in diameter.

Wistman's Wood.—After having said so much of big oaks, I must now mention one of the most remarkable oak woods in Britain, called Wistman's or Welshman's Wood, which is on Crockern Tor, Dartmoor, at an elevation of about 1400 feet. It contains a number, perhaps a thousand, of the most stunted and dwarf oaks in existence, growing among granite boulders in a very exposed and windy situation.

Wistman's Wood was described by Burt in his Notes to the second edition of Carrington's *Dartmoor*, p. 56, and also by Mr. W. Borrer.³ I am indebted to Mr. E. Squarey of Downton, Wilts, for information in a letter to him by Mr. P. F. S. Amory of Druid, Ashburton, which brings our knowledge up to date, with photographs showing the curious appearance of these trees. The *Journal of Forestry*, v. 421, in a description of them, says that no acorns are produced; but Mr. J. B. Rowe, editor of the *Perambulations of Dartmoor* (ed. 1896), in 1895 found two acorns after a long search, one of which, planted at Druid on 9th November 1902, is over 4 feet high.

In September 1868 Mr. Wentworth Buller obtained leave from the Prince of Wales to cut down one of these trees in order to find out its age. One section was sent to Kew; and another now in Mr. Amory's possession is 9 inches by 7 in diameter, and shows 163 years' growth, with distinctly marked medullary rays and several deep shakes. The bark is extremely thin, probably owing to the thick coat of moss and lichen which covered it. The slowness of growth in this tree is remarkable, no less than forty years to the inch.

¹ *Trans. Scot. Arb. Soc.* xii. 313 (1889).

² Compare Plot's account of a similar case quoted on p. 318 *supra*.

³ Loudon, *loc. cit.* 1757.

STRUTT'S OAKS

Strutt in *Sylva Britannica*, published in 1822, figured no less than twenty-one oak trees, and as I have seen a good many of these myself, it may be interesting to notice their present condition after a lapse of over eighty years.

Plate 1. The Swilcar lawn Oak in Needwood Forest was then supposed to be about 600 years old, and was 21 feet 4½ inches at 6 feet, having increased 2 feet 4 inches in 54 years. When I saw it in 1904 it was about 25 feet in girth, but nearly dead at the top.

Plate 2. The Beggar's Oak in Bagot's Park, fully described above. It measured in 1822, 20 feet; in 1904, 24 feet 1 inch.

Plate 3. The Great Oak at Fredville was in 1822, at 8 feet from the ground, more than 28 feet in girth, and contained above 1400 feet of timber. Now, I am informed by the Rev. S. Sargent, who sends me a photograph, showing that it is in good health, it measures at 3 feet, which seems to be about its smallest girth, 33 feet 6 inches.

Plate 4. The Panshanger Oak, near Earl Cowper's house in Herts, seemed to Strutt to have scarcely reached its prime, though his plate shows that the spire was already dead. It measured in 1822, 19 feet at a yard from the ground, and was supposed to contain 1000 feet of timber. When I saw it in 1905 the topmost limbs were dead or dying, and there was a large rift in the trunk on one side. The girth was 21 feet 4 inches at 5 feet.

Plate 9. The Salcey Forest Oak was a mere wreck in 1822. I know not if it still exists.

Plate 10. The Abbot's Oak at Woburn Abbey was never a very large tree, but if it is the same that I saw in 1905 it remains sound.

Plate 11. The Chandos Oak at Michendon House, Southgate, was also not a first-class oak, though a very handsome one. It was then only 60 feet by 15 feet 9 inches. Henry's measurements in 1904 were 80 feet in height and 18 feet in girth, with a spread of branches 143 feet in diameter.

Plate 12. The oak called Beauty at Fredville, not a first-class tree among great oaks and figured with a dead top, measured only 16 feet in girth.

Plate 17. The Shelton Oak near Shrewsbury I have not seen. It was a hollow tree of great age, 26 feet in girth, in 1822, and I am told that it is now a mere wreck.

Plate 18. The Bounds Park Oak, near Tonbridge Wells, was a tree in perfect health and vigour when figured by Strutt, and measured 69 feet by 17 feet 9 inches at 12 feet. It is still standing, and as I am informed by Mr. H. J. Wood, has not much changed in appearance.

Plate 19. The Moccas Park Oak was much decayed in 1822, when it measured 36 feet in girth; it still survives, but is fast going to ruin.

Plate 20. The Wotton Oak was never a first-class tree, judging from the plate, and I do not know what is its present condition.

Plate 25. The Cowthorpe Oak has been already discussed.

Plate 26. Queen Elizabeth's Oak at Huntingfield in Suffolk is, I believe, the same tree which I saw on Lord Huntingfield's property, near the Hill Farm, Strutt quotes from Davy's letters but gives no measurement. It was quite hollow in 1773, and is now divided into three great sections which lean outwards and measure in all 39 feet 8 inches in girth. It has a few green and healthy branches, and the sound parts of the shell are about a foot thick.

Plate 27. Sir Philip Sidney's Oak at Penshurst, Kent, was, in 1822, a very old tree measuring 22 feet in girth.

Plate 28. The King Oak in Savernake Forest was quite hollow when figured by Strutt, and measured 24 feet in girth.

Plate 33. The Twelve Apostles at Burley Lodge, New Forest.

Plate 34. The Squitch Bank Oak in Bagot's Park was in 1822, and still is, one of the finest in England, and is now considered by Lord Bagot the best oak in his park.

Plate 35. Two trees called Gog and Magog near Castle Ashby still survive, and, judging from photographs of them sent me by Mr. Scriven, have not changed much in appearance, though Gog has apparently lost its bark on one side. Though very picturesque, they are not well-shaped trees. The former is now 58 feet by 28 feet, at 3 feet, with contents 1668 feet; the latter is 49 feet by 28½ feet.

Plate 36. The Tall Oak at Fredville is to my eye the best shaped of Strutt's oaks, though not of extraordinary size. He says the stem went up straight and clean to about 78 feet, and the girth at 4 feet was 18 feet.

Among the trees figured in *Sylva Scotica*, a continuation of the work just cited, there is only one oak, namely, Wallace's Oak at Elderslee or Ellerslie, near Paisley. Many larger and finer oaks than this occur in Scotland. Judging from the figure it is not remarkable except from its historic interest, which seems rather mythical.

THE OAK IN SCOTLAND

The oak rarely attains in Scotland the size and vigour so commonly met with in England.¹ Mr. Hutchinson² has catalogued 151 Scottish oaks, remarkable for size; and of these only six exceeded 20 feet in girth at 5 feet above the ground; the largest recorded by him, at Lee, Lanarkshire, was 23 feet girth at 3 feet up, the total height being 68 feet. The tallest oak recorded by Hutchinson was one at Hopetoun, Linlithgowshire, 110 feet high, with a bole of 93 feet, girthing 8 feet 8 inches, but I saw no tree approaching this height at Hopetoun in 1904. In Dr. Christison's³ paper on the "Rate of Girth Increase in Trees," the average rate of increase is given for trees at the Edinburgh Botanic Garden; Craigiehall, Linlithgowshire; Pollok, Renfrewshire; and Methven Castle, Perthshire. The rate of course depends on the age of the trees, and is very variable even in the same locality. At

¹ Sir Herbert Maxwell thinks that this is not owing to soil or climate, but to the fact that Scotland was denuded of trees before the seventeenth century. Planting was carried on slowly and sporadically after the Union, and there are few planted oaks in Scotland over 200 years old.

² *Trans. Highl. and Agric. Soc. Scot.* xiii. 218 (1881).

³ *Trans. Bot. Soc. Edin.* xix. 461 (1892).

Methven, an oak planted in 1811 had attained, in 1893, 16 feet in girth, and during the last sixteen years had increased as much as 18 inches in girth.

The "Capon Tree,"¹ near Jedburgh, in 1893 was 22 feet 7 inches in girth at the narrowest part of the trunk. It divides at 6 feet into two stems, girthing 16 feet 2 inches and 10 feet 9 inches. The "Pease Tree" at Lee,¹ Lanark, measured, in 1890, 23 feet 7 inches in girth.

There is a fine oak at Methven Castle called the Pepperwell Oak, which Henry measured in 1904, 85 feet by 20 feet 4 inches. Colonel Smythe informed him that when his ancestor Peter Smythe was imprisoned in the Tower of London in 1722, his wife, though in sore straits for money, refused 100 marks for this tree.

In the shrubbery of Scone Palace, Perth, in ground which was formerly gardens belonging to a village, there is an oak, planted in 1805 (growing in black loam 4½ feet deep, resting on sand of unknown depth), which in 1904 was 102 feet high, 36 feet to the first branch, and 11 feet 4 inches in girth at 5 feet up. This shows unusually rapid growth. Near it is another oak, probably of the same age, 98 feet in height, 10 feet 8 inches in girth, with a bole of 25 feet.

The finest oak seen by Henry in Scotland is growing in front of the house at Blair Drummond, Perthshire, the seat of H. S. Home Drummond, Esq. It is 118 feet in height and 17 feet in girth, the first bough coming off at 24 feet up. This oak and a number of others near it probably date from some time after 1730, the year in which the house was built. At Drumlanrig, Dumfriesshire, there is an oak 16 feet in girth, with a bole of 22½ feet, which is estimated to contain 361 cubic feet of timber. At Dalswinton, Dumfriesshire, there are two remarkable oak stools, standing close together. The larger is 28½ feet in girth near the base; and gives off five great stems, 81 feet in height, which average 8 feet in girth.

(H. J. E.)

THE OAK IN IRELAND

The most famous oak wood in Ireland was that of Shillelagh in Wicklow, from which is derived the name formerly given to an oak stick, but now erroneously transferred to the blackthorn. From the wood of Shillelagh, according to tradition, were derived the timbers which roof Westminster Hall, and also those on the roof of the chapel of King's College, Cambridge. There is said² to be a record in St. Michan's Church, verified by "Hanmer's Chronicle" in the library of Trinity College, Dublin, which states: "The faire greene or commune, now called Ostomontoune Greene, was all wood, and hee that diggeth at this day to any depth shall find the grounde full of great rootes. From thence, anno 1098, King William Rufus, by license of Murchard, had that frame which made up the roofes of Westminster Hall, where no English spider webbeth or breedeth to this day." According to Hayes,³ the finest trees in Shillelagh were cut down in the time of Charles II. and exported to Holland for the use of the Stadt House, under which hundreds of thousands of piles were driven. In 1692 iron forges were introduced into Shillelagh; and the ruin of the wood

¹ *Trans. Nat. Hist. Soc. Glasg.* 4th Sept. 1894.

² *Woods and Forests*, Jan. 28, 1885, Suppl. p. iii.

³ *Practical Treatise on Planting*, 111 (1794).

speedily followed. Great trees, however, still remained till near the end of the eighteenth century. At that time Mr. Sisson, who had purchased large quantities of timber, was given an oak tree of his own choice as a present, and this tree was so large that though forked at the base, each stem was big enough for a mill shaft at more than 50 feet from the butt. Two pieces being appropriated to this use, he sawed the remainder into panels for coach-building, which were sold for £250. In the MSS. of Thomas, Marquess of Rockingham, it is recorded that in 1731 there were standing in the deer park of Shillelagh 2150 oak trees, then valued at £8317, the timber being rated at 1s. 6d. a foot, and the bark at 7s. a barrel. In 1780 there remained of the old reserves 38 trees, which contained 2588 feet of timber. In the adjoining woods of Coolattin, in Hayes' time, there was a considerable number of young healthy oaks, several being $7\frac{1}{2}$ feet in girth.

I visited Coolattin in 1906 and was shown many fine trees, though none were of great thickness, the best tree seen being 118 feet high with a clean bole to 40 feet and a girth of 13 feet. All the trees were *Quercus sessiliflora*.

The largest oak wood in Ireland is in Viscount de Vesci's park at Abbeyleix, Queen's County, where there are several hundred acres of trees of the pedunculate species, growing very close together, especially on the alluvial flats along the river Nore. The trees are of no great height, and have usually short boles with wide-spreading, stout branches, the largest tree measured being 21 feet in girth.

Hayes gives several instances of the remarkable growth of oak in Ireland. At Ballybeg in Wicklow, a tree growing in alluvial soil, eighty years old, was 12 feet in girth at 8 feet from the ground. At Muckross, Killarney, six trees sown in 1760 measured in 1794, from 3 feet to 4 feet 11 inches in girth at 5 feet from the ground. Ireland, renowned in ancient days for its oak timber, which was valued abroad, is now singularly wanting in even good specimens of solitary oak trees; and Loudon gave in 1838 no examples of fine oak trees growing in Ireland. The finest which have been seen by me are:—At Dartrey, Cootehill, the seat of the Earl of Dartrey, a beautiful symmetrical pedunculate oak, 100 feet high with a girth of 14 feet 4 inches; at Kilmacurragh, Wicklow, a sessile oak $14\frac{1}{2}$ feet in girth; at Glenstal, Limerick, a tree of the same species $16\frac{1}{2}$ feet in girth; and at Shane's Castle, Antrim, a pedunculate oak 19 feet in girth. There are also many fine trees with good boles at Done-raile Court, Co. Cork, the largest about 13 feet in girth. (A. H.)

REMARKABLE TREES ABROAD

As the oak is one of the most characteristic British trees we give only a few details of the remarkable oaks which we have seen on the Continent. A good account of the trees in the forests of Retz, Compiègne, and St. Amand was written by Prof. Fisher in the *Trans. Eng. Arb. Soc.* v. 205. I took part in the excursion which this paper records, and saw the splendid sessile oaks at Compiègne, of which the one called the Czarina's Oak is the finest. This is as well-grown, but not a finer tree than some of those which I have described and figured in England, though in cubic contents inferior to several of them. The French measure-

ments given on the trunk of the tree are—height 36 metres = 118 feet; girth at 1.30 metres, 5.20 metres = 17 feet; volume 32 cubic metres = 1130 feet; value £100. Mr. George Marshall, Past-President of the English Arboricultural Society, who is a timber valuer of great experience, estimated the butt of the tree to contain (46 feet by 42 inches quarter-girth) 550 cubic feet; plus 150 cubic feet for the top, making a total of 700 cubic feet; which, with the addition of an unknown quantity for the branches, always reckoned in France, plus 20 per cent for the difference between the total volume and the English quarter-girth measurement, will come near the French estimate. A photograph of an oak in the Forêt de Bellême was reproduced in this report. Its total height was $119\frac{1}{2}$ feet, and its girth at 4 feet 6 inches was 9 feet 9 inches. It is impossible to imagine a tree containing more useful timber and less waste than this tree, which has rather the appearance of a gigantic mop than of an oak as we know them. Prof. Fisher considers Bellême as the finest oak forest in France, and in the *Gardeners' Chronicle*, xxviii. 220 (1900), speaks of a sessile oak which he measured there 146 feet high, with a clean bole 113 feet by 9 feet 10 inches girth, and a volume of about 500 cubic feet.¹

Another renowned forest in France is that of Bercé near Chateau du Loir (Sarthe), visited by Henry in 1903 and in 1906, which covers 13,350 acres; and is made up of about 90 per cent of sessile oak and 10 per cent of beech. It is situated on a plateau; the soil being a deep loamy sand, poor in lime. There is not a single pedunculate oak in the forest itself, yet, curiously enough, all those in the hedgerows of the surrounding country are of this form. The sessile oak, owing to its ability to bear shade, is grown densely in the forest, and attains an astonishing height, though it is slow in growth, as far as regards diameter of stem, which averages at 200 years old only 20 inches. The best individual tree, the *Chêne Boppe*,² in 1905 measured 115 feet high, 75 feet to the first branch, and 14 feet in girth. Another tree, measured in 1906, was 125 feet total height, 92 feet to the first branch, and 8 feet in girth. In one section, containing a little less than twenty acres, there stood in 1903, aged 211 years, 1314 oaks and 268 beeches; the oaks averaging 28 inches in diameter. The total amount of the timber³ was estimated by an accurate survey in 1895 at 275,000 cubic feet, valued at £14,720, or about £740 an acre. The yield of the first and second series in this forest, 2700 acres in extent, over which felling is done in sections once every 216 years, works out at 66 cubic feet of timber per acre per annum, equivalent to a net annual revenue per acre of £2:3s. A photograph taken by Henry, shows the shape of these forest oaks, all beautiful, clean, cylindrical stems, and illustrates the way in which the

¹ Henry visited Bellême in 1906, and does not consider it to be quite as fine a forest as Bercé. The best tree seen, possibly the same as the one measured by Prof. Fisher, was 125 feet total height, 95 feet to the first branch, 10 feet 4 inches in girth, and about 425 cubic feet in volume. On referring to Prof. Fisher as to this measurement, he sends me two photographs given him by M. Granger, then Garde Général at Bellême, representing (1) the *Chêne de Brignonnais*, which is 37 metres = about 120 feet high; girth at 4 feet 6 inches, 3 metres = 9 feet 10 inches; height to the first branch, 23 metres; (2) the *Chêne Lorentz*, which is 40 metres in height = about 130 feet, girth $4\frac{1}{2}$ metres = about $14\frac{3}{4}$ feet, and 18 metres long to the point where it divides into two nearly equal stems. It therefore appears that we have in England a few oaks at least as tall, and many larger in bulk than any recorded in France.

² Near this tree Henry observed an oak bearing mistletoe on a branch at 60 feet up.

³ Huffel, *Economie Forestière*, i. pp. 370, 372 (1904). The capital or volume of wood in the forest is not diminished by its felling, but is steadily increasing slightly all the time, owing to careful management.

woodcutter, to save the seedlings beneath from damage, lops off the crown of the tree with an axe at a point below the first branch before felling the trunk.

The oaks in the German forest of Spessart have been so frequently mentioned by recent writers on Forestry that I need not say anything of them, but doubt whether they equal the oaks in some of the few remaining virgin forests of Slavonia. In 1900 I saw a splendid lot of clean straight logs 3 to 5 feet in diameter, which had been felled in these forests, and floated down the Save to Bosnabrod.

We are indebted to Dr. Simonyi Semadam Sandor, a member of the Hungarian Parliament, for an account of the oaks of Slavonia in the Forest of Brod Petevarad, which is published in a Hungarian journal called *Erdzesti Lapok*, at Buda Peth, June 1889, with photographs showing splendid clean-stemmed trees, 30 to 40 metres high, and 2 to 3 metres in diameter.

The European oak seems able to grow well in temperate parts of the southern hemisphere. In Chile it seems as much at home as in Europe, and not only grows much faster, but reproduces itself with such ease from seed on land capable of being irrigated that I saw no reason why it should not be cultivated for its timber.¹

In South Africa the original Dutch settlers planted oaks near Cape Town, and under one of these trees the Convention was signed by which the Colony was transferred to Great Britain in 1814. On 5th April 1905 my brother posted me a few acorns from this tree, the trunk of which is now hollow and bricked up. I sowed them in May to see whether they would at once revert to their proper season of growth; and out of twenty acorns, three germinated in June, and are now nice young trees, the others never coming up at all.

In North America I have seen no European oaks of any great size, though there is one in Prof. Sargent's grounds near Boston, which has puzzled several good botanists as to its origin.

INJURIES TO OAKS

The liability of the oak to be struck by lightning was noted by Shakespeare, who, in *King Lear*, Act III. Scene ii., wrote—

You sulphurous and thought-executing fires,
Vaunt-couriers to oak-cleaving thunderbolts.

Mr. Menzies says,² "Of all forest trees oaks are, in my experience, the most dangerous. If they have a large spreading head, they are shivered into shreds when struck. If they have long tapering stems, and thus can act almost as conductors, they are not so dangerous, and the lightning will run down the side, ploughing out a deep furrow. I have once seen a beech struck, an ash once, an elm once, a cedar of Lebanon once, but never any other trees, except the oak. And while the others stood comparatively singly in an open space, the oaks have been selected and struck in the midst of a thick wood."

¹ Sir W. Thiselton Dyer informs me that on the Blue Mountains of Jamaica Sir Daniel Morris found a characteristic English oak.

² *History of Windsor Great Park*, p. 8.

Several interesting particulars of the effect of lightning on oaks are given by Loudon, who also states that the oak, owing to its roots not being so liable to rot in the ground as those of most trees, is not often blown down. He describes the effect of a hurricane in October 1831, on the splendid oaks growing in Lord Petre's park at Thorndon Hall in Essex, which reminds me of a similar case in April 1890, when I saw, at Narford, in Norfolk, oaks of 2 to 3 feet in diameter broken off at 4 to 10 feet from the ground by the force of the wind, which tore up many plantations of spruce and other shallow-rooting trees by the roots.

Sir Charles Strickland tells me that a very tall young oak tree 54 feet to the first branch, and quite straight, growing at Housham in Yorkshire, nearly on a level with the river Derwent, was, in the severe winter of 1860-61, completely killed by a frost which was the severest in his recollection. Though he has no record of the temperature at Housham, yet he believes that at Appleby, in Lincolnshire, it was as low as $15\frac{1}{2}$ below zero,¹ and generally in the northern counties the thermometer went below zero. Many other oaks were killed in the woods and in the hedgerows between Malton and Pickering by the same frost.

The various insects which attack the oak are too numerous to be mentioned in detail, but are described at length by Loudon and by many other authors.

The galls, which are so common on the leaves, are produced by several species of Cynips, and the so-called oak-apples are the result of an injury by an insect of the same family.²

MISTLETOE ON THE OAK

Since the time of Pliny, who describes the worship of the oak, and especially of the mistletoe-bearing oak by the Druids, the occurrence of this parasite on the oak has always been looked on as a rarity. Loudon only mentions two trees known to him, of which one near Ledbury was cut down in 1831, and another at Eastnor Castle is still living; but we have now been able to collect many more authentic records. A paper on the subject by the late Dr. Bull of Hereford³ gives particulars of several, and states that it is considered a dangerous practice to interfere with a mistletoe-bearing oak. One at St. Diels, near Monmouth, was cut down by the bailiff about 1853, and the owner of the estate immediately dismissed him. A woodman who climbed the Eastnor tree to get some mistletoe, fell down and broke his leg, and other similar stories are quoted. The finest mistletoe oak I have seen was shown me by Sir George Cornwall, at Bredwardine, in 1902. When described by Dr. Bull, mistletoe was growing on it in no less than fifteen different places, and it measured 78 feet by 11 feet 6 inches in girth. Sir George has lately found another in his park, and has a third on his estate in Woodbury Wood.

This part of England seems to be, for some reason, the most prolific in England

¹ This is a little lower than any temperature recorded by the Meteorological Office, but the subject of meteorology as affecting trees will be discussed fully later.

² An article in the *Kew Bulletin of Miscellaneous Information*, Additional Series, v. 1906, on Oak Galls, by R. A. Rolfe, gives much information on the subject, but is too long to quote. Nearly one hundred different kinds have been described which occur on the roots, buds, leaves, stamens, ovaries, and fruit.

³ *Trans. Woolhope Nat. Field Club*, 1870, p. 68.

in mistletoe oaks; and it will be observed in the list which follows that there are none reported in the northern half of Great Britain.

The subject has been recently studied by M. H. Gadeau de Kerville,¹ who records in Normandy alone no less than 26 mistletoe-bearing oaks, living or recently felled, of which a list with exact particulars of their locality is given, pp. 298-301. An excellent illustration of one of the finest of these growing on the farm of Bois, at Isigny-le-Buat, Department of Manche, shows a large and well-shaped tree, about 60 feet by 16 feet, of the pedunculate variety, which is covered with tufts of mistletoe, some of them growing on the trunk, and of very large size. M. de Kerville estimates the age of this tree at 200 to 300 years, and says that it has begun to deteriorate, as the dead branches show. M. Eugène Ormont states that a tuft of mistletoe of about a foot in length, which he examined on an oak, was eleven years old and seemed slower in its growth and yellower in colour than mistletoe growing on the apple.

LIST OF REPORTED MISTLETOE-BEARING OAKS IN ENGLAND²

Locality.	Authority.	Date.	Particulars.
Bredwardine, Hereford,	Dr. Bull,	1870	
	H. J. E.	1902	
Moccas Park, do.,	Rev. Sir G. Cornwall,	1904

² Sir Herbert Maxwell in *Memories of the Months*, p. 285, mentions the existence of mistletoe-bearing oaks at Stoulton in Worcestershire, in Sherwood Forest, Windsor Forest, and Richmond Park.

BARK

The bark of the oak was until recently a valuable source of revenue in England, but, owing to the introduction of other materials for tanning, has now fallen so much in price that in some districts it hardly pays to take off, and large areas of coppice oak in the western counties have become almost worthless in consequence. Whether the leather made by these modern substitutes is as durable as that produced under the old system is doubtful, but the comparative slowness of the process of tanning by oak bark seems to be one of the chief reasons for the change.

Professor H. R. Procter of the Leather Industries Department of the Leeds University, whom I consulted on this question, tells me that though he agrees with me that no tree at present grown in England is worth growing for the sake of its bark alone, yet he thinks that it will be long before the demand for oak bark entirely disappears. He considers that though leather tanned with oak bark alone is perhaps the best for boots and shoes, the cost of the slow process is so much greater in proportion to quality, that the leather so tanned is practically an article of luxury.

In the *Land Agents' Record* for October 29, 1904, there is an article on the price of oak bark, which is stated to have fallen from £8 a ton in the writer's experience to 47s. 6d.; and when the cost of peeling, which averages about 25s. per ton, the cost of loading and delivering to the station, and the cost of railway carriage is added, little or nothing is left for bark grown at any distance from its market. Since then the price in some districts has risen a little, but in this case, as in others, it is clear that chemically prepared substitutes are killing an industry of much importance to landowners and labourers.

TIMBER

With regard to the difference in the timber of the two varieties of oak, we have, strange to say, little or no certain experience in England. Laslett says that though he agrees generally with the opinion then prevalent, that *Q. sessiliflora* was slightly inferior to *pedunculata*, he feels bound to admit that during a long experience in working them, he has not been able to discover any important difference between the two varieties. He says that very fine specimens of long clean oaks of the sessile form were found in the Forest of Dean, which, however, were liable both to cup and star shake, and that he is inclined to believe that these defects are less common in *Q. pedunculata*.

Though little attention is now paid to the difference of winter- and spring-felled oak timber, and it seems as if most users of wood will pay as much for the latter as for the former, yet, considering the low price of bark and the importance of durability, I should strongly advise the former being used for all first-class work.

Laslett,¹ who, as timber inspector to the Admiralty, had probably as much experience as any man of his day, and more than any one at the present time,

¹ By far the best account that I know of is in Laslett's *Timber and Timber Trees*, of which a new edition, revised by the late Prof. Marshall Ward, was published in 1894.

gives in chapter xi. many proofs in support of his opinion that winter-felled oak is better than spring-felled; though the practice he recommends was to bark the trees standing, and fell them in the succeeding winter, a custom which is still followed in some parts in England. He also states, on page 73, that having carefully examined and compared many pieces of both winter- and spring- or summer-felled logs, he found almost invariably that the winter-cut timber, after being a few years in store, was in better condition than that which had been cut in the spring. "The winter-felled logs were sounder, less rent by shakes, and the centres or early growths generally showed less of incipient decay than the spring-felled."

So much has been written about the timber of the oak that it seems unnecessary to go into very great detail with regard to this subject, especially as this timber, of which little is now required for the navy, is being ousted by iron and by cheaper imported timber from many of its former uses, and is of far less value than formerly; but though at the present time English oak is out of fashion, there is no doubt that such durable and beautiful wood must always have a considerable value to those who do not sacrifice durability to cheapness, and who have patience to wait until it has been properly seasoned, which requires from two to six years according to the thickness of the plank.

There are so many proofs of its everlasting character in the form of roofs and in the old timbered buildings which are common in Cheshire, and of which so many beautiful illustrations are given in *Country Life*, that I need not repeat them, but an extraordinary instance of its longevity when exposed to the weather was pointed out to me by the late Lord Arundell of Wardour in the ruins of Wardour Castle. This building, according to an account of it published in *The Antiquary*, November 23, 1873, was inhabited before the reign of Edward III., and was besieged and sacked by the Parliamentary army in the reign of Charles I., and blown up by its owner, Lord Arundell, in 1644, rather than allow it to remain in the hands of the enemy. An oak lintel, which must therefore have been exposed to the weather for 260 years, still remained *in situ* in 1903, and as far as I could see from below was not much decayed.

In a paper by W. Atkinson¹ it is said that during the last thirty years he had taken every opportunity of procuring specimens of wood from old buildings, and particularly what the carpenters called chestnut, but never in a single instance had he seen a piece of chestnut, the wood so called being always that of *Q. sessiliflora*, mistaken for chestnut from a deficiency of the flower or silver grain. He goes on to say: "The roof of Westminster Hall has been said to be chestnut; while it was under repair I procured specimens from different parts of the roof, the whole of them were oak, and chiefly the *Q. sessiliflora*. Most of the black oak from trees dug out of the ground I have found to be of the same kind. From finding the wood of the oldest buildings about London to be chiefly of the *Q. sessiliflora*, I should suppose that some centuries ago the chief part of the natural woods were of that kind; at present the greater part of the oak grown in the south of England is *Q. pedunculata*. Specimens of oaks that I have procured from different parts of

¹ *Trans. Hort. Soc. Second Series*, i. p. 336 (1835).

Yorkshire and the county of Durham have all been *Q. sessiliflora*, which is very scarce in the south. There are some trees of it at Kenwood, the Earl of Mansfield's, near Highgate, which I believe to be one of the oldest woods near London, and a greater part of the *Q. sessiliflora* appears to be trees from old stools." To this the Secretary, Mr. G. Bentham, adds a note, as follows:—"Mr. Atkinson's opinion on this subject is confirmed in a remarkable manner by the discovery that the oak in an extensive submarine forest near Hastings is *Q. sessiliflora*."

BROWN OAK

In a paper on British timber which I read before the Surveyors' Institution in February 1904,¹ I called attention to a form of oak timber, known as "brown oak," which does not appear to have been much noticed by any previous writer.² Though after very careful investigation I have failed to ascertain with certainty the causes which produce it, I am inclined to believe that it is not, as some have thought, caused by a fungus; though spores of some fungoid mycelium are often found running through it; but that the change of colour is produced, especially on certain soils and in certain localities, by age. And though I have evidence that in exceptional cases the heartwood of quite young oaks is brown,³ the majority of the trees which produce this beautiful and valuable wood are in an incipient stage of decay, and often hollow, leaving only a shell of more or less sound wood. The change of colour in some trees commences at the ground and extends upwards, or less commonly begins in the upper part and extends downwards. No one can be certain, without boring or felling the tree, whether the wood is brown or how far the colour may extend; but if the tree is allowed to stand too long after it has become brown it loses its "nature," to use a carpenter's expression, and is often so shaky and full of cracks that it is of little use. The sapwood always remains of the normal colour. But when a brown oak of good rich colour contains sound and solid timber it is superior to any wood I know for the interior decoration of houses, and for the making of sideboards and other heavy furniture.

Until about fifty years ago this wood was little valued in England, and I am told that on the Duke of Bedford's estate its use was prohibited in building contracts because it was supposed to be unsound. Even now it is hardly known or recognised as valuable except in certain parts of England, and is often sold far below its real value by inexperienced persons. But the Americans have created such a demand

¹ *Trans. Surveyors' Institution*, vol. xxxvi. pt. vii.

² Laslett, ed. 2, p. 96, only says of it, "and even when in a state of decay or in its worst stage of 'foxiness,' the cabinetmaker prizes it for its deep red colour, and works it up in a variety of ways."

³ Mr. Alexander Howard tells me that he has seen a group of young oaks felled in Essex, which were not more than 12 to 18 inches in diameter, all perfectly sound, in which the wood was of a rich brown all through the trunk up to and beyond the first main branch. He purchased near Chelmsford a very fine oak which had no less than five secondary trunks growing out of the butt, all of a very rich brown colour, and a number of younger trees growing near it in the same park also proved to be of the same colour. Thus it seems that though the conditions of the soil have some influence, yet the colour may in some cases be inherited. Mr. Howard has inquired for many years but never heard of a brown oak on the continent, and believes it to be only found in this country. Some woodmen in Essex have thought that the trees which carry their leaves longest in winter produced "red oak," which is the local term for brown oak, but I could get no definite proof of the truth of this idea.

for it, that most timber merchants are now quick to appreciate the difference between brown and common oak, and the best qualities of it are sometimes sold for as much as 10s. per cubic foot.

When the wood shows the blackish streaks running through it, which is known as tortoise-shell grain, it is most valued for cutting veneers. These are laid in thin sheets on other wood, partly to make it go farther, and also because this wood is so difficult to season properly, and so wasteful in conversion that it is not safe to use in the form of thick boards.

My friend, Dr. Weld of Boston, U.S.A., who is a great connoisseur and admirer of fine woods, and especially of brown oak, showed me at his house the most magnificent specimens of panelling and wainscoting, done under his own supervision by Messrs. Noyes and Whitcombe of Boston, with oak which he selected and purchased himself in England. In their works I saw a quantity of carved brown oak pews, and a very large brown oak organ front designed by Mr. C. Brigham, architect, of 12 Bosworth Street, Boston, for a memorial church at Fairhaven, Mass. Mr. Whitcombe was good enough to show me the manner in which the boards are seasoned after they are cut from the logs, which are imported in the rough as an unmanufactured product to escape the heavy duty. Dry white pine boards fresh from the hot-air kiln are laid on each side of the oak boards, and properly stripped in an open covered shed. When the moisture has been partially absorbed, they are all turned over and again sandwiched between fresh dry pine boards; thus saving a great deal of time, which is rarely given to season timber properly in America, and preparing the wood to stand the conditions of dryness, which are more trying to furniture in American than in English houses.

Mr. C. M'Kim, a distinguished American architect, writes me as follows respecting English oak:—"We regard it as the most beautiful oak in the world, costly because of its scarcity and the duties imposed upon it; requiring the best workmanship in putting it together; but preferred above all others for its finer quality, richer colour, and endurance. The most important and dignified panelled rooms in this country are furnished in English oak." I also was pleased to find that the great dining-room in the White House at Washington is completely panelled with English brown oak.

Mr. F. H. Bacon of the A. H. Davenport Company of Boston, one of the best firms for cabinet work in the United States, writes:—"Mr. Davenport has been using it in his business for at least thirty years, and we think it is a wood which will always be in demand, as a room furnished with English oak has a richness and depth of tone which is impossible to get with any other oak. The wood is becoming more expensive, but I think it will always be used by people who can afford it. It is difficult to work; the plain surfaces are generally veneered. It stands perfectly well without warping and twisting, and is not attacked by worms as walnut wood is."

The best example that I have seen of fine brown oak work in England is at Rockhurst, the residence of the late Sir Richard Farrant, in Sussex. This

was done by Marsh, Cribb, and Company of Leeds, with brown pollard oak, showing very varied figure, and superior in this respect even to that of Dr. Weld's house.

This wood requires no varnish, but when simply polished with wax and shellac only, in the manner adopted by Dr. Weld, is as rich as any mahogany. It is to some extent imitated by a practice called fuming, which is now very commonly used to give a darker colour to foreign oak, and thus make it resemble old oak, which has become so fashionable; but fumed oak can easily be distinguished from, and is far inferior to real brown oak, which also varies a good deal in colour when new.

POLLARD OAK

There is another form of oak wood usually called pollard, which is produced from the burrs or swellings which often appear on old oaks, especially in very dry and in wet ground. The real cause of these excrescences is not yet fully explained; but in some places, and especially in Sherwood Forest, they are very common, and when cut, show a twisted and contorted grain, sometimes full of little eyes which resemble those of the so-called "birds'-eye maple," a variety of the wood of American maple, of which we shall speak later.

Pollard oak is usually full of little cracks, and is best cut into thin slices or "plating" $\frac{1}{8}$ inch thick or less. When polished the little cracks are filled up, and when the wood is mottled with brown, yellow, and pink in various shades it is very beautiful. An oak of this type, which was only about 10 feet high and 9 feet in girth, grew on Chedworth Downs, Gloucestershire, and was given to me by the Earl of Eldon. Its wood, when cut into veneer, was throughout the whole thickness of the tree more like that of birds'-eye maple than oak, and has served to make the front of a very handsome bookcase.

OAK PANELLING

I cannot pass from this subject without alluding to the use of English oak for panelling walls, a practice which was almost universal in houses built in the sixteenth and seventeenth centuries, and of which many beautiful examples still exist. Modern architects, however, do not seem to have properly appreciated, that the beauty and fitness of oak for such work depends on the extent to which the "figure," "flower," "silver grain," or "flash" is shown—all these terms are used to express the bright glossy patches and lines which the medullary rays of oak show when cut "on the true quarter."

In our ancestors' time, when roads were bad or non-existent, and when sawmills were unknown, it was necessary to cut up large oak trees where they fell, either by digging a saw pit near or under them, or by cross-cutting them into suitable lengths, and then "rending," cleaving, or splitting them into slabs. This practice is now adopted principally for making oak palings and for wheel spokes, which are much stronger

when rent than when sawn; but it will be found on examination of the back of old panelling that it was usually rent, and as you can only cleave oak on the line of the medullary rays, the figure shown by rent oak is much better and more abundant than when sawn on the quarter, and though the practice is more wasteful and is only possible in the case of straight-grained trees, yet it should certainly be tried by those who admire finely figured oak.

Strange to say, the importance of selecting and matching the figured pieces, and of placing them in the most conspicuous positions, does not seem to be noticed, for I have seen in modern houses, and in old castles on whose restoration no expense has been spared, panelling in which new and plain pieces have been introduced amongst splendid old panels, and finely figured new and old panels put in dark corners where they were unseen. When one considers how small a proportion the cost of the wood bears to the workmanship, it is extraordinary that this should be allowed, or that American oak should be used, as I have seen sometimes done, in restoring ancient houses, when infinitely better and more beautiful wood was growing, and often rotting on its roots, within a very short distance.

Experienced cleavers are not to be found in every county, but in Kent, Surrey, Sussex, and Hants, and where rent oak palings are much used, as in the neighbourhood of London, such men may be found, who with a tool called a "break-axe" or "flammer," will convert straight-grained oak into slabs of suitable dimensions for panelling, which, when properly seasoned, show better figure than sawn timber. For this purpose logs of not less than three feet diameter should be selected, as straight as possible in the grain, and cut into the lengths of which the panels are required. The slabs come out rather irregular in size, and are, of course, much thicker on the outside. They should be carefully piled for about twelve months in a dry, airy place, when they can be reduced by a thin circular saw and by planing to the proper thickness, choosing whichever side shows the best figure for the face. Longer and narrower pieces, either rent or sawn, must be selected for the stiles and rails, and if put together by a competent joiner, I can say from experience that the effect will be much superior to work done by the best London firms with foreign timber, especially when brown oak can be found fit for rendering.

The diagram, Fig. 1, on the following page shows the best method of rending oak to show its fine figure.

For quartering by the saw different methods are adopted, the best being that shown on the following page, Figs. 2 and 3, taken, by permission of Messrs. Rider and Son, from a very useful little book.¹ By this method, which, though rather wasteful, produces the best results, only the central boards of each cut are on the true quarter, and the others are narrower, and more or less across the natural line of cleavage.

Of the different styles of oak panelling it is not my intention to speak, but it seems to me that elaborate carving is out of place in such wood as this, which wants no extraneous adornment. Many beautiful specimens of ancient panelling in various

¹ *English Timber and its Economical Conversion*, London, 1904.

styles may be seen in the galleries of the South Kensington Museum, among which that taken out of Sizergh Castle, Westmoreland, is, though rough in workmanship, a good example of ornamentation with native wood.

One of the most elaborate instances of room-decoration in woodwork of old times is seen in the dining-room at Gilling Castle, near York, formerly the property of the Fairfax family, now belonging to W. S. Hunter, Esq. It is a room about 30 by 20 feet, and is panelled with large panels of oak, in oblongs 2 feet 4 inches wide and 3 feet deep, surrounded by heavy carved mouldings. Each panel is inlaid with highly intricate and varied geometrical patterns in narrow lines of black and white wood, which I believe to be bog oak and holly, inlaid in narrow lines, and forming an elongated diamond in the middle of the panel. The four corners of each

FIG. 1. (1) Sapwood; best taken off. (2) Feather-edged boards somewhat variable in width and thickness, but following the natural line of cleavage on the medullary rays of the wood.
FIGS. 2 and 3. Methods of quartering by the saw.

panel are also inlaid with flowers done in similar wood. This work runs from the ground up to about 10 feet high, above which an elaborate decoration in colour, containing many family trees and coats of arms, reaches to the ceiling. Some good judges think this is the most beautiful room in England, but without resorting to such minute and fanciful patterns, I may safely say that good plain oak panelling, in which the stiles and rails are duly proportioned, and the silver grain well matched in each panel, gives not only the handsomest and richest effect of any wall covering I know, but is also the most durable, improving in colour with age, and if done with one's own timber, affords an interest which no Italian frescoes or plaster work can give.

In the chapel, in the hall, and in the Earl's study at Powderham Castle, Devonshire, are very good examples of pews and panelling, both of the linen pattern and carved panels, but though the linen pattern was once a favourite one, and is still copied by some decorators, it seems to me a mistaken notion to imitate the folds of a textile material in wood, and especially in oak.

WAINSCOT OAK

What is usually known under this name was for many years imported from the Baltic seaports of Dantzic, Riga, and Libau, and was the produce of forests in the interior of the Russian Baltic Provinces, and of Russian Poland, from whence it was brought to the coast by water, until railways were made. According to Laslett, the Riga timber, though of moderate dimensions, had the medullary rays more numerous and better marked than the Dantzic oak, and came to market in the form of hewn billets of about 18 feet.

But as the supplies of this oak became less, and the demand greater, a fresh source of supply was found in Slavonia and South Hungary, which for many years has furnished about half the total import through the ports of Trieste and Fiume. Mr. A. Howard tells me that the size and quality of this was better than the Baltic oak, but owing to the Austrian Government having recently diminished their cuttings in consequence of the rapid diminution of mature timber, a large quantity of billets are now exported from Odessa, which are believed to come from the forests of Podolia and Volhynia, and other provinces of South-West Russia.

All this imported oak is milder and more easily worked than English oak, and as only selected logs free from knots are shipped, it can be converted into boards with less waste and risk than home-grown timber. We have no certain evidence as to the existence of a sufficient quantity in Russia to keep up the supply either from the Baltic or Odessa, and though the more scientific foresters of Austria are taking steps to restore their oak forests by natural regeneration, it is probable that the French, who consume an immense quantity of oak from this region, will take all they can get, and this, coupled with the approaching disappearance of American oak large enough for quartering, must, sooner or later, cause our own timber when long and clean to be much more valuable than it is at present.

A note in Holinshed's *Chronicles*,¹ vol. i. p. 357 (ed. 1807), seems to show that wainscot oak was already exported from the Baltic as long ago as Queen Elizabeth's reign, but whether "Danske" means that it came in Danish ships or from the port of Dantzic I cannot ascertain, though Colonel Brookfield, H.B.M. Consul at that port, has made inquiry on the subject.

Laslett is the only practical English writer I know of who was personally acquainted with the oak in its native forests in the east of Europe, having been employed by the Admiralty to survey the forests near Brussa, in Asia Minor, as well as in Bosnia, Herzegovina, Croatia, Styria, and Hungary. He states that in the

¹ According to Mr. J. C. Shenstone, Harrison of Redwinter in Essex, who lived in the reign of Henry VIII., was the author of this note. "Of all oke growing in England the parke oke is the softest, and far more spalt and Prickle than the hedge oke. And of all in Essex, that growing in Bardfield parke is the finest for joiner's craft; for often times have I seene of their workes made of that oke so fine and faire as most of the wanscot that is brought hither out of Danske, for our wanscot is not made in England. Yet diverse have assaied to deale with our okes to that end, but not with so good successe as they have hoped, because the ab or juice will not so soone be removed and cleane drawne out, which some attribute to want of time in the salt water."

forests south-east of Brussa he found oaks resembling the English *Q. Robur* on the upper ranges of the mountains, while in the valleys *Q. Cerris* or the mossy-cupped oak was found. In Austria, he says, that in the Kogarate mountains, and in the district between the rivers Verbas and Okvina they were chiefly of the sessile variety, mixed occasionally with *Q. Cerris*, and all of straight growth with long clean stems, generally of good quality, but at that time no attempt had been made to utilise them except for cleaving cask staves.

Of all the oaks of which trials were made in our Government dockyards during the period at which British oak became scarce, Laslett says that the white oak of North America compared very favourably with all the foreign oaks, but proved to be slightly inferior in strength to English oaks.

BOG OAK

This is obtained from trees which have been buried in peat bogs for centuries, and which has become blackened by the peat water. It is very commonly found in Ireland, and in some parts of England and Scotland. When large and sound enough it is used for furniture, picture frames, and for small ornamental work, but as a rule is so full of shakes, and cracks so much in drying after it is dug up, that it is of no use for cabinet-making except in the form of inlay, or marqueterie. Occasionally, however, fine sound logs are dug out, which if slowly seasoned in an airy cellar may be used for larger work. One of the best examples I have seen of black oak was a door exhibited by Mr. E. R. Pratt of Ryston at the Royal Agricultural Society's Show at Park Royal in 1905, made from oak found on his property in Norfolk. He tells me that the planks after being sawn are dressed two or three times with "fuel" or "dead" oil which replaces the evaporated water by the refuse of petroleum, a substance theoretically similar to that lost by age. The result is certainly very successful.

Many cases have been recorded and published of the great durability of the timber of the oak under ground and under water; but I have come across no relic of the past so interesting in this respect as the prehistoric boat which was dug up at Brigg, in Lincolnshire, in 1884, when digging a foundation for a gasometer. This has been well described by the Rev. D. Cary Elwes in a lecture, which was published in 1903,¹ and a photograph of it is published in a recent pamphlet by the Rev. A. N. Claye,² for which I am indebted to Miss Woolward. This wonderfully preserved dug-out was hollowed out of one huge oak log 48½ feet long, and approximately 6 feet in diameter, which showed no signs of branches, a log which must have contained nearly 1000 feet of timber, and which could not be matched now in England, or, so far as we know, in Europe or North America. The boat is 4 feet 3 inches wide by 2 feet 8 inches deep at the bows, and 4 feet 6 inches by 3 feet 4 inches at the stern, which was the root end of the tree. The sides are about 2 inches thick, the bottom 4 inches at the bows, and as much as 16 inches at the stern. The stern piece was

¹ *A Prehistoric Boat*. Stanton and Son, Northampton.

² *Brigg Church and Town*. Jackson, Brigg.

ingeniously fitted in, though not found *in situ*, and a large rift on one side had been still more cleverly repaired with wooden patches caulked with moss. No metal had been used in any part of it. The boat was found embedded in the blue and brown clay which underlies the peat, and is considered on geological evidence, which is given with great detail, to be from 2600 to 3000 years old. It was offered by Mr. Cary Elwes to the British Museum, but was declined as being too large; it is, however, now suitably housed at Brigg.

Many similar oaken boats of smaller dimensions have been discovered in various parts of England, and I saw one myself which had been just dug out of a peat bed close to Shapwick Station, in Somersetshire, in September 1906, which was 20 feet long by 2 feet 10 inches wide.

At Brigg an ancient causeway was discovered, which is described by Mr. Claye in the same pamphlet, and a photograph given. This roadway was found in a brickyard lying between the two branches of the river, under a deposit of blue alluvial clay, and above the forest bed which lies on the top of the glacial drift, and was probably made by the early Britons to secure a safe passage across the valley when it was little more than a swamp. Small trees and branches of yew were laid lengthwise, and across them rough planks of oak, which were fixed in their place by long wooden pins driven through holes at each end. From the photograph the wood appears to have been well preserved, but having been covered up again shortly after the excavation was made, I can give no further details of its condition. In the same place was discovered a sort of raft or flat-bottomed boat, 40 feet long and 6 feet wide, which was also covered up again. From the illustration given, this seems to have been made of five logs placed side by side, and held together by cross ties passing through holes in projections on the upper side of the logs.

In the foundations of Winchester Cathedral, oak piles had been used to form a solid foundation in the wet peaty soil on which part of the structure rested. When the Cathedral was under restoration in 1906, samples of these piles sent me by Mr. Jackson, the architect of the work, who said that they were put down in the time of William Rufus, were in places decayed. Some logs of beech laid horizontally under the same building, which Mr. Jackson attributes to Bishop de Lucy, about A.D. 1206, remained comparatively sound, and, though the wood has changed from its natural colour to a grey, is fit to use as boards for book-binding.

With regard to the foundations of the Campanile at Venice, it has been stated that they were laid on larch piles, which are still used in that city for the same purpose; but when I was at Venice in 1905 I inquired into this, and was given a section of an oak pile only about 6 inches in diameter, but perfectly sound and very hard, which was cut from one of the piles taken from the foundation of the Campanile after it fell.

(H. J. E.)

Abies, A. L. de Jussieu, *Gen.* 414 (in part) (1789).

TREES belonging to the order Coniferæ, with thick scaly bark, irregular and not whorled branches, and deciduous foliage. Branchlets of two kinds, long shoots bearing solitary leaves spirally arranged, and short shoots bearing numerous leaves in tufts at their extremities, these leaves being of unequal lengths and arising each in the axil of a bud-scale. Leaves linear, either flattened or keeled above, always strongly keeled beneath, with a single fibro-vascular bundle and two resin-canals close to the epidermis of the outer angles. Buds of three kinds: (1) terminal on the long branchlets and developing either into long or short shoots; (2) axillary on the long branchlets, scattered, solitary in the axils of the leaves, and developing occasionally into long shoots, or more commonly producing short shoots with apical tufts of leaves; and (3) apical buds on the short shoots, which usually on developing slightly prolong the short shoot and produce again a tuft of leaves, this process being repeated for several years; or occasionally suddenly elongate into long shoots with solitary leaves, or produce flowers. In this way a complicated and irregular system of branching results, very different from that produced by the regular whorled buds of pines, silver firs, and spruces.

Flowers monœcious, fertilised by the wind, arising solitary on the apices of short shoots of two to six years old. Male flowers always much more numerous than the females, directed downwards; globose, ovoid or oblong; sessile or stalked, surrounded at the base by scales, and composed of numerous stamens with short stalks spirally arranged on a central axis; anthers two-celled, dehiscing longitudinally; connective rounded. Female flowers always erect, subglobose, girt at the base by a bundle of leaves, and consisting of a series of orbicular, stalked, ovular scales, each in the axil of a much longer mucronate, oblong bract. The scales, each bearing two ovules, increase in size, as the flower develops into the fruit, while the bracts do not increase.

Fruit a cone, short-stalked and always erect, composed of concave imbricated woody scales, which are persistent and are either longer or shorter than the bracts; cones ripening at the end of the first season, the scales opening and letting out the seeds, which are distributed by the wind in autumn or in the following spring, the

empty cones remaining on the branches for several years. Seeds, two on each scale, with a translucent wing, which remains coalesced with the seed, covering it entirely on the upper side, and extending for some distance along its outer edge.

The genus is confined to the temperate and colder regions of the northern hemisphere, and comprises about fourteen described species. Four of these, which we have not seen either growing wild or in cultivation, will now be briefly alluded to.

Larix Cajanderi, Mayr, *Fremdländ. Wald- u. Parkbäume*, 297, fig. 88 (1906). Discovered by Dr. Cajander in eastern Siberia, where it occurs along the banks of the river Lena from the mouth of the Aldan at 68° N. lat. northwards to 72° N. lat., becoming here a stunted tree only 10 to 20 feet in height. It usually forms mixed woods with the Siberian spruce or *Betula odorata*, assuming in wet soil the same appearance as is presented by *L. americana* in the swamps of Wisconsin; or on unflooded land growing pure to a height of about 70 feet. Judging from the description it is closely allied to, if not a mere variety of, *L. dahurica*. The young branchlets are yellowish brown with scattered hairs, older branchlets becoming ashy grey. The leaves are very long, up to 2 inches in length; and are accompanied on the opening of the bud by a tuft of dense whitish pubescence, which is absent in *L. dahurica*. The cones are small, with about twenty scales, which gape widely when ripe, and are broad and concave on the upper margin.

Larix Principis Rupprechtii, Mayr, *op. cit.* 309, figs. 87, 94, 95 (1906). This species was discovered by Mayr on the Wu Tai mountain in the province of Shansi in northern China; and appears to resemble strongly the European larch, from which it differs in the cone-scales being finely denticulate and glabrous, with bracts short and only visible towards the base of the cone. This species has been introduced into Europe by Mayr, who brought a living plant to Grafrath, near Munich, which is growing there very vigorously.

Larix kamtschatika, Carrière, *Conif.* 279 (1855); *Abies kamtschatika*, Ruprecht, *Beit. Pflanzenkund. Russ. Reich.* ii. 57; *Pinus kamtschatika*, Endlicher, *Conif.* 135 (1847). This species, which occurs in Kamtschatka, is said to differ from *L. dahurica* in having larger cones. It is imperfectly known, and has not been introduced.

Larix chinensis, Beissner, *Mitteil. Deutsch. Dendrol. Gesell.* 1896, p. 68, and 1901, p. 76; and *Nuov. Giorn. Bot. Ital.* iv. 183, t. 5 (1897). A tree, dimensions of which are not stated. Branchlets yellow, glabrous. Leaves up to 1¼ inch long, triangular in section, stomatose on the under surface. Cones ovoid-cylindrical, 1½ to 2 inches long; scales numerous, orbicular, entire, coriaceous, furrowed and tomentose on the outer surface, standing horizontally in the opened cones; bracts lanceolate, truncate at the narrowed apex, with a short mucro, extending considerably beyond the upper margin of the scale, and appressed and not recurved in the unripe cone. Seeds about ¼ inch in length with a broad wing slightly exceeding the seeds in length.

This species, specimens of which I have recently seen in the Museum at Florence, was discovered at 10,000 feet altitude in the Peling mountains of Shensi in China by Père Giraldi in 1893. Beissner has raised seedlings from seeds sent in

1899, and some of these have been grafted on the common larch and are now growing in the Arnold Arboretum, Massachusetts.

This larch in botanical characters stands nearest to *L. occidentalis*. Occurring at a high elevation in Shensi at about lat. 38°, it should prove perfectly hardy in this country; but must not be expected to be of much importance as a forest tree.

The remaining species, ten in number, are tolerably well known, and are readily distinguishable by the characters of the cones and flowers. In the absence of cones, the following arrangement will give a good clue to the species:—

A. *Leaves deeply keeled on both surfaces.*

1. *Larix Lyallii*, Parlatores. Western N. America.

Young branchlets completely covered with a dense greyish tomentum, which persists in part in the second year.

2. *Larix Potanini*, Batalin. Western China.

Young branchlets bright yellow in colour, with a scattered pubescence.

B. *Leaves keeled only on the lower surface, the upper surface being flattened or rounded.*

* *Young branchlets pubescent.*

† *Leaves glaucous, bluish, with two conspicuous bands of stomata, each of five lines, on the lower surface.*

3. *Larix leptolepis*, Endlicher. Japan.

Branchlets of the second year reddish, with a glaucous tinge. Leaves numerous in the bundle, at least forty, long and slender, arranged in an erect cone-like pencil.

4. *Larix kurilensis*, Mayr. Kurile Islands.

Branchlets of the second year shining reddish brown, pubescent, not glaucous. Leaves few in the bundle, often only twenty to thirty, short and very broad, spreading so as to form an open cup around the bud.

†† *Leaves greenish, with two inconspicuous bands of stomata, each of two to three lines, on the lower surface.*

5. *Larix Griffithii*, Hooker. Himalayas.

Branchlets of the second year very stout, dull reddish brown, pubescent. Short shoots broad and fringed above by very large loose reflected pubescent membranous bud-scales.

6. *Larix occidentalis*, Nuttall. Western N. America.

Branchlets of the second year slender, light brown, shining, pubescent. Short shoots slender, with narrow inconspicuous fringe of bud-scales.

7. *Larix sibirica*, Ledebour. Russia, Siberia.

Branchlets of the second year slender, shining, greyish yellow, glabrous, the long hairs present in the furrows between the pulvini of the first year's shoot having fallen off. Leaves very long and slender, up to 2 inches in length.

** *Young branchlets glabrous.*

† *Branchlets yellowish grey in colour.*

8. *Larix europæa*, De Candolle. Europe.

Branchlets of the second year shining, glabrous, yellowish grey.

8A. *Larix sibirica*, Ledebour, *var.* Russia.

In certain specimens of this species the branchlets are indistinguishable from those of *Larix europæa*, and in the absence of cones only show a difference in the leaves, which are very long and slender in *L. sibirica*.

†† *Branchlets brown in colour.*

9. *Larix americana*, Michaux. North America.

Young branchlets often glaucous. Branchlets of the second year shining brown. Short shoots blackish. Leaves short, not exceeding $1\frac{1}{4}$ inch in length.

10. *Larix dahurica*, Turczaninow. Siberia.

Young branchlets never glaucous. Branchlets of the second year shining brown. Short shoots blackish. Leaves long, exceeding $1\frac{1}{4}$ inch.

These two species strongly resemble each other in technical characters, but are readily distinguished, as seen in cultivation in this country, by the appearance of the branchlets, which in *L. dahurica* are vigorous, long, and straight, whereas in *L. americana*, which makes slow growth, they are short, curved, and twisted.

10A. *Larix occidentalis*, Nuttall, *var.* In glabrous specimens of this species the chestnut-brown coloured short shoots will readily distinguish them from either of the two preceding species.

Mayr says that though the various species of larch seem very different at the first sight, yet that they all have the same biological character, and are all inhabitants of the coldest limits of the forest, whether produced by latitude or altitude, and that when introduced into warmer regions or zones, they lose their economic usefulness through premature fruitfulness or fungoid attacks. This opinion, though so often expressed in various forms by foresters of continental experience, is not strictly applicable to Great Britain, as the pages of this work will prove; and though the liability to spring frost is greater with the more northern and alpine species, yet in their native countries larches are also subject to frosts during almost every month in the year, and though the young shoots in spring and the unripened wood in autumn are often much injured by frost, yet no trees have a greater power of recovering from injuries produced by climatic influences, provided the soil is suitable; and Mayr truly says that the warmer the climate in which the larch is cultivated the better the soil it requires. He considers that the timber of all larches is practically of equal value, its quality depending on the slowness at which it is grown, rather than on the species or origin of the parent tree.

LARIX EUROPÆA, COMMON LARCH

Larix europæa, De Candolle¹ in Lamarck, *Fl. Franç.* 3rd ed. iii. 277 (1805); Loudon, *Arb. et Frut. Brit.* iv. 2350 (1838); Willkomm, *Forstliche Flora*, 140 (1887); Mathieu, *Flore Forestière*, 555 (1897); Kent, *Veitch's Man. Coniferae*, 391 (1900).

Larix decidua, Miller, *Dict.* ed. 8, No. 1 (1768); Kirchner, Loew, u. Schröter, *Lebengesch. Blütenpfl. Mitteleuropas*, 155 (1904).

Larix pyramidalis, Salisbury, *Trans. Linn. Soc.* viii. 314 (1807).

Larix vulgaris, Fischer, *ex Spach, Hist. Vég.* xi. 432 (1842).

Larix Larix, Karsten, *Pharm. Med. Bot.* 326 f. 157 (1882).

Pinus Larix, Linnæus, *Sp. Pl.* 1001 (1753).

Pinus læta, Salisbury, *Prod.* 399 (1796).

Abies Larix, Poiret in Lamarck, *Dict.* vi. 511 (1804).

A tree attaining 100 to 150 feet in height² and 10 to 15 feet in girth. Bark of young stems and branches smooth and grey; on older stems (twenty years and upwards) fissuring and scaling off in thin irregular plates, exposing the reddish cortex below; at the base of old trunks in the Alps becoming extraordinarily thick, a foot or more. Young branchlets slender, glabrous, greyish yellow, with linear pulvini separated by narrow grooves; in the second and third year shining yellow with more elevated pulvini, at the apices of which are the scars of the fallen solitary leaves; base of the shoot girt by a sheath of the bud-scales of the previous season, within which is visible a ring of pubescence. Short shoots dark brown, with rings of pubescence marking each year's growth. Terminal buds small, globose, resinous, with glabrous scales, the lowermost of which are subulately pointed. Lateral buds hemispherical, glabrous, broadly conical, surrounded at the base by a dense ring of hairs.

Leaves light green, soft in texture; those solitary on the long shoots shorter, broader, and more acuminate than those in the tufts, the latter differing in length, the longest about $1\frac{1}{2}$ inch long, and rounded at the apex; upper surface flat or rounded, with one line of stomata on each side; lower surface deeply keeled, with two to three lines of stomata on each side.

Male flowers sessile, ovoid, $\frac{1}{8}$ to $\frac{2}{8}$ inch long. Pistillate flowers, reddish or occasionally whitish, ovoid, about $\frac{1}{2}$ inch long; bracts, with their mucronate apices pointing upwards and outwards and not reflected or recurved, about $\frac{1}{4}$ inch long, oblong, widest at the base, deeply notched above between two pointed projections; mucro about $\frac{1}{2}$ inch long.

Cones ovoid, with the tips of the bracts slightly exerted, $1\frac{1}{4}$ to $1\frac{1}{2}$ inch long,³ the terminal scales small and not gaping but closing the rounded or flattened apex of the

¹ We adopt the name *Larix europæa*, although it is not the oldest one, because it has been in general use for over a century. According to a note at Kew of Alph. de Candolle the *Flore Française*, 3rd ed., was published in reality in 1805, and not in 1815, as it is printed in the volume at Kew.

² Kerner, *Nat. Hist. Plants*, Eng. trans., i. 722 (1898), gives the greatest certified height of the larch as 53.7 metres, equal to 176 feet; and this refers to a tree growing in Silesia, mentioned by Mathieu, *loc. cit.* 556.

³ In the Museum at Florence there are specimens from Courmeyeur, in the Piedmontese Alps, with cones two inches in length, the largest which I have seen, and remarkable for the dense velvety pubescence of their scales.

cone. Scales in four to five spiral rows, nine to ten scales in each row, about $\frac{1}{2}$ inch broad and long, convex from side to side but flattened longitudinally, with the apex usually retuse, often emarginate or rounded; margin thin, entire, not bevelled, and neither inflexed nor recurved; outer surface light brown pubescent, the pubescence most marked towards the base. Bracts oblong, widest at the base, truncate or rounded at the apex, with a short mucro extending about half-way up the scale. Seeds in shallow depressions on the scale, with wings narrowly divergent and extending almost quite to its upper and outer margin; body of the seed $\frac{1}{8}$ inch long, wing short and broad, widest near the base; seed with wing less than $\frac{1}{2}$ inch long; wing $\frac{1}{5}$ inch broad.

VARIETIES

The flowers of the common larch are occasionally white in colour.¹ This occurs both in the wild state and in cultivated trees, as at Arley Castle.

Various kinds of weeping larch have been found wild or have originated in cultivation: and some have been propagated by grafting. *Var. pendula*, Lawson, is noted by Loudon, who states that there were large trees of this kind at Dunkeld, which had been raised from Tyrolese seed. In this form there is an erect leader, and the branches are spreading or even ascending, the branchlets being very slender, elongated, and quite pendulous. In another form of weeping larch the habit is quite different, as it has no tendency to form an erect leader, the trunk remaining short and often divided near the top into several secondary stems that are bent downwards, as are the branches and branchlets. A remarkable example² of the latter form, with extremely long slender pendulous branchlets, was growing in 1888 in Mr. Maurice Young's nursery at Milford. *Var. pendulina*,³ Regel, *Gartenflora*, 1871, p. 101, does not seem to be essentially different in habit from this. Loudon⁴ mentions a remarkable pendulous larch at Henham Hall, Suffolk, which was planted in 1800, and was supported on pillars, the main branches forming a covered alley 80 feet long and 16 feet wide in 1841. I am informed by Mr. Simpson, gardener at Henham Hall, that this tree is now in good health, the tall shrubs which surrounded it having been cleared away on one side some three years ago, since when it has made surprising growth. At three feet from the ground it measures 8 feet 2 inches in girth, and at about eight feet forms an angle, and extends laterally for a great distance, being supported on pillars and cross pieces which form a pergola 140 feet long, 8 feet high, and 10 to 14 feet wide, which is almost completely covered by its branches, and will shortly require extension. In a note at Kew, dated 1882, Sir J. Hooker mentions a weeping European larch at Waterer's nursery, Bagshot, which was 50 feet high and had the habit of *Larix Griffithii*.

¹ Referred to in *London Catalogue of Trees*, 43 (1730).

² Well figured in *Gard. Chron.* iii. 430, 531, Supplementary Illustration (1888). *Var. pendula*, Lawson, is figured in *Gard. Chron.* ii. 684, fig. 132 (1887).

³ Cf. Beissner, *Nadelholskunde*, 325, fig. 89 (1891).

⁴ *Gard. Mag.* 1841, p. 353. Another weeping larch is figured in the same journal, 1839, p. 574.

DISTRIBUTION

The most recent account of the distribution of the European larch is by Cieslar,¹ the distinguished Austrian forester, who points out that the tree in the wild state occupies four distinct and separate regions, namely, the Alps, the Silesia-Moravia boundary, Russian Poland, and the Tatra mountains in the Carpathians. Cieslar strongly disputes the commonly accepted view that the larch is everywhere an alpine tree, occurring at high elevations; and holds that the Silesian and Alpine larches are two distinct climatic varieties, differing in habit and mode of growth, in period of vegetation and in the altitude at which they naturally grow. He has not apparently studied the Polish tree, of which I have seen no specimens, nor the Carpathian larch.

In the Alps, the larch is widely distributed, occurring in French territory in Savoy, Provence, and Dauphiné; and in the Maritime Alps it reaches about 44° 30' N. lat., its most southerly and at the same time its most westerly limit. In Switzerland the larch, while generally found, does not occur in the Jura and in the cantons of Glarus, Schwyz, Upper and Lower Unterwald; it reaches its most northerly point in Switzerland on the Gäbris in Appenzell. Extending eastwards it occurs in Vorarlberg, in the Alps of Bavaria and Salzburg, in the Tyrol and in Carinthia. According to Cieslar it is wild in the provinces of Upper and Lower Austria only south of the Danube, but is found near Vienna as a planted tree. It is absent from lower Styria and nearly the whole of the Karst; and in Carniola does not occur wild south of the Sannthaler Alps; from Idria the southern limit of distribution runs westward into Italy through the Isonzo valley. In Italy the larch is confined strictly to the Alps and is not wild in the Apennines, where it has been occasionally planted with unfavourable results, as the tree, after growing rapidly for twenty years, slackens in growth and becomes decrepit at 40 to 45 years old.² Elwes saw it planted in the Sila mountains of Calabria, where it was producing seed at 10 to 15 years old.

In the Alps the larch is certainly an alpine tree, often reaching the timber line in company with *Pinus Cembra* and *Pinus montana*; while lower down, but above the zone of the beech, it is usually met with either pure or in company with the spruce and silver fir. It occurs, mixed with the beech, at low elevations, according to Cieslar in certain valleys of the Tyrol. M. Coaz,³ Inspector-General of Forests of Switzerland, is of opinion that the forests of pure larch which now exist in the Alps are not natural, but have been produced artificially by cutting the ancient mixed woods. The larch has taken possession of the felled areas and has succeeded well as regards growth; but the pure forests are liable to insect attack and possibly also to disease; so that he thinks that it is necessary to restore artificially the ancient and natural condition of the forest. The highest elevation recorded for the larch is 8200 feet in the Dauphiné. The upper limit in the Central

³ See *Garden and Forest*, 1895, p. 238, for a résumé of M. Coaz's monograph on "Insect Ravages in the Forests of Larch on the High Alps."

Alps varies from 6500 to 8000 feet, and in the Engadine is 7622 feet; on Mont Blanc 7218 feet; at Zermatt 7874 feet; in Northern Switzerland, Salzburg, and the Bavarian Alps, 6400 feet; in the Venetian Alps 6700 feet. The lower limit to which the larch descends in the Alps is 1400 feet at Martigny, 2300 feet at Castasegna, 2000 feet at Chur, 3000 feet in the Bavarian Alps, 2000 to 2300 feet in the South Tyrol, 1300 feet in Lower Carinthia, and 1600 feet in Lower Austria.

The Larch occupies on the boundary between Silesia and Moravia a small area, about 30 German square miles, lying between the rivers Mohra and Oppa, and occupying a zone on the mountains between 1170 and 2840 feet elevation; but only occurring in a very scattered condition above 2600 feet. It grows here in mixture with spruce, silver fir, and beech; and appears to be indifferent to soil, as it is met with on primitive schists, grauwacke, and basalt: it occurs also on all aspects. It is absent from the adjacent high mountain of Altvater, which rises to 4900 feet, and is clothed with spruce and mountain ash. According to Cieslar, the Alpine larch has been unadvisedly introduced into Silesia, and it will be difficult in the future to obtain pure seed of the Silesian variety. Cieslar considers this form to be entirely distinct from the larch of the Alps, as it has a cylindrical stem, with slender branches and twigs which are directed upwards, and form a very narrow slender crown. The Alpine larch has stouter branches and twigs, which are directed horizontally, and form a much more spreading crown of foliage, the stem being much more tapering. Introduced into cultivation at low elevations, the Silesian larch is later to come into leaf, and sheds its leaves earlier in autumn, grows much faster, is less liable to damage from snow, and can, on account of its narrow pyramidal form, be planted much more densely. The Alpine larch will not bear crowding, according to Cieslar, and is an inferior tree for planting in every respect.

In Russian Poland, the larch is mainly met with on the hilly land of Lysa Gora, where it forms large forests on sandy soil between Konskie and Szydłowice, near Samsonow. It also extends over the right bank of the Weichsel into Galicia. According to Vrzozowski, the larch at one time was spread over the governments of Piotrkow and Warsaw, as churches and manor houses built 300 to 500 years ago of larch wood are still standing. The distribution of the larch in ancient times must also have extended considerably to the eastward, as a church built of larch in 1419 is reported to exist at Slucz in the government of Minsk in West Russia. Count Dzieduszycki's forester at Poturzyca, near Sokal, in Galicia, reports that larch occurs there between 600 and 800 feet elevation.

The larch occurs also, but not extensively, in the Tatra mountains, between Hungary and Galicia, where it grows on southwest slopes up to 5200 feet, reaching a somewhat higher altitude than the spruce and not ascending as high as the Cembra pine. Cieslar finds no reliable evidence for the larch being wild in the Carpathians east of the Tatra mountains; and does not credit its occurrence in Transylvania.

Prof. Hufferl¹ of Nancy states that the larch occurs, but is very rare, in Roumania, where he saw it in the mountains which separate the valleys of the Ialomitza and Prahova at 6300 to 6600 feet elevation. Here it was growing either in mixture

¹ *Forêts de la Roumanie*, 6.

with the spruce or higher than it. In Moldavia he reports it on the Ceahlău, where it rises on a southern slope to 5550 feet. The larch in Moldavia and Roumania has been considered to be *Larix sibirica*; but Hufferl doubts this.

Herr F. Mack, forest administrator at Azuga in Roumania, states¹ that larch is common at Bucecii above the beech region, at from 1300 to 1600 metres, mixed with spruce. It attains 60 to 65 centimetres, or about 2 feet in diameter, and is often clear of branches to a considerable height. The wood is hard, red, and durable, and was used in the construction of the Royal Palace of Sinaia.

INTRODUCTION

There is little doubt that the larch was introduced into England about the beginning of the seventeenth century, as Parkinson, who published his *Paradisus* in 1629, speaks of the tree as rare. Evelyn,² writing in 1664, mentions "a tree of good stature not long since to be seen about Chelmsford in Essex," and urged its cultivation as a useful timber tree. The earliest trees in Scotland are supposed to be those at Dunkeld, the history of which is given below; but we have no reliable evidence as to the exact date and locality where it was first planted. Loudon's account is very full and should be consulted. The very useful little book by C. Y. Michie on the larch, published in 1885 by Blackwood, must not be overlooked, as it gives a very good résumé by a practical forester whose experience in Scotland was considerable.

A. H.

PROPAGATION

Ever since it was realised by landowners that the larch was the tree which before all others could be looked on as profitable to plant, its propagation has been one of the most important branches of the nurseryman's business, especially in Scotland, where by far the larger part of the trees grown in England are raised; and until the disease spread all over the country, and it became evident that precautions must be taken, which in the palmy days of larch-growing were not considered necessary, the majority of raisers were not very careful as to the source from which their supplies of seed were obtained. It was generally supposed that Scottish seed was best, though in years when it could not be obtained in sufficient quantity foreign seed was used.

So far as I have been able to ascertain from very numerous inquiries, the reason for this idea was, that foreign seed usually germinated more quickly, and that the seedlings were therefore more liable to be killed by severe spring frost just as they were germinating. But as all the old larches in England and Scotland must necessarily have been raised from foreign seed, it seems obvious that though Scottish seedlings may have been most profitable to the nurseryman, yet that unless the seed was gathered from carefully selected trees, they were liable in after-life to show weakness of constitution, and succumb, as they often did, to the attacks of *Peziza Willkommii*.

¹ *Zeit. für Forst. und Jagdwesen*, Oct. 1904, p. 644.

² *Silva*, Hunter's ed., 1776, p. 297.

Another reason has been assigned, with some probability, to the apparently greater liability to disease of larch now than formerly, namely, that the cones are often gathered too early, and exposed to too much heat in the kilns in order to extract them. The cone of the larch does not open of its own accord usually until spring; often in this climate so late that the seedlings make little growth the first year, and the seed cannot be extracted without heat, or by breaking up the cones in a mill, which bruises and destroys many seeds; and in the climate of Scotland they do not often ripen so early or thoroughly as in the drier, colder, and sunnier climate of its native Alps: therefore it seemed to me desirable to make experiments with larch seed from abroad, in order to find out whether there was any real difference in the vigour of foreign and home-grown seedlings; and though my experience in this way now extends over fifteen years, I cannot say that I have solved the question.

On many occasions I have sown seed from Scotland, the French Alps, and the Tyrol, and have found that on my poor calcareous soil, which, though it grows larch very well, is not at all suitable for raising it, a large proportion of these seedlings from all sources either perished in infancy, or grew so slowly in the first two years that they were far inferior to seedlings raised in Scotland on a better soil and climate, and probably on manured land. But many of these weaklings have afterwards grown into robust young trees, and the difference in their liability to suffer from spring frost, which is their greatest enemy, is not sufficiently marked to enable me to form a sound opinion as to which are best.

What I have learnt, however, is that, though seedlings cannot be raised as cheaply or as rapidly at Colesborne as in a Scotch nursery, they are more satisfactory in other ways, because it is better to eliminate the weaklings before they are planted out than to have to replant them afterwards; and I believe that the greater the risk of disease the more careful one must be, not only in the selection of seed, but also in their nursery management. Another point in favour of home raising is that the seedlings are not exposed in their younger stages to the extreme drying of the roots which arises from the careless way in which they are often lifted and packed by nurserymen, and from the long delays in transit on the railway; and, finally, the transplantation in a private nursery is more carefully done, and the roots are better developed and more able to endure the severe check of final transplantation to a soil which is less favourable to their growth than that of the nursery.

Mr. J. P. Robertson, forester to the Duke of Devonshire at Chatsworth, writes me as follows with regard to the comparative hardiness of larch raised from native and foreign seed in 1903:—

“We have two nurseries, one at an elevation of 900 feet, the other at about 600. In both a large quantity of larch from home seed have been put in this spring, while in each a break of the Tyrolese, 10,000 in number of similar size, has been placed. These last were from two different nurserymen. In both nurseries the home variety has suffered severely from the strong white frosts that we had in Easter week, while the Tyrolese in each case is practically untouched.”

But on inquiry in 1905 whether this apparent superiority was still the case, he wrote:—

“I did not require to wait long to see the results reversed, as severe frosts in June of that same year, I think on 21st, 22nd, and 23rd, when we had 9°, 10°, and 8° of frost respectively, nearly put the Tyrolese bed out of existence, while those that had been cut earlier in the season (the home variety) did not suffer to anything like the same extent. I am now so thoroughly convinced in my own mind of the superiority of larch from home or British seed, that I have entirely discarded the Tyrolese.”

Though the seed is ripened in ordinary seasons in all parts of the country, and a few self-sown trees may be found on most estates where rabbits are kept down, yet our conditions of soil and climate are so unlike those of the natural larch forests of the Alps, that it is useless to attempt natural reproduction with any economic advantage. The only cases in which I have seen any number of self-sown seedlings in the southern half of England are where a clean felling has been made of the larch, and the ground more or less broken up by hauling out the logs immediately afterwards. Of the seedlings which germinate, so large a proportion are destroyed by frost, drought, or vermin in the first season, that the number remaining is not worth consideration, and their growth is so slow for five or six years that planted trees of half the age will usually be stronger. On sandy land, however, or at high elevations, and especially in Scotland, it may sometimes be worth while to encourage self-sown trees, but I cannot say that I have ever seen even a small area which is either sufficiently or regularly stocked by self-sown larch.¹ In the Alps, on the other hand, where the soil is covered with snow for three months or more, natural regeneration is both easy and regular, and I have, both in the French and Italian Alps, seen the ground covered with larch seedlings, which, taken up as late as May, when just uncovered by the snow, I have brought to England when a few inches high, with success. Indeed, it is wonderful how long seedlings will live if taken up when vegetation is just commencing, and sent by post in small tin boxes, tightly packed with a little damp moss or soil, and such trees are my most agreeable souvenirs of many visits to distant countries.

The manner in which the seed is collected in the French Alps is described to me as follows by M. Surel, Inspector of Forests at Briançon, a district which is celebrated for its larch forests:—“In February, before the season when the cones are ripe, we choose trees of which the cones are still closed, and spread large cloths round their trunks at about 10 feet from their base. When the cones open, the seed falls on the cloths. It is then dried in the sun, or preferably, in order to avoid excessive drying, under an open shed. The collection takes place at a minimum altitude of 5500 feet, where the snow is still frozen, and the drying of the seed by the sun, which in this district is remarkably strong, the thermometer rising in the sun in February to 30° to 32° Centigrade, is therefore carried on under very favourable conditions. Drying by the stove would give deplorable results. If I were obliged to work in a climate where the climatic conditions made our practice impossible, I should use closed rooms, slightly heated, but of which the air was freed from moisture by chloride of calcium.”

¹ Prof. Fisher tells me that on old roads, and other places where the soil has been exposed, on the shores of Lake Vyrnwy in Wales, and also on old pit banks in Dean Forest, he has seen numerous self-sown larches spring up.

I was informed by M. Mougin, Conservator of Forests at Chambéry, that in the Modane district the cones are collected at the end of November by men who climb the trees, with a long hooked pole, and gather the cones by hand into a bag which they carry. The cones are received twice a week at the drying-place, where they are spread out in an airy shed, and turned over every day to dry them and prevent them from heating. When the fine weather returns, they are spread out on a cemented floor, exposed to the sun, which opens them, after which the seed is collected and cleaned, and put in boxes, which are shaken frequently to prevent the attacks of insects. Sometimes seed can be collected on the snow under the trees in January by shaking the trees. But in no case is a stove used to extract them, as seems to be the usual practice in Scotland.¹

From Prof. A. Fron,² of the Forestry School of Les Barres, I have received valuable information on the germination of larch seed, which I summarise as follows: He considers that the process usually adopted of grinding the cones in a mill is very inferior to either of those which I have described as in vogue in the Alps, because the seeds of good quality which come from the central portion of the cone are mixed with those from its upper and lower ends, which are usually empty or imperfect. In 1905 he made experiments on the germination of larch seed obtained at Modane, which had been extracted by the heat of the sun, and obtained the following result:—

Purity	98 per cent.
Germinative power	61.3 „
Cultural value	60.1 „

whilst the average of the seeds obtained from seedsmen only gave the following result:—

Purity	80 to 85 per cent.
Germinative power	45 „ 50 „
Cultural value	40 „

I may say that the seeds I have gathered from my own trees late in March, and extracted by exposing them to the sun under glass in a garden frame, have germinated quicker and grown better than any which I have purchased.

An ideal way of raising larch would be as follows: To gather cones in the month of March or April from the best and healthiest mature trees in one's own district, or, failing this, from trees known to be healthy on a similar soil; or to purchase seed of known origin direct from a reliable firm abroad, among whom I can highly recommend Messrs. Vilmorin of Paris and Messrs. Jenewein of Innsbruck.

The seed-bed should be in an elevated position, where spring frosts are not likely to be severe, and sheltered as much as possible from the morning sun by trees

¹ Prof. Fisher tells me that in Germany larch seed is extracted from the cones by a toothed axis rotating in a drum, also lined with shorter teeth, and driven by water or steam power.

² For further particulars concerning the purity and germinative power of larch seed from different sources, cf. Fron, *Analyse et Contrôle des Semences Forestières*, 92 (1906).

or by clipped hedges or high walls. The soil, light and friable, and, if naturally poor, enriched by manuring with leaf mould and road scrapings, and as free from weed seeds as possible, should be laid up into beds 4 feet wide, with perfect drainage, in the previous autumn, so as to have a fine mould on the surface.

About the middle of April, but earlier or later according to the climate, the seed should be steeped in warm water for a day or two and dusted with red lead when damp, in order to keep mice and birds from attacking it.¹

On a dry day the seed should be sown broadcast as evenly as possible, and thick enough to have about one plant to the square inch, or less if the seedlings are to remain two years before transplanting. If the soil becomes dry the beds must be watered and shaded as the seed begins to germinate, which should be in fourteen to twenty days after sowing. At this time great care must be taken to prevent the seedlings from damping off, and it is better to keep the bed rather dry than wet. If weeds appear they must be carefully pulled up when quite small. If the soil and season are favourable the seedlings will in the first season be 4 to 6 inches high. If they should be too thick to stand a second season in the seed-bed, the strongest should be lifted and pricked off in lines about the end of March in the second year, and if there is much risk of a severe frost it is wise to transplant them all, as this check will retard their too early growth.

After transplanting they should remain two years in the nursery lines, except in the case of strong one-year seedlings, which may be fit to plant out one year after transplanting, but this must depend on the soil and the nature of the ground where they are to be planted out. Except for planting in woods or in places overgrown with coarse grass or fern, seedlings of one year old plus two years transplanted, or two years old plus one year transplanted, are, in my experience, large enough; and any which, from overcrowding or other causes, are not then strong enough may be rejected and have another year or two in the nursery. There will always be a considerable proportion of young trees which are inferior to the rest in size and vigour, and these are better separated when transplanting; whilst all those whose leaders are frosted or immature should be rejected, no more than forty to fifty per cent of the whole being usually fit to plant out at three years old.

The raising of such trees may cost from 20s. to 30s. per thousand in a private nursery, and though they can often be bought cheaper are, in my opinion, worth the extra cost.

Mr. Robertson writes on the same subject as follows:—

“Here we are now, I am glad to say, as little troubled with larch disease as most people, and the reason is simply that we endeavour to keep the plants strong and healthy *at all stages of their growth*, so as to be better able to resist attack. It must not be forgotten in these days of continental forestry that larch is a light-demanding tree, and ought not to be grown on the same principle of density as

¹ It is a regular practice in some nurseries where large quantities of larch are raised from seed to soak it for a day or more in water, and then spread it out on a floor where it is daily turned over and sprinkled with water until it seems ready to germinate. By adopting this practice the germination is quicker and more regular.

advocated for shade-bearing species; but it is equally dangerous to over-thin, and thus bring about starvation, and consequently weakness, by cold winds."

CULTIVATION

Whether the system of notching or pitting is adopted must depend on the local conditions and the size of the trees to be planted. If not more than 18 inches to 2 feet in height, notching, when carefully done, is sometimes as successful as pitting, but in very dry summers a large proportion of the trees will die whichever way the planting is done. In my own experience allowance must be made, in calculating the cost of planting, for a loss of about 20 per cent on an average, though this is often much exceeded when the trees are planted after Christmas, or when their roots have become dry, or when careless workmen have been employed without very close and constant supervision. This is allowing nothing for damage done by hares and rabbits, which, unless thoroughly killed down before planting and kept out by a really effectual wire fence, will soon destroy a great many of the young trees.

Having once planted the trees, the success of the plantation will depend more on soil and climate than on the skill of the planter. For though larch will, owing to their extraordinary vigour, grow almost anywhere up to fifteen to twenty years old, they will not attain a large size unless the soil is moderately fertile and well drained and the situation open and airy. If large trees are desired, I should always advise a mixture of beech or birch being planted with them or three to four years later; but where the crop can be profitably realised as small poles, or where the soil and climate are really favourable for larch, they may be planted at four feet apart without mixture. The distance apart and the mixture of other trees can only be decided by local experience, the object in view being to keep the trees thick enough to suppress the grass without depriving them of enough light and air to keep their lateral branches alive until they are fifteen to twenty years old. All thinnings should be based on these considerations, and the poorer the soil the more distance is required between the trees to keep them growing. On my own soil I have repeatedly noticed that if grass already exists when the trees are planted, it is impossible to keep the larch thick enough to smother the grass, without crowding each other to the point of starvation and disease, and in such land a mixture of beech, at the rate of one beech to two or three larch, is essential. The result of this mixture is that the larch, instead of beginning to decay at forty to sixty years old, as it often does when on soil deficient in natural fertility, at which period it may be worth 5s. to 15s. per tree, will live and increase in girth till at least 100 years, when they may be worth from £1 to £3 or £4 each. After they have been cut the beech may remain, or if not thick enough to stand with advantage, the land will be left in a very much better condition for replanting than after a crop of pure larch.¹

¹ Prof. H. M. Ward gave in *Nature*, xxxvii. 207 (1887), the following account of an experiment conducted by Prof. Hartig:—"There is a plantation of larches at Freising, near Munich, with young beeches growing under the shade of the larches. The latter are seventy years old, and are excellent trees in every way. About twenty years

With regard to the probable profit arising from a crop of larch planted pure, and realised at 30 to 50 years as compared with a crop mixed with hardwood and realised at 80 to 100 years, I have, with the assistance of Sir Hugh Beevor and Dr. Schlich, made several calculations, but it depends so much on local conditions, on the price realised for thinnings, and on other circumstances which cannot be foreseen, that it seems impossible to estimate it with any certainty.

I have, however, arrived at the conclusion that the short rotation is, as a general rule, the more profitable, especially where a sporting rent varying from 2s. 6d. to 5s. per acre can be realised from pure larch plantations after the age of 15 to 20 years, when rabbits can be admitted freely without risk of serious damage, or where, as in many parts of Scotland, larch plantations are thrown open to sheep grazing.

What is undoubtedly the best system of forestry is not always the most profitable to the landowner, and every one must decide from his own experience which system will suit his own circumstances best.

When mixed with Spruce or Scots or Corsican pine, as is often done, the larch on suitable soil will usually far exceed the other conifers in value at the same age; and I see no advantage, but rather a loss in such a mixture.

In woods which have been treated as coppice-with-standards the larch is a more profitable tree than beech or oak, and may be introduced to the number of thirty to forty per acre immediately after each cutting of the coppice. If left till sixty to eighty years old there would thus be eventually about 100 trees per acre, which will pay much better in these times than the underwood; for if only ten trees, worth say 30s. each, be taken at each rotation, the value will amount to £15 per acre, and there are not many districts in England where underwood is now worth half as much. In Earl Bathurst's extensive woodlands near Cirencester this system has been adopted for many years with great success; but if rabbits exist it is necessary to protect each tree by a wire cage until it is old enough to be safe from their attacks, which it is in this district after twenty to thirty years of age.

The produce per acre of larch in plantations on really good land has in many instances been surprising, and so profitable to the owner that some writers have greatly exaggerated the average returns that may be expected. Prof. Charles E. Curtis,¹ assuming that 300 trees per acre may be grown to maturity, which I greatly doubt, states as a reasonable possibility of production for the larch, no less than 10,000 to 12,000 feet per acre, and says that it will be found possible to bring 1000 to 1200 poles per acre to a useful and profitable size in thirty to forty years. I have

ago these larches were deteriorating seriously, and were subsequently underplanted with beech, as foresters say, *i.e.* beech plants were introduced under the shade of the larches. The recovery of the latter is remarkable, and dates from the period when the underplanting was made. The explanation is based on the observation that the fallen beech-leaves keep the soil covered, and protect it from being warmed too early in the spring by the heat of the sun's rays. This delays the spring growth of the larches; their cambium is not awakened into renewed activity until three weeks or a month later than was previously the case, and hence they are not severely tried by the spring frosts, and the cambium is vigorously and continuously active from the first. But this is not all. The timber is much improved; the annual rings contain a smaller proportion of soft, light spring wood, and more of the desirable summer and autumn wood consisting of closely-packed, thick-walled elements. The explanation of this is that the spring growth is delayed until the weather and soil are warmer, and the young leaves in full activity; whence the cambium is better nourished from the first, and forms better tracheides throughout its whole active period."

¹ *Journ. Roy. Agr. Soc.* lxiv. 36 (1903).

never seen or heard of such an instance, and on writing to Prof. Curtis he could not tell me of anything at all near it.

The best estimate I have is from Sir Hugh Beevor of a plantation at Petworth belonging to Lord Leconfield. It is growing on a steep hill facing east, on sandy loam overlying sandstone, and at thirty-two years after planting contained about 300 trees or more per acre, averaging 15 feet each, which makes about 4500 feet per acre. At Mailscoth Lodge, in High Meadow Wood, Forest of Dean, he saw a small plantation, thirty-four years planted, in which the trees on an area of half an acre numbered 214, averaging 9 feet per tree, equal to about 3800 feet per acre.

The best example on my own property is a plantation at Hilcot, now about fifty-four years old, in which there are 2500 trees on an area of about twenty acres. The trees average about 25 feet on the better parts of the land, and 10 to 15 feet on the worst, or about 18 feet over the whole area, equal to about 2200 feet per acre. There are some beech, wych elm, and other hard woods amongst them, which might make up a total of 3000 cubic feet per acre, and though the larch might stand ten to twenty years longer they are not now making a profitable increment.

Mr. J. E. Hellyar Stooke of Hereford sends me the following particulars of a sale in 1907, of larch sixty to seventy-five years old, growing on a hill 400 to 500 feet high, the soil being stiff clay overlying limestone facing east to south. There was no disease except on some of the smaller branches; the trees were all sound, and would probably have continued to grow for many years.

These trees were sold standing, by auction, at such a distance from a railway station that the hauliers could only make one journey daily.

At what age it pays best to fell a crop of larch is a question which depends entirely on the growth of the trees and the local value: in some cases thirty to forty years may be the most profitable age, in most fifty to sixty; and where the trees are planted with a good mixture of beech, and continue to grow well after this period, it may pay to let them stand to 100 years old, beyond which they will seldom if ever continue to make a profitable increase.

I should say that £100 per acre was a very fair average valuation of a clean

larch crop at forty to sixty years old, and though it is often exceeded, yet in many more instances I believe that at present prices the return will be less, even when disease has not seriously deteriorated the value of the trees by the scars and cankers which disfigure the trunks.

DISEASES OF THE LARCH

Though it is not within the scope of this work to describe the diseases of trees, yet an exception must be made in the case of the larch, because it is a subject of such vast economic importance that it may truly be said, that the losses of all other trees, from all kinds of diseases, whether induced by climatic causes, by insects, or by fungi, do not collectively approach the loss caused to English landowners by larch disease. In using this term without qualification I mean the disease caused by the fungus usually known as *Peziza Willkommii*, but which is now named by mycologists *Dasyascypha calycina*, and which is perhaps best described in English by the name "Canker," or "Blister." This began to attract attention in this country about 1859, when the Rev. M. T. Berkeley¹ made known its existence in England, and Charles M'Intosh in 1860 wrote a small book on larch disease, though what he described more especially was heart-rot, a very different thing from canker.

Hartig and de Bary were the first to describe the fungus. Prof. Marshall Ward in his *Timber and some of its Diseases*, published in 1889, described it more fully; and since then Mr. Carruthers, Dr. Somerville, and other scientific writers have written largely on the subject. In the *Gardeners' Chronicle*, 1896, are many interesting articles respecting the larch disease by J. S. W., Sir Charles Strickland, A. C. Forbes, and C. Y. Michie; and an excellent paper on it with coloured illustrations, by Mr. Geo. Masee, appeared in the *Journal of the Board of Agriculture* for September 1902.

The most practical observations on the larch disease I know of, are in Mr. A. C. Forbes's excellent work on *English Estate Forestry*, pp. 289-307 (1904). These should be studied carefully by every one who is in any degree interested in the subject. After giving a summary of the more important opinions and facts noticed in connection with this disease, he says—and I entirely agree with him—that the disease is as much the result as the cause of the bad health and unthrifty condition of many plantations throughout the country; and that the temporary debility which is induced by the conditions under which planting is conducted is largely responsible for a great deal of disease. He goes on to say that the practically permanent nature of the blister, when once established, renders the result of this temporary debility a much more serious matter than it otherwise would be. If the return to normal health and growth were accompanied by the disappearance of the disease, little harm would be done, but the existence of a blister, once established, is perpetuated indefinitely, and in most cases only ceases with that of its host, so that the occurrence of a blister on the stem of a young tree is much more serious than it would be on a branch or older stem. Cases commonly occur of the disappearance of

¹ *Gard. Chron.* 1859, p. 1015.

the blisters when the trees recover health and vigour; and he mentions a plantation over twenty years old, more or less mixed with beech, on greensand, where a number of old blisters are gradually becoming occluded. That they were genuine blisters is evident from the remains of the *Peziza* cups still present, and the only possible theory respecting their disappearance must be found in the improved health of their host. I have frequently observed similar cases, both on my own land, where in some of the worst diseased plantations, individual trees, which on account of their greater vigour have taken a lead from the first, remain almost untouched and growing vigorously, when most of the surrounding trees are killed or severely injured; and also in Hertfordshire, where tall slender larch trees growing amongst beech showed at various points, from near the ground up to 50 or 60 feet, signs of repeated attacks, which had neither killed them nor apparently checked their growth materially. Forbes says that one may pick up dead twigs or branches under the largest, finest, and most isolated larches that can be found, and the fructifications of *Peziza* are invariably present on them. This fact he thinks is sufficient to prove that the mere existence of the fungus does not necessarily lead to diseased trees, using the term diseased in its practical sense.

The year 1879 will long be remembered by all gardeners, farmers, and land-owners in the southern half of England as the most disastrous in its effects on plants, farm crops, and trees generally. There was practically no summer, and the rainfall was so continuous, that in late districts much of the corn never ripened at all, and being followed by two severe winters, the disease spread to a degree which ruined hundreds of acres of young larch on my own estate, and caused a loss which must have amounted to millions of pounds throughout the whole country. Though after bad seasons and in smaller areas there had been disease before, it was generally assumed by planters that larch might be successfully grown on almost any kind of land without mixture, and without any special precautions, and there is little doubt in my mind that a large percentage of the worst cases originated in that season, and may be directly traced to the exceptionally bad climatic conditions which prevailed.

Mr. A. M'Dougal, forester to the Earl of Feversham at Helmsley in Yorkshire, who has charge of something like 10,000 acres of woodland, and, having been brought up on the Duke of Atholl's estate, has had unusual experience of the larch, tells me that in Yorkshire the disease first began to be prevalent about 1862 when two plantations died clean off. Since then it has been very prevalent on thin red loam overlying limestone rock; and this applies as much to localities which have previously been under oak wood, or cultivation, as to those where larch has been replanted after larch. He considers that severe spring frosts, together with low-lying situations and heavy soil, are the conditions which bring on the disease most severely.

Sir W. Thiselton Dyer, who has been good enough to read this article, does not quite agree with me with regard to the disease, which he considers due to physical causes alone, and not influenced by heredity. He says that the fungus is a wound parasite, whose spores can only develop in lesions where the bark is injured either

by frost, weight of snow, insect punctures, or otherwise, and that it is usually worst in sheltered hollows, where damp air lies and spring frosts are severely felt, and that on high situations facing north and east the disease rarely causes much injury.

All this I admit in full, but I am also convinced that, as the spores of the fungus are now so generally present everywhere, it is impossible to eradicate it, the only way by which it can be combated is by planting only on soils and in situations which experience has shown enable the tree to grow vigorously, and on poor and dry soils mixing it with hardwoods, the fall of whose leaves enriches the soil and keeps it cool and free from grass.

Heart-Rot in Larch.—Though sometimes confused with *Peziza* by careless observers, this is a totally different disease. C. M'Intosh¹ describes it very fully, and Hartig refers to it under the name of root-rot. Forbes believes, as I do, that it is the direct result of unsuitable soil, either too wet or too dry. It is most common on very poor limestone, sand, and chalk, but also occurs on clay and gravelly soils. In my experience it is especially noticeable where larch follows larch on soils containing insufficient nourishment, and can only be avoided by not planting larch where it is found to be prevalent. It usually attacks trees of about twenty years old, when they have got over their first period of vigorous growth and have practically exhausted the available sources of nutrition. According to Mr. Simmonds, late Deputy Surveyor of Windsor Forest, larch grown on what is called iron pan in that district gets red rot at the heart and is then said to be "pumped."

Larch Bug.—What is commonly known as larch aphis or larch bug is an insect called *Chermes laricis*. The life-history of this insect is at present somewhat obscure, some continental observers believing that it passes through an intermediate stage of existence on the spruce, as no males have yet been found on the larch, in which case it is evident that the insect cannot spread or become numerous unless spruce exists in the neighbourhood. But this is contested by Dreyfus, and I have observed that in England at any rate it multiplies exceedingly where no spruce are near. The females pass the winter under the bark, and are wingless, oval, of a purplish-black colour, and have a long bristle-like sucker through which they feed on the sap of the leaves. In spring they lay eggs which produce young, which grow rapidly, and are covered later by a whitish woolly down, and when numerous give the trees a whitish appearance. They increase rapidly by successive broods, and seriously weaken the constitution of the trees when young, rendering them especially liable to succumb to the attacks of *Peziza*, which often accompany and succeed them. Whenever I have seen bad attacks of the bug I have noticed that the *Peziza* is more than usually destructive, and it seems as though the climatic conditions which favour the one also favour the other. In the autumn the bark of the trees in a badly attacked plantation appeared quite black; and though this plantation was in a high situation, exposed to the east, and was heavily thinned the year afterwards, the greater part of the trees, which were thirteen years planted from Tyrolese seed, and had been growing vigorously at first, were so sickly on the thinner and drier parts of the land

¹ *The Larch Disease* (1860).

that many will not survive. In the nursery I have observed that some trees were practically immune, though growing side by side with others whose branches touched them and were covered with the Chermes; but having marked these trees and watched them after they were planted out, I have not as yet been able to assure myself that this immunity is permanent. Though I have not found this insect attack Japanese, American, and Siberian larches at Colesborne as severely as the common species, yet I have seen it upon them all, both there and elsewhere. Blandford¹ says that washing the trees in April with a soft soap and paraffin mixture in hot water may prove effective, and suggests other forms of wash; yet it is evident that such remedies cannot be economically employed in plantations, and I know of no means of preventing the ravages of this insect; though thin planting, mixing with hardwoods, and the avoidance of thin dry soils and damp shady situations are undoubtedly the best means of avoiding severe injury from this pest, as well as Peziza.

*Leaf-Miner of the Larch.*²—The only other insect that I know of which causes serious injury to larch in this country is a small tineid moth, *Coleophora laricella*. This is extremely prevalent almost every year in some of my own plantations having a south-west aspect, and has been supposed by some authors to be directly connected with the attacks of Peziza, which usually accompany or succeed it. According to Stainton the larva is hatched in the autumn, and at first feeds as a miner inside the leaves, and at the approach of winter retires to the stem of the tree, where it passes the winter without feeding. In the spring as soon as the leaves appear it begins to work, and frequently becomes so numerous that most of the buds have several leaves injured. In May it is fully fed, and attaches the case which it has formed for itself from the leaves of the tree to a twig, and appears as a perfect insect in July. The tree is undoubtedly very much weakened by severe and repeated attacks, which render it more liable to die from Peziza, but as far as I know there is no practicable remedy for it in plantations.

A new enemy to the larch which has recently appeared in the north of England was described in the *Journal of the Board of Agriculture* in 1906, p. 375, and more fully in a paper by Mr. J. Smith Hill.³ This is the larva of a sawfly, *Nematus Erichsonii*, Hartig, which was first noticed about 1904 by Mr. Cyril F. Watson, of Cocker-mouth, and which has done considerable damage in the Lake district of Cumberland by defoliating the larch. Mr. Gillanders has recently found the larva near Rothbury, and Mr. Forbes in Chopwell woods, but I have not heard of its appearance in the south of England.

I am informed by Mr. R. D. Marshall, of Castlerigg Manor, that he has known periodical visitations of the same insect for several years, and that, owing to the late period of the season at which the larva appears, the trees have not suffered as seriously as they would if attacked earlier. He states that the plantation alluded to by Mr. Smith Hill first suffered from this cause as much as forty years ago, and has survived the attack in three consecutive years recently. It was noticed that during these

¹ *Journ. Roy. Hort. Soc.* 1892, p. 170.

² Cf. *Gard. Chron.* xxxvi. 181, figs. 70, 71 (1904).

³ *Quarterly Journal of Forestry*, i. p. 67 (1907).

seasons the plantation was full of small birds, which were apparently feeding on the larvæ.

REMARKABLE TREES

To enumerate all the larches which are remarkable for their size and age in Great Britain would be impossible, as in almost all places of sufficient age or importance this was one of the first exotic conifers to be planted, but it will suffice to say that many still exist in a sound condition which are 150 years or more old and exceed 100 feet in height. The tallest trees I have ever heard of were felled about the year 1890 in a deep valley near Croft Castle, Herefordshire, the seat of Capt. H. Kevill Davies, which I visited in 1904 under the guidance of Mr. Openshaw, who assured me that some trees there were 135 feet long at the point at which the tops were cut off, with a diameter of 6 inches. This was confirmed by the woodman on the estate, H. Prince, who estimated the tops to have been 10 to 15 feet long, making the trees nearly if not quite 150 feet high.¹ The soil is Old Red Sandstone and the situation very sheltered. I have a record of a tree measuring 134 feet by 10 feet 8 inches which grew in Yorkshire on Lord Masham's estate, and at Penrhyn Castle, North Wales, Henry measured a tree 118 feet by 7 feet 10 inches, and I saw another at the same place growing in a low, very wet, almost swampy situation very near the sea among hardwoods which was about 90 feet by 12 feet, and judging from the rings of felled trees lying near it was about 130 years old. This is remarkable from the fact of the conditions of growth being so extremely unlike those which are usually considered natural to and suitable for the larch, and I can only explain them by the fact that the natural drainage was better than it seemed. Certainly I would not expect larch now planted in such situations to escape disease.

At Ombersley Court, Worcestershire, the seat of Lord Sandys, a tree is growing on the lawn in deep red loam, which exceeds in girth any larch that I know of in England. It is no less than 15 feet 7 inches at five feet from the ground, though it falls away rapidly higher up, and is only about 80 feet high, and has very large and wide-spreading branches.

At Stoneleigh Abbey, Warwickshire, the seat of Lord Leigh, there are some very large and picturesque larches, near the park-keeper's house, which look as old as any in England. One of them, measuring 14 feet 8 inches in girth, has a mass of rugged branches, some of which touch the ground, where they seem to have taken root. Another is about 80 feet by 14 feet. In the grounds of Warwick Castle there is a group of seven ancient larches, as well as one in the castle yard whose top curves into a drooping form.

In Gloucestershire there are many fine trees of this species on the Cotswold hills, among which may be mentioned two near the Woodhouse in Earl Bathurst's woods (Plate 98). These are growing on dry and rather shallow soil, overlying Oolite rock, and are over 100 feet high by 11 feet and 12 feet in girth respectively.

¹ Mr. T. E. Groom of Hereford writes to me that he measured several of these trees himself, and has a clear recollection that two of them were over 140 feet long as topped for sale, where they would be 5 or 6 inches in diameter. The quarter-girth under bark half-way up was, however, only about 14 inches, which gives their cubic content as about 190 feet.

They seem to have been drawn up by surrounding trees, though now open on one side; and the fine trees beside them are Lawson Cypress, about fifty years old. At Sherborne House, the seat of Lord Sherborne, is a fine group of six old larches on the lawn, planted in a circle of very small diameter, which seed freely, and from which I have raised good plants. They are remarkable for their symmetry and equality rather than for their great size (Plate 99). At Mickleton Manor I measured in 1903 a very curious larch, 10½ feet in girth, but of no great height, whose branches spread to a distance of over twenty yards from the trunk. Plate 100 shows the tallest larches which I have measured myself in England, growing on a very dry, stony bank, composed of Oolite gravel, at Lyde, near Colesborne. These have no doubt been drawn up by the surrounding beeches to their great height, which exceeds 120 feet, the tallest, whose top is now dying, was, when measured in 1903, about 125 feet; but their girth is only 7 to 8 feet. They are remarkable from the fact that a part at least of their roots is under water, and must derive some part of their nourishment from the decaying beech leaves which accumulate there, as the trees higher up the bank are not nearly so large.

The tallest larch mentioned by Loudon in England was at Strathfieldsaye, where one was recorded as being 130 feet high by 3 feet 6 inches in diameter; but none over 80 feet were reported at the Conifer Conference in 1891. At Eridge Park, Kent, are some very fine larch trees growing on sandy soil, in what seems a damp situation below sandstone rocks, which average well over 100 feet in height, and one which I measured was 115 feet by only 5 feet 3 inches, a very unusual proportion of height to girth. Mr. R. Anderson has heard of a tree which was felled near Moorhampton which contained 356 cubic feet as measured over bark on the railway, and trees of over 200 cubic feet were not uncommon near this place. At Savernake House, Wilts, he has measured a tree 12 feet in girth, and tells me that the growth on this estate is sometimes so rapid that eight or nine rings may be found together with an average width of half an inch.

In the north-western counties there are, or have been, many very fine larches. Sir Maurice Bromley Wilson tells me of two on the shores of Windermere, which he thinks are the largest in the Lake district; but the best I have seen myself are at Greystoke Castle, the seat of the Howards of Greystoke, where Lady Mabel Howard showed me a tree in a plantation near the castle called John-by-Park, which is believed to have been planted by Charles, eleventh Duke of Norfolk, about 130 years ago, and which measured 11 feet 10 inches at 5 feet from the ground, and contains about 230 cubic feet. There are also two trees, taller but not so thick as the one at Greystoke, in the sunken garden at Lowther Castle in the same district.

In Wales the larch has been planted as extensively as in England on most of the large estates, and as a rule grows as well as, or better than, in England up to 800 or 1000 feet above the sea. Among the most remarkable trees are two at Chirk Castle, Denbighshire, the seat of R. Myddelton, Esq., one of which measures 74 feet by 13 feet 5 inches, and has very wide-spreading branches. The other forks low down and is 12½ feet in girth. At Maesllwch Castle, Radnorshire, the seat of

W. de Winton, Esq., there is a very fine group of twelve old larches 90 to 100 feet high, the largest of which measured 11 feet 10 inches, 11 feet 1 inch, and 10 feet 6 inches in girth when I saw them in 1906. At Dynevor Castle, in a low-lying damp spot, there is a very fine larch about 100 feet high and 9 feet 10 inches in girth, which may contain as much as 300 feet of timber. At Hafod, in Cardiganshire, the seat of T. J. Waddingham, Esq., there were planted in the year 1800 400,000 larch trees on a surface of 44 acres, for which the then proprietor, J. Jones, Esq., obtained a gold medal from the Society for the Encouragement of Arts.¹ Of these, I am informed by M. D. Barkley, Esq., many still remain, and a section of one which he sent me shows that they have grown to magnificent trees. As a rule, however, the large plantations in Wales are not allowed to stand to any great age, being more valuable when large enough to make pit timber.

In Scotland the number of larches remarkable for their size is so great that it is not easy to make a selection, almost every large estate, especially in the Highlands, having splendid trees of great age. So far as I can learn, the trees on Drummond Hill, near Taymouth Castle, the Perthshire seat of the Marquis of Breadalbane, are actually the largest in Great Britain. I visited this place in April 1904 and carefully measured the best trees myself. They are growing on the slope of a hill facing south in good open loamy soil, overlying rock, from which, in some places, springs of water rise; and seem to owe their immense size in part to the fact of their having been mixed with beech and oak, which were planted at or about the same time, and which they have far surpassed in height. The finest tree is figured in Plate 101, and is about 115 feet in height by 17 in girth. It carries its bulk very well up to at least fifty feet, where some large branches go off, and contains, according to Mr. Peter Mackay, the forester, over 500 feet of timber. I estimated the first length alone at 450 feet, the next at 100 feet, and the top and branches at about 50 feet more, so that this tree must contain nearer 600 than 500 cubic feet. In November 1893 a tree near it on the same hill was blown down, and the butt, which was sold, weighed ten tons on the railway, or about 500 cubic feet, besides which three tons more were cut up on the estate. Near it is a tree (Plate 102) remarkable for being divided at about 20 feet up into four large upright stems, a rare occurrence in this species. It is nearly the same height and girth as the first, and may contain as much timber. A third, as measured by the forester, has a bole of only 6 feet long, girthing at 1 foot from the ground no less than 24 feet, and at 5 feet 17 feet 9 inches; it divides into two huge trunks over 100 feet high. These trees are believed to be from 160 to 180 years old, and were probably planted as early as those at Dunkeld.

The next largest and probably the best known larches in Scotland are the so-called Mother Larches, which stand close to the ruins of the Cathedral at Dunkeld (Plate 103), and which were planted, according to the inscription on a stone slab in the wall close by, in 1738 by James, third Duke of Atholl, who, according to Hunter, obtained them from Mr. Menzies of Culdares, who brought a few small plants from the Tyrol in his portmanteau; but in an account of the larch plantations on the estates of Atholl and Dunkeld, published in the *Transactions of the Highland Society*

¹ Michie, *The Larch*, 63 (1885).

(vol. v.), which is largely quoted by Loudon, it is said that Mr. Menzies of Migenny was the introducer, and Walker¹ gives 1727 as the date of their introduction. When measured in 1831, Loudon says that the largest was 100 feet by 10 feet 6 inches at 5 feet from the ground. In 1888, according to the tablet mentioned above, it was 102 feet high, and girthed at 3 feet 17 feet 2 inches, at 5 feet 15 feet 1 inch, at 17 feet 12 feet 10½ inches, at 51 feet 8 feet 8 inches, and at 68 feet 6 feet 1 inch, the estimated contents being 532 cubic feet. When measured by Mr. Keir, forester to the Duke, in 1899 it was 15 feet 6 inches in girth; and I made it in 1904 15 feet 8 inches and 100 feet high; so it is still growing and vigorous, though the smaller tree beside it has lost most of its top and many of its branches.² There are many other fine larches on this estate, of which the largest perhaps, on the Kennel Bank at Dunkeld, is 120 to 125 feet high by 11 feet 10 inches in girth, with sound top and clean bole to 50 to 60 feet, containing about 350 feet of timber. Three trees of the same age as the Mother Larches are growing near the Castle at Blair Atholl, but are not nearly as large or well shaped.

At Gordon Castle there are some fine larches, one of which, growing in a plantation called Cotton Hill, exposed to the full blast of the North Sea, is figured on account of its remarkable trunk (Plate 104). An immense limb comes off close to the ground, where the trunk girths 20 feet 6 inches, and at about 5 feet, where the tape is seen in the plate, it is 11 feet in diameter. The branches spread to at least 15 yards on each side and measured 198 feet in circumference, and the tree in April 1904 was covered with fine cones, which were beginning to shed their seed, and from which I have raised some plants.

At Monzie Castle, near Crieff, are some splendid larches of the same age and origin as those at Dunkeld, of which the largest, according to Hunter, was 100 feet by 16 feet 3 inches, and contained about 380 feet of timber when he wrote in 1883. I have not seen these trees myself, but Henry measured the largest in 1904 as 109 feet by 17 feet 4 inches, and describes them as very beautiful trees with immense pendent branches in full health and vigour. Hunter says that John, fourth Duke of Atholl, called "the Planting Duke," because he is said to have planted over 10,000 acres of larch, considered them to be the only rivals to the Mother Larches at Dunkeld, and sent his gardener every year to report on their progress. They are figured by Michie on p. 205.

At Inveraray there are some very fine larches on the level ground near the Castle. The best that I measured was about 110 feet by 11 feet, but there may be taller ones;³ none approached the silver firs in the same locality in height or girth. They serve to show, however, that the larch will succeed well in a climate as unlike that of its native mountains as it is possible to find in Scotland, provided the soil is good and there is shelter from the west wind.

¹ *Economic History of the Hebrides and Highlands*, ii. 214 (1812).

² I was told by Mr. Keir in 1906 that the largest tree had lately been struck by lightning and was now quite dead.

³ In *Old and Remarkable Trees of Scotland*, p. 64, it is stated that a larch at Ben-an, in the parish of Inveraray, was 130 feet high and 10 feet in girth at 3 feet, and others are reported at Glenarbuck, in the county of Dumbarton, and at Auchintorlie, in the same county, 143 feet and 140 feet high, but these latter measurements are not reliable, and have never been confirmed. Mr. Renwick has recently measured the Auchintorlie tree, and finds it only 95 feet high.

In the *Scottish Arb. Soc. Trans.*, viii. 233, J. Hutton states that at Keppoch, in Inverness-shire, there were in 1878, 124 larch trees, said to have been brought home as two-year seedlings by Ranald Macdonald of Keppoch in 1753. They grew on an area of about eight acres, and had an average height of about 90 feet, and were then estimated to contain altogether 18,848 cubic feet of timber. The two largest, close to the banks of the Roy, were 108 feet by 12 feet 2 inches, contents 355 feet, and 86 feet by 14 feet 7 inches, contents 358 feet; and he mentions that upwards of forty similar trees were blown down in 1860, so that the timber on this area would have exceeded 3000 feet per acre. This property now belongs to the Mackintosh of Mackintosh, whose forester, Mr. A. Rose, tells me that at the present time there are only seventy-seven trees left, of which twenty-five are small ones which have suffered from various causes; the remaining fifty-two are fine trees with an average content of 120 feet, making, together with the smaller ones, only 7192 cubic feet in all. The largest now standing, which is about twenty-five yards from the banks of the Spean, is 74 feet by 18 feet 6 inches at 3 feet from the ground, and contains 395 cubic feet. The tallest is 108 feet by 11 feet 2 inches. The two largest in 1878 have both been since cut on account of decay, but the rings counted on the stump were 123 and 131 only, which does not agree with their reputed history.

There are very tall and large larches at Brahan Castle and elsewhere in East Ross, one of which was reported by Mr. Pitcaithley¹ as being 115 feet by 11 feet. Mr. Munro-Ferguson tells me that a very large larch was recently felled on his property at Novar; and his factor, Mr. Meiklejohn, sends me the following measurements:—at 5 feet from the ground 12 feet 8 inches, at 25 feet 10 feet, at 40 feet 9 feet 4 inches. The cubic contents of the trunk were 400 feet, and the branches probably contained 50 more.

The highest elevation which I found recorded for the larch in Scotland is in the Ballochbuie forest, where three larches of great size were reported, in 1860, to be in a sound condition at 117 years old and 1110 feet above the sea.

Michie² gives a long account of some fine larches growing in the Paradise at Monymusk, in Aberdeenshire, with details of their measurements; the largest in 1881 was 100 feet by 10 feet 5 inches at 20 feet from the ground, and was supposed to contain 416 cubic feet.

A remarkable instance of the manner in which the roots of the larch may continue to grow after the tree has been cut is described and figured in *Gardeners' Chronicle*³ from a specimen submitted by the late Mr. Webster, head gardener at Gordon Castle. The figure shows the felled stump, rotten in the centre, and with the new wood surging over the edges of the wound, and also two roots of the foster tree, inosculating by means of various branches with those of the stump.

The larch has been extensively planted in Ireland, and has given, when grown on ordinary soils, excellent results, as it has usually remained free from disease. As an instance of good growth, Mr. Mitchell, land-agent at Doneraile and an experienced forester, told Henry that many trees cut in 1891 in a plantation on the Kilworth

¹ *Trans. Scot. Arb. Soc.* xi. 505.

² *The Larch* (1885).

³ *Op. cit.* 31st Aug. 1872, p. 1161.

property in Co. Cork must have been 135 feet in height, as he measured them lying on the ground 120 feet to the small end, where they had been cut off at 6 inches diameter. There are still trees as large growing on the same property. Attempts have been made to plant pure larch on peat-bogs; but even when the bogs have been well-drained and good soil has been added to the pits at the time of planting, the trees have not grown. In such cases a preliminary plantation of Scots pine, or in localities with a mild climate the maritime pine, will prepare the bog for larch, which after a few years can be planted in amongst the pines. The conditions for success in bog-planting are delicate, depending apparently on moderate drainage, as when the bogs are quite dry the trees are starved for want of water, and when they are too wet, trees will hardly grow at all. Mr. Richards, forester at Penrhyn, who has had great experience, is confident that good larch can be grown on peat-bogs; and isolated trees doing well on peat have been seen by Henry in various parts of Ireland. Experiments with larch and various mixtures of trees that will grow easily on bogs should be attempted. The American larch has never been tried, and possibly might succeed better than the common species, as it is a swamp-loving tree.

The most remarkable old larches in Ireland are at Doneraile Court in Cork, the seat of Lord Castletown. The history of these trees, which were seen by Henry in February 1907, is obscure, but there is a tradition that they were sent in the eighteenth century to Doneraile by the Duke of Atholl. Five trees out of six originally planted now remain, all of peculiar habit, with numerous more or less weeping branches, the lowermost of which spread over the ground to a great distance, and in one tree are layering. This tree is about 70 feet high, and is 12 feet 7 inches in girth at 5 feet from the ground, the base of the tree below 4 feet being much swollen and covered with very thick bark, like that of old trees in the Alps. On one side the branches spread to 70 feet distance, and on the other side, where there was less room on account of other trees, to 30 feet. Another tree, 10 feet 10 inches in girth, has a spread of 91 feet in diameter. None of them attain more than a moderate height, which is difficult to explain, as ordinary larch grows very tall in the neighbourhood. From the seed of the old trees, sown in 1890, plants were raised, which were put out in 1893 on a hillside, seven acres in extent, and with good soil. This small plantation is now remarkably healthy, though the trees are very dense on the ground, and, at seventeen years old from seed, they average 37 feet in height and 20 inches in girth.

At Carton Park, the seat of the Duke of Leinster, there is a curious tree with the trunk inclined and pendulous branches, which was in 1903 60 feet high and 9 feet in girth. It is considered to be one of the original importations from Scotland in the 18th century. A fine tree in the same place with a straight stem measured 98 feet by 10½ feet. At Abbeyleix House, the seat of Viscount de Vesci, a tree is growing on the lawn similar to those at Doneraile in having weeping branches, some of which are layering. At Dartrey Castle, Co. Monaghan, the seat of the Earl of Dartrey, there are three very old trees, also with more or less pendent branches, which were in 1903 13 feet 10 inches, 13 feet 8 inches, and 11 feet 7 inches in girth respectively. At Emo Park, Queen's

County, the seat of the Earl of Portarlington, there are about twenty fine trees in the pleasure ground, one of which measured in 1907 105 feet by 7 feet 9 inches, another being 92 by 10 feet.

LARCH IN THE ALPS

In its native home the larch loves a dry cold winter climate, where the snow lies from December to April or May, and at the higher elevations does not begin to vegetate before the end of the latter month. It is not very particular as to the geological character of the soil provided that the rock is sufficiently disintegrated for the roots to penetrate and there is a fair amount of soil in which the seeds can germinate, and as a rule natural reproduction is fairly regular and abundant. It is not often allowed to attain its full age, which may be 150 to 300 years or more, on account of the value of its timber for building and other purposes.

As to the size it attains in its native home I have few exact particulars. The largest that I have measured myself was near Modane, in the forest de Villarodin, at 4500 feet elevation, growing on schist with a north aspect. This tree, said to be the largest in the district, was about 90 feet high by 16 feet in girth, but tapered rapidly, and would not contain more than about 200 feet of timber.

By far the finest specimen of the larch in the Alps is figured in Plate 105, made from a negative which was very kindly lent me by M. Coaz, Chief Forest Inspector of the Swiss Forest Department, and which is described in *Les Arbres de la Suisse*¹ as follows:—

“The larch of Blitzlingen grows opposite the little village of this name in the district of Conches in the upper Valais at an elevation of 1350 metres. At the foot of a slope facing north-west, on a narrow terrace this tree grows in a deep and fresh loam, rich in humus, and overlying gneiss rock. There it has become one of the largest in Switzerland, and measures at its base 8 metres 70 cent., and at 1½ metre is still 7½ metres in girth. Its branches extend 10 metres from the trunk. Its top is dead, and thus it is only 29 metres high. Strongly attacked by decay, its trunk does not allow its age to be exactly determined, but no one can accuse us of exaggeration if we estimate it at about five centuries.”

According to Dr. L. Klein, who gives an excellent account of the larch,² it sometimes attains in the Alps an age of 600 to 700 years. Some stumps which he saw in the so-called Park of Saas-Fee, in the canton of Valais, showed that number of rings, but these trees did not exceed from 1 to 1½ metre in diameter. Dr. Klein counted on a sawn stump near the Findelen glacier 417 annual rings in a diameter of 85 centimetres. He gives several excellent illustrations of Alpine larches taken near the Riffel Alp, one of which shows a tree forking close to the ground into four stems, and another a so-called Candelabra larch with branches rising parallel to the main stem.

¹ Schmid u. Francke, *Baum Album der Schweiz* (1900).

² Karsten u. Schenck, *Vegetationsbilder*, ii. tt. 25-28 (1905).

LARCH IN OTHER COUNTRIES

In Norway, so far as I have seen, the larch does not grow well on the coast, though there are fine trees 70 to 80 feet high at a farm called Kjostad near Trondheim, and in the interior and farther south. Schübeler tells us that it has been successfully grown as a forest tree, especially at Brandvold, in the Glommen valley, where trees planted in 1803 had attained in 1878, according to Forstmeister Mejdele, from 70 to 95 feet high, the largest having a diameter of 14 inches at 58 feet from the ground. A very large tree said to be 150 years old existed in 1866 near Gothenburg in Sweden.

The larch is one of the few European trees which appears to grow really well in New England. The following instances of its success are recorded in *Garden and Forest*:—vol. ii. p. 9, an acre of larch planted in 1877 by Mr. T. H. Lawrence of Falmouth, Mass., on gravelly soil, in an exposed situation, a mile from the coast, was awarded a prize in 1888, when the trees formed a regular and complete cover on the ground, and many of them were over 25 feet high; vol. iv. p. 538, records the success of a plantation made by Mr. J. Russell at East Greenwich, Rhode Island, with 100 small seedlings costing one dollar, which were planted in 1879, and in 1891 were 20 to 27 feet high. Here the larch has been planted alternately with the native *Pinus Strobus*, to which they form an excellent nurse. In 1896 Sargent (vol. ix. p. 491) speaks of it as a tree likely to produce valuable timber in the northern states; but in Virginia, on the lower Chesapeake river, the climate is too wet and hot for it, and the trees did not thrive (vol. i. p. 500).

European larch has been tried in various places in the Himalaya, but not with much success, those at Manáli, in Kulu, being apparently the most successful; in 1881 young trees four years old were 6 feet high.

TIMBER

The value of larch timber for all purposes where durability and strength are required has been so well known for so many years past and is so fully dealt with by Loudon, Michie, "Acorn," and many other writers that I need not say very much about it. There is no home-grown timber so generally used on estates for building and fencing, and though its price has fallen considerably of late years on account of the increasing competition of foreign timber, it is likely to remain in demand, and is easier to market at all ages than almost any timber except ash.

The only country from which larch timber is at present imported or from which any possible supplies can come in future is the north of Russia, and this at present is not used to any great extent; but shipbuilders, collieries, and railway companies are not buying home-grown larch so freely as they used to do except in districts where it can be procured close at hand.

For long telephone poles, for bridge-building and other purposes where lengths of 50 feet and upwards are required, heavy larch poles exceeding 50 cubic feet fetch prices of from 1s. 2d. to 1s. 4d. a foot standing, and cannot always be procured when

wanted. But the greater strength and durability of the red heartwood in trees of great age does not command the increased price which it ought to be worth, and it is often best to keep this for private use and sell the smaller and younger trees, whose timber cannot be expected to last as long. For trees of 30 to 50 cubic feet 1s. per foot and upwards, if not too far from a railway, is about the present price. For trees of 15 to 30 cubic feet 9d. to 1s. should be realised, and for small thinnings the price fluctuates according to the local demand for fencing, hop-poles, and pit-timber.

On account of the durability of larch wood under water, it is specially adapted for piles, wharves, and groins; but owing to its propensity to warp and twist and the difficulty of sawing, planing, and jointing it in comparison with most other coniferous woods, it is seldom used for inside work. It makes very handsome panelling, however, if the red heartwood is carefully selected and seasoned, and is preferred to all other woods in its native Alps for building log-houses, which in some cases are known to have remained sound for 400 years.

The Duke of Atholl informs me that the larch used in the construction of the stables at Dunkeld in 1809 appears to be still quite sound; and I saw at Blair Castle a handsome table 5 feet in diameter made from a transverse section, laid as veneer, of a larch grown on the property, which shows eighty-seven annual rings. In the museum at Innsbruck I saw a very handsome antique chest made from very dark-coloured larch wood, which had been dug out of the ground, akin to bog oak in character; and the wood is used in conjunction with that of *Pinus Cembra* for making artistic furniture by Messrs. Colli Brothers of Innsbruck.

For ship- and boat-building it was at one time much more used than at present, and knees cut from its roots are at least as strong and durable, if not more so, than oak knees.

The bark, though used to some extent for tanning, is now seldom worth stripping except in the case of large trees felled in the spring, when, if taken off in large slabs, it makes a very durable covering for summer-houses, sheds, and other rustic buildings.

Venice turpentine is a resinous product of the larch formerly much valued in medicine and surgery, and for making varnish, of the production of which Loudon gives ample details; but like so many similar products, it has gone out of use in this country at least, but is still sold in Venice, where I procured a sample of it. Manna of Briançon is a saccharine exudation from the leaves of the tree in the form of small white opaque grains which formerly had some repute in medicine.

(H. J. E.)

Abies Ledebourii, Ruprecht,¹ *Beit. Pflanz. Russ. Reich.* ii. 56 (1845).

A tree attaining in Siberia over 100 feet in height and 9 to 12 feet in girth. Bark resembling that of the European larch. Young branchlets slender; in specimens from the Ural mountains and Tobolsk, pubescent with long hairs in the furrows between the pulvini; in specimens from the Altai, glabrous; girth at the base by a sheath of the previous season's bud-scales, within which a ring of pubescence is visible. Branchlets of the second year glabrous, greyish-yellow, shining. Terminal buds broadly conical, resinous, with ciliate scales. Lateral buds hemispherical, dark brown, resinous. Apical buds of the short shoots broadly conical, girth at the base by a dense ring of pubescence. Leaves soft in texture, very long and slender, up to 2 inches in length, narrower than in *L. europæa*, sharp-pointed, agreeing with that species in the arrangement of the stomata, but more deeply keeled on the lower surface. Staminate flowers as in the European larch. Pistillate flowers according to Willkomm, ovoid, pale green. Cones, when unopened, cylindrical, with the terminal scales not gaping and the bracts quite concealed; variable in size, up to 1½ inch long, composed of five spiral rows of scales, five to six scales in each row. Scales convex from side to side and also from the base to the apex, quadrangular, about as long as broad (½ inch); upper margin rounded or truncate, thin, entire, not bevelled, inflected; outer surface finely striate, covered with a reddish-brown pubescence, which is most marked towards the base of the scale. Bract ovate or oblong with a cuspidate point, extending about one-third the height of the scale. Seeds lying on the scale in shallow depressions, with their wings widely divergent and not extending to its upper and outer margin. Seed ⅙ inch long; with its wing ½ to ⅝ inch long; wing about ⅙ inch in width, broadest about the middle.

This species is amply distinct from *L. europæa*, differing in the long and slender leaves, which appear about ten days earlier in the spring; and in the

¹ This name is quoted wrongly as *Larix Ledebourii*, Ruprecht, in *Index Kewensis*, ii. 31, and in Sargent, *Silva N. Amer.* xii. 4.

cones, which have fewer and differently shaped scales and short concealed bracts. In the Siberian larch the scales are convex both laterally and longitudinally, whereas in the European larch they are flattened longitudinally. The seeds, moreover, of the former have longer and differently shaped wings, and do not cover the scales of the cone up to their margin as is the case in the latter.

VARIETIES

In wild specimens both pubescent and glabrous branchlets occur. Cones from a tree, cultivated in the Botanic Garden at St. Petersburg, differ in being narrowly cylindrical, with oblong scales only half the width of wild specimens; and the bracts are also much narrower. The seeds, however, lie on the scales as in wild specimens; and the scales have the convex form and inflected upper margin of typical *L. sibirica*.

A supposed variety, *rossica*, occurring in northern Russia, was distinguished by Regel as having small cones; but as Beissner informs me in a letter, it was subsequently abandoned by Regel, and is now not noticed by Willkomm or by any Russian botanist. Sir C. Wolseley, Bart., vice-consul at Archangel, has kindly sent me excellent fruiting specimens from Archangel, which differ in no respect from the Ural larch.

DISTRIBUTION

The Siberian larch has an extremely wide distribution, occurring in north-eastern Russia and throughout a great part of Siberia.

In European Russia it occurs wild in the governments of Archangel, Vologda, Viatka, Perm, and Orenburg. According to Korshinsky,¹ it grows rather sparingly in the plains of northern Russia, as isolated trees in the pine forests; whereas on the mountains of the Ural chain and its branches it forms extremely large forests, sometimes pure, and sometimes mixed with pine and spruce. Its exact distribution is differently stated by various Russian authorities. Herder² adds to the preceding provinces Ufa, Olonetz, eastern Finland, and the northern parts of Kostroma and of Nijni-Novgorod. Ruprecht³ states that it commences to grow in the northern part of the government of Olonetz beyond the city of Kargopol, from whence extensive woods of it stretch to the Ness river in the Kanin peninsula. In this peninsula it attains its most northerly point in Europe, on the Arctic circle. Further east its distribution sinks to the southward, and its most northerly point on the Ural range is about 58° latitude.

Its distribution in Siberia is not yet clearly known, as it has been confused with *Larix dahurica*. It would appear to be the species common in middle and southern Siberia west of Lake Baikal, while *Larix dahurica* apparently occupies eastern Siberia and Manchuria, a close ally of it, *Larix Cajanderi*, occurring in the extreme north in the lower part of the valley of the Lena, north of lat. 63°. *Larix sibirica* is reported from Olga Bay in Manchuria, but this requires confirmation; and it has

¹ *Tent. Fl. Rossia Orientalis*, 493 (1898).

² *Act. Hort. Petrop.* xii. 101 (1892).

³ *Loc. cit.*

been supposed to occur in Mongolia and north China; but Mayr has recently described the North China larch as a new species—*Larix Principis Rupprechtii*. In Siberia its most northerly limit is lat. 69° on the Yenesei and Kolyma, its southern limit extending from the Ural at lat. 54° to the Altai in lat. 52°.

The Siberian larch was reported by Kanitz¹ to occur as a shrub in upper and middle Moldavia at about 6000 feet elevation. He identified it on the authority of Parlatore in a letter. I have seen no specimens from this locality, and consider the identification very doubtful.² (A. H.)

An excellent account is given by Mayr³ of a plantation of this tree which was made in 1750-1760 for the Czarina Elizabeth at Raivola on the Russian-Finnish frontier north of St. Petersburg. The seed was procured from Ufa, and the trees have on the better land grown remarkably straight and clean without branches for 20 metres up, and attain 40 metres in height with a diameter of 70 centimetres. The wood of these trees, which was shown at the Paris exhibition of 1900, was of remarkably good quality, and Prof. Mayr recommends this tree strongly for cultivation. But as summer does not commence in Finland until June, and the trees had already turned yellow on September 18th, it is probable that the species is not unlikely to succeed in Great Britain except perhaps in elevated districts in the north and east of Scotland.

On my journey to Siberia in 1897 I saw larches in the Ural mountains near Zlataoust, but only after passing the watershed into Asia, and these were of no great size. In the Altai they first appeared at about 3000 feet, and at 4000 feet they became more numerous and larger, some of them 3 feet to 4 feet in diameter and about 100 feet high, but nearly all were dead at the top, and not yet in full leaf on 7th June. They grow scattered in open forest on the drier hillsides as well as on marshy flats, and where the soil is damper are often mixed with *Picea obovata*.

Farther to the south in the upper valleys of the Katuna and Tchuya the larch became the prevalent tree, and extends to a higher elevation than any other, following the banks of the mountain streams on the Mongolian frontier up to about 7500 feet. At this elevation I saw a grove of young larches from 8 to 15 feet high, and cut one of the smallest to count the rings, of which there were twenty-five in a diameter of only 1½ inch. Some of the old trees were remarkably stunted, only 10 to 12 feet high and 5 feet to 6 feet in girth. In this region the climate is extremely severe, frost and snow occurring even in July. The bark of the tree is used all over the region where it grows for covering the winter huts of the nomad Tartars, which are in shape and construction very like the lodges of the Indians in Montana.

CULTIVATION

It was introduced by the Duke of Atholl in 1806 from Archangel, as stated in the fourth volume of the *Transactions of the Horticultural Society*, p. 416, and

¹ *Plant. Romania*, 139 (1881). Cf. also Janka, *Flora Siebenbergens*, xvi. 366 (1866).

² See distribution of the European larch.

³ *Loc. cit.* and *Naturw. Stud. Nordw. Russl. Allg. Forst. u. J.-w.* 1900.

was described as follows:—"The bark quite cinereous, not of a yellowish-brown colour, and not distinctly scarred as in the common larch, but, on the contrary, the vestiges of the scars are scarcely visible; the leaves come out so soon that they are liable to be injured by spring frosts, and what is remarkable, the female flowers are not produced till some time after those of the European larch appear; they are like those of *Pinus (Larix) microcarpa*. Mr. Sabine has a plant of this sort in his garden at North Mimms, which he received under the name of *Larix sibirica* from Messrs. Loddiges, who obtained the seed originally from Professor Pallas, whose *Pinus Larix* it probably is. He contrasts the cinereous bark of his plant with the pale brown colour of the common larch; it may probably prove to be a distinct species." So far as I can learn no trees of this introduction are now living at Dunkeld.

Large quantities of seed were procured by Messrs. Little and Ballantyne of Carlisle, and raised in their nurseries about eight years ago, but the trees from them have generally been a complete failure owing to the very early bursting of their leaf-buds.

I received in 1902, from the Tula Government, through Professor Fischer de Waldheim, some seed of the Siberian larch, and a few of the seedlings look rather more promising than those from North Russia; but we are not aware that any fair-sized tree of this species now exists in England.

In December 1902 I received seed of this tree from Herr E. Rodd, which was gathered in the Ouimon valley in the Altai mountains early in September, but he tells me that it is not naturally shed there until spring. This seed germinated, but the plants raised from it are small and unhealthy, and vegetate very early in the spring, so that they seem likely to grow as badly in this climate as the larch from the Ural.

In England, as a forest tree this species seems likely to be worthless, for it opens its leaves so early, and suffers so much from spring frost, that with few exceptions the young trees I have grown are unhealthy, and many have already died, though planted in a very cold and exposed situation.

In the north of Norway I saw it growing at the Government nurseries in Saltdalen in 1903 from Russian seed sown in 1882. Trees only 15 feet high were already bearing cones, but were much healthier and more vigorous than the common larch; and in the Botanic Garden at Christiania I noticed that though growing at the rate of a foot annually, the leaves were attacked by a Chermes like *C. laricis*.

TIMBER

The tree is common in the north of Russia, where it forms a large part of the forests on the east side of the White Sea; and in the valley of the Petchora, seems to attain very large dimensions. Seebohm¹ says that Alexievka at the mouth of this river is the shipping port of the Petchora Timber Company, where ships are loaded with larch for Cronstadt. "The larch is felled in the forests 500 or 600 miles up the

¹ *Siberia in Europe*, 174 (1886).

river, and roughly squared into logs varying from 2 to 3 feet in diameter. It is floated down in enormous rafts, the logs being bound together with willows and hazel boughs. These rafts are manned by a large crew, many of whom bring their wives with them to cook for the party, sleeping huts are erected on the raft, and it becomes to all intents and purposes a little floating village, which is frequently three months in making the voyage down the river."

This larch is now shipped to London in some quantity for various purposes, and has been considerably used for piles in the Dover harbour works, and elsewhere. Mr. D. J. Morgan of Morgan Gellibrand and Company informs me that it is one of the most durable timbers that can be used, but so hard that when it is being sawn water is poured on the saw to keep it from heating, and this is probably the reason why it is not much used in England. He informs me that all the lighters at Onega were built of larch timbers, which lasted a very long time, and that when an old house at Archangel, which had been built on a foundation of larch logs, was pulled down, they were found to be quite sound after lying on the ground for possibly a hundred years. The experiments which have been made with it in the quays at the Surrey Commercial Docks, where the wood was continually wet and dry, have proved the lasting power of this wood, which, from what I have seen of it, is much closer in the grain than English-grown larch. But Mr. G. Cartwright, engineer of the Grimsby Docks, tells me that though he has no actual personal experience of its use, it is considered inferior to the best English larch, as indeed its lower price would imply, and inferior in strength and durability under water to English oak, greenheart, jarrah, or even to Danzig red fir, and that for constructional purposes he would consider its value less than half that of large oak.

Messrs. Crundall and Company of Dover inform me that Messrs. Pearson and Sons have used a large quantity of larch deals for their block moulds, and for other purposes where much wear and rough usage is entailed, and the wood has given entire satisfaction. I purchased from Messrs. Howard Bros. and Company of London a long clean log of this tree, from north Russia, in order to compare it with that of home-grown larch, and find the wood is very slowly grown, there being fifteen rings in an inch of radius. The heartwood is less red and apparently much less resinous than that of the European larch. My carpenter reports that when free from knots it works as well as some red deal, and he considers it very well suited for the roofs of plant houses. Its present value is from £11 to £13 per standard.

(H. J. E.)

LARIX DAHURICA

- Larix dahurica*, Turczaninow, *Bull. Soc. Nat. Mosc.* xi. 101 (1838); Trautvetter, *Pl. Imag. Fl. Russ.* 48, t. 32 (1844); Regel, *Gartenflora*, xx. 105, t. 684 (1871); Kent, *Veitch's Man. Coniferae*, 390 (1900).

Pinus dahurica, Fischer, ex Turczaninow, *loc. cit.*
Abies pendula, Poiret, *Lamarck's Dict.* vi. 514 (1804).
Abies Gmelini, Ruprecht, *Beit. Pflanz. Russ. Reich.* ii. 56 (1845).

A tree attaining in Saghalien 140 feet to 150 feet in height, but in Siberia usually much smaller. Bark scaling in broad, thin, irregularly quadrangular plates. Young branchlets slender, glabrous, becoming pinkish at the end of the season, shining brown in the second year; older branchlets yellowish grey. Shoots girt at the base by a sheath of the previous season's bud-scales, with no ring of pubescence visible. Short shoots slender, dark brown or blackish, glabrous. Terminal buds globose, glabrous, resinous, with the basal scales subulately pointed. Lateral buds hemispherical, resinous, dark brown, glabrous. Apical buds broadly conical and surrounded by a ring of brown pubescence. Leaves light green, similar to those of *L. europæa* in size and arrangement of the stomata, with the tips usually blunter than in that species.

Staminate flowers sessile, smaller than those of the European larch. Pistillate flowers ovoid, red, with the bracts and scales more closely appressed than in the common larch, making the flower narrower and shorter; bracts slightly recurved, $\frac{1}{8}$ inch long, oblong, with a shallow notch at the upper margin between two pointed projections; mucro short, less than $\frac{1}{12}$ inch long.

Cones variable in size, dependent upon the number of the scales, $\frac{3}{4}$ to $1\frac{1}{4}$ inch long, cylindrical, slightly narrowed at the apex, where the scales gape open in the ripe cone, composed of three to four spiral rows of scales, six to eight in each row, bracts concealed. Scales longer than broad, about $\frac{1}{2}$ inch long; upper margin rounded, truncate, or slightly emarginate, bevelled, slightly denticulate, not recurved; outer surface glabrous,² channelled, shining light brown when ripe. Bracts not exerted, about $\frac{1}{8}$ inch long, much shorter than the scales. Seeds lying upon the scale in slight depressions, their wings narrowly divergent and not extending quite to its upper margin. Seed about $\frac{1}{8}$ inch long; together with its wing scarcely $\frac{1}{2}$ inch long; wing broadest just above the seed.

The Dahurian larch is a native of eastern Siberia, Manchuria, Corea, and

¹ Though this is the oldest correct name under the genus, I have not adopted it, as it has been erroneously applied to the American larch, and its use now would cause considerable confusion.

² Cultivated specimens, as those from Boynton and Murthly Castle, occasionally have slightly pubescent scales; but the cones and seeds in all other respects are typical of *L. dahurica*.

Saghalien. According to Herder¹ it occurs in the northern Ural range at lat. 68°, and at Nijni Kolymsk in north-eastern Siberia at the same latitude; but it is probable that in the former locality he may be referring to *Larix sibirica*, and in the latter case to the form now distinguished by Mayr as *Larix Cajanderi*. It is uncertain whether the larch which occurs in Kamtchatka is *L. dahurica* or a distinct species.²

Larix dahurica is very plentiful on the Stanovoi mountains, and along the southern half of the coast of the sea of Ochotsk. Middendorff found it on the Aldan mountains up to 4000 feet elevation. According to Komarov³ it forms woods in moist situations in the mountain valleys throughout the Amur, Ussuri, S. Ussuri, and Kirin provinces of Manchuria and in northern Corea. Korshinsky⁴ states that it is frequent in the whole Amur region, forming forests in the mountains of the upper Amur and Bureja, but that it does not occur in the plain between the Zeja and Bureja.

It occurs in Saghalien, in the northern half of which it grows mixed with common birch and attains a great size, a fallen tree in the forest having been measured by Hawes⁵ as 145 feet in length. Elsewhere it forms part of the coniferous forest of the island, being mixed with *Abies sachalinensis*, *Picea ajanensis*, and *Picea Glehnii*. It also occurs on the island of Shintar.

Elwes saw at Wellesley, Mass., a young larch raised in the Arnold Arboretum from seed received at Petersburg as *L. dahurica*, which had a peculiar growth of the branches, which, according to Prof. Sargent, is seen in all the trees of the same origin. At the commencement of each season's growth the new wood made a distinct angle, turning upwards a little, so that in four years' growth it became erect. Prof. Sargent states that he saw many larches in eastern Siberia which he considered to be *L. dahurica*, and that they all had the same habit. The young trees at Boston have not yet borne cones, but the main stems were making annual growths about 2 feet long, and the tree seemed more at home in that climate than in England.

HISTORY

Pinus pendula was first described by Aiton in 1789; and Solander's⁶ MS., on which the description was founded, states that the tree is a native of Newfoundland, with leaves longer and cones shorter than the European larch. A sheet of specimens preserved in the British Museum bears in Salisbury's handwriting "*Pinus pendula*"; three specimens are unmistakable *L. dahurica*; the fourth, a small branch, is *L. americana*.

Lambert's figure of *P. pendula*, published in 1803, is certainly *L. dahurica*, the drawing being made from specimens obtained from a tree in Collinson's garden at Mill Hill which was planted in 1739, the supposed first introduction of the species. Lambert also figures and describes, as a distinct species, *P. microcarpa*, identical

¹ *Act. Hort. Petrop.* xii. 98 (1892).

⁴ *Act. Hort. Petrop.* xii. 424 (1892).

² *Larix kantschatica*, Carr.

³ *Flora Manchuria*, i. 190 (1901).

⁵ *Uttermost East*, 105 (1903).

⁶ According to Loudon, *op. cit.* 2401, Solander's description was taken from the tree at Mill Hill, which, according to Lambert's figure, must have been *L. dahurica*.

with *L. americana*. He states that cones of both species were sent annually from America to Loddiges, *P. pendula* under the name of black larch, and *P. microcarpa* as red larch; and that both kinds were growing in Loddiges's nursery.

Lawson's *Manual*, published in 1836, gives a careful description of both species, and repeats the information that they are natives of North America.

So far as we know *Larix dahurica* does not grow in N. America; and no traveller or botanist except Pursh ever claimed to have seen in the eastern part of the continent any species but *L. americana*. Pursh¹ asserts that *L. pendula* and *L. microcarpa* are distinct species, and were seen by him, the former growing in low cedar swamps from Canada to Jersey, the latter occurring about Hudson's Bay and on the high mountains of New York and Pennsylvania. As *L. americana* varies in the size of the cone, it seems certain that Pursh only saw forms of *L. americana*. It is very difficult to understand how seeds of *L. dahurica* from eastern Siberia could have been introduced so early.

Until about 1840 the American origin of *L. pendula* was unquestioned; and a tree planted in that year at Bayfordbury, and recorded in the planting book as *L. pendula*, is still living, and is undoubtedly *L. dahurica*. *Larix dahurica* was noticed first in Lawson's *Manual* as a stunted bushy tree, growing poorly, as it was propagated from cuttings or layers; and is stated to have been introduced in 1827.

(A. H.)

REMARKABLE TREES

The finest specimen we know is figured in Plate 106, and is growing on the edge of a grassy drive at Woburn Abbey, where I first noticed its peculiar bark on the occasion of the visit of the Scottish Arboricultural Society to that place in July 1903. None of the members present could name the tree, and on comparing the foliage with the specimens at Kew I came to the conclusion that it must be a tree which is mentioned in the *Pinetum Woburnense* as *Larix pendula*. I went to Woburn again on purpose to see it in flower, on 31st March 1905, when the difference in the flowers from those of a pendulous form of the common larch growing close by was evident. But the less rugged bark, which resembles that of a cedar, is the best distinction, and is clearly shown in our illustration. It measured 86 feet high by 6 feet 7 inches in girth in 1905. I have raised a seedling from this tree.

A very similar tree is growing by the side of the entrance drive at Beauport, which from its bark and habit we believe to be of the same origin.

At Bayfordbury the tree planted in 1840 as *Larix pendula* is now 56 feet high and 5 feet in girth, with a conical stem, and bark scaling in large thin plates. European larches planted near it at the same time are 70 feet high and 5 to 6½ in girth. A tree at Denbies, near Dorking, the seat of Lord Ashcombe, was in 1903 40 feet high and 2 feet in girth. It is said to have been sent to Denbies as *Larix Griffithii* by Sir Joseph Hooker, but some mistake had evidently been made in the plant that was forwarded from Kew some forty years ago.

¹ *Fl. Amer. Sept.* ii. 645 (1814).

In the Cambridge Botanic Garden there are two trees of this species, one 56 feet high by 5 feet in girth, in 1906. The bark scales off in smaller plates than the common larch, and shows more red-coloured cortex below. The second tree, labelled *L. pendula*, is grafted at 6 feet up on the common larch, and has its stem bent over at a right angle a few feet higher up.

At Ribston Park, Yorkshire, there is a well-grown tree of *L. dahurica* which cannot be more than about forty years old, as Major Dent remembers its being planted, though its origin is unknown. It has somewhat pendulous branches and smooth bark without ridges, and measures 71 feet by 5 feet 2 inches. It had both new and old cones on it in 1906.

There are some larches at Boynton, near Bridlington, Yorkshire, which Sir Charles Strickland has always known as red larches, and supposed to have been of American origin, but which I believe, on account of their smoother bark, to be *L. dahurica*. The best of them is 75 feet by 7 feet 8 inches; another, with a very spreading top, was 9 feet 4 inches in girth; and both had cones from which seedlings have been raised. Sir Charles Strickland has written of these in the *Gardeners' Chronicle*, 1896, pp. 399 and 494. He says that the trees which have been grown at Boynton for eighty or ninety years under the name of red and black larch are the two trees described in Loudon as varieties of *Larix americana*; and that the red larch is more like the European larch, and in loose, rather wet, sandy soil grows at Boynton as fast and to as large a size, but he does not consider the wood quite as good as that of the common larch; it is more liable to twist and warp, though probably as durable. On drier soils the red larch is much less healthy and vigorous than the common one.

At Murthly Castle there is a row of fifteen trees which were planted about 1881 by Mr. D. F. Mackenzie, who informs me that they were probably from the nursery of Messrs. B. Reid of Aberdeen, but their origin cannot now be traced with certainty. Their habit varies very much, the first one, coming from the Castle, having very pendulous branches and a weeping top, which none of the others possess. The cones also vary somewhat in size and colour, but with one exception—which I believe to be a common larch planted subsequently to replace a dead tree of the original lot—are characteristic of *L. dahurica*. The trees average 40 to 45 feet high and 3 to 4 feet in girth, and have the bark distinctly smoother and less corrugated than the bark of common larch growing under similar conditions. They are fairly healthy in appearance, with no evidence of having suffered from Peziza, but are bearing cones so freely that I do not expect they will become large trees. Mr. Mackenzie attributes this to their growing on dry, gravelly soil.

(H. J. E.)

LARIX KURILENSIS

Larix kurilensis, Mayr, *Abiet. Jap. Reiches*, 66, t. 5, f. 15 (1890), and *Fremdländ. Wald- u. Parkbäume*, 300 (1906).

Larix dahurica, Turczaninow, var. *japonica*, Maximowicz, in Regel, *Rev. Sp. Gen. Larix*, p. 59, and *Gartenflora*, xx. 105, t. 685 (1871); Miyabe, *Mem. Boston Soc. Nat. Hist.* iv. 261 (1890).

A tree, attaining in the Kurile Islands a height of 70 feet and a girth of 7 to 8 feet. Bark, according to Mayr, scarcely distinguishable from that of the Japanese larch. Young branchlets covered with a moderately dense, wavy, irregular pubescence. Branchlets of the second year shining reddish brown, pubescent. Base of the shoot girt by a ring of the previous season's bud-scales, the uppermost of which are loose and reflected, no ring of pubescence being visible; short shoots dark red, or almost black, shining. Terminal buds dark red, ovoid, with comparatively few scales, which are acuminate, non-resinous, ciliate with brown silky hairs. Lateral buds ovoid, dark red, with ciliate scales. Apical buds of the short shoots hemispherical, dark red, with no ring of pubescence at the base.

Leaves glaucous, short, broad, and curved, about an inch long, rounded at the apex, few in a bundle, usually twenty to thirty, spreading so as to form a wide open cup around the bud; upper surface flattened, green without stomata; lower surface deeply keeled, with two bands of stomata, each of five lines.

Flowers not seen. Cones small, cylindrical, about $\frac{3}{4}$ inch long, composed of few scales, less than twenty, with the bracts conspicuous at the base of the cone, but concealed elsewhere by the upper scales. Scales oval, longer than broad, about $\frac{1}{3}$ inch long; upper margin thin, emarginate, slightly bevelled, not reflected; outer surface minutely pubescent towards the base. Bract panduriform, about half the length of the scale, terminated by a very short mucro. Seeds lying on the scale in two depressions which are separated by a membranous ridge, with the wings slightly divergent and extending up to the margin of the scale. Seed about $\frac{1}{8}$ inch long; seed with wing about $\frac{1}{3}$ inch long; wing broadest just above the seed.

(A. H.)

This tree was first distinguished as a species by Dr. Mayr, the distinguished dendrologist and traveller, who found it in the Kurile Islands, especially on Iturupp,¹ where it forms forests of some extent. Sargent gives an excellent illustration, plate xxvi. in the *Forest Flora of Japan*, from a photograph taken by Dr. Mayr, and I am able to show its aspect in the same island from two photographs kindly given me by the Imperial Japanese Forest Department (Plate 107). The upper shows a forest of larch on Iturupp; the lower a scattered group near the shore on the same island.

The tree was commonly planted in the neighbourhood of Sapporo, and it was introduced into Europe in 1888 by Dr. Mayr, and seems to grow almost as well as the Japanese larch, at least when young. There is a tree 15 feet high at Grafrath,

¹ We adopt this spelling on Dr. Mayr's authority, as the correct Aino name for the island. Eterofu is the Japanese form of the word, and Eterop a corrupt combination of both forms of spelling.

the experimental forestry station near Munich, where the thermometer goes down to 15° Fahr. below zero, and seedlings only four years old are already 5½ feet high. They resembled *Larix americana* more than *L. leptolepis* in the blackish colour of their young shoots. Dr. Mayr says that it is the first larch to become green in Europe, though in my nursery seedlings of the Altai and north Russian larches are both earlier. He says that its dark shoots have gained it the name of black larch from visitors to his nursery, and that in the park of The Duke of Inn- and Knyphausen at Lütetsburg in east Friesland it grows faster than any other species of larch, being 6 metres high at the age of seven years.¹

So far as our very short experience of this tree in England enables us to judge, it is likely to thrive well, at any rate in its youth. Several young trees which are in my nursery grow fast, and ripen their growths earlier than common larch. Some seed received from Japan in June 1906 germinated very quickly, and made healthy little plants the same season. It should be tried especially in the wetter parts of Great Britain.

(H. J. E.)

LARIX LEPTOLEPIS

Larix leptolepis, Endlicher,² *Syn. Conif.* 130 (1847); Gordon, *Pinetum*, 128 (1858); Mayr, *Abiet. Jap. Reiches*, 63, t. 5, f. 14 (1890), and *Fremdländ. Wald- u. Parkbäume*, 302 (1906); Kent, *Veitch's Man. Coniferae*, 397 (1900).

Larix japonica, Carrière, *Conif.* 272 (1855).

Larix Kaempferi, Sargent, *Silva N. Amer.* xii. 2, adnot. 2 (1898).

Pinus Larix, Thunberg, *Fl. Jap.* 275 (1784) (not Linnæus).

Pinus Kaempferi, Lambert, *Pinus*, ii. preface, p. v (1824).

Abies Kaempferi, Lindley, *Penny Cycl.* i. 34 (1833).

Abies leptolepis, Siebold et Zuccarini, *Fl. Jap.* ii. 12, t. 105 (1842).

Pinus leptolepis, Endlicher, *Syn. Conif.* 130 (1847).

A tree attaining in Japan a height of 100 feet and a girth of 12 feet. Bark of native trees, according to Mayr, similar to that of the European larch, the freshly exfoliating scales being more brownish than red; but in cultivated trees in England the bark begins to scale very early, peeling off usually in large long strips and giving a red appearance to the trunk. Young branchlets glaucous, usually covered with a dense, erect, brown pubescence, but occasionally almost glabrous, only a few brown hairs being present. Branchlets of the second year reddish with a glaucous tinge, retaining some pubescence or quite glabrous. Base of the shoots girt by a sheath of the previous season's bud-scales, the uppermost of which are loose and reflected, with no ring of pubescence visible. Short shoots stouter than in the common larch,

¹ In *Mitt. Deutsche Dendr. Ges.* 1906, p. 27, the age of this tree is stated erroneously as twenty-five to thirty years. Its height in 1906 is given as 9 metres.

² *Pinus leptolepis* was the name preferred by Endlicher; but he quotes *Larix leptolepis*, Hort., as a synonym; and as this is the first publication of *Larix leptolepis*, Endlicher is responsible for the name, and it is credited to him; and being the first published name under the correct genus is adopted by us. Moreover, it is the name by which this species is universally known; and the adoption of Sargent's name, *Larix Kaempferi*, would cause great confusion, as this has been used for *Pseudolarix Kaempferi*, the golden larch of China. The Japanese larch, though known to Kaempfer and Thunberg in the eighteenth century and mentioned by Lambert, was first described by Lindley in 1833.

reddish, glabrous. Terminal buds sharply conical, resinous, glabrous, the lowermost scales subulately pointed. Lateral buds ovoid, glabrous, resinous, directed slightly forwards. Apical buds of the short shoots conical, with loose scales, surrounded at the base by a ring of pubescence.

Leaves glaucous, about 1¼ inch long, rounded at the apex; upper surface flattened, with two bands of stomata, variable in the number of lines, often two to four in each band on leaves of the long shoots, usually one to two irregular lines on leaves of the short shoots; lower surface deeply keeled, with two conspicuous bands of stomata, each of five lines.

Staminate flowers ovoid, sessile, smaller than in *L. europæa*. Pistillate flowers ovoid, pinkish; bracts all recurved, about ⅓ inch long, oblong, broadest at the base, truncate, and scarcely emarginate at the apex, brownish with pink margins, mucro about ⅓ inch long. Cones shortly ovoid, broad in proportion to their length, 1 to 1¼ inch long, readily distinguished by the thin reflected upper margins of the scales, of which there are four to five spiral rows of eight to nine in each row. Scales almost orbicular, about ⅔ inch long and wide; upper margin very thin, reflected, truncate or slightly emarginate; outer surface furrowed, slightly pubescent. Seeds in very shallow depressions on the scale, their wings slightly divergent and extending to its upper margin; seed about ⅓ inch long, with wing ⅔ inch long.

A stunted form, growing on the higher parts of Fuji-yama, was collected by John Gould Veitch, and was considered to be a new species by A. Murray;¹ and is recognised as a variety by Sargent. According to Mayr, it scarcely deserves to be ranked as a variety, as it only differs in being a low tree, with smaller cones than usual, which are only ⅔ inch in diameter and globular in shape. (A. H.)

INTRODUCTION

It was introduced by J. G. Veitch in 1861 from seeds which he procured during his visit to Japan. Nothing is said by Kent as to the number of plants raised and sent out at that time, but probably the number was small, as we know of few trees as old as forty-five years. Larger importations were made later, and the tree grew so well generally that it is now being planted almost everywhere, and some of the older trees have produced good seed for ten years or more.

DISTRIBUTION

In Japan this larch grows naturally on the slopes of volcanic mountains in a sandy soil at 4000 to 6000 feet elevation, in a climate very much warmer and moister in summer, drier in winter, and less liable to late frosts than England.

¹ *Larix japonica*, A. Murray, *Pines and Firs of Japan*, 94 (1863).

Larix Kaempferi, var. *minor*, Sargent, *Silva N. Amer.* xii. 2, adnot. 2 (1898).

Abies leptolepis, Lindley, *Gard. Chron.* 1861, p. 23.

Where I first saw it, on a sandy plain above the Lake Chuzenji on the slopes of the volcano of Nantai-san, the trees were of no great size, averaging perhaps 60 to 70 feet in height, with a girth rarely exceeding 6 feet in mature trees, and more often 3 to 4 feet. They were very similar in habit to the larch in the Alps, and had not an excessive development of branches. Higher up above Yumoto in rich forest soil, thinly scattered among deciduous trees of many species, they were larger, sometimes attaining 80 feet high and 10 to 12 feet in girth; but I saw none anywhere which rivalled our larch in height, and am inclined to think it is not nearly such a long-lived tree, though, as I saw none felled, I was unable to count the rings. Prof. Sargent, who saw the tree in the same place as I did, came to a very similar conclusion. Mayr states that he found it wild on the volcanoes of central Hondo, Fuji, Ontake, Asama, Shiranesan, Norikura, and others, always growing near the timber line, with *Abies*, *Tsuga*, and *Picea hondoensis*.

The tree is valued for its timber, which is used for ship- and boat-building, and has lately come into great demand for railway sleepers and telegraph poles. In consequence of this it has been largely planted at elevations of 4000 to 5000 feet in the central and northern provinces, and many plantations that I saw of ten to fifteen years old were very similar to larch plantations in England in growth and habit. I also saw it planted experimentally in Hokkaido, along the lines of railway, where it seemed to grow as well in this rich black soil as in its native mountains.

CULTIVATION

In 1890 I sowed seeds from three different localities—Dunkeld, Hildenley, and Tortworth—and raised plants from each of them, which grew better than seedlings raised at the same time from Japanese seed; but this may have been partly due to the fact that the latter were dressed with paraffin by my forester to protect them from birds and mice in the seed-bed. At six years old these plants are now from four to eight feet high, and though some of them have been more or less checked by severe spring frosts, they are generally growing well.

As a proof of the hardiness of the tree I may mention that the late Sir R. Menzies showed me three young trees which he had planted, at an elevation of about 1250 feet, in the garden of the inn near the top of the pass between Glen Lyon and Loch Rannoch; and in some of his plantations on the north shore of Loch Rannoch they were growing very vigorously in mixture with Douglas fir.

No conifer of recent introduction has attracted so much attention among foresters as the Japanese larch, which, during the last ten years, has been sown very largely by nurserymen (Messrs. Dickson of Chester are said to have sold no less than 750,000 in the year 1905), and is looked upon by many foresters as likely to replace the common larch, because it is, so far as we yet know, less liable to the attacks of *Peziza Willkommii*. But this pest has already in more than one place been certainly identified on the Japanese larch, and I have little doubt that as time goes on we shall hear more of this. Henry visited in 1904 six plantations of Japanese larch of ages from five to sixteen years, and in none could detect any sign of canker. There

were plantations of European larch in every case adjoining those of the Japanese tree, and the former were all badly affected by disease. Henry concluded that the Japanese larch was practically immune from disease, though on his return to Kew he received specimens from estates in Perthshire and Dumfriesshire which were undoubtedly suffering from *Peziza*.¹ As, with the exception of Prof. Sargent and Dr. Mayr, no one had studied this tree in its native climate, I paid particular attention to it during my visit to Japan in 1904, and, as I have stated² elsewhere, came away with the impression that it is not likely to supersede the European larch as a forest tree, and am very doubtful whether it can be expected to become a profitable one, to plant under ordinary conditions. Though when young its growth is extremely rapid and vigorous, it has a great tendency to form spreading branches, and even in the much more favourable soil and climate of Japan, rarely, if ever, attains anything like the dimensions which the European larch does in Great Britain.

Mayr's opinion on the suitability of the tree for economic plantations in Europe is the same as my own, and he considers that though it may grow faster than the European larch for the first twenty years, yet that it will eventually be surpassed if planted under precisely similar conditions. He also agrees with me that though in selected positions and under careful cultivation it may not seem so liable as the European larch to the attacks of *Peziza*, yet that it is not immune, and the figures which he gives of its growth in Germany show that it has the same tendency to produce spreading branches there as in Great Britain. In a note on this tree by K. Kumé, chief of the Forestry Bureau in Japan, in *Trans. Scot. Arb. Soc.* xx. 28, January 1907, a yield table at various ages is given, which shows that on soils of medium quality in Japan the mean basal diameter at 100 years old is about a foot, the mean height 92 feet, and the stem volume per acre 6330 cubic feet. I will only note that what is meant by land of medium quality in Japan is very superior to what it is in this country. In Germany Mayr says that the seed falls in autumn from the cones, which are busily sought for by squirrels, and that self-sown seed has germinated freely at Grafrath under trees twenty-two years old.

REMARKABLE TREES

There are many specimens now of about 40 feet high in various parts of the country, but of those that I have seen the one figured, which is growing at Tortworth (Plate 108), is perhaps the finest. It measured in 1904, 45 feet by 4 feet 7 inches, and was covered with cones. It is growing on red sandy soil, and Lord Ducie thinks it is one of the earliest introductions. At Hollycombe, Sussex, the seat of J. C. Hawkshaw, Esq., Mr. G. Marshall measured a tree 45 feet by 2 feet 4 inches in 1904. At Hildenley, Yorkshire, there is a fine tree about 40 feet high, which produces good seed. A clump of fine trees is reported³ to be growing at Bothalhaugh, near Morpeth. There is also a fine specimen at Brook House, Haywards Heath, the residence of Mrs. Stephenson Clarke.

¹ See note by Mr. Massee in *Journ. Board Agriculture*, 501 (1904).

² *Trans. Scot. Arb. Soc.* xix. 77 (1906).

³ *Gard. Chron.* xxxix. 282 (1906).

At Dunkeld there is a tree planted close to a common larch, from which seedlings were raised at my suggestion by the late D. Keir, which appear to be hybrids between the two species.¹ His son, who succeeded him as forester to the Duke of Atholl, and who has watched the growth of these seedlings, considers them to be intermediate between the two species; but it is yet too soon to be certain.

At Abercairney, Perthshire, the seat of Col. Drummond Moray, there is a tree, raised from seed brought from Japan in 1883, which, measured by Henry in 1904, was 38 feet by 3 feet 5 inches. At Blair Drummond, in the same county, he measured ten trees planted in 1888, one of which was 44 feet high, and the average girth 2 feet 5 inches. They were all healthy though growing among common larch which was diseased.*

At Cullen House, Banffshire, Mr. Campbell tells me that there is a tree 45 feet by 3½ feet. At Kirkennan, near Dalbeattie, Kircudbrightshire, two larches sown in 1885 were in 1904 41 feet by 2 feet and 35 feet by 1 foot 11 inches. We are indebted for this information to the owner Mr. W. Maxwell.

In Germany at Schloss Lütetsburg, it seems to have grown faster than with us, for it is stated² that trees thirty-five to forty years old are 17 to 20 metres high, with a girth at 1 metre of 1.80 to 2.70 metres. (H. J. E.)

LARIX GRIFFITHII, SIKKIM LARCH

Larix Griffithii, J. D. Hooker, *Ill. Himal. Pl.* t. 21 (excl. ff. 1-4) (1855), *Flora Br. India*, v. 655 (1888), and *Gard. Chron.* xxv. 718, f. 157 (1886); Masters, *Gard. Chron.* xxvi. 464, f. 95 (1886); Kent, *Veitch's Man. Coniferae*, 395 (1900); Gamble, *Indian Timbers*, 720 (1902).

Larix Griffithiana, Carrière, *Conif.* 278 (1855).

Abies Griffithiana, Lindley and Gordon, *Journ. Hort. Soc.* v. 214 (1850).

Pinus Griffithii, Parlatores, DC. *Prod.* xvi. 2, p. 411 (1864).

A tree, attaining in the Himalayas about 60 feet in height, with thick brown bark, and wide-spreading, long and pendulous branches.

Young branchlets, reddish, covered with a dense wavy, more or less appressed pubescence, and girt at the base by a sheath of the previous season's bud-scales, the uppermost of which are very broad, loose, membranous, and reflected. Branchlets of the second year very stout, dull reddish brown, pubescent. Short shoots broad and stout, fringed above by very large, loose, reflected, pubescent, membranous bud-scales. Terminal buds broadly conical, non-resinous, with pubescent scales. Lateral buds ovoid, pointing outwards and forwards, non-resinous, pubescent. Apical buds of the short shoots conical, with loose pubescent scales.

Leaves light green in colour, about 1¼ inch long, ending in a short rounded point; upper surface rounded or flat, with one or two broken lines of stomata near the apex; lower surface deeply keeled with two bands of stomata, each of three

¹ Cf. *Trans. Roy. Scot. Arbor. Soc.* xviii. 62 (1905).

² *Mitt. Deutsche Dend. Ges.* 1906, p. 29.

(occasionally five) lines. In cultivated specimens, the leaves are fringed on each side with a very thin and narrow membranous translucent border.

Staminate flowers, ⅜ inch long, cylindrical, raised on short stout stalks, about 1/16 inch long. Pistillate flowers ovoid; bracts reflected at their bases, with the mucros pointing downwards, oblong, truncate or slightly concave at the apex, the green midrib being prolonged into a mucro about 1/8 inch long.

Cones 3 to 4 inches long, cylindrical, tapering to a narrow, flattened apex, supported on a short stalk, glaucous green or purplish, with orange-brown bracts before ripening, composed of five spiral rows of scales, eighteen to twenty scales in each row, which, on the opening of the cone, stand almost at right angles to its axis, the bracts being exerted with their mucros directed upwards. Scales quadrangular, with a cuneate base, about ½ inch in width and length; upper margin truncate and slightly emarginate; outer surface radially furrowed, densely pubescent towards the base. Bract lanceolate, nearly as long or quite as long as the scale, the mucro, often incurved, projecting beyond the scale about 1/16 inch. Seeds lying in slight depressions on the scale, their wings widely divergent and not extending to its upper margin. Seed, white on the inner side, shining dark brown on the outer side, about 1/8 inch long; seed with wing about 7/16 inch long; wing brownish, rather opaque, broadest about the middle. Cotyledons¹ five to six, which, in the seedling, are linear, pointed, and much longer than the succeeding leaves. (A. H.)

The Sikkim larch is confined, so far as we know at present, to a rather narrow area in the Himalaya, from eastern Nepal to Bhutan, but very possibly will be found farther east. It was discovered by Griffith, but not distinguished until Sir Joseph Hooker found it in E. Nepal in December 1848.² Here it was only a small tree 20 to 40 feet high, differing from the European larch, in having very long, pensile, whip-like branches. It is called "Saar" by the Lepchas, and "Boargasella" by the Nepalese, who said that it was only found as far west as the sources of the Cosi river. In Sikkim it is common in the interior valleys of the Lachen, Lachoong, and their tributaries from about 8000 to 12,000 feet elevation, and here attains a larger size, but is not found in the forests of British Sikkim. In *Illustrations of Himalayan Plants from Drawings by Cathcart*, where it is beautifully figured, Sir Joseph states that it grows to a height of 60 feet in deep valleys, but prefers the dry rocky ancient moraines formed by glaciers, and also grows on grassy slopes where the drainage is good. On my journey to Tibet in 1870 I saw this tree in the Lachoong valley, but nowhere forming a forest, and usually scattered singly in rather open places, where it seemed to me to have a much less erect and regular growth, with branches more drooping in habit than any other larch. Sir Joseph Hooker says that the wood is soft and white, but a specimen from the Chumbi valley, authenticated by cones, is described by Gamble as having red heart-wood with a slow growth, twenty-one rings to the inch, and a weight of 32 lbs. to the foot.

Though introduced by Sir Joseph Hooker, who sent seeds to Kew in 1848, this tree has, except in a few places in the south-west of England, failed to grow in Europe. He says that the seedlings raised from his seeds were 3 to 4 feet high in

¹ Masters, *loc cit.*

² *Himalayan Journals*, i. 255.

1855, and that some had withstood the severe winter of 1854-5 without protection, though others were killed, a difference which he attributes to some of the seed having been gathered from trees which grew at 8000 and some from trees at nearly 13,000 feet. Hooker¹ further states that hundreds of plants were raised and widely distributed by Kew, but in every case these succumbed in a few years to virulent attacks of *Coccus laricis*. As the climate of the Chumbi valley is much drier than that of Sikkim, it is quite possible that seed from that locality would give better results; but I have never been able to keep the tree alive at Colesborne for long, as it suffers from the dry climate, and seems to object to lime in the soil. Mr. Barrie, forester to the Hon. Mark Rolle, has been very successful in growing this tree from English-grown seed, and has sent me healthy young plants of it; but the seedlings I have raised at Colesborne both from imported and home-grown seed have always died, though protected by a frame.

REMARKABLE TREES

The largest specimen of the Sikkim larch we know of in this country is one at Coldrinick, near Menheniot, Cornwall, the seat of Major-Gen. Jago-Trelawney. I have not seen this tree, but the gardener, Mr. Skin, informs me that in 1905 it measured no less than 57 feet by 4 feet 6 inches in girth. It has very spreading branches, the width from point to point of the lowermost branches being 43 feet. The cones were admirably figured in the *Gardeners' Chronicle*,² and have produced fertile seed. The seedlings require careful treatment, as they easily "damp off."

A tree of the original introduction is growing at Strete Raleigh, Devonshire, the seat of H. M. Imbert Terry, Esq., who showed it to me in 1903, when it measured 40 feet high by 4 feet in girth. It is growing on poorish soil at a considerable elevation, where it is a good deal exposed to the damp south-west winds, and perhaps in consequence of this has thriven very well, and has borne fertile seed for some years past (Plate 109).

Another much smaller tree, which also bears cones, is growing at Leonardslee in Sussex. There is also an old tree at Pencarrow, in Cornwall, which in 1905 was only 12 feet high by 15 inches in girth, stunted and covered with lichen. It also bears cones.

Dr. Masters³ received flowering specimens in 1896 from The Frythe, Welwyn, Herts; but the tree from which they were obtained could not be found when Henry visited this place in 1906.

(H. J. E.)

¹ *Gard. Chron.*, *loc. cit.*² After this was printed a good illustration of the tree appeared in the same journal on 2nd March 1907, which shows that it is not only larger, but a better shaped tree than the one I have figured.³ *Gard. Chron.* xxvii. 296 (1900).

LARIX POTANINI, CHINESE LARCH

Larix Potanini, Batalin, *Act. Hort. Petrop.* xiii. 385 (1894); Masters, *Gard. Chron.* xxxix. 178, f. 68 (1906).

Larix thibetica, Franchet, *Jour. de Bot.* 1899, p. 262.

Larix Griffithii, Masters, *Jour. Linn. Soc. (Bot.)* xxvi. 558 (1902). (Not Hooker.)

A tree attaining in western China a height of 70 feet and a girth of 6 feet. Young branchlets bright yellow, with a scattered pubescence, densest near the base of the shoot, which is girt by a sheath of the previous season's bud-scales, showing within a ring of pubescence. Buds ovoid, with ciliate scales.

Leaves slender, up to an inch in length, ending in a sharp cartilaginous point, tetragonal in section, keeled above and below, with two bands of stomata, each of two lines, on both the upper and lower surfaces.

Staminate flowers, $\frac{1}{4}$ inch long, on a short but distinct stalk. Pistillate flowers ovoid, narrow and rounded at the apex; bracts closely appressed, on one side of the young cone with their tips pointing towards its apex, on the other side reflected about their middle with their apices pointing towards the base of the cone, ovate or oblong, rounded and entire at the apex, which is prolonged into a short mucro. The bracts in the pistillate flower, described above as seen in herbarium specimens, are probably all reflected at first; and gradually by the growth of the scale assume the erect position.

Cones cylindrical, rounded at the apex, $1\frac{3}{4}$ inch long, with the scales and bracts pointing upwards and outwards, or more or less spreading. Scales small, about $\frac{1}{3}$ inch long, almost orbicular, reddish brown, pubescent on the lower part of the outer surface; upper margin rounded or truncate, entire, thin, slightly inflected, not bevelled. Bract extending beyond the scale, exerted with the mucro about $\frac{1}{4}$ inch. Seeds in slight depressions on the scale, with their wings widely divergent and not reaching to its upper margin. Seed about $\frac{1}{3}$ inch long; seed with wing $\frac{1}{3}$ inch long; wing broadest just above the seed.

Larix Potanini has been collected in western China by Potanin, Prince Henry of Orleans, Pratt, and Wilson, who found it in the neighbourhood of the Szechuan-Thibetan frontier near Tachienlu at 7500 to 11,000 feet above sea-level. The same species, according to Franchet, was probably collected by Père Delavay farther south on the Likiang range in Yunnan at 11,600 feet altitude. Mr. A. Hosie, Consul-General in Szechuan, informs me that forty miles north-east of Tachienlu, there is a pure forest of this larch between 11,000 and 12,000 feet elevation on the southern slope of the mountain range, and extending for about a mile. It consists of fine straight trees, which he estimated to be about 70 feet high. At lower altitudes the larch gives place to silver fir and birch. The tree is known to the Chinese as "hung-sha," red fir, and produces the most valuable coniferous timber in western China.

Seed was collected by Wilson in 1904, and plants have been raised, which are growing well at Veitch's nursery, Coombe Wood.

This species, being a purely alpine tree of no great size, will probably be of no value as a forest tree, resembling in that respect its immediate allies *L. Griffithii* and *L. Lyallii*, between which it occupies an intermediate position as regards botanical characters.

(A. H.)

LARIX AMERICANA, TAMARACK

Larix americana, Michaux, *Fl. Bor. Am.* ii. 203 (1803); Sargent, *Silva N. Am.* xii. 7, t. 593 (1898), and *Trees N. Am.* 35 (1905); Kent, *Veitch's Man. Conif.* 389 (1900).

Larix americana, Michaux, var. *rubra*, Loudon, *Arb. et Frut. Brit.* iv. 2400 (1838).

Larix tenuifolia, Salisbury, *Trans. Linn. Soc.* viii. 314 (1807).

Larix microcarpa, Desfontaines, *Hist. Arb.* ii. 597 (1809); Lawson, *Agric. Man.* 388 (1836).

Larix laricina, Koch, *Dendrologie*, II. ii. 263 (1873).

Larix pendula, Masters, *Journ. Roy. Hort. Soc.* xiv. 218 (1892). (Not Salisbury.)

Pinus Larix americana nigra, Muenchhausen, *Hausv.* v. 226 (1770).

Pinus laricina, Du Roi, *Obs. Bot.* 49 (1771).

Pinus intermedia, Wangenheim, *Beit. Hölz. Forst. Nord Am. Hölz.* 42, t. 16, f. 37 (1787).

Pinus microcarpa, Lambert, *Pinus*, i. 58, t. 37 (1803).

Abies microcarpa, Poiret, *Lamarck's Dict.* vi. 514 (1804).

A tree attaining in America about 80 feet in height and 6 feet in girth. Bark separating in thin small polygonal or roundish scales about an inch in diameter, which are closely appressed, and show when they fall off the reddish cortex beneath. Young branchlets slender, often glaucous, glabrous, or with a few scattered hairs in the grooves between the pulvini; older branchlets glabrous, shining brown. Base of the shoot girt with a short sheath of the previous season's bud-scales, no ring of pubescence being visible. Short shoots small, blackish, glabrous. Terminal buds globose, slightly resinous, glabrous, with the basal scales subulately pointed. Lateral buds hemispherical, resinous, dark brown. Apical buds of the short shoots broadly conical, surrounded at the base by a ring of brown pubescence.

Leaves short and slender, not exceeding $1\frac{1}{4}$ inch in length, rounded at the apex, light green; upper surface flat or rounded, without stomata, except two broken lines near the tip; lower surface deeply keeled with two bands of stomata, each of one to two lines.

Staminate flowers sessile, shorter than in *L. europæa*. Pistillate flowers ovoid, reddish, very small; bracts pointing upwards and outwards, not reflected or recurved, $\frac{1}{8}$ to $\frac{1}{6}$ inch long, oblong, scarcely emarginate at the apex, reddish with a green midrib and mucro, the latter cuspidate and very short, about $\frac{1}{30}$ inch long.

Cones small, globose, consisting of three to four spiral rows of five scales each, reddish brown when ripe, $\frac{1}{2}$ to $\frac{2}{3}$ inch long. Scales gaping widely at the apex of the cone, longer than broad, about $\frac{2}{3}$ inch long; upper margin rounded, bevelled, slightly crenulate, not recurved or reflected. Bract concealed, minute, about $\frac{1}{8}$ inch long.

Seeds lying on the scale in minute depressions, with their wings only slightly divergent and not reaching to its upper margin, $\frac{1}{7}$ inch long; wing $\frac{1}{3}$ inch long, broadest just above the seed.

(A. H.)

DISTRIBUTION

The American larch is found in the United States from North Pennsylvania, Northern Indiana and Illinois, and Central Minnesota through the New England States, where, however, it is only found in cold and swampy places. In Newfoundland, Labrador, and the eastern provinces of Canada it occupies swampy ground, and extends from York Factory on Hudson Bay as far as Fort Churchill, $67^{\circ} 30' N.$, and west to Athabasca and Peace river districts, and in Alberta where it has been found forty miles S.W. of Edmonton.¹ Northwards it extends to the border of the barren lands. Mr. J. M. Macoun informs me that it was found by Mr. Camsell in the angle between the Snake river and the upper part of Peel river. This place is just within the Yukon district. He also states that it extends westward twenty-two miles up the Dease river, and northward along the upper Liard river to lat. $61^{\circ} 30'$. He has heard several people who have been on the Yukon speak of the larch, so that it must be quite common in some parts, though no definite data are as yet given.

The tamarack, as it is called in most parts of N. America, is a tree which I know but little in a state of nature, and which never seems to have received the attention from foresters which it deserves; for though it nowhere attains the size of the common larch, it seems able to thrive in undrained and swampy ground where that would die; and though a slow-growing tree in comparison with the common larch, its timber has the same valuable qualities as others of the genus.

Henry saw this species in Minnesota in 1906. On the Cass Lake Forest Reserve it occurs in the swampy ground between the pine-covered sand-dunes, in company with balsam fir, Thuya, black and white spruce, birch, and willow. The largest that he saw measured 81 feet by 4 feet 7 inches. The trees are remarkable for their buttressed roots, which branch and extend close to the surface and even above ground for as much as 6 feet. Seedlings were numerous in felled areas near Erskine, where the larch remaining uncut, occurs in swamps either pure or mixed only with birch. They grow very rapidly in the wet ground, taking root in mossy elevated patches and not in the water of the swamps; and averaged 10 feet high at seven years old, and were making leaders of 1 to 2 feet annually. He saw no stumps larger than 2 feet in diameter, and the tree in Minnesota rarely attains a greater size than 80 feet by 6 feet. In *Garden and Forest*, 1890, p. 60, there is, however, mention of a tamarack in Minnesota, which measured 7 feet 8 inches in girth and was estimated at 125 feet high.

In most parts of New England and over the greater part of British North America the tamarack is a well-known tree, but rarely attains any great size. The average in the neighbourhood of Ottawa is not over 50 to 60 feet, but when the tree is planted on drier, better land it will grow faster and attain 80 feet or more. I noticed that though it seeds freely the seedlings require more light than

Bell in *Scottish Geogr. Mag.* xiii. 283.

those of the spruce, balsam fir, and Thuya, which often grow with it, and it was only where clearings had been made, or in wet places on the edge of the groves, that they seemed able to thrive. Their growth is slow at first, but when established may be as much as two feet annually.

Dr. Bell gives the probable life of the white spruce in Canada as from 100 to 140 years, that of the black spruce 150 to 175 years, and that of tamarack 175 or 200 years. Of the latter he says:¹ About 1893 or 1894 the imported sawfly² came up from the direction of New York and got into the forests north of the Ottawa river. In a year or two it reached James bay and killed the tamarack throughout that district, which was only able to live three or four years after it was first attacked by the larva. This destruction continued to spread to the centre of Labrador, and now it has gone pretty well all over that great peninsula. But Mr. J. C. Langelier (*loc. cit.* p. 65), speaking of the same attack in the northern part of the province of Quebec, says that a great portion of the young trees were spared, and that the dead trees which remain standing are not attacked by rot, and would supply excellent railway ties.

REMARKABLE TREES

In this country there are not many large trees of this species, though it was introduced, according to Loudon,³ by the Duke of Argyll in 1760 at Whitton, near Hounslow. It has been entirely neglected by modern arboriculturists, and is seldom or never procurable in English nurseries. The largest trees that I know of are at Dropmore, where there is a well-grown tree 78 feet by 5 feet (Plate 110), and at Arley Castle, where there are three trees of nearly the same size standing together, of which the best measures 71 feet by 4 feet 8 inches. A fourth is nearly as large, and differs in having larger cones.

At Boynton, Yorkshire, there are two in a wet situation among other trees, about 50 feet high and sixty years old, which were raised by Sir Charles Strickland from seed produced by trees planted by his grandfather. These again have produced fertile seeds, from which seedlings are growing vigorously in a low frosty situation at Colesborne and have never suffered from frost or bug, though one of them in 1906 was attacked by *Peziza*. Sir Charles adds that on dry soil they have grown very badly.

At Beauport there are three rather stunted specimens of American larch, one of which, however, is 5 feet 10 inches in girth, and has the bark very smooth in comparison with the common larch. No specimen seems to have been sent to the Conifer Conference, but one is mentioned as growing in the grounds of Dalkeith Palace,⁴ which we have identified with *L. dahurica*. Several trees mentioned by Loudon are either not now in existence or were not correctly named.

(H. J. E.)

¹ *Can. For. Ass. Annual Report*, 1905, p. 59.

² According to Sargent this is *Nematodes Erichsonii*, Hartig, a European insect which was not much noticed in America before 1880, and which has recently attacked the larch in England. Cf. *supra*, p. 364.

³ *Op. cit.* 2400, 2401. The original tree at Whitton was between 40 and 50 feet high in 1837: it has long since been cut down.

⁴ *Veitch's Man. Coniferae*, 390 note (1900).

LARIX OCCIDENTALIS, WESTERN LARCH

Larix occidentalis, Nuttall, *Sylva*, iii. 143, t. 120 (1849); Lyall, *Journ. Linn. Soc.* vii. 143 (1864); Sargent, *Gard. Chron.* xxv. 652, f. 145 (1886), *Silva N. Amer.* xii. 11, t. 594 (1898), and *Trees N. Amer.* 36 (1905); Kent, *Veitch's Man. Coniferae*, 400 (1900); Mayr, *Fremdländ. Wald- u. Parkbäume*, 306 (1906).
Pinus Nuttalli, Parlatore, DC. *Prod.* xvi. 2, p. 412 (1868).

A tree attaining in America 200 feet in height and over 20 feet in girth; narrowly pyramidal in habit, the branches being much shorter than in the other species. Bark of young stems thin, dark-coloured, and scaly; becoming near the base of old trunks 6 inches thick and breaking into irregularly shaped oblong plates, often 2 feet in length and covered with thin reddish scales. Young branchlets covered with a minute dense pubescence intermixed with longer hairs in the grooves between the pulvini. In certain cultivated specimens the branchlets are glabrous from the first. Branchlets of the second year light brown, shining. Base of the shoot girt with a sheath of the previous season's bud-scales, no ring of pubescence being visible. Short shoots chestnut brown, shining. Terminal buds globose, with pubescent and ciliate scales, the lowermost of which are subulately pointed. Lateral buds hemispherical with pubescent and ciliate scales. Apical buds of the short shoots broadly conical, reddish brown, pubescent.

Leaves light green in colour, up to 1 $\frac{3}{4}$ inch long, rounded on the back, deeply keeled beneath, with stomatic lines as in *L. europæa*.

Staminate flowers raised on short stalks at maturity. Pistillate flowers ovoid; the bracts pointing upwards and outwards and not recurved, $\frac{1}{4}$ inch long, brownish in colour with a green midrib and mucro, oblong, emarginate at the apex; mucro $\frac{1}{10}$ inch long.

Cones ovoid, 1 $\frac{1}{4}$ to 2 inches long, with the bracts long-exserted and the scales opening early in the season to let out the seeds and then standing at right angles to the axis of the cone. Scales in six spiral rows, each row of nine to ten scales; orbicular, $\frac{1}{3}$ to $\frac{1}{2}$ inch long; upper margin entire or emarginate, thin, slightly recurved, not bevelled; outer surface densely pubescent. Bracts ovate-lanceolate, extending up to near the margin of the scale, beyond which the mucro projects $\frac{1}{8}$ to $\frac{1}{2}$ inch. Seeds lying in two deep depressions on the scale, their wings narrowly divergent and extending up to its upper margin; body of the seed $\frac{1}{8}$ inch long; wing pale coloured, short and broad, widest at the base; seed with wing $\frac{1}{4}$ to $\frac{2}{8}$ inch long.

VARIETIES

In the wild state the tree shows little variation, except in the pubescence of the branchlets, which in rare cases is entirely absent; while in other cases, noticed occasionally at high elevations, the amount of pubescence becomes so dense as to be almost similar in character to the tomentum of *Larix Lyallii*. In the few cultivated

trees in England, two distinct forms are apparent. Certain trees have pubescent branchlets and bear large cones, up to two inches in length, which have large scales purplish in colour before ripening, long exserted bracts and long-winged seeds. Other trees with glabrous branchlets bear small cones, about $1\frac{1}{4}$ inch in length, with scales green before ripening, shorter exserted bracts and small seeds with short wings. The former trees are more narrowly pyramidal in habit.

HISTORY

This splendid tree is the largest of the genus, and though it has been known to botanists for many years, it was till quite recently, on account of its being neglected by the early explorers of the limited region which it inhabits, one of the rarest exotic conifers in cultivation.

It was first discovered by David Douglas¹ in 1826 near Fort Colville on the Upper Columbia river; but was mistaken by him for the European larch. His specimens in the Kew Herbarium are labelled "in aqueous flats on the mountain valleys near Kettle Falls and in the Rocky Mountains, 1826." The tree was first described in 1849 by Nuttall, who found it on the Blue Mountains of Oregon in 1834.

It was introduced into cultivation in the Arnold Arboretum in 1881, seedlings having been imported from Oregon; but in the climate of New England these have remained small and stunted, though branches grafted on the Japanese larch have grown vigorously. Forty plants were sent from the Arnold Arboretum to Kew in 1881, and one tree survives (the fate of the other plants being unknown), which is remarkable for its beautiful straight stem and narrow, almost columnar habit. This tree bears large purplish cones, and is now (1906) 33 feet in height and 17 inches in girth.

Ten plants were subsequently sent in 1889 from the Arnold Arboretum to Kew, of which two survive. One of these trees is, however, identical in cones and pubescent branchlets with the tree of 1881, and may be erroneously labelled 1889; it has suffered damage at the top. The other tree, which has glabrous branchlets and bears small green cones, is not quite so narrow in habit, and measured in 1906 29 feet in height and $17\frac{1}{2}$ inches in girth.

The only other large tree in Britain with which we are acquainted is growing at Grayswood Hill, Haslemere; and measured in 1906 28 feet high by 19 inches in girth. It has pubescent branchlets, and bears purple cones, which are, however, smaller than those of the Kew tree, labelled 1881. Mr. Chambers informs us that this tree was obtained from Messrs. Dickson of Chester in 1889.

DISTRIBUTION

The western larch is confined to the more humid parts of the region, which extends from the western slope of the Rocky Mountains in British Columbia and

¹ *Comp. Bot. Mag.* ii. 109 (1836), where Douglas states that he measured trees 30 feet in girth.

Montana to the eastern slope of the Cascade Mountains in Washington and Oregon.

In British Columbia it is abundant and large in the Kootenay and Columbia river valleys, reaching as far north as the head of Upper Columbia lake, and attaining its most westerly point, where it was found by Prof. Dawson, in long. 124° E., on a tributary of the Blackwater river. It grows sparingly about the Shuswap lake and in the Coldstream valley near the head of Okanagan lake.

The tree, however, attains its greatest development in Montana, where it is abundant and constitutes a great part of the timber of the Flathead, Lewis and Clarke, and Bitter Root Forest Reserves; and is met with east of Missoula on the Big Blackfoot river. The tree can be most conveniently seen by the traveller on different points of the Great Northern Railway between Nyack and Bonner's Ferry. It attains also great perfection in Northern Idaho and North-East Washington, where it constitutes an important part of the timber of the Priest River Forest Reserve. It also occurs in Oregon, in the Blue Mountains, and on the foothills of the eastern side of the Cascade Mountains,¹ as far south as Mount Jefferson.

The western larch occurs between 2500 and 6000 feet altitude; and attains its maximum height and is most abundant in mountain valleys and on alluvial flats, where the average elevation is 3000 to 3500 feet. On the sides of the mountains, owing to the lack of moisture in the soil, it rapidly diminishes in size and vigour. It requires a wetter soil than either *Pinus ponderosa* or Douglas fir, and is restricted in its distribution where the rainfall is slight.

With regard to the opinion, prevalent even in America, that it grows in a semi-arid climate, my experience is entirely different. The meteorological stations are almost invariably in towns in the prairie regions, where the rainfall is small and trees only occur on the banks of streams; and the maps and statistics of the rainfall give on that account an imperfect picture of the climatic conditions which prevail in the forest regions between the Cascades and the Rocky Mountains. At Kalispell in the Flathead country, which is situated in a treeless plain, surrounded by densely forested mountains, the annual rainfall varies from 13 to 19 inches; whereas at Columbia Falls, placed on the edge of the plain and amidst the larch forests, the rainfall increases to from 20 to 29 inches; and in the mountain valleys, as at Lake Macdonald and Swan Lake, where *Thuja plicata* attains a large size, the rainfall must exceed 30 inches. The meteorological data of Columbia Falls, which is at 3100 feet elevation, give a fair idea of the climate in which *Larix occidentalis* thrives, though it is scarcely here at its best. The figures for 1905, which was a dry year, are:—

¹ Mr. Cohoon, Forest Assistant in the Northern Division of the Cascade Forest Reserve, wrote to me in 1906 as follows: "The only locality in which larch came under my observation in the reserve was on the east slope of the Cascade Mountains about 15 miles west of Duffur, Oregon. It did not occur abundantly, but was more or less scattered, in mixture with yellow pine, red fir, and lodge-pole pine. It was found on moist but well-drained soil at an altitude of about 2500 to 3000 feet." He adds that he never saw it west of the summit of the Cascades, which he has travelled over from Columbia river to California.

At Bridal Veil, Oregon, and other places on the Pacific slope, the term larch is erroneously applied to *Abies nobilis*.

	Precipitation in Inches.		Min. Temp.	Max. Temp.	Mean Temp.
	Snow.	Rain.	Fahr.	Fahr.	Fahr.
January	2.14	...	-1°	46°	24°

November	2.47	...	-11°	56°	30°
December	2.79	...	3°	46°	25°
Total precipitation, 1905	19.56 inches.				

Average precipitation for ten years 21.70 inches.

Rain or snow fell on 76 days; 91 days were cloudy; 49 days were partially cloudy; and the sky was clear on 149 days.

The above figures show that the climate is an extreme one, the winter season being cold and severe and lasting five months, while in summer a high temperature is often reached.

The western larch grows usually mixed with other conifers; and the number of accompanying species and the proportions of the admixture are very variable, being dependent on the climate and altitude, and on the quantity of moisture in the soil. Douglas fir is the most common companion of the larch, and *Pinus ponderosa* steps in where the soil is dry. Engelmann's spruce and *Abies lasiocarpa* descend into the larch forests, but never constitute any large element of it. *Pinus monticola*, *Tsuga albertiana*, and *Abies grandis* are often met with in small quantity at low altitudes in the larch forests of Montana; farther west, in the Priest River Forest Reserve, *Pinus monticola* is more abundant than the larch itself between 2400 and 4800 feet. *Thuja plicata*, in regions with a moist climate, forms a notable part of certain larch stands, often to the exclusion of the other species which usually accompany the larch.

The following notes on a few of the larch forests visited by me will illustrate some different types in Montana.

Near Missoula, in Pattie Cañon, which is a very dry valley at 3500 feet elevation in a rather arid climate, the larch only grows on the cool northern aspect, and is mixed with Douglas fir and *Pinus ponderosa*. An acre contained, of trees over a foot in diameter, twenty larches, four firs, and three pines. An average good larch tree measured 143 feet by 9 feet 7 inches; and a tree which we cut down, 14 inches in diameter, showed 211 annual rings, the sapwood being $1\frac{1}{4}$ inch in thickness and containing thirty-one rings.

On the southern end of Lake Macdonald, at 3500 feet altitude in a humid climate, I saw a fine stand composed almost exclusively of larch and *Thuja plicata*. The soil was glacial clay, very deep, and covered with a thick layer of humus. The

Thuja only attained about 110 by 7 feet, and had been overtopped by the larch, which ran from 140 to 150 feet high, and 7 to 14 in girth. The trees were extremely dense upon the ground, standing often only 12 feet apart, and averaging 200 to the acre. The ground was covered with seedlings of *Thuja*, 3 to 6 feet high, and more than thirty years old. The *Thuja* trees were being felled for telegraph and telephone poles, but never had clean stems, being covered with dead branches to 6 to 20 feet above the ground, and with living branches above this, and when of a large size were always decayed at the heart. The larch, as usual, was quite sound.

A wood near Whitefish, on flat land in a moderately rainy district at 3000 feet altitude, was composed of about nine-tenths larch and one-tenth Douglas fir, *Pinus ponderosa*, and Engelmann's spruce. The larch were 160 feet high by 6 to 9 feet in girth, overtopping the other trees, and with clean stems up to 80 or 90 feet. A stump, 40 inches in diameter, showed 585 annual rings, the sapwood with forty-two rings being only an inch in thickness, and the bark two inches.

The largest tree which I saw was growing on a high bank beside the Stillwater Creek, some miles west of Whitefish. It measured 19 feet 4 inches in girth at 5 feet from the ground, but the top was blown off. Near it were many large trees, 12 feet to 15 feet in girth, but the tallest was only 151 feet in height.

With regard to the height attained by the western larch, Sargent in his *Report on the Forest Trees of North America*, 216 (1884), states that it ranges from 100 to 150 feet, but in the *Silva* he gives the maximum height as 250 feet. I could find no confirmation of the latter figure either at the Arnold Arboretum or Washington, and I am of opinion that 180 feet is rarely if ever exceeded. The tallest tree recorded by any accurate observer is, I believe, the one cut down by Ayres¹ in the Whitefish Valley at 3500 feet altitude, which measured 181 feet high, with a diameter of 3 feet on the stump, and scaled 3500 feet board measure. He mentions¹ also another tree growing on the middle fork of the Flathead river, which was 180 feet high by 4 feet in diameter.

J. B. Leiberger states in his account of the Priest River Forest Reserve that the larch in the sub-alpine zone, above 4800 feet elevation, averaged 60 to 100 feet in height, 1 to 2 feet in diameter, and eighty to a hundred years old; while in the white pine zone, from 2400 to 4800 feet, the trees were 150 to 200 feet in height, 2 to 4 feet in diameter, and 175 to 420 years old. Here the heights are evidently estimates, and cannot be relied on implicitly.

The western larch is rarely seen as pure forest, and then only as the result of forest fires. Mr. Langille in his account of the Cascade Forest Reserve, p. 36, says that the larch "has done more than any other species to restock the immense burns that have occurred on a part of the reserve. This is largely due to the fact that the thick bark of this tree resists fire better than any other species, and more trees are left to cast their seed on the clean loose soil and ashes immediately after a fire. The seeds are small and light, and are carried to remote places by the wind and covered deeply by the fall rains. In the spring a dense mass of seedlings covers the

¹ U.S. Geol. Survey, Flathead Forest Reserve, 256, 314 (1900).

ground and grows rapidly. The thickets become so dense that it is impossible to travel through them. In time only the fittest survive, and there remains a thrifty, vigorous stand of this valuable timber." In Montana the lodge-pole pine usually takes possession of burnt areas; but I saw near Belton on the Great Northern Railway a hillside which had been swept by a fire, leaving a good number of larch trees unharmed, all the trees of other species being destroyed, and larch seedlings were coming up in profusion. On the Stillwater Creek farther west I noticed a burnt area on which the lodge-pole pines were about 30 feet high; and amongst them larch seedlings were growing in openings exposed to sunlight during at least a part of the day. Here in time the lodge-pole pine will be supplanted by the larch. Sargent's statement,¹ that young seedlings of the western larch are able to grow up under the shade of other trees, which they finally overtop and subdue, requires modification. Seedlings never occur in the shade of the forest, and are most numerous in open places exposed to full sunlight; but on good soil, as on a recently burnt area, they will spring up in the partial shade of small pine trees. The western larch is not a fast grower in the young stage; at Belton seedlings twelve years old, growing on rather poor rocky ground, were from 7 to 12 feet high.

As the seed of the western larch had never been collected, so far as we knew, by any one except Mr. Carl Purdy's collector in 1903, I visited Montana in 1906, with the object of collecting a large quantity for Sir John Stirling Maxwell and Lord Kesteven. In the common larch the seeds do not fall out of the cones until spring, and their collection during winter is an easy matter. The western larch behaves very differently, as will be seen by the following notes of my observations in Montana. About the middle of August the squirrels begin to throw down cones, a sign that the seeds are nearly ripe. About the 10th September the leaves, which form a tuft at the base of the cone, begin to turn yellow, and in a day or two become brown and withered, showing that the supply of nutrition to the cone is stopped. The cones, which until now were purplish in colour, become brown, and the scales gape open widely, allowing the seeds to escape. By the 20th September all the cones on the trees have become quite brown, and have emptied all their seeds. The empty cones remain on the branches till the autumn of the following year, by which time their peduncles have rotted and the cones are ready to fall. For collecting seed the larch forests must be visited during the first three weeks of September; and localities where felling is being carried on should be chosen, as the cones occur only at the summit of very tall trees, which are troublesome to cut down, even if permission to do so has been obtained from their owners. The western larch appears to produce a good crop of seed once every two or three years, and this is general over the whole region. 1906 was a remarkably poor year, scarcely any cones having been formed. In 1905, judging from the old cones of that year still remaining on the trees, the crop of seed was very abundant.

(A. H.)

As I had long been trying to find a larch that would in England be less liable to the attacks of *Peziza Willkommii* than the common larch, I made inquiries as

¹ *Garden and Forest*, ix. 491 (1896), where there is an article on the tree, with an illustration of the trunk, fig. 71, showing the very thick bark.

to how seeds could be procured, and Prof. Sargent was good enough to do his best for me. Mr. Leiberg, in 1901, went on purpose to the Flathead Lake country, but found all the seed shed as early as September, and could only send a few seedlings by post. These heated on the way to England, and though I saved a few of them, they were always sickly, and most of them died before coming into leaf. Again I tried through the United States Forestry Bureau, who were also unable to get seed. In 1903, however, I procured a small parcel from Mr. Carl Purdy, and distributed the seed to many arboriculturists in England in 1904. These have germinated fairly well, and I hope that my efforts to make this grand tree better known may succeed.

The seedlings raised in 1904, from the seed which I distributed, have grown in several places, best perhaps at Murthly, under the care of Mr. Lowrie, where in September 1906 I saw some hundreds thriving very well, though not so large as common larch of the same age. At Walcot, in rather dry soil, they were 6 to 9 inches high. At Colesborne they grew slowly, and many were killed or injured in the seedbed by the frost of May 1905; but I have just planted out a number which were raised for me by Messrs. Herd of Penrith, and which are 12 to 18 inches high.

I visited Missoula in June 1904 on purpose to see the tree, and was fortunate enough to do so in company with Prof. Elrod of the Montana University, to whom I am greatly indebted for the excellent photographs of the tree here reproduced (Plate 111). They were taken on the Big Blackfoot river about twenty miles up the valley from Bonner, on the Northern Pacific Railway, where a large sawmill, managed by Mr. Kenneth Ross of the Big Blackfoot Lumber Company, has its headquarters. Guided by this gentleman we reached the logging camp in the Camas prairie and found the larch growing in deep bottom land at about 3500 feet, mixed with *Pinus ponderosa* and Douglas fir, but far exceeding both of them in size. The tree grows on slopes and in ravines where there is a good depth of soil not liable to dry up, and best on slopes with a north and east aspect, and on the rich detritus at their foot, and along the sides of the river. It differs strikingly from other larches in habit when adult, having very short branches, which are not produced singly or at regular intervals but grow in irregular groups of four or five, starting near together on the trunk. It forms a tall, very narrow column, and as it gets old loses many of its branches. It carries its girth to a great height and is, when grown in a thick forest, sometimes clear of branches for over 100 feet. The tallest tree I have heard of was figured in the *Butte Miner* of 29th February 1904, and was said to be the largest in Montana, 233 feet high and 24 feet in girth at or near the ground. This tree grew on the Upper Clearwater between Salmon and Seely lakes. It could be seen for miles above the surrounding trees, and must have contained over 2000 feet of timber. The best I saw, however, were from 150 to 180 feet in height, with a girth at 5 feet of 10 to 15 feet.

Frank Vogel, a timber surveyor who has had much experience with this tree, told me that it grew up to 6000 feet elevation on the hills above the Blackfoot river, and that he saw no difference between these trees and those lower down except in

size. The age of those of which I counted the rings, and which would be about the same age as the one photographed, was 330 to 350 years, these trees showing no signs of decay. The bark in dense forest is very thin for such large trees, sometimes only 2 to 3 inches thick, and though in older and more isolated trees it attains a much greater thickness, as much as 9 to 15 inches near the ground, it struck me as not being so thick and rugged as the bark of old European larch.

The undergrowth in the forest was not dense, and was composed of *Berberis aquifolium*, *Cornus canadensis*, *Linnæa borealis*, *Symphoricarpos*, *Thalictrum*, with violets, strawberries, and in some places that lovely little orchid *Calypto boreale*. There were abundant seedlings of larch and Douglas fir springing up wherever there was enough light and moisture, but in the drier parts of the forest pine only was seen. The young cones were already formed on 29th May, and I came away with the impression that though this tree may not rival the European or Japanese larches in rapidity of growth, it will be valuable in the mountains of Central Europe and will probably succeed on the better soils of England and Scotland.

With regard to the timber of the western larch, Prof. Sargent says that "it surpasses that of all other American conifers in hardness and strength, it is very durable, beautifully coloured, and free from knots; it is adapted to all sorts of construction, and beautiful furniture can be made from it. No other American wood, however, is so little known." Through the kindness of Mr. K. Ross I was able to bring back from the St. Louis Exhibition a door and frame made from this wood which fully bears out Sargent's high opinion of it.

Until a few years ago the timber of the western larch was invariably called tamarack, and was of no great commercial importance. The use of this name, which is properly applied to *Larix americana*, the timber of which is little esteemed, proved prejudicial to the reputation of the western larch in the eastern states. Of late years the timber merchants of Idaho and Montana insist on the use of the term larch; and large quantities of this lumber are now being exported even as far east as New York. Coarse grades are used for joints, beams, and railway ties. Finer grades are sawn into planks, used for flooring, and are converted into materials for indoor finish, as ceiling, laths, mouldings, panelling, etc. The timber is remarkably free from knots, and is variable in colour, being often nearly white, though it is usually reddish in tint.

(H. J. E.)

LARIX LYALLII, LYALL'S LARCH

Larix Lyallii, Parlatore, *Enum. Sem. Hort. Reg. Mus. Flor.* 1863, *Journ. Bot.* i. 35 (1863), and *Gard. Chron.* 1863, p. 916; Sargent, *Gard. Chron.* xxv. 653, f. 146 (1886), *Silva N. Amer.* xii. 15, t. 595 (1898), and *Trees N. Amer.* 37 (1905); Kent, *Veitch's Man. Coniferae*, 399 (1900).

A tree attaining in America 80 feet in height and 12 feet in girth, but usually considerably smaller. Bark of young stems and branches thin and pale grey, on larger stems loose and scaly, on older trunks 2 inches thick and fissuring into irregular plates covered by reddish-brown loose scales. Young branchlets covered with a dense greyish tomentum, concealing the pulvini, and partly persistent on older branchlets, which become greyish black in colour. Short shoots stout and greyish pubescent. Bud-scales fringed with long cilia. Base of the long shoots girt with a sheath of the previous season's bud-scales, the uppermost of which are loose, membranous, and reflected.

Leaves bluish green, rhombic in section, deeply keeled on both surfaces, 1 to 1½ inch long, rigid, ending in a sharp cartilaginous point.

Staminate flowers ovoid, acute at the apex, ½ inch long, raised on stalks ⅓ inch long. Pistillate flowers ovoid, with the bracts reflected about their middle, their mucros curving outwards; bract oblong, ⅓ inch long, truncate at the apex, the midrib being prolonged into a rigid mucro about ¼ inch long.

Cones ovoid, acute at the apex, 1½ to 2 inches long, on a short tomentose stalk: scales numerous, loosely imbricated, thin, ovate, of a beautiful pink colour before ripening, ½ inch long, fringed with matted hairs; outer surface sparingly pubescent: bracts extending up to the margin of the scale, with their mucros projecting beyond about ¼ inch and at first directed upwards; when ripe the scales spread at right angles and finally, together with the bracts, become much reflexed. Seeds in slight depressions on the scale, with their wings narrowly divergent and not reaching its upper margin. Seed together with wing about ⅞ inch long; wing pale pink in colour, broadest near the base.

This species has been supposed to be an alpine form of *L. occidentalis*; but is readily distinguished from it by the structure of the leaves, the tomentum of the branchlets, the beautiful pink cones, which have fringed scales, and the pink-winged seeds.

(A. H.)

This tree was discovered by Dr. D. Lyall when surgeon to the International Boundary Commission in British Columbia in 1858, and though I have raised seedlings which I believe to be this species, it has not as yet been introduced into cultivation either in America or Europe, though it is a tree which must have been seen by thousands of travellers while crossing the Rocky Mountains in the Canadian Pacific Railway. Plate 112 shows a typical tree growing near Laggan, and is from a negative which I purchased at Victoria.

It is a strictly alpine tree, of somewhat limited range, its northern limit being

about 51° N. on the Rocky Mountains, not extending to the moister climate of the Gold or Cascade ranges in British territory, nor has it as yet been discovered in the more northern parts of British Columbia. Southwards, it extends along the Cascade Mountains of Northern Washington to Mount Stewart on the north fork of the Yakima river, and along the continental divide of the Rocky Mountains to the middle fork of Sun river and to Pend d'Oreille pass in North-Western Montana.¹ In its northern habitat—near Laggan, Alberta—I have seen it from about 5000 up to 7000 feet. Though Mr. J. Macout reports it on a mountain near Morley as low as 4500 feet, yet Wilcox,² who must have seen as much of this tree as any one who has written of it, says it is rarely seen below 6000 feet, and that its extreme range of altitude might be placed between 5600 and 7600 feet.

Lyall's larch is a very beautiful tree of moderate size, from 50 to 70 feet high being about the average, with a girth of 5 to 6 feet, but on Mount Stewart Mr. Brandagee reported that it attained as much as 4 feet in diameter. Its growth is extremely slow, Wilcox having counted 30 rings of growth in a branch only $\frac{3}{4}$ inch in diameter; whilst a tree cut by Brandagee on Mount Stewart which showed 562 annual rings was only $16\frac{1}{2}$ inches in diameter under the bark.

Mr. M. W. Gorman says:³—Near Lake Chelan it was not seen at all in the moist valleys, and was generally found to favour the passes and sheltered sides of the crest lines and divides, and here it ranges in altitude from 5800 to 7100 feet. The best grove seen was at about 6700 feet elevation near War Creek pass. The tree ranges in height from 50 to 90 feet, and in diameter from 10 to 25 inches. The mature tree has a rather thick greyish bark, and is well fruited with oval, mostly erect persistent cones. The branches are mostly lateral, very brittle, and quite small in proportion to the tree. The foliage changes colour with the first severe frosts about October 1.

L. Lyallii has to contend with a climate as severe as, and very similar to that of the Altai Mountains, the snow usually lying till late in June or even July, and snow and frost often occurring in July and August. The bark is rough and greyish and the branches short, irregular, brittle, and easily broken by a heavy snowfall. Wilcox says that the trees growing at the highest altitude have a curious development not found on those only a few hundred feet lower. The tufts of leaves spring from a hollow woody sheath, which is sometimes more than an inch long on the trees at high altitudes, whilst elsewhere this is not present.

The seed appears to ripen and shed early like that of the western larch, for though I have made several attempts to procure it from friends visiting the Rockies they have been, like myself, always too early or too late, and though I tried to bring home seedlings in 1893 they died on the journey home.

It is not, however, at all likely to succeed in this country, except possibly on the higher parts of the Grampian Mountains, and even there I fear the climate will be too damp, and the winter too short for it.

(H. J. E.)

¹ Sheldon, in *Forest Wealth of Oregon*, says that it is "rare on the high peaks of the Wallowa Mountains."

² *The Rockies of Canada*, 63 (1900).

³ *U.S. Geol. Survey, Eastern Part of Washington Forest Reserve* (1899). Mr. Gorman calls the tree *L. occidentalis*; but his specimens, which we have seen, are labelled *L. Lyallii* by himself, and are this species.

LYALL'S LARCH IN MONTANA

Larix Lyallii occurs in five isolated areas in the mountains of Northern Montana, between 113° and 115° E. long. and 47° 25' and 49° N. lat.

One of these localities was discovered by Prof. Elrod and myself in our ascent of the unexplored peak of St. Nicholas, which lies just west of the continental divide, about ten miles east of Nyack on the Great Northern Railway. Here about 1000 trees grow on a rocky precipitous slope, with a strictly northern aspect, and extend in scattered groves over about a mile of ground between 6600 and 7500 feet altitude. The tree is, owing to lack of moisture in the soil, unable to exist on the sunny southern slopes, where *Pinus albicaulis* thrives at similar altitudes. Separate groves of Engelmann's spruce accompany the Alpine larch. The largest tree measured 71 feet by 5 feet 2 inches; and another tree, felled by us, which was 8 inches in diameter, showed 220 annual rings, the sapwood with 25 rings being half an inch thick. Younger trees up to 40 feet high are gracefully pyramidal in shape, with wider branches than *L. occidentalis*; older trees have twisted and irregular branches and flattened crowns, the result of age, as is the case in all species of larch. The branches are remarkably brittle. On another part of the mountain, but still on the northern aspect, eighteen trees in two groups were seen at 8250 feet elevation, the tallest of which was only 10 feet high. The trees in Montana bore in 1906 only a few cones, but the crop in the preceding year had been plentiful. I procured only twenty or thirty seeds, which are now being raised at Kew. The cones in this species resemble those of the western larch in the manner in which they quickly cast their seeds in September.

The western larch in this region did not mingle with the Alpine larch, the former ascending, in company with Douglas fir, the northern slope up to 5900 feet; and between this elevation and 6600 feet, where the lowermost Alpine larch was found, no trees were growing.

Two other localities farther south are mentioned by Ayres,¹ who states that on the summit of the continental divide (long. 113°, lat. 47° 25'), between the Sun river and Willow Creek, there is a fine forest of the species, with trees about 70 feet high and 15 inches in diameter. Twenty miles due west on the summit of the range north of Pend d'Oreille pass there are a few scattered trees.

In the Whitefish range and in the mountains between the Kintla and Chief Mountain lakes, the tree is common on northern slopes from the Canadian boundary line to about 15 miles south of it. In the Whitefish range, Ayres² reports that the trees attain a maximum size of 80 feet by 6 feet in girth, the largest growing about the heads of basins where the snow lingers late into summer or lies in banks throughout the season. I visited the Whitefish range, which is a few miles from Fortine, on the Great Northern Railway, late in September, in company with Mr. Eastland, forest ranger, and at 7000 feet altitude could distinguish numerous groves of Alpine larch, extending over the mountains for an immense distance, as the foliage,

¹ *U.S. Geol. Survey, Lewis and Clarke Forest Reserve*, 42, 43 (1900).

² *U.S. Geol. Survey, Flathead Forest Reserve*, 268 (1900).

which had turned yellow at this season, rendered the trees very conspicuous; but in all cases the groves were confined to strictly northern slopes. We encamped in a small grove, where the trees did not exceed 40 feet in height, and observed numerous seedlings; but were forced to descend on account of a heavy fall of snow and to leave the larger and more important forests unvisited.

Further east, in the Kintla lake region, Ayres¹ reports that the mountain slopes are best wooded on the northern slopes, where the Alpine larch reaches a height of 80 feet and a diameter of 30 inches. It is more vigorous here than in any other locality seen by Ayres, who considers that the tree will produce timber suitable for mining purposes.

(A. H.)

A species very variable in habit, dimensions, and foliage, comprising several different geographical forms, which under cultivation preserve in a great measure their peculiarities. The following description is drawn up from wild specimens of the Corsican tree, which is the finest form.

A tree attaining 150 feet in height and 20 feet in girth. Bark on old trees about an inch thick, deeply fissuring into irregular longitudinal plates, which exfoliate in small rounded scales, leaving exposed pale brown, slight oval depressions where they fall off. Buds $\frac{1}{2}$ to 1 inch long, elongated, abruptly contracted to an acuminate apex, light brown in colour, tinged with white, the lowermost scales loose and reflected, the uppermost bound together by white resin. Branchlets stout, glabrous, brown in colour; leaf-bases very prominent, keeled, and imbricated, persisting for several years on the older leafless branchlets.

Leaves, in pairs, densely covering the whole branchlet on barren shoots, forming an apical cup-like tuft above, directed upwards and forwards below; deciduous in the fourth or fifth year; stout, 4 to 6 inches long, about $\frac{1}{16}$ inch wide, straight or curved, often twisted,³ serrulate, ending in a short callous point; semi-terete in section, with

¹ The generic description of *Pinus* will be given in a later part. There is no English name in common use for the whole species. The different forms are well known, as the Corsican, Austrian, and Pyrenean Pines.

² The oldest name for the species is *Pinus nigra*, Arnold, which has lately been revived by some German writers. We adopt the name *Pinus Laricio*, Poiret, as it has been in general use for more than a century.

Pinus pallasiana, Lambert, *Genus Pinus*, i. 13, t. 5 (1832), is impossible to recognise, being supposed by some to be *Pinus Laricio* and by others to be *Pinus Pinaster*.

Pinus tyrenaiaca, Lapeyrouse, *Hist. Pl. Pyrén.*, *Suppl.* 146 (1818), points, so far as the locality is concerned, to the Pyrenean variety of *Laricio*; but the description is doubtful. Mr. H. L. de Vilmoir, who gives a history of this name in *Bull. Soc. Bot. France*, xl. p. lxxvii (1893), considers it to refer to *Pinus Brutia*; but M. Calas, in his account of the *Pin Laricio de Salzmann*, p. 22, controverts this opinion, and believes the description to apply to the Pyrenean *Laricio*.

³ The twisting of the leaves, supposed to be characteristic of the Corsican variety, is an inconstant character.

twelve lines of stomata on the convex surface and eight lines on the flat surface; resin canals median, surrounded by stereome cells, meristele elliptic, fibro-vascular bundle branched. Basal sheath about $\frac{1}{2}$ inch long, brown near the base, whitish above, becoming on old leaves short, lacerated, and blackish.

Male flowers clustered, three to ten or more in number, on the lower half of the branchlet of the first year, which grows beyond the inflorescence and bears leaves above; later, when the flowers drop off, these fertile branches appear to be bare of leaves in their lower half. The male flowers are upright, yellow, cylindrical, stalked, about an inch long; connective crest large, purplish, finely toothed. Female flowers single or two to three at the top of the young branchlets, very shortly stalked and bright red in colour, remaining as small ($\frac{1}{2}$ inch diameter) globular cones till the beginning of the second year.

Cones ripe at the end of the second year, solitary or in pairs or threes, sub-terminal, sessile; variously directed, upwards, horizontally, or even curving downwards; shining brown; ovoid-conic, 2 to 3 inches long by an inch in diameter, straight or curved, symmetrical, ending in a narrow apex. The cones open in the spring or summer of the third year and soon after the escape of the seeds fall off. Scales about an inch long; concealed part thin, dark reddish brown below and light brown above; apophysis or visible part shining yellowish brown, raised, rounded at the upper margin, with a transverse keel, curved on each side of the central umbo, which is reddish brown and bears a minute or obsolete prickle. Seeds greyish or brownish, more or less mottled, about $\frac{1}{6}$ inch long; wing three or four times as long, striated light brown, straight on one side and gently curved on the other, about $\frac{1}{4}$ inch wide at the broadest part, which is at the middle or just below it. Seedling with six or seven cotyledons.

The different geographical forms may be arranged as follows:—

1. Var. *corsicana*, Loudon, *loc. cit.* (var. *poiretiana*, Antoine, *Conif.* 6:1840), Corsican Pine. Occurs in south-east Spain, Corsica, southern Italy, Greece, and Crete.

A tall tree with straight stem and slender branches. Leaves light green in colour, not extremely dense upon the branchlets, the whole aspect of the foliage being lighter in colour and sparser in quantity than in the Austrian pine. Buds not very resinous. Cones usually without radiating cracks on the apophyses.

Var. *calabrica*, Loudon, *loc. cit.*, is scarcely distinguishable. As seen under cultivation at Les Barres, it has perhaps slightly denser foliage than the Corsican variety growing beside it.

2. Var. *austriaca*, Loudon, *loc. cit.* (*Pinus nigra*, Arnold; *Pinus austriaca*, Höss; *Pinus nigricans*, Host; *Pinus Laricio*, var. *nigricans*, Parlatore). Austrian Pine. Austria, Balkan Peninsula, Crimea, Caucasus, Asia Minor.

Shorter tree, with numerous stout branches. Leaves dark green in colour, extremely dense upon the branchlets, giving the whole tree a dense dark crown of foliage. Buds resinous, whitish, stouter than in the Corsican pine. Cones usually showing radiating cracks in the apophyses.

Var. *pallasiana*, Endlicher, *Syn. Conif.* (*Pinus pallasiana*, Loudon, *op. cit.* 2206).

This name is given in England to trees with numerous stout branches, the lowermost of which ascend parallel to the trunk; but in foliage scarcely different from the Austrian pine.¹ The cones are usually larger than in that variety and have the radiating cracks strongly marked. This form is supposed to have come from the Crimea. The Laricio which occurs in the Crimea, Asia Minor, and the Caucasus appears, however, to be identical with the Austrian form.

Var. *caramanica*, Loudon, *loc. cit.* (var. *Karamana*, Masters, *Gard. Chron.* 1884, xxi. 480, fig. 91). This is the Austrian pine as regards the foliage; but producing extraordinarily large cones, up to four inches or more in length. It is supposed to be identical with a form introduced into Paris by Olivier, who sent seeds in 1798 from Caramania in Asia Minor; but is perhaps only a mere sport of the common Austrian pine. The only specimens known to us are two trees at Syon, grown on the lawn west of the mansion; and one of these measured, in 1903, 72 feet by 8 feet 6 inches.

3. Var. *tenuifolia*, Parlatore, *loc. cit.* (vars. *pyrenaiaca et cebennensis*, Grenier et Godron, *Flore de France*, iii. 153 (1856). *Pinus monspeliensis*, Salzmänn. *Pinus Salzmanni*, Dunal). Pyrenean Pine. Cevennes and Pyrenees.

Small trees, often stunted in growth, with remarkably slender leaves, only half the thickness of the other forms. Young branchlets orange-coloured. Cones smaller than in the Corsican variety. Owing to its slow growth, the annual shoots are very short, and the older branchlets remain slender and bare of leaves for a great distance behind the short tuft of leaves at their extremities.

Pinus leucodermis, Antoine, treated by us as a distinct species, is considered by many authorities to be only an alpine form of Laricio; and there appear to be similar forms occurring in high regions elsewhere, as *Pinus Fenzlii*, Carrière, which resembles *P. leucodermis* in having short leaves, almost appressed together in the bundles.

Pinus pindica, Formanek, reported as growing in the Pindus and the Thessalian Olympus, is not recognised by Halacsy;² and is probably only a slightly aberrant form of the ordinary Corsican variety. It has been fully described and figured in *Gardeners' Chronicle*, *loc. cit.*, by Dr. Masters.

Horticultural varieties of Laricio are few and unimportant. Beissner³ mentions pendulous, variegated, and dwarf forms. A golden variety⁴ of the Austrian pine, said to have been raised or introduced by Mr. Mongredien of the Heatherside Nursery, has the leaves, especially those on young growths, tipped with gold. Ilsemann⁵ saw a tree, in which the leaves were beautifully variegated with yellow, growing wild in a forest in Hungary. A peculiar form of Austrian pine with stout falcate leaves has been observed at Breslau.⁶

¹ Probably some trees called *Pallasiana*, on account of their habit, are really of Corsican origin.

² *Consp. Fl. Græcæ*, iii. 452 (1904).

³ *Nadelholzkunde*, 243 (1891). Masters saw at Moser's Nursery, Versailles, in 1903, a dwarf variety of very compact habit with dense bright green foliage: *Gard. Chron.* xxxiv. 338 (1903).

⁴ *Gard. Chron.* xvi. 507 (1881) and ii. 730, 785 (1883).

⁵ *Gartenflora*, 1897, p. 643.

⁶ Baenitz, *Gartenflora*, 1903, p. 58.

INTRODUCTION

According to Loudon,¹ the Corsican variety was introduced into England, as long ago as 1759, under the name *Pinus sylvestris, e maritima*, which was adopted by Aiton.² In France, the tree in the Jardin des Plantes at Paris was planted in 1774; but the date of introduction of the first seed is probably earlier. The Austrian pine was introduced¹ in 1835 by Lawson of Edinburgh. Var. *pallasiana* was first raised by Messrs. Lee and Kennedy, Hammersmith, from seeds sent to them about the year 1790 from the Crimea by Professor Pallas.¹ Captain Cook¹ imported seed in 1834 from the Sierra de Segura in the south of Spain; but the plants raised were probably indistinguishable from the ordinary Corsican variety; and there is no record of the introduction of the Pyrenean or Cevennes variety, of which we know of no large trees in this country.

DISTRIBUTION

The species has a widespread distribution, extending westwards from Spain into the Cevennes in France, finding its northerly limit in Austria, and descending into Corsica, Italy, Sicily, the Balkan peninsula, Greece, Crete, and Cyprus, it re-appears in the Crimea and in Asia Minor, and reaches its most easterly point in the Caucasus.

In Spain, a form considered by Willkomm to be identical with the Corsican variety occurs scattered through the plateaux and mountains of the south-eastern and central provinces, at altitudes between 1000 and 3500 feet. The largest forests occur in the Serrania de Cuenca, and in the sierras of Segura and Cazorla, the most southerly point reached being in the last-named mountain in N. lat. 37° 40' and W. long. 3°.

PYRENEAN LARICIO.—The form³ which occurs in the Pyrenees and the Cevennes is remarkable for its stunted growth and slender leaves. It grows on the Spanish side of the Pyrenees in the province of Aragon, not far from Venasque, between the rivers Esera and Cinca. From this locality, which was visited by Mr. H. L. de Vilmorin in his investigations of the Pyrenean Laricio,⁴ seeds were regularly sent to Paris for many years early in the 19th century, by M. Boileau, pharmacist at Bagnères-de-Luchon.

M. Calas, who has written an elaborate memoir⁵ on this variety, accompanied by a map of its distribution and numerous illustrations of the forests reproduced from photographs, discovered it in 1890 on the north side of the Pyrenees near Prades. Here it covers a scattered area of about 3600 acres in the hills south of the river Têt and north of Mount Canigou, the district being called Conflent; and grows on glacial clay at elevations between 1880 and 3300 feet. In most places the original forest has been ruined by sheep-grazing and fires, and usually only small isolated

¹ *Op. cit.* 2204, 2206, 2208, 2209. The date for the Corsican pine is not improbable, as Loudon (viii. t. 315) gives a figure of a tree at Kew, which was 85 feet high in 1838.

² *Hort. Kew.* iii. 366 (1789).

⁴ *Ibid.* p. lxxvii.

³ Cf. Durand, in *Bull. Soc. Bot. France*, xl. p. ccxxviii (1893).

⁵ *Le Pin Laricio de Salzmann*, pp. 50, tt. 1-19. Published at Paris by the Minister of Agriculture in 1900.

groups of trees are to be seen, in the ravines and on the precipices. There are, however, two woods of considerable extent; and one of these, situated in the basin of the stream of Masos, is considered by M. Calas to be the finest which he has seen, as regards the density, regularity, size, and vigour of the trees, which are, however, only about 80 to 90 years old. The best trees in the district are 50 to 60 feet high by 3 to 4 feet in girth.

In the Cevennes, this variety occurs in three localities. In Hérault, near Saint-Guilhem-le-Désert,¹ it covers, between 1700 and 2300 feet elevation, about 2400 acres, of which 1900 have lately been purchased by the Government. The soil is dolomite limestone and is extremely poor and shallow; and the trees growing either on southern arid slopes or on wind-swept plateaux are in a worse condition than elsewhere. They usually have twisted stems and average 15 feet in height; attaining at their best 30 feet high by 3 feet in girth.

Another locality² occurs north of Bessèges, in the valley of the river Gagnières, which forms the boundary line between the departments of Gard and Ardèche. The tree grows here at 650 to 1100 feet elevation on siliceous soil, and covers a scattered area of 2500 acres, half of which belongs to the State. It often attains, on northern slopes and on slightly better soil than usual, 60 feet high by 4 feet in girth. This appears to be the only locality where the tree is regularly felled, the timber being sold for pit-props. The maritime pine has been planted in the district in the open spaces caused by forest fires, and though slightly faster in growth than the native Laricio, has proved to be a poorer tree, on account of the inferior quality of its timber.

M. Fabre discovered in 1897 a third locality in the Cevennes, at the Col d'Uglas, eight miles west of Alais in Gard. The area is only 250 acres; but is interesting, on account of *Pinus sylvestris* growing wild in company with *Laricio* in the upper part of the forest.

The Pyrenean pine has been planted in a few localities in Ardèche, Hérault, Aude, and Pyrénées Orientales; and has done slightly better than the Austrian pine tried with it. Calas considers it to be a useful tree, on account of its capability of growing on the worst possible soils; and is of opinion that its meagre growth in the wild state is entirely dependent on the poor conditions of soil and climate to which it is subjected.

CORSICAN PINE.—This species is widely spread in Corsica in the great mountain range and its ramifications, which occupy the centre of the island. On northern slopes it grows between 2700 and 5500 feet elevation, the lower margin of the forest being often contiguous with dense woods of *Quercus Ilex* or with scattered groves of *Quercus lanuginosa*. On southern sunny slopes it only descends to 3700 feet, the zone below that altitude being usually occupied by *Pinus Pinaster*, the two species mingling slightly at the line of junction. The forests of *Laricio*, often of great extent, belong almost entirely to the State and to the Communes, and are all treated by the selection

¹ Here this variety was first discovered in France by Salzmann in 1851.

² First mentioned in 1856 by Grenier and Godron, *loc. cit.*

method. The pine usually occurs pure; but in the ravines small and unimportant groups of silver fir are often seen, and the edges of the streams are bordered in many places by *Alnus cordifolia*. The beech in Corsica attains as high an elevation as *Laricio*, and in some cases the two species are mixed, and a struggle occurs for predominance. Birch is occasionally a component of the pine forest, but is comparatively rare. The soil on which *Laricio* grows is usually extremely poor, consisting of debris of granite rocks, and contains very little humus or decayed vegetable matter.

The following observations which were taken in 1906, at 3200 feet altitude, in the midst of the *Laricio* forest at Vizzavona, show the climate in which the tree thrives:—

	Precipitation in inches.	Days of Fall of		Temp. Fahr.	
		Rain.	Snow.	Max.	Min.
January	10.98	4	5	47°	18°
February	3.74	3	13	46°	16°
March	4.05	5	6	64°	21°
April	3.46	12	4	59°	27°
May	5.28	13	1	75°	32°
June	0.31	7	...	75°	43°
July	1.61	8	...	77°	46°
August	0.12	2	...	79°	48°
September	1.73	3	...	77°	39°
October	7.60	5	...	66°	41°
November	14.61	14	1	61°	30°
December	15.44	8	11	59°	16°
Total	68.93 inches.	84 days rain.	41 days snow.		

Snow and low but not extreme temperatures are common during nearly six months of the year, from November to the beginning of May. The sky is generally clouded more or less completely during a greater part of the year; a clear blue sky only being recorded on 77 days out of the whole year.

The *Laricio* forests are easy of access, owing to the railway, which goes through the heart of the mountains from Ajaccio to Bastia; and in spite of a heavy fall of snow I succeeded in seeing some of the most important forests in the last week of December 1906. The finest is Valdoniello, which lies about twenty miles west of Corte railway station, the road to it passing through the magnificent gorge of the Scala di Santa-Regina. This forest occupies the upper basin of the river Golo, which has a north-easterly exposure, and its wooded area covers 6682 acres lying between 3100 and 5100 feet altitude. The soil is very dry and extremely poor, consisting of granite debris; and the few beech and silver fir that were seen could only obtain a footing in the ravines. The forest is divided into two series, one of which, about 4000 acres in extent is being regularly felled, whilst the other series at a greater elevation is left untouched as a zone of protection. In the first series

there are 109,000 trees over 16 inches in diameter, 4000 of which are decayed or diseased. Only trees over 9 feet in girth are marked for felling; and these are being cut down gradually, two or three trees in each spot, so that gaps are left in which seedlings may spring up. Though good seed years occur about once every three years, natural regeneration is always difficult on account of the poverty and dryness of the soil, and only occurs in open spaces exposed to sunlight. As a great deal of the best timber has been removed in past years, the number of excessively large trees is limited, there being only thirteen over 14 feet in girth. The largest tree now standing, the "Roi des Laricios," is growing in a dense part of the forest at 3850 feet altitude, and measured 143 feet in height by 18 feet 9 inches in girth, with a clean stem to 100 feet. Plate 113, from photographs taken by me, shows the stem of this tree and a dense stand of pines. Plate 114, from a negative kindly lent us by M. A. André, Inspector of the French Forest Service, shows very well the peculiar habit assumed by the *Laricio* in old age, the crown becoming remarkably flattened, owing to the bending over of the leading shoot and the increase in size of the upper branches, which become very stout and horizontal or even curve slightly downwards. The frontispiece is reproduced from a sketch taken in Corsica by the late Robert Elwes of Congham, Norfolk.

In this forest the presence of a considerable number of diseased trees is probably explained by the fact that some twenty years previously most of the large trees had been tapped for resin, an operation which was not justified by its financial results, and which exposed the trees to the attacks of fungi. In many parts of the Valdoniello forest, as in *parcelle F*, the trees are very tall, and stand very close together, and have beautifully clean stems, showing that the tree bears crowding without injury. The foliage of the trees in Corsica struck me as being denser than is the case usually in isolated trees growing in England; and I agree with Prof. Fliche that the canopy of *Laricio* is considerably denser than that of the Scots pine, and as a corollary that plantations should not be over-thinned. In Corsica, as only trees of large size are saleable, no thinning operations are ever attempted.

The railway passes through another fine forest, that of Vizzavona, which is about 3400 acres in extent. The trees here are as a rule younger than those at Valdoniello, and in many parts of the forest are mixed with beech, between 3000 and 4000 feet. In one place it was evident that, owing to an excessive felling of *Laricio* several years ago, the young forest coming up will consist almost entirely of beech. In pure stands of young but tall pines there is usually a slight undergrowth of beech and holly. Near the forester's house I measured a large tree, 145 feet high by 12 feet 3 inches in girth, which was growing at 3200 feet altitude.

With regard to the size attained by *Laricio* in Corsica, a tree in the forest of Pietropiano with a short stem measured 23 feet in girth. In the forest of Marmano trees have been felled which were clean in the stem to 115 feet, and yielded 950 cubic feet of dressed and squared logs. At Aitone there is a fine forest of *Laricio* which I was unable to visit from Valdoniello, as the pass across the mountain was impassable owing to deep snow. I was informed that the forest of Asco has been

practically untouched by the axe, and contains many very old trees of peculiar habit.

The *Laricio* grows with extreme slowness in the mountains of Corsica, trees 40 inches in diameter averaging about 360 years old, and those over 5 feet in diameter are often as much as 700 years.

The timber of young trees is valueless in Corsica, as it contains practically only sapwood, which rapidly decays on exposure to the air. The sapwood is white in colour, and always considerable in thickness, varying on an average from 8 inches in young trees (77 years old) to 2 to 3 inches in old trees (250 years old and upwards). The heartwood, which is reddish brown, only develops in quantity when the trees attain an advanced age, exceptionally at 120 to 150 years, usually at 300 years. At the latter age the trees average 3 feet in diameter, and are considered to be mature and at the most profitable period for felling. Most of the timber is exported in the form of logs to Italy, where it is much esteemed, and is used for shipbuilding purposes generally. The logs are squared in the forest, all the sapwood being chipped off except a little at the four corners. Saleable logs must be at least 23 feet in length, and have a minimum section at the small end of 1 square foot. They fetch at Bastia, after a long haulage by road and railway, 36 to 40 francs per cubic metre, or about 10d. to 11d. per cubic foot. A small proportion of the timber in the forests is cut up into planks and joists for local use. The timber is very strong but heavy, and often contains a great deal of resin; when of the first quality it is considered to be as good as American pitch pine. It is very seldom used in France, and the reasons for this are not very clear.

I could obtain no information as to the collection of the seed of *Laricio* in Corsica, though I made inquiries when visiting the forests and also at the Conservator's office in Ajaccio. Mr. M. L. de Vilmorin, however, kindly informs me in a letter that the annual collection amounts to about three or four tons, of which his firm disposes of about one-half. The main localities for collecting are near Corte and Calacuccia, and at Vivario, which is not far from Vizzavona. The cones are put in the ovens which the villagers use for drying chestnuts, and as the amount of heat is not regulated with any precision, the seed is often over-heated. Though the crop of cones in the forest varies very much in different years, there has been no difficulty so far in procuring always a quantity of seed sufficient to meet the demand.

In Sardinia the Corsican pine is recorded from only one locality, the valley of the Flumini Maggiore, where it was collected by Moris.¹

CALABRIAN PINE.—In Sicily the Corsican pine is common, according to Schouw,² on Mount Etna, where it forms woods between 4000 and 6000 feet. It is, however, in Calabria, in Sila and Aspromonte, that *Laricio* occurs in abundance, and there is little doubt that the tree here is identical with that of Corsica. Schouw,² who compared specimens from the botanical garden at Naples with the large Corsican pine growing in the Jardin des Plantes at Paris, is convinced of their absolute identity. Longo, who has recently written an article³ on the flora

¹ Parlatore, *Fl. Italiana*, iv. 53 (1867). Moris's specimens, though without flowers or fruit, are probably *Laricio*, according to Parlatore. ² *Ann. Sci. Nat.*, III Ser., iii. 234 (1845). ³ *Annali di Botanica*, iii. 1-17, tt. 1-6 (1905).

of Calabria, gives five plates, reproductions from photographs, of the Calabrian forests, and a plate showing the variation in the cones; but he has added little to our knowledge of these interesting forests in his short description of them. He states that the finest one is the State forest of Gallipano. (A. H.)

As I could find no account of this tree in its native country, and it was then little known in England; from the information I received from Signor Siemoni, chief of the Forest Department at Rome, I visited Cosenza, a town in Calabria, in April 1903. Here I was kindly received by Signor Carlo Pagliano, Inspector of Forests, who directed me to a village called Spezzano Grande, two hours' drive from Cosenza, from where I rode with Signor D. Greco, the sub-inspector, to the Sila Mountains, on which the largest forests of this tree now exist. The snow was still lying on the pass at about 4800 feet, but on the plateau beyond this it had melted except in shaded places. The forest is composed mainly of pine, here called Pino della Sila, Pino Rosso, or Pino Butello, mixed with beech in some places; but the forest has been considerably diminished by felling in former times, when the dockyards of Naples drew a large part of their timber from this district. The inspector told me that the only place he knew of where virgin forest of this tree still remained, was on a mountain called Femina Morte in the forest of Carigleone, in the district of Cattanzaro, 60 to 70 kilometres south-east of Cosenza. The average size of the trees which I saw being cut for the sawmill was not above 80 to 90 feet by 6 to 8 feet in girth, and smaller where they grew densely. These trees were 80 to 90 years old, and the heartwood, 10 inches in diameter, was reddish. In places where fire and cattle had not destroyed them, the natural reproduction was very good, and the seedlings when once established were making 2 to 3 feet of growth every year. The trees grew best in a south aspect on a soil which appeared to be decomposed granite, and, as far as I could learn, there is no limestone in this district. On my way back I visited Potenza in the Basilicata, whence, according to M. de Vilmorin's information, the seeds of the tree originally were introduced; but if the tree ever existed in the district, I could hear nothing of it.

AUSTRIAN PINE.—The Austrian pine has been the subject of a monograph by Prof. A. von Seckendorff¹ which gives very elaborate details of its literature, economy, and distribution in Austria, with maps and illustrations of remarkable trees in various places, which should be consulted by those who wish to know more than the brief résumé which I give. It occurs as a wild tree abundantly only in Lower Austria in an area extending from Mödling, near Vienna, south to near Pitten and south-west to Reichenrau, especially on the Alpine chalk formation, and attains an elevation of about 4000 feet. It attains a very great age, the rings of one felled near Stixenstein showing no less than 584 years, though the tree was only 65 feet high and about 6 feet in girth. In very rocky situations it grows so slowly that a tree near Mehadia was 270 years old, with a trunk only 8 feet high and about a foot in girth at the base.

Among the trees most remarkable for size may be mentioned a splendid tree at Vostenhofer (fig. ii. of Seckendorff) which is about 75 feet high and 21 feet in girth.

¹ *Beiträge zur Kenntniss der Schwarzföhre* (Vienna, 1881).

It is divided into 4 stems near the ground and has a diameter of branches of about 25 yards. A tree called the Broad Pine at Mödling, near Vienna (fig. iii.), has an umbrella shape, very unusual in this species. It is only about 35 feet high but is no less than 60 feet broad. A tree called the Cross or Picture Pine in the Grossen Föhrenwalde (fig. v.) is considered the finest tree there. It measures about 65 feet high, of which two-thirds are clean trunk, and is 9 to 10 feet in girth at about 9 feet from the ground. The tallest specimen which is mentioned is not much over 90 feet, very much less than those I saw in Bosnia, some of which were considerably over 100 feet and probably over 120 feet, with clean stems to two-thirds of their height.

On good ground, however, in Austria this pine forms very fine timber; an example (shown on fig. viii.) at Gutenstein, near Zellenbach, is said to be 280 years old with an average height of 30 metres. Another of the same age at Fahrafelde is so like the growth of the tree in Bosnia that the photograph illustrating it (fig. ix.) shows the best form of this tree very well.

A hybrid between this tree and *Pinus sylvestris* was described by Reichhardt¹ as growing in the Forest of Merkenstein. (H. J. E.)

In Hungary, according to Pax,² the Austrian pine is only found at Mehadia on the lower Danube, where there are woods on dry stony mountain slopes. He noticed it, however, as a mere shrub at Talmacsel in the valley of the river Alt. In Styria its occurrence as a wild tree is doubtful. In Carinthia there are limited areas of this species on calcareous soil on the southern slopes of the Dobratsch. It is also recorded from Istria, Carniola, Croatia, and the island of Cherso. Ascherson³ mentions one locality in Galicia. In Bulgaria⁴ it grows in several localities in the Rilo-Dagh, and in the Rhodope Mountains above Stanimaka.

An excellent account of the distribution and forest conditions of this species in the western states of the Balkan peninsula is given by Beck.⁵ The most extensive forests in this region lie in south-eastern Bosnia and extend across into Servia, in the district of *Novibazar*. Fine pine forests occur at Semec, on the slopes of the Lim valley, and on the hills between the Lim and Ceatina rivers. Between the middle part of the course of the river Drina in Bosnia and the river Morava in Servia the tree usually grows on palæozoic rocks, though it is occasionally seen on limestone. In Servia the forests of Austrian pine are less extensive, but extend from Ivica to Kapaonik. In middle Bosnia, where the tree is found growing on serpentine, and in western Bosnia, it is not at all common.

Elwes saw the tree growing abundantly in the valley of the Drina, as already mentioned in our account of *Picea Omorika*, and brought home a quantity of seed from this locality in 1901, which he distributed under the MS. name of *Pinus Laricio*, var. *bosniensis*, believing at the time that it was not the same variety as the common Austrian pine; but he now considers that the difference observed is no more than might be caused by a good soil and a more southerly and warmer climate.

⁴ Velenovsky, *Flora Bulgarica*, 518 (1891).

⁵ *Veg. Illyrischen Länder*, 139, 226 (1901).

In Herzegovina, according to Beck, the tree grows down the Neretva valley to the Plasa Planina and the southern slope of the Prenj Planina. In Montenegro it is comparatively rare, *Pinus leucodermis* having been often mistaken for it. It occurs scattered through Albania. In Dalmatia there are peculiar forests of Austrian pine, in which there is a dense undergrowth of evergreen Mediterranean shrubs and *Juniperus Oxycedrus*; and Beck describes the most remarkable of these, which occur at about 2500 feet elevation, on the peninsula of Sabioncello and the island of Brazza. The greatest altitude in these regions at which the Austrian pine was seen growing by Beck was 5300 feet on the west slope of Mount Dinara in south-western Bosnia, on the Dalmatian frontier.

In Greece, *Laricio*, probably of the Corsican variety, occurs in the mountains, often forming extensive woods, and Halacsy¹ mentions various localities in the provinces of Epirus, Thessaly, Eubœa, Ætolia, Peloponnesus, and in Crete. In Cyprus² *Laricio* is only met with on the summit of Troodos and on some crests to the west, at 4000 to 5000 feet altitude, just above the zone of *Pinus halepensis*, the two species mingling slightly together at the line of junction, as is the case in Corsica. Mr. Madon, who cut down a hundred trees, says that the timber is of no value, on account of the large amount of sapwood in immature trees, until it has reached the age of 250 years. Hartmann,³ who has recently visited Cyprus, gives an elaborate account of the *Laricio* forest. He states that pure woods of this species are rarely met, as in its lower zone, from 4000 to 4500 feet, it grows mixed with *Pinus halepensis*; and above this, to the summit of Troodos, it is accompanied by *Juniperus foetidissima*. It attains a height of 80 feet and a girth of as much as 16 feet.

In Asia Minor, according to Tchihatcheff,⁴ it grows mixed with silver fir on Olympus in Bithynia at 2700 to 5000 feet altitude, and in the same province, on Mount Samanly, at 1600 to 2100 feet, and in the island of Thasos, where it forms with *Juniperus excelsa* a wood in the littoral region. He records it near Soma in the mountains of Mysia; in the valley of the Meander in Troas; between Mughla and Eskischer in Caria; in the Antitaurus, where it forms mixed woods with *Juniperus excelsa*, *Abies cilicica*, cedar, and oak; and in various localities in Pisidia, Isauria, and Cilicia.

In the Crimea⁵ it grows on dry, poor, calcareous soil, forming woods on the western slopes of the mountain chain which extends along the coast of the Black Sea. The Crimean pine has been made a distinct variety, *pallasiana*, but it is probably identical with the Austrian pine.

According to Radde,⁶ *Pinus austriaca*, as he terms it, is rare in the Caucasus. Steven discovered it in 1840 in the neighbourhood of Gelentschik; and Kusnezoff has since found it at a place called Wulanskaja, 35 kilometres south-east of Gelentschik, where there is a small open grove with sound trees attaining 2 metres in girth. Radde adds that it grows near the Black Sea at Bulanka. (A. H.)

CULTIVATION: CORSICAN PINE

Of all the conifers introduced into England, of which great expectations have been formed, none except the larch has shown such good results as the Corsican pine, which has proved a hardy and vigorous grower on almost all soils, and in almost all parts of Great Britain and Ireland. It has not, however, been long enough in the country to have established a position in the English timber market, and until it does it is difficult to say much of its economic value in the future. All accounts of this wood for estate purposes, though often used long before it has attained sufficient age to give the best results, agree in saying that though rough and knotty when grown singly, it is at least as good as Scots pine; probably more durable and stronger when used before maturity. Though it does not grow so fast on very barren and stony soils as the Austrian pine, it is far better from a timber point of view, and occupies less space. Its greatest defect is the difficulty of transplanting it when young on account of its very scanty root system, and as this often, indeed usually, entails considerable loss on both nurserymen and planters, the cost of getting a crop of *Laricio* established is very much higher than in the case of the Scots pine.

I have been most successful in avoiding a high death-rate by purchasing two-year seedlings with as many roots as possible from French nurseries in the spring, not before the middle of March, planting them at once in nursery rows on as sandy a soil as possible, and transplanting them to their permanent habitation in March or April, two years afterwards. But the plants will not then be large enough for the better class of land, and may require another transplantation before finally going out, by which time they will have cost 40s. to 50s. per 1000, and in some cases much more. The seedling has a very long primary root at first with very little fibre. By cutting this tap-root when the plant is only a year old, without lifting it from its seed-bed, it may be induced to make more roots, but if left unprotected for the first winter on wet or heavy soil a great many of the seedlings will be thrown out of the ground altogether. In my own ground I prefer to sow the seed in boxes, as their growth in the open ground is slow in comparison with what are raised in France. In order to overcome this difficulty some nurserymen adopt the practice of lifting all their one-year seedlings before winter sets in, and laying them in until spring, when they are lined out for two seasons' growth before being again transplanted.

I have on two occasions tried sowing the seed in the field where I wished the trees to grow, but with little success. The seedlings remain so small for the first two or three years that they cannot be seen among the grass, which soon covers them, and though this species seems to suffer less than any tree from being planted among coarse grass, it takes five or six years before the seedlings become conspicuous, and it will also be found that in some places they are too thick, and in others have entirely failed.

The Corsican pine is distasteful in the young state to hares and rabbits. An experiment to test this was made some years ago at Tortworth Court, where Lord Ducie planted a young *Laricio* in the centre of a rabbit warren, which, until the ground was covered with snow, the teeming population of the spot did not touch;

and even then, when starving, after an attempt to consume the young needles of the buds, they abandoned the experiment.¹

Captain the Hon. R. Coke, a very close observer of trees, sends us the following notes from Holkham:—

“In distinguishing between *P. Laricio* and *P. austriaca*, one must apparently be guided rather by the general appearance and habit of the trees, than by any hard and fast rules. *Laricio* always looks well-bred in comparison with the coarseness of *austriaca*. Even when the former develops great limbs, coarse in themselves, the more delicate foliage will distinguish it from its Austrian relative. A good instance of this may be seen at Wolterton, where a fine specimen of each are growing side by side.

“Though the curved or twisted leaves are usually considered to mark the Corsican, yet this feature has been noticed in trees thoroughly Austrian in every other respect; moreover, some Corsicans have straight leaves. Sometimes the branches being produced in regular whorls up the stem is considered to be the mark of a *Laricio*, but all Corsicans do not follow this rule.

“When planting the sandhills at Holkham at various times between 1855 and 1890, Lord Leicester took the precaution of wiring in *austriaca* against rabbits and omitting to do so in the case of *Laricio*. This was done because it had been found that the *P. Laricio*, which were all raised from the seed of the old trees at Holkham introduced from Corsica in the early part of the 19th century, were unharmed by rabbits, which eagerly devoured *P. austriaca*. At the present time, of the trees growing on the sandhills, namely, *P. Laricio*, *P. austriaca*, *P. sylvestris*, *P. maritima*, practically the only one which reproduces freely is the *Laricio*, as the rabbits, though no longer numerous, seem to be able to distinguish this tree from its congeners, and leave it untouched. On the other hand, some trees bought as *Laricio* from an English nurseryman, which had every appearance of being genuine, were recently planted to fill up gaps in a belt at Holkham, and in this case the rabbits ignored the nurseryman's label, and made short work of the so-called *Laricio*.”

Mr. J. D. B. Whyte, agent to Lord Iveagh, confirms the statement that rabbits will eat Austrian, and will not touch Corsican pines when planted together; but though the gamekeeper says that he has never anywhere seen a Corsican damaged by rabbits, Mr. Whyte does not think that the question has been fully tested at Elveden. This tree and the Austrian pine are sometimes planted in the Eastern counties as belts and hedges, but do not form so dense a shelter, or bear clipping so well as the Scots pine.

The Corsican pine is apparently less liable than some other pines to the ravages of insects and fungi. A specimen, however, sent in July 1905 to Kew by Mr. Wellwood Maxwell of Kirkennan, near Dalbeattie, showed a branch attacked by *Peziza Willkommii*, and Sir Herbert Maxwell showed me a similar case on a tree at Monreith.

On the sandhills of the Norfolk coast, near Holkham, are a number of Austrian

¹ Hutchison, in *Trans. Scot. Arb. Soc.* vii. 55 (1875).

and Corsican pines, planted on what appears to be pure drift sea sand, but Colonel Feilden suggested to me that their health and vigour may be due to the presence of lime, produced by sea-shells in the underlying beds. These trees were, as I was told by Mr. Donald Munro, forester to the Earl of Leicester, partly raised from seeds produced by the old trees in the garden at Holkham, and planted thirty to forty years ago, together with *Pinus insignis*, *P. Pinaster*, and *P. sylvestris*, to form a shelter belt and bind the loose drifting sand. Though some of the trees had preserved the peculiar leaf, colour, and habit of the Corsican and Austrian varieties, there were many others which could not be identified with certainty. A great number of seedlings have sprung up on the south or landward side of the hills, of which the largest were twelve to thirteen years old and 9 to 10 feet high; and many smaller ones of various ages were growing freely even in wet spots among tall rushes. Plate 115 shows the appearance of these seedlings. Rabbits and hares do not seem very abundant here, and I saw none of the Corsican seedlings barked, though one or two of the much scarcer *Pinasters* had suffered.

Mr. Richards, forester to Lord Penrhyn, is enthusiastic as to the merits of this tree, and writes to me that in North Wales it will grow where all other trees fail, that it stands wind better than any other conifer, and if planted in March and April few deaths take place. He grows it from seed collected in March and April and sown in May. He says there are many trees on the Penrhyn estate 80 to 90 feet high, but I did not see any quite so large as this. He considers that the timber is very good, better than that of any conifer he knows.

Captain Rutherford, agent to the Earl of Carnarvon at Highclere, also speaks very well of this tree, and sends me the dimensions of two not over seventy years old, one of which contains 201, the other 150 cubic feet, and a plank which he was good enough to give me certainly bears out his good opinion of the timber. It has pale red heartwood and yellowish sapwood, though it seems somewhat coarser in grain, and inferior to the wood of the Calabrian variety which I brought from Italy.

The Corsican pine¹ has not proved hardy in New England. It may be occasionally seen in the middle States, but there is no evidence, in large or old specimens, that this tree will really become a valuable acquisition for American plantations.

CULTIVATION: AUSTRIAN PINE

This tree is often sold as Corsican pine, but should never be planted knowingly except upon land where no better tree will grow, or to form a shelter belt on windy exposed hillsides of chalk or limestone, or on the sea-coast. For though a tree of extraordinary hardiness and rapid growth, it produces such a mass of large branches, and is so much inclined to fork, that its timber is extremely coarse, rough, and knotty, and would be unsaleable except at a very low rate or for pit-props. My father planted many of this tree, and I have found that though they make girth more rapidly than any other pine, they only thrive on sunny situations, where

¹ *Garden and Forest*, x. 471 (1897).

they have plenty of light and air; and though the great bulk of timber they produce in a short time may make them worth planting on such soils, yet I doubt the possibility of getting a sale at remunerative prices in most districts. In mixed or pure plantations their lower branches die off and leave large snags which are difficult and costly to remove, and though the very resinous nature of the wood may fit it for some purposes, I have never heard of its being utilised to any extent, except for pitwood. Austrian pine¹ has been planted very successfully as a shelter belt on the southern shore of Belfast Lough, about forty yards from the sea, in heavy clay; and behind it hardwoods and other trees are doing well. The tree has been extensively planted in many provinces of Austria and Hungary, mainly, according to Seckendorff, with the object of improving the soil for other trees; it has been recommended for this purpose on the poorer limestone soils of England, but the cost of so doing would in my opinion make the operation very unprofitable.

Though there is no reason why the Austrian pine should not sow itself in Great Britain, as the seeds ripen in hot years freely, yet I have never seen self-sown plants except near Sarsden Park, Oxfordshire, the property of Lord Moreton, and here only two or three young trees have sprung up on the rough limestone close to some old quarries.

The Austrian pine, according to Schübeler, is hardy in Norway as far north as Stenkjaer, at the upper end of the Thronhjem fjord. A tree in the Botanic Garden at Christiania, which Schübeler says was planted in 1842, is over 40 feet high, but was not a fine specimen when I saw it in 1906.

The Austrian pine² has been largely planted in the northern United States as an ornamental tree, and in youth is a handsome tree; but it generally succumbs to the attacks of boring insects before it has lost its bushy juvenile habit, and an Austrian pine in the United States more than fifty feet high is exceptional.

An account of Austrian turpentine,³ which is derived from *Pinus Laricio*, is given by Georg Schmidt in an inaugural dissertation before the University of Berne in 1903.

CULTIVATION: CALABRIAN PINE

The Calabrian variety of *Laricio* was introduced into France by M. de Vilmorin in 1819-21, and a full account of its development at Les Barres was given in a catalogue of the trees cultivated there, published at Paris in 1878 by the Forest Department.⁴ From this it appears that the tree has proved superior to other pines as a forest tree, and is especially recommended for planting in mixture with oak, which it rapidly surpasses in height, but without injuring it, on account of the slight development of its lateral branches. It has attained on this poor sandy soil a considerable size, and the young trees raised from seed grown there have preserved their superiority in the second and third generation. It produces seed abundantly there, but has the same defect as *P. Laricio* of being difficult to transplant. It is not easy to distinguish from the Corsican variety. M. Maurice de Vilmorin tells

¹ *Journal of Forestry*, 1879, p. 165.

³ *Harzbalsam von Pinus Laricio* (Bern, 1903).

² *Garden and Forest*, ix. 453 (1896) and x. 470 (1897).

⁴ Cf. Pardé, *Arb. Nat. de Barres*, 61 (1906).

me that "in nearly every place where this variety has been planted in France, it has proved to be in comparison with true Corsican pines the larger and finer of the two."

In Calabria the cones are gathered in December before they open, and kept till the following July, when they are spread out in the sun, and the seed falls out naturally, not being sown till the year after. I brought back in 1903 a sack of this seed which proved very good, and a large quantity of plants were raised from it by Prof. Fisher at Cooper's Hill, where they grew extremely well; better, as it seemed to me, than the Corsican pine, and much better than they did on my limestone soil. A number of these were sent to Culford, the seat of Earl Cadogan, in Suffolk, where his forester, Mr. Hankins, says that they stood the drought of 1906 very well on sandy soil. So far as I can see at present, the tree is quite hardy, and grows as fast or faster than the Corsican variety. It is equally difficult to transplant. Time alone will prove whether this tree has any economic value in England, but its superiority over the Corsican pine will be, I expect, only on soils deficient in lime, which the latter endures; and on granitic sand, in the warmer parts of England, it would certainly be worth a trial, either as a pure plantation, or, as recommended at Les Barres, in mixture with oak or beech.

A tree¹ reputed to be of the variety *calabrica* is growing in the Royal Botanic Garden, Belfast, and was 39 feet high by 3 feet in girth in 1905. It is said to be columnar in habit. A tree at Glasnevin, growing on the side of a hill, measured in 1906 41 feet by 4 feet, and is pyramidal in habit, with branches ascending at an angle of 45°. It is reported to have been planted in 1888, when four years old from seed.

REMARKABLE TREES

CORSICAN PINE.—One of the oldest, if not the oldest tree in England, stands near the entrance gate of Kew Gardens, and in 1903 measured 86 feet by 9 feet 3 inches. It was figured in the *Gardeners' Chronicle*, 1888, iv. 692, fig. 97, and according to J. Smith² was brought to England by Salisbury in 1814, when a seedling only 6 inches high.

In the pleasure ground at Holkham are three large trees which the Earl of Leicester believes to have been brought to England by a relative early in the nineteenth century, but the date of planting is somewhat uncertain. In 1907 they measured 85 feet by 11 feet, 80 feet by 9 feet 11 inches, and 80 feet by 9 feet 4 inches. Plate 116 shows two of these trees.

The tallest I have seen is at Brocketts, Herts, the seat of Lord Mountstephen, which, growing in a sandy soil and sheltered situation, was, when I measured it in 1905, no less than 119 feet by 8 feet 6 inches.

At Arley Castle, six fine trees, all over 100 feet high, measure 10 feet 8 inches, 9 feet 8 inches, 7 feet 9 inches, 8 feet 1 inch, 7 feet 8 inches, and 6 feet in girth respectively. Plate 117 shows the largest of these. Two of them have the habit of var. *Pallasiana*, but are indistinguishable in cones and foliage from

¹ Mentioned in *Gardeners' Chronicle*, 1870, p. 1537, as a prominent sort, distinct from the Caramanian or Corsican varieties.

² *Records of R. Bot. Gardens, Kew*, 286.

the others. At Albury, Sussex, there is one over 100 feet high by only 6 feet 9 inches in girth. At Highclere, Berks, in Great Pen wood, on sandy soil, are the best plantation *Laricios* which I have seen. At about 70 years old they measure about 90 feet high by 7 to 8 feet in girth, and have clean boles for about half their height: several of these, however, are forked at some distance from the ground. At Bayfordbury there is a tree which in 1906 was 94 feet by 8 feet 7 inches, and in many other places we have seen specimens 80 to 90 feet high, which need not be specially mentioned.

AUSTRIAN PINE.—Of the Austrian pine we have seen no specimens in England which rival the Corsican in height, though at Wolterton Park, Norfolk, the seat of the Earl of Orford, there are two large trees about 85 by 9½ feet, which show the characteristic difference in habit and in the colour of the leaves very clearly. From Grigor's account of this place in the *Eastern Arboretum*, p. 114, they seem to have been planted before 1840. Among the largest is a large spreading tree of this type at Nuneham Park, the seat of the Right Honourable L. Harcourt. Another at Canford Manor, Dorset, measured 83 feet by 9 feet; and at Williamstrip Park, on rather heavy soil, which this tree by no means seems to dislike, there is one of nearly the same dimensions, the largest I know in Gloucestershire.

Var. *Pallasiana*.—The best authentic specimen I know is a fine tree at Elveden, Suffolk, the property of Lord Iveagh. It is a flourishing tree with the foliage and cones of the Austrian variety, and measured when I saw it in 1907 94 feet by 8 feet 3 inches (Plate 118). Prof. A. Newton of Cambridge informs me that this tree was raised from seed sent by his eldest brother General Newton of the Coldstream Guards from Balaclava in 1854. The parent tree stood in a garden, which was used as a cemetery during the early days of the occupation of the Crimea. In the historic gale of 14th November 1854 the tree was blown down, and the graves covered with rubbish, and a cone was sent home in memoriam.

Other noteworthy trees are as follows:—

At Dropmore . . .	108 feet by 11 feet 5 inches	<i>fide</i> A. Henry, 1904.
„ Beauport . . .	85 „ by 11 „ 5 „ „ „	„ „
„ Penrhyn . . .	95 „ by 11 „ 4 „ „ „	„ „
„ Smeaton-Hepburn .	64 „ by 6 „ 5 „ „ „	„ 1905.

At Chiswick House there is a good-sized tree, remarkable for having an immense growth of the character of what is usually called "witches' broom."

M. Gadeau de Kerville has figured¹ a very fine example of this pine, which was considered to be of the Calabrian variety by M. L. Corbiere (though this identification seems to me somewhat uncertain), which measured in 1894 35 metres (about 110 feet) high and 3.84 metres in girth. This tree is growing at Vatimesnil (Eure) in the park of M. de Vatimesnil, who believes it to have been planted by his ancestor about the year 1780. If this is correct, it is the oldest and probably the largest planted tree of the species either in France or England.

¹ *Les vieux arbres de la Normandie*, fasc. iii. p. 317, plate ix.

PINUS LEUCODERMIS, HERZEGOVINIAN PINE

Pinus leucodermis, Antoine, *Oestr. Bot. Zeitung*. xiv. 366 (1864); Beck v. Mannagetta, *Weiner Illust. Gartenzeit*, 1889, p. 136, and *Veg. Illyrischen Länder*, 353 (1901); Ascherson u. Graebner, *Syn. Mitteleurop. Flora*, i. 212 (1897).

Pinus Laricio, Poiret, var. *leucodermis*, Christ, *Flora*, l. 81 (1867); Masters, *Journ. Linn. Soc. (Bot.)* xxxv. 626 (1904).

An alpine tree attaining rarely 90 feet in height and 6 feet in girth. Bark ashy grey, fissuring into irregular plates, averaging 6 inches in length and 3 inches in breadth. Buds like those of *P. Laricio*, but darker brown in colour. Young branchlets glaucous. Leaves in pairs, persisting five or six years, densely covering the branchlets, except at the base of each year's shoot, which is bare for a short distance, forming an apical cup-like tuft, and on the rest of the branchlet directed forwards and slightly outwards; the two leaves in each bundle only slightly divergent; dark green, stiff, short, 2 to 3 inches in length, ending in a sharp cartilaginous point; basal-sheaths as in *P. Laricio*. According to Koehne,¹ the structure of the leaf differs from *P. Laricio* in the resin-canals not being surrounded by stereome cells; and Masters states that the hypoderm projects in wedge-shaped masses into the substance of the leaf, which is not the case generally in forms of *Laricio*.

Cones short-stalked, ovoid-conic, with a flat base, about 3 inches long, resembling generally those of *Laricio*, but differing in the uniform dull brown colour of the whole cone, the umbo being of the same colour as the rest of the apophysis. The lower scales of the cone have very prominent pyramidal apophyses, and the umbo has a well-marked short spine directed backwards. Concealed part of the scales light brown on both surfaces. Seeds as in *P. Laricio*. (A. H.)

Pinus leucodermis was discovered in 1864 by Maly, who introduced it into cultivation the same year in the Belvidere, Vienna. The best account of the tree is given by Beck, who considers it to be specifically distinct from *Laricio*, and names it the Panzerföhre or Smré of the Herzegovinians. It is found in four distinct areas in Bosnia, Herzegovina, and Montenegro; and as the most southerly of these is on the Montenegro-Albanian frontier (lat. 42° 25'), it is probable that it also grows on the Peristeri² mountain, which lies west of Monastir in Albania. The most northerly locality (lat. 43° 40'), where it was discovered by Beck, is the Prenj Planina in the heart of Herzegovina. Here it occupies an area of about sixty kilometres in diameter, surrounding the western part of the Bjelasnica mountain, and forms a coniferous belt at from 4600 to 5500 feet elevation, rising solitary or in small groups to 5800 feet. Another area is the Bjela Gora, where the political boundaries of Bosnia, Montenegro, and Herzegovina unite around Mount Orjen. Reiser found it also in the Sinjavina Planina in Montenegro. Its occurrence in Servia is not yet established.

¹ *Deutsche Dendrologie*, 37 (1893).

² This must not be confused with another mountain of the same name, east of Janina in the Pindus range.

It seems to resemble *P. Cembra* in its way of growth, and is confined to mountains of Triassic and limestone formation, where it forms a zone of scattered forest just below the limit of trees, usually not more than 1000 feet in depth, and finds its lowest level at 1000 metres on the Preslica planina, according to Reiser, near the railway station of Bradina; ascending on the Prenj and Orjen mountains to 1700 or 1800 metres. At the lowest elevation it is mixed with beech; at the highest with *P. montana*, *Juniperus nana*, and *J. sabina*.

In some places at the upper levels, where the snow lies very deep, it becomes very stunted, not rising more than 2 to 4 metres from the ground, but does not assume the procumbent habit of *P. montana*. It roots itself so firmly on the dry bare rocks of these mountains that no wind can hurt it, and it endures the burning sun and bitter winds of this region without injury. I am indebted to Herr Reiser of Serajevo for the photographs showing the habit of this tree (Plate 119).

In the upper Idbar valley there is a forest where *P. leucodermis* grows mixed with spruce, silver fir, Austrian pine, and yew, as well as with beech, ash, sycamore, *Pyrus torminalis*, and *Acer obtusatum*. Its smooth grey bark,¹ divided into irregular segments, makes it very easy to distinguish from the Austrian pine, but Beck does not think the name of whitebark pine so applicable as that of Panzerföhre or armoured pine. The tree attains under favourable circumstances a height of 90 feet, with a diameter of 6 feet at the age of 294 years.

Of its timber Beck says nothing, but a story which was current in Bosnia when I was there in 1899, and which doubtless has some foundation, leads one to suppose that it is very hard. A Bosnian Turk was said to have bought a lot of trees of this species, which he felled and floated down the Narenta, and sold the timber as that of larch.

With regard to the occurrence of this species elsewhere, Christ described as a new species, *Pinus Heldreichii*,² specimens which were collected on Mount Olympus in Thessaly. Afterwards, in a letter to Dr. Masters, he stated that this is only a remarkable alpine variety of *Pinus Laricio*, very reduced, and approaching in some respects *Pinus montana*. Halacsy³ considers that this tree, which grows on Mount Olympus in company with the ordinary form of *Laricio* and with *Abies Apollonis*, is identical with *Pinus leucodermis*.

A tree referred to this species has been recently found in southern Italy by Dr. Biagio Longo. He mentions⁴ two localities, the alpine zone of the Calabrian Apennines from Orsomarso to Mount Montea, and the mountain of La Spina in the province of Basilicata, where it grows in the zone of the beech, and rivals that tree in thickness of trunk; but the foresters in the Sila mountains do not recognise this as a distinct species, or did not know of its discovery when I was there in 1903.

Seeds were sent by Beck to Kew in October 1890; and five plants were raised, which have grown with remarkable slowness, being only 9 to 12 inches high in 1901.

¹ The bark is figured in Hempel u. Wilhelm, *Bäume u. Sträucher*, i. 161, fig. 84 (1889).

² Christ, in *Verh. Naturf. Ges. Basel*, iii. 549 (1863), but later, in *Flora*, l. 83 (1867), he states that *Pinus Heldreichii* is identical with *P. leucodermis*, which he considers to be only an alpine variety of *P. Laricio*.

³ *Consp. Fl. Græca*, iii. 453 (1904).

⁴ *Annali di Botanica*, iii. 13, 17 (1905), iv. 55 (1906).

One of these trees, planted out in a bed near the pagoda, is barely 3 feet high at present. Another which was sent to Colesborne was planted in a high exposed situation in my park, where it grows very vigorously on oolite soil.

When in Bosnia, on my way to collect seeds, I was obliged to return home suddenly, but my companion, Mrs. Nicholl, who visited the Prenj mountain, procured a quantity of seeds which I sowed in 1902, and which have grown as fast as either the Corsican or Austrian pines, and look more healthy and vigorous on my soil than any other pine I have raised. They form a much better root-system when young than either the Austrian or Corsican pine, and in consequence are much more easy to transplant. I moved a number in September last just before a period of drought, and they have passed through a severe winter with very few deaths; I therefore believe that the tree will be a good one for planting in dry limestone soils, and may have a greater ornamental if not economic value than the Austrian pine.

(H. J. E.)

GYMNOCLADUS

Gymnocladus, Lamarck, *Dict.* i. 773 (*ex parte*) (1783); Bentham et Hooker, *Gen. Pl.* i. 568 (1865).

Guilandina, Linnæus, *Gen. Pl.* 518 (*ex parte*) (1742).

DECIDUOUS trees, belonging to the division Cæsalpinieæ of the order Leguminosæ. Branches stout and without thorns. Leaves large, alternate, bipinnate, the number of pinnæ being either odd or even; pinnæ and leaflets usually alternate. Stipules foliaceous, early deciduous.

Flowers polygamous or diœcious, terminal or axillary, in racemes or racemose corymbs, on long pedicels. Calyx tubular, lined with a glandular disc, ten-ribbed, five-lobed, the lobes narrow and nearly equal. Petals four to five, slightly unequal, imbricated, inserted on the margin of the disc, spreading. Stamens ten, free, shorter than the petals and inserted with them, those opposite the calyx lobes longer than the others; anthers oblong. Ovary rudimentary or absent in the staminate flowers, sessile or sub-sessile in the polygamous and pistillate flowers; style short and dilated above obliquely into a two-lobed stigma.¹ Ovules four or numerous.

Pod oblong, thick, coriaceous, dark brown, flattened, beaked at the apex, slightly curved or falcate, on stalks $\frac{1}{2}$ to 2 inches long, pulpy between the seeds. Valves two, narrowly winged on the margins. Seeds on long slender stalklets; seed-coat thick and bony; embryo surrounded by a layer of horny albumen.

Only two species are known, one occurring in China and doubtfully hardy in this country, the other a native of N. America and cultivated in England.

GYMNOCLADUS CHINENSIS, CHINESE SOAP TREE

Gymnocladus chinensis, Baillon, *Compt. Rend. Assoc. Franç. Avanc. Sc.* 1874, p. 418, t. 4, and *Bull. Soc. Linn. Paris*, 1875, p. 33; Oliver, in Hooker, *Icon. Plant.* xv. 9, t. 1412 (1883);

Hemsley, *Journ. Linn. Soc. (Bot.)* xxiii. 207 (1887).

Dialium sp.?, Hanbury, *Science Papers*, 238, fig. 5 (1876).

A tree attaining 40 feet in height. Young shoots rusty pubescent. Leaves 1 to 3 feet long; pinnæ alternate or sub-opposite, all composed of numerous (twenty

¹ The stigma of *Gymnocladus chinensis* is not correctly shown in Hook. *Icon. Pl.* t. 1412.

to twenty-four) leaflets, which are $\frac{3}{4}$ to $1\frac{1}{2}$ inch long, alternate, oblong, rounded at the base, obtuse or rarely acute at the apex, densely silky appressed pubescent beneath, on short pubescent petiolules; rachis densely pubescent, swollen at the base, and forming a conical sheath enclosing the bud.

Flowers polygamous, in pubescent racemes, those with staminate flowers shorter than the others. Calyx pubescent, with subulate lobes. Petals oval-oblong. Ovary glabrous with four ovules. Pod, 4 inches long by $1\frac{1}{2}$ inch broad, glabrous. Seeds, two to four, black, globose, smooth, $\frac{3}{4}$ inch in diameter.

This tree is rather rare in China, though specimens have been collected in the provinces of Anhwei, Kiangsi, Chekiang, Hupeh, and Szechuan. Near Ichang it grows at 1000 to 2000 feet altitude. The pods, called *fei-tsao*, after being steeped in water, produce a liquid esteemed for washing the hair and cleansing silk articles.

Plants¹ were raised at Kew from seeds sent by me in 1888; but died in a year or two. Seeds, which could be easily procured from Shanghai, where they are sold in the shops, might be tried in the warmer parts of England and Ireland, as the tree is worth cultivating on account of its beautiful delicate foliage.

(A. H.)

GYMNOCLADUS CANADENSIS, KENTUCKY COFFEE TREE

Gymnocladus canadensis, Lamarck, *Encycl.* i. 733 (1783); Loudon, *Arb. et Frut. Brit.* ii. 656 (1838).

Gymnocladus dioicus, Koch, *Dendrologie*, i. 5 (1869); Sargent, *Silva N. Amer.* iii. 69, tt. 123, 124 (1892), and *Trees N. Amer.* 554 (1905).

Guilandina dioicus, Linnæus, *Sp. Pl.* 381 (1753).

A tree attaining in America over 100 feet in height and 9 feet in girth. Bark fissured, dark grey, and roughened by small persistent scales. Young shoots covered with short pubescence. Leaves (Plate 125, fig. 4) 1 to 3 feet long, with 5 to 11 pinnæ, which are usually alternate but occasionally sub-opposite, the two or rarely the four lower pinnæ simple, the others composed of six to fourteen alternate pinnate leaflets. Leaflets 2 to 3 inches long, on pubescent stalklets, ovate, rounded at the base, acuminate at the apex, entire and ciliate in margin; under surface with scattered long hairs.

Flowers usually diœcious, the inflorescence of the staminate tree a short racemose corymb, that of the pistillate tree a long raceme. Calyx tomentose, with five narrow oblong lobes. Petals five, tomentose, longer and broader than the calyx-lobes. Ovary pubescent; ovules ten or more.

Pod, 6 to 10 inches long by $1\frac{1}{2}$ to 2 inches broad, minutely pubescent. Seeds,

¹ Cf. Nicholson, *Garden and Forest*, 1889, p. 139.

five to ten, surrounded by dark-coloured sweet pulp, ovoid, $\frac{3}{4}$ inch long, and covered by a hard dark brown shell.

In the young leaf¹ of *Gymnocladus canadensis*, the rachis is prolonged an inch or more above the insertion of the upper pinnæ; and the axes of the pinnæ are similarly prolonged beyond the leaflets. These terminal appendages are very slender and tendril-like, and disappear before the leaf attains its full size. They have been supposed to be rudimentary tendrils, such as occur normally in a developed state in many leguminous plants; but they may represent simply degenerate terminal leaflets.

Sargent states that this species is diœcious; and that in order to obtain fruit male and female trees must be close together. C. M. Hovey,² however, writing from Boston, states that he knows a solitary tree, no other being within two miles, which produces fruit and fertile seeds, from which he has raised many plants. The so-called pistillate flowers have stamens, which doubtless are usually not fully developed; but it is possible that in some cases they may produce good pollen.

The flowers³ in America are visited by bees, which are attracted by the nectar secreted by the inner wall of the calyx tube.

IDENTIFICATION

In summer the foliage of the tree is unmistakable. In winter the fewness of the branches and the stoutness of the branchlets, which are very short in adult trees, are remarkable. The latter show the following characters:—

Twigs coarse, grey, glabrous, with numerous small brown lenticels and wide, circular, orange-coloured pith. Leaf-scars large, obcordate, slightly oblique on prominent pulvini, with a narrow raised yellowish margin and a whitish convex surface, marked by three to five irregular tubercles, which are the scars of the vascular bundles. Buds very small; two to three vertically superposed, in the axil of each leaf-scar, the lower one rarely developing; projecting slightly out of circular depressions in the bark, which form pubescent rings around the buds. Each bud shows two to three minute scales, which become accrescent and green in the spring at the base of the shoots. No true terminal bud is developed, the tip of the branchlet falling off in summer and leaving at the apex of the twig a circular scar.

DISTRIBUTION

The Kentucky Coffee tree, though occupying a wide area in North America, is nowhere common. It is found scattered amongst other trees on hillsides where the soil is rich, and in alluvial land beside rivers. It is met with in central

¹ Cf. B. D. Halstead, in *Torreya*, ii. 5 (1902).

² *Garden*, xiv. 240 (1878).

³ Robertson, *Trans. Acad. Sc. St. Louis*, vii. 165 (1897).

New York and western Pennsylvania, through southern Ontario and southern Michigan to the valley of the Minnesota River and to eastern Nebraska, eastern Kansas, south-west Arkansas, the Indian territory, and central Tennessee.

The tree is noted¹ in America for its habit of suckering from the roots when it is cut down. After a tree is felled the ground around to a distance of often 100 feet becomes filled with numerous suckers; and this is one of the ways in which the trees are reproduced in the American forests. The tree never develops any epicormic branches, and is very seldom attacked by any insect or fungus.

(A. H.)

An article by Sargent in *Garden and Forest*, ii. p. 75, gives an excellent account of this tree, and states that by far the largest and handsomest that he has seen was planted in 1804 directly in front of the historical Verplanck mansion at Fishkill-on-Hudson, and was, in 1889, 75 feet high and a little over 10 feet in girth below the point where it divides into three stems at 3 feet from the ground. Though it was struck by lightning in 1887, the tree is an extremely graceful and well-shaped one, as the picture shows.

The tree grows well as far north as Ottawa, where I saw two spreading trees about 40 feet high, planted in front of Rideau Hall, the residence of the Governor-General. The gardener informed me that they were the latest trees to come into leaf, and, though they flowered in good seasons, produced no fruit.

At Mount Carmel, Illinois, I measured a tree in the forest 92 feet by 8 feet, one of the few remaining relics of the splendid trees described by Ridgway, one of which was 109 feet high, with a clear stem 76 feet to the first limb, but only 20 inches across the stump. Dr. Schneck has measured one in the same locality no less than 129 feet high. It is, however, nowhere an abundant tree in this district, but grows scattered through the richer bottoms.

The tree from which a specimen log in the Jessup collection in the American Museum of Natural History was cut, grew not far from St. Louis, and although only 18 inches in diameter was 105 years old. This represents the average rate of increase of the tree growing naturally in the forest, cultivated trees in favourable conditions growing much more rapidly.

CULTIVATION

Gymnocladus canadensis was introduced into England by Archibald, Duke of Argyll, who had a tree in cultivation² at Whitton in 1748. This tree was afterwards removed to Kew, on the establishment of the gardens there by the Princess of Wales, mother of George III., who obtained it and many other interesting trees as a present from the Duke of Argyll in 1762. This tree died³ about 1870; and as old trees reported by Loudon at Syon and elsewhere cannot now be found, it goes to show that the tree lives little over 100 years in England.

¹ *Garden and Forest*, vii. 358 (1894).

² Aiton, *Hort. Kew.* v. 400 (1813).

³ J. Smith, *Dict. Econ. Plants*, 235 (1882), mentions this tree as if it was still living in 1882; but according to Nicholson it had died several years previously to that date.

According to Nicholson,¹ it is very easy to transplant, and bears drought well. It is propagated either by seeds or by root-cuttings. Pieces of the roots, 4 to 5 inches long, placed in prepared beds and kept moist, will develop in the first year into plants three or four feet high. Some of the cuttings, however, will not start into growth until the following year.

I have raised seedlings from American seeds, which, being large and hard, should be soaked in warm water for some days before sowing. The seedlings grow slowly, and should be kept under glass for a year or two before planting out.

In spite of Loudon's assertion to the contrary, it appears to flower very rarely in England, the only record being at Claremont, where Mr. Burrell² says it produces flowers freely early in summer. Pods have never been produced, so far as we know, in this country.

It is a rare tree in cultivation; but though stiff and peculiar in habit, it is not at all ungainly when well-grown, even when bare of leaves. It comes into leaf very late in the season, and it drops its leaves early in autumn, the stalks, however, often remaining on the tree for weeks. The foliage, like that of many leguminous plants, shows the phenomenon of sleep, the leaflets drooping and closing together soon after sunset in summer.

REMARKABLE TREES

There are two trees at Claremont, which were about 55 feet high in 1888. When I measured them in 1907 the largest was 60 feet by 6 feet 7 inches, and seemed quite healthy; the other was broken.

A tree at Chiswick House measured, in 1903, 53 feet high by 3½ feet in girth. Another at Barton, Suffolk, was in 1904 57 feet high by 5 feet 2 inches in girth at two feet from the ground, and divided above this into two stems. In the Botanic Garden at Cambridge there is a good specimen, which was 45 feet by 3 feet 9 inches in 1906. There are three smaller trees in the Oxford Botanic Garden.

At Kayhough, Kew, in the garden of Mr. Charles Wright, there is a healthy and well-shaped tree, which was in November 1905, 40 feet high by 2 feet 9 inches in girth, with a bole of 6 feet, dividing into two main stems. This tree was purchased from a nurseryman at Kingston in 1878, when it was said to be twenty-two years old, and was then about two-thirds its present height. After transplanting, it made no growth for three years; but since then it has grown steadily though very slowly, and has not been injured in any way by severe winters, though it has never flowered. It has been much surpassed in rate of growth by an *Ailanthus* in the same garden. There is a tree of about the same size growing close to Mr. Clarke's house at Andover, Hants, which is fifty to sixty years old and measures 43 feet by 2 feet 10 inches. There are several small trees in Kew Gardens, the largest one being near the main entrance.

It seems evident that the tree, to attain a large size, requires a much greater

¹ *Garden*, xxiv. 29 (1883).

² *Garden*, xxxiii. 229 (1888) and xlv. 404 (1894).

degree of summer heat than it gets in England, for in the south of France it becomes a splendid tree. I saw in the Museum Gardens at Chambéry, in the grounds of the Castle formerly belonging to the Dukes of Savoy, a tree which, though forked near the ground, had two tall clean trunks each about 100 feet by 5 to 6 feet. The leaves were only just appearing on 18th May, and many of the large bean-like pods full of greenish pulp, which had fallen in the winter, lay on the ground. Seeds from these pods germinated, but the seedlings, with one exception, withered soon afterwards. It is not uncommon in Savoy, and I saw a fine specimen, 81 feet by 9 feet 6 inches, in the Public Gardens at Aix-les-Bains, which in October 1906 had ripe pods on it. It is known in France by the name of "Bonduc."

In the old Botanic Garden at Padua a splendid tree was in 1895, according to Prof. Saccardo,¹ 135 years old, 21 metres high, and 2.60 metres in girth. When I saw it in 1905 the trunk was broken off at about 12 feet, but long shoots, which were in flower, had been produced from the stump.

(H. J. E.)

¹ *L'Orto Botanico di Padova* (1895).

CEDRELA

Cedrela, Linnæus, *Gen. Pl.* 109 (1764); Bentham et Hooker, *Gen. Pl.* i. 339 (1862).
Toona, Roemer, *Synops.* i. 131 (1846).

TREES, belonging to the order Meliaceæ, with unequally pinnate leaves, without stipules, and composed of numerous opposite or sub-opposite stalked leaflets.

Flowers in panicles, perfect, regular. Calyx short, four- to five-cleft. Petals, four to five, nearly erect, imbricated, free. Stamens, four to six, free, inserted at the top of a four- to six-lobed hypogynous disc; filaments subulate, anthers versatile. Ovary sessile on the disc, five-celled, each cell containing in two series eight to twelve pendulous ovules. Fruit, a coriaceous or woody capsule, composed externally of five valves, and almost filled up internally by a central column, between which and the valves are five thin cells, containing the seeds, which are numerous, compressed, and with one or two wings.

The genus is divided into two sections:—

I. *Eu-Cedrela*.—Seed with a single wing on its lower side. Nine species in tropical America.

II. *Toona*.—Seed with either two wings, one at each end, or with a single wing above. Eight species in India, Indo-China, China, and Australia, all in tropical regions except *Cedrela sinensis*.

CEDRELA SINENSIS

Cedrela sinensis, A. Jussieu, *Mém. Mus. Par.* xix. 255, 294 (1830): *Rev. Hort.* 1891, p. 573, figs. 150, 151, 152; Hemsley, *Journ. Linn. Soc. (Bot.)* xxiii. 114 (1886).
Toona sinensis, Roemer, *Synops.* i. 138, 139 (1846); Diels, *Flora von Central China*, 425 (1901).
Ailanthus flavescens, Carrière, *Rev. Hort.* 1865, p. 366.

A tree of moderate size, attaining in China a height of 60 to 70 feet. Bark scaling off in narrow longitudinal strips, 1 to 2 inches in width, and leaving exposed in parts the reddish inner bark below. Young shoots covered with minute pubescence. Leaves (Plate 125, fig. 7), large, 1 to 2 feet in length. Leaflets, eleven to nineteen, about 4 inches long, on pubescent stalklets (nearly $\frac{1}{4}$ inch long), opposite or sub-opposite, divided into two unequal parts by the midrib, the upper part larger and rounded at the base, the other part usually cuneate at the base; apex

caudate-acuminate; margin repand, minutely ciliate, distantly and minutely serrate or with occasional short teeth; nerves, fifteen to eighteen pairs, usually dividing and forming loops close to the margin; upper surface dark green, glabrous; lower surface pale green, glabrescent.

Flowers fragrant, in pubescent terminal panicles, which are a foot or more in length; pedicels short. Calyx with five short, rounded, ciliate lobes. Petals five, white, oblong, sub-cordate at the base, converging at the apex. Stamens five, alternating with five staminodes. Fruit about an inch long; valves, opening longitudinally from above downwards. Seed with an oblong wing attached to its upper side, the wing two to three times as long as the body of the seed.

In summer the large pinnate leaves give the tree much the appearance of *Ailanthus*; but the bark is different, and the leaflets of *Cedrela* are devoid of the glandular teeth near the base, which are so characteristic of *Ailanthus*. In winter the following characters are available (Plate 126, fig. 2):—

Twigs stout, brown, minutely pubescent; lenticels small, scattered; pith white, circular in section. Leaf-scars large, alternate, slightly raised, obcordate or oval, with five bundle-dots. Terminal bud, much larger than the others, broadly conical, of four to six triangular scales, which are swollen externally and hollowed internally, brown, shining, with acuminate pubescent tips. Lateral buds minute, solitary, inserted immediately above the leaf-scars, hemispherical, showing three to five shining brown scales.

Lubbock,¹ who gives a detailed account of the structure and development of the buds, the scales of which are modified leaves, states that the terminal bud usually dies in winter, but sometimes lives, and then is always later in developing in spring than the lateral buds.

Cedrela sinensis is a native of northern and western China. It is very common in the neighbourhood of Peking, and was found in Kansuh, beyond the Great Wall, by Piasetski. According to von Rosthorn and Wilson, it is wild in the forests of the province of Szechuan. It is commonly cultivated in central China, where it never attains a great size, mainly because the Chinese spoil its growth by lopping off in spring the young shoots, which are much esteemed as food. These are eaten after being chopped and fried in oil. The tree is known to the Chinese as the *hsiang-ch'un*.² The timber is good, reddish in colour, and often used in making furniture.

The tree was first made known to Europeans by Père d'Incarville, who sent dried specimens from Peking to Paris in 1743. In China it has been well known from classical times, and references to it occur in the earliest Chinese literature.

Cedrela sinensis was introduced in 1862 by Simon, who sent a living plant from Peking to the Museum at Paris, which was described by Carrière in 1865 as *Ailanthus flavescens*. On the tree flowering in 1875 it was recognised to be *Cedrela sinensis*. This tree, which was planted in the nursery attached to the garden of the Museum, had attained in 1891 a height of 40 feet; and, when Elwes saw it in 1905, it was very little taller, and about 4 feet in girth.

Many trees have been raised in the vicinity of Paris, both by seed and by root-

¹ *Journ. Linn. Soc. (Bot.)*, xxx, 478 (1894).

² Cf. name given to *Ailanthus*, p. 32.

cuttings; and it appears to be perfectly hardy in the north of France, having sustained without injury the severe winter of 1879-1880. Its large fragrant foliage renders it perhaps more suitable than the *Ailanthus* for planting in towns. It is said by Nicholson to be now largely used in Holland for that purpose.

The tree is rather rare in England, and we have seen no specimens remarkable for size. There is a tree in Kew Gardens which measured in November 1905 33 feet by 2 feet 4 inches. This is probably of the same age as an *Ailanthus* of equal height growing beside it. A tree much about the same size is growing and thriving in Messrs. Veitch's Nursery at Coombe Wood. Mr. Cassels informs me that young trees of *Cedrela* are planted in some of the London County Council parks, as Meath Gardens and Bethnal Green.

Cedrela sinensis is also cultivated in the United States,¹ where a tree flowered at Meehan's nurseries, Germanstown, in 1895. Another only eight years old had attained in the same year 20 feet in height in western Virginia. Professor Sargent thinks it might be used as a street tree in New England, though introduced plants have proved rather tender in that climate. It has frequently flowered in France, but has never produced fruit there. There is no record of its having flowered as yet in England.

Mouillefert² speaks of this tree as one which, in his opinion, has a great future in Europe on account of the high quality of its wood, which he compares to that of mahogany and that of the so-called cedar of the West Indies (*Cedrela odorata*). He says that the tree grows fast from seed, attaining 5 feet in the third year, and adds that on calcareous soil of middling quality at Grignon a tree about twenty-five years old measured 10 metres high.

(A. H.)

² *Principales Essences Forestières*, 471, 472 (1903).

PTEROCARYA

Pterocarya, Kunth, *Ann. Sc. Nat.*, sér. I. ii. 345 (1824), Bentham et Hooker, *Gen. Pl.* iii. 399 (1880).

DECIDUOUS trees belonging to the order Juglandæ, with large, alternate, compound, imparipinnate leaves; leaflets serrate; stipules absent. Buds scaly or naked, the lateral ones often multiple, two to three in a vertical row above the insertion of the leaf. Pith chambered. Flowers monœcious, numerous in long pendent catkins. Male catkins usually several, arising singly in the leaf axils; in some species (*caucasica*, *stenoptera*) lateral on the preceding year's shoots, with an occasional catkin on the current year's shoot; in other species (*rhoifolia*, *Paliurus*) all on the new shoots. Stamens nine to eighteen in several series on the axis of a three- to six-lobed scale, to which a bract is adnate on the back, the scale representing two bracteoles and one to four perianth segments. Female catkins solitary, terminating the young shoot. Female flowers with a bract and two bracteoles at the base; perianth four-lobed, adnate to the ovary, which contains one ovule, and is surmounted by a short style, divided above into two papillose stigmatic divisions. Fruit catkins long, with numerous nut-like fruits, which have in most species two lateral wings, in one species a single orbicular wing all round, due to the enlarged bracteoles of the flower, the bract persisting little changed at the base of the fruit. Nutlet, with a thin pericarp and a hardened endocarp, the latter divided below into four imperfect cells, and containing one seed, which is four-lobed below. Cotyledons bi-partite, each division being again deeply divided, forming four linear segments; carried above ground in germination.

Pterocarya and *Juglans* have similar foliage, and agree in the chambered pith of the twigs. They are readily distinguished when in fruit, that of *Pterocarya* being always small and winged. When specimens in leaf only are obtainable, the best mark of distinction lies in the buds, which in *Pterocarya* are either without scales or are enclosed in a long conical beaked funnel-like covering, composed of membranous scales—differing in either case from the short buds of *Juglans* with two to three external scales.

Seven species of *Pterocarya* are known, occurring in Persia, the Caucasus, China, Tonking, and Japan. A hybrid species has been obtained in cultivation, which will be described under *P. caucasica*. The seven species which occur in the wild state may be arranged as follows:—

SECTION I. CYCLOPTERA, Franchet, *Journ. de Bot.*, 1898, p. 318.

Fruit surrounded by an orbicular wing, composed of the connate bracteoles, which cover the nutlet at the base.

1. *Pterocarya Paliurus*, Batalin, *Act. Hort. Petrop.* xiii. 101 (1892); Franchet, *loc. cit.*; J. H. Veitch in *Journ. R. Hort. Soc.* 1903, xxviii. 65, fig. 26. China: mountains of Szechwan, Hupeh, and Chekiang.

Tree 40 feet. Twigs pubescent and glandular. Buds naked. Leaf-rachis villous or pubescent, not winged. Leaflets seven, coriaceous, oblong-ovate, with sub-acute apex, glabrous below except along the midrib. Fruits samara-like, the nutlet in the centre of an orbicular wing, 2 inches across, several on a raceme a foot long.

This species was introduced in 1903 by Mr. E. H. Wilson from the mountains of Central China; and young plants, which seem perfectly hardy, are now growing at Messrs. Veitch's Nursery, Coombe Wood. The tree when in fruit presents a remarkable appearance, and is well worth trial, as it should prove hardier than *P. stenoptera*, which grows at a lower level.

SECTION II. DIPTERA (*Sectio nova*).

Fruit with two lateral wings, the developed bracteoles, which do not cover the nutlet at the base.

* *Buds naked, without scales.*

2. *Pterocarya stenoptera*, C. DC. China, Tonking.

Tree 60 feet. Twigs bristly-pubescent. Leaf-rachis winged. Leaflets nine to twenty-five, coriaceous, underneath glabrescent with pubescent tufts in the axils of the nerves. Fruit with long lanceolate upright glabrous wings. In cultivation. See description below.

3. *Pterocarya hupehensis*, Skan, *Journ. Linn. Soc. (Bot.)*, xxvi. 493 (1899). China: mountains of Hupeh.

Small tree about 30 feet. Twigs glabrous. Leaf rachis not winged, glabrous except for some tomentum near its insertion. Leaflets five to nine, lanceolate; under surface with brown scurfy scales and glabrous except for stellate rusty tomentum in the axils of the nerves. Fruit minutely glandular, with sub-orbicular wings, $\frac{1}{2}$ inch diameter. Introduced by Mr. E. H. Wilson in 1903. Young plants are now growing at Coombe Wood and seem to be perfectly hardy.

4. *Pterocarya Delavayi*, Franchet, *Journ. de Bot.* 1898, p. 317. China: mountains of Yunnan.

This species, which I have not seen, appears closely to resemble the last, differing mainly in the fruits being covered with short hairs. Not introduced.

5. *Pterocarya caucasica*, C. A. Meyer. Persia, the Caucasus.

Tree attaining 100 feet. Twigs glabrous except for some pubescence at the

tips. Rachis of the leaf not winged. Leaflets fifteen to twenty-seven, membranous; under surface without glands and glabrous except for stellate pubescence on the nerves and in their axils. Fruit, $\frac{1}{2}$ inch broad, glabrous; wings semi-orbicular. In cultivation. See description below.

** *Buds long, conical, beaked at the apex, enclosed during summer and autumn by a membranous funnel-like covering, composed of several scales.*

6. *Pterocarya macroptera*, Batalin, *Act. Hort. Petrop.* xiii. 100 (1893). China: mountains of Kansuh.

Small tree, about 20 feet in height. Twigs glabrous. Rachis of the leaf not winged, rusty-tomentose. Leaflets nine to eleven, acute, rusty-tomentose on the midrib and nerves beneath. Fruit: nut pubescent, wings broadly ovate, pilose, $1\frac{1}{4}$ in. long by 1 inch broad. Not introduced.

7. *Pterocarya rhoifolia*, Siebold et Zuccarini. Japan.

Tree, rarely attaining 100 feet. Twigs glabrous. Rachis of the leaf not winged. Leaflets fifteen to twenty-one; under surface glandular with tomentum along the midrib and veins and in their axils. Fruit, 1 inch wide; wings rhombic, broader than long, glabrous. Introduced. See description below.

PTEROCARYA CAUCASICA

Pterocarya caucasica, C. A. Meyer, *Verz. Pflanzen Caucasus*, 134 (1831); Loudon, *Arb. et Frut. Brit.* iii. 1452 (1838).

Pterocarya fraxinifolia, Spach, *Hist. Nat. Veg.* ii. 180 (1834); Lavallée, *Arb. Segrez. Icones.* 73, t. 21 (1885).

Pterocarya Spachiana, Lavallée, *op. cit.* 69, t. 20.

Pterocarya sorbifolia, Dippel (*non S. et L.*), *Laubholz.* ii. 327 (1892).

Juglans fraxinifolium, Lamarck, *Encyc. Meth.* iv. 502 (1797).

Juglans pterocarpa, Michaux, *Fl. Bor. Am.* ii. 192 (1803).

Rhus obscura, Bieberstein, *Fl. Taur. Cauc.* i. 243 (1808).

A tree attaining 100 feet in height and 10 feet or more in girth, usually however smaller, and tending to branch into several stems at no great height above the ground. Bark dark grey and furrowed. Shoots glabrous. Leaves (Plate 125, fig. 1) 16 to 20 inches long, on a stalk 2 to 3 inches long, only slightly swollen at its base; rachis not winged. Leaflets fifteen to twenty-seven, opposite or sub-opposite, sessile or sub-sessile, 3 to 5 inches long; oblong or oblong-lanceolate; acute, acuminate, or obtuse at the apex; unequal and rounded or narrowed at the base; dark green above; under surface lighter green, without glands, glabrous except for some stellate pubescence along the nerves and in their axils; thin in texture; sharply and finely serrate. Staminate catkins several, each in the axil of a leaf-scar on the preceding year's shoot, rarely one or more on the current year's shoot; scale usually five-lobed, stamens twelve to fifteen. Fruiting catkins up to eighteen inches long.

Fruit $\frac{1}{2}$ inch broad; wings semi-orbicular, concave below, conspicuously veined; nutlet with beaked apex.

Seedling.¹—The caulicle terete, erect, and about two inches in length, raises the two cotyledons well above the ground. Each cotyledon is shortly stalked, about an inch in width, and deeply bipartite, the two primary divisions being again divided for nearly two-thirds of their length, the whole forming four linear-oblong obtuse diverging segments. The cotyledons are palmately five-nerved at the base, the three middle nerves each ending at the base of a sinus and sending divisions into the segments. The young stem is slightly glandular near the apex. The first five leaves are alternate, simple, lanceolate or ovate, rounded at the base, acute or acuminate at the apex, penni-nerved, serrate, and vary in length from 1 to 2 inches. Succeeding leaves are compound, unequally pinnate, and with many leaflets.

IDENTIFICATION

In summer this tree is only liable to be confused with *Pterocarya rhoifolia*, which has scaly buds. It is distinguished from all species of *Juglans* by its naked buds.

In winter the following characters are available:—Twigs stout, olive green, glabrous except at the minutely pubescent, glandular tip. Leaf-scars oblique on the twigs, their lower part projecting, large, obcordate, marked by three crescentic prominences, which are the fused cicatrices of the vascular bundles. Pith pentagonal in cross section, chambered in longitudinal section. Buds without covering scales, consisting of a short shoot and three to four undeveloped leaves, which are stalked below, enlarged and lobed above, rusty brown in colour, minutely pubescent and glandular. Lateral buds multiple, two to three superposed vertically above each leaf-scar; the uppermost one like the terminal bud, but smaller and stalked; the lowermost close to the upper margin of the leaf-scar, minute and rudimentary.

VARIETY AND HYBRID

1. Var. *dumosa*, Schneider, *Laubholzkunde*, 94 (1904); *Pterocarya dumosa*, Lavallée, *Arb. Segrez.* 217 (1877). This is a shrubby form, with yellowish brown twigs, and small closely-set leaflets, about $2\frac{1}{2}$ inches long. The fruit and flowers are unknown; but it is probably a horticultural variety of *P. caucasica*.

2. *Pterocarya Rehderiana*, Schneider, *op. cit.* 93. This is a hybrid between *P. caucasica* and *P. stenoptera*, which was described by Rehder in *Mitth. Deut. Dendrol. Gesell.* 1903, p. 116. It grows in the arboretum at Segrez; and plants of it are now cultivated in the Arnold Arboretum,² Massachusetts, where it is perfectly hardy. It is intermediate in character between the two species. The leaflets in texture, serration, etc., resemble those of *P. caucasica*, being a trifle smaller; but

¹ Cf. Lubbock, *Seedlings*, ii. 521, fig. 662 (1892)

² Two seedlings were raised by Elwes from seeds of this tree, one of which is now about eighteen inches high, and shows evidence of its hybrid origin in the leaves.

the rachis shows here and there a very slight wing, like that of *P. stenoptera*, only never serrate in margin. The fruits have oval wings, shorter and broader than those of *P. stenoptera*, the nut being more beaked than in that species. The veining of the fruit-wings resembles *P. caucasica*.

DISTRIBUTION

Pterocarya caucasica has been found in the northern provinces (Astrabad and Ghilan) of Persia, and in Russian Armenia, as well as in the Caucasus. According to Radde,¹ it occurs in the marshy delta of the Rion in company with *Alnus glutinosa*, and along the coast of the Black Sea, mixed with oak, beech, and hornbeam. It grows sometimes as a tree, but oftener as a tall shrub, on the banks of streams. It extends up to about 1200 feet only in Kachetia, and is met with as far eastward as Talysch, on the coast of the Caspian Sea, where in damp places it forms the principal underwood. It is not found wild in the interval between the lower Rion on the west and the lower valley of the Alazan on the south side of the central Caucasus, and is again absent from here to the province of Talysch.

Mr. Younitsky of the Russian Forest Service has kindly sent me the following account of the tree in the Caucasus. He says it is only found in certain stations, rarely over 1200 feet elevation, and always in moist or very wet places, to which it is better adapted than even the alder. In the young stage the tree is very delicate and susceptible to spring frosts, requiring shelter when young; and when older does not bear shade well. Very large trees occur, of 100 feet in height and 10 feet in girth, and logs of it are obtained bare of branches for 50 feet, with a girth of 5 feet at the smaller end. It grows very rapidly in youth, making a height of 30 feet in ten years. The wood is light and soft, resembling much that of the lime-tree, and is chiefly used for making boxes and packing-cases. The bark is used for sandals and roofing. The leaves contain a poisonous matter, and when thrown into water intoxicate the fish, which rise to the surface and are easily caught. The tree is rarely cultivated, but is recommended for planting in the wettest situations, where it will thrive better than almost any other tree.

CULTIVATION

Pterocarya caucasica was introduced into France by the elder Michaux on his return from Persia in 1782. According to Bosc the first tree was planted at Versailles, others a little time after being planted about the Museum in Paris. According to Mouillefert,² there are still growing at the Trianon, Versailles, and at the Museum, Paris, two fine specimens which are probably original trees.³ The tree flowered and produced fruit in 1826 in the park at Malesherbes, according to a note by Gay in the Kew Herbarium. There is a tree 80 feet high and 9 feet in girth in the Old Botanic Garden at Geneva, which was seen by Elwes in 1905.

¹ Radde, *Pflanzenverbreitung in Kaukasusländern*, 109, 139, 159, 182, 205, etc.

² *Traité des Arbres*, ii. 1195 (1898).

³ I could not find either of these trees in 1905.—H. J. E.

This species was introduced into England some time after 1800, the largest tree mentioned by Loudon in 1838 being one 25 feet high and fifteen years planted at Croome; but it is long since dead. (A. H.)

I have raised numerous plants of *Pterocarya* from seed sent me from the Caucasus by the late Dr. Radde in 1903, some of which was distributed by the Royal Horticultural Society. The seedlings grow fast, attaining 2 feet or more in height at two years old, but do not ripen their wood well when young, and are extremely liable to be injured by frost if not protected in spring.¹ The leaves appear about the same time as those of *Liriodendron*. The tree does not seem to dislike lime in the soil, and should be planted out when 3 or 4 feet high, in a situation where the ground is not liable to drought in summer, or near running water.

REMARKABLE TREES

This is one of the most ornamental hardwoods that we have; and is well worth planting in warm and sheltered positions in the south of England, where it thrives from Kent to Devonshire.

By far the largest and finest tree of this species known in England is at Melbury, Dorsetshire, the seat of the Earl of Ilchester. This magnificent tree (Plate 121) is growing on a sheltered bank below the house, on soil which contains lime, close to the finest specimen I know of *Picea Morinda*. It is no less than 90 feet high by 11 feet in girth, and has a straight clean bole about 15 feet long, spreading out into a symmetrical head of branches, and when I saw it in September 1906 had many catkins of fruit hanging on it.

Its spreading habit is shown by a fine tree at Claremont Park, near Esher, Surrey, which grows on deep sandy soil, and is a noble ornament of a lawn. The illustration of this tree (Plate 122) is from a photograph taken in 1903, when it measured about 50 feet in height, with a bole of only 4 feet high but no less than 18 feet in girth. It divides into eight large limbs, each of which is about 4 feet in girth, and the foliage spreads over an area of 30 yards in diameter. The tree is believed by Mr. Burrell, the gardener, to be about eighty years old, and seems to be decaying at the heart. The bark is very rough and deeply furrowed, and the leaves and flower-buds were just appearing, after a very mild winter, on 6th March. A self-sown seedling from it was about 2 feet high.²

Another fine tree is growing at Tortworth Court, from which I gathered ripe seed in October 1900, one of which grew in the following spring. The Earl of Ducie has raised several young trees from the same parent in other seasons. At Linton Park, Kent, there is a fine tree, which was about 50 feet high in September 1902, but not so large as the one at Claremont. Ripe fruiting specimens were sent from Devonshire by Sir John Walrond in 1888, which were figured by

¹ The severe frost of 20th-22nd May 1905 seriously injured all my young trees, and it is evident that this tree should only be planted in situations where spring frosts are not severe.

² Mr. Burrell found a seedling in the summer of 1899. See *Garden*, 1902, lxii. 234, where a figure and description of the tree are given. See also *Garden*, 1894, xlv. 404, fig., and *Gard. Chron.* 1894, xvi. 192. According to a note in the Kew Herbarium, the Claremont tree was, in 1887, 45 feet high by 13½ feet in girth.

Dr. Masters in the *Gardeners' Chronicle*, but I have been unable to procure particulars of the tree from which the specimens were obtained.

In the Botanic Garden, Cambridge, there is an old tree which was 58 feet high in 1903, with eight stems, girthing from 3 feet to 4 feet 3 inches; and from the roots of another tree which was blown down about 1885 a number of strong stems, about twenty, have sprung up, which average about 50 feet in height and $2\frac{1}{2}$ feet in girth. These particulars, which have been kindly sent me by Mr. Lynch, the curator, show the remarkable power of the tree in producing root-suckers (Plate 123).

A tree at Fota, near Queenstown in Ireland, seen by Henry in 1903, measured 42 feet high by 3 feet 9 inches in girth. It produced flowers and fruit in 1902.

Dr. Masters¹ recommends it for planting in towns, and says that there was a good specimen in the Chelsea Botanic Garden (since cut down) in 1891. There are said to be good specimens in some of the towns in Holland. (H. J. E.)

PTEROCARYA RHOIFOLIA

Pterocarya rhoifolia, Siebold et Zuccarini, *Abh. Bayr. Ak. Wiss. Math. Phys. Kl.* iv. 2, 141 (1845); Maximowicz, *Mé. Biol.* viii. 637 (1872); Shirasawa, *Icon. Ess. For. Japon.* text 35, 1. 16 (1900).

Pterocarya sorbifolia, Siebold et Zuccarini, *loc. cit.*; Rehder, *Mitt. Dendrol. Deut. Gesell.* 1903, p. 115.

A tree attaining, according to Shirasawa, 100 feet in height, with a straight stem 10 feet in girth. Bark greyish brown with deep longitudinal fissures. Shoots glabrous. Leaves (Plate 125, fig. 3) 8 to 16 inches long, on a stalk about 2 inches long, which is swollen at its insertion; rachis without wings. Leaflets, fifteen to twenty-one, usually opposite, sessile or sub-sessile, $2\frac{1}{2}$ to 5 inches long, oblong-lanceolate, acuminate at the apex, unequal at the base, which is rounded or somewhat narrowed; dark green above; under surface lighter green, with glandular scales, and some tomentum on the midrib and nerves and in their axils; somewhat thicker in texture than the leaves of *P. caucasica*; margin sharply and finely serrate.

Flowers appearing with the leaves. Staminate catkins two to three at the base of the young shoots; scale three-lobed, pubescent, bearing nine to twelve short-stalked stamens. Pistillate catkins, solitary, terminal at the end of the young shoot, later apparently lateral owing to the growth of the upper axillary bud. Fruiting catkins, 8 to 10 inches long; fruit an inch across; nut with a short, scarcely beaked apex; wings rhombic, broader than long, without any hollow at their base, inconspicuously veined.

The above description applies to the glabrous form, which is in cultivation in England and is common in Japan. In wild specimens from Yezo the leaves appear to be much more pubescent, the rachis and nerves being often covered with dense long hairs.

¹ *Journ. R. Hort. Soc.* 1891, xiii. 86.

This species is readily distinguished by the peculiar buds, which are formed early, and by the scars at the base of the shoot, left by the fall of the bud-scales of the previous year. The buds at first are long, conical, with a curved beak, and are covered by a funnel-shaped membranous sheath, which is composed of two external and two to three internal glabrescent glandular scales. The scales fall off in November, leaving four or five narrow scars at the base of the buds, which in this stage resembles in structure those of *P. caucasica*, but are whitish and densely tomentose. Lateral buds usually solitary at some distance above the leaf scars. Twigs quite glabrous, otherwise as in *P. caucasica*. (A. H.)

In Japan this is a large tree known as *Sawa gurumi*, which I saw in the central provinces of Hondo, where it grows to a height of 50 to 60 feet, old trees attaining a girth of 8 or 10 feet. It generally grows on the banks of streams in mixed forest, and did not seem to be very common or to be valued for its timber, though I got a specimen of the wood from the Government sawmills at Atera, which is now at Kew.

Sargent found it very abundant on the slopes of Mt. Hakkoda, in the north of Hondo, at 2500 to 4000 feet elevation, where it attains as much as 80 feet in height, being next to the beech the largest deciduous tree in the forest. It is a broad-topped tree with stout spreading branches, and when covered with its long hanging slender racemes of fruit, is very handsome. It is hardy at the Arnold Arboretum near Boston and produces seeds there.

Pterocarya rhoifolia is recorded by Diels¹ as having been collected by Von Rosthorn in the province of Szechuan in China.

It seems to have been introduced into cultivation by the Duke of Bedford, to whom seeds were sent from Japan in 1889. Young plants from some of this seed were raised at Kew in 1890; and these have now attained about 12 feet in height. They are the only specimens we have seen in England. (H. J. E.)

PTEROCARYA STENOPTERA

Pterocarya stenoptera, C. de Candolle, *Ann. Sc. Nat. sér. IV.* xviii. 34 (1862); Lavallée, *Arch. Segrez. Icones*, 65, t. 19 (1885); Franchet, *Journ. de Bot.* 1898, p. 317.

A tree, 50 to 60 feet in height, with a girth of stem of 6 or 8 feet. Bark rough. Leaves (Plate 125, fig. 2) about a foot in length; rachis covered with bristles, slightly swollen at its insertion, and having on each side a conspicuous irregular membranous wing, occasionally slightly serrate in margin. Leaflets nine to twenty-five, opposite or alternate, terminal leaflet often wanting; coriaceous; under surface with a few scattered glands, and some pubescence on the midrib and nerves and in their axils; oblong or oblong-lanceolate; acute at the apex, unequal and rounded or narrowed at the base, finely and sharply serrate in margin, 3 to 5

¹ *Flora von Central China*, 274 (1901).

444 The Trees of Great Britain and Ireland

inches long. Male catkins, arising as in *P. stenoptera*; scale glandular, four-lobed; stamens six to ten. Female catkins 8 inches long; bract minute, bracteoles oblong and longer than the style, perianth with four subulate lobes. Fruit: catkins a foot or more in length; nut with conic beak-like apex; wings linear-oblong and erect.

The above description applies to the form in cultivation, which is also common in the wild state. The species is, however, very variable as regards the amount of pubescence, the twigs being often glabrous and the leaf-rachis only slightly pubescent. In many wild specimens the wing of the rachis is very slight.

This species is readily distinguishable in summer by the winged rachis of the leaf. In winter the twigs are slender and covered with a rusty-red bristly pubescence; but in other respects resemble those of *P. caucasica*. The buds, more slender than in that species, but similar in structure and position, are greyish in colour.

This is a common tree in the central and southern provinces of China, extending in a slightly different form into Tonking.¹ It is usually met with in the plains and low hills, along rivers and water-courses; and never grows to be a large tree. It is recorded from near Moukden in Manchuria, where it was collected by James; but was probably only cultivated there. It is usually called *ma-liu*² by the Chinese; and is much planted in the streets of Shanghai, where it is often called "Chinese ash" by the European inhabitants. As the climate of the regions where it grows naturally is very different from that of England, it is liable to be injured by spring frosts, and fails from want of heat in autumn to ripen its wood. The timber is considered in China to be of little value.

The tree was introduced into Europe apparently by Lavallée, who received the seeds from Siebold, about 1860. It supported at Segrez very low temperatures in 1870 and 1871; but succumbed during the severe winter of 1879-1880. Lavallée considered it to be about as hardy as the common walnut.

The only specimen that we have seen in England of any size is at Tortworth, where Elwes measured in 1905 a tree 32 feet high by 2 feet 3 inches in girth, believed by Lord Ducie to have been planted about twenty years. It is in a shady and sheltered valley and produced small racemes of fruit in 1905. (A. H.)

¹ *Var. tonkinensis*, Franchet, *Journ. de Bot.* 1898, p. 318. A geographical form, distinguished by large leaflets, up to 6 inches long, and linear wings to the fruit, which diverge at a wide angle.

² Henry, "Chinese Names of Plants," *Journ. China Branch R. Asiat. Soc.* xxii. 256 (1887).

CLADRASTIS

Cladrastis, Rafinesque, *Cincinnati Literary Gazette*, i. 66 (1824); and *Neogeniton*, i. (1825); Bentham et Hooker, *Gen. Pl.* i. 554 (1865).
Maackia, Ruprecht et Maximowicz, *Mit. Biol.* ii. 440, t. ii. (1856).

DECIDUOUS trees or shrubs belonging to the division Papilionaceæ of the order Leguminosæ. Leaves alternate, unequally pinnate; leaflets opposite, sub-opposite or alternate, on stout petiolules, entire in margin, and without stipels. Flowers in panicles or racemes, on slender pedicels; calyx with four or five short unequal teeth; corolla papilionaceous, petals unguiculate, standard nearly orbicular, wing and keel-petals oblong; stamens ten, free or slightly united at the base; anthers versatile; ovary with numerous ovules; style incurved, subulate; stigma terminal, minute. Pod linear, flattened, thin, thickened on the upper margin; valves membranous; seeds four to six.

Four species of *Cladrastis* have been described, constituting two sections, which have been considered by Sargent and other botanists to form two distinct genera, *Cladrastis* and *Maackia*. The difference in the buds of the two sections is remarkable; but analogous differences occur in other genera, as *Carya* and *Pterocarya*; and in the absence of important differential characters in the flowers and fruit, it is advisable to unite the sections into one genus.

SECTION I. EU-CLADRASTIS.

Buds several together, compressed into a cone, and concealed in the base of the petiole of the leaf. Leaflets usually alternate. Flowers in panicles; calyx five-toothed.

1. *Cladrastis tinctoria*, Rafinesque. Kentucky, Tennessee, Alabama, and N. Carolina.

Shoots glabrous. Leaflets seven to eleven, oval or ovate, acuminate, almost completely glabrous.

2. *Cladrastis sinensis*, Hemsley. Central and western China.

Shoots rusty pubescent towards the base. Leaflets nine to eleven, oblong-lanceolate, obtuse or sub-acute, rusty pubescent towards the base and along the midrib.

SECTION II. MAACKIA.

Buds solitary, axillary, not concealed. Leaflets opposite or sub-opposite. Flowers in racemes; calyx four- or five-toothed.

3. *Cladrastis amurensis*, Benth. et Hooker. Amurland, E. Manchuria, Korea, and Japan.

Shoots pubescent. Leaflets nine to eleven; deltoid, ovate or oval; obtuse or acute; densely appressed pubescent; calyx four-toothed.

4. *Cladrastis Tashiroi*, Yatabe.¹ Loochoo Islands.²

Allied³ to *C. amurensis*, but always a small shrub; with smaller leaflets, acute and not truncate or rounded at the base as in that species, glaucescent and scarcely pubescent beneath. Flowers and pods also smaller; calyx five-toothed.

CLADRASTIS TINCTORIA, YELLOW-WOOD

Cladrastis tinctoria,⁴ Rafinesque, *Neogeniton*, i. (1825); J. D. Hooker, *Bot. Mag.* t. 7767 (1901).

Cladrastis fragrans, Rafinesque (name only), *Cincinnati Literary Gazette*, i. 66 (1824).

Cladrastis lutea, Koch, *Dendrologie*, i. 6 (1869); Sargent, *Silva N. America*, iii. 57, tt. 119, 120 (1892), and *Trees N. America*, 568 (1905).

Virgilia lutea, Michaux, *Hist. Arb. L'Amér.* iii. 266, t. 3 (1813); Loudon, *Arb. et Frut. Brit.* ii. 565 (1838).

A tree attaining 60 feet in height, and rarely 12 feet in girth. Bark smooth and silvery grey. Branchlets brittle, glabrous. Leaves (Plate 125, fig. 5) alternate, unequally pinnate, 8 to 12 inches in length. Leaflets seven to nine, usually alternate; the terminal one largest, articulate and directed to one side, often broadly rhombic; the others gradually diminishing in size towards the base of the leaf, 3 to 4 inches long by 1½ to 2 inches wide, on stout pubescent petiolules, oval or ovate, entire and non-ciliate in margin; base broadly cuneate or rounded, apex acuminate; upper surface light green and glabrous; lower surface pale green with occasional hairs on the midrib and veins. Rachis of the leaf terete, glabrous, with the base swollen and hollowed out, enclosing the buds, which are usually four, the largest and uppermost one developing, the others minute and rudimentary.

Flowers in nodding terminal panicles, 10 to 20 inches long, white, with a yellow spot at the base of the standard. Pedicels slender and not grouped in pairs. Calyx campanulate, enlarged on its upper side; teeth five, short, obtuse, nearly equal. Corolla papilionaceous with clawed petals; standard nearly orbicular; wings oblong and two-auricled at the base; keel-petals free, oblong, and sub-cordate or two-auricled at the base. Stamens ten, free. Ovary linear, stalked, villose; ovules numerous. Pod glabrous, short-stalked, linear, glabrous. Seeds four to six, attached by slender stalklets, oblong-compressed, without albumen.

¹ *Tokyo Bot. Mag.* vi. 345, t. 10 (1892).

² Cf. Ito and Matsumura, *Journ. Science College, Imp. Univ. Tokyo*, xii. 436 (1899).

³ Judging from the description, as I have seen no specimens. There are specimens in the Kew Herbarium (*Cladrastis*, sp. ? Hemsley, *Journ. Linn. Soc. (Bot.)* xxiii. 201 (1887)) which were collected by Millett, probably in the vicinity of Canton, which are very near to the Loochoo species.

⁴ This name is adopted as being the first one with a description published under the correct genus.

SEEDLING

A plant, raised from seed sown at Colesborne on 2nd March, showed the following characters on 7th July:—Root white, fleshy, tapering, 3 inches long, giving off numerous lateral fibres. Caulicle striated, glabrous, 1½ inch long. Cotyledons two, sub-sessile, oblong, tapering slightly at the base, broader towards the rounded apex, green above, white beneath, coriaceous, entire. Stem terete, with a few scattered hairs below, densely white pubescent above. Leaves, all with petioles swollen at the base; first pair opposite, on pubescent stalks, simple, ovate, entire, 2 inches long by 1½ inch broad. The third, fourth, and fifth leaves are alternate; the third simple and like the first pair; the fourth and fifth trifoliolate on a stalk 2 inches long, terminal leaflet ovate, lateral leaflets oval and smaller.

IDENTIFICATION

Cladrastis tinctoria is readily distinguishable in summer by the pinnate leaves with alternate leaflets, of which the terminal one is directed to one side of the leaf; and by the swollen base of the petiole, which encloses and conceals the buds.

In winter the following characters are available (Plate 126, fig. 4):—Twigs zig-zag, shining, brown or grey, terete, glabrous; lenticels minute, numerous. Leaf-scars alternate, obliquely set on slightly prominent pulvini, oval, whitish, with five bundle-dots on the outer rim, the centre of the scar being occupied by a projecting cone, which consists of four buds compressed together and superposed one above the other, the uppermost one the largest, all pubescent. Terminal bud not formed, the apex of the twig showing a small circular scar or a short stump, indicating where the top of the branchlet fell off in early summer.

DISTRIBUTION

Cladrastis tinctoria is one of the rarest trees in the American forest, growing only in a few isolated localities in central Kentucky, central and eastern Tennessee, northern Alabama, and the south-western part of N. Carolina. It is met with on limestone ridges and cliffs, usually in rich soil, and frequently overhangs mountain streams. (A. H.)

CULTIVATION

The yellow-wood is a favourite ornamental tree in American gardens, where, according to Sargent,¹ it adapts itself readily to varied conditions of soil and climate, though it requires deep rich soil in order to attain its full size and beauty. It has a tendency, however, which in England is equally marked, to divide into several spreading stems, which are rather brittle and liable to split the trunk. Its long racemes of white fragrant flowers make it a very pretty tree early in June, but in our climate these are not produced as freely as in America, and I have never seen fruit ripened in this country. In autumn the leaves turn a bright yellow.

¹ *Garden and Forest*, i. p. 92.

Sargent¹ gives an illustration of a beautiful specimen in a garden near Boston which, 35 years after planting, was 35 feet high and had a spread of nearly 60 feet. I saw several in this district, but none so large as those which I have seen in England.

Though it germinates quickly, and seems easy to raise from seed, the tree is now seldom planted in England, but may be recommended for warm sheltered situations in good soil in the south and east, though perhaps the damp climate of the west does not suit it; and as most of the trees mentioned by Loudon have disappeared, it seems to be short-lived in this country. The seedlings which I have raised from American seed are fairly hardy, and after the first two years grow better than many American trees on my soil.

This species was introduced into cultivation in England in 1812, by John Lyon, a Scotsman who travelled in Carolina, Georgia, and Florida.

REMARKABLE TREES

The largest tree known to us is at Syon (Plate 124), which in 1904 was no less than 60 feet in height by 7 feet in girth and still a fine tree, though its trunk is decaying inside. There is another in Kew Gardens, near the Director's office, which measures 35 feet high, with a bole of 3 feet girthing 5 feet 4 inches and dividing into six main stems, which sub-divide into numerous upright branches. At the Knaphill Nursery near Woking is a very well grown tree about 45 feet high and 8 feet in girth, the head spreading to 16 yards in diameter.

At Highclere there is a tree which measures 42 feet by 7 feet with a spread of branches of 45 feet. Although there is some decay near the root the tree seems to have become more vigorous recently. At Blenheim there is an old specimen, with a stem divided close to the ground, and forming rather a large bush than a tree. At Cornbury Park there is also a fair-sized tree. At Barton, Suffolk, a tree planted² in 1832 was in 1904 25 feet high with a short bole, 5 feet 6 inches in girth, dividing into three wide-spreading main branches.

We have not seen any large enough to mention in Scotland or Ireland.

TIMBER

The wood, according to Sargent, is heavy, hard, strong, and close-grained, and is susceptible of a fine polish. At one time it was used in Kentucky for making gun-stocks; but is too rare to have any commercial importance. It produces a yellow dye.
(H. J. E.)

CLADRASTIS AMURENSIS

Cladrastis amurensis, Bentham et Hooker, *Gen. Pl.* i. 554 (1865); Maximowicz, *Mél. Biol.* ix. 72 (1873); Franchet et Savatier, *Enum. Pl. Jap.* i. 115 (1875) and ii. 327 (1879); J. D. Hooker, *Bot. Mag.* t. 6551 (1881); Shirasawa, *Icon. Ess. Forest. Jap.* text 85, pl. L. figs. 1-12 (1900).
Maackia amurensis, Ruprecht et Maximowicz, *Mél. Biol.* ii. 418, 441 (1856) and 534 (1857); Maximowicz, *Prim. Fl. Amur.* 87, 390, t. v. (1859); Morren, *Belgique Horticole*, 1890, p. 301, t. 18; *Gartenflora*, 1875, p. 152.

A small tree, attaining 40 or 50 feet in height, with bark peeling off in old trees like that of a birch. Young shoots minutely pubescent. Leaflets (Plate 125, fig. 6) seven to eleven, opposite or rarely sub-opposite, the terminal one articulate, the lateral ones on short, stout pubescent petiolules; 2 to 3 inches long; deltoid, ovate or oval; base truncate or rounded; apex obtuse or acute; entire; upper surface dark green and minutely pubescent; lower surface pale green, densely appressed pubescent; rachis pubescent, swollen at the base.

Flowers greenish white, on long pedicels, in simple or occasionally branched erect terminal dense racemes. Calyx teeth four, short, broad, unequal. Petal-claws long, slender; standard obovate, emarginate; wings oblong, obtuse, two-auricled at the base; keel petals partially coalesced, one-auricled. Stamens slightly connate below. Pod, 2 to 3 inches long, oblong, flattened, brown, slightly appressed pubescent; seeds, one to five, oblong.

In specimens from the Asiatic continent the leaflets are larger and much less pubescent than in the Japanese tree, which has been distinguished by Maximowicz as var. *Buergeri*,¹ and is characterised by very dense appressed pubescence on the lower surface of the leaflets and white tomentose shoots.

In winter the twigs (Plate 126, fig. 5) are shining, glabrous; leaf-scars on prominent pulvini, semicircular, marked by a central large tubercular bundle-scar and two minute dots close to the upper margin; true terminal bud absent, the top of the branchlet having fallen off in early summer and leaving a short stump at the apex of the twig. Buds solitary, dark brown, shining, pubescent towards the apex, showing two scales visible externally.

Cladrastis amurensis occurs in Amurland as far north as lat. 52° 20', and grows throughout Eastern Manchuria and Korea, the largest tree seen by Maack being only 35 feet high and 1 foot in diameter. According to Shirasawa, it is met with in Japan on moist rich soils in the temperate parts, ascending to 4300 feet in the central chain of the main island, and attaining a height of 50 feet and a diameter of 28 inches. It was collected by Elwes in the forest near Asahigawa in central Hokkaido, where, however, it was not abundant or conspicuous. It is called *Inu-enju* in Japan.

Cladrastis amurensis was introduced from the Amur in 1864 by Maximowicz; and has been spread throughout Europe by the St. Petersburg Botanical Garden. It probably came into England about 1870.

¹ *Mél. Biol.* ix. 72 (1873).

450 The Trees of Great Britain and Ireland

It is propagated either by seed or by root-cuttings. At Kew it is rather a shrub than a tree, and produces flowers when quite young, which appear late in the season, in the end of July or the beginning of August. It ripens its fruit in October, the pods remaining on the tree during winter.

The timber, according to Shirasawa, is hard and tenacious, and is used in building and in making furniture. Elwes purchased planks of it at Sapporo, which are of a yellowish-brown colour, and seem to be of good quality for cabinet-making.

(A. H.)

CLADRASTIS SINENSIS

Cladrastis sinensis, Hemsley, *Journ. Linn. Soc. (Bot.)* xxix. 304 (1892).

A tree attaining 70 feet in height and 10 feet in girth. Young shoots rusty pubescent towards the base. Leaflets nine to eleven, alternate, entire, oblong-lanceolate, obtuse or acute at the apex; broad and rounded, rarely cuneate, at the base; lower surface with appressed pubescence most marked towards the base and along the midrib. Leaf-rachis pubescent, with swollen base enclosing two or three buds. Leaf-scars on older shoots, oblique on prominent pulvini, orbicular; the raised circular rim, discontinuous above, surrounding a central densely pubescent depression, in which lie two or three buds, the upper one of which is the largest.

Flowers pinkish-white, fragrant, in large terminal, rusty-pubescent panicles. Calyx rusty-pubescent; teeth short, broad, rounded. Petals long-clawed, erect, free; standard broadly obovate, bifid; wings and keel-petals oblong. Stamens slightly connate at the base; ovary pubescent. Pod linear-oblong, flattened, with thickened margins.

This tree, which resembles *Sophora japonica* in habit and foliage, was discovered by Pratt, in 1890, in Western Szechuan, where E. H. Wilson subsequently saw large trees at 7000 feet altitude in the Hsiang Ling range, west of Mt. Omei. It also occurs in the high mountains of the Fang district in Hupeh, from whence seeds were sent home by Wilson in 1901. Plants raised at Coombe Wood were, in 1906, 5 feet high, and for so far have proved perfectly hardy. The tree has beautiful flowers, and, growing at high altitudes in western China, should thrive in this country.

THE TREES OF GREAT BRITAIN AND IRELAND

LEBANON CEDAR AT HIGHCLERE CASTLE

From a Drawing by Charlotte Lady Phillimore.

A detailed botanical illustration of tree branches. The top half shows several catkins (male flower clusters) with red and yellow flowers, some on bare branches and some on branches with small, developing leaves. The bottom half shows a branch with large, green, serrated leaves and a single catkin. The illustration is enclosed in a thin black rectangular border.

Pinus, section *Cedrus*, Parlatore in DC. *Prod.* xvi. 2, p. 407 (1864).

Abies, Poiret in Lamarck, *Dict.* vi. 510 (1804) (*ex parte*).

TREES belonging to the tribe Abietinæ of the order Coniferæ, with evergreen foliage, borne, for the most part, in tufted flat masses on the ramifications of the branches, which arise irregularly and not in whorls from the stem. Bark dark grey and smooth on young stems and branches; ultimately on old trunks thick and fissuring into irregular longitudinal plates, roughened externally by small scales.

Branchlets of two kinds: long shoots bearing in spiral order solitary leaves, and short shoots or spurs with leaves in pseudo-verticels. Buds minute ovoid, with a few brown scales, which persist after the opening of the bud, either sheathing the base of the long shoots or surrounding the annual rings of the short shoots. Long shoot with a solitary terminal bud, prolonging the growth of the branchlet in the following year; and with a few lateral buds solitary in the axils of some of the leaves and usually developing into short shoots. Short shoot with a terminal bud only, which, in the following year, either lengthens slightly the spur and adds to it a whorl of leaves with or without flowers, or occasionally develops into a long shoot. Long shoots, slightly furrowed, between the slightly raised decurrent bases of the pulvini, the free ends of which project and bear leaves, and on older branchlets, from which the leaves have fallen, remain persistent as slight prominences.

Leaves, deciduous in the third to the sixth year, variable in length, the shortest on the spurs, articulated at the base, acicular, rigid, sharply pointed, more or less triangular in section, stomatic on all sides; fibro-vascular bundle undivided, hypoderm thick, with two resin canals close to the epidermis on the lower surface.

Flowers, monœcious, terminal, solitary on the older leaf-bearing short shoots. Male flowers, erect, catkin-like, cylindrical, about 2 inches long; anthers numerous, spirally crowded, bi-locular, dehiscing longitudinally; connective prolonged into an ovate denticulate crest; pollen grains globose, without wings, borne to the female flowers by the wind. Female flowers appearing as small purplish cones, about $\frac{1}{2}$ inch in length; composed of numerous spirally arranged, closely appressed, irregularly dentate, sub-orbicular scales, each subtended by a short, included, obovate, denticulate bract; ovules, two on each scale, inverted.

Ripe cones, solitary, erect, on short stout peduncles, dull-brown, resinous, ellipsoid or cylindrical; rounded, flattened or depressed at the apex. Bracts obsolete or minute and ragged. Scales numerous, closely imbricated, woody, fan-shaped; upper expanded part thin, transversely oblong, with denticulate rounded or sloping wings, brown-tomentose in greater part beneath, almost glabrous above; claw thickened, obcuneate, with a raised ridge between the depressions for the seeds on the upper surface, the lower surface being slightly hollowed by the pressure of the seeds of the adjoining scale. Seeds, two on each scale, $\frac{1}{4}$ to $\frac{1}{2}$ inch long, with resin-vesicles on both surfaces, brown, irregularly triangular; surmounted by a membranous brownish wing, broadly triangular or hatchet-shaped, about twice as long as the body of the seed. Cotyledons, nine or ten.

The flowers appear in July or August, the pollen being shed profusely in October. During winter the cones remain small, and only begin to grow in the following April, attaining about half or two-thirds their full size in October of the second year. They are fully ripe in October or November of the third year, *i.e.* about twenty-six months after the first appearance of the flowers. In their native forests the dissemination of the seed is caused by the autumnal rains, the cones not disarticulating in dry weather. After being soaked with rain, the scales and seeds separate from the axis of the cone (which remains persistent on the branch) and fall to the ground, the seeds with their light wings being blown, when there is a breeze, to a little distance from the parent tree. In England, irregularities occur in the period when the cones disarticulate, dependent, probably, on the absence of heavy rains in the autumn in certain seasons.

Seedling.—Plants raised from seed gathered on Mount Lebanon in 1904, and sown at Monreith in April 1905, averaged 9 inches high in the following September,¹ and showed the following characters:—Tap-root, about 9 inches long, slender, with a few lateral fibres. Caulicle, 2 inches long, slightly furrowed, glabrous. Cotyledons, ten, sessile, $1\frac{3}{4}$ inch long, curved, tapering to a sharp point, triangular in section, the upper two sides stomatiferous, the lower side green and narrow. Young stem glabrous, bearing in a whorl, just above the cotyledons, the first seven leaves, $\frac{5}{8}$ inch long, linear, flattened, sharp-pointed, stomatiferous on both surfaces, deeply grooved below, slightly convex above, sharply serrate in margin. Above the whorl, leaves, gradually increasing in size to $1\frac{1}{8}$ inch long, arise in spiral order, similarly serrate and stomatiferous, but almost rounded in section; in addition, the stem gives off at irregular intervals five or six small branchlets.

With regard to the different forms of the cedar, which inhabit four distinct and isolated areas, opinions are much at variance as to their rank. They differ more or less in the length of their leaves, and in the size and shape of the cones, cone scales, and seeds, and in the young stage they differ in habit; but in their native forests they all assume, when old, the flattened form which is sometimes erroneously considered to be peculiar to the Lebanon cedar. This is caused by the inflection of the leading shoot, which is followed by a diminution in the rate of vertical growth, the lateral branches at the same time thickening and growing out horizontally. An

¹ This growth is quite exceptional in my experience.—(H. J. E.)

important difference is the height attained in the wild state, the deodar becoming very tall, the Cyprus cedar remaining short, with the Lebanon and Algerian cedars intermediate in size. They differ in their period of vegetation. At Kew the deodar is the first to put forth young leaves in spring; the Lebanon usually follows a fortnight later; and the Algerian generally comes out last, after an interval of a few days. They may be correctly considered geographical races of the same species; but for arboricultural purposes it is most convenient to rank them as distinct species.

CEDRUS LIBANI, LEBANON CEDAR

- Cedrus Libani*, Barrelier, *Plantæ, Icon.* 499 (1714); Loudon, *Arb. et Frut. Brit.* iv. 2402 (1838); Ravenscroft, *Pinet. Brit.* iii. 247 (1884); Kent, Veitch's *Man. Coniferae*, 415 (1900).
Cedrus patula, Koch, *Dendrol.* ii. 268 (1873).
Pinus Cedrus, Linnæus, *Sp. Pl.* 1001 (1753).
Larix Cedrus, Miller, *Gard. Dict.* ed. viii. No. 3 (1768).
Larix patula, Salisbury, *Trans. Linn. Soc.* viii. 314 (1807).
Abies Cedrus, Poiret in Lamarck, *Dict.* vi. 510 (1804).

Leading shoot of young trees erect or slightly bent, not pendulous. Branchlets not pendulous, glabrous or with slight short pubescence. Leaves up to $1\frac{1}{4}$ inch in length, broader than thick. Cones large and broad, ellipsoid, 3 to $4\frac{1}{2}$ inches long, $1\frac{3}{4}$ to $2\frac{1}{2}$ inches wide; scales 2 inches or more in width, with the claw inflected almost at a right angle.

VARIETIES

1. Var. *argentea*, Antoine et Kotschy, *Iter. Cilic.* No. 417. Trees with glaucous foliage, growing wild in the Cilician Taurus, intermingled with the ordinary form. This variety appears in cultivation, but is rarer than the glaucous form of *C. atlantica*.

2. Var. *decidua*, Carrière, *Conif.* 372 (1867). Leaves deciduous. A tree of this kind, slow in growth and bushy in habit, was obtained by Sénéclauze in 1851. Kent mentions one growing at Westgate near Chichester.¹ Webster reports² another, 65 feet high, growing on Lord Derby's property in Kent, and said to be in perfect health, though from its bare appearance in winter it has often been supposed to be dying.

3. Var. *tortuosa*. On the lawn of a private house at Dulwich, belonging to the Dulwich College estate, there is a remarkable cedar, a photograph of which was sent to Kew in 1903. The stem and all the branches are spirally twisted.

The Lebanon cedar is variable in habit, and numerous supposed varieties are mentioned by Beissner, as *nana*,³ a dwarf form; *stricta*, narrowly pyramidal in habit; *pendula*, with pendulous branches and branchlets; and *viridis*, with bright green shining foliage.

¹ But on writing to Captain Norman, who was the authority for this, he tells me that the tree is now dead, and that in his opinion the deciduous habit, which was regular and unfailing, was due to constitutional weakness, caused by uncongenial surroundings, in proof of which he states that another tree at the same place raised from a seed taken from the same cone, was much more robust and showed no abnormal tendency.—(H. J. E.)

² *Hardy Coniferous Trees*, 27 (1896).

³ A specimen of the dwarf cedar, only 4 feet high and of considerable age, is growing in grounds adjoining one of the oldest parks at Hemel Hempstead. The branches are flattened, horizontal, and very close together, giving the plant a dense, stiff appearance.—*Gard. Chron.* xix. 563 (1896).

Supposed hybrids between the Lebanon and Atlantic cedars have been recorded,¹ but on insufficient evidence. (A. H.)

DISTRIBUTION

The best account of the Cedar of Lebanon known to me is the classical paper by Sir Joseph Hooker published in the *Natural History Review*, vol. ii. p. 11 (1862), and as this gives a careful summary of the facts bearing on the specific identity of the forms of cedar, I summarise it as follows:—In the autumn of 1860 Sir J. Hooker went to Syria in company with Captain Washington, Hydrographer of the Navy, and Captain Mansell, R.N., and arrived at Beyrout on 25th September. The party proceeded to the Lebanon, where Captain Mansell made a detailed survey of the basin where the cedars grow, at the head of the Kedisha valley, 15 miles from the sea in a straight line. At that time the other groves were apparently unknown, though Professor Ehrenberg informed Sir Joseph Hooker that he found many trees in forests of oak on the road from Bsharri to Bshinnate. The Kedisha valley at 6000 feet elevation terminates in broad, flat, shallow basins, and is two or three miles across and as much long. It is three or four miles south of the summit of Lebanon, which is about 10,200 feet in height, the chapel in the cedar grove being about 6200 feet. The cedars grow on a portion of the moraine which borders a stream, and nowhere else; they form one grove about 400 yards in diameter, and appear as a black speck in the great area of the corrie and its moraines, which contain no other arboreous vegetation, nor any shrubs but a few small barberry and rose bushes. The number of the trees is about 400, and they are disposed in nine groups, corresponding with as many hummocks of the range of moraines; they are of various dimensions, from 18 inches to upwards of 40 feet in girth; but the most remarkable and significant fact connected with their size, and consequently with the age of the grove, is that there is no tree of less than 18 inches girth, and that no young trees, seedlings, nor even bushes of a second year's growth were found. Calculating from the rings in a branch of one of the older trees, now in the Kew Museum, the younger trees would average 100 years old, the oldest 2500, both estimates no doubt being widely far from the mark. Sir Joseph goes on to say, that the word cedar as used in the Bible applies to other trees, and he doubts whether the cedar of Lebanon is the one which supplied the timber used in building Solomon's temple. He thinks that the cypress or the tall fragrant juniper of the Lebanon (*Juniperus excelsa*) would have been not only much easier to procure, but far more prized on every account.² Between individuals from the Lebanon and the common Asia Minor form there is said to be no appreciable difference by those who have examined both, but there are two distinct forms or varieties in Asia Minor, one having shorter, stiffer, and more silvery foliage than the other; this is the silver cedar, *C. argentea*, of our gardens. Northern Syria and Asia Minor form one botanical province, so that the Lebanon groves,

¹ Beissner, *Nadelholkunde*, 301, 302 (1891).

² But at a later period Sir J. Hooker changed his opinion on this subject, and believed that the wood used by Solomon and by Nebuchadnezzar in buildings was the Lebanon cedar.

though so widely disconnected from the Taurus forest, can be regarded in no other light than as an outlying member of the latter. After speaking of the Algerian cedar and the deodar, Sir Joseph says that it is evident that the distinctions between them are so trivial, and so far within the proved limits of variation in coniferous plants, that it may reasonably be assumed that all originally sprang from one. There are no other distinctions whatever between them of bark, wood, leaves, male cones, anthers, or in their mode of germination, growth, or hardiness (but this has not been confirmed during the severe winters of a later date in England). Though the difference in the shape of the scales and seeds of *Deodara* and *Libani* are very marked, they vary much, many forms of each overlap, and further transitions between the most dissimilar may be established by the intercalation of seeds and scales from *C. atlantica*. Sir Joseph accounts for the difference in the habit of the three forms in a great measure by the climate of the three localities: the most sparse, weeping, long-leaved cedar is from the most humid region, the Himalaya; whilst *atlantica*, the form of most rigid habit, corresponds with the climate of the country under the influence of the great Sahara desert. No course remains, then, but to regard all as species, or all as varieties, or *Deodara* and *atlantica* as varieties of one species, and *Libani* as another. The hitherto adopted and only alternative of regarding *Libani* and *atlantica* as varieties of one species and *Deodara* as another species must be given up.

Ravenscroft, in *Pinetum Britannicum*, gives a very full account of the cedars of Lebanon from various sources, with four good illustrations from photographs taken by F. M. Good of Winchfield, and there are many points in his account worth referring to.

Mr. Ridgway of Fairlawn, who visited them in 1862, says¹ that there is a young tree 50 yards west of the chapel, of exactly the same form and habit as a deodar in his park near Tonbridge. It has the same graceful drooping habit, the same light silvery green, and none of the usual rigid horizontal form of the cedar. He says the remainder of the race of trees vary from 20 to 25 feet in girth; some are as tall and straight as poplars, some not above 20 feet high, and gnarled and stunted. Ravenscroft gives in a table the facts relating to the number of trees found in the accounts of various authors who have written on the Cedars of Lebanon, commencing with Belon in 1550 and ending with Canon Tristram in 1864. Of the older ones there were 28 in Belon's time, which are now reduced to about half that number. There is a gap of some centuries—Ravenscroft says probably more than 1000 years—between the cedars of the second size and the older ones, and again a very long interval of growth between all the young trees, which are now about 400. I do not find any reliable information, taken from an actual count of the number of rings in any of the old Cedars of Lebanon, as to what their possible age may be. Ravenscroft has gone very carefully into the question of the age of the Cedars of Lebanon, which, he says, may be from 4000 to 5000 years old; and he further gives a table based on 200 measurements of cedars of all ages in England, which shows that the average growth in height in England is about 1 foot per annum for trees up to sixty years

¹ *Gard. Chron.* 1862, p. 572.

old, and from 6 to 9 inches in trees of 100 to 200 years. He gives the average breadth of the annual rings per annum in trees of from twenty to fifty years as from $3\frac{1}{2}$ to $9\frac{1}{4}$ lines, and in trees from 60 to 200 years as $3\frac{1}{4}$ lines.

In *Gardeners' Chronicle*, xii. 204 (1879), S. R. Oliver writes:—"And now about the cedars themselves. The guardian told us that there are exactly 385 trees, large and small, but the smallest must be at least from 50 to 80 years old, and no younger trees are springing up—a fact to which it would be well to draw the attention of the public. At this time of year (28th September) innumerable seeds, which are scattered everywhere beneath the trees from the fallen and expanded cones, are germinating, scattered by the wind; these germinating seeds extend far beyond the actual area covered by the remaining trees; and if it were not that they are trodden under foot, or, what is still more destructive, eaten up by the goats, a few decades of years would soon see a fair sprinkling of healthy young cedars enlarging the borders of the grove. In 100 years the grove would be increased into a wood, and five centuries hence the wood would have become a forest. At present, for want of proper protection against the goats and thoughtless tourists, the present grove is dwindling away, and another generation will exclaim against our supineness in thus allowing a relic of the past to die out prematurely. For a small sum of money a stone wall might be built, enclosing the area of the cedar grove sufficiently well against goats. Future travellers ought to be warned by the guardian to confine their steps to certain paths, so as not to injure the young trees; and stringent precautions should be taken against the disfigurement of the trees now existent, by the cutting of names, tearing down of branches for the cones, etc. It would be easy to build such a wall so as not to be an eyesore or disfigurement, by taking advantage of the sinuosities of the numerous small valleys which permeate the vicinity. I am sure that many travellers would contribute small donations should a subscription list be opened for such a purpose.¹ As the property of the cedars belongs to the Patriarch of the Maronites, by name Butross Massaad, who resides by the Dog river, not far from Beyrout, it would be necessary to obtain his co-operation, and I hope, through the aid of the Consul-General for Syria, to have an interview with him on the subject before I leave the neighbourhood. Most of the single trees of antique growth average 20 to 30 feet in girth at about 6 feet from the ground, but the enormous fathers of the forest are in reality a congeries of two, three, or even more trees which have grown so closely together as to coalesce and actually form a single trunk. Among the younger specimens twin and triplet trees are rather the rule than the exception, and this will explain such a girth as Dr. Wartabet measured round the largest tree on the slope north of the Maronite chapel overlooking the ravine, viz. 48 feet. This tree is by no means one of the oldest, but is at its full growth of maturity, and in vigorous health. The hoar, gaunt, and withered trunks of greatest antiquity are around the usual camping ground at the S.E. corner of the group."

Dr. A. E. Day wrote to me as follows on their actual condition more recently, in a letter dated Beirut, Syria, 9th November 1903:—

¹ Rustem Pasha informed Sir W. Thiselton Dyer that he had built a wall to protect the young cedars from grazing, but at a later period this was broken down.

"To the best of my knowledge there are five groves of cedars in Lebanon. The best known one, and that containing the oldest trees, is one in northern Lebanon above Bsharri. [Plate 127, from a photograph by Dr. Van Dyck, shews one of these trees.] The condition of that has, I think, not changed much in thirty years. I am sure that no new trees have grown up in it. A few of the oldest ones have lost branches, or have entirely perished. The grove is a favourite resort in summer for Syrians and for foreigners. A few hours south and west of Bsharri is the village of Hadeth-el-Jubbeh, or Hadeth, as it is often called, though there are a number of Hadeths in Lebanon. Within a half-hour to the south of Hadeth is a fine grove of young trees which, I think I have been informed, was started and has been preserved by a Greek or Maronite bishop. The remaining three groves are near each other, on the western slope of the main ridge of Lebanon, the most northern one being a few miles south of the Beirut-Damascus road as it crosses the ridge. The most northern of the three is above the village of Ain-Zahalta, the next is above Bârûk, and the third is above Maâsir, each being known by the name of the village near it, being also the property of that village. The smallest grove, but that containing the oldest trees, is that of Maâsir. The Bârûk grove is the most extensive of all the five in Lebanon, and contains many young trees in all stages of growth. Most of the trees are upon a very steep slope, but in the upper part of the grove there are various knolls and hollows, affording a few charming spots for camping. I am sorry to say that this fine grove suffers much from being cut. The people of Bârûk obtain from it roof-beams and wood for fuel, and I am informed that they are discussing selling a large part of it to be felled for pitch. I have failed to find a single large tree in the Bârûk grove which has not been cut off, with the result that several branches have taken the place of the principal stem. The ordinary Arabic name of the cedar is 'Arz,' but the natives of the villages near the three southern groves call the tree 'Ubhul.'"

The cedar is also found in the Taurus and Anti-Taurus ranges in Asia Minor, extending from the province of Caria¹ in the west to near the frontier of Armenia in the east. It forms a considerable part of the coniferous forest, which, in a few scattered localities, covers the mountains between 4000 and 7000 feet. It is usually associated with *Abies cilicica*, *Juniperus excelsa*, and *J. foetidissima*; and is occasionally mixed with *Pinus Laricio*. In Lycia, dense woods of cedar were observed by Luschan² in the Baba Dagh and between Zumeru and the Bulanik Dagh. The tree, however, appears to attain its maximum development in the Cilician Taurus, where there are fine forests of great extent in the Bulgar Dagh, which have been visited by Tchihatcheff,³ Kotschy,⁴ and W. Siehe.⁵ The latter states that the climate in which the cedar grows is a severe one, the snow lying several feet deep on the ground for about five months of the year. He describes

¹ Collected in Caria by Pinard, according to Boissier, *Flora Orientalis*, v. 699 (1881). Dr. Stapf informs us that Luschan also saw the cedar in this province.

² Cf. Stapf, *Beiträge Flora Lycien, Carien, u. Mesopotamien*, 2 (1885).

³ *Asie Mineure*, ii. 496 (1860).

⁴ *Reise Cilicischen Taurus*, 58, 370 (1858).

⁵ *Gartenflora*, 1897, pp. 182, 206. Siehe has sent seed from the Cilician Taurus to various places, and I have two vigorous young trees raised from them.

the forest as an open one, the trees standing isolated and attaining about 130 feet in height and 10 feet in girth, and none of a larger size were noticed. Haussknecht found the cedar in the Berytdagh in Cataonia; Heldreich collected it in the Davros Dagh in Pisidia; and two or three other localities, where the tree is apparently neither abundant nor remarkable for size, are mentioned by Boissier.

I saw the cedar in the Ak Dagh, on the road between Makri and Cassaba, in 1874, where the trees were growing in open woods at about 5000 to 6000 feet elevation, and were not anything like as large as those in the Lebanon.

INTRODUCTION

We have no certain evidence as to the earliest introduction of the cedar into England; but Loudon, p. 2412, considers that Evelyn was most probably the introducer of the tree, as he states in the third edition of the *Sylva* (p. 125), published in 1679, that he had received seeds from Mount Libanus.

It has been supposed that Dr. Uvedale got the seeds which were planted by him at Enfield between 1665 and 1670 from Evelyn, who, however, does not mention this in the second edition of the *Sylva*, published in 1670; and until this tree is dead or cut down we shall not know its age for certain.¹

The oldest specimen² of cedar in the British Museum is in a volume of *Herb. Sloane*, ix. fol. 90, the title-page of which bears the following inscription:—"Plants gathered about London about the year 1682 for my own (*i.e.* Sir Hans Sloane's) collection."

Sir Stephen Fox was credited by his descendant, Lord Holland, with having introduced and planted the cedar at Farley, near Salisbury (cf. Loudon, p. 2413), which was cut down in 1813, when it weighed over 13 tons. Quenby Hall, Leicestershire, is also mentioned as having the oldest cedar in England, but this rests on family tradition only, and the tree at Quenby in 1837 was only 47½ feet by 7 feet 9 inches in girth.

In *Country Life*, May 2, 1903, the late Mr. C. J. Cornish gives an account of a cedar at Childrey Rectory, near Wantage, which, "according to unbroken tradition," was planted by Dr. Edward Pocock, who was chaplain to the Turkey Company at Aleppo in 1629, and afterwards chaplain to the Embassy at Constantinople. He returned home in 1641 and was appointed to the living of Childrey in 1642. In 1903 it was still growing vigorously and increasing rapidly in size, and measured 25 feet in girth at five feet from the ground, and covered an area of about 1600 square yards. Though it has suffered much from the loss of branches broken by the weight of snow about twenty years ago it now presents a very handsome appearance as shown by the photograph which is given on p. 567 of *Country Life*, No. 330.

Lord Savile informs me that a cedar, which he remembers as being the tallest that he ever saw, grew at Rufford Abbey. This is believed to have been planted

¹ Boulger, in his biographical sketch of Uvedale in *Journ. Bot.* xxix. 13 (1891), gives some details of the Enfield cedar, but has not been able to verify the statement that it dates from 1670. The Enfield cedar is figured in *Gard. Chron.* xxxii. 31, f. 12 (1902). Cf. also *Gard. Chron.* viii. 505 (1890).

² The statement in *Gard. Chron.* ii. 194 (1887), that there is mention in Belon's works, which were published in 1553 and 1558, that the cedar of Lebanon existed in France before 1558 is erroneous; and it is probable that the tree was not introduced into France till 1734. Cf. Loudon, p. 2414.

by Charles II., who used to visit and stay at Rufford, where his rooms are now known as "the King's rooms." Its stump is now surrounded by iron railings and labelled "Cedrus Libani, planted by King Charles II."

Loudon considered that the cedars at Chelsea¹ mentioned by Sir Hans Sloane in 1685 as then existing (*Ray's Letters*, p. 176), but now dead, and those at Chiswick House, which are still flourishing, were the oldest in England. But I am informed by Mr. Challis, gardener to the Earl of Pembroke at Wilton House, that "in the year 1874 a very large cedar was cut down there, whose stem up to about 18 feet from the ground was nearly uniform in size, and then divided into twelve distinct branches, each nearly equal in size to a good-sized tree, some of them extending horizontally 70 feet from the trunk. The circumference of the bole five feet from the ground was 36 feet, a transverse section measured when down 11 feet 9 inches, and the number of concentric rings, after several careful counts, some of the rings being somewhat indistinct, was 236. A section of this stem was sent to the South Kensington Museum."

If this is correct, and it seems to me that the exact statement of so experienced a gardener as Mr. Challis cannot be questioned, the tree must have been introduced in 1638, before Evelyn's time, and was not only the oldest but also the largest cedar on record in England. I have taken great pains to verify this statement by seeing the section mentioned; but though careful search has been made in the Records of the British Museum (Natural History), as well as at the Victoria and Albert Museum at South Kensington, and in the letter books of the Royal Horticultural Society, this wonderful specimen cannot now be traced or discovered.

CULTIVATION

The seeds of the cedar, whether imported or home grown, should be sown under glass in the spring; for though they will germinate in the open air, their growth is so slow for the first three or four years that much time and loss will be saved by protecting them with a frame. If sown in pots they should be planted out in a frame at a year old, as the roots soon become cramped and pot-bound, and the young plants do not make good roots for some time if they have once been so checked. At two or three years old they may be planted in rich soil about the beginning of May when the buds are starting, and will require some years more in the nursery before finally planting them out.

The Lebanon cedar requires a warm, deep, well-drained soil to bring it to perfection, and does not grow so well in the colder and moister parts of England. When once established it will endure our most severe winters without much injury, though it often suffers from heavy snowstorms, which break the branches. The seedlings vary considerably in habit, in vigour, and in colour, and as they do not bear pruning well when the branches become large, it is best to cut off the lower ones when quite small, so as to encourage an upright growth.

¹ The last of the cedars in the Physic Garden at Chelsea, which had been dead for some years, was removed in 1904. In 1882 it was 60 feet high and 13 feet 9 inches in girth at 3 feet from the ground. *Gard. Chron.* xxxv. pp. 185, 224 (1904). Cf. also *ibid.* xxvi. 336, f. 70 (1886), where a figure of the tree is given.

As most people prefer the spreading forms of cedar for lawns or parks, the Lebanon cedar is probably the best for such places; but when surrounded by other trees it may be drawn up to a great height with few side branches, though I should prefer the Algerian cedar for planting in such situations.

Generally it may be said that the Lebanon cedar is the best for the hotter and drier parts of England, and the deodar for the moister and milder districts. The Algerian cedar seems to be hardier, and according to Sargent this is also the case in the United States; but none of the cedars succeed in New England, though near Philadelphia, Washington, and at Biltmore, North Carolina, there are fine specimens of the Algerian form.

The transplantation of large cedars is rarely desirable, but has been sometimes effected with success. A case is recorded¹ in which a cedar at Southsea 30 feet high, with a spread of 36 feet, was transplanted at a cost of about £100.

Mr. J. W. Odell, gardener at the Grove, Stanmore, in a communication to the Royal Horticultural Society on 14th February 1899, states that during a recent gale a large branch was broken off a cedar there, which showed that a great mass of adventitious roots had started from the seat of a previous injury and grown downwards towards the base of the tree, between the splintered portions of the wood. I observed a precisely similar occurrence in a cedar which was partly blown down at Stoke Hall, Notts, in October 1903. The roots were bright reddish-brown in colour, and the thicker ones, an inch in diameter, were covered with rough pustules. Some of these were sent to the Museum at Kew.

REMARKABLE TREES

Among the existing trees in England it is difficult to say which is the finest. If height and girth combined are taken there is none to equal the splendid tree at Pains Hill, near Cobham, now the property of C. Combe, Esq., of Cobham Park. An account of this place, published in *Country Life* for March 19, 1904, states that these cedars were probably planted between 1750 and 1760 by the Hon. Charles Hamilton. In 1781 Sir Joseph Banks visited Pains Hill with the younger Linnæus, who said that he saw there a greater variety of fir trees than he had seen anywhere else. Curiously enough, Loudon, though he often mentions Pains Hill, gives no measurements, and neither Strutt, Lambert, nor Lawson alludes to the cedars there; but when I saw them in 1904 I measured the largest (Plate 128) to be from 115 to 120 feet high by 26 feet 5 inches in girth. It grows on sandy soil near the lake and divides into several tall, straight stems, which form a spreading crown, and seems to be in perfect health.

The next finest of this type that I have seen is perhaps a tree standing in Goodwood Park, near the kitchen garden, which, when I measured it in 1906, was about 95 feet high, though its flat top makes the exact height difficult to ascertain, and 26½ feet in girth, the branches spreading over an area of 133 paces in circumference (Plate 129). Goodwood² is perhaps more celebrated for its cedars than any other

¹ *Gard. Chron.* xxv. 42 (1899).

² Cf. *Gard. Chron.* xxvii. 124 (1900), where the finest cedar at Goodwood was reported to be 29½ feet in girth in 1900.

place in England, as in 1761 many hundreds were planted by Peter Collinson for the Duke of Richmond. Loudon, on page 2414, quotes a MS. memorandum of Collinson's as follows:—"I paid John Clark, a butcher of Barnes, who was very successful in raising cedars, for 1000 plants of Cedar of Lebanon, 8th June 1761, £79:6s., on behalf of the Duke of Richmond. These 1000 cedars were planted at five years old, in my sixty-seventh year, in March and April 1761; in September 1761 I was at Goodwood and saw these cedars in a thriving state. This day, 20th October 1762, I paid Mr. Clark for another large portion of cedars for the Duke of Richmond. The duke's father was a great planter, but the young duke much exceeds him, for he intends to clothe all the naked hills above him with evergreen woods." Of the cedars at Goodwood, Loudon goes on to say that 139 remained in 1837. According to Kent (*op. cit.* 419, note *), eleven fine cedars were uprooted in Goodwood Park by the fierce gale of 3rd March 1897.

There are some splendid cedars at Wilton of which Lambert¹ writes as follows:—"I am indebted to the Hon. and Rev. W. Herbert (author of the celebrated work on *Amaryllidaceæ*) for the following interesting particulars respecting the cedars at Highclere, the seat of the Earl of Carnarvon: 'The two oldest cedars at Highclere were raised in 1739 from a cone brought from Lebanon by Dr. Pococke² in 1738. They were stunted plants for some time, and removed to their present situation in 1767. The largest of the two measured, in 1829, 9 feet in circumference, having grown only an inch in the last two years, the chalk being unfavourable to its growth. The largest cedar at Highclere, though much younger, measured in 1830, at three feet from the ground, 10 feet 1 inch in circumference; it was reared from a cone, which came from the Wilton cedars in 1772, and was about 48 years old before it bore. It was known to the late Earl of Carnarvon that the cedars at Wilton were kept by his grandmother, the Countess of Pembroke, in pots at her window, till growing too large, they were planted upon the lawn, between the house and the water, a situation very favourable to their growth. Supposing them to have been 48 years old, when the cone was gathered from them in 1772, they must have been raised as early as 1724. It is most probable they were between 1710 and 1720; for the Countess of Pembroke who cultivated them died before her husband, who married again after her death, and died in 1733. The oldest cedars at Highclere are, therefore, now (in 1831) 92 years old; those at Wilton at least 106, probably between 110 and 120. Dr. Pococke found the circumference of the largest cedar with a round or single stem to be 20 feet; but he does not state how near the ground he measured it.'" I saw these trees in 1903 and measured them carefully; the best was then about 108 feet high and 21 in girth, with a spread of 109 feet. This tree has lost a large limb, the hollow caused by which has been carefully filled with cement.

At Strathfieldsaye there are also some splendid cedars, a group of which on strongish clay soil have the same upright, small-branched character as the Windsor trees. The best of these is 110 feet high by 11 feet 9 inches in girth, with a clean

¹ *Genus Pinus*, ii. 91 (1832).

² This is not confirmed by Mr. Challis's statement on p. 459; and probably all the Wilton cedars were not of the same age. Dr. Richard Pococke travelled in the East during 1737 to 1742.

bole of about 40 feet (Plate 130). When mentioned by Loudon it was considered the tallest in England, being then 108 feet high by 9 feet in girth. At Combe Bank, near Sevenoaks, there is a magnificent cedar, which Henry in 1904 measured about 105 feet high with a girth of 20 feet. There are no really large cedars at Syon, Kew, or Woburn. There is a magnificent tree at Blenheim, 28 feet in girth, but of no great height, and having the spreading habit which we usually see in this tree in England (Plate 132).

Probably the tallest cedar in England is one in the pleasure grounds of Petworth Park, which I measured carefully in 1905, and could not make it less than about 125 feet high by 14½ feet in girth. It is remarkable for having a trunk clear of branches for no less than 56 feet, where a small limb comes off, but, with this exception, it is clean up to about 80 feet. Probably this habit is due to its growing in a sheltered position, more or less shut in by other trees, on a deep bed of sandy loam. Owing to its position this tree is very difficult to photograph (Plate 131).

The next finest tree of this type which I have seen is one in the Belvedere Plantation at Windsor. This, according to Menzies, who says that the ground is marked in a map of 1750 as open, cannot be more than 150 years old; and it is at least 115 feet high with a girth of 16 feet. It is without any large branch until it reaches a height of 60 feet or more, and carries nearly the same girth to this elevation; so that a plank 60 feet long and 3 or 4 feet wide at the top end could probably be cut from it. Menzies figures this tree¹ and gives the dimensions in 1864 as only 75 feet by 12 feet 10 inches, which was probably less than its actual size at that time. There are several other fine trees in the same drive, but none equal to this; and a young one close by, which was planted by Mr. Simmonds, Deputy Surveyor of Windsor Forest, about thirty-five years ago, is now about 40 feet high, and has the same straight-growing upright habit which cedars seem to develop best on deep sandy soil.

In Hertfordshire there are many fine cedars, of which the most notable are growing on a lawn at Bayfordbury.² Mr. Clinton Baker tells me that they were raised from seeds of the Enfield Cedar, and planted in 1765. They have been measured at various intervals by his grandfather, father, and himself, as follows:—

	No. 1 at 3 ft.		No. 1 at 5 ft.		No. 3 at 3 ft. ²		No. 3 at 5 ft.		No. 7 at 1 ft.	
	Ft.	In.	Ft.	In.	Ft.	In.	Ft.	In.	Ft.	In.
1822 . . .	10	0	10	5	10	10	10	8	14	5
1837 . . .	12	2	13	0	17	6
1865 . . .	15	0	16	0	15	11	16	5	22	1
1880 . . .	16	0	17	3	17	3	18	0
1895 . . .	16	7	18	9	26	0
1900 . . .	16	9	18	0	19	5	19	5	27	1
1904 . . .	17	0	18	2	19	5	19	9	27	3

At Langleybury, Herts, a large cedar³ was growing in the grounds of

¹ *History of Windsor Great Park and Windsor Forest*, Plate 14.

² Figured in *Gard. Chron.* xxvi. 521, f. 102, and 553, f. 109 (1886).

³ *Gard. Chron.* xiv. 392 (1880).

E. H. Loyd, Esq., in 1880, which at 4 feet from the ground measured 22 feet 4 inches in girth, with a height of 107 feet. At Chart Park, Deepdene, Surrey, a tree 95 feet high is 19 feet 3 inches in girth, and divides at 12 feet up into ten upright stems.

At Chorleywood Cedars, near Rickmansworth, there are seven very fine cedars, standing on high ground, which form a landmark in the country, and are said to measure about 23 feet in girth. Another at the same place was recently struck by lightning, and cut down.

At Beechwood, near Dunstable, the seat of Sir Edgar Sebright, Bt., there are some very fine old cedars, of which the largest, as I am informed by Miss F. Woolward, measures 100 feet by 28 feet 4 inches, with a spread of branches 46 feet across. Another, 90 feet by 23 feet, has branches from 50 to 60 feet long.

At Chiswick House there are a number of very fine cedars still surviving, though not so many as when the late Mr. Barron, Superintendent of the Royal Horticultural Society's Gardens, measured them in 1882. The two largest trees at that time were 16 feet and 18 feet in girth, and when I saw them in 1904 the two largest were 16 feet 5 inches and 18 feet 5 inches. These are supposed to have been planted about 1720, but are nothing like so fine as many trees at a greater distance from London.

One of the most remarkable cedars in England, on account of its habit, stands in what was probably a dense grove of tall silver firs near the site of the old house at Stratton Strawless, the home of Robert Marsham, who planted it when 1½ feet high, in 1747. When described by Grigor¹ in 1841 its stem was 44 feet high, free from branches, and 12 feet 2 inches in girth at 6 feet. His plate shows that it has changed but little now. When Mr. Birkbeck showed it to me in April 1907 it was about 80 feet high and 16½ feet in girth, and though some branches in the crown had been broken off, it looks remarkably vigorous (Plate 133).

A fine tree of the same type, but not equal to the last mentioned, is in a sheltered part of the grounds at Gosfield Hall, Essex, the property of Mrs. Lowe. It is 80 to 90 feet high, by 14½ feet in girth, with a clean stem up to about 60 feet, and a flat, spreading crown of branches at the top.

A cedar which is growing at Birchanger Place, near Bishop-Stortford, for a photograph of which I am indebted to the owner, T. Harrison, Esq. (Plate 134), is strikingly different in habit, and of its type is one of the most beautiful and perfectly shaped in England. It is about 60 feet high and 17 feet in girth, the branches covering an area at least 100 yards in circumference. Another tree of the same type, but not so symmetrical, grows at Billing Hall, the seat of Valentine Cary Elwes, Esq., near Northampton, and measures about 60 feet by 19 feet 5 inches. The branches, which spread over an area about 100 paces round, are supported by a great number of wooden props.

In the west of England this tree does not attain the same size and beauty as in the drier counties, the largest I have seen in Devonshire being at Bicton, which is about 21½ feet in girth. At Castlehill, in the same county, there is a tree about 80 feet by 14 feet 9 inches; and at Sherborne Castle, in Dorsetshire, there are a

¹ *Eastern Arboretum*, p. 84, plate opposite p. 104 (1841).

number of fine trees, the largest of which I found to be about 105 feet by 16½ feet, dividing at about 15 feet up into five or six tall, straight stems.

In Wales I have seen none remarkable for size except a tree at Maesleugh Castle which is about 100 feet by 16½ feet, with a clean stem about 20 feet high.

In Lincolnshire and Yorkshire, even where the soil is good, the cedar does not attain the same dimensions as in the south of England, but it ripens seed at least as far north as Syston Park, where there are some trees near the house in an exposed position at an elevation of about 500 feet above sea-level, which show remarkable variation in colour. When I saw them on 16th June one was only just opening its buds, and looked quite black in comparison with others whose new leaves were well out and of a very glaucous colour. This colour is reproduced by their seeds, for two young trees raised from them, which were kindly given me by Sir John Thorold, are so glaucous that every one who has seen them in my nursery has mistaken them for *C. atlantica glauca*, while two seedlings of *C. atlantica* from Cooper's Hill are not distinguishable from *C. Libani*.

In Cumberland there are two splendid cedars at Eden Hall, the seat of Sir R. Musgrave, Bart., which, according to a paper¹ by Mr. Clark of Carlisle, were supposed to be 270 years old, and one of them measured 86 feet by 22½ feet, the other 86 feet by 21 feet, with a spread of 101 feet in diameter. At Alnwick Castle, Northumberland, there is a tree in the wood near the Duchess bridge, measuring 69 feet by 7 feet 3 inches.

The finest avenue of cedars I know in England is that at Dropmore, of which I give an illustration taken from a photograph made in 1903 (Plate 135). This avenue is said² to be composed of Lebanon cedars planted probably about 1844, and if really so young as this, is a very remarkable instance of the rapid growth of the cedar in this country. There is, however, some doubt as to whether they are Cedars of Lebanon or Algerian cedars, and though I have made inquiries from Mr. Fortescue I cannot ascertain with certainty their origin.

The best account I know of the Cedar of Lebanon in Scotland is given in the *Transactions of the Horticultural Society*, vi. 429, in 1826, by Mr. J. Smith, then gardener to the Earl of Hopetoun, and as this shows the rate of growth of the cedar to be, even in that latitude, greater than that of any other tree, I quote it as follows:—

“The extensive pleasure grounds at this place were laid out about the year 1740, and in that and the subsequent years a great variety of curious ornamental trees was planted, which are now of considerable size, and in great beauty and perfection: among these are three cedars, which were planted in the year 1748. The two largest are growing in a favourable deep soil, which although not wet inclines to be moist; the third is on a gravelly soil, beside a rill of water. Their situation is well sheltered, and about 100 feet above the level of the sea. In the year 1797 the third tree was the largest, and Dr. Walker,³ who noted its size at that date, ascribes its superiority to the wetness of its situation. He has

¹ *Trans. Eng. Arb. Soc.* 1887, p. 135.

² *Gard. Chron.* xxv. 138, fig. 52 (1899).

³ *Essays on Natural History*, 69 (1808).

stated that it was 5 feet and 1 inch in circumference, but omitted to mention at what height from the ground this measurement was taken. In 1801 the dimensions of these trees, as well as of other kinds planted at the same period, were taken; the observations were repeated in 1820, and I am now enabled to add the present size of those which had been before noticed, as well as some others of different kinds but of the same age, which were not before attended to. The circumference of the trunks is taken in all cases at three feet above the ground, and it will be seen by comparing the different measures how much the cedars have exceeded all the other trees:—

	1801.		1820.		1825.	
	Ft.	In.	Ft.	In.	Ft.	In.
First cedar	10	0	13	1½	14	0
Second cedar	8	6	10	9½	11	4
Third cedar	7	10	9	9½	10	8
Sweet chestnut	10	1	11	7	12	0
Beech	9	4	9	11	10	3
Sycamore	8	11	9	7½	9	11”

I visited Hopetoun, the seat of the Marquess of Linlithgow, in April 1904, and found that two of these cedars still survive in good condition, the larger being about 80 feet high and 23 feet 8 inches in girth, the other about 88 feet by 13 feet.

There is a fine cedar at Biel, East Lothian, the seat of Mrs. N. Hamilton Ogilvy, which is said to have been planted in 1707 by Lord Belhaven, to commemorate the Union of England and Scotland. According to Mr. S. Ross¹ it was, in 1883, 75 feet high by 17½ feet in girth; but I am informed by Mr. T. Muir that it is now 85 feet high by 19 feet 9 inches at 1½ feet from the ground, with a spread of 101 feet.

At Moncreiffe House near Perth, the seat of Sir R. Moncreiffe, there is a well-shaped tree, which Hunter² mentioned as bearing many cones and measuring 66 feet by 11 feet. In 1907, when I saw it, it was about 80 feet by 14½ feet at 3 feet from the ground. At Dupplin Castle, the seat of the Earl of Kinnoull, there are two cedars of which the best shaped measures 86 feet by 16 feet 10 inches, and the other is 18 feet 8 inches in girth at 3 feet. At Murthly there are two good trees, which, though probably not much over seventy years old, measure 74 feet by 9 feet 3 inches and 70 feet by 10 feet 6 inches respectively.

The best I have heard of in the west of Scotland are one at Mount Stuart in Bute, which Mr. Renwick tells me is 64 feet by 8 feet 3 inches, and another at Erskine House, near Renfrew, which is 62 feet by 10 feet at 1½ feet from the ground.

In the N.E. of Scotland it also grows well; there are two very fine trees at Beaufort Castle. According to the measurements given me by Mr. G. Brown the largest of these is 73 feet by 22 feet 8 inches at 3 feet from the ground, dividing at five feet into four large stems, which measure from 9 to 11 feet in girth. The other is the same height and 16 feet in girth. At Brahan Castle there are also some fine cedars.

¹ *Woods and Forests*, Dec. 26, 1883, p. 59.

² *Woods, Forests, and Estates of Perthshire*, p. 135 (1883).

In Ireland the Lebanon cedar has been rarely planted in comparison with its frequency in England; and Henry has not seen any large trees except one at Carton, which in 1903 was 93 feet by 14 feet 9 inches, and is said to have been the first planted in Ireland; and six fine trees¹ at Anneville near Dundrum, Co. Dublin, the largest of which was 14½ feet in girth in 1904.

There is an excellent article on cedars by Dr. Masters in the *Gardeners' Chronicle* for Oct. 17, 1903, giving an illustration of the historic tree in the Jardin des Plantes at Paris, about which many incorrect statements have been published. Carrière² gives 1736 as the date at which it was planted, from seed brought from England by Bernard de Jussieu in 1735. From this seed was also derived the cedar at Montigny (Seine et Oise), and the one at Beaulieu, near Geneva. Carrière states that the cedars at Geneva produce seeds so freely that but for the scythe of the mower it would form forests on the shores of the Lake. In a letter from M. Maurice de Vilmorin I learn that the Montigny cedar³ is now probably the best in France. About 1855 it was 7 metres in girth at two metres from the ground, and it is now 7.90 metres at the same height. There is another tree at Vrigny, the residence of M. Duhamel de Monceau, near Pithiviers, Loiret. His notes of 1874 state that this tree, planted in 1744, had suffered much from the frost of 1870-71, when two-thirds of its branches were frozen. It measured about 8 metres in girth.

I saw a very fine cedar in the grounds of M. Philippe de Vilmorin at Verrières, near Paris, in May 1905, which measured 87 feet by 13 feet; and also visited the tree in the grounds of Madame Chauvet at Beaulieu, near Geneva, which is now considered to be the finest on the Continent, though not equal to several English trees. It is a well-shaped spreading tree about 100 feet high, though difficult to measure exactly, and 16 feet in girth, with a spread of 102 feet.

TIMBER

What is called cedar in commerce is usually the wood of *Cedrela odorata*, a tree found in the West Indies and Central America. The wood of the so-called pencil cedar, *Juniperus virginiana*, is also often known as cedar,⁴ and this can be distinguished at once by its colour and smell from the true cedar. A case was recently tried in London with regard to the quality of the cedar used in panelling a room at Packington Hall, in which it was stated in evidence by a so-called expert that there were three kinds of cedar known in the trade, "English grown, pencil cedar, and Californian cedar," "the latter used for inferior work." This is a not unusual instance of the gross ignorance which prevails in England among users of timbers as to their names and native countries, and this ignorance has led to many costly lawsuits. The Lebanon cedar grows so fast in England under favourable circumstances that the wood is of a much softer character than it is in Syria, but it may be used for

¹ These are said by Loudon, *Arb. et Frut. Brit.* i. 114 (1838), to have been brought direct from the Lebanon by an ancestor of Lord Tremblestown, and to be the oldest in Ireland.

² *Traité Conif.* 78 (1867).

³ An account of it in *Revue Horticole*, 1907, p. 465, gives the dimensions as 105 feet high by 24 feet in girth at one metre from the ground.

⁴ In the Eastern States it is known as red cedar, but this term is applied to *Thuja plicata* in the Pacific States.

many purposes of internal decoration; and the best instance of such use that I know is at Broom House, Fulham, the residence of Miss Sullivan. This lady, having a cedar blown down on her lawn, had it cut into boards, of which there were sufficient to floor and panel the whole of a good-sized drawing-room. When the wood is carefully selected, its pale pink colour and handsome figure make it very ornamental. Its value in commerce is, however, low, because neither the supply nor the demand is regular; and the cost of removing and sawing up large cedar trees is so great, that I was offered a tree containing over 300 cubic feet for nothing if I could get it away; and the Earl of Powis told me that some large trees which were blown down at Walcot were unsaleable, and were eventually used as a cheap material for the kennels of the United Foxhounds. (H. J. E.)

CEDRUS BREVIFOLIA, CYPRUS CEDAR

Cedrus brevifolia.

Cedrus Libani, Barrelier, var. *brevifolia*, Hooker, *Journ. Linn. Soc. (Bot.)*, xvii. 517 (1879); Beissner, *Nadelholzkunde*, 300, fig. 75¹ (1891).

Resembling *C. Libani* in characters of leading shoot and branchlets, but with very short leaves, not exceeding ½ inch in length. Cones smaller than those of *C. atlantica*, which they resemble in other respects.

The cedar was discovered in the mountains of Cyprus in 1879 by Sir Samuel Baker, whose specimens were described in the same year as *Cedrus Libani*, var. *brevifolia*, by Sir J. D. Hooker, who considered this form to agree more closely with the Algerian than the other cedars, resembling it in the small size of the cones and in the general characters of the foliage.

The best account² of this cedar forest is by Sir Robert Biddulph, who wrote as follows in 1884 to the Director of Kew:—

"The cedar forest occupies a ridge on the principal watershed of the southern range, and about 15 miles west of Mount Troodos. The length of the forest is about 3 miles, its breadth very much less. A few outlying cedar trees were visible on neighbouring hills, but on the ridge they were quite thick, and probably many thousands in number. I took the height above the sea by an aneroid barometer, and found it to be 4300 feet. The trees are very handsome and in good condition, but comparatively young. The smallest seemed to be from ten to fifteen years old; the largest, I am told by the principal forest officer, are probably not over sixty or seventy years. The worst feature is that there were no seedlings or young trees under ten years; and indeed this is the same with regard to the pine forests. It would seem as if the great influx of goats has been comparatively recent. I made a tour through the heart of the forest last August. I started from a point on the west coast, and from thence ascended to the main watershed, and kept along the top till I reached Mount Troodos, taking three days to do it. The country through which we passed on the first day was perfectly uninhabited, and a mass of hills and forest, chiefly *Pinus hale-*

¹ Beissner's figure represents a ripe cone, collected on Mt. Troodos by Herr v. St. Paul.

² Published in *Nature*, xxix. 597 (1884). Cf. also *Proc. R. Geog. Soc.* xi. 709 (1889).

pensis and the Ilex. The trees were in very great number, but there was a scarcity of young trees, and most of the old ones had been tapped for resin. On the second day we passed through the cedar forest, and the same sort of country as before, the *Pinus Laricio* beginning at an altitude of 4000 feet. We got as far as the monastery of Kykou that day, and the next day I continued along the watershed to the camp at Troodos. Our road as far as Kykou was a mere track on the side of the hill, in some parts rather dangerous, and we had to lead our ponies on foot, in many parts very steep. The difficulty on the road is the want of water at that elevation. We halted the first night at a beautiful spring, but we had to carry with us food for man and beast for the whole party, muleteers, etc. The scenery was wild and romantic. This spot is the centre of the *moufflon* ground; three of them were at the spring when we approached it. It gave me a clearer idea of the forests of Cyprus than I ever had before."

Madon, who wrote for the Government in 1881 a report¹ on the forests of Cyprus, states that none of the trees were then apparently over eighty years old; but that all were in a vigorous state of vegetation, with numerous young trees of every age covering the soil. In addition to the main forest, three outlying clumps were seen by Madon,—one on the other side of the Ogotina valley, a group of forty-four very young trees at the Kykou monastery, and a third group much lower down. He considered that the cedars formerly covered the whole of the mountain heights from Machera to Livrami, being limited below by the zone of the olive tree. The timber can be recognised in the houses at Campo and in the carvings of the Kykou monastery, showing that the tree was formerly felled for building purposes. Madon noticed what has been confirmed by other observers, that the foliage varied in tint, most of the trees being glaucous.

Hartmann, who has recently visited Cyprus, reports² that the trees are remarkable for their broad, umbrella-like crowns, and average about 40 feet in height, 6 feet in girth, and 100 years in age. (A. H.)

I am informed by Mr. C. D. Cobham, Acting Chief-Secretary to Government, in a recent letter, that the Cyprian cedars now occupy an area of about 500 acres in the centre of the Papho Forest, of which the summit, Tripylos, is 4640 feet above the sea. The cedars are mixed with pines and Ilex. There are also a few young trees at Kykou Monastery, a few in the vineyards at Chakistra, and one good specimen tree at Pedoullas. This last was purchased by the Government to preserve it from being cut for building material. There are a number of seedlings in the cedar forest, but these do not seem to have been affected by the exclusion of goats, as animals avoid the cedar when they can find other food. The largest tree in the forest is in Argakis Irkas Teratsa, near the Kykou goatfold. It stands about 60 feet high, and measures 11 feet 6 inches in girth at five feet from the ground. A photograph of this tree is so precisely like a Lebanon cedar standing on my own lawn, which I see as I write, that I need not reproduce it. I may add that some cones sent from Cyprus in February 1905 were smaller than the cones from Syria

¹ *Parly. Paper: Encl. 2 in Cyprus, No. 366, of 1881, p. 28.*

² *Mitt. Deut. Dendr. Ges. 1905, p. 181.*

or those grown in England. Though at the time I did not think they were mature, yet the seeds contained in them have germinated and produced young plants, which in July were just putting forth their second whorl of leaves, but by the following May had increased very little in size, being much smaller than those of the same age from Swiss and English seed.

Plants were raised at Kew from seed received in 1881; and two, now growing in the cedar collection at Kew, have attained only 6 feet in height, and are remarkable for their singularly short leaves and stunted bushy appearance. A number of them were killed by the winter, having been planted out when too young, which seems to show that this variety is more tender than the Lebanon tree. (H. J. E.)

CEDRUS ATLANTICA, ATLAS OR ALGERIAN CEDAR

Cedrus atlantica, Manetti,¹ *Cat. Plant. Hort. prope Modiciam, Suppl. Secundum*, 9 (1845); Ravenscroft, *Pinet. Brit.* iii. 217 (1884); Kent, Veitch's *Man. Coniferae*, 409 (1900); Masters, *Gard. Chron.* x. 425, f. 53 (1891).

Cedrus africana, Knight, *Syn. Conif.* 42 (1850).

Cedrus Libani, Mathieu, *Flore Forestière*, 564 (1897).

Pinus atlantica, Endlicher, *Syn. Conif.* 137 (1847).

Pinus Cedrus, Linnæus, var. *atlantica*, Parlatores, DC. *Prod.* xvi. 2, p. 108 (1864).

Abies atlantica, Lindley and Gordon, *Journ. Hort. Soc.* v. 214 (1850).

Young trees stiffer in habit than the Lebanon cedar, and with an erect leader. Branchlets not pendulous, covered with short dense pubescence. Leaves up to an inch (occasionally in cultivated specimens $1\frac{1}{4}$ inch) long, usually as thick as or thicker than broad. Cones shorter and more cylindrical than in *C. Libani*; scales $1\frac{1}{2}$ inches in width, claw inflected.

VARIETIES

Var. *glaucæ*.—In the cedar forests of Algeria a certain proportion of the trees have glaucous foliage, the leaves being marked above with conspicuous white stomatic bands; but there is no other difference, and no foundation exists for the opinion, first mooted by Jamin,² that the glaucous variety constitutes a distinct species.³ The glaucous tint is an essentially unstable character,⁴ trees occurring in the wild state in which glaucous leaves appear only on some of the branches. This variety often arises in cultivation.

Beissner⁵ mentions several varieties, which have been obtained in cultivation, as *pyramidalis*, *columnaris*, and *fastigiata*,⁶ characterised by peculiarities of habit; and a variegated form in which the foliage of the young shoots is yellowish,⁷ but so far

¹ Manetti gives the name only without any description, in the second supplement to his catalogue (1845), and not in the first supplement (1844) as usually stated. Endlicher first described the Atlas cedar from plants 6 inches high, sent in 1847 by Manetti from the Royal Gardens at Monza (Modicia) near Milan.

⁴ Cf. Fliche in Mathieu, *Flore Forestière*, 564, note 2 (1897).

⁵ *Nadelholzkunde*, 304 (1891).

⁶ Var. *fastigiata*, a pyramidal form, with branches ascending like those of the Lombardy Poplar, originated as a seedling in Lalande's nursery at Nantes. Cf. *Gard. Chron.* vii. 197 (1890).

⁷ Var. *aurea*, young foliage of a rich golden colour, which changes to the normal green of the species in the second year. This variety is mentioned by Kent, *loc. cit.*

as we have seen these are not distinguishable as they get older. At Glasnevin there is a remarkable tree about forty years old, of which the stem is erect for about 25 feet, and beyond this bends over almost horizontally, extending laterally outwards for almost 12 feet; and Elwes saw one of very slender and pendulous habit at Angers in France.

DISTRIBUTION

This cedar occurs in Algeria and Morocco. In the latter country its distribution is still scarcely known, though it was in Morocco that the Atlas cedar was first discovered. Philip Barker Webb visited¹ Tangiers and Tetuan in the spring of 1827, and from a native received branches of cedar which had been collected in the impenetrable mountains of the province of El Rif, where there were said to be vast forests. Webb's specimens are preserved in the museum at Florence, where I saw them in December 1906. His discovery was published in an article² by De Candolle in 1837. Dr. Trabut³ states that the tree occurs in the mountains behind Tetuan; and it is supposed⁴ to exist to the south-east of Fez, where the traveller Rohlfs states that he saw larch growing.

In Algeria the cedar⁵ forms a considerable number of isolated forests, none of them of great extent, at altitudes between 4000 and 6900 feet. The tree appears to be indifferent to soil, as it grows both on limestone and on sandstone formations. No meteorological observations have been regularly taken in the cedar forests; but in general, where the tree flourishes, snow lies for several months during winter, the temperature descending to 5° Fahr., and frost prevailing until May. In summer the weather is dry with moderate temperatures.

In the following detailed account I have supplemented my own observations by consulting both the special pamphlet⁶ concerning the cedar, published by order of Governor-General Cambon, and M. Lefebvre's excellent book⁷ on the forests of Algeria.

The chief forests are those in the vicinity of Ouarsenis, Téniet-el-Hâad, and Blida, and in the Djurdjura range in the province of Algiers; and those on Mt. Babor, in the Mâadid mountains south of Sétif, and in the Aurès and Belezma mountains near Batna.

The forest⁸ of Ouarsenis, the most westerly in Algeria, lies in the mountains south of Orléansville. Here the cedar, mostly in mixture with *Quercus Ilex*, only covers an area of 250 acres. The forest near Blida, which is often visited by tourists, as it lies near the railway not far from Algiers, is 1700 acres in extent, and consists of cedars either growing pure or in mixture with the evergreen oak; and it is, generally speaking, in a poor condition. In the Djurdjura range, extending in an interrupted band on both slopes for nearly 40 miles, are the remains of an ancient forest, most of the trees either growing singly or in small groups on rocks and precipices,

⁵ A fine picture of a forest in Algeria is given in *Garden and Forest*, viii. 335, f. 47 (1895).

⁶ *Les Forêts de Cèdre* (Alger-Mustapha, 1894).

² *Bibliothèque Universelle de Genève*, 1837, pp. 439, 440.

⁴ Lefebvre, *Les Forêts de Cèdre*, 1 (1894).

⁷ *Les Forêts de l'Algérie*, pp. 406-421 (Alger-Mustapha, 1900).

⁸ Hutchison, *Trans. R. Scot. Arb. Soc.* xiii. 211, states, but does not give his authority, that cedars were cut here, the diameter of which was so great, that it was necessary to join two saw-blades, each 6½ feet long, in order to fell the trees.

between 4900 and 6500 feet; but on the Häizer peak M. Britsch saw a few trees on the north slope as high as 7100 feet.

The forest on Mt. Babor is of no great extent, but is an interesting one, consisting of a mixture of cedar, *Quercus Mirbeckii*, and *Abies numidica*, and will be described in our account of the last-named species. The brigadier in charge of this forest informed me that he had measured there a cedar 62 feet in girth. In the mountains of Mâadid there are four distinct forests, generally speaking in bad condition, and yielding scarcely any timber, though in one of them, called Ouled Khellouf, there are said to be some very large trees.

The forests which are the most important from every point of view are those in the west near Téniet-el-Hâad, and those in the east in the vicinity of Batna, visited by me last January.

The cedar occurs around Batna, both on the Aurès range and its spur Belezma. The forest of Sgag is 23 miles distant from Batna and covers 1200 acres. Between Batna and Biskra, about 20 miles north of the latter place, the forest of Djebel Lazereg is 1350 acres in area, and is noted for producing a peculiar kind of cedar timber, pink in colour and with a juniper-like odour. A very fine forest of considerable extent, 28,000 acres, lies around Mt. Chélia, the highest point in Algeria, 7500 feet altitude, 43 miles to the south-east of Batna; but it was practically inaccessible in January. In one part of it, the forest of Beni-Oudjana, 44,666 trees have been marked for felling, estimated to contain 3,615,000 cubic feet of timber, which will be offered for sale by the Government in the course of the present year.

I visited the forest of Belezma, which is only 12 miles to the north-west of Batna. The whole wooded area here under government control is 140,000 acres in extent; but of this the cedar occupies only 22,000 acres, ascending the mountain to its summit, 6900 feet, and descending on northern slopes to 3600 feet, and on southern slopes to 4300 feet. The forest was badly treated in former years, whole tracts of the finest trees having been clean cut away and the timber used in building the town of Batna. The drought which prevailed from 1875 to 1881 caused serious damage to the remaining trees, and many died, most of which, except those that have been lately felled, are still standing. Felling is done regularly every year, only dead trees being removed. The sapwood of these has rotted away, but the heartwood remains quite sound and unaltered. This timber is mainly used for railway sleepers, though some has been utilised in house-building and for making wood pavement and furniture. None of it appears ever to have been exported; and it is a great pity to see such excellent wood utilised only for rough purposes. The price obtained for it is as it stands very low, 1d. to 2d. per cubic foot; yet it is fairly accessible, as the haulage to Batna is very cheap, but the rate by railway from there to Philippeville, the nearest seaport, is 15s. per ton.

It snowed very heavily during my stay at the forester's house near the top of the mountain; but so far as I could see, the cedar only grows here in a dense condition in the young stage, there being in the ravines fine stands of cedars 30 feet high, which are slightly mixed, like the rest of the forest, with *Quercus Ilex*, *Juniperus thurifera*, and *Juniperus phœnicea*. These young trees are narrowly

pyramidal in form, with erect stiff leaders; but in slightly older trees the leader begins to incline over on one side, and the branches to thicken and elongate, and this process being continued, eventually the tree assumes when old the habit of Lebanon cedars, as we see them in English parks. In other parts of the forest the older trees are more or less scattered with the same admixture of junipers and evergreen oak, the undergrowth being Phillyrea and broom. The cedar appeared to be slow in growth, the annual shoots of young vigorous trees not exceeding three or four inches in length. From observations made in one section of this forest the tree shows at different ages the following dimensions:—

AGE.	Diameter.		Height of Market-able Timber.	Total Height.
	Feet.	Inches.		
125 years	2	7½	46	98
160 "	2	11½	52½	105
200 "	3	3	59	115
255 "	4	3	59	125
305 "	4	11	59	125

An official document, which I saw at Batna, gave the total number of sound trees over 40 inches in girth as 265,500, estimated to contain between ten and eleven million cubic feet of timber, the total timber in the forest, young and old trees, cubing 16,000,000 feet. In addition, there is still standing 900,000 cubic feet of dead timber. In a few spots, as in the Chellala-Bordjen section, there are rather dense stands of old trees, which run to 7000 cubic feet per acre; but there are large tracts in parts of the forest which have scarcely 150 cubic feet to the acre.

The tree produces seed abundantly every two or three years; and regeneration is good in favourable situations, as in northerly ravines. The cones¹ disarticulate in November, after the autumnal rains, but if the weather is exceptionally dry, do not open. Seedlings appear under dense cover, but in such situations grow slowly, and do much better in the partially open places between large trees. The wide-spreading branches which the tree ultimately produces show, I think, that in old age it requires a great deal of light, and tends to grow in a more or less isolated condition; but until middle age the trees bear crowding without injury. In the bare parts of the mountain, where the trees were cut away many years ago, artificial planting has been tried on a small scale, and has succeeded on northern slopes when two-year-old seedlings have been planted in autumn. Plants put out in the spring on the southern slopes have died of drought, which is the great enemy to both artificial and natural regeneration.

The forest of Téniet-el-Hâad is about a day's journey from Algiers—four hours by rail and thence seven hours by the coach to the town, which is distant from the cedars about an hour's walk. The mountain-range runs in a N.W.-S.E. direction, the cedars ascending to the summit of the crest, 5900 feet, and descending on the north side to 4250 feet, and on the south side to 4900 feet, there being a zone of

¹ Only the central part of the cone contains good seed. In January the basal scales of many cones were still remaining around the central axis, the other scales having fallen much earlier.

Quercus Ilex below, with which the cedar slightly mingles. The cedar forest occupies 2300 acres, four-fifths of this being on the north slope and one-fifth on the south slope, and consists of a mixture in varying proportions of cedar and *Quercus Mirbeckii*, the latter a beautiful tall tree with semi-evergreen foliage, often attaining 12 feet in girth. This mixed forest is nowhere very dense, except where there are young stands, and grows upon sandstone—the undergrowth being chiefly *Rosa* and *Rubus*, with *Juniperus* in the lower zone. The tallest cedar does not, I believe, exceed over 120 feet; and the largest, which I measured and photographed (Plate 136, B), are *La Soltane*, 98 feet high by 24 feet in girth, and *Le Massaoud* (Plate 136, A), 108 feet by 23 feet. Trees of peculiar shape are common; one, 108 feet by 19 feet, dividing into two stems at eight feet up; and another, *Le Cèdre Parasol*, which stands on a rocky promontory, being a low tree with a peculiar broad-shaped umbrella-like crown. Around the forester's house, Le Rond Point, at 4600 feet, there is a plateau of some extent, with many fine old trees having the habit of the Lebanon cedar as we see it in England.¹ No felling is done at present in this forest, which is rapidly improving in value owing to the entirely successful natural regeneration, cedars being present in all stages of growth.

The wood of the cedar, though without resin-canals, contains a quantity of resin, which gives it a peculiar, penetrating, and distinctive odour.² At Batna, *libanol*, a kind of resin, is obtained by distillation of the sawdust of old trees. This product is very valuable in the treatment of inflammation of the mucous membranes, and is said to be curative in influenza. Cedar wood contains a large amount of white sapwood, 25 to 50 annual rings, with a brown or brownish-yellow heartwood. The heartwood is homogeneous and fine in the grain, and takes an admirable polish. It lasts indefinitely, trees which were cut down fifty years ago in the forest at Batna remaining still on the ground quite sound, and when not exposed to the air is imperishable. Pieces of cedar wood have been found in tombs which are supposed to belong to the Punic period, and portions of ancient mosques built of cedar are in perfect condition. Placed in water, the heartwood becomes very hard; and vats made of it, which have been buried in sand for thirty years, are not only well preserved, but cannot be cut by an axe. The wood of dead trees can be used at once, but that of living trees requires to be seasoned carefully for six or twelve months. Though the timber is used in building, it is rather heavy for that purpose, and has no great elasticity or resistance to flexion under a heavy weight. It is, however, well suited for the finest kinds of cabinet-making. (A. H.)

CULTIVATION

The seed ripens in most seasons in England at least, as well as that of the Lebanon cedar, and will sometimes come up naturally near the parent trees, as at Cooper's Hill near Windsor, from whence I transplanted two self-sown seedlings to my own garden.

¹ An excellent illustration in *Garden and Forest*, viii. 335 (1895), shows the flat-topped habit of mature trees in their native forest.

² The odour disappears after exposure to the air for a few years, and is not noticeable in the cedar furniture which is so common in the houses at Batna and Téniet-el-Hâad. Cf. Lefebvre, *Les Forêts de l'Algérie*, 350 (1900).

When staying at Heythrop Park, Oxfordshire, in March 1901, I went out on a morning when the frost was so hard that the hounds could not hunt till noon, and found seeds which had germinated on the ground beneath a glaucous cedar. The radicles were protruding from the seeds, in some cones which had not fallen; I took them home and planted them, and have now several healthy young trees about a foot high.

I also sowed a quantity of imported seed in the open field, where they germinated well, but the plants were all destroyed by mice, frost, and drought in the first season, though seedlings raised in the nursery stood the winter without protection. As the seed can be procured in quantity at a cheap rate from Messrs. Vilmorin of Paris, I should recommend its being sown in a frame and protected for two or three years, after which it will require two to three years more in the nursery before planting out.

The tree seems to like lime in the soil, and will, in my opinion, prove a valuable timber tree if planted in open woods, in warm, dry soils, sufficiently close together to prevent its branches from developing too much, and possibly if mixed with beech it might thrive better than alone.

As regards the relative rate of growth of the Atlas and Lebanon cedars we have the evidence of M. André Leroy, the well-known nurseryman of Angers, who, in the *Belgique Horticole*, 1867, p. 59, gives the following measurements:—

LEBANON CEDAR			ATLAS CEDAR		
AGE.	Height.		AGE.	Height.	
	Metres.	Centimetres.		Metres.	Centimetres.
1 year .	0	6-8	1 year .	0	10-15
2 years .	0	12-15	2 years .	0	20-30
3 „ .	0	18-25	3 „ .	0	40-50
4 „ .	0	36	4 „ .	1	0
5 „ .	0	50	5 „ .	1	75
6 „ .	0	75	6 „ .	2	50
7 „ .	1	0	7 „ .	3 and upwards.	

After seven years of age, he states that the annual growth was often more than one metre, and mentions a tree only twelve years old, from seed, which was one metre in circumference (I presume at the ground). He also says that it is easier to transplant, and endures exposure and bad soil better than the Lebanon cedar, and believes that it will prove a valuable tree for planting on barren wastes where nothing else will thrive.

These remarks, no doubt, will apply better to the soil of Central France than to England, but I have the highest possible opinion of the hardiness of the tree, and have found it endure the damp, cold, and early and late frosts of the Cotswold hills in a way that few other conifers will do. So far as my experience goes, however, it is not a tree which can be transplanted without some care in a small state, and when it has had its roots cramped in small pots, as is often done by nurserymen for con-

venience of sale, is rather apt to die. I am not aware that it has ever yet been tried in quantity under forest conditions; but, so far as I have seen, it is not subject to insect or fungoid diseases which attack and kill the deodar.

Many of the grafted trees of the glaucous variety, which are usually sold by nurserymen, are one-sided and unsightly objects, for a good many years after planting at any rate; and though it is claimed by some that grafting, if properly done, does not permanently disfigure the tree, yet I would always prefer seedlings. Even if not quite so glaucous in colour as the best of the others, a certain number of this tint will generally appear among them.

The date at which the Algerian cedar was first introduced to this country is somewhat uncertain; but it must have been subsequent to 1844, and if any older ones exist they cannot be recognised with certainty. Several trees appearing older than this have been supposed to be African, on account of their habit and cones, but there is nothing on record to prove it.

According to Ravenscroft, the oldest of which we have an exact record were raised at Eastnor Castle in 1845, from cones gathered by Lord Somers himself at Téniet-el-Hâad. In December 1860 the tallest of these was 18½ feet; in December 1866, 31 feet. When I measured it in 1906, it was 77 feet by 8 feet 1 inch.

REMARKABLE TREES

The tallest tree that I have measured in England is at Linton Park, Kent, and is a glaucous tree, which, from its shape, seems to be grafted, though there is no evidence of this. It was 80 feet high in 1902.

The largest recorded at the Conifer Conference in 1891 was at Mulgrave Castle, Yorkshire,¹ the seat of the Marquess of Normanby. It was then 66 feet by 5 feet 10 inches. Mr. Corbett informs me that it is now 72 feet by 8 feet 4 inches.

On Ashampstead Common, Berks, there is a handsome and well-grown tree which has grown up in a semi-wild condition among other trees, and which was 63 feet by 6½ feet when I last saw it in 1907 (Plate 137).

At Ashridge there are several fine glaucous trees, raised from seeds, which were brought by Earl Brownlow, in 1862, from Téniet-el-Hâad; the best of them already measures 58 feet by 6 feet. At Merton Hall, Norfolk, there is a very well-shaped tree measuring 60 feet by 6 feet.

At Bicton there is a fine tree measuring 68 feet by 7 feet 6 inches. At Coldrinick, in Cornwall, there is a well-shaped tree which, in 1905, was 64 feet by 5½ feet. At Heanton Satchville, North Devon, I saw a healthy young tree in a shrubbery, which was clear of branches to 20 feet up, and though 48 feet high, was only 2 feet 7 inches in girth, showing the ability of this cedar to thrive without much space, even in a climate so much damper and cooler than that of Algeria.

At Tortworth there is a cedar about 50 feet high with very short leaves, and remarkably fastigiate habit, which seems to belong to the variety named *fastigiata*.

In Scotland I have not seen any so large as in England; but the tree grows

¹ A tree at Grimston, near Tadcaster, Yorkshire, reported in 1900 to be 70 feet high and 13 feet in girth at three feet from the ground, which was said to be sixty-five years old, is probably a Lebanon cedar. Cf. *Gard. Chron.* xxviii. 210 (1900). †

well at Murthly and other places. At Smeaton-Hepburn, a tree,¹ planted in 1847, was, in 1902, 69 feet high and 6½ feet in girth. At Fordell, in Fifeshire, the property of Lord Buckinghamshire, I am informed by Mr. Sibbald that a number of cedars were planted by Mr. Fowler, then head gardener, 42 years ago on a damp sandy soil and well sheltered by other trees. The average height of the Algerian cedars in 1906 was 48 feet, with an average girth of 4 feet 4 inches, and of the deodars 33 feet by 3½ feet. The majority of them are in good health, though the Algerian have made by far the best trees, and as the soil and climate of Fifeshire do not seem to be so favourable to the growth of trees generally as those of Perthshire, Morayshire, or parts of Ross-shire, this seems to prove that the tree may be planted in Scotland with good hopes of success.

The finest Atlas cedar in Ireland is at Fota, and is of the glaucous variety. It was planted, according to Lord Barrymore, in 1850, and measured in 1904 83 feet high by 7 feet 7 inches in girth (Plate 138). At Carton, the seat of the Duke of Leinster, a tree, which is, from its habit, apparently an Atlas cedar, was, in 1903, 80 feet high by 9 feet in girth. At Powerscourt a glaucous specimen was in the same year 50 feet high by 5 feet in girth.

In the south of France and North Italy this tree grows better and faster than in England. Perhaps the best that I have seen are in the public garden at Aix en Savoie, where there is a grove of splendid trees 90 to 95 feet high, though only planted in 1862. They average 6 to 7 feet in girth, and there are many self-sown seedlings near them. On the shores of the Lago Maggiore the tree succeeds perfectly, several fine trees in the grounds of the Villa Barbot near Intra being 90 feet or over, and one 7½ feet in girth. It seemed to me likely to become a most valuable forest tree in this region.

(H. J. E.)

CEDRUS DEODARA, DEODAR

Cedrus Deodara, Lawson, *Agric. Man.* 381 (1836); Loudon, *Arb. et Frut. Brit.* iv. 2428 (1838); Brandis, *Forest Flora*, 516 (1874), and *Indian Trees*, 691 (1906); Ravenscroft, *Pinet. Brit.* iii. 225 (1884); Masters, *Gard. Chron.* x. 423, f. 52 (1891); Kent, *Veitch's Man. Coniferae*, 411 (1900).

Cedrus Libani, Barrelier, var. *Deodara*, Hooker, *Himal. Journ.* i. 257 (1854), *Nat. Hist. Rev.* ii. 11, tt. 1-3 (1862), and *Fl. Brit. Ind.* v. 653 (1888); Collett, *Flora Simlensis*, 486 (1902); Gamble, *Ind. Timbers*, 710 (1902).

Cedrus indica, Chambray, *Arb. Res. Couif.* 341 (1845).

Pinus Deodara, Roxburgh, *Hort. Beng.* 69 (1814).

Abies Deodara, Lindley, *Penny Cycl.* 9 (1833).

Young trees with pendulous leader. Branchlets always pendulous, grey and densely pubescent. Leaves up to 2 inches long, as thick as broad. Cones large and broad, ellipsoid, 4 to 5 inches long by 3 to 4 inches in diameter, rounded at the apex; scales 2 to 2½ inches wide, with claw not inflected, usually less tomentose than in the other cedars.

¹ Sir A. Buchan-Hepburn in *Proc. Berwick Nat. Club*, xviii. 210 (1904).

VARIETIES

A considerable number of varieties have arisen in cultivation, ten being mentioned by Beissner.¹

1. Var. *albo-spica*. Growing shoots during spring and early summer of a milky-white colour. Trees of this kind at Dropmore² are pyramidal in habit, and make splendid growth. At Grayswood,³ Haslemere, a bushy form with this peculiar foliage has been noted.

2. Var. *robusta*. Branchlets stout; leaves longer and thicker than in the ordinary form.

3. Var. *crassifolia*. Branches short and stout; branchlets not pendulous; leaves short and thick.

4. Var. *verticillata*. Branchlets whorled.

5. Var. *fastigiata*. Fastigate in habit.

6. Varieties with variegated foliage and with bright yellow leaves have also been noted. The glaucous tint has appeared in cultivation, and is met with in the wild state. A very glaucous tree at Castlewellan has been named var. *nivea*.⁴ Trees with thin, shining, deep green foliage have been distinguished as var. *viridis*.

(A. H.)

DISTRIBUTION

The deodar is found in the Western Himalaya; and extends eastwards to the Dauli river in Kumaon, occurring at 4000 to 10,000 feet, most common at 6000 to 8000 feet. It extends westwards through Kashmir to the Peiwar forests in the Kuram valley of Afghanistan.

According to Gamble, from whom I take the most of the following account, it is a gregarious tree, but rarely forms pure forests, though exceptions are met with, generally in the form of sacred groves; usually it is associated with *Picea Morinda* and *Pinus excelsa*, and three species of oak in their various zones. Sometimes the silver fir (*Abies Pindrow*) accompanies it, but more rarely; the cypress (*Cupressus torulosa*) in its favourite localities joins it; the yew is often found under it; and at low elevations it mixes with *Pinus longifolia*.

Among other trees commonly found with it may be mentioned *Betula alnoides*, *Populus ciliata*, *Æsculus indica*, elm, hazel, hornbeam, maples, bird-cherry, holly (*Ilex diphyrena*), *Pieris ovalifolia*, and rhododendron; while among the shrubs commonly found in deodar forests may specially be noted species of *Berberis*, *Indigofera*, *Desmodium*, *Cotoneaster*, *Euonymus*, *Salix*, especially *Salix elegans*, *Viburnum*, *Lonicera*, *Parrotia*, and rose, while *Clematis montana*, *Vitis semicordata*, and ivy, are frequently met with climbing over and festooning its branches.

In the outer ranges the deodar forests chiefly clothe the northern and western slopes of the ridges, while in the interior hills, to which the rainfall of the south-west monsoon still reaches, they are found on all aspects, but less pure. Beyond the region of the south-west monsoon the deodar is still found, but gets

² *Gard. Chron.* xxxvii. 44, 76 (1905).

⁴ *Ibid.* xxxv. 399, fig. 146 (1899).

gradually scarcer, and in such places its companions may be *Pinus Gerardiana* and *Quercus Ilex*.

The deodar can attain a very great size.¹ Thomson² mentions one near Nachar, on the Sutlej, that was 35½ feet in girth. Dr. Stewart measured one at Kúarsi in the valley of the Ravi that was 44 feet at 2 feet, and 36 feet at 6 feet from the ground; another about 900 years old was 34½ feet in girth. Minniken records a tree at Punang, in Bashahr, that was 150 feet high and had a girth of over 36 feet, the clean bole being 45 feet long. Dr. Schlich measured a tree in the Sutlej valley 250 feet high with a girth of 20 feet.

In the Dumrali block in the Tehri-Garhwal leased forests a fallen tree was unearthed 90 feet long and over 7 feet in diameter, which had been dead for at least 100 years, and was, when it fell, probably 550 years old. When cut up it gave 460 metre-gauge sleepers. I am indebted to Mr. J. H. Lacey for the illustration (Plate 139) representing a group of deodars in the Himalayas.

A great section in the corridor of the forest school at Dehra Dún is 23 feet in girth, with 665 annual rings. The number of annual rings to the inch varies much according to the elevation and rainfall, but averages about 8 to 12, though in the Kuram valley Bagshawe found an average of about 21.

As an ornamental tree there are few in the world that can compare with the deodar. From the Lebanon cedar and the Atlas cedar it differs somewhat in appearance, but even to an expert, in the collections of Europe, it is not always easy to recognise to which of the three species a given specimen belongs. Roughly, however, the deodar is distinguished by means of its drooping branches and its longer needles. Two well-marked varieties are recognisable in the forests, the one with dark green, the other with silvery foliage. The latter variety, well known in European collections, is found wild in ravines at a comparatively low level. Gamble saw it in Jaunsar, in the upper Dharagadh, in ravines at from 4000 to 6000 feet, and believes that the variety comes true from seed.

Deodar trees are often lopped for litter, and if the leading shoot is not damaged, the tree grows on well enough; when the leading shoot is cut or damaged, the tree shows a great tendency to form others; and frequently several erect shoots, with the appearance of young trees, may be seen growing up straight from its branches. The deodar may be almost said to produce coppice shoots, for, as Brandis remarks, if only a small branch be left to a stump, it will send out shoots and grow well, eventually, perhaps, forming a new tree.

In close forests deodars flower and seed rather sparsely; for good seed bearers we have to look to the old trees on dry ridges, where they can get a large amount of sunlight. When the seeds are ripe the cones break up and the scales fall; the winged seeds are then carried by the wind for a short distance. It may be interesting to record the result of the examination of an average cone by Mr. B. B. Osmaston in October 1900. He found in the top part 25 scales, with 50 bad seeds;

¹ Webber, in *Forests of Upper India*, 331 (1902), says: "I have seen deodars 40 feet in girth and 250 feet high, the age of which must be 1000 years or more"; and Pakenham Edgworth informed Bunbury that he had measured deodars 46 feet in girth. Cf. Lyell, *Life of Sir C. J. F. Bunbury*, ii. 238 (1906).

² *Western Himalaya and Tibet*, 64 (1852).

in the middle 100 scales, with 90 good and 110 bad seeds; in the lower part 94 scales, with 188 bad seeds—the whole cone, therefore, giving 219 scales, with 438 seeds, of which 90 were good.

CULTIVATION

The best account we have of the introduction of the deodar is given by Ravenscroft, who states that the Hon. Leslie Melville sent seeds¹ in 1831 which were sown at Melville in Fifeshire, at Dropmore, and elsewhere.

Lord H. Bentinck sent some to Welbeck in 1832, but it was not until 1841 that the Right Honourable T. F. Kennedy, then at the head of the Woods and Forests, took steps to procure seed in large quantities from the Himalayas. His proceedings are described at great length in the *Thirty-first Report of the Commissioners of Woods*, pp. 168-172, and pp. 440-454 (1853), and further in the *Thirty-fourth Report* (1856), pp. 87, 88, and pp. 120-122. From this it appears that 60,000 seedlings were distributed in the spring of 1856 amongst the New, Dean, and Delamere forests, and a further 40,000 were sent out in the following autumn.

I am indebted to Mr. E. Stafford Howard, C.B., for information as to the results of these experiments as given in letters from the Hon. Gerald Lascelles and the late Mr. P. Baylis. The former says:—"I have made search for any records of the planting of the deodars, but can find nothing worthy of quotation. It is a fact that it was very largely planted here, as we can see for ourselves,—more, however, as an avenue or ornamental tree than, strictly speaking, for timber. Large quantities were raised in the nursery at Rhinefield, which at that time was managed by one Nelson, who in a small book speaks of the very large experience he has had in raising and transplanting deodars. The tree is, however, a failure by reason of the way in which it suddenly dies off, unaccountably, when it is about forty or fifty years old. There are some notable successes, such as the grove at Boldrewood² and others, but I must have cut hundreds which had died off suddenly."

Mr. Baylis wrote on 8th May 1905: "I cannot give much definite information on the subject, though Crown Keeper Smith remembers some deodars being planted about 1857 along the sides of the rides in the High Meadow estate; but large numbers of these have perished, and there are no very fine trees among those that are left. A ride along the top of the Churchill enclosure was also planted about the same time with similar trees; but many of these also have died, and I cannot say that any of them have thriven well, though one tree has occasionally borne cones. I think that the climate here is too cold and damp for them to thrive, and that they cannot stand the damp cold of our winters in the Forest, though on the slopes of the Malvern hills they flourish fairly well."

This liability of the deodar to die after attaining considerable size has been often noticed, and, so far as I have observed, is most common on soils which are poor in lime.

¹ A tree raised from these seeds was planted near the Director's Office at Kew, and had attained a height of 32 feet in 1864. It became diseased and was removed in 1888. Cf. *Kew Hand List of Conifera*, xiv. (1903).

² The best deodar at Boldrewood is now 64 feet high.

The Earl of Ducie informs me that in 1854, and for several years afterwards, he planted many deodars at Tortworth, both on the old red sandstone and on the mountain limestone. Many of these have perished after thirty to forty years' growth, without any apparent reason, except that in one case where only six out of about ninety remain, it is probable that they were infected with disease by the dead roots of beech trees which previously occupied the ground. Very few deodars at this place seem likely to attain a great age, and contrast unfavourably with the Cedar of Lebanon. But at Miserden Park, in the same county, on a dry oolite limestone, at an elevation of at least 600 feet, a line of deodars about sixty years old have remained healthy, though their growth here is much slower than at Tortworth.

At Poltimore, near Exeter, there is a fine avenue of deodars which were planted in 1851-52, and have grown to an average height of 70 to 80 feet in 1906, most of them being extremely vigorous, but there are several blanks in this avenue.

The cause of these deaths is explained by Mr. R. L. Anderson in a note published in the *Quarterly Journal of Forestry*, i. 216, who states that the fungus now known as *Armillaria mellea*, Vahl., was present on the roots of one of these deodars; and as the best means of checking its spread to other healthy trees, recommends trenching the ground round the affected tree, digging up and burning its roots, and scattering gas lime over the ground where they have been.

At Castle Menzies, in Perthshire, of a number of deodars, which were planted by the late Sir R. Menzies about 1852 to commemorate the birth of his son, on soil which was too wet to suit them, though *Tsuga albertiana* and *Picea sitchensis* have succeeded very well close by, several are dead, and all are more or less stunted, though one of these trees measuring $7\frac{1}{2}$ feet in girth was successfully transplanted in February 1907, and had not lost a leaf when I saw it in the following July.

I have not myself gathered any ripe seed of the deodar in England, but there is a tree growing in Kew Gardens between the main gate and the Director's office which measures 37 feet by 4 feet 8 inches, and was raised from seed produced in 1861 or 1862 by a tree at Killerton, and sent by the late Sir Thomas Acland to Kew in February 1868. Mr. Smith, the then Curator of Kew, was so much impressed by the good quality of the soil from the top of Killerton Hill in which this tree was raised, that two truck loads of it were sent to Kew.

The earliest record¹ of the deodar producing fruit in England is of a tree at Bury Hill, near Dorking, which produced cones in 1852, when it was 28 feet high. Cones have also been borne on trees at Dropmore,² Sunninghill,² Bishopsteignton² near Teignmouth, Enys² in Cornwall, and Fota² in Ireland. Seedlings have been raised from home-grown seed at Rozel Bay² in Jersey and at Bicton.³

A deodar in Kew Gardens produced cones in 1887, according to a note in *Gardeners' Chronicle*, ii. 248 (1887), where it is stated that the production of cones on this species in this country has hitherto been a rare occurrence. At The Coppice, Henley, the seat of Sir Walter Phillimore, Bart., and at Shiplake House, the

¹ *Gard. Chron.* 1852, p. 582, and x. 279 (1891).

² *Ibid.* x. 423, 435, 436, 492, 679 (1891).

³ *Ibid.* 1869, p. 1279.

residence of Miss Phillimore, there are deodars coning profusely at present, probably on account of the hot summer of 1906. At White Knights Park, Reading, there is a seedling now about 8 feet in height, and supposed to be 16 years old, which germinated on a vine border, the seed having come from a tree which measures 75 feet in height and 10 feet in girth.

In India the cones are often much damaged by the larvæ of a Pyralid moth which eats out the seeds, and the saplings are attacked by the well-known fungus *Trametes radiciperda*, which spreads underground through the roots from tree to tree. The leaves are also attacked by Uredinous fungi, especially by *Æcidium cedri*, Barclay, which forms small yellow spots and causes them to fall.

As regards the comparative hardiness to severe winter frosts of the three cedars we have valuable evidence¹ collected by Mr. Palmer in 1860-61. Reports were received from no less than 211 places in England, Scotland, and Ireland. "The winter of 1860-61 was the most severe that has happened since its introduction. It was a winter such as had scarcely any parallel for severity in the memory of man, and unless some general change of climate should take place, it may be looked upon as exceedingly improbable that any cold of greater intensity should again visit us. The effect of that winter upon the deodar may therefore be taken as a safe guide in judging of its suitability for our climate; what the effect was we are, as already mentioned, enabled, through the kindness of Mr. Palmer, to state with accuracy.

Mr. Palmer's record of observations shows that the deodar is by no means so hardy a tree as the larch, and also that it is the least hardy of any of the cedars. There is no instance of any of the larches reported to him having been injured by the cold of 1860; while out of the deodars growing at 211 places in Great Britain and Ireland, plants were killed at 55, and were uninjured only at 80, having been more or less injured at the remaining 76, a percentage of frailty much greater than we should have anticipated. The Cedar of Lebanon and the *Cedrus atlantica* proved more hardy, and about equal between themselves. The following summary will show the actual results of Mr. Palmer's report on all three:—

	Total Places reported on.	Not injured.	Injured.	Much injured.	Killed.	Proportion of Killed and Much injured.
Cedrus Deodara .	211	80	50	26	55	1 in $2\frac{1}{2}$
Cedrus Libani .	81	51	19	6	5	1 in $7\frac{1}{2}$
Cedrus atlantica .	74	48	19	2	5	1 in $10\frac{1}{2}$

It may be interesting to notice in what proportion the three different parts of the kingdom suffered. It was as follows:—

	Total Places reported on.	Not injured.	Injured.	Much injured.	Killed.	Proportion of Killed and Much injured.
Scotland .	64	19	26	14	5	1 in $3\frac{1}{2}$
England .	142	61	24	13	50	1 in $2\frac{1}{2}$
Ireland .	4	3	1			"

¹ Published in Ravenscroft, *Pinet. Brit.* iii. 242 (1884).

REMARKABLE TREES

The two finest deodars, as regards size and symmetry, that I have seen in Great Britain are at Bicton, where cones were produced, according to *Pinet. Brit.*, as long ago as 1858. One of these on the lawn measured in 1902 was 80 feet by 11 feet 8 inches (Plate 140). The other is near the ornamental water in a more sheltered situation, and was then 90 feet by 9 feet 1 inch.

Another of about the same height at Beauport has an erect top, and looks as if it might become much taller. The tallest reported at the Conifer Conference was at Studley Royal, and was then 70 feet by 7½ feet; but when I visited that place I saw no very large tree of the kind.

At Dropmore there is a handsome tree which in 1905 was 77 feet by 8 feet 10 inches, and had many of the woody knots embedded in the bark that are sometimes seen in the cedars. It is said to have been planted¹ in 1834.

At Westonbirt, a tree, planted by the late Mr. Holford, about 85 feet by 8 feet 9 inches, is one of the largest and best shaped that I have seen. A deodar of peculiar habit at Linton Park, Kent, reported to be 79 feet high, is figured in *Gardeners' Chronicle*, December 12, 1903, fig. 159.

At Barton there is a fine tree branched to the ground, which in 1904 was 76 feet by 9½ feet. At Highclere there is a handsome tree about 75 feet by 8 feet 4 inches, which was planted by the then King of Spain in 1844. At Williamstrip, on rather heavy soil, there is a healthy tree of 72 feet by 8 feet.

At Ombersley Court, near Worcester, there is a very fine tree 84 feet by 8 feet 4 inches, which has the erect habit of *atlantica*; but the drooping branchlets show it to be a deodar.

At the Frythe, near Welwyn, Herts, a large deodar was cut down some years ago; and from the side of the stump there is now (1906) a young tree springing up, quite vigorous and healthy, and about 25 feet high. At Chart Park, Surrey, there is a tree 89 feet by 8 feet 11 inches; and adjoining this place, in the Tunnel Park, Deepdene, there is another fine tree 77 feet by 9 feet, both measured by Henry in 1905. At Fulmodestone, Norfolk, a tree planted in 1861 was in 1905 66 feet by 7 feet 4 inches in girth. At Shiplake House, near Henley, a tree, planted in 1852, was 73 feet by 7 feet 9 inches in 1905, and is bearing numerous cones in the present year. A deodar, growing on Haddington Hill, near Wendover, at 800 feet elevation, is 63 feet by 5 feet 10 inches.

There are many trees of from 60 to 70 feet in other parts of England, but we have seen none which call for special notice.

In Scotland the deodar is only hardy in the warmer parts of the country, and does not seem to have attained anything like the same dimensions as in England or Ireland. At Poltalloch, notwithstanding the wet and windy climate, it grows fairly well and has attained over 50 feet. At Rossdhu, on Loch Lomond, it is even taller.

In Perthshire there are good specimens at Abercairney, Castle Menzies, and Dunkeld, which seem to have been planted after the great frost of 1860-61, which

¹ *Gard. Chron.* xxv. 138 (1899).

destroyed so many of this tree in the north. The tree at Abercairney is remarkably weeping in habit, and measured, in 1904, 51 feet high by 4 feet 8 inches in girth. The best that we know in this county is perhaps one at Murthly, which is older and bore cones in 1892. It grows well at Gordon Castle, where there is a tree about 50 feet high, and as far north as Dunrobin in Sutherlandshire. At Conan House, Ross-shire, there is a healthy tree 47 feet by 9 feet 9 inches. At Leny, near Callander, there is a very old-looking but rather stunted deodar, which may have been introduced by the distinguished Indian naturalist Buchanan Hamilton, grandfather of the present owner, but when I saw it in 1906 it was only about 45 feet by 7 feet.

At Smeaton-Hepburn, a tree¹ planted in 1841, when it was 2½ feet high, measured in 1902, 55 feet in height and 6 feet 7 inches in girth.

The finest deodar in Ireland is growing at Fota, Co. Cork, and measured, in 1903, 84 feet high by 7 feet 2 inches in girth. At Coollattin, Wicklow, there are two trees, one of which measured, in 1906, 53 feet by 6 feet 10 inches. At Hamwood, Co. Meath, a tree, supposed to have been planted in 1844, was 74 feet by 7½ feet in 1905. At Mount Shannon, Limerick, there is a tree 66 feet by 8 feet 5 in. in 1905. At Emo Park, Portarlinton, a tree measured, in 1907, 61 feet by 7 feet 4 inches, and was thriving; but in the dry climate of Queen's County, the deodar as a rule is not a satisfactory tree.

TIMBER

The timber is the most important of any in North-Western India, and supplies a large quantity of railway sleepers, bridge, and building timber. Gamble says that it is rather brittle to work, and does not take paint or varnish well. It has also a very strong odour which, although pleasant in the open air, is not so in a room. It is extremely durable, probably with cypress (*Cupressus torulosa*) the most durable of Himalayan woods. Stewart mentions the pillars of the Shah Hamadin Mosque at Srinagar in Kashmir, which date from 1426 A.D., and were quite sound when he wrote. Its grain is so straight that the logs can be split into boards, which are afterwards trimmed with an adze; and shingles for roofing, according to Webber,² stand the changes of climate for centuries without any sign of decay.

The weight of well-seasoned dry wood of average growth is about 35 pounds per cubic foot, branch wood being very much heavier and more full of resin.

Oil is extracted from it by distillation, which is a dark brown, strong, and unpleasant smelling fluid, said to be a good antiseptic, and serves to coat the inflated skins known as "mussucks" used for crossing the Himalayan rivers. (H. J. E.)

LIBOCEDRUS

Libocedrus, Endlicher, *Syn. Conif.* 42 (1847); Bentham et Hooker, *Gen. Pl.* iii. 426 (1880); Masters, *Journ. Linn. Soc. (Bot.)*, xxx. 19 (1892), and *Gard. Chron.* xxx. 467 (1900).
Heyderia, Koch, *Dendrologie*, ii. 2, p. 179 (1873).
Calocedrus, Kurz, *Journ. Bot.* xi. 196 (1873).
Thuya, Baillon, *Hist. Pl.* xii. 34 (1892).

EVERGREEN trees with aromatic odour, belonging to the tribe Cupressineæ of the order Coniferæ, closely resembling *Thuya* in habit and other characters, the branches as in that genus ending in frondose "branch-systems," which are flattened in one plane and three- to four-pinnately divided, with their axes bearing scale-like leaves in four ranks. On the main axes the leaves are often remote by the lengthening of the nodes; on the lateral axes they are closely imbricated, and vary in the different species in size and form, as detailed in the three sections below. In seedling plants the leaves are always linear-lanceolate and spreading.

Flowers: monœcious with those of the two sexes on different branchlets, or rarely diœcious, solitary, terminal. Male flowers oblong, subsessile, with six to twenty stamens decussately opposite on a slender axis; filaments short, dilated into broadly ovate or orbicular scale-like peltate connectives, which bear usually four sub-globose anther-cells, two-valved and opening on the back. Female flowers oblong; subtended at the base by several pairs of leaf-like scales, which persist slightly enlarged under the fruit; composed of four or six decussately opposite acuminate bracts; lowest pair small, unfertile; next pair above fertile, bearing at the base two erect ovules on a minute accrescent ovular scale; uppermost pair when present unfertile.

Cones small, pendulous or erect, ripening and letting out the seed in the first year, persistent empty on the branchlets in the second year. Scales decussate, four or six; the lowermost pair short, thin, often reflexed; the next pair long, thickened, woody, widely spreading at maturity, marked externally close to the apex by the shortly acuminate or long-beaked tip of the bract; third pair, when present, connate into an erect median partition. Seeds, two or one by abortion on each of the two fertile scales, with two lateral wings, one broad, oblique, nearly as long as the scale; the other short, narrow, or rudimentary; cotyledons two.

Eight species of *Libocedrus* have been described, remarkable for their distribution over widely separated areas in the two hemispheres. Three sections may be distinguished:—

Libocedrus

I. Ultimate branchlets on mature trees tetragonal, bearing leaves all alike and uniform in size.

1. *Libocedrus tetragona*, Endlicher. Chile, Patagonia.
Leaves spreading.
2. *Libocedrus Bidwilli*, Hooker. New Zealand.
Leaves closely appressed.

II. Ultimate branchlets flattened, with leaves of two kinds; lateral boat-shaped, median flat and appressed.

A. Median and lateral leaves equal in length.

3. *Libocedrus decurrens*, Torrey. Oregon, California, W. Nevada.
Leaves green on both surfaces.
4. *Libocedrus macrolepis*, Bentham et Hooker. China, Formosa.
Leaves glaucous on the lower surface, with white stomatic bands.

B. Lateral leaves much longer than the median leaves.

5. *Libocedrus chilensis*, Endlicher. Chile.
Median leaves minute, rounded at the apex, with a conspicuous gland.
6. *Libocedrus Doniana*, Endlicher. New Zealand.
Median leaves ovate, acute, mucronate, scarcely glandular.

The two following species, imperfectly known and not introduced, will only be mentioned here. They belong to the last section:—

7. *Libocedrus papuana*, F. v. Mueller.¹ New Guinea.
8. *Libocedrus austro-caledonica*, Brongniart et Gris.² New Caledonia.

LIBOCEDRUS TETRAGONA

Libocedrus tetragona, Endlicher, *Syn. Conif.* 44 (1847); Lindley and Paxton, *Flower Garden*, i. 47, f. 32 (1850); Kent, Veitch's *Man. Coniferae*, 256 (1900).
Libocedrus cupressoides, Sargent, *Silva N. Amer.* x. 134 (1896).
Thuya tetragona, Hooker, *London Journ. Bot.* iii. 148, t. 4 (1844).
Pinus cupressoides, Molina, *Saggio Sulla Storia Naturale del Chile*, 168 (1782).

A tree³ attaining in South America, though rarely, a height of 160 feet. Branchlets tetragonal. Leaves equal in size and uniform in shape in the four ranks; those on the ultimate branchlets about $\frac{1}{2}$ inch long, adnate only at the base, the remaining part free and spreading; ovate, acute, or rounded at the apex, keeled on the back, concave and glaucescent above; those on primary axes larger, adnate for the most of their length, the apices only being free and spreading.

Cones on long branchlets, less than $\frac{1}{2}$ inch long, brown. Scales four, minutely

¹ *Trans. Roy. Soc. Victoria*, i. 32 (1889).

² *Bull. Soc. Bot. France*, xviii. 140 (1871).

³ This tree has been confused by travellers with *Fitzroya patagonica*, which has very similar foliage when old. In the former, the leaves gradually taper to a rounded or acute apex; in the latter they are broadest in their upper third, close to the rounded apex. The cones are entirely different.

pubescent on the margin, each bearing above the middle on the back a lanceolate, subulate, erect, incurved spine; the two smaller scales lanceolate; the two larger scales oblong, each bearing a solitary seed; the larger wing oblique, obovate, obtuse, twice as long as the seed, the shorter wing narrow. (A. H.)

This tree inhabits the western slopes of the Andes of Chile from latitude 35° southwards, and was collected by me in February, 1902, on the west end of Lake Nahuel-Huapi at two to three thousand feet. It was growing both on swampy ground, where it attained a considerable size, and on the steep hill-sides above Puerto Blest. The natives of the district call it Alerce,¹ which is the usual name in South Chile for *Fitzroya patagonica*, and use it for making long straight thin shingles, which seem to be extremely durable. Owing to the inaccessible nature of the country and the scarcity of inhabitants, little or no timber has as yet been cut in the dense forests which clothe the shores of this large and picturesque lake. Judging from the climate, which is severe in winter, this beautiful tree should be hardy in the west and south-west of Great Britain and Ireland. According to Dusen and Macloskie,² it is common in Western Patagonia, extending through Fuegia to Cape Horn, rising up to the snow-line in the mountains, and met with of all sizes, from 2 to 160 feet high. As a rule it never forms forests, but grows either in small thin groves or sparingly mixed with *Nothofagus betuloides* and *Drimys Winteri*.

It was introduced by W. Lobb³ in 1849, but is excessively rare in cultivation, the only specimen we have seen being a small tree 15 feet high, in 1906, at Kilmacurragh, Co. Wicklow. This tree is narrowly pyramidal in habit, with bark scaling off in long papery ribbons. (H. J. E.)

LIBOCEDRUS CHILENSIS

Libocedrus chilensis, Endlicher, *Syn. Conif.* 44 (1847); Lindley, *Journ. Hort. Soc.* v. 35 (1850); Lindley and Paxton, *Flower Garden*, i. 48, f. 33 (1850); Kent, *Veitch's Man. Coniferae*, 252 (1900).

Thuja chilensis, Don, in Lambert, *Pinus*, ii. 19 (1824); Hooker, *London Journ. Bot.* ii. 199, t. 4 (1843).
Thuja andina, Poeppig et Endlicher, *Nov. Gen. et Spec.* iii. 17, t. 220 (1845).

A tree, attaining in Chile 50 feet in height, usually with a short trunk branching into a compact pyramidal head, or becoming at high altitudes a dense shrub. Branchlets compressed, slender; leaves scale-like in four imbricated ranks, those of the lateral ranks much longer than the others, boat-shaped, free at the apex, and spreading for one-third their length, keeled, acute, marked above and below with a white stomatic band; median leaves, minute, appressed, rounded at the apex, the dorsal with a prominent gland.

¹ Sir W. T. Thiselton-Dyer suggests that this is no doubt a Spanish corruption of the Arabic *El Arz*, a name which seems to include any coniferous tree, e.g. *Cedrus Libani* and *Pinus halepensis*. According to Pearce, the tree producing the valuable alerce timber is *Fitzroya patagonica*. Cf. *Hortus Veitchii*, 46 (1906).

² Scott, *Princetown Univ. Exped. Patagonia*, viii. 6, 18, 142 (1903).

³ *Gard. Chron.* 1849, p. 563.

Cones¹ on short branchlets, $\frac{1}{2}$ inch long; scales four, each with a minute projecting point below the apex, bright brown, two larger fertile and two smaller unfertile. Seeds one or two on each of the larger scales, oblique, with a narrow short wing on one side below, and an oblique broad oval wing on the other side above, the two wings being upper and lower, rather than lateral in position. (A. H.)

A tree, said by Bridges—who was the first to send home seeds to Low of Clapton in 1847—to attain occasionally 80 feet in height. It grows on the lower slopes of the Andes of Southern Chile, from lat. 34° southward to Valdivia; and was collected by me in the valley of the Rio Limay below Lake Nahuel-Huapi at 3500 to 4500 feet. Here it grows scattered on grassy hillsides or in open groves, and is a graceful tree of 50 to 60 feet in height. A photograph of our camp in this valley, taken by Mr. Calvert, gives a good idea of its appearance (Plate 141).

Though from the climate of the region in which it grows, this tree ought to be hardy in the warmer parts of England, and though in Mr. Palmer's tables a small number of trees seem to have survived the frost of 1860-61, as at Bishopstowe, Nettlecombe, Southampton, and even at Keir in Perthshire, yet by far the greater number of the plants introduced in 1847 were killed; and it is now very rare in cultivation; but seems, though slow in growth, to thrive at several places. By far the largest specimen I have seen is at Whiteway near Chudleigh, Devon, the property of Lord Morley, which in 1907, according to the measurements of the gardener, Mr. Nanscawen, was 46 feet 8 inches by 5 $\frac{1}{2}$ feet. We have also seen specimens in England at Blackmoor, Hants, the seat of Lord Selborne; and in Ireland at Castlewellan, the largest tree there being 20 feet high in 1903; at Powerscourt, where in 1906 there was a tree 28 feet high by 3 feet 3 inches, with the bark scaling off in long, narrow, papery slips, the habit being much wider than that of *L. decurrens*, with ascending branches; and at Kilmacurragh, Wicklow, where there is a tree 25 feet in height. (H. J. E.)

LIBOCEDRUS DONIANA

Libocedrus Doniana, Endlicher, *Syn. Conif.* 43 (1847); Kirk, *Forest Flora New Zealand*, 157, tt. 82, 82A (1889); Kent, *Veitch's Man. Coniferae*, 254 (1900); Cheeseman, *New Zealand Flora*, 646 (1906).

Libocedrus plumosa, Sargent, *Silva N. Amer.* x. 134 (1896).

Dacrydium plumosum, D. Don, in Lambert, *Pinus*, ed. 2, Appendix 143 (1828).

Thuja Doniana, Hooker, *London Journ. Bot.* i. 571, t. 18 (1842).

A tree, attaining in New Zealand 100 feet in height and 15 feet in girth, with reddish, stringy bark scaling off in ribbons. Branchlets flattened, with leaves similar in shape and arrangement to those of *L. chilensis*; lateral leaves adnate in the lower half, free and spreading in the upper half, acute, mucronate, green and shining above, glaucescent with a white band below; median leaves appressed, ovate, acute, mucronate, scarcely glandular.

Cones about $\frac{1}{2}$ inch long; scales four, each with a lanceolate acuminate, erect,

¹ Cones ripened on young trees at Les Barres in France in 1900. Pardé, *Arb. Nat. des Barres*, 31 (1906).

incurved spine above the middle on the back; two lower scales half the size of the others, acute; two upper scales rounded at the apex, each bearing one seed, which has two lateral wings, one short and narrow, the other broad and entire or sub-dentate.

This tree occurs in the North Island of New Zealand, in forests from Mongonui southward to Hawke's Bay and Taranaki, at elevations from sea-level to 2000 feet, usually rare and local. Kawaka is the native name, and it is also known as the New Zealand *Arbor Vitæ*, the dark red wood, beautifully grained and durable, being used in cabinet-making.

It is occasionally seen in conservatories; the only tree growing in the open, that we know of, being one at Powerscourt, which was 20 feet high and 18 inches in girth in 1903.

(A. H.)

LIBOCEDRUS BIDWILLI

Libocedrus Bidwilli, J. D. Hooker, *Flora New Zealand*, i. 257 (1867); Kirk, *Forest Flora New Zealand*, 159, tt. 82A, 83 (1889); Cheeseman, *New Zealand Flora*, 647 (1906).

A tree similar to *L. Doniana*, but smaller, attaining a maximum of 80 feet in height and 12 feet in girth; but often bushy at high altitudes and on peat-bogs.

Branchlets on young trees like those of *L. Doniana*, but more slender; on old trees tetragonal, $\frac{1}{20}$ th to $\frac{1}{10}$ th inch in diameter, clothed with densely imbricated, minute, scale-like leaves, uniform in size and shape in the four ranks, closely appressed, boat-shaped, ovate, acute, green in colour. Cones like those of *L. Doniana*, but smaller, $\frac{1}{4}$ to $\frac{1}{3}$ inch long.

This tree occurs both on the North and South Islands of New Zealand, from Te Aroha mountain and Mount Egmont southward to the Foveaux Strait, not uncommon in hilly and mountain forests at 800 to 4000 feet elevation. It is known as cedar or Pahautea, and has soft, red, and rather brittle wood. This species has not apparently been introduced, though judging from its occurrence higher in the mountains and more southerly in latitude than *L. Doniana*, it ought to be hardy in the milder parts of the British Isles.

(A. H.)

LIBOCEDRUS MACROLEPIS

Libocedrus macrolepis, Bentham et Hooker, *Gen. Pl.* iii. 426 (1880); Kent, Veitch's *Man. Conifera*, 255 (1900); Masters, *Gard. Chron.* xxx. 467 (1901); Henry, *Garden*, lxii. 183, with figure of tree (1902).

Calocedrus macrolepis, Kurz, *Journ. Bot.* xi. 196, t. 133 (1873).

A tree, attaining in China 100 feet in height, broadly pyramidal in habit, with whitish, scaly bark. This species resembles *L. decurrens* in foliage—the frondose branch-systems being, however, more flattened, and the leaves thinner in texture and larger at the corresponding stages of growth than in that species—the best mark of distinction being the glaucous tint of the leaves beneath. Staminate flowers oblong,

tetragonal; stamens sixteen to twenty. Cones on very slender branchlets (which are modified in being tetragonal, with minute appressed leaves uniform in the four ranks), about $\frac{3}{4}$ inch long, purplish or dark brown, roughened externally by longitudinal ridges; scales six, resembling those of *L. decurrens*, but smaller and with blunter minute processes. Seed, one on each of the two middle scales; two-winged, with the larger wing broader in the middle and more obtuse than in the Californian species.

This species occurs in the forests of Southern Yunnan in China, at 4000 to 5000 feet, but is rarely met with wild, and only in ravines near water-courses. It was discovered by Anderson near Hotha in 1888; and was subsequently seen by me wild, near Talang, and frequently planted in temples. It is known to the Chinese in Yunnan as Poh or Peh; and the wood is much esteemed, especially that of logs often found buried, the result of inundations in past times. Specimens of this species, so far as one can judge by the foliage alone, have been sent to Kew from North Formosa by Bourne.

The Chinese Libocedrus was introduced by Mr. E. H. Wilson, who collected seeds when he was paying me a visit at Szemao in the autumn of 1899. Young plants,¹ raised at the Coombe Wood Nursery, have beautiful, glaucous, large, flat foliage, the apices of the leaves being tipped with very fine, long, cartilaginous points. They may also be seen in the temperate house at Kew. The tree would probably be hardy in Cornwall and the south-west of Ireland, and being highly ornamental, is worth a trial in warm, sheltered spots.

(A. H.)

LIBOCEDRUS DECURRENS, INCENSE CEDAR

Libocedrus decurrens, Torrey, *Smithsonian Contrib.* vi. 7, t. 3 (1854); Sargent, *Silva N. Amer.* x. 135, t. 534 (1896), and *Trees N. Amer.* 73 (1905); Kent, Veitch's *Man. Conifera*, 253 (1900); Mayr, *Fremdländ. Wald- u. Parkbäume*, 315 (1906).

Thuja Craigana, Murray, *Botan. Exped. Oregon*, 2, t. 5 (1853).

Thuja gigantea, Carrière, *Rev. Hort.* 1854, p. 224 (in part) (not Nuttall).

Heyderia decurrens, Koch, *Dendrologie*, ii. 2, p. 179 (1873).

A tree, attaining in America 180 feet in height and 21 feet in girth, with a straight stem tapering from a broad base. Bark nearly an inch thick, light cinnamon-red, irregularly fissuring into ridges covered with appressed flat scales.

Leaves shining green, each set of four equal in length, adnate for most of their length to the branchlets, but free at the tips, which end in fine cartilaginous points; about $\frac{1}{8}$ inch long on the conspicuously flattened secondary and tertiary axes, increasing to $\frac{1}{2}$ inch on the main axes, which are only slightly flattened: those of the lateral ranks boat-shaped, gradually narrowing to an acuminate apex, keeled and glandular on the back, covering in part the median leaves, which are obscurely glandular and flattened, with broadly triangular cuspidate apices.

¹ A seedling is figured in *Ann. of Bot.* xvi. 557, fig. 30 (1902), concerning which Sir W. Thiselton Dyer says:—"The primitive leaves are not very different from the cotyledons, with which they are serially continuous; but after a time there is a complete change in the form and disposition of the foliar organs."

Flowers appearing in January at the end of short lateral branchlets of the previous year; staminate, $\frac{1}{4}$ inch long; pistillate, with ovate, acute, greenish-yellow scales, subtended at the base by two to six pairs of slightly altered leaves, which persist yellowish, sharp-pointed and membranous at the base of the fruit.

Cones about an inch long, pendulous, reddish-brown, on short branchlets with ordinary leaves. Scales six; lower pair short with a reflexed process; middle pair long, lanceolate, gradually narrowing to a rounded apex, below which is a minute deltoid spreading or reflexed process, and concave on the inner surface at the base, with depressions for the seeds; upper pair connate into a thick, woody, median partition, slightly longer than the fertile scales, crowned by three minute spines. Seeds four, two collateral on each of the middle scales; body, $\frac{1}{3}$ to $\frac{1}{2}$ inch, lanceolate, pale brown, containing liquid resin, marked with a white hilum on each surface at the base; wings two lateral, one short and narrow, the other oblique, produced above the seed, nearly as long as the scale, rounded at the narrow apex, and about one-third as broad as long in the middle widest part.

Seedling.—Seedlings sown at Colesborne in spring were about 3 inches high in August, and had a slender tap-root, about 5 inches long. Caulicle, $1\frac{1}{4}$ inch long, terete, brownish, glabrous. Cotyledons, two, $1\frac{5}{8}$ inch long, linear, nearly uniform in width, rounded at the apex, green beneath, marked above with numerous inconspicuous stomatic lines. Primary leaves variable in number, first pair opposite, succeeded by three or four whorls in sets of four each, or only one or two whorls are produced; linear, $\frac{3}{4}$ inch long, tapering to an acuminate apex, glaucous on both surfaces with indistinct stomatic lines. Above the primary leaves the stem gives off branches, and produces scale-like small leaves, arranged in four ranks, and intermediate in character between the primary leaves and the adult foliage. (A. H.)

DISTRIBUTION

Libocedrus decurrens was discovered by Fremont in 1846 on the upper waters of the Sacramento river. It was introduced in 1853 by Jeffrey, who collected for the Oregon Botanical Association of Edinburgh; and his specimens were named by Murray *Thuja Craigana* in honour of Sir W. Gibson Craig, one of the members of the association. Carrière confused the tree with *Thuja gigantea*; and for some time there was great confusion in the nomenclature of the two species. *Libocedrus decurrens* is the name now universally adopted.

According to Sargent, the distribution extends from the north fork of the Santiam river in Oregon, lat. $44^{\circ} 50'$, southward along the western slopes of the Cascade Mountains, and through the Sierra Nevada in California, occasionally crossing the range into Western Nevada; also along the Californian coast ranges from Mendocino county to the San Bernardino, San Jacinto, and Cuyamaca Mountains, reaching its most southerly point on Mount San Pedro Martin, half-way down the peninsula of Lower California. Sargent states that it is rather rare in Oregon, ascending to 5000 feet, and in the Californian coast ranges, where it rises to 5000 to 7000 feet; being most abundant and of largest size in the sierras of Central California at 3000 to 5000 feet, thriving best on warm, dry hillsides, plateaux, and

the floors of open valleys, usually growing singly or in small groves, often mixed with *Pinus ponderosa* and black oak.

Henry saw it in Oregon on the eastern spurs of the coast range near Kerby; and found it common on the road from there south-west across the Siskiyou range into Northern California, where it grew near Gasquet's Inn, about twenty miles inland from Crescent City on the coast. In these localities it occurred scattered on dry, sunny hills, in situations similar to that of *Pinus ponderosa*, at 2000 to 3000 feet altitude, and was not seen in shaded, moist ravines. The trees here are broadly pyramidal in habit, not assuming the columnar form of English cultivated trees, and of no great size, the largest measured being 123 feet by 11 feet 1 inch.

Plummer, in his report on the Cascade Forest Reserve, where a good illustration is given, on p. 102, of a grove of this tree, says:—"The incense cedar is almost always hollow-trunked or dry-rotted at the heart, even though the tree may have every outward appearance of perfect health. The wood has been very little used for any purpose but fuel or fencing, and is not cut when better is obtainable. It is said by Rothwell and Rix to ascend the mountains as high as 5750 feet."

Sudworth in his report on the Stanislaus and Lake Tahoe forest reserves¹ says that it is here an abundant tree at between 3500 and 5500 feet, but extends from 2000 to 7000 feet. Mature trees are from 80 to 100 feet high, and 4 to 7 feet in diameter, attaining these dimensions in from 100 to 200 years. Large trees, as shown by a photograph (plate cxiii. of Sudworth), are almost always rotten at heart. Reproduction by seed is good and abundant almost everywhere, especially in the drier situations.

The largest trees I have seen were on the lower slope of Mount Shasta at about 4000 feet, where I measured a tree 130 feet by 12 feet 7 inches which had been left standing when the surrounding forest was cut. Here it grew in company with Douglas fir, *Abies concolor*, and *A. magnifica*, on dry soil, and though the fruit on 1st September was fully formed the seeds were not ripe. The average size of the trees here was 90 to 100 by 8 or 9 feet. Prof. Sheldon says that it attains 100 to 150 feet high by 3 to 7 feet diameter, but such dimensions are not common.

CULTIVATION

When raised from seed it is somewhat slow in growth at first, but in good nursery soil soon makes a well-rooted plant, which is proof against the worst spring and winter frosts, and seems hardy on heavy soil and in damp situations, where *Thuja plicata* is sometimes injured when young. It produces very little seed in this country, and these do not always mature, and in consequence is usually propagated by cuttings.

Though it seems doubtful at present whether this tree can be looked on as a timber tree in England, yet on account of its rather stiff and formal habit it is well suited for the formation of small avenues, and when planted close together, as at Ashridge Park, forms a dense shelter without any clipping.

¹ Washington, 1900.

REMARKABLE TREES

The finest tree that I know in England is the one figured (Plate 142) which grows in the grounds at Frogmore. This was planted, as I am told by Mr. M'Kellar, by H.S.H. the Princess of Hohenlohe on 16th March 1857, and must be about 54 years old. It has been stated on a photograph taken for the late Hon. Charles Ellis to be 82 feet high, but when I measured it in 1904 I could not make it more than 65 feet, and being forked at about five feet from the ground its girth was about 9 feet.

Another very fine tree grows close to the house at Bicton, which in 1900 was 60 feet by 7 feet 7 inches; and at Killerton there is a tree 55 feet by 5 feet 5 inches. At Orton Hall, near Peterborough, the tree succeeds very well on rather heavy soil, which does not suit many conifers, and here a tree 60 feet by 6 feet 9 inches has borne fruit, from which Mr. Harding, gardener to the Marquess of Huntly, has raised seedlings, some of which are now 9 feet high; smaller ones which he sent me are growing at Colesborne. At Hardwicke, near Bury St. Edmunds, one of the healthiest young trees I have seen, which was only planted in 1873, is already 48 feet by 4 feet 5 inches. At Crowsley Park, Oxfordshire, a tree planted about 1850 was, in 1907, 53 feet high by 8 feet 1 inch in girth, dividing into two stems at 10 feet from the ground, but forming a very narrow column. At the Wilderness, White Knights, Reading, an extremely narrow tree is 60 feet high by 4½ feet in girth. At Nuneham Park, Oxford, there is a fine tree in the pinetum, which is 58 feet by 7 feet. At Bayfordbury, Herts, the best specimen is 52 feet by 5 feet 9 inches.

In Herefordshire the best specimen I know of is at Eastnor Castle, which forks at about 6 feet, and measured in 1906 53 feet by 7 feet 6 inches. There is a nice avenue of it in the grounds at Ashridge Park, and also a circle consisting of 32 trees at only 1 yard apart, which were planted by Earl Brownlow thirty-five years ago, and are now about 35 feet high.

Other remarkable trees which we have seen are at Fulmodestone, Norfolk, 58 feet by 5 feet 11 inches in 1905; at Highnam, Gloucester, 50 feet by 5 feet 3 inches in 1905; at Beauport, Sussex, 53 feet by 6 feet 2 inches at 2 feet up, dividing into two stems, a conical tree, with extremely dense foliage, in 1904; at Dropmore, a large tree not measured. At Coldrinick, Cornwall, there is a tree which Mr. Bartlett informs us, was, in 1905, 51 feet by 6½ feet. Mr. R. Woodward, jun., measured in 1906 a tree at Wexham Park, Stoke Pogis, 56 feet by 3 feet. At Salhouse, Norfolk, Sir Hugh Beavor measured, in 1904, a tree 57 feet by 6 feet 8 inches. A fine specimen at Tittenhurst, Sunninghill, is figured in *Gardeners' Chronicle*, xxxvi. 284, fig. 127 (1904).

In Scotland the tree is not so common, though specimens 40 to 50 feet high are growing in various places; the tallest reported at the Conifer Conference of 1891 was at Torloisk in Mull, and then measured 37 feet in height.

At Smeaton-Hepburn, East Lothian, a tree planted in 1843 was measured by Henry in 1905 as 53 feet by 5 feet 4 inches. A tree at Keir, Perthshire, seen

by Henry, was 42 feet by 4 feet 10 inches in 1905. At Brahan Castle, Ross-shire, Col. Stewart Mackenzie of Seaforth informed us in 1904 that he had a tree 4 feet 10 inches in girth, height not stated.

In Ireland, *Libocedrus decurrens* is rare in cultivation. At Stradbally Hall, Queen's County, a fine tree measures 53 feet high by 5½ feet in girth. There is a tree at Fota 45 feet high, dividing into two stems at 2 feet from the ground. At Churchill, Armagh, a fine healthy specimen, growing in sand, was 45 feet by 4 feet 10 inches in 1905. At Adare a tree measured, in 1903, 47 feet high by 7 feet 9 inches in girth.

In North Italy this tree grows larger than in England and ripens seed freely, which it rarely does here. At Pallanza, in Rovelli's nursery, I measured a splendid tree over 90 feet high by 9 feet 3 inches in girth. Another on the Isola Madre was 90 feet by 9 feet 10 inches, from which I gathered seed in October 1906, which have produced a good crop of seedlings.

It also ripens seed and grows well in the climate of Paris, and also at Les Barres, and has produced self-sown seedlings at Thiollets (Allier).¹ The largest I have seen in France is at Verrières, near Paris, a handsome and well-shaped tree, which measured, in 1905, 50 feet by 5 feet 5 inches, and is figured on plate vii. of *Hortus Vilmorinianus* (1906). (H. J. E.)

CUNNINGHAMIA

Cunninghamia, R. Brown, in Richard, *Conif.* 80, t. 18 (1826); Bentham et Hooker, *Gen. Pl.* iii. 435 (1880); Masters, *Journ. Linn. Soc. (Bot.)* xxvii. 304, fig. 18 (1889), and xxx. 25 (1892).
Belis,¹ Salisbury, *Trans. Linn. Soc.* viii. 315 (1807).
Jacularia, Rafinesque, in Loudon, *Gard. Mag.* viii. 247 (1832).
Raxopitys, Nelson (Senilis), *Pinaceæ*, 97 (1866).

A GENUS, belonging to the Coniferæ, with only one known living species,² and doubtfully represented in the fossil state.³

Cunninghamia is considered by Bentham and Hooker, and by Masters, to be a member of the family Araucariæ; but it is placed by Eichler⁴ in Taxodineæ. Seward and Ford, who have lately published an exhaustive monograph⁴ of *Araucaria* and its allied genus *Agathis*, agree with Eichler that it has no close relationship with those genera. It appears, however, to be a connecting link between the Araucariæ and the Taxodineæ; and mainly differs from *Araucaria*, some species of which it closely resembles, in foliage, in having three ovules on the bract, and not one only, as in that genus.

The generic characters are given in the following detailed account of the species:—

CUNNINGHAMIA SINENSIS

Cunninghamia sinensis, R. Brown, *loc. cit.* (1826); Lambert, *Genus Pinus*, ed. 2, t. 53 (1832); Loudon, *Arb. et Frut. Brit.* iv. 2445 (1838); Murray, *Pines and Firs of Japan*, 116, figs. 216-224 (1863); Kent, *Veitch's Man. Conifera*, 292 (1900); Shirasawa, *Icon. Ess. Forest. Japon.* text 23, t. 9, ff. 1-24 (1900).
Cunninghamia lanceolata, W. J. Hooker, *Bot. Mag.* t. 2743 (1827).
Pinus lanceolata, Lambert, *Genus Pinus*, ed. 1, t. 34 (1803).
Belis jaculifolia, Salisbury, *loc. cit.* 316 (1807).
Belis lanceolata, Sweet, *Hort. Brit.* 475 (1830).

¹ This name, though the earliest, is not adopted on account of its close resemblance to the genus *Bellis*, used for the daisies.

² While the above was passing through the press, there has been received at Kew a specimen of a new species of *Cunninghamia*, lately discovered in the mountains of Formosa at 7000 feet altitude. This species, which will shortly be published by Mr. Hayata, differs from *C. sinensis* in having shorter leaves, acute and not acuminate at the apex. Mr. Hemsley is inclined to think that a specimen, preserved in the Herbarium, which was collected on Mt. Omei, in Western China, by Faber, is possibly a third distinct species.

³ Engler u. Prantl, *Natur. Pflanzenfamil.* ii. 85 (1889). *Cunninghamites*, an allied fossil genus, has been found in the Keuper and Chalk deposits in Saxony, Bohemia, Westphalia, Southern France, and Greenland. Cf. Schimper u. Schenck, *Palæontologie*, 283 (1890).

⁴ *The Araucariæ: Phil. Trans. Roy. Soc.*, vol. cviii. p. 308 (1906).

Cunninghamia

495

An evergreen tree, attaining in China 150 feet in height and 18 feet in girth of stem, with brownish bark scaling off in irregular longitudinal plates, and exposing a reddish cortex beneath. Branches at first in pseudo-whorls, afterwards given off irregularly. Young branchlets sub-opposite or in pseudo-whorls, covered with green epidermis; older shoots brownish except for the green leaf-bases. Leaves persistent alive five to seven years, afterwards remaining dry and dead for many years on the branches and even upon the stem; densely and spirally arranged on the branchlets, but twisted on their bases so as to be thrown into two lateral spreading ranks; narrowed at the base and decurrent on the shoot to the insertion of the next leaf; rigid, more or less curved, narrowly lanceolate, acuminate, 1 to 2 inches long; upper surface dark green, concave with slightly raised margins; lower surface convex, with a green midrib and two white stomatic bands, the stomata in several regular lines; sharply and finely serrate; with one resin-canal beneath the single unbranched fibrovascular bundle.

Staminate flowers, five to ten in an umbel at the apex of a branchlet; the umbel surrounded at its base by numerous triangular imbricated serrulate bracts; each flower a spike-like cylindrical column of spirally crowded stamens; each stamen consisting of a slender stalk with an ovate serrulate connective, from which hang three longitudinally-dehiscing anther-cells. Female flowers, single or three or four together at the apex of a branchlet; erect ovoid cones, composed of numerous spirally imbricated lanceolate mucronate bracts in a continuous series with the leaves; lower bracts sterile, resembling leaves but with thickened bases; ovular scale on the upper fertile bracts visible only as a slight projection; ovules three on the base of each bract, reversed.

Fruit, an ovoid-globose brownish cone, about 1½ inch long, composed of thin woody scales, which are the bracts of the flowers increased in size and hardened, but otherwise little altered; loosely imbricated, serrate in margin, broadly ovate or reniform, with a cusped apex often reflected outwards. Seed-scale visible only as a transverse narrow membranous fimbriated projection on the inner surface of the woody bract, below its centre and above the seeds. Seeds three on each bract, about ¼ inch long, brown, oblong compressed, surrounded by a membranous narrow wing. Cotyledons two. The cones persist for a year or more on the branchlets after the escape of the seed; and are occasionally proliferous, the elongated shoot above the cone producing leaves and growing to be several inches in length.¹

Seedling.—Seedlings sown at Colesborne in spring were about 3 inches high in August, and had a short flexuose tap-root, provided with a few lateral fibres. Caulicle brownish, terete, glabrous, 1 inch long. Cotyledons two, about ½ inch long, coriaceous, entire, linear, with a median groove beneath. Young stem glabrous, ridged by the decurrent bases of the leaves. Leaves numerous, spirally arranged on the stem, ½ to 1½ inch long, soft in texture, linear, curved, broad at the base, whence they taper gradually to a fine bristle-pointed apex, serrulate in margin, green above, marked beneath with two narrow white stomatic bauds.

In *Cunninghamia*, as in *Araucaria*, root-suckers are often produced, which grow

¹ Cf. *Woods and Forests*, 1884, p. 593, and *Garden*, xxix. 173 (1886).

into young trees, close to the parent stem. Coppice shoots are also produced freely from the stools in China, when the trees are felled.

Cunninghamia¹ was discovered in 1701 by J. Cunningham in the island of Chusan; and his specimens, preserved in the British Museum, were early described by Plukenet.² The first accurately scientific description, however, is due to Lambert, and was based on specimens brought home by Sir G. Staunton, who accompanied Lord Macartney's embassy to China in 1793.

The tree has been known to the Chinese from the most ancient times, being mentioned in their earliest classical writings. It is called *sha*, a name, however, which is often applied also to *Cryptomeria* and other conifers yielding valuable timber. It was introduced³ by William Kerr from Canton into Kew Gardens in 1804; but no trees of that date now exist there. Probably most of the existing trees in England were raised from seed collected by Fortune about 1844.

Cunninghamia is widely spread throughout the central, western, and southern provinces of China, extending southwards from Szechwan, Hupeh, Kiangsi, and Kiangsu to Yunnan and Kwangtung. It is usually a tree of mountain valleys, requiring a hot summer and considerable humidity to thrive; and ranges in altitude from sea-level to 5000 feet, occurring in Central China below the zone, which, in the high mountains, is covered by silver fir and spruce. There appear to be large forests of it in the interior of Hunan and Fokien, judging from the vast quantities of its timber which are exported from there. In Fortune's time it was abundant on the islands of Chusan and Pootoo, but was rare in Hongkong, where the only wild trees of this species grew as isolated specimens in the Happy Valley. Fortune,⁴ in 1849, passed through fine forests of *Cunninghamia* in the mountains of Northern Fokien, many of the trees being 80 feet in height, and perfectly straight; and he noticed variations in the tint of the foliage. He met with dense woods in the Snowy Valley and other parts of Chekiang, but the trees were usually young, and not remarkable for size.

Mr. E. H. Wilson informs me that there are magnificent forests of *Cunninghamia* in Western Szechwan. One which he specially noted in the Upper Ya Valley extended for fifty miles between 2000 and 5000 feet altitude, the best trees ranging from 100 to 150 feet in height, and from 15 to 18 feet in girth; and when growing in close stands, with straight stems clean to 40 feet or more, the branches above being short, slender, and horizontal. In the open the trees have much longer pendulous branches. The foliage is occasionally glaucous. Where trees had been cut down, new growth was being everywhere produced by shoots from the stools. Mr. Wilson mentions the common use of the timber in China for house-building purposes generally, and for the masts and planking of native craft. The bark is also used in the mountains for roofing houses. In the Chien Chang Valley in

¹ In a note in King's *Survey of the Coasts of Australia*, ii. 564 (1826), R. Brown states that he requested Richard to change the name *Belis*, given by Salisbury, into *Cunninghamia*, in honour of both J. Cunningham, the discoverer of the tree, and of the collector Allan Cunningham.

² *Amaltheum Botanicum*, i. t. 351, f. 2. (1705).

⁴ *Wanderings in China*, 379 (1847); *Tea Countries*, ii. 178, 212 (1853); *Residence among the Chinese*, 189, 277 (1857).

Szechwan, owing, according to tradition, to earthquakes some two centuries ago, landslips occurred which have buried whole forests in certain places beneath the soil. The dead timber is now being dug out, and is in an excellent state of preservation, being redder and more fragrant than the ordinary timber. It is known to the Chinese as fragrant *Cunninghamia*, *hsiang-sha*, and sells for extraordinary prices, selected thick planks for coffins often being worth £12 to £60 a piece.

The wood, according to Mayr,¹ is extraordinarily light, with a broad sap-wood and a dark yellow heart-wood. It is used extensively in the coast ports of China for making tea-chests.

Cunninghamia appears to be confined as a wild tree to China; but it is occasionally planted² in Japan, the Loochoo Islands, and Formosa. M. Hickel has lately received seeds from Tongking, but these may have been gathered from cultivated trees.

(A. H.)

REMARKABLE TREES

The growth of this tree in England depends mainly on the amount of heat in summer, which in most places is evidently insufficient; and though it endures severe winter frosts without much injury on well-drained soil, it suffers much from wind and frost in spring. It rarely ripens seed in this country, the only case I know of being a tree at Penrhyn Castle which is now dead, but from whose seed some young trees were raised. The best of these, when I saw them in 1906, was about 10 feet high.

The tallest trees of this species that we know are at Killerton, where, in 1904, there were two which measured 62 and 60 feet in height by 4 feet in girth. One of these has since been cut down, its branches having become ragged, and a section sent to the Kew Museum shows the age to be at least 63 years. Another, at Bicton, was, in 1906, 56 feet by 4 feet 10 inches, also rather ragged in its branches. There is a tree at Highnam, in Gloucestershire, about 25 feet high.

At Heanton Satchville, the seat of Lord Clinton, in North Devon, there is a slender but healthy-looking tree 50 feet by 3 feet, and another one which has thrown up a shoot from the stool. At Escot in South Devon, the seat of Sir John Kennaway, Miss Woolward measured one in 1905, 45 feet high. At Pencarrow in Cornwall Mr. Bartlett showed me a tree, planted by Sir W. Molesworth in 1850, which was in 1905 40 feet by 4 feet 8 inches, and one of the healthiest that I have seen; and there is a smaller tree, 30 feet by 4 feet, at Coldrinick, in the same county.

Coming farther east there is a splendid tree at Bagshot Park, the seat of H.R.H. the Duke of Connaught, which, when I saw it in May 1907, was no less than 47 feet high by 7 feet in girth, and 48 yards in the circumference of its branches. Being on very well drained soil, and well sheltered by other trees, it has suffered

¹ *Fremdländ. Wald- u. Parkbäume*, 285 (1906).

² Cf. Hayata, in *Tokyo Bot. Mag.* xix. 50 (1905).

498 The Trees of Great Britain and Ireland

little from frost and wind, and is the handsomest and best-shaped tree¹ I have seen (Plate 143).

At Beechlands, near Lewes, the seat of Captain Rose, I am told by Mr. Chisholm that there is a *Cunninghamia* 50 feet high by 5 feet 1 inch in girth, forked near the top. It bears many cones, which, however, do not produce fertile seeds.

At Grayswood, Haslemere, a tree planted in 1882 is 30 feet high by 2 feet 7 inches in girth, but has not a very thriving appearance. Another at Redleaf, near Penshurst, Kent, the seat of Mrs. E. Hills, though forked near the ground, has one good trunk 47 feet by 5 feet 4 inches, and healthy foliage. At Langley Park, near Norwich, the seat of Sir Reginald Beauchamp, there is a tree 35 feet by 3 feet, which though healthy looking has grown but little for many years. At Tittenhurst,² near Sunninghill, there is a fine healthy tree over 20 feet in height. At Bayfordbury, Herts, *Cunninghamia*, though planted several times, has never succeeded, being much injured by spring frosts, and only one specimen, a few feet high, survives.

The most northern point at which I have seen the tree growing in England is in the sheltered Duchess' garden at Belvoir Castle. This, I was told by Mr. Divers, was planted in 1844, and in 1907 measured 39 feet by 3 feet 2 inches; but Mr. Fenner informs me that there is one 32 feet high at Holker Hall, Lancashire.

In Scotland, as might be expected, there are no trees of any great size. At Brodick Castle, in the Isle of Arran, a tree, which was planted about the year 1858, had only attained, according to the Rev. Dr. Landsborough,³ 10 feet high in 1895, and never throve. There was formerly a tree at Smeaton-Hepburn, East Lothian, which died about five or six years ago after a drought.

In Ireland, *Cunninghamia* is a very rare tree. There is one in Mr. Walpole's garden at Mount Usher in Co. Wicklow, which was in 1903 31 feet high by 2 feet 2 inches in girth. It was supposed to be then about 28 years old. In Mr. Acton's arboretum at Kilmacurragh, in the same county, there is a thriving specimen, which Henry measured in 1903 as 25 feet high by 1½ feet in girth.

Around Paris⁴ the tree always looks suffering, the leaves turning yellowish and assuming a burnt aspect; but it grows well at Les Barres,⁵ and fructifies annually. In North Italy the climate evidently suits the tree much better, as I saw, in the grounds of the Villa Ceriana near Intra, a tree 76 feet by 7 feet 4 inches, producing cones freely in 1906, from which I have raised healthy seedlings. At Locarno,⁶ on the northern end of Lake Maggiore, a tree planted fifteen years is 23 feet in height.

(H. J. E.)

¹ John Smith, in *Records of Kew Gardens*, 290 (1880), states that a *Cunninghamia*, possibly the same tree as the one mentioned above, bore cones at Bagshot in 1838.

LIQUIDAMBAR

Liquidambar, Linnæus, *Gen. Pl.* 463 (1742); Bentham et Hooker, *Gen. Pl.* i. 669 (1865); Engler u. Prantl, *Pflanzenfam.* iii. pt. 2, 123 (1891).

DECIDUOUS trees belonging to the order Hamamelideæ. Leaves alternate on long shoots, crowded and almost fascicled on short shoots, long-stalked, simple, palmately lobed, glandular-serrate. Stipules two, attached to the petiole near its base, lanceolate or subulate, caducous or persisting throughout the summer.

Flowers monœcious, or in rare cases polygamous, in heads subtended at the base by caducous bracts. Staminal heads, globose or elongated, several in a raceme on an erect axis, which is subterminal; each head composed of numerous stamens, interspersed with minute scales, without corolla or calyx; filaments slender; anthers basi-fixed, oblong-obcordate, dehiscing longitudinally. Pistillate heads solitary, on long pendulous stalks, arising in the axils of the uppermost leaves, composed of numerous confluent flowers, the ovaries embedded in the axis of the inflorescence; calyces minute, united together and with the ovaries, and bearing on their summits each four or more stamens, with usually aborted anthers; corolla absent; ovary two-celled, each cell with numerous ovules; styles two, recurved, stigmatic above on their inner surface.

Fruit: a woody spherical head, composed of numerous capsules, consolidated together. Capsule with two valves, opening above to let out the seeds, each valve terminating in a beak (the hardened woody persistent style); calyx persistent, either minutely tuberculate or produced above into long spines. Perfect seeds, angled, winged above, one or two in a capsule, the remaining ovules having aborted. Most of the capsules, however, contain only numerous minute unfertile seeds without wings.

The leaves of *Liquidambar* resemble strongly those of certain maples; but in the latter they are always opposite, and not alternate or fascicled as in the former. Moreover, stipules or their scars are present on the petiole near its base in *Liquidambar*, and are absent entirely in *Acer*.

Three species of *Liquidambar* are well known, and occur in cultivation. Besides these there are apparently two species,¹ wild in China, which are imperfectly known and not introduced.

¹ These are:—

1. *Liquidambar Rosthornii*, Diels, *Flora von Central China*, 380 (1901), a small tree occurring in Szechwan; flowers and fruit unknown. It resembles in foliage *L. orientalis*.

2. *Liquidambar* sp., Hemsley, *Journ. Linn. Soc. (Bot.)* xxiii. 292 (1887). Specimens, consisting of detached leaves and fruits, were sent to Kew from Hankow by Consul Alabaster. Judging from the imperfect material, this is a distinct species. Mr. E. H. Wilson has recently observed a species of *Liquidambar*, growing on the plain near Kiukiang, in Kiangsi, which is probably the same. Cf. *Gard. Chron.* xlii. 344 (1907).

The species in cultivation are :—

1. *Liquidambar styraciflua*, Linnæus. North America.

Shoots glabrous. Leaves large, usually five-lobed, only occasionally lobulate in margin; under surface glabrous, except for dense tufts of pubescence in the axils of the main nerves at the base, and occasional minute tufts at the junctions of the lateral and main nerves.

2. *Liquidambar orientalis*, Miller. Asia Minor.

Shoots glabrous. Leaves small, five-lobed, margin with large lobules; under surface quite glabrous.

3. *Liquidambar formosana*, Hance. China, Formosa, Tonking.

Shoots pilose. Leaves large, usually three-lobed; under surface pilose, without conspicuous axil-tufts.

LIQUIDAMBAR STYRACIFLUA, SWEET GUM

Liquidambar styraciflua, Linnæus, *Sp. Pl.* 999 (1753); Loudon, *Arb. et Frut. Brit.* iv. 2049 (1838); Oliver, in Hooker, *Icon. Plant.* xi. 13 (1867); Sargent, *Silva N. Amer.* v. 10. t. 199 (1893), and *Trees N. Amer.* 340 (1905).

Liquidambar macrophylla, Oersted, *Am. Cent.* xvi. t. 10 (1863).

A tree, attaining in America 160 feet in height and 17 feet in girth. Bark deeply and longitudinally fissured, with broad ridges covered by thick corky scales.

Young shoots green, glabrous. Leaves (Plate 199, Fig. 7) large, averaging 6 inches broad and 5 inches long, variable in form, cordate or almost truncate at the base, five-nerved, palmately and deeply cut into five oblong-triangular acuminate lobes, the terminal lobe largest, the basal lobes smallest, rarely lobulate; serrations shallow, non-ciliate; upper surface dark green, shining, glabrous; lower surface light green, shining, glabrous except for dense tufts of pubescence in the axils of the nerves at the base and occasional minute tufts at the junctions of the lateral and main nerves. Petiole glabrous, slightly grooved on its upper side, dilated at the base, near which are two scars indicating where the lanceolate stipules have fallen off in early summer.

Fruiting heads, about 1½ inch in diameter, hanging on the tree during winter after the fall of the seeds in autumn, calyx margins with irregular small tubercles; capsules with two stout style appendages, forming woody spines, one terminating each valve. Perfect seeds few, with short terminal wing; imperfect seeds numerous, minute, angled, without wings.

The branchlets¹ of many trees of this species are remarkable for their corky wings, which begin to develop in the second season and increase in width and thickness for many years. These wings occur on lateral branches, on the upper side only, in three or four parallel ranks; but on vertical branches they are borne irregularly on all sides. Trelease² observed in the case of *Liquidambar* trees

¹ See Miss Gregory in *Botanical Gazette*, xiii. 282 (1888).

² *Garden and Forest*, 1890, p. 195.

growing in Tower Grove Park, St. Louis, that about half the trees either showed no sign of the corky wings or in some cases only a slight trace of them. In Kew Gardens the same difference is noticeable in trees of the same age growing close together, some being without corky-winged branchlets, while others have them much developed.

The leaves usually turn a most brilliant colour in autumn, the tint being red purple, or yellow.

IDENTIFICATION

In summer the maple-like but alternately-placed leaves are unmistakable. In winter (Plate 200, Fig. 2) the following characters are available: Twigs moderately stout, slightly angled, greenish, glabrous; lenticels scattered, prominent. Leaf-scars alternate, obliquely set on projecting pulvini, arcuate or semicircular, marked by three bundle-dots. Terminal bud about ½ inch long; lateral buds smaller, varying in size, and directed outwards from the twig at an angle of about 45°; all ovoid, acute at the apex, and composed of six to seven imbricated scales, which are green with brown margins, vaulted on the back, shining, glabrous, ciliate, and often minutely cuspidate at the apex.

Short shoots are numerous in this species, and, unlike the long shoots, are pubescent. All the shoots show at the base ring-like marks, indicating where the accrescent scales of the terminal bud of the preceding year have fallen off in spring.

VARIETIES

Though Oersted considered the Mexican and Guatemalan trees to constitute distinct forms, no varieties have been clearly made out. The species occurs over a wide extent of territory and in diverse climates; and certain differences are observable in the shape, size, and pubescence of leaves in wild specimens; but these scarcely warrant the division of the species into geographical forms. In dry regions in Mexico the under surface of the leaf is covered with dense pubescence. Leaves with only three lobes occur on adult trees in Mexico and Guatemala; but as three-lobed leaves are frequently borne on young shoots of the common form, this peculiarity scarcely merits the rank of a variety. (A. H.)

DISTRIBUTION

The *Liquidambar* or Sweet Gum,¹ as it is usually called in the United States, has a very wide range of distribution. Its most northerly station is, according to Sargent,² near Newhaven, Connecticut, where it only grows near the coast as a small tree, 40 to 60 feet high. Farther south it extends westwards as far as S.E. Missouri and Arkansas, and in the south to Florida and Texas, reappearing on the mountains of Mexico and Guatemala. In the maritime region of the South Atlantic States and in the Lower Mississippi basin it is one of the most abundant

¹ Also known as Red Gum.

² *Garden and Forest*, ii. p. 232.

forest trees, but only attains its full size and perfection in deep rich swamps and river bottoms. I have seen it of immense size in the Lower Wabash Valley in Southern Illinois, where Ridgway measured a tree no less than 164 feet high by 17 feet in girth with a clear stem 80 feet long, and another 137 feet high by 11½ feet in girth, which was 94 feet to the first branch. Plate 144 A, taken from a photograph for which I am indebted to the U.S. Bureau of Forestry, represents the tree (Example M) mentioned in *Proc. U.S. Nat. Mus.* v. 67, by Ridgway, which was 12½ feet in girth at the base, 78 feet to the first limb, and contained 7888 feet board measure. It grew two miles from Mount Carmel on land now cleared. Such trees, however, are now hardly to be found except in very inaccessible places. On the coast region of North Carolina, Ashe and Pinchot give its dimensions as 100 feet high and 5 or 6 feet in diameter.

The largest that I saw in the Eastern States was a tree in the Clifton Park, near Baltimore, which was 71 feet by 5 feet 9 inches. In New England, near Boston, Sargent says that it suffers from frost in severe winters, and I saw none in cultivation so large as those in England. I found it in a very different and more beautiful form in the mountains near Jalapa, Mexico, at about 4000 feet elevation, where in the month of March in open forests its leaves were conspicuous by their scarlet colour, but the trees were not of extraordinary dimensions. In America it grows mixed with *Nyssa*, *Liriodendron*, maples, and oaks. Ashe says that it fruits annually or every other year, but that much of the seed is abortive, and that it springs up commonly on damp hillsides and bottom lands, and also shoots from the stool after the trees have been felled.

HISTORY AND CULTIVATION

According to Loudon, this tree was first mentioned by Francis Hernandez, a Spanish naturalist, who published a work on the natural history of Mexico in 1651 at Rome. In 1681 it was sent home by Banister to Bishop Compton, who planted it in the Palace Gardens at Fulham. It had become common in cultivation in Michaux's time, but he says that even in France it had never produced seed. In Northern Italy it grows well, and I found a good-sized tree on the Isola Madre in Lake Maggiore, which bore seed, from which I have raised plants.

Though this tree will grow to considerable size in the warmest parts of England, and on account of its beautiful autumnal tints is highly ornamental, yet it requires a much greater degree of heat and moisture than our climate affords to bring it to perfection, and has been somewhat neglected by nurserymen on account of its tenderness when young. I have raised it from imported seeds, which do not keep well when extracted from the fruits, but the seedlings grow so slowly that the more common way of raising it is from layers. It does not transplant well, and requires a good deal of moisture in the soil and a warm, sheltered situation. Its branches are easily broken by the wind, and though it does not come early into leaf, is often injured by late frosts.

REMARKABLE TREES

The largest trees mentioned by Loudon were at Strathfieldsaye (64 feet) and at Syon (59 feet), the latter tree being reported in 1849 to measure 84 feet by 4 feet. We cannot identify either of them now; but at Syon there is a tree, leaning considerably to one side, which was about 75 feet by 6 feet in 1904. The tallest which I have seen is at Godinton, the property of G. Ashley Dodd, Esq., near Ashford, Kent, which in 1907 was 82 feet by 6 feet, a piece estimated at 12 feet long having been broken off the top; and the next to it is one at Petworth, which Sir Hugh Beevor measured in 1894, 84 feet by 5 feet 7 inches; another tree at the same place, 7 feet 6 inches in girth, has been damaged at the top by wind.

Miss Woolward tells me of a fine tree at Escot, Devonshire, the seat of Sir John Kennaway, which was referred to by Bunbury as the largest known to him, and in 1905 measured 75 feet by 7 feet 8 inches. At Cobham Hall, Kent, there is one which I measured as 80 feet by 5 feet 9 inches; and at Broom House, Fulham, there are two trees on the lawn of about the same height and over 6 feet in girth.

At Barton,¹ Suffolk, there are four trees, which were planted in 1825-26, the two largest measuring, in 1904, 71 feet by 5 feet 6 inches and 52 feet by 3 feet 2 inches. At Arno's Grove, Middlesex, a tree drawn up in a plantation, measured by Henry in 1904, was 83 feet by 3 feet 10 inches. A large tree which we have not seen was reported² to be growing on the lake side at Chevening Park, near Sevenoaks, Kent. At Arley Castle there is a tree 65 feet by 4 feet 3 inches.

In Scotland we have no records worth mentioning, though the species exists in the south-west.

In Ireland there is a good tree at Fota, which in 1903 measured 57 feet high by 8 feet in girth.

TIMBER

Though neglected until recent years this tree is now very largely cut for timber in the Mississippi valley, and has been introduced to Europe under the name of satin walnut. Owing to its low price it has been tried, under the name of red gum, for street paving with very bad results, though, according to Stone,³ it is very resilient, and if creosoted may be a useful wood for this purpose.

A careful investigation of the mechanical properties of this wood was made by A. K. Chittenden of the U.S.A. Bureau of Forestry in 1905,⁴ from which I take the following:—"Red Gum is perhaps the commonest timber tree in the hardwood bottoms and drier swamps of the Southern States, growing best on alluvial soil of great fertility, which is liable to heavy floods in winter and spring, and often covered with water from January till May. In the best situations it reaches a height of 150 feet and a diameter of 5 feet. It reproduces well only where there is sufficient light, as the seedlings will not bear shade. It also sprouts readily from the stump up to about fifty years of age, but such shoots rarely form large trees. The demand for

¹ Bunbury, *Arboretum Notes*, 28.

² *Garden*, xxxviii. 208 (1890).

³ *Timbers of Commerce*, 113 (1904).

⁴ *U.S. Dept. of Agriculture, Bureau of Forestry, Bulletin*, No. 58 (1905).

the timber has increased rapidly during the last few years, owing to the increasing scarcity of better timber, and about 75 per cent. of the best grades, 'Nos. 1 and 2 clear heart,' are exported to Europe for furniture and inside fittings. It is said to make very good flooring, and is now largely used for railway waggon box boards, the price in the U.S.A. being about 27 dollars per 1000 feet for firsts and seconds, as compared with 41 dollars for cypress. From 1900 to 1902 much of the wood was cut into 3-inch by 9-inch planks, to be used for cutting paving blocks in London, but in 1902 the market for this gave way, and the mills are now trying to introduce this wood as a paving-block material in the United States, where several large cities were in 1905 considering the use of this wood. The qualities necessary for a good paving block are durability, close grain, and the power of resisting abrasion. These qualities are found in red gum."

A very unfortunate experiment was made in Whitehall in the autumn of 1901, when the Corporation of Westminster accepted the tender of an American contractor to pave this street with "red gum." The surveyor seems to have supposed that red gum in America was the same as red gum in Australia, where the name is applied to several species of eucalyptus, which have a good reputation for street paving. Be this as it may, the paving wore out so soon that a large proportion was taken up again in July 1902, and a long and costly lawsuit followed. The contractor alleged (1) that the defects arose from the bad foundations of the road; (2) from excessive watering; (3) from stones having been forced into the pavement; and the case was not finally settled till October 1905.

Mr. Weale tells me that an inferior quality of this wood containing much sapwood is also known in the trade as "hazel pine." "Satin walnut" is worth wholesale from 2s. to 2s. 3d. per cube foot, and "hazel pine" only 1s. 3d. to 1s. 6d. In colour the former is a light fawn, often marked with a rich dark stripe; but is so deficient in strength and durability, and even when well seasoned is so liable to warp and twist, that it is only used for the cheapest classes of furniture.

Michaux says that though much inferior to black walnut and cherry, it was used a good deal in his time in America for picture-frames, bedsteads, coffins, and furniture. Red gum is now much used for veneer in the United States. It furnishes 17 per cent of all the veneer produced, the quantity in 1905 being over 187 million square feet.¹ I brought from St. Louis a slab of this timber cut from a tree of 30 inches diameter, of which the sapwood was about 6 inches thick and much paler in colour. Though cut 4 inches thick this plank cracked badly in drying; and it will evidently be a very difficult wood to dry without warping. It has a very close, fine grain, and takes a good polish.

(H. J. E.)

¹ U.S. Dept. Agric. Forest Service Circular, No. 51 (1906).

LIQUIDAMBAR ORIENTALIS

Liquidambar orientalis, Miller, *Gard. Dict.* No. 2 (1768); Oliver, in Hooker, *Icon. Plant.* xi. 13, t. 1019 (1867); Hanbury, *Science Papers*, 139, with figure (1876); Bentley and Trimen, *Medicinal Plants*, ii. No. 107, t. 107 (1880).

Liquidambar imberbe, Aiton, *Hort. Kew.* iii. 365 (1789); Loudon, *Arb. et Frut. Brit.* iv. 2053 (1838).

A tree attaining in Asia Minor 40 to 60 feet in height. Bark longitudinally fissured, with corky irregularly quadrangular scales on the ridges, the orange-coloured inner bark visible in the fissures. Young shoots glabrous. Leaves (Plate 199, Fig. 6) small, averaging 3 inches wide by 2½ inches long, palmately cut about half-way into five oblong triangular acute lobes, the upper three lobes usually with one to four lobules; base truncate or widely cordate; margin with shallow glandular serrations; upper and lower surfaces quite glabrous in cultivated trees, but with axil tufts of pubescence at the base of the under surface in wild specimens. Petiole glabrous, swollen at the base, and bearing near its insertion two minute triangular stipules.

Flowers and fruit similar to those of *Liquidambar styraciflua*, but smaller. Fruiting head about 1 inch in diameter; capsules with more slender beaks than in the preceding species; calyx slightly tuberculate and not spiny.

In winter the twigs resemble those of the American species, but are more slender, with smaller leaf-scars and buds, which are reddish and have six glabrous ciliate scales; short shoots glabrous.

This species does not apparently develop corky ridges on the branches.

DISTRIBUTION

Liquidambar orientalis is known to occur wild only in the south-western part of Asia Minor lying opposite to the island of Rhodes, and in Cilicia, near Alexandretta. It forms woods of considerable extent in the district of Sighala, near Melasso, and in the vicinity of Budrum, Mughla, Djova, Ughla, Marmoriza, and Isgengak. According to Maltass, who obtained specimens for Hanbury, there is a fine forest of this species between the village of Caponisi and the town of Mughla, many trees attaining 40 feet in height, while in other forests, according to native report, they were as high as 60 feet.¹

Liquid storax, a balsamic resin, obtained from the inner bark of the tree by boiling it in water, is exported in considerable quantity from Smyrna and other Levantine ports, the bulk of this product going to China and India, where it is known in commerce as rose maloes.² Liquid storax is used to a small extent by druggists in this country, and is one of the ingredients of "Friar's Balsam."

¹ Elwes passed through this district in 1874 on the way from Makri to Ephesus, but saw no trees of any size. This is a very hot country in summer, myrtle, oleander, and arbutus being the common shrubs.

² Rose maloes is a corruption of rassamala, the Javanese and Malay name for *Altingia excelsa*, Noronha, a tree allied to *Liquidambar*, which yields by incisions in the bark a sweet-scented resin. Cf. Bretschneider, *Bot. Sincum*, iii. 464 (1895).

CULTIVATION

The Oriental Liquidambar was introduced into France about the middle of the eighteenth century by the French Consul at Smyrna, and speedily passed into England, where it was cultivated in 1759 by Miller.

It grows very slowly in this country, where it is very rarely seen in cultivation. There is a tree in Kew Gardens, about 15 feet high, the age of which is unknown. According to Nicholson it was 10 feet high in 1884. It has a twisted, crooked trunk, dividing about 6 feet up into two main stems. The branches are numerous and drooping, the habit of this tree being in marked contrast to that of a tall *Liquidambar styraciflua* close beside it, and probably results from the young branchlets being continually killed by the frost.

A larger and very old tree at White Knights, near Reading, in the grounds of Mr. J. Heelas, was in 1904 about 25 feet high by 3 feet 4 inches in girth, and was decayed at the top, with many dead branches and a hole in the butt close to the ground.

This tree is commonly cultivated in the Mediterranean region; and Mr. Hickel, Inspector in the French Forest Service, informs us that there is a very large specimen, rivalling in size the American species, in the square near the railway station at Montpellier. In the park at Baleine¹ (Allier) there is a tree 75 feet high by 7 feet in girth.

Elwes measured a tree in the Jardin des Plantes, Paris, which was 40 feet high; but was told that it did not ripen seed; and in the Botanic Garden at Padua he saw a tree about 50 feet high by 4 feet in girth, which in May had abundant fruit of the preceding year upon it, but could find no seeds in them. (A. H.)

LIQUIDAMBAR FORMOSANA

Liquidambar formosana, Hance, *Ann. Sc. Nat. 5^{me} série*, v. 215 (1866), and *Journ. Bot.* 1870, p. 274; Oliver, in Hooker, *Icon. Plant.* xi. 14, t. 1020 (1867); Hemsley, *Journ. Linn. Soc. (Bot.)* xxiii. 291.

Liquidambar acerifolia, Maximowicz, *Mél. Biol.* vi. 21 (1866) and viii. 419 (1871).

Liquidambar Maximowiczii, Miquel, *Ann. Mus. Bot. Lugd. Bat.* iii. 200 (1867).

A tree² attaining, in China, 80 feet in length and 15 feet in girth. Young shoots with scattered long hairs. Leaves (Plate 199, Fig. 8) widely cordate at the base, usually with three broad oblong-triangular acute or acuminate lobes, the outer lobes occasionally giving off two short additional lobes; margin, occasionally lobulate, sharply serrate, ciliate; palmately three-nerved with two strong lateral nerves; upper surface dull with scattered long hairs; lower surface light green

¹ Pardé, *Arbor. Nat. des Barres*, 205, note 1 (1906).

² The peculiarities of the buds, leaves, and stipules have been fully described by Lubbock, in *Journ. Linn. Soc. (Bot.)* xxx. 495 (1894).

with dense long pubescence. Petiole pilose, with two subulate, persistent, pubescent, glandular stipules.

Fruiting heads spiny, 1½ inch in diameter, each capsule surrounded by several long spines arising from the calyx, and resembling the two indurated styles which terminate the valves. Perfect seeds few, or absent in many capsules, with narrow short wings.

This species is widely distributed over the central and southern provinces of China, and occurs also in Tonking, Hainan,¹ and Formosa. In Hupeh, where it has not been seen over 1000 feet altitude, the tree is valuable, as its timber is used for making the Hankow tea-chests. The Chinese call it Fêng tree.²

It is doubtful if it will prove hardy, and is extremely rare in cultivation in Europe, the only plant known to us being one in Kew gardens, which is trained against a wall, and is interesting for its beautiful foliage, which lasts till late in November. It was introduced by seeds sent by Consul Alabaster from Hankow in 1884. (A. H.)

¹ Swinhoe, *Journ. Bot.* i. 257, says it is the commonest tree in the mountain forests of Hainan. Hance, *loc. cit.*, says that at Canton old stumps buried beneath the soil sucker freely.

² It yields a resin, *Fêng-hsiang*; and a caterpillar, which feeds on its leaves, produces a coarse kind of silk, used for fishing-lines.

Agathisanthes, Blume, *loc. cit.* 645.
Daphniphylopsis, Kurz, *Journ. Asiat. Soc.* 1875, ii. 201.

DECIDUOUS trees or shrubs belonging to the order Cornaceæ. Leaves alternate simple, stalked, with margin entire or remotely one- to four-toothed, without stipules. Branchlets with discoid pith.

Flowers small, diœcious or polygamous, borne at the summit of axillary peduncles, the staminate flowers numerous in heads, umbels, or short racemes, the pistillate and perfect flowers solitary or aggregated in two- to eight-flowered heads, umbels, or short racemes. Staminate flowers: calyx short, flat or cup-shaped, five- to seven-toothed or entire; petals five to seven or ten to fourteen; stamens five to ten, inserted on the margin of an entire or lobed disc; filaments slender, anthers oblong. Pistillate flowers: calyx campanulate or urceolate, five-toothed or entire; petals four to five, seldom three or six to eight; stamens absent or equal in number to the petals and alternating with them, bearing fruitful or barren anthers; ovary coalesced with the receptacle, crowned above by a disc, one- rarely two-celled, one ovule in each cell; style one, recurved, stigmatic along one side near the apex. Fruit a drupe, oblong or ovoid, urceolate at the apex; flesh thin, oily; stone bony, thick-walled, terete or compressed, ridged or winged, one- or rarely two-celled, containing one seed, which has a membranous testa and copious albumen. Cotyledons flat and leafy.

The alternate stalked simple leaves, entire and ciliate in margin; and the branchlets with true terminal buds, without stipules or their scars, showing on section the peculiar discoid pith, are characteristic of *Nyssa*.

Seven species of *Nyssa* have been described:—*Nyssa sessiliflora*, Hooker, a tree attaining 60 feet in the Himalayas and Java; has not been introduced and would probably not be hardy in England. *Nyssa sinensis*, Oliver, has recently been introduced from Central China. The remaining five species are natives of Eastern North America. *Nyssa acuminata*, Small, a species imperfectly known, is a small shrub growing in pineland swamps in Georgia. *Nyssa Ogeche*, Marshall, a tree of moderate size, occurring in river swamps in South Carolina, Georgia, and Florida, is unknown in cultivation outside of its native home, and would probably not grow in England.

Nyssa biflora, Walter, a small tree, growing in ponds, from North Carolina to

Louisiana, is probably only a variety of *Nyssa sylvatica*, Marshall; and no trees referable without doubt to it are known to us in England. *Nyssa sylvatica*, Marshall, and *Nyssa aquatica*, Marshall, occur rarely in cultivation in England.

NYSSA SYLVATICA, TUPELO, PEPPERIDGE, BLACK GUM

- Nyssa sylvatica*, Marshall, *Arbust. Am.* 97 (1785); Sargent, *Silva N. Amer.* v. 75, t. 217 (1893), and *Trees N. Amer.* 707 (1905).
Nyssa multiflora, Wangenheim, *Nordam. Holz.* 46, t. 16, f. 39 (1787).
Nyssa villosa, Michaux, *Fl. Bor. Am.* ii. 258 (1803); Loudon, *Arb. et Frut. Brit.* iii. 1317 (1838).

A tree, occasionally attaining in America 100 feet in height and 15 feet in girth. Bark thick and deeply fissured longitudinally. Young shoots glabrous or with short, erect pubescence. Leaves (Plate 199, Fig. 2, leaf from a tree in Arnold Arboretum, U.S.; and Fig. 9, leaf from a tree at Kew) extremely variable in shape and size, obovate, oval or elliptical; base tapering or rounded, apex acuminate or acute, margin entire or repand and ciliate; upper surface glabrous, dark green, usually shining; lower surface glabrous or with slight pubescence on the midrib and principal veins. Petiole channelled or winged, glabrous or pubescent, $\frac{1}{4}$ to 1 inch long. Flowers on pubescent peduncles, appearing after the leaves; staminate flowers numerous, stalked and in crowded clusters; pistillate flowers sessile, two to fourteen in a head. Fruit ovoid, bluish-black, $\frac{1}{3}$ to $\frac{2}{3}$ inch long; stone terete or more or less flattened, with ten to twelve indistinct ribs.

Seedling.—The caulicle, glabrous, terete, and about 2 inches long, ends in a long flexuose whitish tap-root, which gives off numerous lateral fibres. The cotyledons are ovate-lanceolate, rounded at both base and apex, about $1\frac{1}{2}$ inch long by $\frac{5}{8}$ inch broad, on petioles $\frac{1}{8}$ inch long, slightly coriaceous, entire in margin, pale beneath, glabrous, pinnately veined. The stem, reddish and pubescent, gives off alternately the true leaves, which are oval, with a cuneate base and acuminate apex, entire or one- to two-toothed and ciliate in margin, pale and glabrous on the under surface with the exception of some pubescence at the base of the midrib, and with a pubescent petiole. The preceding description was drawn up in the summer of 1905, from a seedling at Colesborne, raised from seed gathered by Elwes at Boston at the end of the preceding September.

IDENTIFICATION

Nyssa sylvatica, with leaves quite glabrous or pubescent only on the midrib and principal veins beneath, is readily distinguishable from *Nyssa aquatica*, with leaves grey and pubescent all over the under surface, and with one or two teeth often on the margin. *Nyssa sinensis*, which resembles in foliage *Nyssa sylvatica*, is distinguished by the appressed pubescence of the shoots.

In winter *Nyssa sylvatica* (Plate 200, Fig. 5) shows the following characters:—

Twigs slender, glabrous, or with slight pubescence near the tip only; stipule-scars absent. Leaf-scars small, crescentic, set somewhat obliquely on slightly prominent pulvini, surrounded by a narrow raised rim, marked with three bundle dots. Buds conical, pubescent, and acute; scales five or six, imbricated, pubescent, ciliate, reddish or greenish; terminal bud larger than the lateral buds which arise at an angle of about 45° . Pith solid, but interrupted by transverse woody partitions, showing on longitudinal section a ladder-like appearance.

The inner scales of the bud are accrescent; and the base of the shoot is marked by ring-like scars, indicating where these scales have fallen off in the preceding spring.

VARIETIES

This species is extremely variable in leaf, both in wild specimens and cultivated trees. This is well shown in the Strathfieldsaye tree, the leaves of which vary from a long elliptical acuminate to a short broad obovate obtuse outline; some are quite glabrous, whilst others are pubescent on the midrib and principal veins beneath. Usually the leaves are very shining above and coriaceous; but in a tree growing at Kew in a wood, they are dull above and thin in texture. In some specimens there are numerous glands on the under surface of the leaf; whilst in others, as in a specimen growing in the Arnold Arboretum collected by Elwes, no glands are visible. The fruit is also variable, being either terete or flattened. The tree occurs in America in very diverse stations, both on wet soils and on dry mountain slopes; and this may explain the remarkable extent of its variation.

Var. *biflora*, Sargent, *Silva N. Amer.* v. 76, t. 218 (1893).

Nyssa biflora, Walter, *Fl. Carol.* 253 (1788); Loudon, *Arb. et Frut.* iii. 1317 (1838); Sargent, *Trees N. Amer.* 709 (1905).

Leaves smaller than in the type, very narrow, glabrous and glandular beneath, quite entire in margin. Fruit with an oval, flattened stone, narrowed at both ends and prominently ribbed. This variety is a small tree, rarely more than 30 feet high, growing in ponds on the pine barrens near the coast from N. Carolina to Louisiana. It usually has a trunk with a swollen base, and appears to be a form of the species which has adapted itself to life in water.

The cultivated trees mentioned by Loudon as being *Nyssa biflora* were all probably *Nyssa sylvatica* of the typical form. (A. H.)

DISTRIBUTION

Nyssa sylvatica is found in North America from Southern Ontario, where it grows to a good size near Niagara, and in New England, where I saw it in the neighbourhood of Boston 60 or 70 feet high, westwards to Central Michigan and South-Eastern Missouri, and southwards to Florida and Texas. It attains its largest size, according to Sargent, in the southern Appalachian Mountains, growing as high as 100 feet with a maximum girth of about 15 feet.¹ It is found generally in wet soil on

¹ But Ridgway measured a black gum in Wabash Valley, 125 feet high by 13 feet in girth, and 64 feet to the first limb.

the borders of swamps; but in the south grows also on high wooded mountain slopes. It is very variable in form, sometimes branching close to the ground; but oftener has a stout straight trunk, covered with light brown deeply furrowed bark, which is often curiously divided into hexagonal scales. Plate 144 B shows the trunk of a tree in America. The upper branches are twiggy and usually crooked. The glossy green leaves are rarely disfigured by fungi or insects, and turn to deep red in autumn. An excellent illustration of a group of trees growing near a pond in Massachusetts is given in *Garden and Forest*, iii. 491, which resemble in habit the Siberian or Japanese larch; and this is the form which the trees often assume in low swampy ground in New England. Another figure in the same journal, vii. 275, fig. 46, shows the habit of a tree growing in drier ground in Pennsylvania.

CULTIVATION

Nyssa sylvatica was in cultivation at Whitton, near Hounslow, in 1750. It is, when well grown, a very distinct and beautiful tree, the brilliant scarlet assumed by its leaves in autumn rendering it a very desirable ornament for the park or pleasure ground.

Sargent says that one reason why this tree is not more generally planted is that its long roots with few rootlets make it difficult to transplant, and that it must be either planted out when quite young or frequently transplanted in the nursery. Those which I have raised from seed grew slowly the first year, but seemed to ripen their young wood better than many American trees. When pricked out singly into pots in the following spring they all died.

We have seen very few specimens in this country, the only one of great size being the tree¹ at Strathfieldsaye, which measured in 1897 74 feet high by 5 feet 5 inches in girth. It grows on rather heavy soil. This tree was reported by Loudon to be about 30 feet high in 1838, and is probably over 100 years old (Plate 145). It produced seed in 1906 which appeared to be mature.

There is a tree at Munden, near Watford, the seat of the Hon. A. Holland Hibbert, which has a short bole of $4\frac{1}{2}$ feet long with a girth of 3 feet 3 inches, dividing into two stems, the branches of which are very spreading, forming a crown of foliage 38 feet in diameter; the total height is only 20 feet. Mr. Daniel Hill of Watford, who kindly sent these measurements, says that the fork has been leaded over; and it is possible that the tree lost its leader early from some accident, and in consequence subsequently assumed its present peculiar habit.

At White Knights, near Reading, there was a large tree of this species which was cut down some years ago; and there are now many suckers arising from the roots.² There is another tree at Bicton about 35 feet high by $3\frac{1}{2}$ feet, which in August 1906 had full-sized fruit upon it which seemed likely to ripen.

¹ The girth of this tree given in *Gard. Chron.* xxvi. 162 (1899), is evidently erroneous, 14 feet $10\frac{1}{2}$ inches being a misprint for 4 feet $10\frac{1}{2}$ inches.

² Schenck, in *Biltmore Lectures on Sylviculture*, 56 (1905), says that in the forest old trees are often surrounded by an abundance of seedlings; but on abandoned fields it seems to come up from sprouts and not from seeds.

There are three small trees in Kew Gardens, the largest about 20 feet high, growing in a densely wooded part close to the Arboretum Nursery.

A tree growing in the garden at Harpton in Radnorshire, at an elevation of 700 feet above sea-level, was in 1905 27½ feet high by 2 feet 8 inches in girth. The owner, Sir Herbert E. F. Lewis, Bart., who kindly sent us particulars, has not noticed during the last forty years any considerable increase in the size of this tree. Its leaves turn bright yellow in autumn.

TIMBER

The wood seems to be unknown in commerce, and is not mentioned by any of the English writers, but Sargent says it is very durable under water and used for keels of boats, and being extremely difficult to split, is also used for yokes, rollers, wheel-hubs, and pumps. Sections of it in Hough's *American Woods*, Pt. I. No. 9, show a pale or reddish-brown wood of very close texture, somewhat resembling sycamore in appearance.

(H. J. E.)

NYSSA AQUATICA, COTTON GUM, TUPELO GUM

Nyssa aquatica, Marshall, *Arbust. Am.* 96 (1785); Linnæus, *Sp. Pl.* 1058 (*ex parte*) (1753); Sargent, *Silva N. Amer.* v. 83, t. 210 (1893), and *Trees N. Amer.* 711 (1905).

Nyssa uniflora, Wangenheim, *Nordam. Holz.* 83, t. 27, f. 57 (1787).

Nyssa denticulata, Aiton, *Hort. Kew.* iii. 446 (1789).

Nyssa tomentosa, Michaux, *Fl. Bor. Am.* ii. 259 (1803).

Nyssa angulisans, Michaux, *loc. cit.*

Nyssa grandidentata, Michaux f., *Hist. Arb. Am.* ii. 252, t. 19 (1812); Loudon, *Arb. et Frut. Brit.* iii. 1319 (1838).

A tree, attaining in America 100 feet in height, with a trunk 12 feet in girth above the greatly enlarged base. Bark thick, longitudinally fissured, and roughened on the surface by small scales. Young shoots pubescent towards the tip, becoming glabrous below in summer. Leaves (Plate 199, Fig. 10) elliptical or ovate-oblong, base rounded or tapering, apex long-acuminate; margin entire or repand, ciliate, often with one to three or more triangular teeth, usually ending in a bristle; upper surface dark green, glabrous; lower surface greyish in colour and with a scattered, fine pubescence; petioles more or less pubescent, 1 to 1½ inch or more in length.

Flowers on long, slender, pubescent peduncles: staminate flowers pedicellate in dense clusters, with a cup-shaped, obscurely five-toothed calyx and oblong short petals rounded at the apex; pistillate flowers solitary, with long, tubular calyx, ovate minute spreading petals, and included stamens with small mostly fertile anthers. Fruit solitary, on long, drooping stalks, oblong, dark purple, about an inch long; stone obovate, rounded at the apex, pointed at the base, flattened, with about ten wing-like ridges.

IDENTIFICATION. (See under *Nyssa sylvatica*)

In winter, specimens from the tree at White Knights showed the following characters:—Twigs stout, pubescent near the tip, glabrescent elsewhere. Leaf-scars slightly oblique on prominent pulvini, almost orbicular or obcordate, notched in the upper margin, surrounded by a slightly raised rim, and marked by three conspicuous bundle-dots. Lateral buds minute, globose, two-scaled, reddish, shining, glabrous, arising in the notch of the leaf-scar. Terminal buds nearly globose, short and broad, with four to five thick, pubescent, reddish scales, keeled on the back and apiculate at the apex; in December the three outermost scales had dropped the apiculus and showed a truncate apex with a terminal scar. The base of the shoot is marked by ring-like scars as in *Nyssa sylvatica*.

DISTRIBUTION

Nyssa aquatica is found growing in swamps throughout the coast region of the United States, from Southern Virginia to Texas, and in the Mississippi valley, in Arkansas, Southern and South-Eastern Missouri, Western Kentucky, and Tennessee, and in the valley of the lower Wabash River in Illinois.

An interesting account of the peculiar habit of this tree, as observed in the swamps of Arkansas, is given by Coulter.¹ Occurring in company with *Taxodium distichum*, wherever the ground is inundated with water, the trunk develops an enlarged, dome-like base, often of immense size. A tree only 45 feet high, of which a figure is given, had a swollen base 55 feet in girth at the point where the roots entered the ground. When the water-supply is scanty the base is only slightly enlarged; and trees growing in dry soil show no swelling of the trunk. Coulter saw numerous seedlings of *Nyssa*, and concludes that it is gradually ousting from the swamps the Deciduous Cypress, which rarely seeds itself. Wilson² states that around the swollen base of these trees in the swamps there are masses of roots extending 6 to 8 inches above high-water line, each root going vertically up out of the water, and after a sharp bend going down into the water again. He compares these roots, rising above the water for purposes of aeration, with the knees of *Taxodium*.

CULTIVATION

Nyssa aquatica was cultivated³ by Collinson near London in 1735. It is now scarcely known in cultivation in England, the only tree which we have found being one at White Knights Park, Reading, the residence of T. Friedlander, Esq. It is a slender tree, about 36 feet by 2 feet 2 inches, which looks of considerable age and is not vigorous in growth. Loudon⁴ states that most of the trees which he saw at White Knights in 1833 were planted between 1790 and 1810; and one was a fine specimen⁵ of *Nyssa aquatica*, perhaps identical with the tree now living.

¹ *Report Missouri Bot. Garden*, 1904, xv. 56, plates 18, 19.

⁵ This tree is not referred to by Loudon in his large work, published in 1838.

514 The Trees of Great Britain and Ireland

Michaux states that it endures the climate of Paris, and does not exact in Europe as moist a soil as it constantly requires in the United States. (A. H.)

TIMBER

According to Holroyd,¹ it has only recently been possible to market the timber of this tree, and under a fictitious name, so great has been the prejudice against this and others known as gums. Formerly when lands bearing tupelo and cypress were logged, the cypress alone was taken, and tupelo trees from 2 to 3 feet in diameter were left, because the lumbermen considered them to be worthless. At present, however, tupelo timber is extensively cut in Alabama, near Mobile, as well as in Southern and Central Louisiana. The best grades closely resemble the Yellow Poplar (*Liriodendron*). The wood has a fine uniform texture, is moderately hard and strong, not elastic, but very tough and hard to split, and easy to work with tools. It is not durable in contact with the ground, and requires much care in seasoning. It is now extensively used for house flooring and indoor finish. Mr. Weale informs me that it has a tendency to warp and split which cannot be prevented by any known process of seasoning; and only a small quantity has as yet been imported to England, in the form of boards, which are worth from 1s. 9d. to 2s. per cubic foot, and are used by the makers of cheap furniture. But he thinks that if it was sent in boards as well planed as those of the so-called Hazel Pine, it would be more attractive, and its consumption would increase.

(H. J. E.)

NYSSA SINENSIS, CHINESE TUPELO

Nyssa sinensis, Oliver, in Hooker, *Icon. Plant.* t. 1964 (1891).

A tree, attaining in China 40 feet in height. Young shoots covered with a dense appressed white short pubescence, retained in the second year. Leaves (Plate 199, Fig. 1) elliptical, base tapering, apex acuminate, margin entire and ciliate; upper surface dull, dark green, and glabrous except for some slight pubescence on the midrib towards the base; lower surface light green, shining, pilose on the midrib and chief veins and occasionally on the veinlets; petiole, $\frac{1}{4}$ to $\frac{3}{8}$ inch long, pilose.

Flowers, on long slender axillary peduncles, pedicellate, crowded in racemose clusters. Staminate flowers with a minute calyx, narrow oblong petals, and five to ten stamens on a fleshy disc. Pistillate flowers imperfectly known, but with bifid style and glabrous ovary. Fruit in clusters of about three, on short pedicels at the ends of long (two to three inches) erect or ascending pubescent peduncles; oblong, bluish, $\frac{3}{8}$ inch long; flesh scanty; stone with ten inconspicuous longitudinal ribs.

This is a rare tree, occurring in mountain woods in Central China, in the western part of Hupeh, and on the Lushan Mountains, near Kiukiang, in Kiangsi.² It was discovered by me in 1888, and was subsequently found by Mr. E. H. Wilson, who sent home seed to Messrs. Veitch in 1902, from which a single plant has been raised at Coombe Wood, where it is perfectly hardy so far. (A. H.)

SASSAFRAS

Sassafras, Nees ab Esenbeck u. Ebermaier, *Handb. Med. Pharm. Bot.* i. 418 (1830); Bentham et Hooker, *Gen. Pl.* iii. 160 (1880).

DECIDUOUS trees belonging to the order Lauraceæ, with alternate pinnately-veined simple leaves without stipules. Flowers diœcious or rarely perfect, in few-flowered racemes in the axils of bud-scales at the ends of the previous year's shoots. Calyx six-lobed, the lobes in two series, imbricated in bud; petals absent. Staminate flowers; stamens nine in three series, the three inner ones each with two stalked glands at the base; anthers opening with four valves. Pistillate flowers with flattened ovate pointed or slightly two-lobed staminodes, or occasionally with fertile stamens like those of the male flowers; ovary ovoid, glabrous, superior, one-celled; ovule solitary, suspended; one style elongated with a capitate stigma. Fruit an oblong-ovoid, one-seeded dark-blue berry, surrounded at the base by the enlarged and thickened calyx-limb, and supported on pedicels much thickened above the middle.

The genus comprises only two species, one occurring in North America and the other in China.

SASSAFRAS TZUMU, CHINESE SASSAFRAS

Sassafras Tzumu, Hemsley, in *Kew Bull.* 1907, p. 55, and in Hooker, *Icon. Plant.* t. 2833 (1907).
Litsea laxiflora, Hemsley, *Journ. Linn. Soc. (Bot.)* xxvi. 383, t. 8 (1891).
Lindera Tzumu, Hemsley, *op. cit.* 392 (1891).

This species grows sparingly in China in mountain woods at 3000 to 5000 feet elevation, south-west of Ichang, in the province of Hupeh; near Kiukiang in Kiangsi; and inland from Ningpo in Chekiang. It attains a height of 50 feet and yields a timber esteemed by the mountaineers, who call it the *tzu-mu* or *huang ch'iu* tree. Resembling very closely the American species in the characters of the foliage and inflorescence, it was considered by Prof. Sargent¹ and Mr. E. H. Wilson to be indistinguishable. Mr. Hemsley, however, points out certain differences in the floral organs, which entitle it to rank as a distinct species. The flowers are slightly smaller than those of the American tree, and are pubescent within and not glabrous as in that species. The male flowers have three staminodes alternating with the glandular row of stamens and a prominent pistillode, which are wanting in *Sassafras*

¹ *Trees N. Amer.* 336 (1905).

officinale. The female flowers have twelve staminodes in three rows of six, three, and three; only six staminodes in two rows of three each occurring in the American species.

There is a tree of this species, 10 feet high, growing in the Coombe Wood nursery, which was raised from seed sent by Wilson in 1900. It has made wonderful growth during the past summer, and is very handsome. It differs from the American species in having glabrous non-ciliate leaves, which are very lustrous on the upper surface; and the young branchlets are also devoid of pubescence.

SASSAFRAS OFFICINALE, SASSAFRAS

Sassafras officinale, Nees ab Esenbeck u. Ebermaier, *loc. cit.*; Bentley and Trimen, *Medicinal Plants*, iii. 220 (1880).

Sassafras Sassafras, Karsten, *Pharm. Med. Bot.* 505 (1882); Sargent, *Silva N. Amer.* vii. 17, tt. 304, 305 (1895), and *Trees N. Amer.* 337 (1905).

Sassafras variifolium, O. Kuntze, *Rev. Gen. Pl.* ii. 574 (1891); Sargent, in *Bot. Gazette*, xlv. 226 (1907).

Laurus Sassafras, Linnæus, *Sp. Pl.* 371 (1753); Loudon, *Arb. et Frut. Brit.* iii. 1301 (1838).

A tree, attaining in America 90 feet in height and 18 feet in girth. Bark,¹ according to Sargent, dark red-brown, deeply and irregularly divided into broad scaly ridges. Young shoots green or reddish, pubescent when young, becoming glabrous, remaining green in the second year. Leaves (Plate 199, Fig. 5) deciduous, entire, or two- to three-lobed; the entire leaves oval with an obtuse apex and cuneate base; the others obovate, with a large triangular or oblong lobe on one or both sides, directed forwards and outwards; margin entire or repand, ciliate; upper surface dark green with a scattered short pubescence; lower surface pale with a long pubescence, often falling by the end of summer; petiole, 1 to 2 inches long, pubescent. The nerves are pinnate, the two lowest arising near the base of the leaf, running nearly parallel with the margin, and ending in the lobes when these are present.

Berry² gives an account with illustrations of the extraordinary variation which occurs in the leaves of wild trees growing in America. He has found leaves with four, five, and even six lobes.

SEEDLING

Out of some seed gathered by Elwes at the Arnold Arboretum late in September and sown at Colesborne in October 1904, only one germinated in the following June, and the seedling showed the following characters in August:—The cotyledons remain in the seed-case, the young stem emerging between them after the splitting of the seed into two halves. The terete glabrous and reddish stem first gives off alternately two minute scales, which are succeeded by true leaves; the first, $\frac{1}{2}$ inch long, arising $1\frac{1}{2}$ inch above the ground, is half-oval in shape, one side of the leaf

¹ In cultivated trees in England the bark is grey and fissured into longitudinal narrow ridges.

² *Bot. Gazette*, xxxiv. 426 (1902).

being scarcely developed, entire in margin, and on a short stalk about $\frac{1}{3}$ inch long. The second leaf, $\frac{3}{4}$ inch long, is obovate-spathulate, entire in margin, very unequal-sided, rounded at the apex, and tapering at the base. Succeeding leaves (six in all being produced by August) are oval, $1\frac{1}{2}$ to $2\frac{1}{2}$ inches long, stalked, unequal-sided, pinnately-veined, slightly undulate in margin; pale green and glabrous, with a raised midrib beneath.

IDENTIFICATION

In summer Sassafras is readily distinguishable by the aromatic leaves of different shapes, entire and two- to three-lobed, and by the branchlets, without stipules or their scars, remaining green for two or three years. In winter (Plate 200, Fig. 6) the following characters are available:—Twigs glabrous, green, shining, brittle, and strongly aromatic in odour when broken; lenticels few and inconspicuous; pith wide and mucilaginous. Leaf-scars alternate, oblique on prominent pulvini, very small, semicircular with a raised rim, and showing a transverse band of minute coalesced bundle-dots. Terminal buds ovoid, with a long sharp beak; external scales, four to five, imbricated, slightly pubescent, ciliate, green, often ridged or veined. Lateral buds minute, arising from the twigs at about an angle of 45° . Base of the shoot marked by ring-like scars, indicating where the scales of the previous season's terminal bud have fallen off. (A. H.)

DISTRIBUTION

Sassafras occurs usually in rich, sandy, well-drained soil; and is widely spread in the eastern half of the United States, crossing into Canada in Southern Ontario. The northern limit passes through the southern parts of Maine, Vermont, and Ontario to Central Michigan, whence the western limit is continued through Eastern Kansas and the Indian Territory, to the valley of the Brazos river in Texas. On the eastern side it extends from Maine to Central Florida. In the South Atlantic and Gulf States it often takes possession of abandoned fields.

In America the tree is very handsome at all seasons of the year, the light green foliage of summer turning delicate shades of yellow, orange, and red in autumn. The fruit, which is abundantly produced in some years, is showy, the berries dark blue in colour contrasting with the scarlet cups in which they sit. The tree produces root-suckers very freely.

In New England the Sassafras does not often become a tree of considerable size. Emerson¹ states that it rarely reaches 30 feet in height by a foot in diameter, and Michaux says that near Portsmouth, N.H., it is only a tall shrub rarely exceeding 15 to 20 feet high. But near Boston it sometimes grows much larger, and Emerson mentions one which grew at West Cambridge in 1842, and measured nearly 60 by 8 to 9 feet, with a clean straight stem 30 feet long. This tree was felled in order, as he says, "to allow a wall to run in a straight line." But such vandalism as this, which a generation ago was common in New England, is now disappearing; and great care is taken of the few surviving old trees of the original forest. Tree

¹ *Trees and Shrubs of Massachusetts*, p. 359.

wardens are appointed in most parishes, who are often ladies; and I am indebted to one of the most enthusiastic and active of them, Miss Emma G. Cummings of Brookline, Mass., for showing me some of the large Sassafras trees which still survive in the suburbs of Boston. These form a group on a slope on the south side of Covey Hill, the smallest being 6 feet in girth, and the largest 9 feet 7 inches and over 50 feet high. But these are far inferior to the trees in the forests of the south and west, where Ridgway measured, in the Wabash valley, a Sassafras 95 feet high by $7\frac{1}{2}$ in girth, and where, he says, it sometimes attains 12 feet in circumference.

CULTIVATION

The Sassafras was one of the earliest American trees introduced into England, having been cultivated in 1633 in a garden near London.¹ The tree is propagated by seeds, which should be sown as soon as ripe, and by suckers and root-cuttings. When large it is difficult to transplant, as the thick fleshy roots are scantily provided with rootlets.

Cobbett,² who gave an interesting account of the Sassafras, and was very enthusiastic in its praise, found that the seeds rarely if ever come up in the first year, and apparently often lie over for two years. Fresh seeds gathered by me in the Arnold Arboretum and sown in autumn, only produced one seedling in the first year, and no more have since germinated. This seedling though kept in a greenhouse grows very slowly, and at three years old is only 10 inches high. But though the tree is now rare in England there is no reason why it should not be grown on rich sandy soil in those districts where the summers are warm and dry, if young trees can be procured and established.

REMARKABLE TREES

The only really fine specimen of this species that we have seen in England is in the garden at Claremont, the seat of H.R.H. the Duchess of Albany. This is a handsome, healthy tree which in 1907 measured 48 feet by 6 feet 8 inches at 1 foot from the ground. It forks low down, and the main stem is 4 feet 10 inches at 5 feet. This tree flowers freely in the month of May, but Mr. Burrell has observed no seeds on it (Plate 146). A tree formerly grew at Beeston Hall, near Norwich, which Grigor states to have been 38 feet high in 1840, but this, as I am informed by Mr. Wall, the gardener there, died and was taken down about 1898.

There are four small trees in Mr. Friedlander's garden at White Knights Park, Reading, which appear to be suckers from the roots of an older one now dead; and in the adjoining properties, White Knights and the Wilderness, there are also trees of which the tallest is about 35 feet by 2 feet 10 inches. There is a younger tree in Mrs. Robb's grounds at Goldenfield, Liphook, and a small one in Kew Gardens planted by Sir W. T. Thiselton-Dyer. There is also a healthy young tree at Tortworth.

¹ Gerard, *Herball* (ed. Johnson), 1524 (1633).

² *Woodlands*, Nos. 489 seq. (1825).

The trees reported by Loudon to be growing in his time at Syon and at Croome cannot now be found.

MEDICINAL PROPERTIES

An interesting article on this tree by Prof. Sargent, with a figure of the trunk of an old one on Long Island showing the peculiar bark, is given in *Garden and Forest*, vii. 215; and from this I take the following:—

The Sassafras is one of the most interesting trees of eastern North America. The last survivor of a race which at an earlier period of the earth's history was common to the two hemispheres, it is the only tree in a large family which has been able to maintain itself in a region of severe winter cold. Towards the middle of the sixteenth century the French in Florida heard from the Indians wonderful accounts of the curative properties of a tree which they called *Pavame*, and which for no obvious reasons the Europeans called Sassafras. The tree and its virtues were first described by the Spanish physician, Nicholas Monardes, in his *Natural History of the New World*, published in Seville in 1569.

The reputation of the roots and wood as a sovereign cure for most human maladies soon spread through Europe, and extraordinary efforts were made to procure them. To collect Sassafras was one of the objects of the English expedition which landed in Massachusetts in 1602, and eight years later Sassafras is mentioned among the articles to be sent home, in the instructions of the English Government to the officers of the young colony in Virginia.

For nearly two centuries the reputation of Sassafras was maintained, and many medical treatises have extolled its virtues, though now it is generally recognised as simply a mild aromatic stimulant. Recently the thick pith of the young branches has been found to yield a mucilage useful to oculists, as it can be combined with alcohol and subacetate of lead without causing their precipitation. The oil of Sassafras, obtained from the wood and roots by distillation, is used to perfume soap and other articles; and perhaps after all the most useful product of the Sassafras tree is the yellow powder prepared from the leaves by the Choctaw Indians of Louisiana, used to give peculiar flavour and consistency to "Gumbo filé," one of the best products of the Creole kitchen.

TIMBER

The wood has little or no economic value and is unknown in Europe. Michaux says that it was never seen in the lumber yard, and was only occasionally used for joists, rafters, and bedsteads; and that it is not attacked by beetles on account of the odour, which it preserves as long as it is kept dry. Ashe says it is light, soft, weak, brittle, and coarse-grained, very durable in contact with the soil, and apt to crack in drying. But the unusual orange-brown colour of the heartwood seems to me to give it a value for ornamental carpentry, if it can be procured of sufficient size.

(H. J. E.)

CORYLUS

Corylus, Linnæus, *Sp. Pl.* 998 (1753); Bentham et Hooker, *Gen. Pl.* iii. 406 (1880); Winkler, in Engler, *Pflanzenreich*, iv. 61, *Betulaceæ*, 44 (1904).

DECIDUOUS trees or shrubs, belonging to the order Betulaceæ. Leaves alternate, distichous on the branchlets, stalked, simple, penninerved, doubly serrate; stipules two, caducous. Buds composed of numerous imbricated scales, corresponding to stipules.

Flowers monœcious, arising from buds on the branchlets of the previous year. Male flowers in cylindrical catkins, appearing in autumn; fascicled, or two to five on a common peduncle; composed of numerous imbricated bracts, each bearing on its inner side two partly adnate bracteoles and four stamens, without a perianth; filaments bifid, each branch bearing a single anther cell, tufted with hairs at its apex. Female flowers in buds resembling those which contain leaves only, but distinguishable in spring by the projecting styles. The lower scales of the buds bear leaves in their axils, the flowers, few in number, arising only in the axils of the uppermost scales, each scale bearing two flowers. Each flower, surrounded at the base by two minute bracteoles, more or less deeply cut and forming an involucre, consists of a two-celled ovary, surmounted by a short, denticulate perianth and two long styles; each cell containing one ovule.

Fruit, in clusters at the end of the short leafy branch into which the bud has developed; a one-celled, one-seeded nut, the remains of the other cell and ovule, which have aborted, being visible in its upper part. The nut is contained in a leafy involucre, open at the summit, and variously lobed or dentate. Seed without albumen; cotyledons thick, fleshy, containing oil, remaining on germination underground.

Eight or nine species of *Corylus* are known, all natives of northern temperate regions, and mostly shrubs or small trees. Only one species, *Corylus Colurna*, attains the dimensions of a timber tree, and comes within the scope of our work.

CORYLUS COLURNA, CONSTANTINOPLE OR TURKISH HAZEL

Corylus Colurna, Linnæus, *Sp. Pl.* 999 (1753); Loudon, *Arb. et Frut. Brit.* iii. 2029 (1838); Willkomm, *Forstliche Flora*, 377 (1887); Winkler, *op. cit.* 50.

A tree of moderate size, attaining 60 to 80 feet in height and 7 to 8 feet in girth of stem. Bark of trunk grey, thick, and scaling off in small irregular plates.

Corylus

Twigs brittle, the young shoots glandular pubescent, those of a year old glabrous and brown in colour, the bark of older shoots becoming corky. Leaves 3 to 5 inches long by 2 to 4 inches wide, broadly oval, ovate, or obovate, deeply cordate at the base, acuminate at the apex, doubly serrate or with large serrate teeth, dark green above, lower surface lighter green and sparingly pubescent, with glandular hairs on the principal nerves and midrib; nerves usually eight pairs; petiole $\frac{1}{2}$ to 1 inch long, glandular pubescent or glabrescent. Catkins¹ $1\frac{1}{2}$ to 3 inches long. Fruits crowded, three to ten in number, long, compressed, pubescent towards the apex. Involucres tomentose with intermixed glandular hairs, deeply and irregularly divided into linear, acute, stiff, long-pointed segments, which are either entire or toothed, exceeding in length two to three times the nut.

SEEDLING

The germination resembles that of the oak, the cotyledons, which are short-stalked, plano-convex and obovate, remaining in the seed and not being carried above ground. Caulicle stout, terete, tapering, ending in a long tap root with numerous branching fibres. Stem stout, terete, covered with numerous scattered glandular hairs, giving off an inch above the cotyledons a pair of opposite leaves, which are about 2 inches long, broadly ovate, acute at the apex, cordate at the base, with three to five pairs of lateral lobes, unequal in size, toothed and ciliate in margin; petiole $\frac{3}{4}$ inch, glandular-pubescent. Succeeding leaves are alternate and larger in size.

VARIETIES

In addition to the typical form described above, several geographical varieties occur, as the species is distributed over a wide area.

1. Var. *glandulifera*, A. de Candolle, *Prod.* xvi. 2, p. 132 (1864).—Occurs with the type in Europe and western Asia. In this variety the pubescence on the petioles, peduncles, and fruit-involucres is intermixed with glandular bristles; and the segments of the involucres are less acute and often dentate.

2. Var. *lacera*, A. de Candolle, *op. cit.* 131 (*Corylus lacera*, Wallich, *List*, 2798).—Leaves obovate, larger, up to 7 inches long, with ten to twelve pairs of nerves. Involucre-segments linear-lanceolate with glandular hairs. This variety occurs in the western Himalayas, from Kashmir to Nepal, at elevations of 6000 to 10,000 feet, and in many places is gregarious. Sir George Watt informs me that it is a handsome tree, usually growing in the mixed forests, and often attaining 80 feet in height.

3. Var. *chinensis*, Burkill, *Journ. Linn. Soc. (Bot.)* xxvi. 503 (1899) (*Corylus chinensis*, Franchet, *Journ. de Bot.* 1899, xiii. 197).—Leaves large, up to 7 inches long, with ten to twelve pairs of nerves, broadly ovate, unequal, acuminate; petioles bristly. Involucres striate and constricted above the fruit, lobes forked, lobules

¹ Abnormal male flowers with enlarged bracteoles are figured in *Gard. Chron.* xxvi. 691, fig. 135 (1886).

acute and falcate. This variety occurs in China, and grows to about 40 feet high in mixed forests in Yunnan, Szechwan, and Hupeh.

Apparently no varieties have originated in cultivation, but a hybrid has been obtained between this species and the common hazel, viz. :—

Corylus intermedia, Loddiges, *Catalogue* (1836) (*Corylus avellana* × *Corylus Colurna*, Rehder, *Mitth. Deuts. Dendrol. Gesell.* 1894, p. 43).—This is a tall shrub or small tree with the bark of the common hazel, *i.e.* darker and less scaly and fissured than that of *C. Colurna*. The fruit resembles that of the last species, but is shorter and scarcely glandular. Specimens of this are growing in the Botanic Gardens of Jena and Göttingen and in the Forestry Garden at Münden, but we know of none in England.

IDENTIFICATION

In summer the Turkish hazel is readily distinguishable by the scaly bark and the obovate leaves deeply cordate at the base and distichously placed on the branchlets. In winter (Plate 126, Fig. 6) the following characters are available :—Twigs : brittle, shining, brownish-yellow, with few and inconspicuous lenticels and scattered glandular pubescence, usually, however, dense near the base of the shoot, which is ringed with the scars of the previous season's bud-scales, one or two of the lowermost scales often persisting dry and darkened in colour; second year's shoot with corky bark, which fissures and exfoliates slightly. True terminal bud absent, a small oval scar at the apex of the twig, on the side opposite to the highest leaf-scar, indicating where the tip of the shoot fell off in summer. Leaf-scars semicircular with three to six bundle-dots,¹ somewhat obliquely set on prominent pulvini. Stipule-scars small, transverse, lunate, one on each side of the leaf-scar. Buds pretty uniform in size, alternate and distichous on the twig, from which they arise at a wide angle, ovoid, rounded at the apex; scales about ten, imbricated, pubescent, ciliate in margin. Pith small, circular. Male catkins present in winter on flower-bearing trees.

DISTRIBUTION

The Turkish hazel has a wide distribution, extending from south-eastern Europe, through Asia Minor and the Caucasus, to the Himalayas and Western China. In Europe it is found growing wild in Banat, Slavonia, Herzegovina, Bosnia, Servia, Roumania, and Greece.² In Banat, according to Willkomm, it sometimes forms pure woods in the mountains; and in Northern Albania it ascends as a bush to 3000 feet altitude.³ It occurs in Asia Minor in Bithynia, Paphlagonia, and Anatolia. According to Radde,⁴ it grows in small groups on the south side of the main chain of the Caucasus and in many localities in Georgia, at 3500 to 5000 feet elevation, where it is a stately tree 50 to 70 feet in height, and with a

¹ The cicatrices left by the leaf-bundles on the leaf-scar are very irregular in number and shape, being circular dots or curved lines.

² In Thessaly and Acarnania, according to Halacsy, *Consp. Fl. Græca*, iii. 135 (1904).

³ Beck, *Veg. Illyrischen Länder*, 300 (1901).

⁴ *Pflanzenverbr. Kaukasusland*. 187 (1899).

stem diameter of 18 inches. The nuts of the wild tree are small, with a thick and hard shell. It also grows in the mountains of Karabagh, but does not occur in the Talysch district. (A. H.)

CULTIVATION

The Turkish hazel was first cultivated in western Europe by Clusius, who obtained it from Constantinople in 1582. Linnæus states that in 1736 the finest specimen known was a tree in the Botanic Garden at Leyden, which had been planted by Clusius. It was apparently first cultivated in England about the year 1665 by John Rea,¹ who states that he had then "many goodly trees of the filbeard of Constantinople." He grafted these upon ordinary hazel stocks.

The Turkish hazel is now a rare tree in England, seldom to be got from a nursery, though perfectly hardy and easy to grow from seed, which it ripens in most seasons in the southern half of England. I have raised many from a tree at Tortworth Court, and the Earl of Ducie has done the same. The seed usually germinates in the following spring if sown when ripe, but if kept till spring, sometimes not until the next year. The seedlings, on my soil at least, have more inclination to become bushes than to make a single stem, but, if cut down two or three years after planting, will throw up strong suckers which may be trained into a tree, and should be planted in half-shady places or in an opening in a wood, as they are liable when young to be injured by spring frosts.

REMARKABLE TREES

No other place can show so many fine trees as Syon, where there are in the grounds at least five, all apparently of about the same age. The largest of these stands near the east bridge over the lake, and is about 75 feet high, with a bole about 30 feet long and 6 feet 9 inches in girth. Near the gardener's house is another fine tree more spreading in habit, about 70 feet by 7 feet 6 inches, which is probably not the same as one figured by Loudon, which was then 61 feet high. This has been figured by the Hon. S. Tollemache as the Hazel.²

At Bute House, Petersham, Henry measured a well-shaped tree which, in 1904, was 56 feet by 6 feet 7 inches.

At Corsham Court there is a remarkable tree about 50 feet high, which divides near the base into two stems, one of which is quite decayed, and the other, which has the appearance of having originated as a sucker from it, is quite sound and 6 feet 8 inches in girth. Lord Methuen tells me that he can remember this tree as formerly producing fruits which were sent up to table, but now it no longer bears any nuts.

At White Knights I saw a grafted tree from which seedlings had sprung up in the shrubbery, and one of these, growing at the base of a stump, is 10 feet high at about ten years old.

At Arley Castle there is a good tree which, in 1904, was by Mr. Woodward's measurement 60 feet by 5 feet 7 inches.

¹ *Flora*, 225 (1665).

² *British Trees with Illustrations*, 9 (1901).

524 The Trees of Great Britain and Ireland

At Wollaton Hall, near Nottingham, the property of Lord Middleton, there is a tree 43 feet high which at 5 feet girths 7 feet 10 inches, and at 10 feet, where it forks, 8 feet. It has a spread of not less than 78 feet, which for this tree is very unusual (Plate 147). It is perhaps the most symmetrical of its kind that I have seen anywhere. In the Botanic Gardens at Oxford and Kew there are fair-sized specimens.

In Scotland and Ireland we know of no trees of great size, and none were recorded by Loudon; but at Glasnevin there is one about 35 feet in height, which divides into three stems close to the ground, and has very pendent wide-spreading branches.

TIMBER

Little or nothing is known of the timber in England, but a wood has been imported to France under the name of "Noisetier," which I believe to belong to this species, and which, as exhibited by M. Hollande of Paris, is very handsome. I purchased some very handsome veneer from Mr. Witt of London, which he told me had come to him direct from Constantinople, and which I believe was cut from the root of *C. Colurna*. Two good-sized logs of this tree were in the collection of Servian timbers shown at the Balkan States Exhibition in London in 1907; one of them is now in the Kew Museum. Gamble¹ says that in the Himalaya it is a well-grained timber, which does not warp, of a pinkish-white colour, and often shows a fine shining grain resembling that of bird's-eye maple. (H. J. E.)

¹ *Mau. Indian Timbers*, 684 (1902).

CARPINUS

Carpinus, Linnæus, *Gen. Pl.* 292 (*ex parte*) (1737); Bentham et Hooker, *Gen. Pl.* iii. 405 (1880); Winkler, in Engler, *Pflanzenreich*, iv. 61, *Betulaceæ*, 24 (1904).
Distegocarpus, Siebold et Zuccarini, *Flor. Jap. Fam. Nat.* ii. 103, t. 3 (1846).

DECIDUOUS trees belonging to the order Betulaceæ. Leaves, alternate, distichous on the branchlets, stalked, ovate, doubly-serrate, penninerved, the nerves ending in the points of the teeth; stipules scarious, caducous or persistent. Flowers appearing in early spring with the unfolding of the leaves, unisexual, monœcious, without petals. Staminate flowers in pendulous, cylindrical catkins, arising from buds produced near the ends of lateral branches of the previous year; stamens, three to twenty, crowded on a pilose receptacle adnate to the base of a concave scale; filaments short, two-branched, each branch bearing a one-celled anther, tipped with a cluster of long hairs. Pistillate flowers, in loose, semi-erect catkins, which are terminal on the branchlets of the year; in pairs at the base of an ovate, acute, deciduous scale; each flower subtended by a small bract and two minute bracteoles, and consisting of a two-celled ovary, surmounted by a minute epigynous calyx and two elongated styles; each cell containing one ovule.

Fruit, in pendent, stalked strobiles, composed of imbricated, foliaceous or membranous involucre, resulting from the developed bract and bracteoles of the flower, each with a nutlet at its base. Nutlet, ovoid, compressed, longitudinally ribbed, crowned by the calyx and remains of the style, one-seeded, and falling from the involucre in autumn. Seed, filling the cavity of the nutlet, without albumen; cotyledons fleshy, carried above ground in germination.

The genus consists of about eighteen species inhabiting the temperate regions of North America, Europe, and Asia. Two sections are distinguished:—

I. DISTEGOCARPUS, Sargent, *Silva N. Amer.* ix. 40 (1896).

Scales of the staminate catkins lanceolate, stalked. Fruit-involucre, membranous, infolded below, completely covering the nutlet, closely imbricated in the strobile. Trees with scaly bark. Two species, *C. japonica*, Blume, and *C. cordata*, Blume.

II. EU-CARPINUS, Sargent, *loc. cit.*

Scales of the staminate catkins ovate, sub-sessile. Fruit-involucre, foliaceous, open or only slightly infolded over the nutlets, loosely imbricated in the strobile. Trees usually with smooth bark. This section includes the remaining species.

Carpinus and Ostrya are very similar in foliage; and the following key, based upon the characters of the leaves and branches (Plate 201), distinguishes all the species of both genera which are in cultivation in England. *Carpinus laxiflora*, though not yet introduced, has been included, as it has been much confused with the other Japanese hornbeams.

KEY TO CARPINUS AND OSTRYA

- I. *Leaves not exceeding 2 inches in length.*
1. *Carpinus orientalis*, Miller. South-eastern Europe, western Asia.
Leaves $1\frac{1}{2}$ inch long, acute, deeply plicate.
 2. *Carpinus polyneura*, Franchet. Central China.
Leaves 2 inches long, acute, smooth and only slightly plicate.
- II. *Leaves exceeding 2 inches in length.*
- A. *Leaves lanceolate.*
3. *Carpinus japonica*, Blume. Japan.
Leaves about 4 inches long, much longer in proportion to their width than in the other species, with numerous (eighteen to twenty-four pairs) nerves.
- B. *Leaves ovate, acute at the apex.*
4. *Carpinus yedoensis*, Maximowicz. Central China. Cultivated in Japan.
Leaves $2\frac{1}{2}$ inches long, rounded at the base, with conspicuous bands of appressed pubescence on the upper surface. Branchlets pilose.
- C. *Leaves ovate, acuminate at the apex.*
- * *Leaves deeply cordate at the base.*
5. *Carpinus cordata*, Blume. China, Korea, Manchuria, and Japan.
Leaves 4 to 5 inches long, broad in proportion to their length, with fifteen to twenty pairs of nerves.
** *Leaves rounded or only slightly cordate at the base.*
† *Under surface glabrous between the nerves.*
6. *Carpinus laxiflora*, Blume. China, Japan.
Leaves $2\frac{1}{2}$ inches long, rounded at the base, abruptly contracted into a very long acuminate apex. Branchlets with scattered long hairs. Buds minute, $\frac{1}{8}$ inch long.
7. *Carpinus Betulus*, Linnæus. Europe, western Asia.
Leaves 3 inches long, slightly cordate at the base, turning yellow in autumn. Branchlets with scattered long hairs. Buds fusiform, $\frac{1}{4}$ to $\frac{1}{3}$ inch long.
8. *Carpinus caroliniana*, Walter. North America.
Leaves as in *C. Betulus*, but turning red in autumn. Branchlets with scattered long hairs. Buds ovoid, $\frac{1}{8}$ inch long.
†† *Under surface pubescent between the nerves.*
9. *Ostrya carpinifolia*, Scopoli. Southern Europe, Asia Minor, Syria.
Leaves 3 inches long, not velvety to the touch above, rounded at the base. Branchlets with dense appressed pubescence.

10. *Ostrya japonica*, Sargent. China, Japan.

Leaves 3 to 4 inches long, velvety to the touch above, slightly cordate at the base. Branchlets with dense, scarcely appressed, pubescence.

11. *Ostrya virginica*, Willdenow. North America.

Leaves 3 to 4 inches long, not velvety to the touch above, slightly cordate at the base. Branchlets glandular-pubescent. (A. H.)

CARPINUS ORIENTALIS

Carpinus orientalis, Miller, *Gard. Dict.* ed. 7, No. 3 (1759); Loudon, *Arb. et Frut. Brit.* iii. 2014 (1838); Winkler, *Betulaceæ*, 37 (1904).
Carpinus duinensis, Scopoli, *Fl. Carniol.* ii. 243, t. 60 (1772); Boissier, *Fl. Orient.* iv. 1177 (1879); Willkomm, *Forstliche Flora*, 366 (1887).
Carpinus nigra, Moench, *Verz. Ausländ. Bäume u. Staud.* 19 (1785).

A small tree or large shrub, rarely attaining 50 feet in height; bark smooth and greyish. Young branchlets covered with a very minute dense pubescence, with which are intermixed scattered long hairs. Leaves (Plate 201, Fig. 7) small,¹ strongly plicate, the nerves being deeply impressed above, about $1\frac{1}{2}$ inch long by $\frac{3}{4}$ inch wide, ovate or ovate-elliptical, acute at the apex, unequal and slightly cordate at the base; margin sharply bi-serrate, ciliate; upper surface dark green, shining, with scattered long hairs; lower surface light green, pilose on the midrib and nerves, glabrous between the nerves, with minute axil-tufts; nerves nine to thirteen pairs; petioles, $\frac{1}{4}$ to $\frac{3}{8}$ inch, pilose; stipules linear-lanceolate, pubescent at the apex, $\frac{1}{4}$ inch long, often persistent during summer. Fruit: strobiles, up to 2 inches long; bracts densely imbricated, $\frac{3}{4}$ inch long, obliquely ovate, not lobed, sharply and irregularly serrate.

This species is a native of south-eastern Europe and western Asia. It occurs in Italy and Sicily, reaching its northern limit in Istria, Croatia, Slavonia, Banat, and Transylvania, and extending southwards through the Balkan States to Macedonia and Greece. It is also met with in the Crimea, Asia Minor, and the Caucasus.

It was introduced into cultivation in England in 1739 by Miller. It appears to be exceedingly rare, the only specimens we have seen being at Kew, where there are several small trees, one of which, planted in 1878, is now about 20 feet high.

(A. H.)

CARPINUS POLYNEURA

Carpinus polyneura, Franchet, *Journ. de Bot.* xiii. 202 (1899); Burkill, *Journ. Linn. Soc. (Bot.)*, xxvi. 501 (1899).
Carpinus Turczaninowii, Hance, var. *polyneura*, Winkler, *Betulaceæ*, 38, f. 12 (1904).

A small tree, attaining 30 feet in height; bark greyish, slightly fissuring and scaly. Young branchlets with scattered long hairs. Leaves (Plate 201, Fig. 5)

¹ In wild specimens the leaves are often larger, 2 to $2\frac{1}{2}$ inches in length.

small, weakly plicate, the nerves being only slightly impressed above, about 2 inches long by $\frac{7}{8}$ inch broad, ovate, acute at the apex, unequal and slightly cordate at the base; margin bi-serrate, ciliate; upper surface dark green, shining, with scattered, appressed hairs; lower surface as in *C. orientalis*; nerves nine to twelve pairs; petiole, $\frac{1}{4}$ to $\frac{3}{8}$ inch, pilose; stipules linear, pubescent along the margins, $\frac{1}{4}$ inch long, persistent during summer. Fruit: strobiles 2 inches long; bracts loosely imbricated, obliquely ovate, $\frac{1}{2}$ inch long, outer margin slightly serrate, inner margin sub-entire, not lobed, without a basal auricle.

This species is a rare tree in the mountains of Eastern Szechwan and Western Hupeh in China; and is closely allied to, if not a mere variety of, *C. Turczaninowii*, Hance, which is common in Northern China. *C. polyneura* differs little in technical characters from *C. orientalis*, but is very distinct in appearance owing to the leaves being smooth and flat and not deeply plicate, as in the other species of hornbeam.

It is only represented in cultivation by a single tree, about 15 feet high, in Kew Gardens, which was raised from seed sent by me in 1889. (A. H.)

CARPINUS JAPONICA

Carpinus japonica, Blume, *Mus. Bot. Lugd. Bat.* i. 308 (1850); Shirasawa, *Icon. Ess. Forest. Japon.*, text 47, t. 24, ff. 1-17 (1900); Winkler, *Betulaceae*, 25 (1904).

Carpinus Carpinus, Sargent, *Garden and Forest*, vi. 364, f. 56 (1893); *Forest Flora Japan*, 64, t. 21 (1894).

Distegocarpus Carpinus, Siebold et Zuccarini, *Fl. Jap. Fam. Nat.* ii. 103 (1846).

A tree attaining in Japan 50 feet in height and 5 feet in girth; bark furrowed and scaly. Young branchlets with scattered long hairs, which fall off in autumn. Leaves (Plate 201, Fig. 1) ovate-oblong, up to 4 inches long by $1\frac{1}{2}$ inch broad, acuminate at the apex, oblique at the base, which is rounded or slightly cordate; margin finely bi-serrate, non-ciliate; upper surface dark green, pubescent on the midrib and nerves; lower surface pale green, with scattered long hairs on the midrib and nerves and slight axil tufts; nerves, eighteen to twenty-four pairs, impressed above; petiole $\frac{1}{2}$ inch long, pubescent; stipules $\frac{1}{2}$ inch long, linear-lanceolate, pubescent, persistent during summer. Fruit: strobiles $2\frac{1}{2}$ inches long; bracts densely imbricated, $\frac{3}{4}$ to $\frac{7}{8}$ inch long, ovate, sharply serrate; nutlet covered by a minute orbicular lobe, attached merely by its base to the bract, the outer margin of the latter being slightly infolded below.

This species is a native of central and southern Japan, and, according to Sargent, is common on the Hakone and Nikko Mountains between 2000 and 3000 feet elevation. It was collected near Nikko by Elwes, and at Nagasaki by Oldham.

It was introduced by Maries in 1879; but no trees of this date are now to be found, there being only small plants about 3 feet high in the Coombe Wood Nursery. It is perfectly hardy in New England, where it produced fruit for the first time in 1891 in the Arnold Arboretum, where it had been introduced a few years previously.

Young plants were sent by Prof. Sargent in 1895 and 1897 to Kew, which have now attained about 10 feet in height. At Tortworth a young tree has produced fruit.

The foliage of this species is remarkably distinct and handsome. (A. H.)

CARPINUS YEDOENSIS

Carpinus yedoensis, Maximowicz, *Mél. Biol.* xi. 314 (1881); Burkill, *Journ. Linn. Soc. (Bot.)*, xxvi. 502 (1899); Franchet, *Journ. de Bot.* xiii. 203 (1899); Winkler, *Betulaceae*, 35 (1904).

A small tree. Young branchlets densely covered with long hairs. Leaves (Plate 201, Fig. 3), $2\frac{1}{2}$ inches long by $1\frac{1}{2}$ inch wide, ovate, acute at the apex, rounded at the base; margin biserrate and ciliate; upper surface with conspicuous bands of long appressed pubescence in the intervals between the lateral nerves; lower surface pilose on the midrib and nerves, glabrous or with scattered long hairs in the intervals between the nerves; nerves ten to twelve pairs; petiole, $\frac{3}{8}$ to $\frac{1}{2}$ inch long, pilose; stipules, linear-lanceolate, caducous. Fruit: strobiles, $2\frac{1}{2}$ inches long; bracts loosely imbricated, $\frac{3}{4}$ inch long, semi-ovate, coarsely serrate on the outer side, subentire on the inner side, which is slightly infolded at the base, forming a small auricle partly covering the nutlet.

This species is only cultivated in Japan, where it was first seen by Maximowicz. It was discovered growing wild in the mountains of North-Eastern Szechwan in China by Père Farges, and may have been brought to Japan by Buddhist monks in early days, like many other Chinese plants. Young plants were raised from Japanese seed in 1901 by Purpus, in the Botanic Garden at Darmstadt. In the nursery at Kew there are two or three plants, growing vigorously, and about 3 feet in height, which were obtained from Simon Louis in 1904. (A. H.)

CARPINUS CORDATA

Carpinus cordata, Blume, *Mus. Bot. Lugd. Bat.* i. 309 (1850); Sargent, *Garden and Forest*, vi. 364 (1893), viii. 294, f. 41 (1895), and *Forest Flora Japan*, 65 (1894); Burkill, *Journ. Linn. Soc. (Bot.)*, xxvi. 501 (1899); Shirasawa, *Icon. Ess. Forest. Japon.*, text 46, t. 24, ff. 18-32 (1900); Winkler, *Betulaceae*, 26 (1904); J. H. Veitch, *Hortus Veitchii*, 359 (1906).

Distegocarpus (?) cordata, De Candolle, *Prod.* xvi. 2, p. 128 (1864).

A tree, attaining in Japan and China a height of 50 feet and a girth of 6 feet; bark, dark grey, deeply furrowed and scaly. Young branchlets covered with a very minute pubescence, intermixed with scattered long hairs. Leaves (Plate 201, Fig. 2), ovate, up to 5 inches long and $2\frac{3}{4}$ inches wide, acuminate at the apex, unequally and deeply cordate at the base; margin finely bi-serrate, non-ciliate; upper surface dark green, with scattered long hairs; lower surface light green, pubescent between the nerves, pilose on the midrib and nerves, without axil tufts; nerves fifteen to twenty

pairs, impressed above; petiole, $\frac{3}{4}$ inch long, with scattered long hairs; stipules caducous. Fruit: strobiles, 3 to 6 inches long, long-stalked; bracts densely imbricated, membranous, 1 to $1\frac{1}{8}$ inch long, irregularly serrate; the inner margin furnished below with an orbicular lobe, infolding and concealing the nutlet; the outer margin slightly inflected at the base. The basal lobe is much larger than in *C. japonica*, and is united to the bract, not only by its base, but also along one side.

Var. *chinensis*, Franchet, *Journ. de Bot.* 1899, p. 202.—Leaves, ovate-oblong, 3 inches long by $1\frac{3}{4}$ inch broad, with eighteen to twenty pairs of nerves, slightly cordate and unequal at the base, shortly acuminate at the apex. This variety strongly resembles in the shape of the leaf certain forms of *C. japonica*, but has the fruit of *C. cordata*. It seems to be intermediate between the two species, and is found in the mountains of Eastern Szechwan in China. It was introduced into cultivation by Mr. E. H. Wilson in 1901, and young plants are growing in the Coombe Wood Nursery.

According to Sargent, *Carpinus cordata* is one of the largest and perhaps the most beautiful of the hornbeams. It grows on the main island of Japan only at high altitudes, its true home being in the deciduous-leaved forest of central and northern Yezo. It is also a native of Korea and Manchuria; and occurs in China, in the typical form, in the province of Shensi,¹ the variety *chinensis* growing more to the south.

This species was introduced from Japan by Maries in 1879, and produced fruit in 1886 in the Coombe Wood Nursery, where the largest specimen now living is only 15 feet in height. A tree at Tortworth is about 20 feet, and has borne fruit, from which, however, Elwes did not succeed in raising seedlings. There is also a small tree at Grayswood, Haslemere. It seems to be very rare in cultivation, and there are no specimens growing in the Hornbeam Collection at Kew. (A. H.)

CARPINUS LAXIFLORA

Carpinus laxiflora, Blume, *Mus. Bot. Lugd. Bat.* i. 309 (1850); Oliver, in Hooker, *Icon. Plant.* t. 1989 (1891); Sargent, *Garden and Forest*, vi. 364 (1893), and *Forest Flora Japan*, 64 (1894); Burkill, *Journ. Linn. Soc. (Bot.)*, xxvi. 501 (1899); Shirasawa, *Icon. Ess. Forest. Japon*, text 48, t. 25, ff. 15-30 (1900); Winkler, *Betulaceæ*, 33 (1904).
Carpinus Fargesii, Franchet, *Journ. de Bot.* 1899, p. 202.

A tree, attaining in Japan 50 feet in height and 5 feet in girth; bark smooth, grey, sometimes almost white in colour. Young branchlets with scattered long hairs. Leaves (Plate 201, Fig. 8), $2\frac{1}{2}$ inches long by $1\frac{1}{2}$ inch broad, ovate or ovate-elliptical, contracted above into a long acuminate apex, rounded or slightly cuneate at the base; margin, bi-serrate, non-ciliate; upper surface with scattered long appressed hairs; lower surface with long appressed hairs on the midrib and nerves, glabrous between the nerves; nerves thirteen to fifteen pairs; petiole, $\frac{1}{2}$ inch long, pilose;

¹ Burkill, *loc. cit.*

stipules caducous. Fruit: strobiles, up to 3 inches long; bracts very loosely imbricated, about $\frac{5}{8}$ inch long, semi-ovate, outer side irregularly serrate, inner side sub-entire, with a lobe near the base, which is infolded, but does not conceal the nutlet.

This species is a native of China and Japan. According to Sargent, it is very like the European hornbeam in habit, fluted stem, and smooth bark. It is common in all the mountain forests of Hondo, where it is most abundant at elevations between 2000 and 3000 feet. Near Agematsu, in Shinshu, at 2000 feet altitude, it was collected by Elwes, who saw no tree of any great size or beauty, though the leaves turn red and yellow in autumn. In Yezo, it descends to sea-level on the southern shores of Volcano Bay, where, near the town of Mori, it is common in oak forests, and grows to its largest size. In China, this species grows in the mountains of Hupeh, Eastern Szechwan, and Kiangsi; but is rare, displaying considerable variation in the character of the leaves and fruit.¹

It has not yet, apparently, been introduced into cultivation. Plants at Kew, sent under the name of *C. laxiflora*, from the Arnold Arboretum in 1895, are *C. japonica*. (A. H.)

CARPINUS CAROLINIANA, AMERICAN HORNBEAM

Carpinus caroliniana, Walter, *Fl. Carol.* 236 (1788); Sargent, *Silva N. Amer.* ix. 42, t. 447 (1896), and *Trees N. Amer.* 190 (1905); Winkler, *Betulaceæ*, 31 (1904).
Carpinus americana, Michaux, *Fl. Bor. Amer.* ii. 201 (1803); Loudon, *Arb. et Frut. Brit.* iii. 2013 (1838).
Carpinus Betulus, Koehne, *Deutsche Dendrologie*, 116 (1893).²

A bushy tree, attaining, in America, rarely 40 feet in height and 6 feet in girth, with stem and bark like the common hornbeam. Young branchlets with a few scattered long hairs, the minute glandular pubescence often seen in *C. Betulus* never being present. Leaves (Plate 201, Fig. 6) as in the common hornbeam, but usually with fewer nerves, nine to ten pairs; and unequal, rounded, or slightly cuneate at the base. Stipules lanceolate, $\frac{1}{3}$ inch long, caducous. Fruits: strobiles, 2 to 3 inches long; bracts loosely imbricated, triangular-ovate, $\frac{3}{4}$ to 1 inch long, with two short unequal lateral lobes, and a much longer middle lobe, which is usually serrate on only one margin; pedicels of each pair of bracts united only at the base.

In the absence of fruit, this species is difficult to distinguish from *C. Betulus* from which Koehne could not distinguish it even as a variety. In autumn, the beautiful red tint of the foliage of the American species is diagnostic. The best mark of distinction lies, however, in the buds, which are small, ovoid, acute, $\frac{1}{8}$ inch long, with glabrous ciliate scales; those of *C. Betulus* being large, fusiform, $\frac{1}{4}$ to $\frac{1}{3}$ inch long, with pubescent ciliate scales.

This species, which is known in America as the blue beech or water beech, is found along the borders of streams and swamps, from Southern and Western Quebec

¹ Three varieties are distinguished by Burkill, *loc. cit.*

to Florida, extending westward to Northern Minnesota, Eastern Nebraska, Kansas Indian Territory, and Eastern Texas. It is also met with in a slightly modified form¹ in the mountainous regions of Southern Mexico and Guatemala. It is most abundant and of its largest size in the southern Alleghany mountains and in Southern Arkansas and Texas.

It was introduced into England by Pursh in 1812; but is very rare in cultivation, the best specimen we have seen being at Arley Castle. It has no claim to be considered as a forest tree, its only merit being the scarlet colour of the foliage in autumn. Elwes gathered seeds of this species near Ottawa in 1904, which did not germinate. (A. H.)

CARPINUS BETULUS, COMMON HORNBEAM

- Carpinus Betulus*, Linnæus, *Sp. Pl.* 998 (1753); Loudon, *Arb. et Frut. Brit.* iii. 2004 (1838); Willkomm, *Forstliche Flora*, 358 (1887); Mathieu, *Flore Forestière*, 396 (1897).
Carpinus vulgaris, Miller, *Gard. Dict.* ed. 8, No. 1 (1768).
Carpinus sepium, Lamarck, *Fl. Franç.* ii. 212 (1778).
Carpinus compressa, Gilbert, *Exerc.* ii. 399 (1792).
Carpinus ulmoides, Gray, *Nat. Arrang. Brit. Pl.* ii. 245 (1821).
Carpinus carpinizza, Host, *Fl. Austr.* ii. 626 (1831).
Carpinus intermedia, Wierzbicki, in Reichenbach, *Icon. Fl. Germ.* xii. f. 1297 (1850).
Carpinus nervata, Dulac, *Fl. Haut. Pyrén.* 141 (1867).

A tree, usually attaining only a moderate size, 60 or 70 feet in height and 8 feet in girth; but in England occasionally as large as 90 feet by 12 feet. Stem never perfectly circular in section, being more or less longitudinally fluted or ridged, with shallow rounded depressions between the ridges; bark smooth, thin, grey. Young branchlets with scattered long hairs, a very minute dense glandular pubescence being also often present. Leaves (Plate 201, Fig. 4) about 3 inches long by $1\frac{3}{4}$ inch broad, oval or ovate, acuminate at the apex; broad, unequal, and rounded or slightly cordate at the base; margin bi-serrate, non-ciliate; upper surface dark green, glabrous, or rarely pilose on the midrib and nerves; under surface light green, with appressed long hairs on the midrib and nerves and minute axil tufts; lateral nerves, ten to fifteen pairs, impressed on the upper surface, prominent beneath; petiole $\frac{1}{4}$ to $\frac{1}{2}$ inch long, pubescent; stipules narrow, lanceolate, $\frac{1}{2}$ inch long, caducous.

Male catkins, about $1\frac{1}{2}$ inch long; scales ovate, acute, entire, veined longitudinally; stamens, 4 to 12, with long yellow anthers. Female catkins, nearly 1 inch long; scales ovate, acuminate, ciliate. Fruit: strobiles up to 3 inches long; involucre loosely imbricated, in pairs, with their pedicels connate for the greater part of their length, three-lobed, the lateral lobes small and usually entire, the middle lobe, about $1\frac{1}{2}$ inch long, entire or minutely serrulate; nutlet, $\frac{1}{3}$ inch long, seven- to eleven-nerved, glabrous, with the apex umbonate and surrounded by a six-lobed calycine ring, within which are the remains of the style.

¹ Var. *tropicalis*, Donnell Smith, *Bot. Gaz.* xv. 28 (1890).

In winter, the twigs are smooth, shining, glabrous, with five-angled pith, and are marked at the base of the year's growth by ringlike scars, due to the fall of the accrescent scales of the bud of the previous season. Terminal bud not formed, the tip of the branchlet falling off in summer and leaving a small circular scar close to the uppermost axillary bud, the latter prolonging the shoot in the following season. Leaf-scars small, crescentic, three-dotted, with a short stipular scar on each side. Buds, distichous on the branchlets, unequal in size, on prominent leaf-cushions, appressed against the stem, fusiform, $\frac{1}{4}$ to $\frac{1}{3}$ inch long; scales, ciliate and pubescent towards the tips, brownish.

Seedling:¹ Primary root tapering, wiry, flexuose; caulicle terete, pubescent, $\frac{1}{2}$ inch long; cotyledons fleshy, rounded-obovate, $\frac{1}{3}$ inch long, auricled at the base, shortly stalked, glabrous, green above, whitish beneath; stem zigzag, pubescent, giving off alternate stalked bi-serrate leaves, which resemble those of the adult plant, but are smaller and occasionally lobulate in margin.

VARIETIES

The common hornbeam shows little variation in the wild state, the only form worth noticing being var. *carpinizza*, which is found in Transylvania. In this variety the leaves are often distinctly cordate at the base with only seven to nine pairs of nerves; and the fruit-involucre has very short lateral lobes.

Under cultivation, pyramidal,² fastigiate, pendulous, and variegated forms have originated. In var. *purpurea*, the young leaves have a reddish tint. Var. *incisa*, Aiton,³ has leaves with large sharp serrated teeth. A wide-branching tree of this variety at Beauport, Sussex, is 6 feet 3 inches in girth; and there is also a fine specimen at Smeaton-Hepburn, East Lothian. In var. *quercifolia*, Desfontaines,⁴ the leaves are smaller than in the type and are irregularly and deeply cut or lobed. In this variety, leaves of the ordinary form are often present on the same branch with those of the pinnatifid kind. Two remarkable trees of this variety are reported⁵ to be growing on the bowling green of the Woodrow Inn, in Cawston Parish, near Aylsham, Norfolk.

DISTRIBUTION

The common hornbeam is indigenous in the south of England; but its true native limits cannot now be exactly determined. It is recorded⁶ from Somerset, Wilts, Dorset, Hants, Berks, Oxford, Bucks, Herts, Surrey, Sussex, Kent, Essex, Cambridge, Suffolk, and Norfolk; but in many cases, especially in the south-western counties, the records are probably of planted and not really wild trees. In Dorset,⁷ it is a very rare tree; and Townsend⁸ considers it to be a doubtful native of Hampshire. Druce⁹ considers it to be indigenous in Oxfordshire on the chalk, but always

¹ Cf. Lubbock, *Seedlings*, ii. 532, f. 667 (1892).

² A solitary wild specimen of the pyramidal hornbeam formerly grew in the forest of Gremsey, near Vic in France. Godron, *Les Hêtres Tortillards* (1869).

⁸ *Flora of Hampshire*, 313 (1883).

⁹ *Flora of Oxfordshire*, 268 (1886).

planted on other formations. There is no doubt, however, that it formed a considerable part of the ancient forests, which existed to the north and east of London; and in the Lea division of Hertfordshire¹ it still forms the chief portion of the underwood; whilst it is common in Essex and Kent, where it is usually treated as coppice.

The hornbeam has been found in the fossil state in Suffolk, in the interglacial strata at Hoxne, and in the preglacial strata at Pakefield.²

Carpinus Betulus is widely distributed on the continent of Europe, and occurs also in Asia Minor, the Caucasus, and Persia. In Europe, its northern limit, beginning in Norfolk in England, crosses over to Denmark and South Sweden, where it ascends on the west coast to lat. $56^{\circ} 30'$, and on the east coast to $57^{\circ} 13'$, reaching its extreme northerly point on the island of Gothland in lat. $57^{\circ} 20'$. In Norway, Schubeler says, it is not wild; but he has seen a tree at Christiania, planted in 1818, which in 1885 measured 36 feet by 4 feet. In Russia, the hornbeam occurs as far north as lat. $56^{\circ} 10'$ on the coast of Courland, and is confined to the provinces which lie west of an irregular line drawn from near Riga to the Sea of Azov, its most easterly localities being in the governments of Vitebsk, Mohilef, Chernigof, and Poltava, and in the Crimea. South and west of the above limits, the hornbeam is spread through France, Belgium, Holland, Germany, Austrian Empire, Balkan Peninsula, Greece, Switzerland, and continental Italy; but is not found wild in Spain, Portugal, Corsica, Sardinia, and Sicily.

In France, the hornbeam is most common in the north and east, where it forms a large part of the coppice forests, and also occurs as undergrowth in the high forests of beech and oak. Its southerly limit in France is a curved line extending from Grenoble through Toulouse to near Bordeaux. Towards the west and south, it becomes a rare tree, and is totally absent from Brittany. It is rather a tree of the plains and low hills than of the mountains; but ascends in the Vosges to 2000 feet, in the Jura to 2300 feet, and in the French Alps to 2800 feet. Treated as coppice, its growth is very rapid in France, where it takes the first rank as firewood.

In Germany the hornbeam is widely spread in the plains and low hills, where it grows usually, as in France, in company with the beech and other deciduous trees, either as scattered individuals or in small groups. In east Prussia, where the beech does not occur, the hornbeam replaces it and grows to great perfection, often forming part of the spruce and pine forests. Pure woods are rare, though some of considerable extent occur, according to Willkomm, in Alsace, Baden, and South Bavaria. In Austria, Hungary, the Balkan States, and Greece, the hornbeam is no longer a tree of the plain, but grows in the mountains in the beech forests. It ascends in the Harz mountains to 1250 feet, in the Bavarian Alps to 2900 feet, and in the Swiss Alps to 3000 feet.

According to Radde,³ it is met with through the whole region of the Caucasus, at elevations ranging from sea-level to 5600 feet. It is also recorded from the northern provinces of Asia Minor, and from Ghilan in Northern Persia.

(A. H.)

CULTIVATION

The seeds of the hornbeam ripen in October, but with few exceptions do not germinate until after a second winter, and must be treated in the same manner as those of the ash. The seedlings though very hardy as regards spring frosts, grow slowly at first, and require about four years in the nursery before they are strong enough to plant out. Though on sandy soil the tree produces fruit freely and the seedlings bear shade as well as those of the beech, yet the hornbeam does not in England, as in some parts of France, tend to overpower the oak; and its economic value was formerly much greater than it is now, on account of its being one of the very best trees for firewood. It may, however, be used for underplanting, and as a nurse for other trees on soils too wet for beech, and is admirably suited for making clipped hedges. When the shoots are interlaced they form an impassable barrier, and bear clipping as well as any tree. It also bears pollarding and coppicing extremely well, some of the old pollards which are seen in the eastern counties being of very great age; but when not so treated it does not appear to be a very long-lived tree, and rarely exceeds 200 years. In France, Mouillefert says, it lives 100 to 120 years, and rarely over 150 years, but I think it must considerably exceed this age in some parts of England.

The hornbeam is more critical as to soil and climate than most of our native trees; and though Loudon says it is always found on stiff clay and on moist soils where scarcely any other timber tree will grow, this is hardly correct. I have never seen a really fine tree on any but fertile soils, and though it is the most abundant tree of Epping Forest, from which Loudon probably derived his idea; there is not, so far as I know, a really fine specimen in that district, though this may be partly due to their being nearly all pollards. I searched in vain for self-sown seedlings, with roots fit to transplant, and of fifty sent me by Mr. M'Kenzie, superintendent of Epping Forest, only one survived. He tells me that though large numbers of seedlings may be seen after a good seed year, yet most of them very soon disappear, as the deer and cattle bite them off when not protected by bushes. As a wild tree it is principally found in the south-eastern and eastern counties where the lowest rainfall occurs, but it grows well in the west and in Ireland, and even as far north as Morayshire. Mouillefert says that in France fresh and permeable sandy soils suit it best; and that sandy, gravelly, and flinty clays also suit it well, even when calcareous, but that it languishes or perishes on those which are too stiff, marshy, peaty, or very dry; and I think this is correct as regards England also. On account of its weak development of roots when young it requires shelter at first, and though it will stand shade fairly, it succeeds best as an isolated tree when adult.

As a forest tree it can only be considered of secondary importance, and Forbes does not include it in his *Estate Forestry*. As an ornamental tree, it has great value, both on account of the graceful pendent branches, which when in flower and fruit are very beautiful, and for the brilliant yellow colour of the leaves in autumn.

REMARKABLE TREES

Large hornbeams are not at all common, and exist so far as I have seen in comparatively few places, mostly old parks. The largest and finest that I know of, though by no means the tallest, is near the reservoir at Cornbury Park, Oxford, where there is a tree whose height I could not measure exactly, though it probably exceeds 75 feet, with a bole 11 feet 10 inches in girth and 12 to 14 feet long, which spreads out at that height into an immense number of branches covering a circle of 95 paces (Plate 148). There are two other trees of nearly similar size and habit on the north side of the beech avenue, one of them leaning very much on one side with drooping branches. Sir Hugh Beevor has recently measured a tree, 100 feet in height and 9 feet 8 inches in girth, on Sir Robert Dashwood's property near West Wycombe.

But there is no place where I have seen hornbeams so tall or so numerous as at Cobham Park, Kent, where there must be hundreds of trees 70 to 80 feet high, and many with clean boles 20 to 40 feet long. Among so many it is hard to say which are the largest, but one which I measured near the old heronry, and not far from the ash grove, was over 90 feet high, dividing at about 7 feet into four stems, each of which ran up straight and clean for about 40 feet. Another, a pollard, hollow on one side, measured 13 feet 6 inches in girth. These grow on a soil which suits the ash perfectly. Four shoots from a stool in a wood here measured 76 feet high and 2 to 3 feet in girth.

At Mersham-le-Hatch, Ashford, Kent, the seat of Sir Wyndham Knatchbull, Bart., I saw, in 1907, a remarkable wood called Bockhanger, composed of very old pollard hornbeams many of which are hollow and much decayed. They grow on a sandy loam, covered in spring with bluebells, and have for generations served to supply the mansion with firewood, of which the steward told me twelve to fourteen cords were annually consumed. The largest of these trees was about 16 feet to the crown, and had a very large kidney-shaped wen on one side, over which it measured 16 feet 4 inches in girth. Another tree here showed the remarkable power of the hornbeam in repairing wounds in its trunk. A large double-stemmed tree, widely split and hollow at the base, had higher up completely covered the open cleft with young healthy wood and bark in the same way that old yews often do.

A most remarkable hornbeam, on account of its very wide-spreading branches, grows in Fredville Park, Kent, and though not over 35 to 40 feet high, covers an area of no less than 103 paces round. It has about fifteen main branches which show the characteristic irregularities that old hornbeams always have. The branches are so thick that foxes often choose the crown of this tree as a lair, and when covered with fruit, as it was when I saw it in June 1907, it is a most striking and beautiful tree. It grows in a deep fertile loam overlying chalk, but rather wet in winter.

The hornbeam is, in Essex, especially in Epping Forest, most commonly seen as a pollard, the practice of lopping the branches for firewood having been very general in old times. A photograph showing the appearance of the tree when so

treated was taken for me by Mr. Elsdon of Hertford, at Waterhall, a farm on Mr. H. Clinton Baker's property near Bayfordbury, Herts, in January 1907 (Plate 149). At Essendon, Herts, Mr. Baker, in 1906 measured a tree, 81 feet by 11 feet 2 inches; a pollarded tree at the same place being 56 feet high by 18 feet in girth. Sir Hugh Beevor measured in 1891 a hornbeam in Hatfield Park, Herts, which was 17½ feet in girth at about 4 feet from the ground.

The finest and largest examples of pollard hornbeams that I have seen are in Easton Park, Essex, the seat of the Earl of Warwick. A group of these trees, growing near the park-keeper's house, which was shown me by Mr. Rogers, agent for the Easton property, contains several trees of great beauty, which were in flower on 7th April. The largest of these measures no less than 28 feet round the head at about 8 feet from the ground, and 12 feet 2 inches at 2 feet (Plate 150). Another near it, dividing into two stems which are united at the crown, was 25 feet in girth at 7 feet and 17½ feet at 2 feet. A third, growing at some distance, has perhaps the finest head of all, and measures 26 feet round the head with a bole about 11 feet high. Mr. Shenstone tells me that the largest he has seen in Epping Forest is 27 feet in girth round the head, and he showed me another very old one in Braxted Park which was over 20 feet round.

Mrs. Delves Broughton has sent me a photograph (Plate 151) of a very fine group of hornbeams in Weald Park, Essex, the seat of C. J. H. Tower, Esq., in which, according to the measurements sent me by Mr. T. W. Bacon, the two largest trees are 75 feet by 16 feet 9 inches, and 88 feet by 15 feet 4 inches.

At Elveden, Suffolk, there is a very well-shaped and handsome tree in front of the house, which, as I was told by the late Prof. A. Newton, is probably not more than 140 years old, and measured, when I saw it in 1907, 75 feet by 10 feet.

At Nibley, Gloucestershire, there is a tree, of which Col. Noel has been good enough to send me a photograph, which measures about 80 feet by 11 feet 6 inches with a bole of 8 feet and a spread of 80 feet diameter. In Bitton churchyard, Gloucestershire, there is a tree planted since 1817 by Canon Ellacombe's father which is 65 feet by 8 feet 2 inches. At St. Pierre Park, near Chepstow, Major Stacey showed me a very fine hornbeam which, though not very tall, and with a bole only 10 feet high by 11 feet 7 inches in girth, spreads over an area 112 paces round.

In the wooded part of Kew Gardens, there are several fine trees, the best of which is 70 feet high and 10 feet in girth, dividing into three stems at 7 feet from the ground. One tree, 5½ feet in girth, has bark on the lower part of the trunk, divided into raised longitudinal ridges, which are covered with small scales. At Heron Court, Hants, there is a beautiful tree near the front entrance, 70 feet by 10 feet 5 inches with a spread of 25 yards.

At Brocklesby, Lincolnshire, Lord Kesteven measured, in 1906, a tree 77 feet high by 9 feet 4 inches in girth. At Castle Howard the hornbeam grows well and there are several large trees, the tallest being about 80 feet high, the thickest 9 feet 3 inches in girth. At Studley Park, Yorkshire, in the valley below Fountains Abbey, there are several very fine hornbeams, probably the same as those figured by Loudon (ff. 1933, 1934, 1935), which were in 1838 50 to 60 and one 73 feet high.

I measured three from 70 to 80 feet with a girth of $6\frac{1}{2}$ to $8\frac{1}{2}$ feet, one being covered with dense tufts of twigs, a kind of witches' broom, caused by *Exoascus Carpini*.

In Scotland the hornbeam is less common than in the south, but grows to a large size in the warmer districts; though, as it is not mentioned either by Hunter, or in the *Remarkable Trees of Scotland*, it is evidently looked on as a rare tree in the north. Walker¹ speaks of one formerly growing at Bargally, which was 70 feet high, with a clear trunk of 20 feet.

The finest I have seen is a tree at Gordon Castle, perhaps the one mentioned by Loudon as being then 54 feet high; in 1904, it was 68 feet by 8 feet (Plate 152). At Murthly, in the lower park near the Tay, there is an old tree measuring, in 1906, 65 feet by 9 feet 8 inches; and Henry measured one at Scone of the same dimensions.

Mr. J. Renwick sends me particulars of a very remarkable hornbeam at Douglas Support, in Lanarkshire, which, in 1900, measured 78 feet by 8 feet 1 inch, with a bole of 17 feet long, and a spread of 60 feet, the branches having long pendulous twigs, which form a screen all round the tree and hang nearly to the ground.²

Another remarkable tree is at Eglinton Castle, Ayrshire, which separates into three stems near the ground, and measures at the narrowest point below the fork 14 feet in girth; its three stems girth 5 feet 9 inches, 5 feet 6 inches, and 4 feet 11 inches respectively. Mr. Renwick sends me particulars of other fine hornbeams as follows:—at Househill, Renfrewshire, 10 feet girth, 72 feet spread; at Tullichevan Castle, Dumbartonshire, 60 feet by 8 feet 3 inches; at Gargunnoch House, Stirlingshire, 8 feet 11 inches girth, 83 feet spread.

The hornbeam is rarely planted in Ireland. The largest tree, which Henry has seen, is growing beside the Killarney Lake, at Mahony's Point. It measured, in 1904, 15 feet 8 inches in girth, at 18 inches above the ground, giving off six great stems, the three largest of which were—8 feet 4 inches, 7 feet 7 inches, and 6 feet 3 inches in girth. This tree is about 70 feet in height, and the diameter of its spread is 80 feet. It is in perfect health and bears fruit regularly.

At Adare, Co. Limerick, in 1903, Henry saw a fine tree, which measured 53 feet by 8 feet 8 inches, the spread of branches being 65 feet. At Glenstal, in the same county, there is a tree of exactly the same dimensions, as regards height and girth. At Kilruddery, Co. Wicklow, a tree, which had been blown down, measured 8 feet 9 inches in girth; and here there is a very fine hornbeam hedge, about 15 feet in height.

TIMBER

The wood of the hornbeam is the hardest, heaviest, and toughest of our native woods, but though extremely strong, is not flexible; and as it is seldom found large enough and clean enough to cut into planks, it is little used in England except for fuel, for which it is one of the best woods known, burning slowly with a

¹ *Essays*, p. 95, *file* Loudon.

² I am informed by Mr. Douglas that the peculiarity of this tree consists in the long drooping twigs, which are 20 to 30 feet in length, and hang like small cords to the ground on all sides, concealing the trunk, whilst the upper branches do not droop at all. He thinks that this is due to its being a grafted tree. A photograph, which he is good enough to promise me, will be given in a later volume.

bright flame, and making the best of charcoal. As it decays quickly when exposed to wet, it is of no use for outside work, and will not take creosote. The trunk of the tree is often very deeply furrowed, and the wood is said to be cross-grained and difficult to work. It is or was considered the best wood for cogs, mallets, and wooden screws for carpenters' benches, also for pulleys and butchers' blocks. Its value is uncertain, and depends largely on the locality, and on the size and age of the tree.

With regard to the use of this wood by pianoforte manufacturers, Mr. J. Rose, of Messrs. Broadwood and Sons, to whom I am indebted for much information, writes me as follows:—

“Hornbeam is still used for piano action work in England, though American maple has replaced it to a considerable extent. French hornbeam, and, I believe, Dutch also, are used for the purpose, because of larger size and more freely grown than the British product, and also because, when all charges are included, it is probably cheaper. There is a marked difference in the English hornbeam and that grown in France and elsewhere on the Continent. This is perhaps hardly perceptible in a small sample, but the English wood is smaller and more irregular, but of a distinctly firmer texture, so hard and close as sometimes to resemble ivory. It works beautifully with fine saws and small drills; but the waste is serious. The foreign timber is larger and more freely grown, producing much larger boards, but the grain is coarser, and the texture of the wood less firm, and more liable to split when in small pieces, such as are used in action work.”

(H. J. E.)

OSTRYA

Ostrya, Scopoli, *Fl. Carniol.* 414 (1760); Bentham et Hooker, *Gen. Pl.* iii. 406 (1880); Winkler, in Engler, *Pflanzenreich*, iv. 61, *Betulaceae*, 24 (1904).
Carpinus, Linnæus, *Gen. Pl.* 292 (*ex parte*) (1737).

SMALL deciduous trees, belonging to the order *Betulaceae*, agreeing with the genus *Carpinus* in the characters of the branchlets, buds, foliage, and staminate flowers. Pistillate flowers, in dense erect spikes, inserted in pairs on the base of ovate acute leafy scales, each flower enclosed in a sac-like involucre, formed by the union of a bract and two bracteoles, which is open at the apex at the time of flowering, afterwards becoming closed. Calyx dentate, adnate to the two-celled inferior ovary; style short, divided into two linear subulate stigmatic branches; ovules solitary in each cell. Fruits: disposed in stalked ovoid strobiles, composed of densely imbricated involucre, which are vesicular, closed, flattened, membranous, longitudinally nerved, reticulate, pubescent at the apex, and hirsute at the base with sharp, rigid, stinging hairs. Nutlet, sessile in the involucre, ovoid, compressed, longitudinally ribbed, crowned by the remains of the calyx; seed solitary, pendulous.

Four species of *Ostrya* have been distinguished:—*Ostrya Knowltoni*, Coville, a rare tree in Arizona, not yet introduced, and three species, occurring in North America, Eastern Asia, and Europe and Asia Minor, which are so closely allied that they have been considered by most botanists to be only geographical races of one species. These three species are all in cultivation, and as they can be distinguished (see Key to *Carpinus* and *Ostrya*, p. 526), will be treated by us separately.

OSTRYA CARPINIFOLIA, HoP HORNBEAM

Ostrya carpinifolia, Scopoli, *Fl. Carniol.* ii. 244 (1772); Willkomm, *Forstliche Flora*, 368 (1887); Mathieu, *Flore Forestière*, 403 (1897).
Ostrya vulgaris, Willdenow, *Sp. Pl.* iv. 469 (1805); Loudon, *Arb. et Frut. Brit.* iii. 2015 (1838).
Ostrya italica, Spach, *Ann. Sc. Nat. sér. 2*, xvi. 246 (1841).
Ostrya italica, sub-species *carpinifolia*, Winkler, *Betulaceae*, 22 (1904).
Ostrya Ostrya, Sargent, *Silva N. Amer.* ix. 32 (1896).
Carpinus Ostrya, Linnæus, *Sp. Pl.* 998 (1753).

A tree attaining 60 feet in height and 10 feet in girth; stem cylindrical, bark greyish, finely fissured, and scaly. Young branchlets with dense appressed

Ostrya

pubescence. Leaves (Plate 201, Fig. 11) about 3 inches long by $1\frac{3}{8}$ inch wide, ovate, shortly acuminate at the apex, unequal and rounded at the base; margin sharply bi-serrate and ciliate; covered above and below with appressed pubescence, spreading more or less over the whole surface, and not confined to the midrib and nerves, as in *Carpinus Betulus*, and with minute axil tufts on the lower surface; nerves twelve to fifteen pairs; petiole $\frac{1}{4}$ to $\frac{3}{8}$ inch long, appressed pubescent; stipules persistent during summer. Nutlet ovoid, $\frac{1}{8}$ inch long, crowned by a tuft of hairs; calyx-limb obsolete.

In winter the twigs are slender, zigzag, more or less pubescent. No true terminal bud is formed, the apex of the branchlet falling off in summer and leaving a minute circular scar at the side of the uppermost axillary bud. Buds small, $\frac{3}{8}$ inch long, ovoid, viscid, set obliquely on prominent leaf-cushions; scales 6 to 9, imbricated, greenish with a dark brown margin, more or less pubescent. Leaf-scar semicircular, with two bundle-dots above and one group of three smaller dots below.

Ostrya carpinifolia reaches its most westerly point in the extreme south-eastern corner of France, where it occupies a few isolated stations in the Basses-Alpes and Alpes-Maritimes Departments. In the forest of Miolans,¹ in the Basses-Alpes, which is mainly composed of *Pinus sylvestris*, it is found on a northern slope, over an area of about 400 acres, occurring chiefly as undergrowth and ascending to about 2700 feet altitude. In the Alpes-Maritimes it descends in some places to nearly sea-level. It extends eastward through Southern Switzerland, the Tyrol (where,² near Botzen, it ascends to 3500 feet altitude), Carinthia, and Lower Styria to Southern Hungary, and spreads southwards through Carniola, Croatia, and the Balkan States to Greece, growing usually in rocky situations, more commonly on limestone than on other formations. It is common throughout Italy and Sicily in the oak and chestnut regions, ascending to 3800 feet elevation; and forms woods of considerable extent around Lake Como, especially above Lecco, on the shores of Lake Lugano, and at Gaudria and Salvatore.³ It occurs as a rare tree in Corsica and Sardinia. It is also met with in Asia Minor and in the Lebanon. It attains about a hundred years of age; and according to Pardé⁴ produces coppice shoots like the hornbeam.

(A. H.)

CULTIVATION

It was introduced into cultivation in England some time before 1724, as it is mentioned in Furber's Nursery Catalogue published in that year. Though an ornamental tree which attains a good size and is perfectly hardy, it has always been very rare in this country. According to Mouillefert⁴ its growth is about equal to that of the Hornbeam. I have raised plants from French seed which grow faster on my soil than those of the hornbeam, and seem at least as hardy, as they were

¹ Fliche, *Bull. Soc. Bot. France*, xlv. 8 (1899). Cf. also *ibid.* xxxv. 160 (1888).

² Christ, *Flore de la Suisse*, 238 (1907). In the same work, p. 507, it is stated that this species has been found in the fossil state in miocene beds at Ardeche; and another species, probably a mere variety, has been found in the same strata at Var.

³ *Arb. Nat. des Barres*, 281 (1906).

⁴ *Principales Essences Forestières*, 148, note (1903). At Grignon in France, planted together in the arboretum, on calcareous soil with a chalky subsoil, at thirty years old the Hornbeam is 11 metres high by 70 centimetres in girth at 1 metre above the ground; and the *Ostrya* 11½ metres by 73 centimetres in girth. It bore here without injury the severe winter of 1879.

uninjured by the severe spring frost of May 21-23, 1905, and ripened their young wood well in October. They may be distinguished by the larger leaves with a pair of persistent linear stipules at the base.

REMARKABLE TREES

From the dimensions given by foreign authors I doubt whether in its native country the Hop Hornbeam ever attains a much larger size than the one which I figure (Plate 153). This remarkable tree is at Langley Park, near Norwich, the seat of Sir Reginald Beauchamp, and cannot be of great age, as it is not mentioned in an account of this place in Grigor's *Eastern Arboretum*, published in 1841. It is grafted on a stock of the hornbeam which measures 8 feet in girth below the graft, while the trunk above it is no less than 15 feet 8 inches. Its height is difficult to estimate, but may be about 50 feet.

A large tree formerly grew at Kew, on which Mr. J. G. Jack, in *Garden and Forest*, v. 602, remarks as follows:—"An unusually fine specimen of a hop hornbeam, 50 feet high, branching near the ground and spreading about 70 feet, with a trunk over 3 feet in diameter, was grafted on a stock of hornbeam at 2½ feet from the ground, and is a good deal larger than its stock, with a swelling at the point of juncture. No one can help remarking the striking contrast between the rough bark of the *Ostrya* and the comparatively smooth bark of the *Carpinus*."

This tree was perhaps the one figured by Loudon¹ in 1838, which was then said to be 60 feet high, with a trunk 3 feet in diameter, and the finest specimen in England at that time. In 1890 it was figured in the *Gardeners' Chronicle*² as a handsome wide-spreading tree, but soon after began to decay, and was cut down in 1897,³ when it measured 59 feet high by 9 feet 4 inches in girth at 3 feet. Fruit was abundantly produced; but no perfect seeds were ever developed. A part of its trunk is preserved in the Museum at Kew, and I am indebted to the Director for a sample of the timber, which somewhat resembles that of the pear. According to Mouillefert it has all the qualities of hornbeam wood in a superior degree.

There is a fine specimen in the Botanic Garden at Oxford, which measures about 40 feet by 4 feet. This tree, though quite healthy, is much infested by mistletoe. At Tortworth there is a tree about 40 feet high by 2 feet 7 inches in girth. At Munden, Watford, a tree, 32 feet by 2 feet 11 inches, is said to have been planted about 1830.

In Scotland we know of no tree of this species of large size now existing, though a large one formerly grew at Bargally,⁴ a place between Gatehouse and Newton-Stewart, once the property of Andrew Heron, a celebrated planter, who died in 1729. Loudon went there in 1831, and gives the dimensions⁵ of the *Ostrya*

¹ *Op. cit.* viii. 244 a.

² *Gard. Chron.* viii. 275, Fig. 47 (1890). Also figured in *Woods and Forests*, 1884, p. 318. The shapes of the trees figured in Loudon and in the *Gardeners' Chronicle* are very different.

³ *Kew Bull.* 1897, p. 404.

⁴ Walker, *Essays on Natural History and Rural Economy* (1812).

⁵ Bargally is fully described by Loudon, *op. cit.* i. 95-99 (1838).

from a letter of the then owner, J. Mackie, as 60 feet high and 4 feet 1 inch in girth at 4 feet in 1835. Henry could find no trace of this tree when he visited Bargally in 1904. At Glasnevin, Dublin, there are two trees, 30 and 25 feet high, narrowly pyramidal in habit. These are 34 years old and are growing on the bank of a stream.

(H. J. E.)

OSTRYA VIRGINICA, IRONWOOD, AMERICAN HOP HORNBEAM

Ostrya virginica, Willdenow, *Sp. Pl.* iv. 469 (1805); Loudon, *Arb. et Frut. Brit.* iii. 2015 (1838).
Ostrya virginiana, Koch, *Dendrologie*, ii. pt. ii. 6 (1873); Sargent, *Silva N. Amer.* ix. 34, t. 445 (1896), and *Trees N. Amer.* 192 (1905).
Ostrya Ostrya, Macmillan, *Metasperma Minnesota Valley*, 187 (1892).
Ostrya italica, sub-species *virginiana*, Winkler, *Betulaceae*, 22 (1904).
Carpinus Ostrya, Linnæus, *Sp. Pl.* 998 (1753) (in part).
Carpinus virginiana, Miller, *Dict.* ed. 8, No. 4 (1768).

A tree attaining 60 feet in height and 6 feet in girth, but usually smaller. This species, as seen in cultivation, is mainly distinguished from *Ostrya carpinifolia* by the presence on the young branchlets, petioles, and midrib of the leaf beneath, of short, erect, gland-tipped hairs. The leaves (Plate 201, Fig. 9) are usually larger, 3½ inches long, slightly cordate at the base, with fewer nerves, about twelve pairs. The nutlet in this species is larger, ¼ to ⅓ inch long, fusiform, flattened, without a tuft of hairs at the apex, surmounted by a plainly visible calyx-limb.

Two forms of this species occur in the wild state, which have been distinguished by Spach,¹ as follows:—

Var. *glandulosa*.—Young branchlets, petioles, and peduncles covered with gland-tipped short bristles. Specimens in the Kew herbarium from Ontario, Niagara Falls, and the Alleghany Mountains belong to this variety, which is the one known in cultivation in England.

Var. *eglandulosa*.—Glandular bristles not present on any part of the plant. Young shoots pubescent. This variety appears to be common in the western and southern parts of the United States, and does not appear to have been introduced into cultivation. In the absence of fruit, it would be difficult to distinguish this variety from *Ostrya carpinifolia*. (A. H.)

The tree grows, according to Sargent, on dry gravelly slopes and ridges, often in the shade of oaks and other large trees; and is a native of Canada and the United States, occurring on the northern shores of Lake Huron in western Ontario, eastward through the valley of the St. Lawrence to Chaleur Bay and Cape Breton Island; extending southward to Northern Florida and Eastern Texas, and westward to Northern Minnesota, the Black Hills of Dakota, Nebraska, and Kansas. It is most abundant and of its largest size in Southern Arkansas and Texas.

I saw it at Mt. Carmel in Illinois, and in the Arnold Arboretum, where it was a finer tree in size and habit than *Carpinus caroliniana*. It is known in America as

¹ *Ann. Sc. Nat.* sér. 2, xvi. 246 (1841), and *Hist. Vég.* xi. 218 (1842).

544 The Trees of Great Britain and Ireland

Ironwood, and is used for levers and tool handles, the wood being very tough and strong. Michaux states that on the estate of Duhamel du Monceau, in France, there were trees 20 feet high, from which self-sown plants had sprung up.

It was introduced into England by Bishop Compton in 1692, but is rarely met with except in botanic gardens. At Kew there are four trees, 20 to 30 feet in height. Others are growing at Eastnor Castle and at Grayswood, near Haslemere, where, though not planted above twenty years, it is growing vigorously, and looks as if it would make a handsome tree. A tree in the Edinburgh Botanic Garden was, in 1905, 39 feet high by 3 feet 3 inches in girth. Seedlings raised in my garden grow more freely than those of the common hornbeam; but not so fast as those of *Ostrya carpinifolia*. (H. J. E.)

OSTRYA JAPONICA, JAPANESE HOP HORNBEAM

Ostrya japonica, Sargent, *Garden and Forest*, vi. 383, f. 58 (1893), *Forest Flora Japan*, 66, t. 22 (1894), and *Silva N. Amer.* ix. 32 (1896); Shirasawa, *Icon. Ess. Forest. Japon.* text 49, t. 25, ff. 1-14 (1900).

Ostrya virginica, Maximowicz, *Mél. Biol.* xi. 317 (1881).

Ostrya italica, sub-species *virginiana*, Winkler, *Betulaceæ*, 22 (1904).

A tree attaining in Japan a height of 80 feet, with a tall straight stem, 5 feet in girth, but usually smaller. This species is considered by Maximowicz and Winkler to be identical with the American species, and there is said to be little or no difference in the fruit, which I have not seen. In cultivation, the Japanese tree is readily distinguished as follows:—Leaves (Plate 201, Fig. 10) velvety to the touch on the upper surface, which is covered with a dense erect pubescence; nerves, ten to twelve pairs, fewer than in the other species; base slightly cordate. Young branchlets densely white pubescent, without glandular hairs, which are also absent from the petiole and midrib of the leaf.

According to Sargent, this species is nowhere abundant in Japan, occurring only as scattered individuals in the forests of deciduous trees which cover Central and Southern Yezo, and growing also in the province of Nambu in Northern Hondo. Shirasawa, however, gives a more extensive distribution, stating that it is found also throughout the central chain of Hondo, in the provinces of Musahi, Kai, and Totomi, and also at Nikko; and farther south, in the island of Shikoku. *Ostrya japonica* is also a native of China, being an exceedingly rare tree in the mountain forests of Eastern Szechwan and Western Hupeh, where it was discovered by Père Farges and by myself. *Ostrya mandschurica*, Budischtschew,¹ recorded from Manchuria, is probably identical with this species.

The Japanese Hop Hornbeam was introduced in 1888 into the Arnold Arboretum by seed sent from Japan by Dr. Mayr, and has proved hardy in the climate of Eastern Massachusetts. There are two trees at Kew, sent by Prof. Sargent in 1897, which are now about 15 feet high and growing vigorously. There is also a healthy young tree at Grayswood, Haslemere. (A. H.)

¹ In Trautvetter, *Act. Hort. Petrop.* ix. 166 (1884). I have seen no specimens of this.

NOTHOFAGUS

Nothofagus, Blume, *Mus. Bot. Lugd. Bat.* i. 307 (1850); Oerstedt, *Vidensk. Selsk. Skrift.* V. ix. 331 (1873); Solereder, *System. Werth Holzstructur*, 253 (1885); Krasser, *Ann. K.-K. Naturhist. Hofmuseums, Wien*, xi. 149 (1896).

Calucechinus and *Calusparassus*, Hombron et Jacquinot, *Voy. Pôle. Sud.* Atlas, tt. 6-8 (1853).

Lophozonia, Turczaninow, *Bull. Soc. Imp. Nat. Mosc.* xxxi. 396 (1858).

Fagus, section *Nothofagus*, Bentham et Hooker, *Gen. Pl.* iii. 410 (1880).

THIS genus comprises the beeches inhabiting extra-tropical South America, Australia, Tasmania, and New Zealand, and was formerly considered to be a section of the genus *Fagus*, which, however, as now limited, includes only the species of the northern hemisphere. The two genera are distinguished as follows:—

NOTHOFAGUS.—Trees or shrubs, with deciduous or evergreen foliage.¹ Flowers monœcious or rarely diœcious, either solitary or in groups of threes. Fruit: involucre, two-, three- or four-valved, usually bearing externally transverse entire, toothed or lobed lamellæ, with or without gland-tipped processes; or in rare cases the valves are smooth and without appendages; nuts, solitary or three in each involucre.

FAGUS.—Trees with deciduous foliage. Flowers monœcious; the staminate numerous in globose heads, the pistillate in pairs. Fruit: involucre, covered externally with bristly, deltoid or foliaceous processes; nuts, two in each involucre.

About seventeen² distinct species of *Nothofagus* are known, constituting three natural sections, based on the characters of the foliage:—

I. Leaves deciduous, soft in texture, folded in bud along the lateral nerves, crenate or serrate in margin.

1. *Nothofagus antarctica*, Oerstedt. Large tree, S. America. Introduced into cultivation. Leaves ovate, $\frac{3}{4}$ to 1 inch long; lateral nerves three to five pairs; margin slightly lobed, unequally crenate, with three to five teeth between the ends of each adjacent pair of nerves.

2. *Nothofagus Montagnei*,³ Reiche. Shrub or low tree. Chonos Archipelago. Not introduced. A little-known species, of which I have seen no specimen; leaves $\frac{1}{2}$ inch long, firmer in texture and more conspicuously veined above than those of the preceding species, from which it is also distinguished by the yellow-coloured pubescence on the branchlets.

¹ Bunbury, in *Bot. Fragments*, 322 (1883), writes an interesting article on the different types of foliage which are met with in this genus.

² *N. alpina*, Reiche (*Fagus alpina*, Poeppig et Endlicher), is a doubtful species.

³ *Calucechinus Montagnei*, Hombron et Jacquinot, *loc. cit.* t. 7 (1853). *Fagus Montagnei*, Philippi, *Linnaea*, xxix. 45 (1857).

3. *Nothofagus pumilio*,¹ Krasser. Shrub or low tree, S. America. Not introduced. Leaves ovate, 1 to 1½ inch long; lateral nerves five to seven pairs; regularly bicrenate in margin, with two teeth between the ends of each adjacent pair of nerves. Young branchlets clothed with dense yellow pubescence.

4. *Nothofagus obliqua*, Blume. Large tree, S. America. Introduced. Leaves, 1 to 2½ inches long, ovate-oblong, glaucous beneath; lateral nerves seven to eleven pairs; lobulate and serrate in margin.

5. *Nothofagus procera*,² Oerstedt. Large tree, S. America. Not introduced. Leaves, 2 to 3½ inches long, oblong; lateral nerves fifteen to sixteen pairs; doubly serrate in margin.

6. *Nothofagus Gunnii*,³ Oerstedt. Shrub, Tasmania. Not introduced. Leaves, ½ inch long, ovate; lateral nerves six pairs, prominent beneath; margin regularly crenate, with one tooth between the ends of each adjacent pair of nerves.

II. Leaves evergreen, margin not entire. In this section, the leaves are usually very coriaceous, and glabrous, or with only slight pubescence.

A. *Leaves minutely crenulate in margin.*

7. *Nothofagus apiculata*,⁴ Krasser. Tree attaining 40 feet in height, New Zealand. Not introduced. Leaves 1 inch long, elliptical, conspicuously mucronate at the apex.

B. *Leaves crenate in margin.*

8. *Nothofagus Menziesii*, Oerstedt. Large tree, New Zealand. Introduced. Leaves, ½ inch long, ovate, rhomboid or orbicular, doubly crenate, with two pubescent pits on each side of the midrib near the base on the lower surface.

9. *Nothofagus Cunninghami*, Oerstedt. Large tree, Australia, Tasmania. Introduced. Leaves, ½ inch long, ovate, deltoid or rhomboid, simply crenate; lower surface without pits or resinous papillæ.

10. *Nothofagus betuloides*, Blume. Large tree, S. America. Introduced. Leaves, ¾ to 1 inch long, ovate, crenate or obtusely dentate; lower surface dotted with resinous papillæ.

C. *Leaves serrate in margin.*

11. *Nothofagus Dombeyi*,⁵ Blume. Large tree, S. America. Not introduced. Leaves, 1 inch long, lanceolate; nerves six pairs; lower surface dotted with resinous papillæ.

12. *Nothofagus nitida*,⁶ Krasser. Large tree, S. America. Not introduced. Leaves, 1 to 1½ inch long, trapezoid-ovate, acuminate; nerves six pairs; lower surface not dotted.

13. *Nothofagus fusca*, Oerstedt. Large tree, New Zealand. Introduced.

¹ *Fagus pumilio*, Poeppig et Endlicher, *Nov. Gen. et Sp.* ii. 68, t. 195 (1835). *Fagus antarctica*, var. *bicrenata*, DC. *Prod.* xvi. 2, p. 120 (1864).

² *Fagus procera*, Poeppig et Endlicher, *Nov. Gen. et Sp.* ii. 69, t. 197 (1835).

³ *Fagus Gunnii*, Hooker, *Icon. Plant.* t. 881 (1852).

⁴ *Fagus apiculata*, Colenso, *Trans. N. Zeal. Instit.* xvi. 335 (1884).

⁵ *Fagus Dombeyi*, Mirbel, *Mém. Mus. Paris.* xiv. 467, t. 24 (1827).

⁶ *Fagus nitida*, Philippi, *Linnaea*, xxix. 44 (1857).

Leaves, 1 to 1½ inch long, thin in texture, ovate, rounded at the apex; serrations large, few, irregular; nerves four to seven pairs.

14. *Nothofagus Moorei*, Krasser. Large tree, Australia. Introduced. Leaves, 2 to 3 inches long, ovate-lanceolate, acuminate; sharply and finely serrate; nerves ten to fifteen pairs.

III. Leaves evergreen, entire in margin. In this section, the leaves on young trees are glabrous; but on older trees they become densely tomentose on the under surface. They resemble considerably the leaves of certain species of *Vaccinium*.

15. *Nothofagus cliffortioides*, Oerstedt. Large tree, New Zealand. Introduced. Leaves, ¼ to ½ inch long, ovate, rounded at the base; tomentum whitish.

16. *Nothofagus Solandri*,¹ Oerstedt. Large tree, New Zealand. Not introduced. Leaves ¼ to ½ inch long, oblong, cuneate at the base; tomentum whitish.

17. *Nothofagus Blairii*,² Krasser. Large tree, New Zealand. Not introduced. Leaves ¾ inch long, ovate, rounded at the base, apiculate at the apex; tomentum yellowish. (A. H.)

NOTHOFAGUS CLIFFORTIOIDES

Nothofagus cliffortioides, Oerstedt, *Vidensk. Selsk. Skrift.* V. ix. 355 (1873).

Fagus cliffortioides, J. D. Hooker, in *Hook. Icon. Plant.* tt. 673 (1844) and 816 B (1852), *Flora New Zealand*, i. 230 (1854), and *Handb. New Zealand Flora*, 250 (1864); Kirk, *Forest Flora New Zealand*, 201, tt. 101, 101 A (1889); Cheeseman, *New Zealand Flora*, 643 (1906).

An evergreen tree, attaining, in New Zealand, about 50 feet in height and 6 feet in girth. Young branchlets pubescent; buds minute, ovoid, shining, brown. Leaves (Plate 202, Fig. 4) persistent for two or three years, distichous and crowded on the branchlets, coriaceous, minute, ¼ to ½ inch in length, entire in margin; on young plants ovate, rounded at both base and apex, green and glabrous on both surfaces; on adult trees, ovate or ovate-oblong, rounded and unequal at the base, subacute at the apex, minutely punctate above, greyish-white with dense appressed pubescence beneath; petioles short and pubescent. Male flowers solitary; stamens eight to twelve. Fruit: involucre ⅓ to ¼ inch long, three-lobed, each lobe with two or three entire transverse lamellæ; nuts one to three, winged, one or two triquetrous, the third flattened.

This tree is known in New Zealand as the "mountain birch," and is confined to mountainous regions except in the south-western corner of the South Island, where it descends to sea-level. It is not found in the northern part of the North Island; but elsewhere is very common in the forests³ between 2000 and 4000 feet elevation,

¹ *Fagus Solandri*, Hooker, *Icon. Plant.* t. 639 (1844).

² *Fagus Blairii*, Kirk, *Trans. N. Zeal. Inst.* xvii. 297, 306 (1885).

³ A view of a forest of this species in the South Island at 3000 feet, showing a dense undergrowth of young beech and tall smooth stems of older trees, is given in Schimper, *Plant Geography*, 760, f. 460 (1904).

often forming the timber line, when it becomes a mere bush. The wood, though of no great size, is used for telegraph-poles, fencing-posts, railway sleepers, and wharf-piles, the heartwood being very durable in situations where it is exposed to alternations of dryness and moisture.

N. cliffortioides is extremely rare in cultivation. There are two specimens at Enys, Cornwall, which, according to Mr. John D. Enys, were 35 feet and 28½ feet high respectively in 1905; but when Elwes saw them in that year they were very slender and not thriving. These trees are semi-deciduous, most of the leaves, after turning brilliant red in autumn, falling off during winter; whereas, in New Zealand, the foliage is strictly evergreen. Another tree is growing at Messrs. Veitch's nursery at Coombe Wood, where it stands out of doors without any protection. It is very slow, however, in growth, and is only about 12 feet in height. (A. H.)

NOTHOFAGUS MENZIESII

Nothofagus Menziesii, Oerstedt, *Vidensk. Selsk. Skrift.* V. ix. 355 (1873).
Fagus Menziesii, J. D. Hooker, *Icon. Plant.* t. 652 (1844), and *Flora New Zealand*, i. 229 (1854);
Kirk, *Forest Flora New Zealand*, 175, t. 89 (1889); Cheeseman, *New Zealand Flora*, 640 (1906).

An evergreen tree, attaining in New Zealand 100 feet in height and 15 to 25 feet in girth. Bark silvery-white, resembling that of the common English birch. Young branchlets covered with dense erect brown pubescence. Leaves (Plate 202, Fig. 9) persistent for two or three years, distichous on the branchlets, about ½ inch long, coriaceous, deltoid, ovate or rhombic; cuneate at the base, obtuse at the apex; glabrous; upper surface dark-green, shining; lower surface pale-green, with usually two (occasionally only one or none) small pits fringed with brownish hairs near the base of the midrib; lateral veins about three pairs; margin irregularly and doubly crenate; petioles short, pubescent. Male flowers solitary; calyx four- to six-lobed; stamens six to twelve. Fruit: involucre ¼ to ⅓ inch long, cleft into four narrow lobes, each with five transverse scales, cut to the base into recurved linear gland-tipped processes; nuts three, one two-winged, two three-winged, the wings produced upwards into sharp points.

This species, which is known in New Zealand as the "silver birch" or "red birch," is common in the mountain forests of both the North and South Islands, ascending from sea-level to 3500 feet. The wood is dark-red, strong, and compact, and being easily worked, is suitable for making furniture.

A small tree of this species is growing in the Temperate House at Kew; and we are not aware that it has ever been tried in the open air. The tree has handsome foliage, and should be hardy in Cornwall and the south of Ireland. (A. H.)

NOTHOFAGUS FUSCA

Nothofagus fusca, Oerstedt, *Vidensk. Selsk. Skrift.* V. ix. 355 (1873).
Fagus fusca, J. D. Hooker, *Icon. Plant.* t. 630, 631 (1844), and *Flora New Zealand*, i. 229 (1854);
Kirk, *Forest Flora New Zealand*, 179, t. 90 (1889); Cheeseman, *New Zealand Flora*, 641 (1906).

An evergreen tree, attaining in New Zealand 100 feet in height and 25 feet in girth. Bark of young trees white and smooth, becoming on old trees furrowed longitudinally and brown in colour. Young branchlets minutely pubescent. Leaves (Plate 202, Fig. 8) persistent for two years, distichous on the branchlets, ¾ to 1½ inch long, thin in texture, glabrous, broadly ovate, cuneate at the base, rounded at the apex, dark-green and shining above, pale-green beneath; sharply serrate with a few large teeth in the upper two-thirds of the leaf; lateral nerves four to five pairs; petioles about ⅛ inch, pubescent. Male flowers solitary or in threes; calyx five-toothed; stamens eight to sixteen. Fruit: involucre nearly ½ inch long, viscid-pubescent, four-lobed, each lobe with three to five transverse entire or fringed scales; nuts three, as in *N. Menziesii*.

This species is a native of New Zealand, where it is known as the "black birch" or "red birch." It grows in forests at elevations between sea-level and 3500 feet, being a splendid tree. Its distribution is North Island from Monguni and Kartaia southwards, but local to the north of the East Cape; South Island from Nelson to Foveaux Straits, but rare in Canterbury and Eastern Otago. The wood is dark-red, strong and compact, and more durable than that of the other species; it is frequently used for wharves, bridges, and fencing posts.

A small tree of this species about 10 feet high, and said to be thirty years old, is growing in the Coombe Wood Nursery. At Castlewellan, Co. Down, there is a tree¹ about 18 feet high, which was imported from New Zealand some years ago as a small plant in a Wardian case. It is growing rapidly, making an annual growth of a foot. The old leaves remain on the branches till the new ones appear, changing before they fall to a brilliant red, which contrasts well with the light green of the young growths. (A. H.)

NOTHOFAGUS MOOREI

Nothofagus Moorei, Krasser, *Ann. K.-K. Naturhist. Hofmuseums, Wien*, xi. 163 (1896).
Fagus Moorei, F. v. Mueller, *Fragm. Phyl. Austral.* v. 109 (1865); Bentham, *Fl. Australiensis*, vi. 211 (1873).

An evergreen tree, attaining in Australia 150 feet in height. Young branchlets pubescent; buds ovoid, acute, brown. Leaves (Plate 202, Fig. 7) persistent for two or three years, distichous on the branchlets, coriaceous, glabrous; shining, dark-

¹ This is figured as *Fagus cliffortioides* in Earl Annesley's *Beautiful and Rare Trees*, 71 (1903).

green above; pale-green beneath; ovate or ovate-lanceolate; 2 to 3 inches long on barren branchlets, about 1 inch long on flowering shoots; unequally cuneate at the base, acuminate at the apex, finely and sharply serrate; lateral nerves 8 to 12 pairs, prominent on the upper surface; petioles very short, pubescent. Flowers unknown. Fruit: involucre about $\frac{5}{8}$ inch long, four-lobed; lobes lanceolate, acute with pubescent scales terminating in glandular processes; nuts three, two three-winged, the other two-winged.

This tree was discovered by Mr. C. Moore, Curator of the Botanic Gardens, Sydney, in New South Wales, and is the only southern beech occurring in a subtropical region. It forms dense forests at the head of Bellinger River and Bealsdown Creek, at about 4000 feet altitude; and a few trees have also been seen near the source of the Macleay River.

It was introduced into cultivation at Kew about fifteen years ago, and there is a small tree now growing there in the Temperate House. The only specimen living in the open air, so far as we know, is growing in the garden of Mr. Thomas Acton at Kilmacurragh, Co. Wicklow. It was 18 feet high in 1906, and had bark resembling that of *Prunus avium*. (A. H.)

NOTHOFAGUS CUNNINGHAMI

Nothofagus Cunninghami, Oerstedt, *Vidensk. Selsk. Skrift*, V. ix. 355 (1873).
Fagus Cunninghami, J. D. Hooker, *Journ. Bot.* ii. 152, t. 7 (1840), and *Flora Tasmania*, i. 346 (1860); F. v. Mueller, *Fragm. Phyt. Austral.* v. 110 (1865); Bentham, *Flora Australiensis*, vi. 210 (1873); Rodway, *Tasmanian Flora*, 182 (1903).

An evergreen tree, said to attain in Tasmania 200 feet in height and 40 feet in girth. Bark, as seen in cultivated trees, roughened by small scales and fissuring longitudinally. Young branchlets densely and minutely pubescent. Buds conical, sharp-pointed and curved at the apex, shining, brown. Leaves (Plate 202, Fig. 5) persistent for two or three years, distichous and crowded on the branchlets, coriaceous, about $\frac{1}{2}$ inch in length; broadly ovate, deltoid or rhombic; cuneate or cordate at the base, acute at the apex; unequally crenate in margin; both surfaces glabrous, veins inconspicuous and scarcely prominent beneath; petioles short, pubescent. Male flowers solitary; stamens eight. Fruit: involucre $\frac{1}{4}$ inch long, four-lobed, each lobe with five or six rows of dorsal transverse scales, split up into gland-tipped processes; nuts usually three, two lateral triquetrous and three-winged, the other flattened and two-winged.

This species is very common in Tasmania, where it is known as the "Tasmanian myrtle," and forms a large proportion of the forests in the mountainous and western humid districts. It ascends to 4000 feet, becoming at this elevation a mere shrub, a few feet in height. It also occurs on the mainland of Australia, in Victoria, in a few scattered localities, being most common according to F. v. Mueller on the Baw-baw mountains, and less common at Dandenong, Mount Juliet, Wilson's Promontory,

La Trobe, Tyre's and Thomson's Rivers, and in a few places in the cooler and moister parts of Gipp's Land. The wood¹ apparently varies: one kind, "red myrtle," being of a bright pink colour, with a grain like that of the English beech, and considered to be suitable for cabinetwork; another kind, "white myrtle," brownish-grey in tint, is not so attractive in appearance.

N. Cunninghami is very rare in cultivation. The finest tree (Plate 154), said by Lord Barrymore to have been planted about fifty years ago, is growing at Fota, Co. Cork, and measured, in 1904, 48 feet high by 3 feet 3 inches in girth. This tree has numerous branches, many of them ascending from near the base of the trunk. A tree at Kilmacurragh, Co. Wicklow, with branches ascending and curving at the tips, was 40 feet high by 3 feet 4 inches in 1906. This tree has excrescences on the trunk, similar to the so-called "wood-balls," which are often seen on the common beech. It flowered in 1906. At Osborne, Isle of Wight, there is a tree, 30 feet by 2 feet 2 inches, which when Elwes saw it in 1906 seemed thriving.

It seems to be as hardy as any of the genus, and might be planted with good prospects of success in the extreme south-west of England near the sea.

(A. H.)

NOTHOFAGUS BETULOIDES

Nothofagus betuloides, Blume, *Mus. Bot. Lugd. Bat.* i. 307 (1850); Reiche, *Chil. Buch.* 15 (1897); Wildeman, *Voy. Belgica*, 74 (1905); Macloskie, *Princeton Univ. Expedit. Patagonia, Botany*, 329 (1903-6).
Fagus betuloides, Mirbel, *Mém. Mus. Paris*, xiv. 465, t. 4 (1827); Loudon, *Arb. et Frut. Brit.* iii. 1982 (1838); Hooker, *Journ. Bot.* ii. 155 (1840), and *Fl. Antarct.* ii. 349, t. 124 (1847).
Fagus Forsteri, Hooker, *Journ. Bot.* ii. 156, t. 8 (1840).
Betula antarctica, Forster, *Comm. Goett.* ix. 45 (1789).
Calusparassus betuloides and *C. Forsteri*, Hombron et Jacquinet, *Voy. Pôle Sud*, Atlas t. 7 (1853).

A large evergreen tree. Bark smooth, grey; scaling near the base in old trees. Young branchlets slender, viscid, covered with short pubescence. Buds minute, brown, ovoid. Leaves (Plate 202, Fig. 3) persistent for two or three years, distichous and crowded on the branchlets, rigid, coriaceous, $\frac{3}{4}$ to 1 inch long by $\frac{1}{2}$ inch or slightly more in breadth, ovate, rounded at the base, acute at the apex, crenate or serrate in margin; upper surface shining, glabrous, often viscid; lower surface finely reticulate, glabrous, dotted with resinous papillæ; petioles short. Male flowers solitary; calyx funnel-shaped, four- to seven-lobed; stamens ten to sixteen, with long and slender filaments. Fruit: involucre four-lobed, with erect filiform glandular processes.

According to Loudon, both *N. betuloides* and *N. antarctica* were introduced in 1830, but he had not seen a specimen of either. Sir W. J. Hooker² states that healthy young trees of both species, the first, as far as he knew, that ever had reached Europe, were sent in Wardian cases to Kew from Cape Horn in 1843, being

¹ Report on Tasmanian Timbers by Mr. R. A. Ransome, of the Stanley Works, Chelsea, in *Kew Bull.* 1889, pp. 114, 115.

² *Notes Bot. Antarctic Voyage*, 64 (1843); cf. also Loudon, *Gard. Mag.* 1843, p. 442.

a consignment from his son, who was attached as botanist to the Antarctic expedition of the *Erebus* and *Terror*. (A. H.)

The largest and finest specimen which I have seen in cultivation is at Bicton (Plate 155). It measured in 1906 about 50 feet in height and 6½ feet in girth; but bore no fruit on two occasions when I saw it. At Pencarrow, Cornwall, a tree,¹ reported by Mr. Bartlett to have been obtained from Messrs. Veitch in 1847, was 36 feet by 4 feet 3 inches in 1903. One at Coldrinick in the same county was measured in 1905 by Mr. Bartlett, who gives its dimensions as 45 feet by 5 feet 5 inches. There is another specimen,² about sixty years old, growing on Sir John Llewellyn's property at Caswell Bay, near Swansea, which he tells me measured 25 feet by 3 feet 2 inches in 1907. It is close to the sea and in consequence has been shorn off by the sea wind to the same height as the Portugal laurels and poplars which grow beside it.

At Grayswood, Haslemere, at 600 feet elevation, a tree, said by Mr. B. C. Chambers to have been planted in 1882, measured 34 feet by 2 feet 3 inches in 1906. At Hafodunos, Denbighshire, a tree, reported by Col. Sandbach to have been planted in 1855, was in 1904 36 feet high by 5 feet 2 inches in girth at 3 feet from the ground, dividing at 5 feet up into two stems. There is no tree growing now at Kew, one, a healthy specimen, having been killed³ by frost in January 1867. There is also a tree growing at Ashridge Park, Herts, which is about 30 feet by 3 feet, on which Miss Woolward has observed fruit, and a smaller one is in the Knap Hill Nursery, near Woking. A tree at Powerscourt, Co. Wicklow, was, in 1906, 33 feet high by 2 feet 10 inches in girth.

I have a sample board from a tree of this species, which grew on the rockery at Lucombe and Pince's Nursery, Exeter. This was cut down when the nursery was cleared for building in March 1903. In 1886, it was 35 feet high and 2 feet 8 inches in girth at 3 feet from the ground,⁴ and had not grown much in the succeeding years. The timber was of poor quality, and had begun to decay.

(H. J. E.)

NOTHOFAGUS OBLIQUA

Nothofagus obliqua, Blume, *Mus. Bot. Lugd. Bat.* i. 307 (1850); Reiche, *Chil. Buch.* 8 (1897); Wildeman, *Voy. Belgica*, 75 (1905).

Fagus obliqua, Mirbel, *Mém. Mus. Paris*, xiv. 465, t. 23 (1827); Hooker, *Journ. Bot.* ii. 153 (1840).

Fagus glauca, Philippi, *Linnaea*, xxix. 43 (1857).

Lophozonia heterocarpa, Turczaninow, *Bull. Soc. Imp. Nat. Mosc.* xxxi. 396 (1858).

A deciduous tree, attaining in Chile a height of over 100 feet. Bark, according to Reiche, dark in colour and fissured. Young branchlets glabrous; buds small,

¹ Figured in *Gard. Chron.* xxxiii. 10, f. 5 (1903), where it is erroneously stated to have been introduced from New Zealand.

² Figured in *Gard. Chron.* 1872, p. 466, f. 136, and 1886, xxv. 104, f. 18.

³ J. Smith, *Records of Kew Gardens*, 277 (1880).

⁴ *Gard. Chron.* xxv. 104 (1886).

conical, sharp-pointed, glabrous, brown, few-scaled, and appressed to the branchlets. Leaves (Plate 202, Fig. 2) variable in size, 1 to 2½ inches in length, ½ to 1 inch in breadth, thin in texture, ovate-oblong, unequal at the rounded or cuneate base, sub-acute or obtuse at the apex; dark-green above, very pale beneath, both surfaces glabrous except for slight pubescence on the midrib and nerves; margin shallowly lobulate in the lower half, the lobules and upper part of the leaf serrate with minute triangular acute teeth; nerves 8 to 11 pairs, prominent on the lower surface, running obliquely to the margin; petiole ⅛ to ¼ inch long. Male flowers solitary; calyx irregularly lobed, stamens thirty to forty. Fruit: involucre four-valved, valves pubescent on the back with lobed appendages bearing stalked glands; nuts three, two trigonous and three-winged, one flattened and two-winged.

This species is very variable, especially as regards the size and pubescence of the leaf, and De Candolle¹ distinguished three varieties:—Var. *valdiviana*: leaves small, glabrous, with cuneate base; var. *macranthera*: stamens long, leaves pubescent beneath; and var. *macrocarpa*, with the nuts longer than the valves of the involucre.

N. obliqua was introduced² into England by Lobb in 1849, and in the following year it was said to have been growing freely in the open air in Messrs. Veitch's nursery at Exeter. None of the original plants appear, however, to have survived.

Plants raised from seed, brought from Chile by Elwes in 1902, have grown with great vigour at Kew,³ being now about 8 feet in height. At Monreith, Sir Herbert Maxwell, who received a plant from Kew, reports that it has borne without injury 20° of frost, and may be assumed to be perfectly hardy. In Lord Ducie's garden at Tortworth, this tree has grown with astonishing vigour, being now 12 feet high and 8 inches in girth; it endured the severe frost of May 1905 without any apparent injury. The seedlings which were raised at Colesborne, however, never throve, and died before attaining any size, which is possibly due to the presence of lime in the soil.

(A. H.)

NOTHOFAGUS ANTARCTICA

Nothofagus antarctica, Oerstedt, *Vidensk. Selsk. Skrift.* V. ix. 354 (1873); Reiche, *Chil. Buch.* 11 (1897); Wildeman, *Voy. Belgica*, 73 (1904); Macloskie, *Princeton Univ. Exped. Patagonia*, Botany, 326 (1903-1906).

Fagus antarctica, Foster, *Comm. Goett.* ix. 24 (1789); Loudon, *Arb. et Frut. Brit.* iii. 1982 (1838); Hooker, *Journ. Bot.* ii. 149, t. 6 (1840), and *Fl. Antarct.* ii. 345, t. 123 (1847).

Calucechinus antarctica, Hombron et Jacquinot, *Voy. Pôle Sud*, Atlas, tt. 6, 7 (1853).

A deciduous tree, attaining in Terra del Fuego at low elevations a very large size. Young branchlets covered with dense erect pubescence, persistent in the second year. Buds, ⅛ inch long, ovoid, slightly compressed, glabrous, few-scaled. Leaves (Plate 202, Fig. 1) ½ to 1 inch long, crumpled and uneven in surface, oblong-

¹ *Prod.* xvi. 2, p. 119 (1864).

² *Gard. Chron.* 1849, p. 563; Lindley, *Journ. Hort. Soc.* vi. 265 (1851); Lindley and Paxton, *Flower Garden*, ii. 166 (1852).

³ Cf. *Kew Bull.* 1906, p. 379.

ovate, unequal and usually cordate at the base, rounded at the apex, variable in pubescence, dark-green above, light-green beneath; nerves usually four pairs; margin with three or four pairs of shallow lobes, which are minutely and irregularly dentate, the teeth being rounded or acute; petiole $\frac{1}{8}$ to $\frac{1}{4}$ inch, pubescent. Male flowers solitary; calyx five-partite; stamens ten, as long as the calyx. Fruit: involucre four-partite, each lobe with three to four transverse reddish scales; nuts three, the central one two-winged, the lateral pair three-winged.

Two distinct forms occur:—

1. Var. *sublobata*, DC.¹—Petiole and upper surface of the leaf glabrescent; lower surface glabrous except on the nerves, which are clothed with long appressed hairs.

2. Var. *uliginosa*, DC.¹—Leaves pubescent on both surfaces with minute erect hairs.

This species was introduced in 1843, as mentioned in our account of *N. betuloides*, but it is doubtful if any of the original plants are still living. The only specimen which we have discovered is a bushy tree, about 15 feet high, which is growing alongside a fine tree of *N. betuloides* at Hafodunos, Denbighshire. Colonel Sandbach believes it to be about thirty years old.

Plants raised from seed, collected by Elwes in Chile in 1902, are now in cultivation at Kew,² in a peat-bed, and have attained about 6 feet in height. They are vigorous in growth, and have passed through the severe frosts of 1906-1907 without injury, and look as if they might grow to be trees of considerable size. (A. H.)

DISTRIBUTION OF THE SOUTH AMERICAN BEECHES

In extra-tropical South America, the beeches are the dominant trees, extending from a point on the west coast of Chile about lat. 33°, southward to Patagonia and Tierra del Fuego, and crossing the Andes into Argentina. The best account of the Chilean beeches is given by Reiche,³ from whom, supplemented by my own observations in 1901-1902, I take the following particulars.

The most northerly species is *N. obliqua*, which extends on the coast up to about lat. 33°, but in the extreme north does not form forest except in the interior valleys. About lat. 35° it is the principal tree in the forest which formerly clothed the lower slopes of the Andes, but which is now fast vanishing before the attacks of man. The tree is called Roble Pellin by the Spaniards, and grows to a large size with a tall straight trunk, attaining a height of 120 feet or more, and a girth of 20 to 30 feet. In the forest country, which commences south of the Maule River, it is mixed with *N. Dombeyi*; and these two species form the principal timber supplies of Chile, and are largely cut for house-building, railway sleepers, and other purposes. Some cargoes of this timber have lately been imported into England, under the name of Chilean Oak; and by the courtesy of the Great Western Railway Company, I have received one of these sleepers, which has a dense reddish wood, not at all resembling

¹ *Prod.* xvi. 2, 120 (1864). De Candolle's var. *bicrenata* is *Nothofagus pumilio*.

² Cf. *Kew Bull.* 1906, p. 381.

³ *Beiträge Kenntniss Chilen. Buchen* (Valparaiso, 1897).

that of the European beech, and apparently suitable to take the place of the lower grades of mahogany in the manufacture of furniture. It cracks, however, badly in drying, and will require very careful seasoning. In the forests of Chillan (lat. 36°), *N. obliqua* grows up to 4000 or 5000 feet, being replaced at higher elevations by *N. antarctica* and *N. pumilio*; and reaches its southern limit in the region of Lake Llanquihue. A photograph by Mr. Bartlett Calvert, who accompanied me on my journey, shows the appearance of this tree in the forest at about 3000 feet, near the source of the Renaico River (Plate 156). Here the undergrowth is usually composed of a dense thicket of the Chilean bamboo (*Chusquea sp.*); and in the more open places the ground is often carpeted with a dense bed of *Alstroemeria aurantiaca*, whose brilliant orange flowers produce a most lovely effect. In the wetter places it is associated with *Drimys Winteri* and many beautiful shrubs and herbaceous plants, of which *Eucryphia pinnatifida*, *Embothrium coccineum*, *Tropæolum speciosum*, and several species of Fuchsia and Calceolaria are the choicest ornaments of our gardens in the warmer and damper parts of the south-west of England and Ireland. In many parts of the Chilean forests it is often covered with a lovely parasitic plant, *Myzodendron linearifolium*, DC.,¹ which hangs in silvery masses from the branches.

Nothofagus Dombeyi is known to the Chileans by its Indian name of *Coigue*, and is a large and common tree in Chile. It is usually associated with *N. obliqua*, but does not extend so far to the northward, not being found to the north of the Maule river. It is widely spread in Araucania, Valdivia, and Llanquihue, and occurs also on the Argentine side of the frontier. It grows on the island of Chiloe, and has been collected on the river Aysen (lat. 45°); but its extreme southern limit is not accurately known.

Nothofagus nitida, which has been much confused with *N. Dombeyi*, is a common forest tree in the coast mountains of Valdivia, and grows on Chiloe and the Guaitecas Islands. The distribution of this species has not yet been satisfactorily determined.

Nothofagus procera, known as *Rauli*, is less common than *N. obliqua*, to which it is allied, and usually grows scattered in the forest. Its northerly limit lies between 35° and 36° lat., and it does not occur farther south than the province of Valdivia, where it becomes a stately tree. It does not cross the frontier into Argentina.

Nothofagus antarctica is widely distributed, extending from about lat. 38° to Tierra del Fuego. It is the commonest species which I found on my tour at high elevations, both on the Chilean and Argentine sides of the frontier. It is associated with Araucaria at 4000 feet, and is common also in the plain of Valdivia in marshy situations. In the mountains around the great lake of Nahuelhuapi, the leaves of this species had already assumed their autumnal tint in February. *N. antarctica* and *N. betuloides* are the dominant trees in Patagonia and Tierra del Fuego; and

¹ I found this species in the low country about Temuco in Chile, and also on the Argentine side of the frontier in two or three localities. Two other species also occur:—*M. oblongifolium*, DC., which I found on *Nothofagus antarctica*, near the baths of Chillan at 5000 to 7000 feet elevation; and *M. punctulatum*, DC., which I gathered on *Nothofagus Dombeyi* at Lake Meliquina, and in the dense evergreen forest which skirts the glaciers of the great Tronador mountain at 2000 feet in lat. 40°.

according to Dusén,¹ their distribution is regulated by the amount of rainfall. In the western parts of Tierra del Fuego, where the rainfall is heavy, the coast forest is evergreen and is mainly composed of *N. betuloides* and *Drimys Winteri*; and *N. antarctica* is only met with in the mountains. In the eastern part of Tierra del Fuego, where the rainfall is slight, the latter species descends to sea-level and grows in mixture with *N. betuloides* and *N. pumilio*.

In Western Patagonia, the evergreen forest predominates in the Archipelago and on the western side of the mountain range, where much rain falls and the prevailing winds are south-westerly; whereas, on the eastern slopes of the mountains, where the climate is comparatively dry, the forests are composed of deciduous trees. According to Dusén, the deciduous-leaved forest is well seen at a point 30 miles up the River Aysen. In the inland region the ground is covered by a thin park-like forest, which is almost exclusively composed of one species, *N. antarctica*. This tree does not grow in such close masses as the European beech, and, owing to the absence of dense shade, there is a luxuriant undergrowth of herbs and shrubs. These park-like forests prevail up to 2300 feet. Above this elevation steppes occur, which are studded with small groves of *N. pumilio*, the ground being covered with mosses. At 3000 feet *N. pumilio* is only a low tree, which gradually becomes smaller as it ascends, until at 4300 feet it forms a stunted forest of dwarfed trees, with their branches interlaced together.

An earlier account of the Antarctic beeches is given by Sir J. D. Hooker,² who states that *N. antarctica* strongly resembles the European beech in its deciduous leaves, form of trunk, and smooth bark. It ascends much higher at Cape Horn than *N. betuloides*, and is much the larger tree of the two when it is found growing at sea-level. *N. betuloides*, however, grows to a very large size about the Straits of Magellan, and being evergreen, is a marked feature of the scenery in winter, as its upper limit is sharply defined, and contrasts with the dazzling snow that covers the matted and naked branches of *N. antarctica*. Captain King³ observed many trees of *N. betuloides* 3 to 4 feet in diameter, one being as large as 7 feet. He describes the wood as heavy and far too brittle for masts or even boat-hooks, but cutting up into tolerable planks. Hooker considered the timber of the deciduous species to be superior.

N. betuloides, while much commoner in the south, extends along the coast range as far north as Valdivia.⁴ It is replaced in the Guaitecas Islands by *N. Dombeyi* and *N. nitida*.⁵

Nothofagus pumilio has been much confused with *N. antarctica*, of which it was made var. *bicrenata* by De Candolle. It is very distinct in both foliage and fruit. It extends from Chillan and Nahuelbuta in Chile southward to the Straits of Magellan, and is usually a shrub, constituting the scrubby growth which prevails

¹ Princeton Univ. Exped. Patagonia, Botany 2, 10, 26 (1903-1906); and Engler, Bot. Jahrbüch. xxiv. 179 (1897).

² Fl. Antarct. ii. 345.

³ Voyage of the "Adventure" and "Beagle," i. 576 (1839). Ball, Notes of a Naturalist in S. America, 225, says that *N. betuloides* "has a thick trunk, commonly three or four feet in diameter, but nowhere attains any great height. Forty feet appeared to me the outside limit attained by any that I saw at Eden Harbour or elsewhere."

⁴ Reiche, loc. cit.

⁵ Dusén, loc. cit.

above timber-line in the mountains. I saw this species near the baths of Chillan, lat. 37°, where it grew as a bush at 6000 to 8000 feet on the crests of the ridges in volcanic soil. According to Reiche, it occurs as undergrowth in the Araucaria forests at 4000 to 5000 feet elevation; but in sheltered situations in the mountains of Valdivia and Llanquihue it occasionally becomes a tree 60 feet in height.
(H. J. E.)

ARBUTUS

Arbutus, Linnæus, *Gen. Pl.* 123 (1737); Bentham et Hooker, *Gen. Pl.* ii. 581 (1876).
Unedo, Hoffmannsegg et Link, *Fl. Port.* i. 415 (1809).

EVERGREEN trees or shrubs, belonging to the order Ericaceæ. Leaves simple, alternate, spirally arranged on the branchlets, coriaceous, persistent, stalked, pinnately-veined, entire or serrate, without stipules. Buds with spirally imbricated scales, within which the young leaves lie flat and are not rolled or folded. Flowers perfect, regular, in terminal compound racemes or panicles. Pedicel with two bracteoles, in the axil of an ovate bract; bracts and bracteoles scarious, persistent. Calyx five-lobed, free, persistent, unaltered at the base of the fruit. Corolla gamopetalous, hypogynous, urceolate or globose, with five obtuse, recurved, imbricated teeth. Stamens ten, included; filaments free, inserted on the base of the corolla, dilated and pilose at the base; anthers deflexed, dorsifixed, two-celled, opening by two pores, each anther with two awns on the back, against which insects knock in their search for honey and scatter the pollen through the pores. Pollen-grains united in tetrahedral masses of four grains each. Disc annular. Ovary superior, five- or occasionally four-celled; style columnar, stigmatose and obscurely five-lobed at the apex; ovules numerous. Fruit a berry or drupe, the endocarp often being imperfectly developed. Seeds numerous, small, angled, with a coriaceous testa and a horny albumen.

About twenty species are known, inhabiting the western and south-western parts of North America, Central America, Ireland, the countries in Europe bordering upon the Mediterranean, the Canary Islands, Morocco, Algeria, Asia Minor, the Crimea, and the Caucasus. Many of the species are only shrubs or very small trees, and others are not hardy or have not been introduced. Only four species¹ attaining a considerable size in cultivation in the open air in England, one of which is a hybrid, will be dealt with:—

A. *Leaves serrate. Young branchlets glandular-pubescent.*

1. *Arbutus Unedo*, Linnæus. Ireland, Southern Europe, Asia Minor, Morocco, and Algeria.

Leaves green beneath; petiole $\frac{1}{4}$ inch. Older branchlets dark brown, rough, and fissuring.

¹ *Arbutus canariensis*, Lamarck, growing in the open air, is five feet high at Mount Usher in Wicklow; but at Newry this species requires protection in winter.

Arbutus arizonica, Sargent, a native of the high mountains of Southern Arizona, if introduced, might be hardy.

Arbutus

2. *Arbutus hybrida*, Ker-Gawler. A hybrid.

Leaves slightly glaucous beneath; petiole $\frac{1}{2}$ inch. Older branchlets fawn-coloured, smooth.

B. *Leaves entire. Young branchlets glabrous.*

3. *Arbutus Andrachne*, Linnæus. Albania, Greece, Asia Minor, Crimea, Caucasus.

Leaves slightly glaucous beneath, contracted into short broad points at the apex, tapering at the base in cultivated trees; petiole $\frac{1}{2}$ inch.

4. *Arbutus Menziesii*, Pursh. Western N. America, from British Columbia to California.

Leaves glaucous, almost white, beneath; rounded or with a minute sharp point at the apex; sub-cordate or rounded at the base; petiole 1 inch.

ARBUTUS UNEDO, STRAWBERRY TREE

Arbutus Unedo, Linnæus, *Sp. Pl.* 395 (1753); Loudon, *Arb. et. Frut. Brit.* ii. 1117 (1838); Boswell-Syme, *Eng. Bot.* vi. 28, t. 882 (1866); Hooker, *Stud. Fl. Brit. Islands*, 243 (1878); Mathieu, *Flore Forestière*, 225 (1897).

Unedo edulis, Hoffmannsegg et Link, *Fl. Port.* i. 415 (1809).

A small tree, attaining in Ireland 40 feet in height and 10 feet or more in girth, usually a shrub in the Mediterranean region. Bark rough, brownish-red, more or less fissured, and only rarely scaling off in part. Young branchlets reddish or green, covered with gland-tipped hairs, which persist in the second year; older branchlets brown, rough, slightly fissuring on the surface. Buds minute, reddish; scales imbricated, ovate, acute, ciliate. Leaves 2 to 4 inches long by 1 to 2 inches broad, very variable in shape, oblong, oblong-lanceolate, elliptic, or ovate, acute at the apex, tapering at the base; upper surface dark-green, glabrous and shining; lower surface pale-green, glabrous, with prominent midrib and inconspicuous pinnate-reticulate venation; margin serrate or biserrate, the serrations acute or rounded. Petioles short, about $\frac{1}{4}$ inch long, glandular-pubescent.

Flowers appearing in autumn, inodorous, in short drooping glabrous terminal panicles. Calyx-lobes minute, triangular. Corolla usually white, rarely pinkish, urceolate, with rounded ciliated teeth; ovary glabrous. Fruit ripening in the following autumn, at the same time as the appearance of the flowers of the succeeding year; a stalked berry, pendulous, sub-globose, $\frac{3}{4}$ inch in diameter, orange-scarlet, densely covered with minute pyramidal spine-like excrescences, edible, superficially resembling a strawberry, but entirely different in structure.

Seedling.—Cotyledons two, raised above ground on a short caulicle, oval, rounded at the apex, abruptly narrowed at the base into a flat petiole, entire, $\frac{1}{4}$ inch long, dull-green above, pale-green beneath. Young stem reddish, with short glandular hairs; primary leaves alternate, minute, oval or obovate, serrate and minutely glandular-pubescent in margin; tap-root about 2 or 3 inches long.

VARIETIES

In the wild state there is considerable variation in the size and shape of the leaves, dependent upon conditions of soil, shade, and climate. Fliche¹ describes two distinct forms in France. In the hot and dry region of the Esterel, the leaves are small in size, not exceeding $2\frac{1}{2}$ inches in length by $\frac{3}{4}$ inch in breadth, and are very coriaceous, spathulate, with feebly serrated and revolute margins. In the forest of La Pinouse, near Quillan in Aude, which is mainly composed of *Pinus sylvestris* with a slight mixture of beech and silver fir, the climate being cool and the altitude considerable, the *Arbutus* has very large leaves, often 5 inches long by 2 inches broad, which are lanceolate with sharply serrate and non-revolute margins.

The following varieties are often cultivated:—

1. Var. *rubra*, Aiton, *Hort. Kew*, ii. 71 (1789). (Var. *Croomei*,² Hort.)—Flowers pink or reddish. Mackay³ noticed a single plant of this variety, growing on red slate near Glengariff.
2. Var. *integerrima*, Sims, *Bot. Mag.* t. 2319 (1822) (vars. *integrifolia* and *rotundifolia*, Hort.)—Leaves entire and smaller than in the type. This is said to have been raised by Loddiges from seed of the ordinary form. The leaves vary in shape, often being obovate or almost orbicular.
3. Var. *quercifolia*, Hort.—Leaves obovate-lanceolate, with a few irregular teeth in the upper half, about 2 inches long by $\frac{3}{4}$ inch broad. In cultivation at Kew.
4. Var. *turbinata*, Persoon.—This variety occurs wild in Greece, and is remarkable for its large top-shaped fruit, more than an inch in length.
5. Other varieties have been noted, which I have not seen, as *salicifolia* with narrow leaves, *crispa* with crumpled leaves, and *plena*, with semi-double flowers.

DISTRIBUTION

This species is widely spread throughout the maritime regions of the countries bordering on the Mediterranean, occurring in Spain, France, Corsica, Sardinia, Italy, Istria, Herzegovina, Dalmatia, Greece, Turkey, Syria, Algeria, and Morocco. It is also met with in the maritime belt along the Atlantic from Portugal to Kerry in Ireland. It occurs either as undergrowth in the forests, where in favoured situations it reaches the dimensions of a small tree, or is one of the shrubs composing the *maquis* or heaths, which spread over large tracts of siliceous soil that have been denuded of trees in past ages. It is apparently only in Ireland that the *Arbutus* grows to be a forest tree, moderate in size, but equalling in height and girth the trees of other species, with which it is associated.

In France, the *Arbutus* is common in the departments whose shores are bathed by the Mediterranean and extends inland as far as Drôme and Lozère; it is not unfrequent along the west coast from Bayonne to La Rochelle, and is recorded⁴ from

¹ *Bull. Soc. des Sciences*, 1886, p. 26. ² Figured in *Garden*, xxxiii. 320 (1888). ³ *Fl. Hibernica*, 182 (1836).

⁴ *Arbutus* is very abundant, in company with oak and mountain ash, in a wood, about $1\frac{1}{2}$ mile in length, on the abrupt and rocky slope of the cliff of Trieux, near Paimpol, in Côtes-du-Nord. Cf. Dr. Avicé, in *Bull. Soc. Bot. France*, xliii. 123 (1896), and Coste, *Flore de la France*, ii. 506 (1903). In a note on the occurrence of this species in the Landes, in *Bull. Soc. Bot. France*, xlix. p. lvii. (1902), it is stated that wherever the *Arbutus* grows, in that region, holly is absent, the two species seeming to exclude each other.

an outlying station in Brittany. In Corsica, it is very common as a shrub in the *maquis*; but in some of the forests grows to be a considerable size, as in that of Bonifatte near Calvi, where I measured trees 25 feet in height and 1 foot in diameter, which were growing at 2000 feet altitude. In Corsica, a liqueur, called *acqua vida de bagui*, is made from the berries. In Spain and Algeria, I noticed it as a shrub, growing in ravines in the forests; but in Italy it sometimes attains a considerable size.

The *Arbutus* is unquestionably wild¹ in the south-west of Ireland, where it is associated with other plants, which like it are Mediterranean in type and not indigenous to other parts of the British Isles. It has been known to the Irish since early times, and is called *caithne* (pronounced *cahney*) in Kerry and *cuince* in Clare. The former name occurs in several place-names in Kerry, as Derrynacahney, the "oak-wood of the *Arbutus*," two miles south-east of Crusheen; Cahnicaun wood, near the Eagle's nest, Killarney, which is *coill caithneacan*, the "wood of the little *Arbutus*," in Irish; Ishnagahiny Lake, five miles south-east of Waterville, which is *uisge-na-geathne*, "Arbutus water," in Irish. The Clare name, *cuince*, is supposed to occur in several place-names, anglicised as *quin*, which, however, often represents a family name of another signification. Cappoquin, in Waterford, means the field of the *Arbutus*, and Feaquin, in Clare, the wood of the *Arbutus*. The occurrence of names like Quin, a parish in Clare, and Quinsheen, one of the islands in Clew Bay, Mayo, may point to an extension of the distribution of this plant far to the north in ancient times.

At present, *Arbutus Unedo* is restricted to Co. Kerry and the extreme south-western part of Co. Cork. In the latter county it is thinly scattered through the woods in the vicinity of Glengariff, growing in company with oak, birch, holly, hazel, and mountain ash, and attaining about 25 feet in height and 3 feet in girth. It is said to grow here and there among the mountains to the west of Glengariff, and was seen by R. A. Phillips at Adrigole, ten miles to the west, high up in the mountains amongst rocks, and without the shelter of other trees. Phillips believes that it does not now grow to the eastward of Glengariff; and he could not find it in its former station, Ballyrizzard, near Crookhaven.

The *Arbutus* has its head-quarters in Co. Kerry, in the Killarney district, being particularly abundant and luxuriant on the islands and shores of the lakes generally, where it forms a considerable part of the natural forest. At the base of Cromaglaun mountain, near the tunnel on the Kenmare road, there is a wood composed almost exclusively of *Arbutus*; and it is also met with on the Cloonee lakes south of the Kenmare River.²

About Killarney the tree is indifferent as regards soil, as it grows on limestone on Ross island, on sandstone on Dinis island, and on slate, grit, and conglomerate

¹ Its right to be considered an indigenous plant was contested by Smith, who, in his *History of the County of Kerry* (1756), states that it was introduced by the monks of St. Finian, who founded the Abbey of that name on the banks of the lake, in the sixth century. Babington, in *Mag. Nat. Hist.* ix. 245 (1836), says this idea is inconceivable as the tree grows in isolated spots far up in the mountains, and is truly an aboriginal. All Irish botanists, and they are supported by authorities like Sir J. D. Hooker and Prof. Fliche of Nancy, are agreed as to the tree being an undoubted native of the south-west of Ireland.

² There are six trees on the islands in Glenmore Lake near Dereen, and a few on the mountains beside the lake, according to information I received when visiting Dereen in July 1907.

elsewhere. It is much more affected by climate and aspect than by soil, and seeks the most humid and mildest situations. In the Killarney basin it occupies practically the whole northern shore of the northern lake, but does not grow on the exposed islands of this lake. It is absent from the shore itself, when this is marshy or composed of shingle or sand, and grows on the rocky headlands, where it forms a natural wood with oak, holly, and mountain ash. It is very common on the long indented promontory of Muckross, and reaches its greatest dimensions on Dinis Island, which is perhaps the dampest and most sheltered spot in the whole district, protected by high mountains on the east and west, but open to the south. It usually does not extend far from the lake shore, but in the very humid and shaded Torc ravine it recedes into the general woodland along the rocky banks of the torrent, and ascends to an elevation of several hundred feet. It flourishes also on the rocky and sheltered islands of the southern lake.

In dense woods it has a fairly straight and single trunk; but in the open it usually divides at a short distance from the ground into two or more stems, which tend to be spirally twisted and are often curved, each of them terminating in a much-branched wide crown of foliage. The bark of old trees scales off in longitudinal strips and becomes purplish-grey in colour, assuming in the sunlight a reddish tinge, resembling in this respect the branchlets, which are pale-green on the shaded side and crimson on the sunny side.

The largest trees seen by me were about 40 feet in height; one had three stems 4 feet 10 inches, 4 feet 3 inches, and 3 feet 2 inches in girth respectively, the butt measuring close to the ground 17 feet round. Plate 157 represents one of the finest of these trees on Dinis island. Major Waldron has recently found trees up to 5 feet 7 inches in girth. Much larger trees existed formerly, as one measured by Mackay in 1805, which was $9\frac{1}{2}$ feet in girth. The *Arbutus* woods, like those of Kerry generally, suffered much from the ironworks, which were established in the eighteenth century, and the largest trees were cut down at this period.

INTRODUCTION

The date of the introduction of the *Arbutus* into English gardens is unknown; but Mrs. J. R. Green has kindly sent me the following extract from the State Papers,¹ showing that its existence in Kerry attracted in the sixteenth century the attention of the English settlers, who called it *wollaghan*, a corruption of *ubhla caithne* (pronounced *oolacahney*), or "arbutus apples," a name used for the edible fruit:—

"You shall receive herewith a bundle of trees called wollaghan tree, whereof my Lord of Leicester and Mr. Secretary Walsingham are both very desirous to have some, as well for the fruit as the rareness of the manner of bearing, which is after the kind of the orange, to have blossoms and fruit green or ripe all the year long, and the same of a very pleasant taste, and growing nowhere else but in one part of Munster, from whence I have caused them to be transported immediately unto you,

¹ *Cal. State Papers, Ireland*, A.D. 1586, p. 240.

praying you to see them safely delivered and divided between my said Lord and Mr. Secretary, directing that they may be planted near some ponds or with a great deal of black moory earth, which kind of soil I take will best like them, for that they grow best in Munster about loughs and prove to the bigness of cherry trees or more and continue long." (A. H.)

CULTIVATION

Though the *Arbutus* can hardly be called a tree in most parts of England, because it is rarely planted in situations which will enable it to assume a tree-like habit, yet it is so beautiful as a shrub, that no garden should be without it in districts which are warm enough in winter and damp enough in summer to allow it to thrive. It is easily raised from seed, and I have found little difference between the growth of seedlings raised from English and from French seed. Both suffer severely from frosts exceeding about twenty degrees, and from cold dry winds, and should therefore be kept under glass in winter till they are 2 or 3 feet high, when they should be planted out in a well-drained but not dry or heavy soil, in a place well sheltered from the north-east, but not overhung by other trees. Severe winters injure and often kill *Arbutus* in the eastern and midland counties, and large specimens are rarely seen except on the west and south-west coasts. Even there I have never seen one rivalling what Henry describes in Ireland, and it does not seem to be a long-lived tree in England. The best I have seen, perhaps, is on Sir E. Loder's beautiful grounds at Leonardslee, which is about 30 feet high, with a clean stem 8 or 10 feet high and 3 feet 4 inches in girth. The largest tree on record¹ was one growing at Mount Kennedy, Wicklow, which in 1773 was 13 feet 9 inches in girth. It was supposed then to be somewhat more than 100 years old. In 1794 it was still living, though it had been split by the wind, and torn up by the roots; and fresh healthy shoots were springing up from some branches which had layered.

The wood, which is of a reddish-brown colour, is hard and takes a good polish, but is very liable to split in drying, and so far as I know is not used for anything but small ornamental work, though it seems very suitable for inlaying or parquet.

(H. J. E.)

ARBUTUS HYBRIDA²

Arbutus hybrida, Ker-Gawler, *Bot. Reg.* t. 619 (1822); Loudon, *Arb. et Frut. Brit.* 1119 (1838); *Gard. Chron.* ix. 211, f. 37 (1878).

Arbutus andrachnoides, Link, *Enum. Hort. Berol.* i. 395 (1821).

Arbutus serratifolia, Loddiges, *Bot. Cab.* t. 580 (1821).

Arbutus intermedia, Heldreich, *Flora*, 1844, p. 14.

Arbutus Unedo-Andrachne, Boissier, *Fl. Orient.* iii. 966 (1875).

Arbutus hybrida, being a cross between *A. Unedo* and *A. Andrachne*, is variable in the wild state, sometimes being exactly intermediate between the two

¹ Hayes, *Practical Treatise on Planting*, 128 (1794).

² This name, though not the oldest, is the one by which the species has been usually known, and is adopted by us.

parents, and sometimes more closely resembling one of them. As seen in cultivation, the bark is smooth, like that of *A. Andrachne*. The branchlets have the glandular pubescence of *A. Unedo*, and the leaves are serrate, as in that species; but have the slightly glaucous tint and conspicuous veins of the other species; petioles glandular-pubescent. The flowers are borne in spring in large drooping panicles, which are usually glandular-pubescent. The fruit is of moderate size, and slightly tubercular on the surface.

According to Loudon, var. *Milleri*, with large leaves and pink flowers, was raised in the Bristol nursery, being a cross between the red-flowered variety of *A. Unedo* and *A. Andrachne*. This seems to be rare in cultivation.

Arbutus hybrida originated in the Fulham nursery early in the nineteenth century. It is, however, known in the wild state, being recorded by Heldreich and Halacsy for several localities in Greece. It is also reported to have been found by Albow¹ at Pizunda, on the north-eastern shore of the Black Sea, which is remarkable, as *A. Unedo* does not occur wild in this district, and the identification was possibly erroneous.

A tree growing at Sedbury Park, near Chepstow, the residence of Colonel Marling, V.C., is by far the finest we have seen of this hybrid. It measures 39 feet high by 5 feet 10 inches at 5 feet, and 7 feet 4 inches at 3 feet from the ground. It is grafted on a stock of *A. Unedo*, but shows more of the character of *A. Andrachne* in its habit and bark. It has been propagated by inarching, and seems to be a hardier tree than *A. Unedo* (Plate 158).

There are fair-sized trees at Kew.

(A. H.)

ARBUTUS ANDRACHNE

Arbutus Andrachne, Linnæus, *Sp. Pl.* 566 (1762); *Bot. Reg.* ii. t. 113 (1813); *Bot. Mag.* t. 2024 (1819); Loudon, *Arb. et Frut. Brit.* ii. 1120 (1838).

Arbutus integrifolia, Salisbury, *Prod.* 288 (1796).

Arbutus Sieberi, Klotzsch, *Linnaea*, xxiv. 71 (1851).

A large shrub or small tree, attaining 30 to 40 feet in height. Bark peeling off in thin papery layers, smooth, thin, and reddish brown. Young branchlets reddish or green, glabrous; older branchlets olive-green or brownish, smooth. Buds minute, reddish. Leaves, larger usually in cultivated trees than those of *Arbutus Unedo*, oval-oblong, contracted into short blunt points at the apex, tapering at the base; upper surface dark green, glabrous, shining; lower surface glaucescent, glabrous, with prominent midrib and distinct lateral veins; margin entire. Petiole glabrous, about $\frac{1}{2}$ inch long.

Flowers in erect viscid glandular-pubescent panicles, yellowish white, appearing in spring. Calyx-lobes deep, ovate, acute. Corolla contracted at the apex, with five reflexed short rounded ciliate lobes. Ovary pubescent. Fruit small, about $\frac{1}{3}$ inch,

¹ Radde, *Pflanzenverb. Kaukasuslind.*, 127, note (1899).

rarely $\frac{1}{2}$ inch in diameter, globose, orange coloured, smooth, hard, glandular on the surface.

Arbutus Andrachne is a small tree or large shrub, resembling *A. Unedo* in habit, and like it occurring often in heaths and occasionally in the forests; and only rarely forming small pure woods. It occurs in Albania, Greece, Cephalonia in the Ionian Islands, Crete, Rhodes, Cyprus, in the maritime regions of Asia Minor, Syria, and Palestine, in the Crimea and in the district of the Caucasus bordering upon the Black Sea.

(A. H.)

It was introduced into England from Smyrna in 1724, and cultivated at Eltham by Dr. Sherard.

This tree though rarely planted in modern gardens¹ is, on account of its superior hardness and its extremely beautiful bark, a more ornamental tree than the native species. Though I have never seen or heard of its producing ripe fruit in England, seedlings may be obtained from Continental nurseries, and some that I brought from Pallanza, in October 1906, have survived the journey without injury. The tree seems to enjoy lime in the soil. The bark is like smooth reddish-brown leather, covered with a thin silvery paper-like skin which peels off annually, and for this alone it is well worth growing. There was a very fine though not tall tree of this species on the lawn at Williamstrip Park, Gloucestershire, on rather heavy soil, which endured the inclement season and severe winters of 1879-80-81 without much injury, but is now dead. I saw in 1903 another which was 36 feet high and 4 feet in girth lying on the ground at Haldon near Exeter, which had been blown down some years before but was still living. The best that I know now living is in the Botanic Garden at Bath, and measures 27 feet by 6 feet 3 inches at 1 foot from the ground, shortly above which it divides into several stems. There is also a handsome tree about 25 feet high at Westonbirt, and one at Mamhead, 30 feet high, which is decaying at the butt.

(H. J. E.)

ARBUTUS MENZIESII, MADROÑA

Arbutus Menziesii, Pursh, *Fl. Amer. Sept.* i. 282 (1814); Sargent, *Silva N. Amer.* v. 123, t. 231 (1893), and *Trees N. Amer.* 728 (1905).

Arbutus procera, Lindley, *Bot. Reg.* xxi. t. 1753 (1836); Loudon, *Arb. et Frut. Brit.* ii. 1121 (1838).

Arbutus laurifolia, Hooker, *Fl. Bor. Amer.* ii. 36 (1840). (Not Lindley.)

A tree attaining in America 100 feet in height and 20 feet in girth, but usually much smaller. Bark of branches and young stems thin, smooth, reddish, peeling off in large thin scales; of older trunks dark reddish brown and covered with small thick scales. Young branchlets glabrous; older branchlets reddish brown, smooth. Buds stouter than in *A. Unedo*, $\frac{1}{3}$ inch long; scales ovate, acute, apiculate. Leaves oval or oblong, larger than in *A. Andrachne* or *A. Unedo*, up to 5 inches long by 3 inches broad, rounded or contracted into minute sharp points at the apex,

¹ A tree in Kew Gardens, 20 feet high, is figured in *Gard. Chron.* iv. 724, f. 100 (1888).

subcordate or rounded (rarely tapering) at the base; upper surface dark green, shining, glabrous; lower surface glaucous, almost white in colour, glabrous, with prominent midrib and conspicuous lateral veins; margin entire, occasionally serrate on young plants. Petiole stout, $\frac{1}{2}$ to 1 inch long, glabrous, usually winged on one or both sides for some distance by the decurrent base of the leaf.

Flowers appearing in spring, in erect pubescent panicles, about 5 or 6 inches long and broad. Calyx-lobes scarious, white. Corolla white, urceolate. Ovary glabrous. Fruit ripening in autumn, sub-globose, $\frac{1}{2}$ inch in diameter, bright orange-red, glandular on the surface, with a thin flesh and a five-celled thin-walled cartilaginous stone.

Arbutus Menziesii occurs in the Pacific coast region from Southern British Columbia, where it grows on Vancouver Island and the islands at Seymour Narrows, through Washington and Oregon to California, reaching its most southerly point in the Santa Lucia Mountains. In Washington it is not uncommon on the cliffs along Puget Sound, and on high slopes, where it receives plenty of light. It usually grows on rich soil and, according to Sargent, is common and attains its largest size in the redwood forest of Northern California, becoming smaller to the north and south, and only growing as a shrub to the south of the bay of San Francisco. I did not observe it in the dense redwood forest near Crescent City; but found it common inland to the east of the coast range in South-Western Oregon. Here it grew on dry hills at 2000 to 3000 feet altitude, in mixture with *Pinus ponderosa*, *Libocedrus decurrens*, and oak, in thinly forested country; and resembled very much in habit, with its short trunk and broad branching crown, the *Arbutus* of Killarney. In a ravine near Kerby I measured a tree, 99 feet high by 5 feet 1 inch in girth, with a straight stem, clear of branches to 40 feet; but this grew in exceptionally good soil, and was crowded by other trees—Lawson Cypress, Sugar Pine, *Quercus densiflora*, *Acer macrophyllum*, etc. (A. H.)

The largest tree of this species known, which has been figured by Sargent,¹ is growing in the grounds of the reservoir at San Rafael in Marin county, California. It measures 100 feet in height and 23 feet in girth at 3 feet from the ground.

Arbutus Menziesii was introduced by Douglas in 1827; but is rather a rare tree in cultivation in England. It appears to be less hardy than the other species now described, and at Kew makes slow growth and often has its leaves and shoots injured by frost. It is found in gardens usually under the name of *A. procera*, and commonly attains the size of 20 to 30 feet. The largest that I have seen is at Bassetwood, near Southampton, the residence of J. R. Anderson, Esq. This tree is no less than 50 feet high, with a stem clear for about 20 feet, and 3 feet 2 inches in girth. A tree at Tortworth is 35 feet high by 4 feet 4 inches.² In Scotland, at Castle Menzies, I measured one in 1907 which was 37 feet by 5 feet 2 inches, and did not seem to have suffered much from the severe frost of the previous winter, though the flower buds were killed. (H. J. E.)

¹ *Garden and Forest*, v. 146, f. 23 (1892). In the same journal, iii. 509, f. 515 (1890), the tree is figured in its native forest.

² Mr. Clinton Baker informs me that there is a tree at Bayfordbury which was sent to his grandfather about twenty-five years ago from America, as a very small plant. It is now 30 feet high, and bears fruit every year.

SCIADOPITYS

Sciadopitys, Siebold et Zuccarini, *Fl. Jap.* ii. 1, tt. 101, 102 (1844); Bentham et Hooker, *Gen. Pl.* iii. 437 (1880); Masters, *Journ. Linn. Soc. (Bot.)* xviii. 502 (1881), xxvii. 276, 320 (1889), xxx. 21 (1893), and *Journ. Bot.* xxii. 97 (1884).

AN evergreen tree, belonging to the tribe Taxodineæ of the order Coniferae, attaining in Japan a height of 120 feet and a girth of 12 feet. Bark reddish brown, scaling off in long strips. Branches sub-verticillate. Branchlets brown, glabrous, bearing minute scales, which represent true leaves, and cladodes, which are long, green, and leaf-like, performing the functions of true leaves, but differing from them in structure. The scales are borne spirally on the internodes, and are dry, brown, membranous, ovate-lanceolate, and decurrent. At the apex of the shoot there is a ring of similar scales, deltoid in shape, and densely pubescent on their inner surface, out of the axils of which arise a whorl of cladodes, ten to thirty in number, spreading all round the branchlet. These are 2 to 5 inches long, averaging $\frac{1}{8}$ inch in width, linear, rigid, narrowed towards the base, obtuse and minutely rigid at the apex; upper surface dark green, shining, with a median groove; lower surface green on each side of a deep white stomatiferous central furrow. Buds globose, composed of numerous spirally imbricated greenish scales; terminal bud, at the apex of the shoot, in the centre of the whorl of cladodes, continuing the growth of the main axis in the following year; a smaller bud, often present at the side of the terminal bud, developing into a lateral branch in the next season. As a rule, the main axis is bare, except for the scales, below the apex, which bears the whorl of cladodes and the buds; but on strong-growing shoots a lateral branch is occasionally developed half-way up the internode. The cladodes are leaf-like shoots, and not true leaves, each representing an axillary branch with two coherent leaves; but their true nature has given rise to a great deal of discussion; and the elaborate papers of Dr. Masters cited above may be consulted on this subject.

Male flowers in a terminal compact raceme, about an inch in length; each flower $\frac{3}{8}$ inch long, subsessile; anthers numerous, spirally arranged, short-stalked, with an acute and reflexed crest and two pendulous cells, opening by a vertical slit; pollen-grains globular, minutely tuberculate. Female flowers, terminal small cones composed of spirally arranged lanceolate bracts, which are serially continuous with the true leaves, empty at the base of the cone, higher up with fleshy semi-lunar ovular scales in their axils, half the size of the bracts and bearing one to nine ovules in a transverse series on their inner surface. As the cones increase in size, the

ovular scales outgrow the bracts, and in the mature cone are much larger than and almost entirely coalesced with them.

The cones, which are borne on short stout stalks, clothed with a few membranous bracts, either remain terminal and erect or are pushed aside by the growth of a lateral branch. They take two years to ripen, and remain persistent on the tree for some months after the dehiscence of the seeds. Ripe cones, about 3 inches long by $1\frac{1}{2}$ inch in diameter, oblong-ovoid, obtuse at the apex, composed of woody scales, which result from the coalescence of the ovular scales and bracts of the flower. The scales are fan-shaped, about $\frac{3}{4}$ inch wide; upper margin rounded and reflexed; outer surface convex, marked by a transverse rugged irregular ridge; inner surface concave, with slight depressions for the seeds. Seeds, five to nine on each scale, reversed, oval, compressed, dark brown, surrounded by a narrow membranous reddish-brown wing, notched at the base and marked at the apex by the white hilum; seed with wing, about $\frac{3}{4}$ inch long by $\frac{1}{4}$ inch wide. The seedling has a long slender tap root, and a terete green glabrous caulicle about an inch in length, which bears two cotyledons. These are sessile, linear, tapering to an obtuse apex, a little more than $\frac{1}{2}$ inch long, dark green above, paler below with indistinct lines of stomata. Primary leaves like the cotyledons, but longer.

Sciadopitys is a monotypic genus, only one species being known, which is a native of Japan.

SCIADOPITYS VERTICILLATA, UMBRELLA PINE¹

Sciadopitys verticillata, Siebold et Zuccarini, *loc. cit.* 1844; Kent, *Veitch's Man. Coniferae*, 287 (1900); Shirasawa, *Icon. Ess. Forest. Japon.*, text 22, t. 8, ff. 15-36 (1900); Thistelton-Dyer, *Bot. Mag.* t. 8050 (1905); Mayr, *Fremdländ. Wald- u. Parkbäume*, 407 (1906).
Taxus verticillata, Thunberg, *Fl. Jap.* 276 (1784).

The species has been described above. The tree is known in Japan as *Koyamaki*, or pine of Mt. Koya, one of the localities where it is found growing wild. Thomas Lobb sent a living plant in 1853 from the Botanic Garden at Buitenzorg in Java to Veitch's nursery at Exeter; but it soon died. It was afterwards introduced by seeds brought from Japan by J. Gould Veitch in 1861, some being also sent about the same time by Fortune to Standish at Ascot.

A variety in which the leaves are striped with yellow was introduced by Fortune; but this seems to be now unknown in cultivation.

Plants only 3 feet high produced cones in 1876 in the nursery of Messrs. Thibaut and Keteleer at Sceaux.² The tree appears to have first borne fruit in Scotland³ at Ardkinglas, in 1878, and in England⁴ at Kew and Coombe Wood, in 1884. Proliferous cones,⁵ which bear cladodes at their apex, are of frequent occurrence in Japan, and have also been borne by trees cultivated in Europe. In

¹ This is a translation of *Sciadopitys*, a name given on account of the leaf-like cladodes spreading out from the apex of the shoot, like the ribs of an umbrella.

² *Gard. Chron.* v. 827 (1876).

³ *Jour. of Forestry*, 1879, p. 508.

⁴ *Gard. Chron.* i. 80 (1884).

⁵ Masters, *Journ. Bot. loc. cit.* f. 4.

these the bracts, which are ordinarily completely coalesced with the fruit-scales, become detached from them towards the apex of the cone, and are scale-like in character, producing cladodes in their axils. (A. H.)

Shirasawa states that the tree grows wild in mixture with *Abies firma* and *Cupressus pisifera* at 600 to 5000 feet in the forests of Kiso and Shinano. Matsumura adds Mt. Hoonokawa in Tosa.

According to Mayr, the tree is similar to the silver fir in its capacity for bearing shade; but is extremely slow in growth, only attaining in Kiso, where the climate is favourable to it, a height of 30 feet in fifty years. Trees 110 feet in height and 2 feet in diameter average about 250 years old. Mayr gives a figure of two old trees, growing at Agematsu, which were nearly 120 feet in height and 4 feet in diameter; and this shows how the tree, even at an advanced age, preserves a narrow pyramidal form with an upright leader, without any sign of flattening of the crown.

I saw this tree in its native forest to the best advantage in the lovely valley of Atera, on the west side of the Kisogawa, below Agematsu, at from 2000 to 3000 feet elevation. Here it was scattered in a forest of mixed conifers and hardwoods, and seemed to grow only on rocky slopes and ridges, where its narrow-pointed top made it conspicuous. The seedlings were numerous in dense shade growing on a bed of humus, and those that I took up had long but scanty roots, running deep, but spreading little. Their growth was very slow, not more than 3 to 6 inches annually for the first twenty years at least. On a steep rocky hill above the forester's house, at the end of the tramway which has been made up this valley, the largest trees were growing, mixed with *Thujopsis*, the undergrowth being very dense, and composed of *Rhododendron*, with *Shortia uniflora* spreading over the ground in great sheets. The largest that I was able to measure were 90 to 100 feet high and 9 to 10 feet in girth, one being 11 feet 9 inches at 5 feet from the ground. Plate 159A fairly represents the appearance of the tree here.

In the forest near Koyasan I saw it again, mixed with *Cupressus obtusa*, but not attaining so large a size, though it seemed that in the dense shade the seedlings of *Sciadopitys* were more numerous and vigorous. Though often planted in parks and temple gardens, I never saw any trees as fine as those figured by Mayr at Agematsu, and it is clear that shade, perfect drainage, and a rich forest soil are essential to this species.

According to Mayr, the wood is white in colour, the sapwood only $\frac{2}{8}$ inch thick being like the heartwood. The wood is comparable to the best kind of spruce, and is soft and elastic. It is used in Japan for boat-building, making bath-tubs and casks, planking, etc.

CULTIVATION

Though this interesting tree has been planted in many places, yet it usually grows very slowly and seems to require a high summer temperature, with a warm and sheltered situation. Ripe seed was produced in Ireland at Castlewella in 1900,

570 The Trees of Great Britain and Ireland

but the seedlings which I raised from this source were always weakly, and notwithstanding every care died after two or three years. Seed sent from Japan in 1906 also germinated weakly, and many of the seedlings damped off in the winter without making roots, though very carefully watered. They seem to require a very light, sandy peat when young, and refuse to grow in soil which contains lime, or where moisture is deficient during the summer. By far the finest tree that I have seen in England is at Hemsted, in Kent, where a tree was in 1905 no less than 38 feet high by 2 feet in girth, and showed its true habit very well. Owing to its being rather crowded by other trees, a photograph of this was difficult to take, but after several attempts had been made, Mr. Edwards was able to get the one reproduced in Plate 159B. The next largest I have seen is at Coombe Royal, in South Devon, where a tree about 25 feet high is growing, with a forked stem.

As usually seen in gardens in England, it forms a shrubby pyramid, and I have seen no others over 15 to 18 feet high. At Castlewellan, however, it seems to thrive very well, and should do well in the south and west of Ireland and Wales.

At the Villa Trubetskoi, near Intra, on Lake Maggiore, I saw a vigorous tree about 45 feet high, which had divided into three stems, and in 1906 bore no cones.

Sciadopitys is perfectly hardy, and bears without injury the severe winter climate of Boston in New England, and of Grafrath in Bavaria, the thermometer descending in the latter locality to -18° Fahr.; but in severe winters the foliage turns brown.

(H. J. E.)

PINUS SYLVESTRIS, SCOTS PINE

Pinus sylvestris, Linnæus, *Sp. Pl.* 1000 (*excl. var.*) (1753); Lambert, *Genus Pinus*, i. tab. I. (1803); Loudon, *Arb. et Frut. Brit.* iv. 2153 (1838); Willkomm, *Forstliche Flora*, 193 (1887); Mathieu, *Flore Forestière*, 579 (1897); Kent, in *Veitch's Man. Conifera*, 379 (1900); Kirchner, Loew u. Schröter, *Lebensgesch. Blütenpfl. Mitteleuropas*, i. 175 (1904); Mayr, *Fremdländ. Wald- u. Parkbäume*, 347 (1906); Borthwick, in *Trans. R. Eng. Arb. Soc.* vi. 205 (1906).

A TREE commonly 100 feet, rarely attaining 150 feet in height, with a girth of 10 to 15 feet. Stem usually straight and cylindrical, with the branches regularly whorled in young trees, forming a pyramidal crown; in older and isolated trees, branching irregular, with a flattened crown. Bark different in the lower and upper parts of the trunk; towards the base thick, fissured into irregular longitudinal plates, scaly, and reddish brown or greyish brown in colour; on the upper part of the stem,¹ owing to the outer portion continually falling off in thin papery scales, the bark remains very thin, smooth, shining and bright red. Young shoots greenish, smooth and shining; becoming greyish brown in the second year; marked with the pulvini of the scale-leaves, which are early deciduous. Buds long-oval, pointed, usually non-resinous, covered by lanceolate acuminate scales, fimbriated on their edges, the upper ones with their tips free and not recurved. Leaves two in a bundle; sheaths at first white, $\frac{1}{3}$ inch long, speedily becoming shrivelled, brown, and short; the pair of leaves close together, but not appressed, usually about 2 inches long but varying under different conditions from 1 to 4 inches, dark green with interrupted lines of stomata on the convex side, glaucous with many well-defined lines of stomata on the flat inner side, plano-convex in cross-section, linear, stiff, acute at the apex, somewhat bent, smooth, finely serrate in margin; resin-canals marginal. The leaves persist usually three years.

Male flowers in dense clusters at the lower part of the current year's shoot, $\frac{1}{4}$ inch long, oval, short-stalked, surrounded at the base by four yellowish bracts; anther with small rounded upright connective. Female flowers, solitary, opposite or occasionally whorled, apparently terminating the young shoot, erect at first, but becoming pendant immediately after pollination, stalked, globose, reddish, composed of rounded bracts and almost circular ovular scales, the latter having a beak-like process on the upper side and bearing two minute ovules.

Cones shortly stalked, variable in shape, usually ovoid-conic with an acute apex, oblique or nearly symmetrical at the base, greyish or dull brown in colour, 1 to 3

¹ According to Shaw of Boston, who is the greatest living authority on the genus *Pinus*, this peculiarity of the bark of the upper part of the tree being thin and reddish, owing to the constant shedding of scales, occurs only in three pines, viz. *P. sylvestris*, *P. densiflora*, and *P. patula*.

inches long. Scales dark brown on the inner surface, oblong, ending in a rhomboidal apophysis, which is variable in form in different varieties and even in the same cone; flattened, with a transverse keel and an elevated or depressed umbo, or raised and pyramidal, with four to five concave sides; occasionally the apophysis ends in a hooked process. The cones open in spring to let out the seeds, which may be carried by strong winds to an immense distance; and the empty cones usually remain on the tree till the following autumn. Seeds long-oval, $\frac{1}{8}$ to $\frac{1}{5}$ inch, some blackish, others grey in colour, surmounted by a wing half-oval in shape, which is three times as long as the body of the seed.

Seedling.—Cotyledons, four to seven, triangular in section, linear, slightly curved upwards, about $\frac{1}{8}$ inch long; stomata absent on the outer surface, present on the inner two surfaces, without wax, so that the cotyledons are green in colour and not glaucous. Primary leaves elliptic in section with hairs on their edges. The seedling grows about 2 to 4 inches high in the first year, ordinary needles being produced in the second year; branches usually appear in the third year. The primary root is long, attaining about 8 inches in the first year, and giving off many lateral fibres.

VARIETIES

The common pine, spread over an immense geographical area and growing in the most diverse conditions of soil and climate, exhibits considerable variations in most of its characters. The stem may be straight and cylindrical with a single leader, only branching at the top and giving rise to a flattened crown of foliage in old age; or it may be dwarf, branched from the base and crooked, simulating the smaller forms of *Pinus montana*. The young cones are usually reversed immediately after flowering; but in certain regions they remain erect. The adult cones vary in size and shape and in the form of the apophyses, which may be flat or raised, pyramidal or hooked; but all these variations in the apophysis may occur on the same cone. The male flowers may be yellow or reddish in colour. The leaves vary in length from one to four inches, and may be broad or narrow, stiff and sharp-pointed or soft in texture; and in some cases they are much more glaucous than in others. They vary in duration from two to five years.

Many of these varieties occur in individual trees in the same forest; and in many cases, when the condition of the soil is changed as by draining, pines which have been small and stunted assume the ordinary tall form, and the shape of the cones probably does not remain constant, when the seedlings are raised in a new locality. It is difficult on this account to establish clearly marked geographical varieties.

The experiments, which have been carried out at Les Barres,¹ over a long term of years, show, however, that there are races of pines, which preserve their characters of straightness of stem, quickness of growth, or the reverse; but these races cannot be distinguished by characters of cones or leaves; and are the result of the selection of seed from vigorous or weak individuals.

¹ Cf. Pardé, *Arboret. Nat. des Barres*, 71 (1906), where a full account is given of the plots of Riga, Haguenu, Scotch, and certain French varieties of *Pinus sylvestris*, which were mostly planted between 1823 and 1835.

The following varieties, occurring in the wild state, have been distinguished, though they are not so clearly defined in nature, as they seem to be from their description.

1. Var. *genuina*, Heer. Cones usually solitary, long-stalked, symmetrical, acute at the apex; apophysis flat or convex, not hooked. Needles about 2 inches long, persistent three years.

This is the common pine, growing on good soil in Germany, Southern Scandinavia, Poland, and North-Western Russia. Two races have been distinguished on the Continent in cultivation:—

(a) *rigensis* (*Pinus rigensis*, Desf.). Riga pine, raised from seeds collected near Riga. At Les Barres, this is the best race of *P. sylvestris*, the stem being very straight and cylindrical, rising to a great height, and with few lateral branches; bark very red, stripping off above in very thin papery scales. Von Sievers states that the form native to the Baltic provinces of Russia is superior in growth and timber to that introduced there by seed from Germany. Willkomm, however, is of opinion that the so-called Riga pine is only a fine tall-growing form, and occurs in North Germany and Poland, as well as in Russia.

(b) *Haguenensis*, Loudon. Haguenu pine, raised from seed obtained in the forest of Haguenu in Alsace. At Les Barres, this form, though vigorous in growth, is defective, on account of its tendency to form numerous irregular branches, so that the stem is not so clean and does not reach the same height as the Riga variety. The bark is not so red, and is not so fine-scaled as in that variety.

Two trees of the Haguenu variety, raised from seed, procured by Loudon in 1828, are growing at Seggieden in Perthshire, and are now about 65 feet high by 8 feet in girth. According to the forester, they are distinguishable in bark, buds, shoots, and leaves from the Scots pine growing near them.

2. Var. *scotica*.—This variety, which grows wild in the Highlands of Scotland, differs in the redder bark of the stem; in the shorter more glaucous leaves ($1\frac{1}{2}$ inch long), often persistent four years; and in the shorter cones ($1\frac{1}{2}$ inch long), which are symmetrical, with apophyses usually flat near the base, tending to be pyramidal in the upper part of the cone.

3. Var. *engadinensis*, Heer.—Bark reddish; needles short, 1 to $1\frac{1}{2}$ inch long, thick and stiff, persistent for five years; buds resinous. Cones ovoid-conic, 2 inches long, oblique at the base; apophyses convex on the outer side of the cone, umbo large and blunt. A small tree, rarely 30 feet high, growing in the Engadine Alps.¹ It is perhaps a hybrid between *P. sylvestris* and *P. montana*.

4. Var. *lapponica*.—*Pinus lapponica*, Mayr, *Fremdländ. Park. u. Waldbäume*, 348 (1906). This variety, which grows in the north of Norway and Sweden and in Finland, is considered by Willkomm and Christ¹ to be identical with var. *engadinensis*, with which it agrees in the short, straight stiff leaves, persistent for

¹ Dr. Christ, in *Flore de la Suisse*, 197, and *Suppl.* 31 (1907), considers the Engadine pine to be precisely the same as specimens he examined, which were collected at Quickjock in Lapland (lat. 67°). He also mentions (p. 285) a curious form of the common pine, slender and tall in habit, with very short green needles, which grows at Flims in Switzerland, and also in one or two places in Silesia.

five years, in the resinous buds, and in the small cones with hook-like apophyses. Mayr, however, considers it to be a distinct species, and gives the characters which distinguish it from the common form of *P. sylvestris*, without pointing out in what respect it differs clearly from var. *engadinensis*.

5. Var. *nevadensis*, Christ.—Needles broad, short and stiff, very white on their flat surfaces. Cones nearly sessile, oblique, with very pyramidal apophyses. Occurs in the Sierra Nevada in the south of Spain.

6. Var. *reflexa*, Heer.—Needles as in the common form. Cones long and slender, conic, with long hooks to the apophyses. This variety has been found growing on high peat-mosses in Switzerland and on poor sandy soil in Prussia, and occurs sporadically elsewhere.

In the Caucasus and Asia Minor, *P. sylvestris* differs from the European form, in having very long and broad needles ($3\frac{1}{2}$ inches long), and very oblique cones with hooks on their outer side directed downwards. Specimens from the Amur have very long leaves (4 inches or more) with cones of the ordinary form. The pine of the Ural and Altai mountains (var. *uralensis*, Fischer) is only distinguished by having short and stiff leaves. In the dry climate of the south of France, in the Cevennes and in Provence, the needles of this species become short and are often disposed in slender tufts at the ends of the branchlets.

In the French Alps near Modane, *P. sylvestris* grows in mixture with *P. montana*, var. *uncinata*; and it is difficult to distinguish between these trees in this locality,—the branches densely covered with short leaves, persistent for four or five years, being alike in both species; and the cones of both have hooked apophyses.¹ However, at Modane, as elsewhere, the reddish bark and the dull colour of the cones will distinguish *P. sylvestris*; while in the other species the bark is never red and cones are shining brown.

Similar forests occur in Switzerland, where *P. sylvestris* and *P. montana* appear to pass one into the other; and the occurrence of these apparently transitional forms has given rise to the belief that they are hybrids between the two species; but this is not established beyond doubt.

Willkomm describes two interesting varieties, due to poverty of soil and exposure. One is the shore-pine of the Baltic provinces of Prussia, which has a short bent stem with an irregular crown of foliage or is a mere bush; the cones are very oblique and hooked. Another form is peculiar to the peat-mosses in Austria and Germany; the stems are rarely more than 6 feet high, very slender, and branched to the base; needles very stiff and short (about 1 inch long), persistent for two years; cones very small, with hooked apophyses.

Several varieties have arisen in nurseries or as sports in the wild state.

Var. *virgata*, Caspary.—Main branches irregularly whorled, arising from the stem at an angle of 30° to 60°, elongated and giving off a few twig-like branchlets, only the outermost of which are furnished with leaves. This curious variety² was first

¹ The young cones of *P. sylvestris* at Modane remain erect (like those of *P. montana*) and are not reversed immediately after pollination, as is usually the case elsewhere.

² Willkomm, *Forstliche Flora*, 199 (1887).

noticed in France; and some years later, in 1881, was found in the forest of Wandsburg in Prussia.

Var. *argentea*, Steven.—Cones and leaves with a silvery tint. Found in the Caucasus.

Var. *monophylla*, Hodgins.—A shrub, with the needles in each sheath attached to each other throughout their length, apparently forming one needle, but easily separated. Originated at Dunganstown, near Wicklow, about 1830.

Var. *microphylla*, von Schwerin.—Needles thin, sharply pointed, only $\frac{1}{2}$ inch long. Originated as a seedling in 1883 at Wendisch-Wilmersdorf.

Var. *aurea*.¹—A low tree of dense habit, with leaves of a golden yellow colour usually in spring, the foliage becoming green in summer.

Var. *variegata*.—Leaves variegated. This form has arisen several times in cultivation; but was once found wild in Prussia by Caspary.

Var. *pyramidalis*.—Fastigate in habit. Schübeler says that trees of this kind are common in the forests of Norway and Finland.

Var. *pendula*, Caspary.²—A weeping form, found in a wood near Tilsit, in East Prussia.

Various dwarf forms are known, as *pumila*, *nana*, *globosa*.

DISTRIBUTION

The common pine has an extraordinarily wide distribution, occurring in regions of the most diverse climates and on almost all soils, and in the mountains as well as in the plains. It grows in Eastern Siberia, where the temperature falls to -40° Fahr., and the period of vegetation hardly lasts for three months; and is met with in Southern Spain, where the summer heat reaches 95° Fahr., and the period of vegetation lasts for nine months of the year. It occurs in dry regions like Provence, where there is little humidity in the air, and in the west of Scotland, where the air is laden with moisture all the year round. It is by preference a tree of siliceous soils, but occurs on almost all geological formations; and in Scotland, Norway, and Sweden grows on peat-bogs too wet for the spruce to exist on.

The area of distribution includes almost all Europe and the greater part of Northern Asia. The northerly limit, commencing on the north-west coast of Norway at Alten (70° N. lat.), passes through Lapland, south of the Enara lake ($68^{\circ} 50'$), and touches Pasvig Fjord on the Arctic Sea at $69^{\circ} 30'$. Extending through the Kola peninsula from Kola bay, it crosses the White Sea at $66^{\circ} 45'$ and in the Petchora territory goes as far north as $67^{\circ} 15'$; and crosses the Ural at about 64° . In Siberia it never reaches quite as far north as the Arctic circle, though it nearly touches it on the Ob and the Yenisei rivers; east of the Lena river it descends to about 64° . It reaches its extreme easterly point (about 150° E. long.) in the Werchojansk Mountains. The eastern limit descends from there through the Stanovoi Mountains

¹ There is a useful note on the propagation of this variety in *Gard. Chron.* xi. 405 (1892).

² *Schrift. Phys. Oekonom. Gesell. Königsberg*, 1866, p. 49, fig. 1.

and the Seja territory to the Upper Amur. According to Komarov,¹ it is a scarce tree on the banks of rivers in Manchuria. Its southerly limit in Siberia is not well known; but it is known to occur in the mountains of Dahuria, in the territory around Lake Baikal, and in the Altai Mountains. Its southern limit in European Russia is a very irregular line, which begins in the Ural south of Orenburg at about lat. 52°, is most to the north in the government of Tula (lat. 54° 30'), and descends from there to Kharkof (lat. 49°), passing into Galicia about lat. 50°. Far south of this line, and separated from it by the Russian Steppes, on which no pine trees grow, occurs an area of distribution, not yet well made out, which includes the Caucasus, the mountains of the Crimea, Asia Minor,² and North-Western Persia. There is also an isolated area, in which the pine is found growing wild, in Macedonia, on Mount Nidjé. From Galicia the southern limit in Europe (exclusive of the last-mentioned area) passes southwards to the Transylvanian Alps; thence it extends along the mountains to Servia, where the tree grows on the Kopavnik mountain (about lat. 43°), continues through the mountains of Bosnia, Dalmatia, Illyria, Venetia, and through Lombardy to the Ligurian Apennines (about lat. 44°). It passes into France, across the Maritime Alps, into the Cevennes, and reaches the Eastern Pyrenees; in Spain it descends through the mountains of Catalonia, Aragon, and Valencia to the Sierra Nevada in Andalusia, which is its extreme southerly point in Europe (lat. 37°). The westerly limit beginning here, stretches north-west through the mountains of Avila to those of Leon in North Spain; and is continued through the mountains of Scotland to the north-west coast of Norway.

In this vast area the pine is very irregularly distributed. The largest forests occur in the Baltic provinces of Russia, in Scandinavia, in Northern Germany, and in Poland. Towards the south it only occurs in mountains, and rarely forms pure forests of considerable extent. According to Huffer,³ it is rare in Roumania, where he saw it at the confluence of the Lotru and Oltu rivers at 1700 feet altitude, and in the valley of Bistritza.⁴

In the British Isles, the common pine is found wild at the present day only in the Highlands of Scotland, where a few forests still remain. These occur in the valley of the Spey at Rothiemurchus, Duthill, Abernethy, and Glenmore, and in the valley of the Dee at Invercauld, Braemar, and Glen Tanar. There is also a fine wild forest, the "Black Wood," on the south side of Loch Rannoch in Perthshire.⁵ That of Ballochbuie near Invercauld is probably the finest now existing.

The pine was widely spread over the British Isles in ancient times, as is evidenced by the occurrence of remains of logs, stumps of trees, and cones in the

¹ *Flora Manchurica*, i. 175 (1901).

² *Pinus sylvestris* grows on the Armenian plateau, and has been described in *Linnaea*, xxii. 296 (1849), as *P. armena*, Koch; *P. Kochiana*, Klotzsch; and *P. pontica*, Koch. Cf. *Moniteur Jardin Botanique Tiflis*, ii. 26 (1906).

³ *Forêts de la Roumanie*, 6 (1890).

⁴ M. B. Gulesco, in an article on the forests of Roumania, in *Bull. Soc. Dendr. France*, i. 171 (1907), states that in the Muscel district *P. sylvestris* is only found on calcareous soils; and in a letter to Elwes confirms this statement, adding that it attains a diameter of one metre, and does not grow on the adjoining schist.

⁵ Buchanan White, *Flora of Perthshire*, 282 (1898), gives as additional localities for wild trees in Perthshire, Breadalbane, in Glen Lyon and near Killin and Tyndrum; and mentions one or two other places where the pine is doubtfully native. According to the Rev. E. G. Marshall, *Journ. Bot.* xlv. 160 (1906), it is certainly native in the forest of Glenavon, but quite scarce, and the seedlings appear to be destroyed by deer browsing on them.

peat-mosses and submerged forests.¹ In the south of England extensive forests occurred in Neolithic times, when the existing peat-mosses began to form; but in other parts of the three kingdoms it is probable that the pine existed in many places in historic times.²

Of its existence in a wild state until lately in England, the evidence is very meagre. Holinshed,³ writing in 1586, says: "The firre, frankincense, and pine we do not altogether want, especiallie the firre, whereof we haue some store in Chatleie Moore in Darbshire, Shropshire, Andernesse, and a mosse neere Manchester, not far from Leircesters house; although that in time past not onelie all Lancastershire, but a great part of the coast betweene Chester and the Solme were well stored." According to the Rev. Abraham de la Pryme⁴ there was a wood of wild pine on a hill at Wareton in Staffordshire in his day, the beginning of the eighteenth century; and, in an old deed, fir trees were mentioned as growing scattered in Hatfield Chase in Yorkshire about the year 1400, the last surviving aboriginal pine here being cut down about 1670. The Wareton pines were described by Ray in a note⁵ dated Oct. 14, 1669: "We rode to see the famous fir-trees, some 2½ miles distant from Newport, in a village called Wareton in Shropshire,⁶ on the land of Mr. Skrimshaw. There are of them thirty-five in number, very tall and straight, without a bough till towards the top. The greatest, and which seems to be the mother of the rest, we found by measure to be 14½ feet round the body, and they say 56 yards high, which to me seemed incredible. The tenant's name of the house close by these fir-trees is Firchild, whose ancestors have been tenants to it for many generations." These trees, according to Dr. Higgins⁷ of Newport, are mentioned in an old book, *Historia Vegetabilium Sacra*, published in 1694 by Westmacott, who says there were thirty-six of them, one of them being 47½ yards high. Withering,⁸ writing in 1776, states that the trees at Wareton were no longer existing in his time. Pine forests apparently occurred in Roman times in the north of England, and remnants of these may have existed down till a recent period, concerning which the late Professor Newton told me of some very old Scots pines that used to grow about forty-five years ago on Wretham Heath, Norfolk, which local tradition said had never been planted, but grew there wild. They were always spoken of as the "Deal⁸ Trees," all other trees of this species that were planted being named Scotch firs. Whether there is any real foundation for this tradition is very hard to say, but it is possible that the seed

¹ Cf. Clement Reid, *Origin British Flora*, pp. 16, 152 (1899):—"Remains of this tree are found in Neolithic deposits, in 'submerged forests' and at the base of peat-mosses, nearly throughout Britain and in Ireland. In late Glacial times at Bovey Tracey, Devon, and at Hoxne, Suffolk (in bed C?). Abundantly in the preglacial strata of Norfolk, but not in any of the interglacial deposits in Britain. During the Neolithic period it seems to have been one of our commonest trees; but afterwards disappeared from the southern half of England."

² The orchid, *Goodyera repens*, which was formerly supposed to grow only in wild coniferous forests, as in the Highlands of Scotland, has begun to appear, of late years, in various localities, where the Scots Pine has been planted, both in England and in France; and the problem as to how the seeds of the orchid reach these plantations is still unsolved. Cf. *Kew Bulletin*, 1906, p. 293; *Actes Premier Congrès Internat. Bot. Paris*, 382 (1900); and Fliche, in *Mém. Acad. Stanislas*, 1878.

³ *Holinshed's Chronicles*, i. 358 (1807), reprint of the edition published in 1586.

⁴ *Phil. Trans.* No. 275, p. 980 (1701).

⁵ Derham, *Memorials of John Ray*, 25 (1846).

⁶ Wareton, now usually written Warton, is in Staffordshire, not far from the Shropshire boundary.

⁷ *Botany*, ii. 593 (1776).

⁸ According to Britten and Holland, *Dict. Eng. Plant-Names*, 146 (1886), *deal-tree* is used for *Pinus sylvestris* in East Anglia and Northamptonshire, the cone being commonly called *deal-apple*.

from which these trees grew might have been brought from Norway in early times; and Sir H. Howorth suggests that the existence of the Capercaillie, whose bones have been found in Tertiary deposits in the eastern counties, would have been impossible unless either pines or spruce existed to feed them in winter.

The Rev. Leonard Blomfield read a paper before the Bath Antiquarian Field Club on December 9, 1885, in which he tried to prove that the numerous Scots pines, now growing in the neighbourhood of Bournemouth,¹ are descended from aboriginal trees; and gave the following list of names of places in England in which the word *fir* occurs, indicating that these localities were in early days probably noted for woods of *Pinus sylvestris*:—Firbank in Westmoreland; Furbecke or Firbeck, and Firbie or Firby, in Yorkshire; Furbie, Firby, or Firsby in Lincolnshire; Furcombe in the parish of Farnborough, Berkshire; Furler or Furleigh in Pevensey Rape, Sussex; Furland, a tithing of Crewkerne in Somerset; and Furland Hill, between Brixham and Dartmouth.

Loudon, p. 2167, says that the tree only began to be planted in Britain about the end of the seventeenth century; but the following extract from a letter² of James I. to the Earl of Mar, dated Oct. 30, 1621, shows that the introduction of the Scots pine into England was earlier.

"The Marquis of Buckingham, being desirous to have firre trees planted aboute his house at Burleigh on the Hille, hath earnestlie requested us to cause him to be furnished as well with the seede as with young trees, which his desire wee willinglie wold have performed with all expedition. And because wee know none who so readilie can give us satisfaction in this pointe as your selfe, we have thoughte good by these presentes to require you with all expedition to cause some store of seede to be gathered eyther in your owne boundes or in those of the Marquis of Huntlie, where it may be soonest had, and so soone as possiblie may be, sende a man of purpos to Burleigh on the Hille with so much of the freshest and fairest thereof as convenientlie may be caried. And that yee cause sette downe in writing at what time and in what kinde of grounde the same is to be sowed, and with the maner of sowing thereof; also when the time of year is fitting for removing and setting of plantes and young trees. Yee shall likewise sende one to Burleigh with four or five thousand of them, with the like instructions of time, place, and maner of setting and preserving."

There is no reference to these trees in the *History of Burley on the Hill*, published in 1901; and enquiries have elicited no information, except that there are now on the estate six or eight Scots firs, which are not more than 25 feet high. A local woodman, about 60 years of age, whose father was woodman before him, never heard of the existence of old pines at Burley.

The common Gaelic word for Pine is *gius*. It occurs in a few Scottish names of places, as Craiggush, Kingussie Altnaguish, Dalguise. This word is commonly used for pine also in Ireland, and *ochtach* occurs in books. In spite of the wide prevalence in ancient times of pine in Ireland, place-names with either of these words

¹ The submerged pine forest on the sea-coast at Bournemouth is described by Sir C. Lyell in *Principles of Geology*, ii. 536 (1872).

² *Historical MSS. Commission, Report on MSS. of Earl of Mar*, p. 103 (1904).

are rare. Mr. T. P. O'Nowlan, a competent Gaelic scholar, has given me the following list:¹—

- GOOSE ISLAND, *oilean gius*, in Lough Derg, Co. Tipperary, "island of pines."
 CLONYGOOSE, *cluain gius*, parish in Carlow, north of Borris, "meadow or plain of pines."
 MULLAGHANUISH, *mullach an gius*, near Ashford, Limerick, "hill-top of the pine."
 GARROOSE, *gardha gius*, near Bruree, Limerick, "garden of pines."
 KNOCKNAGUISE, *cnocan an giuis*, about three miles north of Kenmare, "little hill of pine." KNOCKNAGUSSY, similar in meaning, is situated about three miles south-west of Lough Mask in Co. Galway, "hill of the pine."
 KNOCKHOUSE, *cnoc gheainas*, three miles south-west of Mullinavat, Co. Kilkenny, "hill of pines"; the Gaelic word used here being a local variation of the common form.
 OUGHTY ISLAND, *oilean ochtaigh*, near Roundstone, Co. Galway, "pine island."
 DROMOGHTY, *drom ochtaigh*, about three miles north of the tunnel on the Kenmare road, Co. Kerry, "pine ridge."

Apparently, though the pine tree was centuries ago well known in Ireland, there is very scanty evidence as to its existence as an indigenous tree in modern times. Everywhere in Ireland the roots of pine trees are often found *in situ* in the upper layers of the peat-mosses, showing that forests of pine grew in the peat and attained a considerable size. These peat-mosses are probably of late formation.²

Ray³ quotes Mr. Harrison as an authority for pine "growing wild in the mountainous parts of Kerry where the *Arbutus* grows," about the beginning of the eighteenth century. Smith,⁴ writing in 1761, says that "these trees have been much destroyed in recent years; for, except a small shrub here and there among the rocks, there are none standing at present of any large size."

Mackay⁵ mentions, in 1825, a solitary pine tree standing near the foot of Mount Nephin in Mayo, which was supposed to be the last remnant of the pine forest of that county. This tree,⁶ very large and very old, was living in 1866, the exact locality being an open bog at Deal Castle, near Crossmolina, at the head of Lough Conn, and had been fenced in by the Earl of Arran.

Hayes,⁷ writing in 1794, speaks throughout his valuable book of *Pinus sylvestris* as Scots fir; and evidently in his day all the pines in Leinster at least were the product of Scotch seed.

In France the common pine is never met with growing wild in the plains. It is confined in the wild state to the Alps of Savoy, of Dauphiné, and of Provence, the

¹ While the above was passing through the press, Mr. O'Nowlan sent me a further list, as follows:—Lough Aguse, name of two lakes, one near Pettigo, Donegal, and another in Fermanagh; Lough Ayoosy and Aghoos, in Mayo; Cappayuse in Roscommon; Meenaguse in Donegal; Drumgoose and Derrynoose in Armagh; and Annagoose Lake in Monaghan.

² The evidence for this is too large a subject to be entered upon here. In certain peat-mosses no less than three distinct forests are discernible, occupying different depths; and the uppermost forest, always of *Pinus sylvestris*, probably dates from historic times.

⁴ *State of the County Kerry*, 372 (1761).

⁵ *Catalogue of Plants in Ireland*, 83 (1825).

⁶ *Cybele Hibernica*, 277 (1866).

⁷ *Practical Treatise on Planting*, 133, 167 (1794).

mountains of Auvergne, the Cevennes and Pyrenees, and is specially noted as occurring chiefly on the slopes with a southerly aspect.¹ It is common in the eastern part of the Pyrenees, between 4000 and 6600 feet altitude.

In Spain the common pine is also restricted to the mountains, only forming woods on northern slopes; and in the Sierra Nevada, forms the large and splendid forest of La Granja on the north side of the Sierra de Guadarrama, where it ascends to 6500 feet.²

In Germany very extensive and pure forests of pine occur in the north-east, always on sandy soil in the plain. These forests are called heaths, as they contain wide stretches covered only with heather and many swampy areas. Such forests are common in the provinces of East and West Prussia, Pomerania, Brandenburg, Posen, upper Silesia, Saxony, and in the kingdom of Saxony. Other large forests of the same kind occur more isolatedly in north Schleswig, Hanover, Jutland, and Holland. In the valley of the Rhine, both in Alsace and Baden, very fine forests of pine are also met with, as at Haguenau, likewise on sandy soil. In the mountains of Middle and Southern Germany, the pine only grows in small groves or as isolated trees. Similarly throughout the Alps and Carpathians, in Hungary, and on both shores of the Adriatic the pine is rare, only occurring in small woods.

The pine does not occur wild in the islands belonging to Denmark, and is totally absent from the Hungarian plain, the Bakony forest in Hungary, the Central Carpathians, Banat, and Slavonia, and is not met with in the alpine and subalpine regions of the high mountains of Central Europe. (A. H.)

In Switzerland this tree does not seem to attain such a large size as in Scandinavia. A tree at Campodials in the Grisons, figured on Plate xi. of *Les Arbres de la Suisse*, is said to be 80 feet high by 10 feet 6 inches in girth at 4 feet from the ground. It grows on the edge of a forest at about 3000 feet elevation, on crystalline rocks.

In Norway and Sweden the common pine constitutes by far the largest portion of the forest, and flourishes farther north than any other tree except the birch. Though truly virgin forest is now becoming a rarity in Norway, and in the more accessible parts of Sweden and Finland, yet the area of land covered with pine and spruce is still so large and so much better suited than England for the production of commercial timber that we shall, in my opinion, never be able to produce it of such good quality and at so low a price. I have seen *Pinus sylvestris* at its best in the forests of South-Eastern Norway in the valley of the Glommen; where the bright yellow bark of the upper part of the tall trunks on the banks of the river is a marked feature of the scenery; and in the far north in upper Saltensfjord where the oldest pines known to me now exist; though here, as elsewhere, they are rapidly being felled to supply the great demand for building and mining timber. In the more central provinces of North and South Trondhjem, and on the coast, the pine does not seem to grow to such a great size, probably because the soil and climate are too wet to suit

¹ It is not a native of the French side of the Vosges, but occurs on the German side at 1300 to 3000 feet altitude. It is not wild in the Ardennes or in the Jura.

² Mentioned by Christ in *Flore de la Suisse*, 198 (1907). Cf. *supra*, p. 574, var. *nevadensis*.

it as well as the spruce, for the pine is a lover of a sandy soil and a dry long winter, with a hot sunny summer.

Dr. Schübeler, in his *Viridarium Norvegicum*, i. 375, gives many details about the pine, from which I gather that its range extends from the south, where it reaches an elevation of 3500 feet above the sea, to the inner valleys of Finmark, where in lat. 70° N. it attains in Alten and Porsanger fjords as much as 60 feet high and 7½ feet in girth. He tells us that formerly there were pines on the Dovrefjeld, near Jerkin, at an elevation of 3200 feet, as much as 1 foot in diameter, where no trees now exist; and that near Roros, now one of the bleakest and coldest towns in Norway, the forest was, in 1773, so dense as to be almost impassable. The tallest pines in Norway that he mentions were near Holden in Lower Thelemarken, where one was measured 104 feet high, with a diameter at the ground of 2 feet 10 inches, and at 70 feet high of 9½ inches. Another at the same place was 105 feet high, and 5 inches in diameter at 96 feet up. At Klosterskogen in Skien, one was measured 108 feet by 6 feet 5 inches at breast height. The greatest girth that he mentions is about 15½ feet.

I have myself measured at Graddis in Junkersdal, within the Arctic Circle, and at an elevation of at least 1200 feet, pines of over 50 feet high and 12 to 13 feet in girth. One of these, which was cut down, was 34 inches in diameter and about 240 years old, but the outer rings were so close that I could not count them accurately, the first 100 years' growth being over 26 inches in diameter, showing that in this latitude at least the increase after this time is very slow. The tallest that I saw in this valley was 84 feet high near the Government Forest Nursery at Storjold. I observed that in Junkersdal the natural regeneration from seed was poor, and that in the upper parts of the valley the young seedlings were very small and stunted, and birch seemed to be taking their place. In this valley on July 10, 1904, vegetation had only just commenced, and the pines had not pushed their young growth, though *Cypripedium Calceolus* was in flower. A severe frost which took place in April, -14° to -16° Réaumur, after warm weather in March, had killed most of the young shoots where not protected by snow.

Schübeler gives several illustrations of the curious forms which this tree sometimes assumes. His Fig. 59 shows a tree in which the branches are very short and which has the shape of a northern spruce rather than that of a pine. Fig. 60 shows a branch with a great bunch of forty to fifty closely packed cones surrounding it. Figs. 61 and 62 show the power which the tree possesses of sending out upright stems of considerable size from a fallen trunk whose roots still retain their hold on the ground. Fig. 63 shows an immense witches' broom, forming a dense mass of living twigs in a ball 10 feet in diameter, which surrounds the trunk of a pine growing at Aaseböstäl in Nordfjord.

It is occasionally planted in Iceland,¹ but does not long survive the severe climate, though Hooker was told that a single dwarf tree grew on an island in a lake between the head of Borgarfjord and Reyholt.

As little is known with regard to the so-called Riga pine, which was for long

¹ Babington, in *Journ. Linn. Soc. (Bot.)* xi. 50 (1870).

the most celebrated for masts and shipbuilding purposes, and has been found in France to be the best variety in cultivation, we may refer our readers to a recent publication by Von Sivers,¹ with a map of the distribution of pine and spruce, which shows a comparatively small area of the former. The author states that though the pine is everywhere at home, it grows best on sand, especially where that is underlaid by good soil, and that in favourable places it reaches often a height of 150 feet. The area which is occupied by pine plantations in Estland, Livland, and Kurland is estimated at 638 square kilometres. It would, therefore, seem that the production of pine timber is not sufficient to continue the large export upon which in the past reliance could be placed. And though there are still large reserves of pine forest in Northern Sweden and Finland, yet it was stated by Mr. A. Howard at a recent meeting of the Society of Arts, in a discussion on Sir Herbert Maxwell's paper on Forestry, that the size of the deals imported from the Baltic is steadily diminishing, and that a much smaller proportion of 11-inch boards is now sent than was formerly the case.

In the forests of the lower valleys of the Altai Mountains in Siberia I have seen the pine attain a greater size than anywhere in Europe, some trees in the valley of the Biya river, a tributary of the Ob, which I observed in 1899, being estimated at 150 to 160 feet in height, and clean to 100 feet, at which height they looked as if they were 5 or 6 feet in girth.²

CULTIVATION³

Of all the many species of pine, none is so widely distributed in Europe, so common all over Great Britain, so easy to grow as the Scots pine, or Scotch fir, as it is often incorrectly called. Its vigorous constitution and rapid growth when young enables it to exist and even to thrive in almost all situations, and though the variations which it has produced in a wild as well as in a cultivated state are innumerable, yet the most casual observer can hardly fail to distinguish it from any other species which is likely to be seen in cultivation. I have seen the tree in the greatest perfection on the sandy soils of Surrey, Sussex, Bedfordshire, and Notts, on the rich loams of the south-western and midland counties, on the dry sandy glacial deposits and heath-clad hills of the Highlands, and in many parts of Europe.

Whether the Scots pine was at first principally propagated in England from native Scotch seed or from German seed is doubtful, and probably the earliest planted trees came from various sources; but so far as my experiments have gone, it seems as though the seedlings grown from acclimatised trees are now more flourishing, and grow faster in the south of England than those from German, Highland, or Scandinavian seed. I have tried plants of the same age from all these sources in Gloucestershire, and have found those sent me from the New Forest the most promising in their younger stages. If rapidity of growth at first is any indication

¹ *Die Forstlichen Verhältnisse der Baltischen Provinzen*, Riga, 1903.

² Farther east, near Krasnoyarsk, a pine has been measured, which at 200 years old was 40 archines (93 feet) high, and 11 vershoks (19½ inches) in diameter; but this is far surpassed by the pines found near Bélovège, where trees 150 years old are said to measure 60 archines (140 feet) high by 12 vershoks (21 inches) in diameter, and contain as much as 100 sagènes (about 250 cubic feet) of timber. Cf. *Les Forêts de la Russie*, Paris Exp. 1900.

³ Loudon's excellent account of the culture should also be referred to, pp. 2178-2183.

of vigour, I should prefer them, though I would not plant Scots pine as a forest tree on any soil where I could get larch to grow even fairly well; and on dry chalk and limestone soils it never grows with the vigour that it does on sandy soils.

Large parts of the open heath of the New Forest, though constantly pastured by horses, are becoming overgrown with Scots pine to such an extent that if they escape fire it seems as though they would eventually turn those open wastes into a more or less dense pine wood.¹ But on clay soils, and wherever a rank growth of grass, ferns, or briars is found, natural reproduction is comparatively rare, and over the whole of the Cotswold Hills I only know of a few places where self-sown pines can be seen.

If natural reproduction is desired, the best way of encouraging it is to uncover lines or patches of soil in the winter, on which the seed falling in April can germinate; but the growth of these self-sown plants is, as usual with almost all natural seedlings, at first much slower than that of planted trees. In very old pine woods of 100 to 150 years' growth, such as are found in Strathspey and in a few parts of England, the accumulated carpet of dead pine needles seems to prevent the young seedlings from establishing themselves; and in the Belvidere plantation at Windsor Park, which is one of the finest in England, I saw no self-sown seedlings under the fine old trees, many of which are 100 feet and more in height.

In such cases it is best to burn the heather or to graze it closely with sheep and cattle, and in many cases this is a necessary preliminary to preparing the ground for natural reproduction in Scots pine woods; but if the soil produces grass rather than heather, the regeneration is always less successful and requires more assistance.

I shall not attempt to give any estimate of the financial results of planting Scots pine as an unmixed plantation, because the conditions of soil and climate are so varied that any estimates, such as we see commonly given in books on forestry, are usually misleading. On very sandy, dry soil it will probably pay as well or better than any other tree, because it can be planted so cheaply, and will regenerate itself so easily.² But it must be kept thick enough to clean its stem before the branches get large, and in fact it may be better not to thin at all until 20 to 30 years old, when the weaker stems which will hardly pay to cut and carry out will be killed by their stronger neighbours. On high moorlands also it may be, and now often is, as profitable a crop as larch, because it grows well in windy and exposed situations; but I would not plant it, except as a nurse to other trees, on any soil where experience has shown that a more valuable tree will grow to fair timber size, and the plan often adopted of mixing it in larch plantations on calcareous soil has led in many places to absolute failure.

With regard to the possible yield of Scots pine in England, I have heard of nothing better than a part of the Dipton Woods near Hexham, Northumberland, the property of Lord Allendale. This was described in *Trans. Scott. Arb. Soc.* xx.

¹ I was informed during a recent visit to the New Forest that the commoners already complain that the pasture is deteriorating from this cause.

² I have seen no better example of natural regeneration than on the Duke of Bedford's property at Old Wavendon heath, near Woburn.

84 (1907), as containing something like 9000 cubic feet per acre, which at 4d. per foot works out at £150 per acre. Mr. Gillanders informs me that the soil is fine fresh sand, the elevation 550 feet, and the aspect north-east.

Some of the best foresters consider it an excellent nurse for oak, but beech is now usually preferred for this purpose, on any soil where the latter will thrive.

From 70 to 100 years, or in the Highlands 120 to 150 years, is about the age at which the tree is usually mature for felling; as, when younger than this, the timber is comparatively soft and inferior, though after creosoting it may be utilised for many purposes where strength is not important. Where pit-props are saleable, it is more profitable to cut the crop as soon as large enough for that purpose.

PROPAGATION

No coniferous tree is more easy to raise from seed, or easier to transplant. In Scotland the cones are usually gathered in autumn and the seeds extracted by kiln drying when required for sowing; but they are better left on the trees till spring, and the seeds may then be easily extracted by damping the cones and exposing them to the sun till they open. The seeds will keep good for several years, and if not wanted to sow at once, are better extracted in the summer after they are ripe and kept until the following March, when they will germinate as readily as, and perhaps produce stronger plants than, those extracted by artificial heat in winter and sown the next spring.

The best nursery practice is to sow them broadcast on slightly raised beds of sandy soil about three feet wide, and cover with about half an inch of fine earth, some of which may be raked off just before they begin to germinate, leaving a fresh surface uncaked by the rain and sun.

If sown too thickly, the plants will be drawn up closely, and will not remain two years in the seed-bed without becoming crowded. Some people advise transplanting at one year old, but in my experience two years is better, and, if carefully handled, the percentage of loss caused by transplanting is very small.

If the plants are to be put out on heath or sandy land, the stronger ones may be permanently planted out from the seed-bed; but in all soils which are grassy and weedy, it is better to keep them one or two years in nursery lines, which should be about 1 to 1½ feet apart, and the plants 3 to 6 inches apart in the rows, according to whether they are intended to remain one or two years in lines.

It is rarely desirable or necessary to allow them to remain more than four years in the nursery; but if plants larger than 1½ to 2 feet are required for special purposes, they must be transplanted when four years old and put in rows about one foot apart and two feet apart in the rows.

The best time for planting out large trees is in the autumn, as soon as the terminal buds become hard; but small plants should not be transplanted till after the period of severe frost has passed, or they will in most soils be lifted by frost. If, however, it is necessary to do so, stones should be put round the collar of the tree, not only to keep them fast in the ground, but also to keep out the drought during

the first year. I have found that this is a very successful method to adopt with all small trees on stony soil liable to drought.

An account of the best way of growing the Scots pine from seed was written by the Earl of Haddington in 1760 to his grandson, and is quoted in the Highland and Agricultural Society's volume on the *Old and Remarkable Trees of Scotland*, published in 1864. This account is very practical and based on personal experience, and interesting as showing how much care was taken by the planters of those days to ensure good results.

REMARKABLE TREES

As to the height the Scots pine attains in Great Britain, many particulars have been given by Loudon, which in most cases cannot be relied on for accuracy, but we have reliable measurements which show that the tree rarely exceeds 110 feet, and more usually is not over 100 feet.

In the *Victoria County History of Hants*, it is stated in vol. ii. p. 469, that trees 130 feet high were growing at Beaulieu, but Lord Montagu tells me that he has never actually measured one over 116 feet, of which height one was blown down some years ago. I saw these trees in June 1906, and though many exceed 100 feet, and are clean to 70 or 80 feet, with a girth of about 7 feet, I could find none over 110 feet. At Rooksbury Park, near Wickham, Hants, there are some which, I think, are taller, growing, mixed with beech and oak, in a dense thicket of rhododendron. The largest I measured here was about 115 feet by 10 feet 4 inches, dividing at about 17 feet into three tall, clean stems.

At Carclew, Cornwall, the seat of Colonel Tremayne, there is a fine avenue of pines, the tallest of which I found to be about 110 feet (Plate 160). At Pain's Hill, Surrey, Henry measured a tree of 106 feet. In the Belvidere plantation in Windsor Park, one of the finest old pine woods in England, planted about 1760, there are many trees of 100 feet and some perhaps a little more. There were some very tall trees at Hursley Park, Hants, of which I have no exact measurement, but I hear that few, if any, of them remain.

At Blickling Hall, Norfolk, the property of the Marchioness of Lothian, there is an immense tree, perhaps one of the oldest in England, which, when described by Grigor in 1841,¹ was 70 feet high and 16 feet in girth at 6 feet from the ground. He thought it the largest tree of the kind in Norfolk. When I saw it in April 1907 it was 96 feet by 17 feet 1 inch, dividing at about 10 feet into two main trunks, which were chained together 40 feet up. It had a large burr at the base. At Stratton Strawless there are some fine trees planted about 1740 by Robert Marsham, measuring about 100 feet by 9 feet. A tree was reported by Loudon at Castle Howard, Yorkshire, as being 120 feet high, with a bole 100 feet long, but I could not identify this tree as still living in 1905. At Cocklode House, in Sherwood Forest, there is a fine avenue of Scots pines about 160 years old, which are 90 to 100 feet high, and 9 to 10 feet in girth, but many of them have been blown down.

The tallest that I have ever seen or heard of is in the grounds at Petworth,

¹ *The Eastern Arboretum*, p. 100.

Sussex, the seat of Lord Leçonfield, where the soil seems particularly favourable to very tall trees. A careful measurement of this in 1905 gave the height as 120 feet by 11 feet in girth, and a bole of 35 to 40 feet, where it divides into two stems. Sir Hugh Beevor, who saw it in 1904, did not make it quite so tall. This tree appears in the foreground of Plate 162.

No park in England contains a greater number of fine and picturesque old pines than Bramshill Park, Hants, the seat of Sir Anthony Cope, who tells me that he believes them to have been planted about the year 1600, and to be some of the oldest in England. The soil here is very light and sandy, and the oldest pines are in avenues, which have become rather irregular in course of time. The tallest trees that I measured here were not over about 80 feet high by 10 to 12 feet in girth, but there is one splendid tree in the Gravel Pit drive which is about 80 feet by 16 feet, of which I give an illustration (Plate 161). There are many self-sown seedlings of various ages in this park, but no other trees of remarkable size.¹

At Dyrham Park, Gloucestershire, the seat of the Rev. W. T. Blathwayt, there is a very fine tree, of which I am indebted to the owner for a photograph, which measures about 73½ feet high by 14 feet 9 inches in girth, dividing at 4 feet into three trunks. There are some very fine clean Scots pines in Stowe Park, near Buckingham, one in the Queen's Quarter being over 100 feet high, with a clean bole over 60 feet long and 11 feet 3 inches in girth. In the Fir Grove, at Bayfordbury, Herts, there is a tree,² with a clear stem of over 50 feet, which measured in 1905, 95 feet high by 9 feet 7 inches in girth.

In Wales I have heard of no Scots pine of greater size than one at Penrhyn Castle, which Henry measured in 1904, and found to be 110 feet by 7½ feet, and about 70 feet to the first branch. At Gwydyr Castle he measured one about 85 feet by 11 feet 2 inches on which a mountain ash seedling was growing.

In Scotland there are so many fine old trees that it is impossible to mention more than a few of them. Perhaps the finest, if not the tallest, is a tree at Inveraray, of which a beautiful photograph by the late Vernon Heath is in the museum at Kew. I measured this tree in September 1905, when it seemed to have changed very little in appearance, and though supported by chains above the fork, is very sound and healthy. It measures 110 feet by 14 feet, forking at about 35 feet, and leaning considerably to one side. The Duke of Argyll informs me that it was probably planted about 1620. Plate 162 shows the present appearance of this tree. There are many other very fine Scots pines at Inveraray on the lower slopes of Dun-i-cuach, but none equal to this in height or girth.

On the banks of the Tay, near Dunkeld, there is a very graceful tree of weeping habit though of no great size (Plate 163), which measures 77 feet by 11 feet 6 inches in girth; and at Blair Atholl there are some curious old pines in a row

¹ Bunbury, who visited Bramshill Park in 1859, mentions the tradition that these trees were introduced by James I. from Scotland at the same time that he began building Bramshill, and states that there were three magnificent Scots pines at Eversley Rectory, which were coeval with those of Bramshill. Cf. Lyell, *Life of Sir C. J. F. Bunbury*, ii. 138, 139 (1906).

² This tree measured, in 1816, 5 feet 8 inches in girth, according to an entry in an old note-book, now in the possession of Mr. H. Clinton Baker.

by the Inverness road, which the Duke of Atholl informs me are probably part of the booty carried off by his ancestors in 1684 from Inveraray, as described in *Chronicles of the Atholl Family*, by the present Duke.¹ Nothing can better illustrate the importance which was paid to trees and planting even at this early period, when the Highlands were hardly civilised; than that so many exotic trees should have existed at Inveraray, and that it should have been thought worth while to carry them to such a distance when wheeled carriages could not have traversed the country.

An immense Scots pine, which I have not yet been able to visit, grows at Guisachan, Inverness-shire, now the property of Lord Portsmouth, whose forester, Mr. Davidson, informs me that in February 1907 it was 53 feet 10 inches high and 16 feet 8 inches in girth at the ground, and 15 feet 7 inches at 5 feet. At 11 feet from the ground, below the first branch, it is 16 feet 10 inches in girth. The trunk has been cut into at the base, which is believed by old people living near to have been done by smugglers, as an illicit whisky-still once existed near it. A drawing of this tree was made for the late Sir Dudley Marjoribanks, of which I have a copy. Mr. E. Ellice tells me that there are a number of very large old pines in the Guisachan Woods, girthing over 14 feet.

Mr. E. Ellice of Invergarry informs me that there are a considerable number of old native Scots pines at that place, among them one which attracted the late Mr. Gladstone's attention, and of which he sends me a sketch, with the following measurements:—Height, 70 to 80 feet; girth at the ground, 20½ feet; at 5 feet, 16 feet 3 inches; at 10 feet, 15 feet 9 inches; at 13 feet, 17 feet. A figure of this will appear in Vol. IV. Other trees near it measure 14 feet 3 inches, 12 feet 10 inches, and 12 feet 9 inches; and these appear to be the parents of many more which may be divided, according to their age, into three classes: those of 120 to 150 years, of which there are some hundreds; those of from 80 to 100, of which there may be 15,000 to 20,000; and younger trees.

The finest forest in this locality is in Glen Malie, on Lochiel's property,

¹ "In 1684 or 1685 the Marquis of Atholl did carry out of the orchard enclosures and shrubberies at Inveraray—

This claim was settled for £13,000 Scots or £1333, 6s. 8d.—*Chronicles of Atholl Family*, i. 265.

£13,553 6 8 Scots.

running up from the shore of Loch Arkaig for five miles, and in it there is one tree, even larger than that last mentioned, of which Mr. Ellice has sent me a sketch. At the narrowest part of the trunk, three feet from the ground, this tree measures 18 feet 8 inches in girth, and at about 10 feet divides into three tall trunks, each of which girths between 11 and 12 feet. Just below this fork it girths about 30 feet, and appears to be sound throughout.

At Novar, in Ross-shire, there is an old plantation containing a number of very fine Scots pines, one of which measures 105 feet by 10 feet 3 inches, and larger ones can probably be found in this district, as well as in the sandy district which extends east from Inverness, where many large plantations of this tree flourish exceedingly.

The finest individual trees and the finest Scots pine plantation that I have seen is in a place called Wishart's Burn, near Gordon Castle, Banffshire, on red sandstone soil. Though supposed to be about 180 years old, most of the trees are still in good health and quite sound, though wind has made some gaps in the plantation. When I visited them in April 1904 the tallest tree was about 117 feet high by 10 feet 11 inches in girth. It forks at about 45 feet, but carries its girth so well that the bole would, I think, measure 45 feet by 28½ inches quarter girth, about 245 cubic feet, and the tops might contain 50 feet each, making a total of 345 cubic feet (Plate 164). Another tree standing near it was 114 feet by 8 feet 10 inches, and I estimated that the older trees here average over 100 feet high by 8 feet in girth. Mr. Webster, gardener to the Duke of Richmond, who showed me this beautiful spot, agreed with me that the average number of trees to the acre here was about sixty, and their average contents about 100 cubic feet; but many have been cut and sold at as much as £7:10s. each, to make masts for large herring boats. One of these trees probably is the one figured by Loudon (p. 2162) as a model of a fine Scots pine clear of branches to 50 feet, and containing 260 feet of timber.

There are also very fine plantations of Scots pine in the neighbourhood of Castle Grant, the seat of the Dowager Countess of Seafield, in Inverness-shire, a place celebrated for its good forestry, and where better examples of thickly grown self-sown pine may be seen than anywhere else in Scotland. Mr. Grant Thomson, who has had charge of the extensive woods here for forty-five years, told me that the oldest planted trees are about 180 years old; many of these are 80 to 90 feet high and 8 feet in girth, and number sixty to seventy per acre. Some have already begun to decay at the heart, and it was noticeable that on the thick bed of decayed pine needles under them seedlings would not grow. This has been referred to by Prof. A. Schwappach in a paper on the "Forests of Scotland" in *Trans. Roy. Scot. Arbor. Soc.* xv. 13 (1898).

In this neighbourhood are the most celebrated and extensive natural forests of Scots pine in Great Britain, which I visited in April 1904. Glenmore forest, the property of the Duke of Richmond, was perhaps the best of these until 1783, when a great part of the mature timber was sold to an English merchant named Osbourne, who cut it down in twenty-two years and floated the timber to Spey-

mouth, where forty-seven ships of upwards of 19,000 tons burden were built from them at an expense for labour only of £70,000 (cf. Loudon, p. 2161). Glenmore Lodge lies at an elevation of 1050 feet on the shore of Loch Morlich, where some of the finest pines still stand. One of them (Plate 165) is interesting as having for many years been the eyrie of an osprey whose nest is visible in the photograph, which was taken in the interval between two snowstorms; but the birds, though carefully protected, have not bred there since 1900.¹ This tree measures 56 feet by 13 feet, and is very characteristic of the native Scots pine in its habit. But perhaps the most interesting tree in this forest is one from which a plank, now preserved at Gordon Castle, was cut and presented by Mr. Osbourne to the Duke, in 1806, as a memento of the forest. I could not count the rings of wood in it exactly, but the Duke of Richmond informs me that there are about 236. I measured the plank 5 feet 5 inches wide at the butt end and 4 feet 4 inches at the top. The sapwood is worm-eaten, and the colour of the wood has become very dark. I saw still lying on the hillside above Glenmore Lodge, near the upper limit of the Scots pine, at an elevation of about 1400 feet, a huge top, over three feet in diameter where it was cut off, and was assured by Francis M'Pherson, an old woodman, who showed it to me, that it was the top of the identical tree from which the above-mentioned plank was sawn. Though overgrown with moss and heather, much of the wood appeared to be still sound, after lying for nearly a hundred years. In confirmation of this I may state that Mr. J. Michie showed me, in Ballochbuie Forest, the remains of a pine which was sawn up and found sound after lying seventy years on the ground.

In Abernethy Forest there are also many fine old pines, one of which, Mr. Grant Thomson's favourite, is shown in Plate 166. It measures about 60 feet high by 14 feet 3 inches in girth, and, though it divides into five tops, is a most graceful tree. Much of this forest was burnt down many years ago, but has become self-sown with young trees, and is now open wood covered with long heather, and a favourite wintering ground for deer. We measured a group of the best clean self-sown trees supposed to be about 120 years old, and estimated them at about 120 per acre, with an average timber height of 40 to 50 feet and a cubic content of about 25 feet (Plate 167). Such trees, where they stand, are worth about 6d. per foot. Many cones are gathered in this forest for seed, of which about 8 ounces from a bushel is the average produce; and there is a large nursery where they are raised, the growth being very slow as compared to what one sees in England, on account of the cold and damp situation.

I next visited Ballochbuie Forest, by the kind permission of His Majesty, who preserves this beautiful forest with great care. It is now perhaps the largest area of natural forest in Scotland, extending for several miles along the south side of the upper valley of the Dee. The photographs, Plates 168 and 169, give a good idea of the picturesque scenery of this forest and of the fine trees in it, many of which are 80 to 90, and some as much as 100 feet high, by 7 to 8 feet in girth. The

¹ Mr. S. R. Clarke has sent me a photograph of a Scots pine at Fasnakyle, which is used annually as an eyrie by the Golden Eagle.

best of those which I saw might measure 60 feet timber height by 18 inches quarter-girth or 135 cubic feet. In the best stocked areas the trees might average 120 per acre at 120 years old, of which forty trees of the first class would average perhaps 40 feet, forty second class 25 feet, and forty of the third class perhaps 12 feet each, or about 3000 feet to the acre. But these figures are only a rough estimate, as the King's trees are not cut for sale, and in consequence Mr. Michie could not give me exact figures, but thinks they are worth from 6d. to 8d. per foot standing.

The Black Wood of Rannoch is an ancient natural pine wood extending for about three miles along the south shore of Loch Rannoch, and though there are no trees of exceptional size, there are many very picturesque ones, which are protected by the owner, B. C. Vernon-Wentworth, Esq., whose residence at Dell is near the east end of the wood. The largest which I measured was 91 feet by 11 feet 7 inches, with a very spreading base 15 feet 5 inches round at one foot from the ground. The greater part of the wood is open and covered with long heather, among which seedlings were fairly numerous wherever the soil was exposed. Many of the large trees were blown down thirteen years ago, and their timber, which was of very fine quality, was used by Sir J. Stirling Maxwell in the interior work of his house at Corrour.

There is an excellent account of the Black Wood of Rannoch and its history in chap. xxxiv. of that admirable book, Hunter's *Woods and Forests of Perthshire*, which, though now getting out of date, as it was published in 1883, gives a better account of the great estates and their trees than exists for any other county in Great Britain. In this work dimensions are given of the finest trees then existing in the Black Wood, which are remarkable more for their great girth, spreading and massive branches, and picturesque appearance than for their height.

On the shores of Loch Hourn, on the west coast of Inverness-shire, there are many native pines scattered among the birches, but none of large size, a few of those near the sea resembling the stone pine of Italy in habit. Henry observed that many of these trees do not ripen seed.

With regard to the elevation at which the Scots pine grows in Scotland, we have various somewhat conflicting estimates. Mr. Michie tells me that Craig Doin (1900 feet) is about the highest level he knows it to reach in Ballochbuie. Mr. Seton P. Gordon, however, says¹ that he has seen a young Scots pine growing at a height of about 2700 feet not far from the source of the river Dee on the south slopes of Brae Riach, though he regards this as very exceptional. Mr. Hugh Boyd Watt² also considers 2700 feet quite an unusual altitude, and says, "From personal observations made on and around the Cairngorm mountains (and in no other district in this country do forest trees attain higher levels) I can say that even at 2000 feet above sea-level the Scots pine has difficulty in holding its ground. . . . On the southern slopes of Beinn a' Bhuird (Glen Quoich) considerable numbers of fairly well-grown Scots pines reach up from 2000 feet to 2100 feet, and I know no other place where what may be called the forest line is so high. . . . In other localities, apparently favourable to their growth, the pines do not in any numbers exceed an

¹ *Country Life*, 17th Aug. 1907, p. 245; 31st Aug. 1907, p. 322.

² *Op. cit.* 7th Sept. 1907, p. 359.

altitude of 1500 to 1700 feet. This is approximately the level at which they die out in Abernethy, Rothiemurchus, Glen Feshie, Glenavon, Invercauld, Birse, and Glen Tanar." When stalking on Ben Avon I saw with the telescope some pines in the upper part of Glen Derry which I supposed to be at an elevation of about 2000 feet, and Mr. Michie, who has seen these trees, thinks that this estimate is not far from the mark.

(H. J. E.)

In Ireland the common pine grows with great vigour and beauty, the bark becoming bright red in colour and the leaves very glaucous. The tallest trees, which I have seen, are at Curraghmore, the seat of the Marquess of Waterford, where, near a stream, I measured one 110 feet high and 7 feet in girth; some, but difficult to measure accurately on account of their position in a dense wood, were probably 120 to 125 feet in height, the largest of these having a girth of 9 feet.

At Doneraile Court, Co. Cork, there are some fine pines, growing scattered in an oak wood, the largest of which I made 97 feet by 11½ feet, with a clean stem to 50 feet. These trees are supposed by local tradition to be of native origin, and are called Irish pines; but they have evidently been planted, and there is no means of determining whether they originated from seed collected in Kerry from aboriginal pines still existing there in the 18th century, or, as is more probable, from Scotch seed, as they are probably about the same age as the famous larches at this place, which are reputed to have been sent to Doneraile by the Duke of Atholl.

At Emo Park, Portarlinton, there are many fine trees, the largest seen measuring 91 feet by 7½ feet and 88 feet by 9 feet 1 inch. There is also a splendid tree, growing near the gate of Mr. Walpole's beautiful garden at Mount Usher, on the Rossanagh property, which is 11 feet 9 inches in girth, and probably 80 feet in height. At Castledawson, Co. Derry, an old tree measures 80 feet in height by 11 feet 4 inches in girth. There are many fine trees scattered through Coollattin in Wicklow. These grow on moist boggy soil; and I measured two clean of branches to 60 feet, which were 87 feet in height, and 9 feet 5 inches and 8 feet 1 inch respectively in girth.

At Luttrellstown, near Dublin, Hayes¹ measured a "Scots fir, eighty-five years' growth from the seed, of 11 feet 6 inches in circumference, and another of very great height 11 feet 10 inches round." He gives several other instances of the rapid growth of the tree in Ireland.²

Mr. T. W. Webber, late Deputy Conservator of Forests in India, in the appendix to his book on the *Forests of Upper India*, gives an interesting account of the growth of Scots pine in Ireland, the planting of which he strongly advocates. To the objection that home-grown timber is of inferior quality, he replies that the wood of *Pinus sylvestris* found in bogs in Ireland is often of great length and thickness, sound, fine-grained, solid and straight, and so excellent that it has been used by coach-builders as superior to Memel timber. Where such timber grew ages ago,

¹ *Practical Essay on Planting*, 133, 167 (1794).

² At Powerscourt an immense Scots pine was blown down by the great gale of February 1903, which I saw on the ground soon afterwards and which measured about 12 feet in girth. Some boards cut from the tree were kindly sent me by the late Lord Powerscourt, which show its growth to have been very rapid.

(H. J. E.)

similar material might be produced to-day, if close planting and slow growth were the rule. To prove this, he gives the actual dimensions of Scots fir grown under two different conditions in Ireland.

Grown thirty to the acre, with spreading crowns.	Grown 200 to the acre, with small crowns.
Girth 5 feet	5 feet.
Height 50 "	75 "
Age 40 years	100 years.
Diameter 20 inches	20 inches.
Heartwood 12 "	19 "
Sapwood 8 "	1 inch.
Rings per inch 4, uneven	10, regular.

These trees are quickly grown on deep soft soil, and are liable to be blown over. Timber, coarse, knotty, light, and perishable; large amount of sapwood.

These trees were slowly grown on a hill-side on poor and stony soil; standing close they resist storms. Timber fine-grained, hard, heavy, durable, and equal to best Memel. Scarcely any sapwood.

Mr. Webber has kindly written to me that the trees just mentioned grow on his own property at Kellyville, near Athy, in Co. Kildare. A beam, made out of the fine pine timber grown on the hill-side, placed in the front of a conservatory twenty-five years ago, is still sound and good. Mr. Webber has Scots pine thriving on pure rock, where there is little or no soil. He states that at Emo Park near Portarlinton and on the road to Maryborough there are striking instances of pine succeeding on pure black bog, and self-sown seedlings may be seen spreading all over the turf-moss. He reiterates the conclusions given above, namely, that the pine should be planted densely on poor soils, where it will resist the wind and yield timber without any appreciable sapwood, whereas on deep soft soils it is easily blown over and yields coarse and valueless timber. In the bog in Emo Park, Mr. Webber found great bases of Scots pines with their roots in the boulder clay, of gigantic size, showing that the tree was indigenous before the bog began to grow ages ago.

In some parts of Ireland, Scots pine may be seen thriving on deep peat-moss, the condition necessary for success being judicious preliminary drainage. In mosses soaking with water, trees languish and die on account of the lack of air at their roots. On the other hand, if the drainage is too deep, the upper layer of the peat becomes so dry, that the trees suffer from want of water. Near Castledawson in Co. Derry, a considerable area of undrained peat-moss is covered by healthy and vigorous pine trees, which are natural seedlings, the product of seeds blown from an adjoining plantation. Here, however, the peat-moss rests on the side of a sloping sandhill and is not waterlogged. Natural pine seedlings are often seen on peat-mosses, struggling for life in the wettest situations; and doubtless, if cattle and rabbits were excluded, these would in time take possession. At Churchill in Co. Armagh, the property of Harry Verner, Esq., considerable plantations of Scots pine, intermixed with a small proportion of larch, were made in 1861 on deep peat-moss, which had been thoroughly

drained. These trees, planted $3\frac{1}{2}$ feet apart, are now forty-four years old and average 44 feet in height by 3 feet in girth. Two-year-old seedlings, one year transplanted, were used and a system of pitting was adopted. The holes were made about a foot deep, and were filled in with a mixture of clay and peat. The clay was brought from a distance, and no doubt its use added considerably to the cost of planting. Possibly peat-ashes, obtained by burning peat, heather, etc. on the spot would have answered equally well, and been less costly. The Scots pine succeeds better than any other tree on pure peat-moss, though alder and larch may be added in a certain proportion. At Clonbrock, in Co. Mayo, on an overcut bog, where the peat left uncut was 3 to 4 feet deep, Scots pine eighty years old averages only 47 feet in height by 4 feet in girth. Probably the lesser growth in this case is due to insufficient drainage. As there are immense areas of peat-mosses in Ireland, now yielding no return whatever, the possibility of afforesting them with Scots pine, or with a mixture of Scots pine and larch, is an important question; and the success of the Churchill plantations is encouraging.¹

Throughout Ireland there are extensive mountain tracts of barren land, covered with stones and rocks, which are of merely nominal value for grazing and are impossible to reclaim for agricultural purposes except at a ruinous expenditure. The Scots pine renders excellent service in turning these wastes to account. The late Lord Powerscourt made extensive plantations on the hill-sides of Co. Wicklow at 500 to 900 feet above sea-level, which paid handsomely. These plantations consisted in the main of a mixture as follows:—200 larch, 1500 Scots fir, and 500 spruce per acre, the plants being notched in, as, in Lord Powerscourt's opinion, they came on eventually as well as those which had been pitted at a much greater expense. The Scots fir have been gradually thinned out, the larch being left as the final crop. Lord Powerscourt was favoured by ready access to the sea, and by proximity to Wales, where his thinnings were readily sold as pit-props. He estimated that the initial cost of planting and fencing is £4 to £5 per acre, and that, during the first twenty to twenty-five years, the thinnings pay for the expense of cutting and the interest on the first cost. After that the thinnings should bring in annually eight shillings an acre; the final crop of larch at fifty years being probably worth about £50 an acre.

(A. H.)

In the United States the Scots pine has been planted with more or less success, but does not seem likely to be as valuable for timber as the native pines. The largest I saw was in the Wellesley Arboretum, near Boston, which was 49 feet high in 1904. In Professor Sargent's grounds it seems to be short-lived, only living for thirty to forty years. Ten miles from Boston, however, near Ponkapoag, it succeeds better on dry sandy soil, and I found some self-sown seedlings. At the Central Experimental Farm, near Ottawa, trees planted in 1888 were about 30 feet high in 1906, but Mr. W. T. Macoun² reports that it suffers much from shade, and does not grow so fast as Norway spruce or European larch; though he recommends it for nurses to other trees, and for producing fuel.

¹ The plantations on bog land at Knockboy, Co. Galway, were badly made, and turned out a disastrous failure. Cf. Dr. Schlich's report in *Kew Bull.* 1903, p. 22; and in *Trans. Roy. Scot. Arbor. Soc.* xvi. pt. ii. 249 (1901).

² *Canadian Forestry Journal*, iii. 77 (1907).

Cases of inosculation are rare among pines, but a remarkable instance of this was pointed out to me by Mr. Savile Foljambe in the Catwhins, near the lodge leading out of Thoresby park into the Retford road. It seems probable that when the trees were young they had come in contact, and eventually fused; the iron bands were put on afterwards, but the trees are now dead.

Another case, somewhat similar, occurs in a pine tree growing on the estate of Chenevières, near Montbour (Loiret), France, which a photograph kindly sent me by M. Maurice de Vilmorin illustrates. Here it seems that one tree had forked at or close to the ground, and become connected by a thick branch at a much later period. A third instance of natural inarching in the Scots pine is described and figured by Count von Schwerin¹ from a tree near Teltow in Germany. In this instance a branch of one tree grew into the bark of another and broke off, eventually forming just such a living connection between the two trees as is shown in Vol. I. Plate 4, but much thicker in proportion. The sap of the left hand tree appears to pass through this branch to the other, as the stem is thicker above the junction, and the branch has assumed the yellow bark of the upper part of the trunk.

The large, usually globular masses of dense shoots which sometimes appear on this species, and more rarely on larch and spruce, are not caused by a parasitic fungus. Prof. von Tubeuf² says that their origin is unknown, no insect or fungus having yet been discovered which might have caused the growth, which is composed of a mass of small buds, producing densely crowded tufts of short leaves. A specimen which was found at Schwarzenraben in Germany measured 53 centimetres in height and about the same in diameter, the weight of this mass being over eleven pounds.³ Such growths are not uncommon⁴ in England, and I have a photograph of one on a tree at Colesborne, which was about a foot in diameter.

TIMBER

On the timber of the Scots pine so much has been written that I will refer specialists to Laslett,⁵ who gives a long account, mostly from a shipbuilder's point of view, of the various foreign varieties known to him as Dantzic, Memel, Riga, and Swedish fir; but makes no reference to the quality of native-grown timber, which, though men-of-war were built from it by Osbourne in the last century, seems to have been unused by the Admiralty since then, as it is now by the Post Office authorities in England, and by architects and builders generally. The reason of this is, no doubt, that the rapid growth of the tree in this country, in our mild climate, causes the wood to be much softer,

¹ *Mitt. D. D. Gesell.* 194 (1906).

² *Ibid.* 222, fig. 13 (1905).

³ Count von Schwerin, *Mitt. D. D. Gesell.* 222 (1905), says that in Bavarian Allgau, between Oberstaufen and Weiler, he has seen a forest of sixty-year-old spruce in which almost every tree was more or less affected by these growths, and supposes that the cause, whatever it is, must be contagious. He has seen similar growths on *Picea orientalis* and suggests that some of the horticultural monstrosities such as *Picea excelsa echiniformis* and *C. Lawsoniana forsteckensis* have originated from a similar cause.

⁴ A specimen from a tree growing at Hunstanton Hall, Norfolk, was shown at a meeting of the Scientific Committee of the Royal Horticultural Society in April 1899. Cf. *Gard. Chron.* xxv. 270 (1899).

⁵ *Timber and Timber Trees*, ed. 2 (London, 1894).

coarser, and less durable than that from North Germany, Russia, and Scandinavia; whilst over-thinning causes it to be much more knotty. It is hardly possible to believe that the same tree can produce timber so different as examples which I showed at a lecture on English timber at the Surveyors' Institute, on 22nd February 1904, taken from an immense tree grown at Powerscourt, of about 12 feet in girth; and the beautiful fine-grained wood which I brought from Northern Norway, and which when well planed shines with a silky gloss. Every intermediate form may be found in this country; but, as a rule, it is little valued in England except for mining timber, for cheap fencing, packing cases, and other uses. In Scotland, where it is as a rule slower grown, and better in quality, its value is kept down by foreign importations, though it is very largely used in making staves for herring barrels and many other purposes.

But when old enough to have produced a large proportion of red heartwood, and free from knots, I have sold Scots pine for as much as 8d. per foot, and have found it very useful and durable timber for roofing and many other estate purposes; and I am informed by Mr. Mitchell, forester to the Duke of Bedford at Woburn, that in that neighbourhood, where it is of good quality, it is largely used for rending lath, and that the buyers will give a high price for it when suitable for that purpose.

Loudon gives many interesting particulars of the uses and quality of pine timber at home and abroad, and quotes¹ Mr. T. Davis who, in 1798, was the Marquess of Bath's forester at Longleat, to the effect that a cart-house, built from it on that estate, remained perfectly sound after eighty years' use. And Pontey, in his *Forest Primer*, published in 1805, also defends the Scots pine against the "almost universally prevalent prejudice against it, which is no doubt based partly on ignorance and partly on the fact that it is often used when too young and unseasoned."

But, whatever may be said against the wood when grown in the south of England, there can be no question that the Highland native pine timber, when clean, is a valuable, and in some cases also a very ornamental timber. I have seen at Castle Grant a very beautiful sideboard made on the estate, which showed the curiously twisted red and yellow grain which Mr. Grant Thomson tells me is only produced by the self-sown native trees; and I am indebted to the kindness of Lady Seafield for some of the same wood, which was cut in the Forest of Abernethy. The entrance hall and a room at Balmoral Castle have been recently panelled with the same sort of wood, which has a very ornamental effect, and Mr. Michie tells me that it has also been largely used for internal decoration in Mar Lodge. I saw in the house of the postmaster of Bodö, in Norway, a very handsome table made from a variety of the wood, which is there called "Rie," and which seems to be caused by a disease in the tree producing excrescences and distortion in a part of its trunk, and I possess a piece of this wood which is so unlike pine wood that no one could recognise it as such. But these trees seem to be as rare in Norway as in Scotland, and command a high price locally.

The oldest example of this wood in the form of panelling that I have seen or heard of is in the room known as Queen Mary's room in Castle Menzies, which was

596 The Trees of Great Britain and Ireland

occupied by Mary Queen of Scots in 1577. This is now perfectly sound, and much darkened in colour by age. The width and somewhat knotty character of the boards tend to confirm what the late Sir R. Menzies told me, that it was made from locally grown Scots pine, which may have come from the Black Wood of Rannoch, or from other native forests that have now disappeared.

It is remarkable that, notwithstanding all that has been written since the Earl of Haddington first raised the question as to the existence of different varieties of this tree in his *Treatise on Forest Trees*, in 1760, there seems to be as yet no exact knowledge as to whether the different kinds of timber produced by different trees are, as I believe, individual variations, largely due to soil, or whether, by sowing seeds from trees possessing superior qualities, they may be reproduced in other soils and situations. The best and most exact records of such experiments that I know of are given by M. M. de Vilmorin in his account of the varieties of *Pinus sylvestris* collected by his grandfather at Les Barres in France, and published in the *Catalogue des vegetaux Ligneux sur le Domaine des Barres* (Paris, 1878), which show how much one family have done for the better knowledge of the economic value of trees, and for the benefit of their country.

Briefly, this trial, extending over a period of over sixty years, shows that, in the soil and climate of Central France, the Riga variety of *P. sylvestris* has, on its first introduction as well as in the second generation, preserved its superiority over other varieties of the same tree—from the various parts of France, from Haguenau on the Rhine, from Switzerland, and from Scotland—by its good growth, freedom from branches, quality of timber, and facility of transplantation. Though this superiority might not be as marked in England, it points to the necessity of careful trials of seed from Riga which, so far as I know, have not yet been made in this country.

In *Scott. Arb. Trans.* ix. 176 (1881), there is a very valuable paper by J. M'Laren and W. M'Corquodale, on "The Supposed Deterioration of the Scots Pine"; it having been stated by George Don and other writers that there were two or more varieties, one of which was very inferior to the other. They conclude, after reviewing the experience of many competent foresters, that the quality of the timber depends on the subsoil and the climate more than on the variety, and that the rich red resinous timber, for which the Highland pine is distinguished, is not to be expected in the south. They say that, since the days of the fine old Memel pine, there is no pine timber imported to our country equal to the old Highland pine, and that what has caused it to fall into disrepute is that it is grown too fast and cut too young, coupled with the fact that it is more difficult to manufacture and dress than foreign timber.

(H. J. E.)

CARYA

Carya,¹ Nuttall, *Gen. Am.* ii. 220 (1818); Bentham et Hooker, *Gen. Pl.* iii. 398 (1880).

Scoria, Rafinesque, *Med. Repos. New York*, v. 352 (1808).

Hicorius, Rafinesque, *Fl. Ludov.* 109 (1817).

Hicoria, Rafinesque, *Alsog. Am.* 65 (1838).

DECIDUOUS trees belonging to the order Juglandaceæ. Branchlets with solid continuous pith, not chambered as in Juglans and Pterocarya. Leaves alternate, compound, unequally pinnate, without stipules; leaflets sessile or sub-sessile, serrate, penninerved.

Flowers monœcious, without petals. Staminate catkins slender, drooping, in threes on a common peduncle or clustered and sessile or subsessile, arising either from buds in the axils of the leaf-scars of the previous year's branchlets or from the base of the current year's shoot, and appearing after the unfolding of the leaves; flowers numerous in the catkin; calyx two- to three-lobed, subtended by an ovate bract; stamens three to ten, filaments short. Pistillate flowers, two to ten, in a cluster or spike, terminal on a leafy branchlet of the year; ovary superior, one-celled, surrounded by a four-lobed cup-shaped involucre, formed by the union of a bract and two bracteoles; calyx one-lobed; stigmas two, sessile; ovule solitary.

Fruit, a nut, enclosed in a four-valved, thickened, hard and woody involucre, four-celled at the base, two-celled at the apex, tipped by the remains of the style; seed solitary, without albumen, filling the cavity of the nut.

The cotyledons remain underground in germination, the plumule being carried by the lengthening of their petioles out of the nut, which splits into two valves. The germination resembles that of the oak, the young stem bearing at first three to eight alternate minute lanceolate scales, above which the leaves are developed. The first leaf is simple, tri-lobed, or trifoliolate; those succeeding, about five or six in the first year, being trifoliolate; all are serrate and stalked. The difference observed in the length of the stems, in two or three seedlings, seen at Colesborne, may not be constant for each species.²

Twelve species of hickory are distinguished by Sargent,³ all natives of North

¹ The generic name, *Carya*, though not the first one published, has always been used in England, and is now sanctioned by the regulations drawn up by the International Congress of Botany at Vienna in 1905. Cf. *Verhand. Internat. Bot. Kongress. Wien*, 1905, p. 239. With regard to the specific names, I have not altered those of Nuttall, which have been long in use.

² Rowlee and Hastings, *Bot. Gaz.* xxvi. 349, pl. xxix. figs. 9, 10, 12 (1898), give figures of the seedlings of *C. alba* and *C. porcina*.

³ In *Trees N. Amer.* 132 (1905). Ashe, in *Flora South-Eastern United States*, 333 (1903), raised two varieties to the rank of species, making fourteen species in all.

America, four species extending as far north as Canada, and one species confined to the high lands of Mexico. Six species¹ (Plate 203) are in cultivation in the British Isles, and will be dealt with in the following account.

The genus is divided into two sections:—

I. *Apocarya*, De Candolle, *Prod.* xvi. 2, p. 144.

Buds, with four to six valvate scales, which are often obscurely pinnatifid at the apex; axillary buds, often two to three superposed, the uppermost one stalked. Husk of the fruit thin, and prominently ridged at the sutures.

1. *Carya olivæformis*, Nuttall.

Buds greyish, densely pubescent, without glands. Leaflets, eleven to thirteen, rarely nine; margin densely ciliate.

2. *Carya amara*, Nuttall.

Buds yellowish, slightly pubescent, glandular. Leaflets, seven to nine; margin irregularly ciliate.

II. *Eucarya*, De Candolle, *Prod.* xvi. 2, p. 142.

Buds with ten to twelve imbricated scales, the outer falling early, the inner accrescent and becoming much enlarged and reflexed at maturity. Husk of the fruit thick, not ridged at the sutures.

* *Leaflets five, pubescent.*

3. *Carya alba*, Nuttall.

Young branchlets with brown stellate hairs; base of the shoot marked with a dense pubescent ring. Leaflets, stellate-pubescent beneath, ciliate in margin.

** *Leaflets five or seven, glabrous.*

4. *Carya porcina*, Nuttall.

Young branchlets glabrous or with only an occasional hair; base of shoot without pubescent ring. Leaflets glabrous beneath, except for axil-tufts, non-ciliate in margin.

*** *Leaflets, seven or nine, pubescent.*

5. *Carya sulcata*, Nuttall.

Branchlets reddish-brown, glabrous towards the tip. Leaves not fragrant; rachis nearly glabrous; nerves in upper lateral pair of leaflets more than twenty pairs.

6. *Carya tomentosa*, Nuttall.

Branchlets purplish-grey, pubescent and glandular. Leaves fragrant; rachis pubescent and glandular; nerves in upper lateral pair of leaflets less than twenty pairs. (A. H.)

¹ *Carya aquatica*, Nuttall, the water hickory, a native of river swamps in the southern parts of the United States, is not likely to succeed in any part of the British Isles. Loudon, *op. cit.* 1444, mentions a tree of this species 40 feet high growing at Milford near Godalming; but his identification was probably incorrect.

CARYA OLIVÆFORMIS, PECAN NUT

- Carya olivæformis*, Nuttall, *Gen. Am.* ii. 221 (1818); Loudon, *Arb. et Frut. Brit.* iii. 1441 (1838).
Carya angustifolia, Sweet, *Hort. Brit.* 97 (1827).
Carya illinoensis, Koch, *Dendrol.* i. 593 (1869).
Carya Pecan, Schneider, ex Sargent in *Bot. Gazette*, xlv. 226 (1907).
Juglans Pecan, Marshall, *Arbust. Am.* 69 (1785).
Juglans illinoensis, Wangenheim, *Nordam. Holz.* 54 (1787).
Juglans angustifolia, Aiton, *Hort. Kew.* iii. 361 (1789).
Juglans cylindrica, Poirer, in Lamarck, *Dict.* iv. 505 (1797).
Juglans olivæformis, Michaux, *Fl. Bor. Am.* ii. 192 (1803).
Hicoria Pecan, Britton, *Bull. Torrey Bot. Club.* xv. 282 (1888); Sargent, *Silva N. Amer.* vii. 137, tt. 338, 339 (1895), and *Trees N. Amer.* 133 (1905).

A tree, attaining in America 170 feet in height and 18 feet in girth. Bark, brownish, deeply and irregularly divided into narrow forked ridges. Buds, similar to those of *C. amara*, but greyish-white in colour, densely pubescent and without glands; lateral buds ovoid, pointed. Young branchlets densely pubescent, especially towards the tip, where no glands are present, but with minute glands at the base of the shoot. Leaves (Plate 203, Fig. 6), 12 to 20 inches long. Leaflets, eleven to thirteen or more, rarely nine, lanceolate, falcate, sessile, acuminate, very unequally divided by the midrib; upper surface with stellate pubescence on the midrib and nerves; lower surface covered throughout with fine scattered pubescence and numerous glands; margin plainly ciliate; rachis densely pubescent.

Staminate flowers in sessile or subsessile clustered catkins, usually on the previous year's branchlets. Fruit in clusters of three to eleven, pointed, four-winged and -angled, 1 to 2½ inches long, ½ to 1 inch broad; husk thin, brittle, dark-brown, coated with yellow pubescence, splitting when ripe nearly to the base; nut, thin-shelled, reddish-brown with irregular black markings; seed sweet, reddish-brown.

(A. H.)

The Pecan is a native of the Middle States, occurring from Indiana, Southern Illinois and Iowa, southward through Western Kentucky and Tennessee to Alabama and Mississippi, and extending westward through Missouri, South-Eastern Kansas, Arkansas, Indian Territory and Louisiana to the valley of the Concho River in Texas. It is also met with in the mountains of Mexico.

It chiefly grows on rich alluvial soil, along the banks of streams, and attains a greater size than any other hickory. Ridgway says it is one of the very largest trees of the forest, being only exceeded in height by the tulip tree and the scarlet oak. He records one tree, measured by Dr. Schneck, which was 175 feet high by 16 feet in girth, and another 30 feet in girth at the ground. It is largely cultivated in the Southern States for its fruit, which has been improved by selection and grafting, and is considered the best of the nuts of North America.

It requires a much longer and hotter summer than any part of Great Britain affords; and even in the south of Europe we have not heard of its being successfully

grown. Pardé¹ has not heard of its having ever produced fruit in France, where it is hardy as far north as Grignon,² but grows very slowly.

It was introduced, according to Loudon, in 1766 into England, and he mentions, with some doubt as to the species, trees growing in the Horticultural Society's garden and other places near London; but it is probable that this tree has never attained a considerable size in England. At Tortworth, a tree with the bark beginning to scale was, in 1905, 24 feet high and 1½ foot in girth. Dr. Warre, the late headmaster at Eton, raised, from seed sent to him from New York, a tree, which is growing in the garden of Mr. E. C. Austen Leigh, at Eton, who informs us that it is about 11 feet high. Miss Woolward raised at Belton in Lincolnshire a plant, which is now about 4 feet high; but it suffers severely from frost, the young growths being killed back every year. None of the seedlings which I have raised at Colesborne have thriven, as the summer here is evidently much too short and cold. (H. J. E.)

CARYA AMARA, BITTERNUT

- Carya amara*, Nuttall, *Gen. Am.* ii. 222 (1818); Loudon, *Arb. et Frut. Brit.* iii. 1443 (1838).
Carya cordifolia, Schneider, ex Sargent in *Bot. Gazette*, xlv. 226 (1907).
Juglans alba minima, Marshall, *Arbust. Am.* 68 (1785).
Juglans cordiformis, Wangenheim, *Nordam. Holz.* 25 (1787).
Juglans angustifolia, Poiret, in Lamarck, *Dict.* iv. 504 (1797).
Juglans sulcata, Willdenow, *Berl. Baumz.* 154 (1796).
Juglans minima, Borkhausen, *Handb. Forstbot.* i. 760 (1800).
Juglans mucronata, Michaux, *Fl. Bor. Am.* ii. 192 (1803).
Juglans amara, Michaux f., *Hist. Arb. Am.* i. 177 (1810).
Hicoria minima, Britton, *Bull. Torrey Bot. Club*, xv. 284 (1888); Sargent, *Silva N. Amer.* vii. 141, tt. 340, 341 (1895), and *Trees N. Amer.* 135 (1905).

A tree, attaining in America 100 feet in height and 9 feet in girth. Bark grey, smooth, ultimately separating on the surface into small thin scales. Buds bright-yellow, glandular; terminal buds elongated, pointed and oblique at the apex, about ½ inch long, with two pairs of valvate scales, often obscurely pinnatifid at the tip; lateral buds, often two superposed, the uppermost stalked, four-angled, and pointed, the lowermost minute. Young branchlets, with scattered short pubescence, glandular towards the tip. Leaves (Plate 203, Fig. 5) 6 to 10 inches long. Leaflets, five to nine, variable in shape, lanceolate, ovate-lanceolate, or obovate-oblong, long-acuminate; margin with occasional cilia; lower surface with stellate hairs, especially along the midrib; rachis minutely pubescent.

Staminate catkins, pubescent, in threes on a slender peduncle, usually on the previous year's branchlet. Fruit, one, two, or three at the top of the branchlet, about an inch long; husk thin, glandular, four-winged from the apex to about the middle; nut thin-shelled; seed bitter, reddish-brown. (A. H.)

This species has a wide distribution, extending to the northward as far as Southern Maine, Ontario, Central Michigan, and Minnesota. It was the only hickory which I found near Ottawa, where it was common in the Gatineau Valley,

¹ *Arbor. Nat. des Barres*, 253 (1906).

² Seen by Henry in 1906.

but not there a large tree. It extends westward to South-Eastern Nebraska, Eastern Kansas, Indian Territory, and Eastern Texas, and reaches its southern limit in North-Western Florida and Northern Alabama. It is usually found in lower and moister situations than the other species, and is one of the largest and commonest hickories in Southern New England, where it attains 70 to 80 feet in height and 10 to 12 feet in girth. It grows to its largest size on the alluvial lands of the lower Ohio basin; and in Southern Indiana, Ridgway records a tree 113 feet in height and 6 feet 3 inches in girth.

The bitternut is the commonest species of hickory in England, and grows to a considerable size. The finest tree is perhaps the one at Bute House, Petersham, which was, in 1903, 76 feet in height by 7 feet 5 inches in girth (Plate 170).

At Barton, near Bury St. Edmund's, there are three trees, two in the arboretum, one of which I found in 1905 to be 80 feet by 5 feet 4 inches, and the third on the lawn, 74 feet by 7 feet 6 inches, but forked near the ground. These trees ripened fruit¹ in 1864; but of late years do not appear to have borne any.

At Syston Park, Lincolnshire, there are four trees of this species, one of which was flowering freely on 16th May 1905, when it measured 71 feet by 5 feet 3 inches. Two of these are figured on Plate 171 from photographs taken by Miss F. Woolward.

At Arley Castle there are five trees, the tallest of which measures 72 feet by 4 feet, the others being about 60 feet high with girths ranging from 3 feet 7 inches to 4 feet 7 inches. These are supposed to have been planted about 1820.

At Bicton, a tree measured, in August 1906, 65 feet by 4 feet; and another growing at the Wilderness, White Knights, near Reading, is exactly the same size. At Devonhurst, Chiswick, a tree, now cut down, measured, in 1903, 68 feet by 5 feet.

There is a tree, 58 feet by 6 feet 2 inches, in the Botanic Garden, Glasnevin; but we have heard of no others in Ireland, where hickories seem to have been very little planted. (H. J. E.)

CARYA ALBA, SHAGBARK HICKORY

- Carya alba*, Nuttall, *Gen. Am.* ii. 221 (1818); Loudon, *Arb. et Frut. Brit.* iii. 1446 (1838).
Carya ovata, Schneider, ex Sargent in *Bot. Gazette*, xlv. 226 (1907).
Juglans ovata, Miller, *Dict.* ed. 8, No. 6 (1768).
Juglans ovalis, Wangenheim, *Nordam. Holz.* 24 (1787).
Juglans compressa, Gaertner, *Fruct.* ii. 51 (1791).
Juglans alba, Michaux, *Fl. Bor. Am.* ii. 193 (1803).
Juglans obcordata, Poiret, in Lamarck, *Dict.* iv. 504 (1797).
Juglans squamosa, Michaux f., *Hist. Arb. Amer.* i. 190 (1810).
Hicoria ovata, Britton, *Bull. Torrey Bot. Club*, xv. 283 (1888); Sargent, *Silva N. Amer.* vii. 153, tt. 346, 347 (1895), and *Trees N. Amer.* 139 (1905).

A tree, attaining in America usually 70 to 90 feet, rarely 150 feet in height and 15 feet in girth. Bark grey, ultimately separating into long strips, attached by the

¹ Bunbury, *Arboretum Notes*, 100 (1889).

middle and free at one or both ends, giving the trunk a characteristic appearance. Terminal buds ovoid, obtuse, $\frac{1}{2}$ to $\frac{3}{4}$ inch long, with ten to twelve imbricated scales; outer scales persistent during winter, falling a little before the unfolding of the leaves, triangular, keeled, apiculate or contracted into long points, dark-brown, pubescent; inner scales downy, enlarging to 2 or 3 inches long, as the bud opens. Lateral buds about $\frac{1}{3}$ inch long, with four to five scales visible externally. Branchlets purplish-grey, covered with brown stellate hairs, scattered below, denser nearer the tip, and with a few yellow glands; base of the shoot girt with a dense ring of pubescence. Leaves (Plate 203, Fig. 1) 8 to 14 inches long. Leaflets, five, upper three obovate, lower pair ovate, all shortly acuminate; margin ciliate with irregular tufted hairs, densest near the points of the serrations; upper surface glabrous, except for stellate hairs on the midrib and nerves; lower surface with a fine stellate pubescence, densest on the midrib and nerves; rachis stellate-pubescent.

Staminate catkins, glandular-hirsute, pedunculate in threes at the base of the year's shoot. Fruit solitary or in pairs, sub-globose, 1 to $2\frac{1}{2}$ inches long, splitting freely to the base; husk dark reddish-brown, glabrous, $\frac{1}{8}$ to $\frac{1}{2}$ inch thick; nut four-angled and -ridged, white; seed large, lustrous, light-brown, sweet with an aromatic flavour.

The above description is drawn from trees cultivated in England, which resemble in all essential characters, except the imperfect development of the fruit, specimens obtained by Elwes at the Arnold Arboretum. The size and shape of the leaflets, which are always five in number, and the amount of pubescence on the branchlets and on the rachis and surface of the leaves are very variable. Two or three trees¹ of this species at Kew, which are about 25 feet high, have very large leaves which turn a brilliant yellow in autumn. Another tree at Kew, which was labelled *Carya alba*, differs from all other specimens which I have seen, as follows:—Branchlets and leaf-rachis almost glabrous, only showing when young a few stellate hairs. Leaflets, five, lanceolate, narrow, long-acuminate, nearly glabrous, with only a few stellate hairs, confined on the upper surface to the midrib, and scattered over the lower surface; margin non-ciliate. Buds, as in the typical form, but pointed and smaller. This tree, which is about 30 feet high, has very smooth bark, and is growing very vigorously. It is probably a glabrous form of *Carya alba*, and may possibly be *Hicoria borealis*, Ashe,² which grows in Michigan and Southern Ontario.

(A. H.)

The Shagbark, according to Sargent, is widely distributed from the St. Lawrence valley near Montreal, along the northern shores of Lakes Erie and Ontario, west to South-Eastern Nebraska, and south throughout the Middle States and along the Appalachian mountains to Western Florida, Northern Alabama, Eastern Texas, and Central Kansas.

It attains its largest size in the Southern Alleghanies and in the lower Ohio basin, the largest trees recorded, one of which is figured in *Garden and Forest*, ii.

¹ These have been labelled *C. tomentosa*, from which they differ in having five-foliolate non-fragrant leaves; and are the trees referred to in *Gard. Chron.* xxviii. 295 (1900).

² Ashe, *Notes on Hickories*, 1896; Britton and Brown, *Illust. Flora N. United States*, iii. 512, fig. 1156 b (1898). This form is not recognised by Sargent as a distinct species.

463, being in Southern Indiana, where Ridgway¹ says that trees of 130 feet high by 3 to 4 feet in diameter were not rare, and that some were certainly 150 feet, many trunks which seemed less than half the total height being 70 or 80 feet to the first limb. One of these in Wabash Co. measured 78 feet to the first limb, and was $14\frac{2}{3}$ feet in girth.

Such giants, however, hardly exist now; and during my travels in America I never saw a hickory more than about 100 feet high; whilst those in New England and Canada are usually from 60 to 80 feet in height, and seldom exceed 6 feet in girth. The bark, which separates externally into long loose flakes, serves to distinguish this species readily from the others. The nuts, which vary much in size and shape and thickness, are superior in quality to any other native nut (except that of the Pecan), and are largely eaten. Some of the better varieties, which have thin shells and larger kernels, have been selected and propagated, so that the improvement of this fruit in cultivation is likely to be as great as that of the walnut.

This species was introduced in 1629, according to Loudon, who mentions large trees growing in 1838 at Syon, Fulham Palace, and other places near London. None of these are now living, and apparently the tree does not attain a great age in England. It succeeds about as well as the Bitternut.

The largest tree that I have seen in England is hidden in a thick shrubbery at Botley Hill, Hants, the residence of Lady Jenkyns, and has an historic interest from the fact that it is almost certainly one of the trees planted by Cobbett, who lived there for some years about 1820. The old brew-house and oven, which, in his opinion, were two of the most necessary parts of an Englishman's house, still remain, as well as some rather stunted black walnuts. This hickory is about 75 feet high by 5 feet 4 inches in girth, with a bole of 30 feet.

At the Wilderness, White Knights, near Reading, a tree measures 55 feet by 5 feet 8 inches. At Castle Howard, Yorkshire, there is a healthy symmetrical tree, growing on the site of an old nursery near the timber yard, which may have been sown *in situ*. I found it in 1905 to be 50 feet high by 3 feet 3 inches in girth.

In the Pinetum, Brocklesby Park, Lincolnshire, there is a fine tree, which Mr. W. B. Havelock informs us is 79 feet high by 4 feet 10 inches in girth, with a straight stem running nearly to the top. It is growing in strong loam, sheltered by surrounding belts of trees, and is supposed to be about sixty years old. The bark is shaggy, and hangs in strips from the trunk (Plate 173).

A fine tree of this species is growing in Syston Park, near Grantham, the seat of Sir John Thorold, who told me that his father planted it and the four bitternut trees mentioned above about fifty years ago. It measured in 1905 62 feet by 4 feet 4 inches, and has the characteristic scaly bark.

At Boynton Hall, Bridlington, Yorkshire, there are three trees of this species, which Sir Charles Strickland informs us are respectively 50 feet by 7 feet, 40 feet by 4 feet, and 25 feet by 6 feet, the last being very bushy in habit, and growing in a very exposed position. These trees were raised from seed brought from America by

¹ *Proc. U.S. Nat. Mus.* 1882, p. 77.

Sir William Strickland, grandfather of the present owner; and several other hickories planted at the same time have disappeared, one being blown down.

At Golden Grove, Carmarthenshire, a seat of Earl Cawdor, a tree, which is supposed to have been planted in 1865, is 42 feet by 3 feet 1 inch. At Fonthill Abbey, Wilts, a tree, with very scaly bark, is 62 feet by 4 feet 1 inch. At Althorp there is a tree 75 feet by 3 feet 6 inches, growing in a dense thicket of laurels near the house.

A hickory which was perhaps of this species grew close to the house at Moncreiffe near Perth, and is mentioned by Hunter as being the finest in Scotland. It had a bole 20 feet long by 5 feet 9 inches, and was cut down about six years ago. The timber was used for making gates.

At Kinblethmont, Arbroath, H. Lindsay Carnegie, Esq., reports a tree 46 feet high by 2 feet 11 inches in girth. It was planted by his father about 1825.

In Ireland, the only specimens which Henry has seen are two small trees about a foot in diameter, growing in the Botanic Gardens at Glasnevin, and two at Kilmacurragh, in Wicklow, about 35 feet high. (H. J. E.)

CARYA PORCINA, PIGNUT

Carya porcina, Nuttall, *Gen. Am.* ii. 222 (1818); Loudon, *Arb. et Frut. Brit.* iii. 1449 (1838).

Carya obcordata, Sweet, *Hort. Brit.* 97 (1827).

Carya glabra,¹ Spach, *Hist. Vég.* ii. 179 (1834).

Juglans glabra, Miller, *Dict.* ed. 8, No. 5 (1768).

Juglans squamosa, Poir., in Lamarck, *Dict.* iv. 504 (1797).

Juglans obcordata, Muehlenberg u. Willdenow, *Neue Schrift. Ges. Nat. Fr. Berlin*, iii. 392 (1801).

Juglans porcina, Michaux f., *Hist. Arb. Amer.* i. 206 (1810).

Hicoria glabra, Britton, *Bull. Torrey Bot. Club*, xv. 284 (1888); Sargent, *Silva N. Amer.* vii. 165,

tt. 352-355 (1895), and *Trees N. Amer.* 144 (1905).

Hicorius glaber, Sargent, *Garden and Forest*, ii. 460 (1889).

A tree attaining in America 90 feet in height and 12 feet in girth. Bark greyish, ultimately fissuring into narrow longitudinal ridges, occasionally on old trees breaking on the surface into loose thick scales. Terminal buds, $\frac{1}{4}$ to $\frac{1}{3}$ inch long, globose or ellipsoidal, with ten to twelve imbricated scales; outer scales usually deciduous in winter, keeled, acute, or pointed, glabrous, ciliate, often glandular; inner scales pubescent, enlarging to 2 inches long as the bud unfolds. Lateral buds small, ovoid, often glandular, with two scales visible externally. Branchlets glabrous, or rarely with a minute pubescence speedily disappearing. Leaves (Plate 203, Fig. 2) 8 to 12 inches long. Leaflets, five to seven, upper three obovate, lower one or two pairs oblong lanceolate, all acuminate; margin without cilia; upper surface glabrous, with numerous minute glands; lower surface glabrous, except for slight tufts of pubescence in the axils of the midrib and lateral nerves, covered with numerous glands; rachis glabrous.

¹ This is given as *Carya glabra*, Schneider, by Sargent in *Bot. Gazette*, xlv. 226 (1907).

Staminate catkins, scurfy-pubescent, pedunculate in threes at the base of the current year's shoot. Fruit, single or in pairs, very variable in size and shape; husk thin, reddish brown, glandular, opening only at the apex or splitting to the middle or to near the base; nut obscurely four-angled; seed small, light brown, poor in flavour.

Carya microcarpa, Nuttall¹ (*Hicoria microcarpa*, Britton²), appears to be only distinguished by the nuts, which are very small, compressed and globular. It is impossible to say whether it is in cultivation, as all the hickories in England produce smaller nuts than they do in America. This form is called by Sargent,³ var. *odorata*, a misleading name, as the tree has apparently no marked odour either in the foliage or in the fruit. (A. H.)

The pignut, which grows usually on dry ridges and hillsides, has a most extensive distribution, ranging from Southern Ontario and Southern Maine in the north to Florida and Mississippi in the south, and extending westward to Nebraska, Kansas, and Texas.

This species of hickory⁴ seems to succeed fairly well in England, though we know of very few trees. The best is at Kew, where there is a fine tree near the Temperate House (Plate 172), which is, however, becoming stag-headed. It measured, in 1907, 77 feet by 6 feet. It produces fruit abundantly, but the seed, so far as we have observed, is infertile.

Another tree is growing at Leny, near Callander, Perthshire. Though in a somewhat exposed situation and at an elevation of several hundred feet, it had a stem 3 feet 4 inches in girth and might have been 50 feet high before the leading shoot was broken. (H. J. E.)

CARYA SULCATA, BIG SHELLBARK, KINGNUT

Carya sulcata, Nuttall, *Gen. Am.* ii. 221 (1818); Loudon, *Arb. et Frut. Brit.* iii. 1448 (1838).

Carya pubescens, Sweet, *Hort. Brit.* 97 (1827).

Carya cordiformis, Koch, *Dendr.* i. 597 (1869).

Carya laciniosa, Schneider, ex Sargent in *Bot. Gazette*, xlv. 226 (1907).

Juglans laciniosa, Michaux f., *Hist. Arb. Amer.* i. 199 (1810).

Juglans sulcata, Pursh, *Fl. Am. Sept.* ii. 637 (1814).

Hicoria laciniosa, Sargent, *Silva N. Amer.* vii. 157, tt. 348, 349 (1895), and *Trees N. Amer.* 141 (1905).

A tree attaining in America 120 feet in height and 9 feet in girth. Bark grey, ultimately separating in plates, which sometimes remain for many years hanging on the trunk. Terminal buds, ovoid, obtuse, $\frac{3}{4}$ to 1 inch long, composed of ten to twelve imbricated scales; outer scales not deciduous in winter, dark brown, ovate, keeled, pointed, tomentose, with scattered glands; inner scales silky pubescent,

¹ *Gen. Am.* ii. 221 (1818).

² *Bull. Torrey Bot. Club*, xv. 283 (1888).

³ *Silva*, loc. cit. This varietal name is adopted by Sargent, as the tree appears to have been first described by Marshall, in *Arb. Am.* 68 (1785) as *Juglans alba odorata*.

⁴ The date of introduction is uncertain. Loudon states that in 1838 there were plants in the Hackney Arboretum.

becoming 2 to 3 inches long at the opening of the bud. Axillary buds, $\frac{1}{2}$ inch long, with four to five scales visible externally. Branchlets light reddish brown, glabrous towards the tip, covered below with a short dense pubescence. Leaves (Plate 203, Fig. 4) not fragrant, 15 to 22 inches long. Leaflets seven to nine, upper three or five obovate-oblong, lower one or two pairs lanceolate; margin ciliate, the cilia more numerous towards the base; upper surface glabrous, shining; lower surface with scattered short stellate tomentum; nerves in upper pair of leaflets more than twenty pairs; rachis with slight pubescence near the insertion of the leaflets, elsewhere glabrous.

Staminate catkins, glabrous, pedunculate in threes at the base of the current year's shoot. Fruit, solitary or in pairs, 2 inches long; husk downy or glabrous, hard and woody, $\frac{1}{4}$ to $\frac{1}{3}$ inch thick; nut compressed, four- to six-ridged, with a hard bony shell; seed light brown, sweet. (A. H.)

This species usually grows on deep rich alluvial soil, which is inundated for several weeks in the year, and is one of the commonest trees in the great river swamps of Central Missouri and of the Ohio basin. It is rare and local east of the Alleghany Mountains, being occasionally met with in New York, Pennsylvania, and North Carolina; and extends through the central states from South-Eastern Nebraska, Iowa, Illinois, and Indiana, southward to Kansas, Indian Territory, Arkansas, and Tennessee.

It is exceedingly rare in cultivation¹ in England, the largest tree we are acquainted with being one in Tortworth Churchyard, which bore a few nuts in 1905, when it was about 30 feet high by 1 foot 8 inches in girth. There are small plants growing at Hildenley Hall, Yorkshire, and at Grayswood, Haslemere.

(H. J. E.)

CARYA TOMENTOSA, MOCKERNUT

Carya tomentosa, Nuttall, *Gen. Am.* ii. 221 (1818); Loudon, *Arb. et Frut. Brit.* iii. 1444 (1838).

Carya alba, Koch, *Dendr.* i. 596 (1869); Sargent, *Bot. Gazette*, xlv. 226 (1907).

Juglans alba, Linnæus, *Sp. Pl.* 997 (in part) (1753).

Juglans rubra, Gaertner, *Fruct.* ii. 51 (1791).

Juglans tomentosa, Poiret, in Lamarck, *Dict.* iv. 504 (1797).

Hicoria alba, Britton, *Bull. Torrey Bot. Club*, xv. 283 (1888); Sargent, *Silva N. Amer.* vii. tt. 350, 351 (1895), and *Trees N. Amer.* 143 (1905).

Hicorius albus, Sargent, *Garden and Forest*, ii. 460 (1889).

A tree attaining in America 100 feet in height and 9 feet in girth, but usually much smaller. Bark grey, slightly ridged by shallow irregular interrupted fissures, and ultimately covered by closely appressed scales. Terminal buds broadly ovoid, $\frac{1}{2}$ to $\frac{3}{4}$ inch long, of 10 to 12 imbricated scales; outer scales, usually deciduous in winter, dark brown, keeled, apiculate, pubescent, glandular; inner scales silky

¹ Loudon states that it was introduced in 1804; but he appears to have been only acquainted in 1838 with small plants growing at the Horticultural Society's Garden, Loddiges' Nursery, and White Knights. None of these now survive.

pubescent, enlarging to 1 to $1\frac{1}{2}$ inch long, as the bud unfolds. Lateral buds much smaller, with 4 scales visible externally. Branchlets densely covered with stellate hairs and shining glands, without any definite ring of pubescence at the base of the shoot. Leaves (Plate 203, Fig. 3) very fragrant, eight to twenty inches long. Leaflets seven or nine, upper three obovate, lower pairs ovate; acuminate; margin regularly ciliate; upper surface glabrous, except for stellate hairs on the midrib, and with minute shining glands; lower surface covered with scattered stellate pubescence and numerous glands; nerves in the upper pair of lateral leaflets usually less than 20 pairs; rachis with stellate pubescence and shining glands.

Staminate catkins, pubescent, pedunculate in threes at the base of the current year's shoot. Fruit, single or in pairs, globose, 1 to 2 inches long; husk hard, thick, glandular, splitting to the middle or nearly to the base; nut four-ridged near the top, thick-shelled; seed small, dark brown, lustrous, sweet. (A. H.)

This species has a distribution similar to that of the shag-bark and bitternut; but is comparatively rare in the north, though it is found in Southern Ontario. It commonly grows on poor and sandy soil, and is the only hickory in the maritime pine-belt of the Southern States. It does not usually exceed 60 feet in height, except in the rich valleys of the Southern Alleghany Mountains and in Missouri and Arkansas. Ridgway records a tree in Southern Indiana 112 feet by $10\frac{1}{2}$ feet, and says it is a common species in upland woods, being known as the black- or white-heart hickory. Its name of mockernut is derived from the thickness of the shell and the smallness of the kernel of the fruit, which makes it hardly worth eating. The fruit and leaves have a strong fragrant resinous smell, not present in the other species.

Loudon states that this species was "introduced in ? 1766"; but he does not seem to have known of any trees in cultivation in 1838. This hickory is extremely rare, the finest specimen that we know of being one at Golden Grove, Carmarthen-shire, which is 50 feet high by 4 feet in girth. It is supposed to have been planted in 1865. Near the Azalea Garden at Kew there is a fine healthy young tree, procured in 1872 from Booth's Nursery, near Hamburg, and now 46 feet high by $2\frac{1}{2}$ feet in girth, remarkable for its fine large foliage, the fragrance of which is especially strong and can be perceived at a distance in the early morning. There are small trees growing at Tortworth and Hildenley. (H. J. E.)

CULTIVATION OF THE HICKORIES

Though so long introduced into cultivation, and at one time much more commonly planted than at present, no species of hickory has as yet established a reputation which justifies the hope that it may become a tree of real economic importance in this country. As ornamental trees the hickories are not equal either in size or in beauty to others which can be more easily grown, and though at least three of the species may be planted with good hopes of success, as an interesting addition to parks and pleasure grounds, yet their cultural peculiarities must be carefully studied before doing so.

Hickories though easily raised from imported nuts, require special treatment on account of their long thick tap-roots, which make them so difficult to transplant; and as they grow slowly for several years and do not ripen their wood when young, in most places, their ultimate success must always be to some extent a matter of chance. Though they are found in America, in places where the soil is not specially deep or good, they require a hotter summer than we get to enable them to ripen fruit, and when a tree will not ripen seed, it can hardly be called acclimatised.

I have made many experiments in raising them from seed, which at present have not given very good results, principally, I think, because of unfavourable local conditions; but believe that if the following points, which are based on those adopted in the Arnold Arboretum,¹ are attended to, the trouble will not be thrown away.

The nuts must be procured from America as soon as ripe; and if there is any influence in heredity, as I believe there is, from the Northern, rather than from the Southern or Western States; but it is only fair to say that the seed which I collected myself in Canada and near Boston, did not produce such strong seedlings the first season as those which I procured from Philadelphia.

The nuts should be sown at once in boxes of about 18 to 24 inches deep in rich sandy loam, about 2 inches apart, and covered with an inch or so of light soil. The boxes may be stored for the winter in a shed, and in spring brought into a frame or greenhouse to induce earlier germination. They should be kept under glass until all risk of spring frost has gone by, and perhaps are better kept in a frame the whole summer lightly shaded, and watered when necessary. The leaves will remain on throughout the autumn, when the box should be exposed to the full sun; and as soon as the shoot, which does not exceed 4 to 8 inches in height the first year, is ripe, may again be put away for the winter in a dry place covered with leaves, and protected from mice.

In the following May the seedlings may either be turned out and planted in a deep rich nursery bed, after cutting off the tap-root at about a foot, or if a warm sheltered spot can be found in a wood, where they can be cultivated and sheltered for some years, they may be planted out permanently without cutting the tap-root. But as the danger from vermin and early or late frosts will continue for some years, it may be better to keep them in the nursery till they are 3 to 5 feet high, provided that when transplanted a deep trench is first made on one side, so as to get up the whole of the root with as little injury as possible. Woods being their natural home they are more likely to grow into good trees when drawn up with others than when exposed in the open; but we cannot point to an instance in Great Britain where they have been so treated, though some of the best trees we know are in dense shrubberies.

As regards soil, it cannot be too deep, rich, or well drained, and a southern or western aspect is to be preferred. Under such conditions they may attain 50 to 60 feet in height in as many years, and in some parts of England even more. A certain amount of lime in the soil does not seem to be harmful.

The hickories are not either in America or in England very long-lived trees,

¹ Cf. *Garden and Forest*, x. 116 (1897).

and none of great age are recorded here. When cut down, or when killed to the ground by frost in their young state, they push shoots freely from the stool, though they do not produce suckers.

Dawson in *Garden and Forest*, ix. 77 (1896), gives an account of his method of grafting the cultivated varieties of hickory, and says that the best stock is the bitternut, which grows twice as fast at Boston as the common shagbark. He performs the operation under glass in the month of January, by side-grafting close to the collar of the stock, and plunging the pots into sphagnum moss up to the top bud of the graft.

TIMBER OF THE HICKORIES

The best account of the wood is given by Michaux and Emerson. The timber of the different species is so similar in appearance, that I doubt if any one could identify without the names, the six species illustrated by Hough; and as this author rarely mentions the age or origin of the trees from which his specimens were taken, or shows much personal knowledge of their peculiarities, his work is not of so much practical value as it might have been.

Michaux specially commends the timber of the shellbark and the pignut. Emerson does not say which is best, but says that the most valuable is that which has been grown most rapidly, and places the pignut and shellbark first for weight.

As fuel hickory is, or rather was in days when it was abundant, preferred to all other woods. But its greatest value is for carriage building, axe and tool handles, and especially for cask hoops, of which in Michaux's time large quantities were exported, as well as used at home. Now, however, it is superseded to a great extent for this purpose by iron.

An article on hickory by Mr. J. F. Brown in *Arboriculture*, vi. No. 4, states that the great demand for hoops in the apple-growing districts of Virginia, is rapidly exhausting the local supply of young trees, which is now being filled from Southern Indiana, and that in consequence the supply of second-growth timber fit for wheels and carriage work is likely to become diminished, and in well-settled regions is already exhausted. He states that when the trees are cut and put on the market, no discrimination is made between the different species, though second-growth hickory is always preferred to the timber of old trees, because it is more elastic, tougher, and stronger. He quotes a report of a meeting of over 200 representatives of the carriage-building industry at Chicago, at which it was stated that the hickory trees have recently been attacked by insects to such an extent, that unless some means can be taken to check their ravages, there will be no more hickory available in ten years; and though ash, maple, and other woods have been tried as a substitute, there is no other wood so suitable for this industry as hickory. It is imported to some extent to Europe, usually in the form of second-growth poles, which are produced from the stool and are used by carriage builders.

Cobbett,¹ with his usual enthusiasm for everything from America, urged that the hickory should be planted for coppice wood on account of the value of the hoops

¹ *Woodlands*, arts. 295, 296 (1825).

610 The Trees of Great Britain and Ireland

which are made from it, and stated that he had a young tree at Kensington which was seven feet high when only five years old from the seed. Mayr also thinks that the hickory might have some economic value in the warmer parts of Germany, as it has stood the hardest frosts at Munich without injury. But so far as we know, none of the trials which have been made in France, where the tree was introduced on a large scale by Michaux 100 years ago, have been successful, and I could not hear that any of the trees which he planted near Paris are now alive. (H. J. E.)

PLATANUS

Platanus, Linnæus, *Gen. Pl.* 358 (1737); Bentham et Hooker, *Gen. Pl.* iii. 396 (1880); Jankó, in Engler, *Bot. Jahrb.* xi. 412 (1890); Usteri, *Mém. Herb. Boissier*, No. 20, p. 53 (1900); Schneider, *Laubholzkunde*, 435 (1905).

TREES belonging to the order Platanaceæ, which consists of the single genus *Platanus*. Bark, at the base of old trunks, dark-coloured and scaly; above on the stem and on the branches smooth, thin, light-grey or greenish, separating in large thin scales, which on falling expose large irregular surfaces of pale-yellow or whitish inner bark. Branchlets rounded, zigzag; the apex withering and falling off in summer (no true terminal bud being formed), leaving an elevated orbicular scar close to the uppermost axillary bud, which prolongs the shoot in the following year. Buds in summer concealed in the funnel-like base of the leaf-stalk, after the fall of the leaf surrounded at the base by an incomplete narrow ring-like scar, sinuous in margin and divided into five parts, each marked by a group of bundle dots; a line extending round the twig from the sides of the leaf-scar indicating where the connate stipule fell off. Buds all axillary, uniform in size, conic, covered by a scale in the form of a cap, which contains immediately within two similar scales, and more internally, several scales open at the apex and each with a young leaf at its base. Flower-buds similar, but larger. The three outer cap-like scales split longitudinally as the bud expands, the second and third continuing to grow after the bud is unfolded, ultimately falling and marking the base of the branchlet with ring-like scars.

Leaves deciduous, alternate, simple, stalked, palmately three- to seven-lobed; lobes entire or dentate with minute or coarsely sinuate teeth; venation pseudo-palmate, two strong lateral nerves diverging from the midrib a little above its base, and each often giving off on the outer side a basal nerve, thus forming with the midrib three to five main nerves, each of which ends in the apex of a lobe. Stipules two, lateral, united below into a tube embracing the branchlet above the insertion of the leaf, dilated above and more or less free, thin and scarious on flowering shoots, broad and leafy on vigorous barren branchlets, caducous or occasionally persistent.

Flowers monœcious, fertilised by the wind, appearing with the leaves, the females developing first, minute, densely aggregated in unisexual heads, which are solitary or several in spikes or racemes; the staminate heads on axillary peduncles, the pistillate heads on long terminal peduncles. Staminate flowers; sepals, three to six, scale-like, half as long as the scarious, cuneiform, acute, three to six petals; stamens, three to six, with very short filaments and clavate two-celled anthers,

crowned by a pilose capitate connective. Pistillate flowers; sepals, four (three to six), rounded, short; petals, four (three to six), long, acute; staminodes pilose at the apex; ovaries as numerous as the sepals, superior, sessile, surrounded at the base by long hairs, gradually narrowing above into long simple styles; ovules one, rarely two. Head of fruit composed of numerous elongated obpyramidate achenes, surmounted by the persistent style, surrounded at the base by long rigid hairs. Seed solitary, oblong, suspended, containing a thin fleshy albumen and an axile erect embryo. The fruiting heads remain hanging on the tree during winter, the component achenes being ultimately dispersed by the wind.

The dispersal of the pollen in the flowers of plane trees is effected by a peculiar mechanism, which bears some resemblance to that of the yew, and is well described by Kerner.¹

The planes are readily distinguished by the simple alternate palmately-lobed leaves, the base of the stalks enclosing and concealing the buds. In winter, the conical buds, all lateral, with stipule-lines around the twig and the peculiar narrow sinuous leaf-scars are diagnostic.

The genus is a very ancient one, fossil species² having been found in North America in Cretaceous, Eocene, and Oligocene strata. In the Miocene and Tertiary epochs numerous species were spread throughout all Europe, Northern Asia, and North America as far north as the Arctic Circle. In the glacial period those became extinct in the northern parts of their area, and the existing species are confined to Canada, the United States, and Mexico in the New World, and to the Eastern Mediterranean region in the Old World. Their entire absence from Eastern Asia is remarkable, as tertiary plants of circumpolar distribution, which have survived to the present time, are usually found existing both in Eastern North America and in China and Japan.

Six species³ are now living, which may be conveniently arranged as follows:—

I. Adult leaves glabrous or nearly so, conspicuously toothed in margin.

1. *Platanus orientalis*, Linnæus. Albania, Macedonia, Thrace, Greece, Crete, Cyprus, Rhodes, and Asia Minor.

Leaves distinctly lobed, the sinuses extending at least one-third the length of the leaf. Fruiting heads bristly, several on the peduncle. Achenes, with long hairs arising not only at the base, but along the body of the achene; apex pyramidal or conic, acute, passing gradually into the long style.

2. *Platanus occidentalis*, Linnæus. Eastern North America from Ontario to Texas.

Leaves indistinctly lobed, the sinuses not extending one-third the length of the leaf. Fruiting heads smooth, solitary, and terminal on the peduncle. Achenes with basal ring of long hairs, elsewhere glabrous; apex truncate or rounded, with a depression, from which arises a very short style.

¹ *Nat. Hist. Plants*, Eng. Transl. ii. 146 (1898).

² Cf. L. F. Ward, in *Proc. U.S. Nat. Museum*, 1888, p. 39, who states that a prominent characteristic of these archaic forms is the presence of basal lobes on the leaves. These basal lobes are occasionally met with on the young shoots of the species now living.

³ *Platanus glabrata*, Fernald, *Proc. Am. Acad.* xxxvi. 493 (1901), is an imperfectly known species from Coahuila in Mexico.

II. Adult leaves densely tomentose beneath, margin entire or minutely and remotely toothed.

* *Lobes elongated.*

3. *Platanus racemosa*, Nuttall, *Sylva*, i. 47 (1842). A tree, attaining 120 feet in height and 18 feet in girth, common on the banks of streams in California. Introduced on the Continent, unknown in cultivation in Britain.

Leaves three- to five-lobed to below the middle; lobes acuminate, tomentose on both surfaces; occasionally with remote minute teeth; base slightly cordate or truncate. Fruiting heads bristly, two to seven on the peduncle. Achenes with ring of basal hairs, elsewhere glabrous; apex pyramidal or rounded, without a central depression; style long.

4. *Platanus Wrightii*, Watson, *Proc. Am. Acad.* x. 349 (1875). A tree, attaining 80 feet in height and 15 feet in girth, common in mountain cañons up to 6000 feet altitude in Southern New Mexico and Southern Arizona in the United States; and in Sonora in Mexico. Not introduced.

Leaves three- to five-lobed to below the middle or near the centre; lobes acuminate, usually quite entire, tomentose on both surfaces, deeply cordate at the base. Fruiting heads smooth, two to four, racemose on the peduncle. Achenes with ring of basal hairs, elsewhere glabrous; apex rounded, with a central depression, from which arises a short style.

** *Lobes short and broadly triangular.*

5. *Platanus mexicana*, Moricand, *Bull. Ferr. Bot.* 79 (1830). A large tree in Mexico, in Nuevo Leon and the provinces to the south of it; frequently planted in the cities of North-Eastern Mexico; the handsomest of all the plane trees.¹ Not introduced.

Leaves three- to five-lobed, densely white tomentose beneath, base truncate or cuneate. Fruiting heads bristly, solitary. Achenes with ring of basal hairs; upper part of the body pubescent; apex pyramidal, continued directly into the long style.

6. *Platanus Lindeniana*, Martens et Galeotti, *Bull. Acad. Brux.* x. 2, p. 343 (1843). Tree, 100 to 150 feet in height. South Mexico, near Jalapa, at 4000 feet altitude. Not introduced.

Leaves with usually three very short lobes, ending in long bristle-like points, densely rusty tomentose beneath; base truncate. Fruiting heads bristly, several on the peduncle. Achenes as in *P. orientalis*.

¹ *Garden and Forest*, ix. 51 (1896).

PLATANUS ORIENTALIS, ORIENTAL PLANE

- Platanus orientalis*, Linnæus, *Sp. Pl.* 999 (1753); Loudon, *Arb. et Frut. Brit.* iv. 2033 (1838); Boissier, *Flora Orientalis*, iv. 1161 (1879); Gamble, *Manual Indian Timbers*, 661 (1902); Schneider, *Laubholzkunde*, 436 (1905).
Platanus palmata, Moench, *Meth.* 358 (1794).
Platanus cuneata, Willdenow, *Sp. Pl.* iv. 473 (1805).
Platanus acerifolia, Willdenow, *Sp. Pl.* iv. 474 (1805).
Platanus laciniata, Du Mont de Courset, *Bot. Cult.* vi. 436 (1811).
Platanus vulgaris, Spach, *Ann. Sci. Nat.* xv. 291 (excl. ϵ *angulosa*) (1841).
Platanus hispanica, Tenore, *Cat. Ort. Nap.* 1845, p. 91.
Platanus digitata, Gordon, *Garden*, 1872, p. 572.

A tree, with several forms distinct in foliage and habit, most of which appear to have arisen in cultivation. Bark scaling off in thin plates; furrowed and thick at the base of old trunks, variable in the different varieties.¹

Young branchlets at first densely stellate-pubescent, becoming green and glabrous in summer; brown in the second year. Leaves at first covered with dense loose white stellate pubescence on both surfaces, later nearly glabrous, the pubescence being only retained here and there, mainly on the veins and midrib of the lower surface, which is paler than the dark-green shining upper surface. Petioles at first densely stellate, white pubescent, ultimately glabrescent.

Fruiting heads several (two to seven) on the peduncle, bristly. Achenes with basal ring of rigid long hairs, similar hairs arising also along the body of the achene, the apex of which is more or less acute and ends in a long persistent style.

Seedling:² caulicle slender, about $\frac{1}{2}$ inch long, surmounted by two narrow spatulate cotyledons, obtuse at the apex, tapering to a very narrow base, sessile, one-nerved, entire, glabrous, dark-green, about $\frac{1}{3}$ inch long. First leaf resembling a petiole in shape, minute and glandular-pubescent. Second leaf spatulate-cuneate, with three teeth at the apex, alternately penninerved, two of the stronger nerves running into the teeth. Third leaf like the second, but larger. Succeeding leaves palmately five-lobed.

In summer, the oriental plane and its varieties are readily recognisable by the leaves, bark, and habit. In winter, the twigs are rounded, striate, glabrous, with numerous inconspicuous lenticels, the apex ending in a short stump, bearing an orbicular scar, marking where the tip of the branchlet fell off in summer. Leaf-scars, on prominent pulvini, almost but not completely surrounding the bud as a narrow ring, sinuous in margin, and with five groups of bundle-dots. Stipular line surrounding the twig at the level of each leaf-scar. Base of the shoot ringed with scars,

¹ Boissier states that the bark of the wild tree is rugose, and does not exfoliate, as is usually the case in cultivated trees, especially in var. *acerifolia*, of the origin of which he knew nothing. As there is considerable variation in the size of the scales of the bark on plane trees, it is probable that the difference noted by Boissier is individual and not varietal or specific. Var. *acerifolia* grows usually very fast, and scales off in much larger plates as a rule than is the case in the other varieties, which are slower in growth.

² Cf. Lubbock, *Seedlings*, ii. 505, f. 653 (1892).

marking the fall of the previous season's bud-scales. Buds distichous and alternate on the long shoots, arising at an angle of 45°, uniform in size, conical, smooth, lustrous, covered by a glabrous cap-like scale.

VARIETIES

1. Var. *typica*.—The form in cultivation, known generally as *P. orientalis*, slightly different in foliage from the wild form, known as var. *insularis*.

A tree, attaining enormous dimensions in South-Eastern Europe and Western Asia, with a short trunk, dividing into many wide-spreading branches. Leaves (Plate 204, Fig. 4) large, generally exceeding 6 inches broad by 5 inches long, usually five-lobed; lobes extending about half-way to the base of the blade, oblong-triangular with an acuminate apex, entire¹ in margin or with a few sinuate entire teeth; sinuses deep, variable in shape. Each of the two basal lobes often gives off a short lobe below, making the leaf seven-lobed. Base of the leaf truncate or widely cordate, but usually extending along the midrib $\frac{1}{8}$ to $\frac{1}{4}$ inch below where the two main lateral nerves are given off. Upper surface dark-green, glabrous, shining; lower surface paler, glabrous except along the nerves and midrib, and in their axils.

2. Var. *insularis*, DC. *Prod.* xvi. 2, p. 159 (1864). The wild form, occurring in Albania, Greece, Cyprus, Crete, Rhodes, and Asia Minor.

A tree, not reported to be very large in size, and said to have rough bark, with small scales, which fall off less readily than in the typical form. Leaves smaller than in the type, scarcely exceeding 5 inches broad and 4 $\frac{1}{2}$ inches long, very variable in shape, usually five-lobed; lobes oblong-triangular or triangular, coarsely three- to four-toothed, extending about halfway to the base of the blade, which is always cuneate, the lamina descending along the midrib $\frac{1}{8}$ to $\frac{1}{4}$ inch below the insertion of the first pair of main nerves; sinuses deep, variable in form.

Mouillefert² distinguishes two varieties of the wild form, one with narrowly lanceolate entire lobes and wide sinuses, the other with lanceolate sinuately-toothed lobes and very deep narrow sinuses. The range of variation in the shape of the leaf in the wild form is considerable.

3. Var. *cuneata*,³ Loudon, *Arb. et Frut. Brit.* iv. 2034 (1838).

Platanus cuneata, Willdenow, *Sp. Pl.* iv. 473 (1805).

A tree, moderate in size, with bark resembling that of var. *acerifolia*. Leaves (Plate 204, Fig. 3) usually about 5 inches wide by 4 $\frac{1}{2}$ inches long, occasionally 8 inches by 7 inches; three- to five-lobed, the lobes as in var. *typica*; base of the leaf broadly cuneate, the lamina extending along the petiole $\frac{1}{2}$ to $\frac{3}{4}$ inch below the insertion of the main lateral nerves; petioles short. This variety only differs from var. *typica* in the markedly cuneate base, and approaches in character var. *insularis*. As seen in cultivation it usually forms imperfect small fruiting heads.

¹ The form with entire lobes is sometimes distinguished as var. *liquidambarifolia*, Spach, *loc. cit.*

² *Essences Forestières*, 221 (1903).

³ Probably var. *undulata*, Aiton, *Hort. Kew*, iii. 364 (1789).

According to Koch,¹ this is a good species, growing as a shrub on the south-eastern slope of the Caucasus, and having a very short stem from which spring many upright branches. Koch, however, did not find it in flower or fruit; and as no plane has been observed growing wild in the Caucasus, it is probable that what he saw were stunted trees of ordinary *Pl. orientalis*, occurring as escapes from cultivation.

At Grayswood, Haslemere, there are two plants, 4 feet high, with a fastigiate habit, which Mr. Chambers raised eight years ago, from seed sent from Kashmir.

4. Var. *digitata*, Jankó, in Engler, *Bot. Jahrb.* xi. 412 (1890).

Platanus digitata, Gordon, *Garden*, 1872, p. 572.

This is a form of var. *typica*, in which the leaves are smaller than usual, with wider and deeper sinuses, the lobes extending three-fourths the depth of the blade and having large triangular toothed lobules.

Gordon supposed this form to be a native of the Caucasus, and says that it was introduced by Messrs. Loddiges in 1842. He describes the fruiting heads as only half the size of those of the type; but in the number and structure of the component achenes there is no difference.

5. Var. *acerifolia*, Aiton, *Hort. Kew*, iii. 304 (1799).

Platanus acerifolia, Willdenow, *Sp. Pl.* iv. 474 (1805). London Plane. Maple-leaved Plane.

A tree, with a tall upright stem, giving off shorter branches than the typical form. Leaves (Plate 204, Fig. 1) large, at least 8 inches wide by 7 inches long, with five short, broad, triangular lobes, separated by wide rounded or acute shallow sinuses, which only extend one-third the length of the blade; base truncate or widely cordate, the lamina often descending on the midrib a short distance below the insertion of the two main lateral nerves. Fruiting heads very variable in size and in number on the peduncle, often badly developed in English trees; achenes similar in structure to those of the typical form, and never resembling those of *P. occidentalis*.

Several forms of the London plane have been distinguished:—

Var. *pyramidalis*. Pyramidal in habit.

Var. *kelseyana*. Leaves variegated with yellow.

Var. *Suttneri*. Leaves creamy-white, more or less splashed or streaked with green, often very large, as much as 12 inches wide by 10 inches long. This is identical with var. *argenteo-variegata*, which was exhibited at the Royal Horticultural Society in July 1897, by Messrs. Russell of Richmond. It is one of the handsomest of variegated trees, the variegation usually lasting the whole season.²

A form with large leaves has been sent out under the misleading name of var. *californica*.

Though var. *acerifolia* exhibits a wide range of variation in the cutting of the leaf, it always shows very distinct lobes, and cannot be confused with *P. occidentalis*, in which the lobes are indistinctly marked.

¹ *Dendrologie*, II. Part i. p. 470 (1872).

² Cf. *Gard. Chron.* xxiv. 190 (1898).

DISTRIBUTION

The oriental plane has been in cultivation from very early times in the Mediterranean region; and the limits of its distribution in the wild state are difficult to determine accurately.

It occurs wild in woods and along torrents in the mountainous regions of Albania and Greece. It grows in chestnut groves and in mountain forests from sea-level to 2500 feet elevation in Macedonia, Thrace, and Bithynia. It is undoubtedly indigenous in the mountains of Crete, Cyprus, and Rhodes; and in Western and Southern Asia Minor up to 5000 feet, not ascending into the zone of the cedars, and also occurs in the Lebanon. M. Gadeceau, in *Rev. Hort.* 1907, p. 207, quotes a letter from a correspondent in Syria to the effect that the plane, known to the Arabs as *Dolbe*, does not grow in the forests, but only in valleys and along the banks of rivers; on Mt. Hermon it reaches 4000 to 5000 feet elevation.

Its occurrence in the wild state elsewhere is very doubtful, as all the specimens which I have seen from other localities were collected near villages. The great plane trees described by travellers as occurring in Persia, Afghanistan, Kashmir, etc., are evidently planted.

Radde,¹ who paid particular attention to the subject, denies its occurrence in the wild state in the Caucasus. Dr. Stapf only saw it cultivated in Persia, where it always grows near villages. In Afghanistan, according to Aitchison,² it is certainly not indigenous; but he found it naturalised in one district, where it had been originally planted in a valley and was gradually taking possession of the adjoining hill. According to Brandis,³ it is cultivated in the North-West Himalaya, particularly in the Kashmir valley, east of the Bias and Sulej, ascending to 8300 feet in Western Ladak. It grows well at Peshawar; and attains 75 feet in height in Kashmir and Chamba, the largest girth noted by Dr. Stewart at Srinagar being 28 feet. The Nasim Bagh, on the border of the great Kashmir lake, is a large grove planted by Akbar the Great, soon after he had taken Kashmir in 1588. Originally this grove contained 1200 trees, a large proportion of which are still standing. In 1838 Vigne found the average girth to be 13 feet, some of the trees growing near water being as large as 20 feet.

Tchihatcheff states that in Cyprus and Zante it is evergreen; but this statement is not confirmed by other travellers, although occasionally an evergreen variety occurs, as in the case of a tree at Lutraki in Crete, which was mentioned by Admiral Spratt.⁴ Mr. Sandwith wrote to Kew in 1884 that this tree had been cut down several years before, but that several vigorous shoots were springing from

¹ *Pflanzenverb. Kaukasuslând.* 170, 187, 189 (1899).

² *Journ. Linn. Soc. (Bot.)* xviii. 94 (1881).

³ *Forest Flora N.W. India*, 434 (1874).

⁴ *Travels and Researches in Crete*, ii. 40. Pliny mentioned the existence of an extraordinary evergreen plane tree which grew on the banks of the Lethæus. Tournefort searched for it without success; but its existence was made known to Captain Spratt by Mr. Agnew, an English merchant who owned property at Lutraki, where he showed him two young and branching plane trees growing by a rivulet, which retained their leaves all the winter. Mr. Agnew said that these were suckers from the roots of a very large tree of the same kind, which he had cut down, without knowing its rarity; and Spratt adds that he heard of two others growing near the village of Vourvalet on the banks of the Platanos river in the west of Crete. Spratt speaks, *op. cit.* p. 191, of a grove of large and beautiful plane trees, mixed with elm and oak, and covered with wild vines which climb to their very top.—(H. J. E.)

the stool, and cuttings from these had been grafted by a Cretan farmer on the ordinary plane tree and were preserving the evergreen habit. (A. H.)

The stellate tomentum, which covers the young leaves of the plane, is gradually cast off; and floating in the air, has been found in some parts of Europe to produce serious bronchial irritation. This was known to the ancient Greeks,¹ being mentioned by Galen and Dioscorides. In Alsace-Lorraine, the planting of plane trees is forbidden in the vicinity of schools; and workmen in nurseries on the Continent, where young trees are raised, are often affected.² We have, however, not heard of any complaint of this happening in England.

The young leaves and shoots of var. *acerifolia* are frequently affected by a disease,³ caused by the fungus known as *Gleosporium nervisequium*, Saccardo, which in early summer attacks the nerves first and soon causes them to wither. Small black spots appear on the dead parts, which are the conidia of the fungus. In England, it is remarkable that the true oriental plane appears to be practically immune from the attacks of this fungus, though its leaves are sometimes blotched between the veins. Mr. Massee informs us that after a thorough examination of dried and living material, he has failed to find the slightest evidence in support of the statement that *Gleosporium nervisequium* is parasitic on typical *P. orientalis*. The London plane is almost invariably affected, though less in London than in the country, where almost everywhere some of the leaves and young shoots become brown and wither; but the healthy growth of the tree is scarcely ever seriously interfered with. Some gardeners believe that this withering is due to cold winds and late frosts; but, though leaves may be injured by climatic conditions, this fungus is undoubtedly the principal cause. A plane tree, var. *cuneata*, in the Cambridge Botanic Garden, which had the habit of var. *acerifolia*, had the leaves badly attacked in June 1907. A tree, 30 feet high, of the same variety, at Grayswood, had the young wood seriously injured by a fungus, which Mr. Massee identifies with *Gleosporium*.

The fungus is apparently more severe in its attacks on the Continent; and at Ghent in 1891, all the plane trees lost their leaves.⁴ In the United States, the occidental plane⁵ is very liable to be attacked by this fungus, and as a street tree in New England is unsuccessful on that account, though *P. acerifolia* succeeds as well as it does in England.

Klebahn⁶ states that *Gleosporium nervisequium* occurs more especially on *P. occidentalis*, less frequently on *P. orientalis*. He believes that *G. nervisequium* is only a conidial form of a higher fungus, called *Gnomonia Veneta*, Klebahn.

⁴ Cf. *Gard. Chron.* x. 491 (1891).

⁵ Cf. *Garden and Forest*, 1891, p. 591, 1896, p. 51, and 1897, p. 257. In an article on Leaf-blight of the Plane Tree, by Murrill in *Journ. N. York Bot. Garden*, viii. 157 (1907), an account is given of an epidemic of the disease occurring this year in New York, believed to have been caused by the late and damp spring. Murrill observed the oriental plane to be attacked in Italy in 1906; and states that *P. racemosa* is also subject to the disease.

⁶ *Jahrb. Wissensch. Bot.* xli. 515 (1905).

HISTORY OF THE CULTIVATED PLANES

The oriental plane was introduced into Italy from Greece about 390 B.C.; and Hehn¹ gives a full account of the classical allusions to the tree.² It came into England³ some time before 1562. In Turner's *Herball*, published in that year, a figure is given, and the author states: "I have sene the leves of that Platanus that groweth in Italy and two very yong trees in England which were called there Playn trees, whose leves in all poyntes were lyke unto the leves of the Italian Playn tree. And it is doubtles that these two trees were either brought out of Italy or of som farr countrie beyond Italy where unto the freres monkes and chanones went a pilgrimage."

The American plane, *P. occidentalis*, was introduced into England by Tradescant,⁴ in whose garden two small plants were growing in 1636, when Johnson published his edition of Gerard's *Herball*. It was undoubtedly in cultivation in the eighteenth century, as a specimen from a tree cultivated at Kew in 1781 exists in the British Museum; but another specimen from the Chelsea Physic Garden, dated 1789 and labelled *P. occidentalis*, is undoubtedly *P. acerifolia*. The figure given in Evelyn's *Sylva* of *P. occidentalis* really represents *P. acerifolia*. Similarly Loudon's description and figure of the American plane are inaccurate, and in part refer to *P. acerifolia*. The confusion between these two forms is thus shown to have begun early, and has lasted until quite recently; and it is probable that most of the references to the occidental plane in this country and on the continent of Europe refer to *P. acerifolia*.

Platanus acerifolia was first distinguished by Tournefort⁵ in 1703. Miller,⁶ in 1731, gives an account of three kinds of plane: *P. orientalis vera*, *P. occidentalis*, and *P. aceris folio*; but he was unaware of the real distinctions between the two latter, attributing to *P. occidentalis* the property of being easily propagated by cuttings, whereas it is *P. acerifolia* of which this is true. He asserts that his *P. aceris folio* is only a seminal variety of *P. orientalis*.

Bolle⁷ states that Bourgeau found considerable forests of *P. acerifolia* in Lycia. This statement has not been confirmed, and there is no evidence of the occurrence anywhere of this form in the wild state. The difference between it and the wild form of *P. orientalis* (var. *insularis*) is mainly in habit, and taking into account the variability of the leaves on the wild tree, no two of which are alike in the specimens which I have examined, there is little doubt that *P. acerifolia* is a seedling variety of *P. orientalis*, which has been fixed in cultivation. Intermediate forms between it and the ordinary typical variety are not unusual. Bolle states that seedlings of *acerifolia* often exhibit the characters of typical *orientalis*. Further experiments on this point are desirable, as well as a thorough investigation of the range of variation

¹ *Kulturpflanzen*, ed. 6, p. 283.

² The Romans planted it in their gardens for shade: Ovid calls it *genialis*, and Horace *celebs* because it did not support the vine.

³ It was probably introduced into France in Provence about the same time. Cf. *Le Jardin*, 1896, pp. 116, 162.

⁴ Cf. Parkinson, *Theat. Bot.* 1427 (1640).

⁵ *Coroll.* 41 (1703).

⁶ *Gard. Dict.* ed. 1 (1731).

⁷ *Gard. Chron.* i. 564 (1876).

of the tree in the wild state in Greece and Asia Minor. At what time *acerifolia* came into cultivation is unknown; but the evidence points to its having become common in the eighteenth century. All the very old trees in the Levant of which we have specimens, are, however, of the typical form.

Considering the difficulty of distinguishing between *acerifolia* and *occidentalis*, in the absence of fruit, a character to which no attention was paid until 1856, when Sir W. J. Hooker¹ cleared up the confusion until then existing between them, it is probable that in the eighteenth century, as at the present time, the commonest plane in cultivation was *P. acerifolia*, and that *P. occidentalis* was very rare. The latter could never have been common, as it is quite unsuitable for our climate. It dies at Kew after a few years, and we know of no specimen, older than nursery plants, in England.

This we believe to be the true solution of the difficulty, namely, that *acerifolia* was always the common tree in cultivation in England, that it was perpetually confused with *occidentalis*, and often passed under that name, and that the American plane never reached adult size in this country.

The origin and date of the first cultivation of *acerifolia* must remain in doubt; but I see no grounds for assenting to Schneider's view that it is a possible hybrid between *occidentalis* and *orientalis*. It does not resemble the former in any way in the characters of the fruit; and the similarity in the shape of its leaves to those of the American plane is more apparent than real. (A. H.)

CULTIVATION

As the true oriental plane is now hardly to be procured in nurseries, where the maple-leaved or London plane has alone been propagated for many years, it is necessary either to sow seeds or make layers from the branch of an old tree. The seeds ripened in this country often (I think I may say usually) fail to germinate, probably on account of the insufficient heat of our autumn, yet I have raised a few seedlings from a tree at Fulham, which, however, soon died when planted out. As the fruiting heads hang on the tree till spring, it seems best not to sow them till then, and I have been successful in raising seedlings from seed gathered at Venice as late as May.

The seeds should be rubbed out with sand, covered very lightly with fine soil, and kept shaded in a greenhouse until they germinate, as they grow very slowly the first year. It is better not to transplant them to the open ground until they are two or three years old, as the young wood does not ripen well; and for these reasons it has been found by nurserymen much better to raise them by layering, or from cuttings, which Boutcher says should be about a foot long and torn asunder at the joints, with a knob of the old wood left on, and buried about eight inches deep. I have struck cuttings from the true oriental plane by this method.

The trees are easy to transplant even when of considerable size, and require a deep rich soil to make them grow well. Though often planted by the side of water

¹ *Gard. Chron.* 1856, p. 282.

they do not like cold wet soil or heavy clay; and a seedling which I brought in a bottle from the Temple of Diana at Ephesus in 1874, and planted out at Colesborne, has never been able to make good growth on account of the spring frosts, which cut it back in most seasons; and after thirty-three years' growth is only a stunted bushy tree 20 feet high.

The true oriental plane is always liable to be cut by frost at any age, and the branches and twigs assume a zigzag habit in consequence; but no tree succeeds better in the smoky air of towns than the maple-leaved or London plane, which is by far the largest tree in all the London squares, parks, and gardens, and seems likely to live to a very great age.

As regards hardiness, the plane seems, when of sufficient size, to endure the severest winter frosts, but requires a higher summer temperature than the north and west of England usually affords. In the south-east it is almost everywhere one of the finest exotic trees we have, but should not be planted on poor, stony land or in places exposed to cold winds.

The oriental plane is one of the very few trees that will grow on strongly alkaline soil, and has been successfully planted on the alkaline lands of the San Joaquin valley in California.¹

REMARKABLE TREES

Var. *typica*.

Perhaps the finest specimen in England of the oriental plane is one which was planted by Bishop Gunning in the palace gardens at Ely, of which he was bishop from 1674 to 1684. This tree seemed to be failing some years ago, probably owing to a succession of dry seasons, and on the advice of Sir W. Thiselton Dyer was liberally top-dressed with good soil; the result was so good that when I saw it in 1903 it was in good health, and measured 104 feet high by 20½ in girth. In 1896 it was found by the shadow to be about 100 feet high and 23 feet in girth at 3 feet from the ground. It forks at about 10 feet, where an immense limb comes off, and the branches almost touch the ground all round. It grows on a low hill 50 to 60 feet above the level of the fens, but is sheltered on the north and east by buildings. On 15th October 1903 (a very wet season), the leaves were still quite green, but there was no fruit. Plate 174 is selected from several photographs taken at different times, as giving the best representation of this noble tree.

In the garden of the Lady Margaret Professor of Divinity at Christ Church, Oxford, there is a very old plane, said to have been introduced by Dr. E. Pococke, who was Professor of Arabic in 1636. It is of no great height and throws out an immense limb close to the ground, where it measures 18 feet 10 inches in girth. When I saw it in September 1907, fruit of the last year was still hanging on it, together with full-grown fruit of the current year, and in some cases six or seven balls were borne on one peduncle.

At Hawsted Old Place, near Bury St. Edmunds, there are three very large

¹ Hilyard, *Soils*, 480 (1906).

oriental planes in a grass field near the farm, where an old manor-house formerly stood, and these, according to the Rev. L. Mercer, vicar of Hawsted, are said to have existed in Queen Elizabeth's time, and to be the oldest in England.¹ They are difficult to measure accurately on account of their broad round tops and the trunks being covered with shoots, but the two largest are 75 to 80 feet high and 17 to 18 feet in girth, and the third is not much smaller. When I saw them on 24th June 1905, they were still covered with last year's fruit, three to five on a peduncle, and new half-grown fruit was also growing on them. Their branches spread over a very wide area.

At Corsham Court, Wilts, the seat of General Lord Methuen, there is an oriental plane with very deeply-cut leaves whose branches spread over a larger area than those of any tree I have seen in England (Plate 175). It is 75 to 80 feet high and 18½ feet in girth. One of the branches, which is self-layered in several places, extends no less than 27 paces from the main bole, and the total circumference of the branches is 140 paces. Three of the principal stems grown from the layered branches are 6 feet 3 inches, 4 feet 10 inches, and 4 feet respectively in girth. Lord Methuen believes that this tree was planted soon after his ancestor built the house in 1757, and a cedar recently cut down, probably of the same age, showed about 133 rings and thus tends to confirm his opinion.

Another very large tree of great age is growing close to the banks of the Test, at Mottisfont Abbey, Hants, which has layered its branches in the damp alluvial soil. When I saw it some years ago it was in good health, and in 1898 measured 29 feet 8 inches at 4½ feet where it forks, the branches having a diameter of 129 feet.² At Bisterne Park near Ringwood, in the same county, there is a very fine old tree measuring, in 1906, 100 feet by 18 feet.

At Weston Hall, Staffordshire, the seat of the Earl of Bradford, there is a very fine plane which I have not seen myself, but which was measured³ in 1875 as 80 feet by 18½ feet with a bole 11 feet high, and twelve large limbs from 4 to 7 feet in girth.

At Blickling Hall, Norfolk, there are two very old trees growing close together, the largest of which was, in 1907, 11 feet in girth and almost 60 feet high, with remarkably spreading branches, covering a space of 140 feet in the largest diameter, and 127 paces in circumference. The lowermost branches lying upon the ground had taken root, and growing erect for a time had again bent down and taken root a second time.

At Chiswick House, London, there is another example of a large oriental plane with very spreading pendulous branches, many of which are lying upon the ground and one has taken root. This tree was, in 1903, 13½ feet in girth, 74 feet in height, and the diameter of the spread was 100 feet.

At Greycourt, Ham, in Surrey, the residence of Colonel Biddulph, there is a tree which measured, in 1906, 16 feet 11 inches in girth and 72 feet in height, and had a short bole of 7 feet dividing into three great limbs, the diameter of the spread of branches being 94 feet.

¹ Cf. *Woods and Forests*, 1884, p. 153.

² Cf. *Gard. Chron.* xxiii. 24, figs. 9, 10 (1898).

³ Geo. Berry, in *Garden*, xx. 370 (1881).

The well-known tree in Kew Gardens, near the Palace, is about 80 feet high, and measures 14 feet 8 inches in girth.

In Scotland, the oriental plane is rare; and seems to be much injured by late spring frosts. The Rev. D. Landsborough¹ speaks of one planted in 1864 in Kay Park, Kilmarnock, which was killed by the frost of 15th April 1903; others, however, in a sheltered position had not suffered. A large oriental plane at Kelso, which was a favourite tree of Sir Walter Scott's, was destroyed by the great frost of 1814. This was probably the tree referred to by Walker² in 1812, who states that the oriental plane grows at Mount Stewart, Bute, like a willow, and nowhere else so good in Scotland except at Kelso.

In Ireland the oriental plane is rather a rare tree. The finest specimen we know of is at Carton, the seat of the Duke of Leinster, which was, in 1904, 82 feet in height by 11 feet 9 inches in girth. Mr. W. E. Gumbleton has sent us specimens from a very fine tree growing in his grounds at Belgrove, near Queenstown in County Cork. Another good tree is reported to be growing at Curragh Chase, in Co. Limerick. There are smaller trees at Clonmannin, in Co. Wicklow.

The oriental plane attains an enormous size and great longevity in the eastern parts of Europe, Asia Minor, and Persia.

One of the most remarkable was a tree growing in the village of Vostiza, on the Gulf of Lepanto, in Greece, which measured,³ in 1842, 37 feet 4 inches in girth at 5 feet from the ground, and was estimated to be 130 to 140 feet in height. This tree is supposed to be the one referred to by Pausanias, who wrote in the second century A.D.; yet in 1842 the trunk appeared to be perfectly sound, though many of the larger branches have succumbed to age and storm. Sir F. Elliot, British Minister at Athens, was good enough to make enquiry about this tree from Mr. Wood, British Consul at Patras, who informed him that when he last saw the tree, only a few feet of hollow stump remained. There are two remarkable oriental planes at Cannosa, near Ragusa in Dalmatia, which measure at breast height 32 feet 1 inch and 30 feet in girth. They are about 120 feet high.⁴

The famous plane at Bujukdere on the Bosphorus is not a single trunk, but is formed of nine stems fused together. According to Ch. Martins,⁵ in September 1856, the height was 200 feet—evidently an exaggeration—with a spread of branches 373 feet in circumference. One trunk girthed 18 feet; two trunks united together for some distance girthed 36 feet, the remaining six trunks being in an ellipse of 76 feet. One of the stems was hollow and afforded stable room for two horses. This tree is typical *orientalis*.⁶ This tree is also sometimes called the "Seven Brothers" or the plane tree of Godfrey de Bouillon, as tradition states that he and his crusaders encamped in its vicinity in 1096.⁷ Sir N. O'Connor informed me in 1903 that it has suffered much within the last few years owing to some excavations made close to its roots, and is evidently declining rapidly. A sketch of it made for the late Mr. C. Ellis, is now in Lady Emlyn's possession.

⁷ Mouillefert, *Essences Forestières*, 215 (1903); and *Garden and Forest*, ii. 349 (1889).

The tree of the Janissaries, the ancient plane, which stands in the Court of the Janissaries in the Old Seraglio at Constantinople, was 39 feet in girth at 3 feet from the ground in 1890; but the trunk was hollow, the branches and foliage, however, being sound and vigorous.¹

In the *British Medical Journal* of 21st June 1902, there is an excellent account, with illustrations, of a plane tree in the island of Cos, which from its appearance must be one of the oldest trees in the Mediterranean, if not so old as its somewhat mythical history alleges. Local tradition says that under this tree Hippocrates, the celebrated Greek physician, taught the art of healing no less than 2300 years ago. The tree grows near the landing-stage, between an ancient castle and a mosque, close to a drinking-fountain. Mr. von Holbach, who measured it, gives the girth of its hollow trunk as 18 metres; but all the upper part has decayed away, and the lower part of the tree now consists of immense branches which are supported on antique marble columns, over the tops of which their great weight has caused them to grow. Dr. Clapton, of 41 Eltham Road, Lee, procured a section of one of the branches of this tree, and has presented a photograph of it to the Hunterian Museum.

Bonvalot,² on his way from Samarcand to Amu, states that he halted at Sarijui, near the residence of the chief, under a plane tree, which was about 37 feet in diameter at 6 feet above the ground. In his book, a picture of the tree is given, and a great limb comes off low down, which evidently was included in the above measurement. The tree appears to be about 50 feet in girth at the base below where the limb comes off. Another enormous tree,³ 49 feet in girth, stands in the grounds of the mosque of Tajrish, a village in the Elburz Mountains, north of Teheran, in Persia.

Var. *acerifolia*.

The variety *acerifolia* seems to have generally replaced the cut-leaved form at some period above a hundred years ago, but we cannot find any certain evidence of this, because it was generally confused with the western plane.

All the planes that we have seen in the squares, parks, and gardens about London of less age than about 100 years are *acerifolia*, and the finest specimen that I know of is the one in the Ranelagh Gardens, which measured, in 1903, 105 feet high, with a girth of 20 feet 4 inches.

The planes in Berkeley Square are worth notice on account of their uniform burry trunks swelling at the base. They all appear to have been propagated from the same stool and to have retained this peculiarity throughout. They were planted by Mr. Edward Bouverie in 1789 and are probably the oldest plane trees in London.⁴ According to Mr. R. Birkbeck the two largest, in 1906, girthed at 5 feet, 13 feet 10 inches and 13 feet 4 inches, and were about 85 feet high. Tradition says that this area was a burial-ground during the Plague of London in 1665.

On the banks of the river Rother at Woolbeding Rectory, Sussex, in the garden

⁴ Hare, *Walks in London*, ii. 74 (1894).

of Archdeacon Elwes, are two of the largest planes in England, one of them, which is partly hollow at the base, but has been filled up with brickwork, being about 105 feet high by no less than 25 feet in girth. The other, a better-shaped and very vigorous tree, is 100 feet by 10 feet, with a bole 12 feet long. In Colonel Lascelles' grounds close by, there is another splendid plane, 110 feet high by 11 feet in girth, with a bole 30 feet long. At Cowdray, in the same neighbourhood, there are some fine old planes at the bottom of the park, two which I measured being about 80 feet high and over 15 feet in girth.

There is a very fine tree at Rickmansworth which, when measured by Henry in 1904, was 105 feet by 16 feet 3 inches. Another at the same place was 103 feet by 15 feet. Sir Hugh Beevor tells us of a fine tree at Shotesham, Norfolk, the seat of R. Fellowes, Esq., which, in 1904, was 100 feet by 17 feet 8 inches.

I measured a very tall and handsome tree, which appears to be growing fast, at Albury, in 1905, when it was at least 105 feet high by 11 feet 3 inches (Plate 178).

A tree which appears from its leaves to be more or less intermediate between the oriental and London planes is growing at Boconnoc in Cornwall, and is decaying, the climate being probably too damp for it, as I have seen no very large plane trees in the far west. In 1905 it was about 85 feet by 11 feet 2 inches.

At Hampton Court, Herefordshire, there is a fine tree on the lawn, which was measured in 1881 by Hogg, when it was 80 feet by only 8 feet 6 inches, and when I saw it in 1905 had increased to 95 feet by 14 feet 6 inches. I cannot help suspecting a mistake in the earlier measurement of girth, as an increase of 6 feet in twenty-four years seems extraordinary.

At Eastwell Park, Kent, there is a tree in a shrubbery drawn up by surrounding trees to a height of 105 feet, though the trunk is only 8 feet 6 inches in girth.

At Fawley Court, Oxfordshire, there is a row of four large trees about 100 feet high, and from 16 to 18 feet in girth, which are probably of no great age. In this damp alluvial soil they seem likely to become as large as any in England.

At Ashleigh College, on the east side of Mortlake, close to the Thames, a group of five trees form a conspicuous feature in the landscape. One of these is 110 feet in height and 10 feet in girth.

At Pains Hill, Cobham, Surrey, there are six or seven very large trees, one of which measured, in 1904, 100 feet high by 15 feet in girth.

At Chipleigh, near Minehead, a very fine plane, said to be an occidental plane, but undoubtedly a London plane, which was planted in 1760, is recorded by Mr. E. C. Batten¹ as being, in 1888, 105 feet high by 15½ in girth, with a spread of 120 feet.

At Heron Court, Ringwood, the seat of the Earl of Malmesbury, there is a London plane, which measures 90 feet by 11 feet 5 inches, and has a stone at the base with the date 1707 cut on it. A woodpecker's hole in the trunk, which is clean for about 35 feet, shows that this tree has begun to decay.

At Ribston Park,² Yorkshire, there is a tree which appears to be as old as any that I have seen. Tradition says that it was brought over by the Knights Templars,

¹ *Trans. Eng. Arb. Soc.* ii. p. 221.

² *Gard. Chron.* xxx. 34 (1901).

who had a preceptory here. It measured, in 1906, 72 feet high by 13 feet 9 inches in girth, but has the habit of *typica* rather than of *acerifolia*.

In Wales the finest plane that I have seen is a tall tree growing near the icehouse at Dynevor Castle. In 1906 it measured about 100 feet by 10½ feet with a clean trunk about 40 feet long.

In Scotland we have seen no plane remarkable for size, but there is one growing in the grounds at Benmore, Argyllshire, which has a curious resemblance in its foliage to the occidental plane.

In Ireland, the largest London plane, seen by Henry, is growing at Lismore Castle, and measures 12 feet 10 inches in girth, with an estimated height of about 90 feet. Mr. R. D. O'Brien informs us that a tree at Cooper Hill, near Limerick, is 10 feet 5 inches in girth, with a spread of 74 feet in diameter.

TIMBER

The wood of the plane is so little known in the timber trade of this country that it is not even mentioned by "Acorn," except as a name in use for sycamore, which is commonly called plane in Scotland; and in a recent letter in the *Timber Trade Journal*, what is known as lace-wood in the trade is spoken of as wood of the sycamore, imported from America, though it is really that of *Platanus occidentalis*. The ignorance which prevails among English timber merchants and builders about many of our useful woods is remarkable, and has led to many lawsuits, but there is no doubt that the wood of the oriental plane is one of much greater value than is supposed, both for ornamental work and for coach-building.

Mr. George Berry of Longleat¹ says that the timber of the plane tree is used almost exclusively by coach-builders and pianoforte-makers. No wood takes the paint and stands so well for the sides of large waggonettes as this. In the case of pianos, it was used exclusively for bridges, the toughness and hardness enabling the pins to be most securely held. He considers that plane timber exported from America is of very inferior value as compared with that of English growth.

Dr. Day sent me from the Lebanon a large board which shows a very beautiful and varied figure produced by the medullary rays, and I have seen in Prof. Sargent's house at Brookline, near Boston, very handsome panelling made of the wood of the western species. This wood is converted into veneer or three-ply, and sold as lace-wood, for covering the walls of rooms, and would make very pretty furniture if properly cut and seasoned. Gamble says that the wood is not valued in Kashmir, except to make boxes, trays, pencases, and similar articles, which are lacquered or painted. I have seen very ornamental boxes made from this wood in Russia.

(H. J. E.)

¹ *Garden*, xxii. 83 (1882).

PLATANUS OCCIDENTALIS, WESTERN PLANE, BUTTONWOOD

Platanus occidentalis, Linnæus, *Sp. Pl.* 999 (1753); Loudon, *Arb. et. Frut. Brit.* iv. 2043 (1838) (in part); Sargent, *Silva N. America*, vii. 102, tt. 326, 327 (1895), and *Trees N. Amer.* 344 (1905).

Platanus lobata, Moench, *Meth.* 358 (1794).

Platanus hybridus, Brotero, *Fl. Lusit.* ii. 487 (1804).

Platanus vulgaris, *ε. angulosa*, Spach, *Ann. Sci. Nat.* xv. 291 (1841).

A tree, attaining in America a height of 170 feet and a girth of 35 feet. Bark furrowed near the base of large trunks into broad rounded scaly ridges, higher on the tree separating in large thin scales, exposing irregular surfaces of pale-yellow or whitish inner bark. Branchlets and buds indistinguishable from those of *P. orientalis*.

Leaves (Plate 204, Fig. 2) large, about 8 inches broad by 7 inches long, broadly ovate, obsolete three- to five-lobed, the lobes much less marked than in *P. acerifolia*, not reaching to one-third the length of the blade, separated by very broad and very shallow sinuses, entire or with long acuminate teeth; base widely cordate or truncate, with often a slight cuneate part decurrent on the petiole.

Fruiting heads solitary¹ at the end of a glabrous stalk (3 to 6 inches in length), about an inch in diameter, not bristly, but smooth, the persistent styles being minute or obsolete. Achene truncate or rounded at the apex, which has a central depression bearing the short remains of the style, glabrous on the body, surrounded by a ring of long stiff hairs arising from the base only.

This species differs from all forms of *P. orientalis* in the solitary fruiting head, composed of glabrous achenes, with only a basal ring of long hairs. The foliage is nearest to *P. acerifolia*, but differs in the obsolete ill-defined lobes. (A. H.)

DISTRIBUTION

According to Sargent the western plane grows on the borders of streams and lakes in rich alluvial soil, and is widely distributed throughout the eastern half of the United States, crossing into Canada, where it is confined to the northern shores of Lake Ontario. In the United States it extends from South-Eastern New Hampshire and Northern Vermont southward to Northern Florida, Central Alabama, Mississippi, and Texas, as far as the valley of the Devil's River; and westward to Eastern Nebraska and Kansas. It attains its largest size in the bottom-lands of streams in the basins of the lower Ohio and Mississippi rivers.

The buttonwood, or sycamore, as it is often called in the United States, is the most massive, if not the tallest, deciduous tree of North America. The younger Michaux² states that his father measured, on an island in the Muskingum valley, a "palm-tree or *Platanus occidentalis*," 40 feet 4 inches in girth at 5 feet. The same

¹ Sargent in a letter to Kew, dated 1884, states that he had received from three different collectors specimens showing two heads on the peduncle; but this is rare and abnormal.

² *Travels in the Alleghanies*, 86 (1805).

tree had been measured twenty years earlier by Washington, when it was nearly the same size. Michaux measured one, 36 miles from Marietta on the road from Wheeling, on the Ohio, 47 feet in girth at 4 feet, which kept the same size for 15 to 20 feet, and then forked into several branches. This tree was hollow.

Ridgway records¹ a tree in Gibson County, Indiana, 160 feet high, 30 feet in girth at the smallest part of the trunk, with a spread of 134 feet by 112 feet; another in Wabash County 168 feet high, 25 feet in girth, and 68 feet to the first branch; another 83½ feet to the first branch, but only 9 feet in girth. He found the prostrate trunk of a tree near Mount Carmel, in Illinois, which was much larger than any of those above mentioned. The decayed base measured 60 feet in circumference; and at 20 feet from the ground, where the tree divided into three large limbs, it was still about 62 feet round. Each of the three limbs was about 70 feet long by 5 feet in diameter, so that the total cubic contents by quarter-girth measurement must have been over 8000 feet. None of these were quite so tall, but much larger in girth than, the largest Tulip tree on record, and I know of no broad-leaved tree in the northern hemisphere which equals these dimensions. The largest which I actually saw myself, shown me by Dr. Schneck near Mount Carmel, measured 150 feet by 25 feet, and was standing in a cornfield. In New England it does not attain anything approaching these dimensions, the largest mentioned by Emerson, near Lancaster, Mass., being 18 feet in girth at 6 feet, and holding its size for 20 feet, and with a broad head of great height.

CULTIVATION

This tree is unsuited to our climate, and though seedlings are frequently raised at Kew, they never live more than a few years, and suffer severely from frosts. One tree raised from Michigan seed attained a height of about 12 feet, but became badly attacked by disease, and was removed about a year ago. So far as we know, there is not a single tree of this species of any size now growing in Britain.

Thomas Rivers, in an interesting article,² states that in 1820 there were in his nursery stools of *P. occidentalis*, which had been planted by his grandfather in 1780. These stools gave shoots with enormous, almost circular slightly-lobed leaves; but the young shoots always died down. From 1830 to 1840 he imported seeds of the American tree, which gave plants like these stools, but never lived for any length of time. He quotes Sir W. J. Hooker's statement: "We often raise young plants of *P. occidentalis* from American seed; but the annual shoots are killed every winter."³ Rivers believed that the American plane had never existed in England so as to form large specimens, and that those mentioned as being large trees by Miller in 1759 and by Loudon in 1838 were not the true *occidentalis*.

The tree is equally rare on the Continent. M. Gadeceau, who wrote two papers⁴ on the differences between the occidental and oriental planes, knew of

¹ *Proc. U.S. Nat. Museum*, 1882, p. 288.

² *Gard. Chron.* 1856, p. 86, and 1860, p. 47.

³ But this is not always the case, as I planted out two seedlings of *P. occidentalis*, raised at Kew in the autumn of 1906, and they have remained healthy throughout the cold wet summer of 1907.

⁴ *Bull. Soc. Sc. Nat. Nantes*, iv. 105 (1894), and *Rev. Hort.*, 1907, p. 205.

the existence of only one true American plane in France, which is growing in the Jardin des Plantes at Angers; but I saw in the rich collection of M. Allard at La Maulevrie near Angers, a tree about 30 feet high which, though it bore no fruit, seemed quite healthy. M. L. Henry¹ says that another tree exists in the Botanic Garden at Nantes. There are three trees of this species, about 50 feet high, growing in the garden of Messrs. Simon Louis at Plantières-lès-Metz.² Schneider knows of no trees in Germany or Austria.

(H. J. E.)

A C E R

Acer, Linnæus, *Sp. Pl.* 1054 (1753); Bentham et Hooker, *Gen. Pl.* i. 409 (1862); Pax, in Engler, *Pflanzenreich*, iv. 163, *Aceraceæ*, 6 (1902); Schneider, *Laubholzkunde*, ii. 192 (1907).
Negundo, Ludwig, *Gen. Pl.* 308 (1760); Bentham et Hooker, *loc. cit.*

TREES or shrubs, belonging to the natural order Aceraceæ, which is often considered to be a division of Sapindaceæ. Leaves usually deciduous, rarely evergreen, opposite, without stipules—simple, in which case they are undivided or palmately lobed—or compound with three to five leaflets. Buds covered by several scales arranged in decussate pairs, or protected by two valvate scales, sessile or occasionally stalked. Twigs with epidermis persisting for more than one year and remaining green in the second year; or becoming corky on the surface and changing colour in the first season. Inflorescence terminal on two- to four-leaved branchlets, or arising out of lateral buds without leaves, in racemes, corymbs, or fascicles. Flowers appearing at the same time as the leaves or earlier; regular, diœcious, or with male and perfect flowers on the same tree, or with male flowers on one tree and perfect flowers on another tree. Parts of the flowers in fours or fives or multiples of those numbers. Calyx with four, five, to twelve sepals, usually free, occasionally connate. Petals equal in number to the sepals, absent in some species. Disc secreting honey usually present, absent in a few species, annular, lobed, or reduced to small teeth. Stamens four to ten, usually eight, inserted either outside the disc, inside it, or upon it. Ovary, two-lobed, two-celled, each cell containing two ovules. Styles or stigmas two, free or connate at the base. Fruit of two samaræ, attached by their bases, with long and diverging wings. Seeds one or two in each samara, without albumen; cotyledons appearing above the ground on germination.

About 110 species of maple are known, occurring usually in mountainous regions; in Europe, south of lat. 62°, in Algeria, Asia Minor, the Caucasus, Persia, Turkestan, the Himalayas, China, Manchuria, Japan, Formosa, the Philippines, Java, Sumatra, Celebes, and in North America from Southern Canada and Oregon to Mexico and Guatemala. A large number have been introduced into cultivation, fifty-seven species being enumerated in the Kew Hand-List; but many of these are shrubs or small trees, the detailed treatment of which does not come within the scope of our work.

The genus is divided by natural characters into thirteen sections by Pax, whose monograph and that of Schneider should be consulted by cultivators of the

rarer species. The following synopsis, in which the species are arranged artificially according to the shape of the leaves, will help to distinguish most of the species in cultivation.

SYNOPSIS OF THE MAPLES IN CULTIVATION

I. Leaves simple, not lobed.

* *Leaves entire in margin.*

1. *Acer oblongum*, Wallich. Himalayas, China.

Leaves coriaceous, 3 to 6 inches long, narrowly elliptical, long acuminate, glabrous and glaucous beneath; nerves, eight to twelve pairs, not reaching the margin; stalks 2 to 3 inches long.

A tree, about 50 feet high. The Himalayan form was introduced in 1824, and has been long in cultivation in the temperate house at Kew; it is doubtfully hardy. The Chinese form, introduced by Wilson in 1901, is growing rapidly out-of-doors at Coombe Wood; but is slightly tender. The young leaves of the latter are bright-red in spring, and are slightly toothed with distinct serrations.

** *Leaves serrate.*

2. *Acer carpiniifolium*, Siebold et Zuccarini. Japan.

Leaves about 4 inches long, plicate, and resembling those of the Japanese hornbeam (*Carpinus japonica*), long acuminate, pubescent beneath, sharply bi-serrate; nerves, twenty pairs, extending to the margin; stalks $\frac{1}{4}$ to $\frac{1}{2}$ inch long.

A tree, attaining 50 feet in height. Introduced by Maries in 1881. Trees at Coombe Wood are about 15 feet high, and are remarkably distinct in foliage from the other species of maple.

3. *Acer distylum*,¹ Siebold et Zuccarini. Japan.

Leaves 5 inches long, 4 inches broad, ovate, long acuminate, finely serrate, pubescent on both surfaces when young, later glabrescent; nerves, eight to ten pairs, looping and not reaching the margin; petioles pubescent, about $1\frac{1}{2}$ inch long.

A tree, the height of which is not stated, introduced by Maries in 1881. At Coombe Wood, a specimen is about 25 feet high, and produces fruit, borne in erect racemes.

4. *Acer tataricum*, Linnæus. South-Eastern Europe, Southern Russia, Asia Minor, Caucasus.

Leaves (Plate 207, Fig. 33) 3 inches long, 2 to $2\frac{1}{2}$ inches wide, ovate, rounded or slightly cordate at the base, rounded or shortly acuminate at the apex, unequally bi-serrate, green and scattered pubescent beneath. The leaves, usually without lobes, show occasionally slight and irregular lobes.

Introduced in 1759. A shrub or small tree,² coming early into leaf.

¹ Figured in *Gard. Chron.* xv. 499, f. 93 (1881).

² At Arley Castle a good specimen is 29 feet high and 1 foot 9 inches in girth.

5. *Acer Fargesii*, Rehder.¹ Central China.

Leaves 3 to 4 inches long, $\frac{3}{4}$ to 1 inch broad, coriaceous, lanceolate, cuneate or rounded at the base, caudate or long acuminate at the apex, serrate on young plants, entire on old trees; nerves indistinct, about ten pairs, looping and not reaching the margin; green and glabrous on both sides, except for minute axil-tufts beneath, developed occasionally on leaves of old trees.

A small tree, introduced by Wilson in 1901; spring foliage and fruit bright crimson. Young plants at Coombe Wood are rather tender, and have only attained $1\frac{1}{2}$ foot high in six years.

6. *Acer Davidi*, Franchet.² Central China.

Leaves 3 to 4 inches long, $1\frac{1}{2}$ inch broad, ovate, cordate at the base, long acuminate, slightly lobulate and crenately bi-serrate; nerves prominent, about twelve pairs, looping before reaching the margin; upper surface dark-green, shining, glabrous; lower surface pale, glabrous, except for reddish-brown axil-tufts.³

A tree, 50 feet in height, introduced by Maries in 1879. Young plants raised from seed sent by Wilson in 1902 are 10 to 12 feet high and perfectly hardy at Coombe Wood. Bark green, striped with white.

6A. *Acer cratagifolium*. See No. 10.

Leaves of this species, without lobes, are distinguishable from *A. Davidi* by the absence of the conspicuous axil-tufts on the lower surface.

II. Leaves simple, three-lobed.

* *Leaves entire in margin.*

7. *Acer monspessulanum*, Linnæus. Southern Europe, North Africa, Asia Minor, Caucasus.

Leaves (Plate 207, Fig. 31) $1\frac{1}{4}$ inch long, $2\frac{1}{4}$ inches broad, coriaceous, greyish beneath; lobes ovate, obtuse. Petiole without latex. (See description, p. 665.)

** *Leaves minutely crenulate.*

8. *Acer creticum*, Linnæus. Greece, Crete, Lycia.

Leaves (Plate 207, Fig. 32) $\frac{3}{4}$ to $1\frac{1}{2}$ inch long, coriaceous, variously three-lobed, or with the lobes obsolete on some of the leaves, short-stalked, cuneate, or rounded at the base; margin non-ciliate; bright-green and glabrous beneath; petiole without latex. Fruit small, glabrous; wings parallel and not diverging.

A small tree, scarcely exceeding 30 feet in height, introduced in 1752. Old trees exist at Syon (mentioned by Loudon), Barton, and White Knights.

*** *Leaves irregularly toothed.*

9. *Acer trinerve*, Dippel. A juvenile form of the Chinese *Acer trifidum*, Hooker et Arnott, cultivated in Japan.

Leaves $2\frac{1}{2}$ inches long, 2 inches broad, variable in lobing; lobes acuminate;

¹ In Sargent, *Trees and Shrubs*, i. 180 (1905). Cf. *Acer levigatum*, Wallich, var. *Fargesii*, Rehder, in J. H. Veitch, *Journ. Roy. Hort. Soc.* xxix. 353, fig. 91 (1904).

² Cf. J. H. Veitch, *op. cit.* 348, figs. 86, 90.

³ These axil-tufts are partly covered by a small membrane at the junction of the lateral nerve and midrib.

three-nerved at the rounded base; under surface glaucous, glabrous, without axil-tufts. Petiole without latex. Young branchlets slightly pubescent.

A young tree is growing vigorously at Kew.

10. *Acer cratagifolium*, Siebold et Zuccarini. Japan.

Leaves 3 inches long, coriaceous, ovate, cordate at the base, acuminate at the apex, usually with two short lateral lobes, occasionally undivided, dark-green and shining above, pale and glabrous beneath. Petiole without latex. Bark striate.

A small tree, attaining about 20 feet in height, pyramidal in habit. Introduced by Maries in 1881. Var. *Veitchii* is variegated with irregular blotches of pink and white.

11. *Acer ginnala*, Maximowicz. Amurland, Southern Mongolia, China, Japan.

Leaves 3 inches long, $2\frac{1}{2}$ inches wide; terminal lobe elongated; under surface bright-green, scattered pubescent or glabrescent, without axil-tufts. Petiole without latex.

A small tree, with leaves assuming in autumn a brilliant red tint. Var. *Semenovii*, from Turkestan, has smaller leaves, occasionally five-lobed.

**** *Leaves regularly bi-serrate.*

12. *Acer pennsylvanicum*, Linnæus. North America.

Leaves (Plate 206, Fig. 13) 7 inches long, 6 inches wide; lobes arising from the upper part of the leaf, triangular, acuminate; under surface with scattered minute pubescence; petiole without latex. Young branchlets not glaucous.

Introduced in 1759, and remarkable for its striated bark, green branchlets, and fruit in drooping long racemes. It rarely attains a height of 40 feet.

13. *Acer rufinerve*, Siebold et Zuccarini. Japan.

Leaves $3\frac{1}{2}$ inches long, 3 inches wide, resembling in shape those of *A. pennsylvanicum*, but smaller, and with reddish pubescence along the sides of the primary nerves, forming axil-tufts. Racemes erect and reddish-tomentose. Young branchlets glaucous.

This is the representative in Japan of *A. pennsylvanicum*, which it resembles in bark, habit, and size. The type was introduced by Maries in 1881, and there are thriving small specimens at Kew. A variety, with the leaves white on the margin, was exhibited by Standish in 1869 at the Horticultural Society, and was figured in the *Botanical Magazine*, t. 5793.

14. *Acer capillipes*, Maximowicz. Japan.

This species strongly resembles the last, but differs in the glabrous leaves, and non-glaucous young branchlets; racemes glabrous, pedicels long.

A small tree or shrub, introduced by Sargent in 1892, and represented at Kew by a thriving young specimen. The autumn tint is purplish-brown, suffused with yellow along the nerves.

15. *Acer spicatum*, Lamarck. North America.

Leaves about $3\frac{1}{2}$ inches long and wide, broadly ovate, acuminate, ciliate in margin, glabrous above, pubescent beneath. Petioles and young branchlets pubescent.

A bushy tree, occasionally 30 feet high. According to Loudon,¹ introduced in 1750, and common in his day in ornamental plantations, one tree at Croome, Worcestershire, being reported as 40 feet high. This tree, which was probably incorrectly named, no longer exists. This maple² is extremely rare at the present day, and small specimens at Kew have a miserable appearance.

III. Leaves five-lobed, the basal lobes very small, obscure or obsolete in some of the leaves.

* *Leaves quite glabrous beneath.*

16. *Acer coriaceum*, Tausch. Hybrid between *A. Pseudoplatanus* and *A. monspessulanum*.

Leaves $2\frac{1}{2}$ inches long, 3 inches wide, coriaceous, pale beneath, often deeply cordate, slightly crenulate in margin; lobes broadly ovate, acute or obtuse.

A small tree, rarely seen except in botanical gardens.

17. *Acer glabrum*, Torrey. Western North America.

Leaves 3 inches long and wide, membranous, dark-green and shining above, pale beneath, bi-serrate; lobes acuminate; sinuses very acute at their base; petiole without latex.

A small tree, young specimens of which are thriving at Kew. In the wild state the leaves are extraordinarily variable, being often tri-partite or trifoliolate. It is readily distinguished by its perfectly glabrous thin leaves.

** *Leaves glabrous, except for slight pubescence on the nerves at the base.*

18. *Acer rotundilobum*, von Schwerin.³ Hybrid between *A. Opalus*, var. *obtusatum*, and *A. monspessulanum*.

Leaves $3\frac{1}{2}$ inches long and broad, pale beneath, slightly crenate in margin; lobes short, broadly ovate, cuspidate; sinuses rounded at their base; petiole without latex.

This species, which has leaves thinner in texture and much more glabrous than *Acer Opalus*, is represented at Kew by a fast-growing young specimen, obtained from Simon Louis of Metz.

19. *Acer hybridum*, Spach. Hybrid between *A. Pseudoplatanus* and *A. Opalus*.

Leaves $3\frac{1}{2}$ inches long, 4 inches broad, pale beneath, irregularly and slightly serrate; lobes broadly ovate, shortly acuminate; sinuses acute at their base; petiole with latex.

There are small trees in the collection at Kew.

*** *Leaves pubescent beneath.*

20. *Acer Opalus*, Miller, var. *obtusatum*. Southern Europe, Caucasus, North Africa.

Leaves (Plate 206, Fig. 16) $3\frac{1}{2}$ inches long, 4 inches wide; under surface pale with the pubescence densest on the nerves; lobes broadly ovate or

¹ *Arb. et Frut. Brit.* i. 407 (1838).

² Seedlings which I raised in 1905, from seed collected by me near Ottawa in 1904, have grown vigorously at Colesborne, and are now 3 to 4 feet high.—(H. J. E.)

³ In *Mitt. Deut. Dend. Gesell.* 1894, p. 76, von Schwerin considers the parents to be *A. Opalus*, var. *obtusatum*, and *A. Pseudoplatanus*.

rounded, short, obtuse or acute; margin with small irregular teeth; petiole without latex. In var. *neapolitanum*, the leaves (Plate 206, Fig. 15) are more obscurely lobed, with very dense long pubescence beneath. (See description, p. 663.)

21. *Acer grandidentatum*, Nuttall. Montana southwards to New Mexico.

Leaves (Plate 205, Fig. 4) 3 inches long, 4 inches broad, with three large oblong lobes, separated by sinuses extending half-way to the base of the blade; margin with a few large obtuse lobules, otherwise entire; under surface covered with pale dense pubescence; basal lobes represented by the lowest pair of the marginal lobules.

A small tree, rarely forty feet in height, representing the sugar maple in the West. There is a small specimen thriving in the Kew Collection.

22. *Acer rubrum*, Linnæus. North America.

Leaves (Plate 207, Fig. 27) averaging 3 inches long and broad, variable in shape; under surface silvery white with scattered pubescence; lobes usually triangular, acute or acuminate, sharply toothed or bi-serrate in margin; sinuses acute at the base, variable in depth; base of the leaf truncate or rounded, rarely cordate. (See description, p. 671.)

23. *Acer tetramerum*,¹ Pax. Central China.

Leaves 3 inches long, 2 inches broad, ovate, cordate at the base, indistinctly five-lobed; basal lobes obscure or obsolete; lateral lobes short, triangular, acute and sharply serrate; terminal lobe with two or three pairs of serrated teeth, and prolonged into a long narrow acuminate apex; margin ciliate; upper surface dark-green, scattered pubescent; lower surface pale, covered with white pubescence, densest in the axils; petiole without latex.

A small tree, introduced by Wilson in 1901. Young plants at Coombe Wood are perfectly hardy and free in growth, having already attained 16 feet in height.

IV. Leaves five-lobed; basal lobes well-developed; white or pale beneath; petiole without latex.

* *Leaves not serrate.*

24. *Acer Opalus*, Miller. Southern Europe.

Leaves (Plate 206, Fig. 14) $2\frac{1}{2}$ inches long, 3 inches wide; lobes short, acute, irregularly toothed; under surface with scattered pubescence, denser on the nerves and forming axil-tufts. (See description, p. 663.)

25. *Acer saccharum*, Marshall. North America.

Leaves (Plate 206, Fig. 12) 5 inches long, 6 inches wide; lobes triangular, acuminate, with one or two pairs of sinuate teeth; lower surface with axil-tufts of pubescence, elsewhere glabrous or more or less pubescent. (See description, p. 677.)

26. *Acer hyrcanum*, Fischer et Meyer. South-Eastern Europe, Crimea, Asia Minor, Caucasus.

¹ Cf. J. H. Veitch, *Journ. Roy. Hort. Soc.* xxix. 353, fig. 97 (1904).

Leaves (Plate 207, Fig. 22) $2\frac{1}{2}$ inches long, 3 inches wide; lobes oblong, acute or acuminate, with one to four small teeth; sinuses reaching half the length of the blade, usually rounded at the base; lower surface glabrous except for pubescence along the nerves and forming axil-tufts.

A small tree, representing *A. Opalus* in the Orient and Balkan Peninsula. There are good specimens in the collection at Kew.

27. *Acer Heldreichii*, Orphanides. Balkan Peninsula, Greece.

Leaves (Plate 206, Fig. 17)¹ 4 inches long, 5 inches broad, deeply five-lobed; the middle sinuses narrow, acute at the base, and reaching nearly to the base of the blade; lobes acuminate, with two or three pairs of triangular teeth; under surface with brown pubescence along the primary nerves, forming axil-tufts, glabrous elsewhere.

There is a small tree of this species in the Maple Collection at Kew.

28. *Acer Trautvetteri*, Medwedjeff. Caucasus.

Leaves (Plate 206, Fig. 19) averaging $5\frac{1}{2}$ inches long and 6 inches broad, deeply five-lobed; the middle sinuses acute at the base, reaching two-thirds the length of the blade; lobes long acuminate, with four or five pairs of irregular teeth; under surface glabrous except for conspicuous tufts of reddish-brown pubescence in the axils, at the base, and at the junctions of the primary and secondary nerves. (See description, p. 669.)

** *Leaves distinctly serrate.*

29. *Acer Pseudoplatanus*, Linnæus. Europe, Asia Minor, Caucasus, Northern Persia.

Leaves (Plate 206, Fig. 20) averaging 5 inches long and 6 inches wide; lobes acuminate, coarsely and irregularly serrate and lobulate; sinuses acute at the base, and extending half-way the length of the blade; under surface pubescent along the primary nerves. (See description, p. 641.)

30. *Acer insigne*, Boissier et Buhse. Caucasus, Northern Persia.

Leaves (Plate 206, Fig. 18) resembling those of the sycamore, but usually longer than broad, averaging 7 inches long and 6 inches wide; under surface with pubescence dense along the nerves, forming axil-tufts, and spreading over the leaf between the nerves. (See description, p. 667.)

31. *Acer Volxemi*, Masters. Central Caucasus.

Leaves considerably larger than in the preceding species, attaining 10 to 12 inches in width and length, glaucous beneath, with pubescence confined to the sides of the nerves. (See description, p. 668.)

32. *Acer dasycarpum*, Ehrhart. North America.

Leaves (Plate 207, Fig. 28) about 5 inches long and wide; sinuses rounded at the base, and concave on the sides, extending half-way the length of the blade; lobes long acuminate, with serrated triangular teeth or lobules; under surface silvery white, scattered pubescent, without axil-tufts. (See description, p. 674.)

¹ In the mountains of Greece, the leaves are smaller than is the case in trees growing in Southern Servia, Montenegro, Herzegovina, and Bulgaria, and average only 2 to 3 inches in diameter.

- V. Leaves simple, five-lobed; basal lobes well developed; green beneath; margin entire or with a few teeth and without cilia; petiole containing latex.

* *Margin entire.*

33. *Acer pictum*, Thunberg. Asia Minor to Japan.

Leaves (Plate 205, Fig. 9) about 4 inches long and $4\frac{1}{2}$ inches broad; lobes acuminate, bristle-pointed; basal lobes pointing outwards; glabrous beneath, except for pubescent tufts in the basal axils. Young branchlets green and not glaucous, turning grey in the second year in the type, remaining green in var. *colchicum*. (See description, p. 660.)

34. *Acer Lobelii*, Tenore. Italy.

Leaves (Plate 205, Fig. 8) 4 inches long, $4\frac{1}{2}$ inches wide; lobes acuminate, ending in long sharp points; basal lobes directed forwards; glabrous beneath, except for pubescent tufts in the axils of the primary and secondary nerves and at the base; young branchlets glaucous, remaining green in the second year. (See description, p. 659.)

35. *Acer truncatum*, Bunge. Northern China.

Leaves (Plate 205, Fig. 6) about $2\frac{1}{2}$ inches long and 3 inches wide, truncate or widely cordate at the base; lobes¹ acuminate, bristle-pointed; basal lobes directed outwards; glabrous beneath, except for a slight trace of pubescence at the base. Young branchlets not glaucous, becoming brown in their first winter.

A small tree, attaining 25 feet in height. Introduced some years ago by seeds received from Dr. Bretschneider, and thriving at Kew.

36. *Acer Dieckii*,² Pax. Hybrid between *A. platanoides* and *A. pictum*, var. *colchicum*.

Leaves (Plate 207, Fig. 30) 3 inches long, 4 inches broad; lobes five, shortly acuminate, not bristle-pointed; brown pubescent beneath at the base and in the axils of the primary and secondary nerves. Young branchlets not glaucous, becoming brown in their first winter.

** *Margin toothed.*

37. *Acer platanoides*, Linnæus. Europe, Asia Minor, Caucasus.

Leaves (Plate 206, Fig. 11) 5 inches long, 7 inches wide; lobes acuminate, bristle-pointed; sinuses wide, rounded and open; margin with a few sinuate pointed teeth; glabrous beneath, except for pubescence at the base and in the axils of the primary and secondary nerves. Young branchlets not glaucous, becoming brown in their first winter. (See description, p. 656.)

38. *Acer neglectum*, Lange.³ Hybrid between *A. campestre* and *A. pictum*, var. *colchicum*.

Leaves (Plate 205, Fig. 7) 4 inches long, 5 inches wide; lobes acuminate, not bristle-pointed, the upper three with one or two short teeth; glabrous beneath, except for pubescence along the nerves, densest at the base. Young branchlets not glaucous, pubescent, becoming brown in their first winter.

¹ The terminal lobe in leaves of young trees has often one or two sharp teeth.

² Sometimes known in cultivation as *Acer platanoides*, var. *integrilobum*, Zabel. There is a small tree at Kew, the bark of which is striped with white lines.

³ There are small trees in the Botanic Gardens at Kew and Edinburgh, the bark of which is striped with white lines.

VI. Leaves simple, five-lobed; basal lobes well developed; green beneath; margin serrate; petiole without latex.

39. *Acer Oliverianum*,¹ Pax. Central China.

Leaves $3\frac{1}{2}$ inches long, 4 inches broad; lobes long acuminate, finely and simply serrate; glabrous beneath, except for pubescent tufts at the base and in the axils of the primary and secondary nerves.

A small tree, 20 feet in height. Introduced by Wilson in 1901. Plants at Coombe Wood are thriving, and are about 12 feet high.

40. *Acer argutum*, Maximowicz. Japan.

Leaves about 3 inches long and broad; lobes triangular, acuminate, sharply bi-serrate; lower surface with scattered white pubescence, dense on the nerves and veinlets. Young branches densely pubescent.

A small tree, introduced by Maries in 1881. There are small specimens in the Kew Collection, and a good-sized one at Westonbirt.

40A. *Acer palmatum*, Thunberg. (See No. 46.)

VII. Leaves simple, five-lobed; basal lobes well developed; green beneath; margin with a few teeth or lobules, ciliate.

* *Petiole containing latex.*

41. *Acer campestre*, Linnæus. Europe, Caucasus, Northern Persia.

Leaves (Plate 207, Figs. 23, 24, 25) $2\frac{1}{2}$ inches long, 3 inches broad; margin irregularly and obtusely dentate; dark-green, and pubescent on the nerves above; light-green beneath with scattered pubescence, densest on the nerves, and tufted in the axils. (See description, p. 651.)

42. *Acer macrophyllum*, Pursh. Alaska to California.

Leaves (Plate 205, Fig. 3) about 9 inches long and broad; margin with large triangular lobules or teeth; upper surface dark-green, shining, scattered pubescent; lower surface light-green, glabrescent between the nerves, with tufts of white pubescence in the axils. (See description, p. 681.)

43. *Acer Miyabei*, Maximowicz. Yezo.

Leaves 5 inches long, 6 inches broad; lobes with long acuminate obtuse-tipped apex, and with one or two pairs of obtuse lobules; sinuses narrow, acute at the base; both surfaces pubescent, densest on the nerves; petiole and young branchlets pubescent.

A tree, attaining 40 feet in height. Introduced by Sargent, who obtained seeds from Miyabe in 1892. There are young trees at Kew and Coombe Wood; and one at Grayswood, near Haslemere, was about 18 feet high in 1906.

** *Petiole without latex.*

44. *Acer diabolicum*,² Blume. Japan.

Leaves (Plate 207, Fig. 26) 6 inches long, $6\frac{1}{2}$ inches wide; lobes short,

¹ *Acer* sp. in J. H. Veitch, *Journ. Roy. Hort. Soc.* xxix. 354, fig. 98 (1904).

² Specimens of reputed *Acer Francheti*, Pax, from Coombe Wood, introduced by Wilson in 1901, are indistinguishable from this species. Cf. *Journ. Roy. Hort. Soc.* 353, fig. 88 (1904).

ovate, with obtusely tipped acuminate apex, and one or two pairs of coarse teeth; upper surface dark-green, shining, with scattered pubescence densest on the nerves; lower surface pubescent, dense on the nerves, and forming axil-tufts; petioles and young branchlets pubescent.

A tree, 30 feet high, remarkable for the stinging hairs on the fruit-carpels. Introduced by Maries in 1881, and about 20 feet high at Coombe Wood.

45. *Acer villosum*, Wallich. North-Western Himalayas.

Leaves about 8 inches long and wide; lobes broadly ovate, caudate-acuminate, with a few crenate teeth; pubescent on the primary nerves above; lower surface, petioles, and young branchlets densely pubescent.

A large tree in its native home. A specimen, the only one seen in cultivation, at Grayswood, Haslemere, remains shrubby.

VIII. Leaves simple; lobes more than five, sharply bi-serrate; petiole without latex.

* *Petioles glabrous.*

46. *Acer palmatum*, Thunberg. Japan, Central China.

Leaves about 3 inches in length and breadth; lobes usually seven, occasionally five, long acuminate; sinuses extending half the length of the blade or to near the base; glabrous on both surfaces, except for minute axil-tufts of pubescence beneath. Young branchlets glabrous.

A tree, rarely attaining 50 feet in height. The type was introduced¹ in 1820, and in cultivation is a small tree, occasionally 25 feet high, with numerous small branches and extremely dense foliage. A very large number of horticultural varieties² have been produced in Japan, which are highly valued on account of the varied shape and colour of their leaves, and are commonly cultivated in Europe.

47. *Acer circinatum*, Pursh. British Columbia to California.

Leaves (Plate 205, Fig. 5) about 4 inches long and broad; lobes seven to nine, acute; sinuses reaching about one-third the length of the blade; scattered pubescent on both surfaces at first, ultimately glabrous except for minute traces of pubescence at the base on both sides. Young branchlets glabrous.

A shrub or small tree, rarely 40 feet high. Introduced in 1826, perfectly hardy, and producing fruit freely.

** *Petioles, with dense white long pubescence in spring, more or less persistent till autumn.*

48. *Acer japonicum*, Thunberg. Japan.

Leaves about 4 inches long and broad; lobes usually nine, acuminate; sinuses reaching one-third the length of the blade; both surfaces scattered pubescent, with a tuft at the junction of the blade and petiole above, and axil-tufts beneath. Young branches glabrous.

A small tree, attaining about 20 feet in height. Several varieties are

¹ Loudon, *Encycl. Trees*, 90. The largest specimen which we have seen is at Waterer's Nursery, Knaphill, Woking.

² Cf. J. H. Veitch, *Journ. Roy. Hort. Soc.* xxix. 338 (1904).

mentioned by Mr. J. H. Veitch, one of which, growing well at Mount Usher, Wicklow, Ireland, has deeply-cut leaves, figured on Plate 207, Fig. 29.

49. *Acer Sieboldianum*, Miquel. Japan.

Leaves about 2 inches in length and breadth; lobes usually nine, acuminate; sinuses reaching nearly half the length of the blade; glabrous above with a tuft of hairs at the base; pubescent beneath on the main nerves. Young branchlets covered with dense white pubescence.

A small tree or shrub, very rare in cultivation.

IX. Leaves compound; leaflets three or five.

A. *Leaflets entire in margin.*

50. *Acer Henryi*,¹ Pax. Central China.

Leaflets three, narrowly elliptical, acuminate; under surface green, pubescent on the midrib and lateral nerves, forming axil-tufts. Young branchlets pubescent.

A small tree, attaining about 30 feet in height. Introduced by Wilson in 1900. Young plants at Coombe Wood are now about 10 feet high, and are hardy and thriving.

B. *Leaflets serrate or toothed.*

* *Leaflets green beneath.*

51. *Acer Negundo*, Linnæus. North America.

Leaflets (Plate 205, Fig. 2) usually five, occasionally three; coarsely and irregularly toothed and serrate, sometimes three-lobed; under surface with scattered pubescence, dense on the primary and secondary nerves; petioles glabrous. Young branchlets glabrous, green or glaucous. (See description, p. 684.)

52. *Acer Negundo*, var. *californicum*, Wesmael. California.

Leaflets (Plate 205, Fig. 1) three or five, resembling those of the last species, but with coarser teeth and serrations; lower surface covered with a dense white pubescence. Petioles and young branchlets pubescent. (See description, p. 684.)

53. *Acer cissifolium*, Koch. Japan.

Leaflets three, obovate or oblong, with a long acuminate or cuspidate apex; margin ciliate with serrations ending in fine points; under surface glabrous, except for axil-tufts and slight pubescence along the midrib. Young branchlets pubescent.

A small tree, perfectly hardy, and fruiting freely in this country. A specimen of this species about 30 feet high, which Prof. Sargent says is as large as he saw it in Japan, is growing at Westonbirt.

¹ *Acer sutchuense*, Franchet, also from Central China, differs in the glabrous branchlets and serrate leaflets, which are pale beneath, and has not yet been introduced, the plants referred to this species in *Journ. Roy. Hort. Soc.* xxix. 353, figs. 93, 96, being *A. Henryi*, Pax. *Acer manschuricum*, Maximowicz, a native of Manchuria, which differs little from *Acer sutchuense* in foliage, is said to be in cultivation in Germany (*Mitt. Deutsche Dendrol. Ges.* 1906, p. 30).

** *Leaflets pale beneath.*

54. *Acer nikoense*, Maximowicz. Japan, Central China.

Leaflets three; terminal one about 4 inches long; lateral leaflets slightly smaller and unequal-sided; elliptical, acute; margin crenate, ciliate; under surface villous on the midrib and nerves, scattered pubescent between the nerves. Petioles stout, and like the young branchlets, densely woolly.

A tree, attaining 50 feet in height, with smooth, dark, slightly furrowed bark; leaves turning brilliant scarlet in autumn. Introduced by Maries in 1881. A tree at Coombe Wood is about 30 feet high.

55. *Acer griseum*, Pax. Central China.

Leaflets three; terminal leaflet about 2½ inches long; lateral leaflets smaller and unequal-sided; coarsely toothed and ciliate in margin; woolly pubescent on the midrib and nerves beneath. Petioles slender, and, like the young branchlets, pilose.

A tree, attaining 40 feet in height, with bark peeling off like a birch. Introduced by Wilson in 1901. Young plants at Coombe Wood are about 3 feet high. (A. H.)

ACER PSEUDOPLATANUS, SYCAMORE

Acer Pseudoplatanus, Linnæus, *Sp. Pl.* 1054 (1753); Loudon, *Arb. et Frut. Brit.* i. 414, 448, (1838); Willkomm, *Forstliche Flora*, 749 (1887); Mathieu, *Flore Forestière*, 37 (1897).

A large tree, attaining about 100 feet in height and 20 feet in girth. Bark¹ smooth and greyish on young trees, fissuring and scaling off in large strips on old trunks. Leaves (Plate 206, Fig. 20) 4 to 8 inches in length and width, cordate at the base; lobes five, ovate, acuminate, coarsely and irregularly serrate, lateral lobes larger than the basal ones; sinuses extending about half-way to the midrib, and very acute at the base; upper surface dark-green, shining, glabrous; lower surface paler green and glaucous or sometimes reddish, pubescent along the principal nerves; petiole without latex. The leaves usually turn brownish in autumn, and are often disfigured by black blotches, caused by the fungus known as *Rhytisma acerinum*, Fr., which, however, does little or no harm to the vitality of the tree.²

Flowers in long pendent racemes, composed of umbellate cymes of three flowers each, the central flower in the cyme usually perfect, the two lateral flowers staminate, with longer stamens and abortive ovaries; pedicels short; sepals five, deciduous, greenish-yellow; petals five, greenish-yellow, imbricate, inserted at the margin of a fleshy hypogynous disc. Stamens eight, inserted on the disc; filaments subulate; pubescent below, ovary tomentose. Fruit: keys divergent at a varying

¹ In the Edinburgh Botanic Garden there are trees about a foot in diameter, which have remarkably white bark, resembling that of a birch. The largest sycamore in the garden measured, in 1906, 78 feet in height, and 13 feet 7 inches in girth.

² Cf. *Board of Agriculture, Leaflet No.* 183.

angle, generally directed forwards, about $1\frac{1}{2}$ inch long; wings green, narrow below, scimitar-shaped. Seed obovate, without albumen; cotyledons narrow, long, either spirally coiled or plicate.

Seedling.¹—Cotyledons normally two, rarely three, carried above ground on germination, $1\frac{1}{2}$ to 2 inches long, oblong, sessile, obtuse, entire in margin, obscurely three-nerved, glabrous, pale-green. Caulicle, $\frac{1}{2}$ to 1 inch long, glabrous, ending in a tapering, flexuose, primary root, which gives off a few lateral fibres. Young stem terete, glabrous. First pair of leaves, ovate, cordate at the base, palmately five-nerved, acuminate, irregularly serrate. Second and third pairs similarly cordate and five-nerved, distinctly three-lobed; terminal lobe long, triangular-ovate; lateral lobes short, broad, with two indistinct lobules or teeth. Succeeding pairs resemble those of the adult plant.

Seedlings with three cotyledons, observed by Sir W. Thiselton Dyer,² bore leaves in whorls of threes in their first and second years; but in the third and following years they reverted to the ordinary type with opposite leaves.

IDENTIFICATION

In summer the sycamore is readily distinguishable by the shape of the leaves, and can only be confused with *A. insigne*, from which it differs markedly in the buds, as explained under the latter species.

In winter the twigs are shining, glabrous. Buds sessile, ovoid; terminal buds larger than the lateral buds, which arise from the twigs at an angle of 45° ; scales, six to eight visible externally, in opposite decussate pairs, green with dark edges, glabrous or slightly pubescent near the tip, ciliate in margin. Leaf-scars not joining around the twig, crescentic or V-shaped, three-dotted. The bud-scales are homologous with leaf-bases, and fall off when the bud opens, showing at this stage a minute three-lobed projection at the tip, which corresponds to a leaf-blade.

VARIETIES

The sycamore is remarkably constant in foliage in the wild state,³ only one well-marked geographical form being known:—

Var. *villosa*, Parlatores, *Fl. Ital.* v. 404 (1872). Leaves coriaceous; base widely cordate, margin coarsely toothed, lower surface pubescent throughout in early spring. Fruits usually tomentose, with very broad wings. This variety occurs in the mountains of Sicily, Calabria, and Dalmatia.

In the common wild form the leaves are scarcely coriaceous, and are only pubescent along the nerves beneath, while the fruit is glabrous. From the common form, numerous varieties have arisen in cultivation, as many as fifty being

¹ Cf. Lubbock, *Seedlings*, i. 360, f. 252 (1892).

² *Ann. of Botany*, xvi. 553, plate xxiv. (1902). In plate xxv. an abnormal seedling is figured, in which three cotyledons are followed by two leaves, one of which is bi-partite. Cf. Loudon, *op. cit.* p. 415.

³ On a tree growing in Tullymore Park, Co. Down, Ireland, many of the branchlets bore the leaves alternately and not in pairs. Specimens of this were sent to the Kew Herbarium in 1871.

enumerated by Pax and von Schwerin;¹ but many of these show only trifling variations, often inconstant in character; and only the most important varieties will be mentioned here:—

1. Var. *pyramidale*, Nicholson.² Pyramidal in habit with ordinary foliage; originated in a row of trees, close to the gate of Roger, M'Clelland and Co.'s Nursery, Newry.

2. Var. *erythrocarpum*, Carrière. Fruits red in colour and abundant, producing a fine effect in autumn. This variety is said to have originated in M. Ferrand's nursery at Cognac; but according to von Schwerin is of common occurrence in the wild state in the Bavarian Alps.

3. Var. *palmatifidum*,³ Duhamel. Leaves deeply cut, being five-partite.

4. Var. *ternatum*, von Schwerin. Leaves tri-partite to the base, so that they are ternate or nearly so.

5. Var. *vitifolium*, Tausch. Leaves large, deeply cordate at the base, with three broad rounded lobes, the basal lobes being very small or obsolete.

6. Var. *clausum*, von Schwerin. Leaves deeply cordate, with the sinus closed by the overlapping of the basal lobes.

7. Var. *crispum*, von Schwerin. Leaves wrinkled in margin. Forms also occur in which the leaves are rolled either backwards or inwards from the margin.

8. Var. *cruciatum*, von Schwerin. Leaves three-lobed, the lateral lobes being exactly at right angles to the median lobe.

9. Var. *jaspideum*, von Schwerin. Bark yellowish; leaves of the ordinary form.

10. Var. *euchlorum*, Nicholson.² Leaves deep-green above, normal in shape. This variety originated in Späth's nursery at Berlin.

11. Var. *splendens*, von Schwerin. Leaves red at the time of opening, afterwards becoming green. This includes var. *Rafinesquianum*, Nicholson, in which the young leaves are blood-red; var. *cupreum*, Behnsch, in which they are copper-red at the time of opening; and var. *metallicum*, von Schwerin, with the leaves at first yellowish, afterwards copper-coloured, and ultimately green.

12. Var. *albo-variegatum*, Loudon. Stripe-leaved sycamore. Leaves splashed and marked with white. This variety is mentioned in the *London Catalogue of Trees*, published in 1730, which states that it comes true from seed. It often grows to a large size, a tree at Highmore Hall, Oxfordshire, the seat of G. T. Inman, Esq., being 72 feet high by 9 feet in girth.

13. Var. *corstorphinense*, von Schwerin.⁴ Corstorphine or Golden Sycamore. Leaves often three-lobed, coming out yellow in spring, and in some places appearing about a fortnight earlier than those of the ordinary form. The colour is a fine golden one, and usually lasts till summer is advanced.

Loudon named this variety *flava-variegata*, variegated with yellow, which is

¹ *Gartenflora*, xlii. 258 (1893). Cf. also Nicholson, *Gard. Chron.* xv. 300 (1881).

² *Gard. Chron.* xv. 300 (1881).

³ This is var. *longifolium*, Loudon, *Trees and Shrubs*, 86 (1842).

⁴ *Gartenflora*, xlii. 263 (1893).

scarcely a happy designation, and states that the original tree grew in the grounds of Sir T. Dick Lauder in the parish of Corstorphine, near Edinburgh.

The Corstorphine sycamore is well illustrated and described by Sargent,¹ who quotes from a book, published locally by Mr. G. Upton Selway, called *A Midlothian Village*. The tree has a romantic history, as being the only survivor of an avenue which formerly led to an old manor-house belonging since 1376 to the Forrester family. James Baillie, second Lord Forrester, who took an active part against the Commonwealth, and became involved in difficulties on account of a heavy fine laid on him by Cromwell, is said to have quarrelled with his sister-in-law on August 26, 1679, and to have been murdered by her at the foot of this tree.

Mr. R. Galloway, Secretary of the Royal Scottish Arboricultural Society, informs us that this tree now stands in a garden attached to one of the houses in the village of Corstorphine, and measured in 1905, 61 feet in height and 11 feet in girth. A tree of this variety, which in 1904 measured 62 feet high by 5 feet 10 inches in girth, grows at Kilmarnock, and is believed by the Rev. Dr. Landsborough to be 112 years old. He says that this variety does not grow so fast or attain such a large size as the common sycamore, as owing to its early leafing, the golden sycamore is liable to suffer from spring frosts.

14. Var. *Worlei*, Rosenthal. Another form of the golden sycamore, with reddish leaf-stalks and bright-yellow leaves, which are orange-coloured at the time of opening.

15. Var. *aucubæfolium*, Nicholson. Leaves marked with yellow spots, similar in appearance to those on the leaves of the common *Aucuba japonica*. Originated as an accidental seedling in Little and Ballantyne's nursery at Carlisle.

16. Var. *Leopoldi*, Lemaire, *Illust. Horticole*, xi. t. 411 (1864). Leaves deep pink at the time of unfolding, afterwards variegated with pink and purple. This originated in the seed-bed in the nursery of M. Vervaene, at Ledeborg-les-Gand, by whom it was sold to Van Geert.

17. Var. *Webbianum*, Nicholson. Leaves with silvery streaks. This originated in the nursery of C. Lee and Son at Isleworth.

18. Var. *purpureum*, Loudon. Purple-leaved sycamore. Leaves purple beneath. The petiole and wings of the fruit are often also bright-red. This variety originated in 1828 in Sanders' nursery in Jersey.

Various sub-varieties are known as var. *atropurpureum*, Späth, under surface of the leaves very dark purple; var. *Nizeti*, von Schwerin, leaves purple beneath, spotted with yellow above; var. *Handjeryi*, Späth, vinous-purple beneath, upper surface with yellow minute spots; var. *purpureo-variegatum*, Nicholson, with rose-coloured or white stripes on a purple ground. The latter originated in Van Volxem's nursery at Perck, and is considered by Nicholson to be identical with var. *variegatum*, Carrière, *Rev. Hort.* 1877, p. 334, which originated as a branch sport from the ordinary purple-leaved variety in the Bois de Boulogne nurseries at Longchamps in 1874.

19. Var. *flavo-variegatum*, Hayne.² Leaves splashed and marked with yellow.

¹ *Garden and Forest*, vi. 202, f. 32 (1893).

² *Dendrol. Flora*, 212 (1822).

DISTRIBUTION

The exact limits of the distribution of the sycamore are difficult to define, as the tree has been extensively planted for centuries outside of its original home, which in Europe may be roughly described as the great central chain of the Pyrenees, Alps, and Carpathians, with the mountains and hilly districts radiating from them in all directions. It is truly wild in the Pyrenees, and reaches its western limit in the Iberian Peninsula in the Cantabrian Mountains, being absent from the greater part of Spain and all Portugal.¹ It occurs in all the mountainous and hilly districts of France except in the north-west; in the Alps generally; in the mountains of Germany, as far north as the Harz Mountains; in the Carpathians, Apennines, mountains of Sicily, Dalmatia, Bosnia, Servia, and in the mountains of Thessaly and Epirus in Greece.² In Russia it occurs in the provinces along the Black Sea, extending inland along the banks of the great rivers, and in the mountains of the Crimea. It is widely spread in the mountains of Asia Minor, Armenia, and the Caucasus,³ where it grows at all altitudes from sea-level to 4000 feet. Its extreme easterly point is near Astrabad, south-east of the Caspian Sea, about lat. 37°.

The tree is not a native of the British Isles, North-West France, Belgium, Holland, the North German plain, Denmark, Scandinavia, or the greater part of Russia. In these countries the sycamore, however, flourishes, and is extensively cultivated, reaching its northerly limit as a planted tree, according to Schübeler, in Norway and Sweden about lat. 64°.

It is usually met with, in the wild state, as an isolated tree or in small groups, being only known to form pure woods, and those of no great extent, in the Thuringian forests. It does not occur naturally on light soils, on heavy clay soils, or on wet ground; and apparently, in order to compete with other trees, must grow on a soil rich in mineral constituents, such as often occurs in valleys or ravines, or in pockets here and there in forests, where the soil is generally poor. It forms a part of the great beech and silver-fir forests; but reaches higher than either of these species on the mountains, where it dwindles to a sub-alpine shrub near the timber line. In the Bavarian forests it grows in the zone between 1000 and 4400 feet altitude, and a peculiar form occurs, with twisted curved branches, which Dr. Christ⁴ has not observed elsewhere. In Switzerland,⁴ it ascends to 5300 feet, and is most plentiful at Sernfthal above Elm. In France it ascends to about 5000 feet, and is most generally met with in the beech forests, its abundance and flourishing condition being considered a sure index of a fertile soil.

The sycamore has not been found in the fossil state in the British Isles. Clement Reid⁵ hazards the suggestion that it was perhaps introduced by the

¹ Willkomm, *Pflanzenverbreitung auf der Iberischen Halbinsel*, 94 (1896).

² Halácsy, *Consp. FL. Græca*, i. 285 (1900).

⁴ Christ, *Flore de la Suisse*, 278, 279 (1907).

⁵ *Origin British Flora*, 16 (1899).

Romans. Ray states, *Synopsis*, 230, published in 1690, that the sycamore was then planted in cemeteries and about the houses of the nobility, and that it was nowhere wild in England. It would appear from this that it was by no means a common tree in Britain in the seventeenth century. (A. H.)

CULTIVATION

The sycamore, or plane as it is commonly called in Scotland, is a tree which thrives in almost any dry soil, and seems to reach its greatest size or perfection in the colder hilly parts of England and Scotland, where nearly all the finest specimens we know of are to be found. In the Cotswold hills it is the only tree, except the wych-elm and the beech, which attains a maximum of size, and even here there are none quite equal to some trees in Scotland.

It is absolutely unaffected by the severest frosts¹ at any season, and is rarely attacked by insects or fungoid diseases, ripens seed profusely almost every year, and reproduces itself almost everywhere with such ease that in my own district I believe it might overrun the country if allowed to do so. It grows rapidly when young, and, though not usually planted as a forest tree, is well suited to produce timber in windy situations, where more valuable trees will only languish. Its foliage in spring and summer is very handsome, but assumes a dirty and ragged aspect in autumn, especially in smoky districts, and therefore it is not suitable for town planting. It does not grow so well, or live so long on sand, gravel, or on heavy clay as on limestone. Its branching habit makes careful pruning or close crowding necessary if clean tall stems are desired, and as its timber is most valuable in the form of clean boles of considerable girth, it must be looked on as of somewhat uncertain economic value as a forest tree. But I have found the sycamore a very useful tree for filling up blanks in thin woods, where, when once established, it grows on dry soil at least twice as fast as the ash, and four or five times as fast as the oak.

No tree can be raised from seed more cheaply and easily than the sycamore, and grafting or budding is only resorted to in the case of varieties. The seed falls in the late autumn and winter, and grows in abundance in gravel paths, so that when only a few are wanted, self-sown seedlings can usually be obtained. The seed germinates very early, often in February, though if kept dry it should not be sown before March. It is very liable to be smothered by grass in the first year, and is so easy to transplant that it will be found better to move self-sown seedlings at a year old to the nursery.

In the spring of 1900 I found great quantities of young plants recently germinated on the top of a bare hill pasture, where I wished to renew a clump of trees forming a conspicuous landmark, and had a fence put round them, in order to protect the seedlings from rabbits and cattle; but in the summer I found that every one had been suppressed by grass. In the following year I sowed sycamore seeds with many other tree seeds in lines in cultivated soil, where I

¹ According to Lord Leicester it is on the coast of Norfolk the hardest tree, except *Quercus Ilex*, which bears better the force of the gales from the sea.—(A. H.)

wished to establish a plantation by sowing, and they were the only species of which the plants showed up well in the lines the first summer. As they were much too thick in the rows, about 10,000 were transplanted the following winter, when 4 to 8 inches high, and these grew so fast in the nursery that in two years more I had trees 4 to 6 feet high, whilst those which were left where they were sown, after four years' growth had made very little progress, few exceeding 12 to 18 inches in height, and many remaining so stunted that they could hardly be recognised among the grass.

Though rabbits will not eat it so readily as beech or ash, yet where they are found, the sycamore is not safe from their attacks until it is a foot or more in diameter; after which I have not seen them touch it; and in a park, deer, however hungry, do not bark this tree, though they will peel the branches when cut. It shoots freely from the stool when treated as coppice wood, and on dry soil produces a much greater bulk of poles than ash or lime will do, but in this form is not so valuable as ash or oak, because the poles are neither strong nor durable, and are not used for hurdle-making.

REMARKABLE TREES

Among the many large sycamores which I have measured, it is hard to say which is the finest, but in England I think the palm must be awarded to a tree near the Marquess of Ripon's house at Studley Royal, Yorkshire. This tree is about 104 feet high, by 17½ feet in girth. It has a very large burr close to the ground, where it is 29½ feet round, and a clear bole of about 30 feet.

An almost equally fine tree, growing in front of the Earl of Darnley's house at Cobham Hall, Kent, was figured by Strutt, plate xxx. He gave its height as 94 feet, its girth at the ground 27 feet, and its cubic contents 450 feet. When I measured it in 1905, I found that it was about 105 feet by 17 feet 9 inches at 5 feet up, and still quite healthy. At Penshurst, in the same county, there is a fine tree 104 feet by 13 feet 10 inches.

The tree figured in Plate 179 grows on my own lawn, constantly in sight as I write, and though not quite so large as some others, is still a beautifully-shaped tree, 100 feet by 15 feet. Its top, I grieve to say, has been dying back for some years. At Lypiatt Park, near Stroud, there is a fine tree close below the house, of which Sir John Dorington has sent me a photograph. It measures about 90 feet by 18 feet, dividing near the base into three main stems.

At Essendon Place, Herts, Mr. H. Clinton Baker measured a tree in 1906 as 94 feet high by 9 feet 9 inches in girth. At Fawley Court, near Henley, close to the Thames, in a dense plantation, a tree, estimated by Henry in 1907 to be 100 feet or more in height, was 12 feet 8 inches in girth. At Shiplake House, also near Henley, there is a widespreading tree, 85 feet high and 10 feet 3 inches in girth.

At Lowther Castle, Westmoreland, the seat of the Earl of Lonsdale, there is an immense tree no less than 19 feet 9 inches in girth, but not so tall as,

some I have mentioned; and at this fine place I also remarked a large sycamore, with the bark scaling off in a very unusual way, so that it resembled the bark of an old hickory. I am indebted to Capt. Parkin for a good photograph of this curious tree.

At Mitford Castle, near Morpeth, Northumberland, the seat of Edward Mitford, Esq., Mr. W. H. Mason informs me that there is a very fine tree, about 100 feet in height, with a girth of $18\frac{1}{2}$ feet, and a spread of branches 102 yards in circumference.

In Wales there are many fine trees, the largest that I know being at Dynevor Park, where the Hon. Walter Rice has measured one 81 feet by 15 feet 3 inches in girth. At Gwydyr Castle, Carnarvonshire, a tree, dividing into two stems at ten feet from the ground, is 86 feet high by 14 feet 8 inches in girth.

In Scotland nearly every large place has fine sycamores, some of great age; but I have seen none to surpass in size, shape, and perfection the one which I figure (Plate 180) in front of Newbattle Abbey. This tree in 1904 was about 95 feet high by 16 feet 6 inches in girth at 5 feet, below which its roots spread out very widely. There are other large sycamores here, said by Loudon to have been planted before the Reformation, and one, which I could not identify, before 1530. Judging, however, from a beautiful photograph taken by Col. Thynne, the Newbattle tree is exceeded in height and equalled in girth by one (Plate 181) at Drumlanrig Castle, the seat of the Duke of Buccleuch, of which he gives the height as 105 feet and the girth 19 feet 6 inches. Henry, however, who measured the same tree in December 1904, made it 101 feet by 18 feet, with a bole 22 feet high dividing into two large stems.

At Castle Menzies, Perthshire, there are two magnificent trees, the largest of which is figured by Hunter.¹ I found it in April 1904 to be 92 feet high by 19 feet 2 inches in girth. Probably this is the same of which Hunter says that it contains upwards of 1000 feet of timber. I have a good photograph of it, but prefer to figure (Plate 182) another sycamore, also at Castle Menzies, which, though not so tall, is 20 feet 4 inches in girth, and is remarkable on account of its short trunk, covered with great burrs and excrescences.

The tallest tree of this species which we know in any country is one at Blair Drummond, Perthshire, the seat of H. S. Home Drummond, Esq., which is drawn up in a dense wood behind the house. It was measured by Henry in 1904 as no less than 108 feet in height, though only 10 feet in girth. In open ground on the same property there is another tree² of an entirely different character, which is $19\frac{1}{2}$ feet in girth with a short bole of 9 feet, dividing into two great limbs and forming a very widespreading crown. Its height is only 85 feet. Large variegated sycamores, one 70 feet high by 13 feet 10 inches in girth, also are growing at Blair Drummond.

At Kippenross, near Dunblane, the seat of Captain Stirling, there are the

¹ *Woods, Forests, and Estates of Perthshire*, 397 (1883).

² In Loudon, *Gard. Mag.* 1840, p. 505, there is a list of measurements of trees at Blair Drummond; and a sycamore, 80 feet high and 16 feet in girth in 1841, is probably this tree.

remains of an immense sycamore which was struck by lightning in 1860. It measured in 1821 as follows:—

	Feet.	Inches.
Height	100	0
Girth at smallest part of trunk	19	6
„ where branches separate	27	4
„ at ground	42	7
Extreme width of branches	114	0
Cubic contents	875	0

Captain Stirling informs me that its age, which can be determined from an entry in the records of the estate, is about 440 years. Hunter¹ says that this tree was known as the big tree of Kippenross in the time of Charles II., and in 1806 was described by Mr. Ramsay of Ochertyre, as “now much the greatest in this country.” He adds that in 1740 the late John Stirling of Keir was told by a woman over eighty, that though all the other trees had grown much in her recollection, she knew of no change in the great tree which many people came to see as a curiosity.

At Keir, Perthshire, there is a remarkable sycamore stool, with eleven stems, 85 feet in height and averaging in girth about 6 feet.

Sir Herbert Maxwell sends me the measurement of a sycamore behind the Birnam Hotel at Dunkeld, which Hunter figures on the frontispiece of *Woods and Forests of Perthshire*, and says² that it was supposed to be 1000 years old; this of course is without foundation, and the girth, 19 feet 8 inches, as taken by Sir H. Maxwell, is precisely the same as Hunter gave 25 years before.

In the parish of Cramond, county of Edinburgh, a tree of this species is stated in the *Old and Remarkable Trees of Scotland*, p. 198, to have attained 130 feet in height, but I must doubt the accuracy of this statement, of which I can obtain no confirmation.

Many large trees in the south-west of Scotland are recorded by Renwick,³ of which one at Erskine House, Renfrewshire, is 75 feet high and 19 feet 4 inches in girth, but this has only a short bole of 7 feet. Another at Logansraes, in the same county, is 80 feet high and 18 feet 3 inches in girth, with a spread of 95 feet. Strutt figures, on plate 3 of *Sylva Scotica*, a sycamore at Bishopton, in Renfrewshire, which was about 60 feet by 20 feet and contained 720 feet of timber.⁴

At Inveraray Castle, close to the big Scots pine, there is a fine sycamore about 100 feet high, with a bole of about 35 feet, but its girth in 1906 was only 12 feet 2 inches.

At Invergarry Castle there is an avenue of sycamores, said to date from 1689.

In Ireland, the sycamore is commonly planted and grows with great vigour, but Henry has seen no specimens rivalling those of Scotland in size. At

¹ *Woods, Forests, and Estates of Perthshire*, 286 (1883).

³ *Measurements of Notable Trees*, Glasgow, 1901.

⁴ Sir C. Renshaw informs me that this tree still survives, and that, according to local tradition, John Knox formerly preached under it, but that it is not so fine a tree as one at Erskine House, the property of W. A. Baird, Esq.

² *Ibid.* 73.

Kilmacurragh, Co. Wicklow, there is a fine tree, 15 feet in girth with an estimated height of 90 feet. This is supposed to be the tree referred to by Hayes,¹ as being in 1794 the largest then living in Wicklow; but if this is the case the tree must have remained stationary in growth for many years. At Powerscourt there is a fine widespreading tree 80 feet high by 14 feet in girth. At Carton, a sycamore, remarkable for its small leaves, which are only half the ordinary size, measured, in 1903, 87 feet in height and 11 feet in girth. At Woodstock, Co. Kilkenny, a tree was, in 1901, 73 feet high by 11½ feet in girth; and, according to the records kept here was 7 feet 10 inches in 1825, 8 feet 2 inches in 1830, and 8 feet 11 inches in 1846. At Cushendun, Co. Antrim, in a situation completely exposed to the blasts from the sea, in the garden of Miss M'Neil, a sycamore is 60 feet high by 13 feet in girth.

On the Continent the sycamore is not so often planted as in England, but in Switzerland and the Austrian Alps it attains a great size. Two are figured in the *Baum-Album der Schweiz*,² of which one, formerly growing at Truns in the Oberland at an elevation of 853 metres, close to the old chapel of St Anna, is interesting on account of its great age. Under this tree the Grey League, one of the three bodies which, when confederated in 1525, formed the canton of Grisons, were sworn in 1424; and though the last remnant of the veteran was torn up by a storm in 1870, it shows that the sycamore may attain an age of about 600 years. A figure of it, taken from a painting in the possession of M. Descurtins of Coire, is given in the work from which I quote. A young tree raised from its seed was planted in 1870 on the spot, and was in 1896 already over 30 feet high and 4 feet 4 inches in girth.

By the kindness of M. Coaz, Director of the Swiss Government Forests, I am able to reproduce a beautiful photograph (Plate 183) of an even finer tree, now standing on the land of the commune of Kerns, in Melchthal, canton of Unterwalden, at an elevation of 1350 metres, in deep loamy soil, on a formation described as *calcaire schrattique*. This immense tree measures 12.20 metres in circumference above the point where its trunk expands, and at 5 feet from the ground 8.85 metres, equal to about 29 feet, thus exceeding any tree of which we have a record in this country. At 12 feet from the ground a branch about 9 feet in girth is given off. The height is not stated, but the branches spread to a diameter of about 25 yards, and though the trunk is hollow and covered in places with a moss (*Leucodon sciaroides*), the tree still bears fruit. Its aspect reminds me strongly of many sycamores which grow on the Alps of the Vorarlberg in Austria, and especially of one, from the cover of whose trunk I shot my last chamois, a cunning old buck, which for four seasons I had hunted in vain.

TIMBER

The wood of the sycamore is of a white colour, close grain, and moderately hard; and when of large size is one of the most valuable woods we have, as it has been found the most suitable for making the large rollers, technically called

¹ *Practical Essay on Planting*, 121 (1794).

² Published by Schmid, Francke & Co., Bern, 1896.

"bowls," which are used in cotton-dyeing and washing machines. For this purpose it must be cut early in the winter, in order to preserve the purity of its colour, and removed as soon as possible, for if left standing till the sap begins to rise, which it does early in spring, or left lying exposed to the weather, it is soon depreciated in value. Butts of moderate age, free from branches or knots and over 18 or 20 inches quarter-girth, are worth from 3s. 6d. to 5s. per foot, or even more when near their best market, which is in Lancashire. The measuring of this timber presents a difficulty when, as often happens, the logs are not round or quite straight, as in conversion they have to be turned down to a true cylinder, and in trees grown in the open, as is usually the case, large buttresses and swellings often occur, for which allowance must be made.¹

Smaller and rougher trees are worth much less than large clean ones, and are converted into planks and smaller rollers, which are used by manufacturers of dairy utensils and mangles, brush-makers, toy-makers, and turners, for bobbins and many small articles. From 1s. to 2s. per foot is a fair price for such timber, but the price varies much, according to the locality. A certain quantity of sycamore is cut into veneers, and when the wood has a wavy grain, like that of the so-called fiddle-backed maple, it is very ornamental, and may be used with good effect for the interiors of cabins, railway carriages, and furniture. What is known in the furniture trade as "hare wood" is, I believe, nothing more than fine wavy sycamore, which by age or staining has taken a pinkish-brown colour.

(H. J. E.)

ACER CAMPESTRE, COMMON MAPLE

Acer campestre, Linnæus, *Sp. Pl.* 1055 (1753); Loudon, *Arb. et Frut. Brit.* i. 428 (1838); Willkomm, *Forstliche Flora*, 764 (1887); Mathieu, *Flore Forestière*, 42 (1897).

A tree, rarely attaining 70 feet in height, usually smaller. Bark, corky on young trees, ultimately becoming fissured and scaly. Young branchlets usually pubescent, in some forms glabrous, and not remaining green throughout the first year. Leaves variable in size, averaging 2½ inches long and 3 inches broad, cordate at the base, five-lobed, the two basal lobes occasionally obsolete; lobes shortly acuminate; margin plainly ciliate, usually with a few coarse obtuse teeth; upper surface dark-green, pubescent on the nerves; lower surface light-green, with scattered pubescence, dense on the nerves and tufted on the axils. Petiole with milky sap. Plate 207, Figs. 24 and 25, taken from adult trees growing in England, show considerable variation in the shape of the leaves and the amount of pubescence on the branchlets. Fig. 23 represents the foliage of a coppice shoot in a French forest.

Flowers, in corymbs, at first erect, afterwards pendent, opening with or soon after the leaves, green in colour, with pubescent pedicels and sepals; lateral flowers

¹ William Low, Esq., of Monifieth, Scotland, informs me that in his neighbourhood there is a large consumption of sycamore for making rollers used in the jute and flax-spinning industry. These are from 7 to 9 inches in diameter, and 1½ inch thick. They cost about 30s. per gross, and are preferred when made of hard and slowly grown Scotch timber, which is considered to be less liable to crack in drying, when cut in transverse sections.

staminate, others mixed; ovary in perfect flowers glabrous. Fruit¹ with horizontally spreading wings, glabrous or pubescent.

In summer it is distinguishable from all the other small-leaved maples by the leaves being ciliate in margin, with petioles containing milky sap. In winter the corky ridges on older twigs are characteristic; young branchlets are glabrous or pubescent towards the tip, with crescentic three-dotted leaf-scars, which join at their ends around the twigs. Terminal buds sessile, about $\frac{1}{5}$ inch long, with scales pubescent at the apex and fringed with white cilia. Lateral buds almost appressed to the twigs.

VARIETIES

Two varieties occur in the wild state both in England and on the Continent; var. *hebecarpum*, in which the carpels of the fruit are pubescent, and var. *leiocarpum*, with glabrous fruit. The leaves show considerable variation in shape and in the amount of pubescence on the lower surface; and six sub-varieties are distinguished by Schneider,² as follows:—

1. *subtrilobum*. Leaves three-lobed; fruit pubescent.
2. *lobatum*. Leaves with five obtuse, toothed lobes; fruit pubescent.
3. *acutilobum*. Leaves with five acute, almost entire lobes; fruit pubescent.
4. *pseudomarsicum*. Leaves three-lobed; fruit glabrous.
5. *normale*. Leaves with five obtuse, toothed lobes; fruit glabrous. Var. *collinum* is a form of this, with the leaves glabrous beneath.
6. *austriaca*. Leaves with five acute, almost entire lobes; fruit glabrous.

In var. *pulverulentum*, as cultivated at Kew, the leaves are spotted with white. This appears to be a very slow-growing tree. In var. *variegatum* the leaves are white in margin.

A hybrid² between this species and *A. monspessulanum* has been found wild in Herzegovina, and has been named *A. Bornmülleri*, Borb. *A. neglectum*, Lange, described above in the Synopsis, p. 637, is a hybrid between *A. campestre* and *A. pictum*, var. *colchicum*.

DISTRIBUTION

Acer campestre is spread generally throughout Europe, with the exception of the greater part of Scandinavia, Finland, Northern Russia, and the south of the Iberian Peninsula; and extends into Western Asia, where it is found in the Caucasus and in the province of Astrabad in Persia, where it reaches its most easterly and southernmost point.

In Norway, according to Schübeler, it is not indigenous; but it lives as far north as Trondhjem and grows as tall as 25 feet in the south. Its northern limit as a wild tree, beginning in the province of Scania in South Sweden, crosses into the province of West Prussia in Germany, where it grows at Thorn, and extends through Poland and Central Russia to Vladimir, where it reaches its northernmost

¹ A series of abnormal fruits, each with three to eight keys, instead of two, the normal number, is exhibited in the Kew Museum. Cf. Sir W. Thiselton-Dyer in *Ann. of Bot.* xvi. 556 (1902).

² Schneider, *Laubholzkunde*, ii. 230, 231 (1907).

and most easterly point in Russia. Its easterly limit extends from here through Voronej and Kharkof to the Crimea, where it grows in the mountains. It is also met with in the region of the steppes, growing on the banks of streams. The southern limit in Europe is not exactly known; but the tree occurs in the mountains of Turkey, Dalmatia, Italy, and Sicily, and in the Pyrenees and the mountainous parts of the northern provinces of Spain and Portugal.

Inside these limits, its distribution over the continent of Europe is not at all uniform, and is very scattered, as it is totally absent from many districts where the climate or the conditions of the soil are unfavourable. It is rather a tree of the plains, valleys, and hills, than of the mountains; and is especially met with in the broad-leaved forests, often growing as underwood in coppice with standards, and on the edges of woods, on the banks of streams, and in hedges. It ascends in Southern Bavaria to 2500 feet elevation. In France, it is scattered through coppice woods on the plains and low hills; but is rather rare in the Mediterranean region, and is not a native of Corsica. It has been found in Algeria in one or two restricted localities. It grows throughout the Caucasus¹ at elevations ranging from sea-level to 6000 feet.

Acer campestre is abundant as a wild tree in Southern England, and is recorded by Watson² from most of the counties of England and Wales, as far north as Durham. It is clearly native, according to Baker,³ in the denes of the magnesian limestone of Durham, but is doubtfully so north of the Tyne, though it may be indigenous in the woods of the steep banks of the Wansbeck about Morpeth and Mitford, where there are trees about 30 or 40 feet high; but in the Cheviot Hills it seems to have been introduced. Most of the English county records⁴ mention it as common in woods, hedges, and on the banks of streams; and in North Yorkshire⁵ it ascends to 300 feet and in West Yorkshire⁶ to 600 feet.

It is probably not indigenous in Scotland, though Woodforde⁷ records it in woods at Queensferry, near Edinburgh, and Gardiner⁸ says it grows in a wood at Mains of Hallerton in Forfarshire. In Ireland,⁹ though it grows in hedges and woods in many places, it is in all cases planted or derived from plantations.

It has been found in the fossil state¹⁰ in neolithic deposits at Crossness in Essex, and in preglacial deposits at Pakefield in Suffolk. (A. H.)

CULTIVATION

The maple is common in hedgerows in many parts of England, but can hardly be considered as a forest tree, though it forms a considerable part of the underwood in some woods in the Cotswold Hills, and attains considerable size even on

poor soil. Though the autumn colour of the leaves is pretty, yet as an ornamental tree it is inferior to the Norway, American, and Japanese maples. It seeds itself freely in hedges, growing slowly and living to a great age. Lees¹ mentions a hollow tree at Powick which he estimated to be near 600 years old, and says that one almost as ancient stood near Hanley Castle.

It likes a dry, somewhat stony soil, and is most commonly seen in open sunny places in the form of a large shrub of very irregular growth. It is often pollarded, and in such cases becomes hollow, usually with a burry stem and spreading roots. So far as I have observed, the seeds germinate in the first year if sown when ripe, and are easy to raise. It bears pruning very well and is therefore suitable for hedges, which in France are often made of this tree.

According to Mouillefert,² it suffered much at Grignon in the severe winter of 1879-1880, when the thermometer fell to -27° Cent.; and is much less hardy than the sycamore, which sustained this low temperature without being injured in the least; but I have never seen it damaged by frost in this country.

REMARKABLE TREES

There are many good-sized trees of this species in England, of which one at Cobham Hall, Kent, is the tallest we have seen. This is a twin tree in a wood near the house, with two tall straight stems from the same root, which are 6 feet 4 inches and 6 feet respectively in girth, and about 75 feet high. Another tree, in the deer park here, is 70 feet high, with a trunk girthing, at three feet from the ground, 8 feet 11 inches, and dividing at 4 feet up into four stems. At Chilham Castle, Kent, the seat of C. S. Hardy, Esq., there is a splendid tree 55 feet high by 13 feet 8 inches in girth which covers an area 86 paces round, but the bole is only 7 feet high.

One of the best-shaped large trees that I have seen, grows in the park at the Mote near Maidstone: it measures 60 feet by 10 feet 3 inches. I lately discovered a magnificent tree past its prime at Langley Park, Norfolk, which, though only 45 feet high, girths 9 feet 5 inches and has branches which spread to a width of 24 paces.
