At Hursley Park, Hants, the property of Sir G. Cooper, Bart., there is a tree which Sir Joseph Hooker told me was the finest that he had ever seen. Mr. J. Clayton, who was forester there, tells me that it has a short bole 9 feet 6 inches in girth, with ten large spreading limbs, and contains about 111 feet of measurable timber. The tree in Boldre Churchyard, figured by Strutt, and said by him to be the largest in England, was, however, only 45 feet by 7 feet 6 inches, but I cannot learn that it still exists.

In Cassiobury Park there is a very well shaped tree on the golf ground, which measured, in 1907, 60 feet by 9 feet 6 inches (Plate 184), being little less than the one at the Mote. At Moor Park, Herts, Sir Hugh Beevor found in 1902 a quite sound tree, which was 10 feet 3 inches in girth at 4 feet from the ground, and no less than 76 feet in height.

¹ *Botany of Worcester*, p. xxxviii (1867).

² *Essences Forestières*, 208 (1903).

At Casewick, Lincolnshire, the seat of Lord Kesteven, a maple measured, in 1907, 53 feet high by 9 feet 1 inch in girth, with a bole of 9 feet. At Arley Castle, near Bewdley, a slender tree measured, in 1906, 66 feet high by 4 feet 8 inches in girth. At Colesborne, just below the church, there is one about 60 feet high by 9 feet in girth; and this is the largest that I know in Gloucestershire.

None of the trees recorded by Loudon approach those mentioned above in size, and though the tree is so hardy in the south of England, it usually does not attain a considerable size in the north. I have myself seen no specimens in Scotland worth recording; and it is not mentioned either in the *Old and Remarkable Trees of Scotland* or in Hunter's *Woods and Forests of Perthshire*. Loudon records a tree at Hopetoun House, near Edinburgh, 46 feet high, and another at Blairlogie in Stirlingshire, said to have been 302 years old and no less than 55 feet high by 4 feet in diameter. The Hon. Vicary Gibbs, however, measured in 1905 a pollarded tree at Armadale Castle, in the Isle of Skye, 42 feet high by $7\frac{1}{2}$ feet in girth at $2\frac{1}{2}$ feet from the ground. Mr. Renwick also reports a large one at Ardgowan, Renfrewshire, which was, in 1904, 12 feet 2 inches in girth at 1 foot up, and another at Auchentorlie, Dumbartonshire, which was, in 1907, 41 feet high by 9 feet 5 inches in girth at 3 feet from the ground. Henry measured in 1905 a tree in the Edinburgh Botanic Garden, 54 feet high by 6 feet 2 inches in girth, dividing into two stems at 8 feet from the ground.

The common maple is often planted in Ireland; but Henry has seen no trees of great size. It thrives well at Castlewellan, where there is a young tree about 30 feet in height.

TIMBER

Though the wood is one of the best of its class, on account of its fine grain, close texture and hardness, and though it sometimes shows a most beautiful figure, which when polished is highly ornamental, this wood, formerly much sought after for turning, inlaying, and cabinetmaking, is now hardly known in commerce, and is not mentioned by most recent writers. Stevenson,¹ however, says that waved or mottled specimens when cut into veneer are little, if anything, inferior to American bird's-eye maple.

The so-called mazer bowls which in ancient times were carried by every pilgrim to drink from, just as they now are by the Tibetans,² were turned from the roots and burrs of the common maple, and when mounted in silver the few remaining specimens of these bowls are very highly valued by collectors. The colour of the wood is normally white, but in old trees it turns to a pinkish or brown colour, and so far as my experience goes it is a wood which shrinks and warps very little. For parquet flooring it would be admirable, and might be very well used for table legs. In *English Timber and its Economical Conversion* it is said to be subject to the attacks of worms, but I do not know whether this statement is based on experience.

(H. J. E.)

¹ *Trees of Commerce*, p. 112.

² Cf. p. 662, note 3.

ACER PLATANOIDES, NORWAY MAPLE

Acer platanoides, Linnæus, *Sp. Pl.* 1055 (1755); Loudon, *Arb. et Frut. Brit.* i. 408 (1838); Willkomm, *Forstliche Flora*, 757 (1887); Mathieu, *Flore Forestière*, 41 (1897).

A tree, attaining occasionally 90 feet in height, but usually smaller. Bark smooth on young trees, but ultimately becoming rough and fissured longitudinally. Young branchlets glabrous, not remaining green throughout the first year. Leaves (Plate 206, Fig. 11) averaging 5 inches long by 7 inches wide, five-lobed; lobes oblong with an acuminate bristle-pointed apex; sinuses wide, rounded and open, not reaching the middle of the leaf; base cordate; margin non-ciliate and with a few large sinuate pointed teeth; both surfaces shining, green, and glabrous, except for tufts of pubescence in the axils of the primary and secondary nerves beneath; petiole with milky sap.

Flowers, opening early before the leaves expand, in erect corymbs, yellowish-green; the earliest mostly staminate, those opening later perfect; stamens 8, as long as the sepals; pedicels, calyx, corolla, filaments, and ovary glabrous. Fruit pendulous, on long stalks, glabrous; keys about $1\frac{3}{4}$ inch long; wings widely divergent.

In summer the Norway maple is readily distinguishable by the leaves shining on both surfaces, with long pointed lobes and teeth, and by the milky sap in the petioles. In winter the twigs are shining, glabrous, with very narrow three-dotted leaf-scars, the opposite pairs of which are joined at the ends around the stem. Terminal buds $\frac{1}{2}$ inch long, sessile; scales shining, either green at the base and reddish-brown above, or reddish-brown throughout, glabrous, ciliate. Lateral buds appressed to the stem.

VARIETIES

A large number of varieties have appeared in cultivation, of which the most noteworthy are:—

1. Var. *laciniatum*, Aiton,¹ Eagle's Claw or Hawk's-foot Maple. Said by Loudon to have originated in the seed-bed. Leaves (Plate 205, Fig. 10) about half the size of the type, cuneate at the base; lobes acutely, deeply, and irregularly cut; margin rolled up. This variety usually attains to no great size, but Sir Hugh Beever tells us of a tree at Gelderstone Hall near Beccles, Suffolk, 50 feet high by 2 feet 8 inches in girth; and Renwick in 1907 measured one at Auchendrane, Ayrshire, 48 feet by 3 feet 2 inches.

2. Var. *dissectum*, Jacquin fil. (var. *palmatum*, Koch²) (*A. Lorbergi*, Van Houtte). Leaves (Plate 206, Fig. 21) deeply cut to near the base, which is cordate; lobes five, ending in long sharp points, the three upper lobes again divided into three lobules; margin with a few sharp-pointed teeth. First introduced from Belgium in 1845 by Knight of Chelsea, it grows to be a fair-sized tree, and is worth cultivating on account of its elegantly cut foliage.

¹ *Hort. Kew*, iii. 435 (1789).

² *Dendrologie*, i. 530 (1869).

3. Var. *heterophyllum*, Nicholson.¹ Leaves asymmetrical and irregularly cut.

4. Var. *Schwedleri*, Koch.² A tree, vigorous in growth, with large leaves, bright-red when young, changing to dark-green. A valuable ornamental tree.

5. Var. *Reitenbachii*, Nicholson.¹ Leaves pale-red when unfolding, turning a dark blood-red in late summer. This variety originated in Reitenbach's nursery at Plicken in Prussia, and was sent out by Van Houtte. It comes fairly true from seed, and grows at Colesborne as fast as the type.

6. Var. *rubrum*, Herder.³ Leaves green when young, but towards autumn assuming a fine red colour. This variety is cultivated in the Imperial Park at St. Petersburg, and in gardens and parks in Germany.

7. Var. *albo-variegatum*. Leaves irregularly blotched with white. In a form⁴ sent out by Messrs. Drummond of Stirling, the leaves are green in the centre, with a very deep edging of white. In var. *maculatum* the leaves are spotted with white, and are very pretty.

8. Var. *aureo-marginatum*.⁵ Leaves with a yellow margin.

9. Var. *cucullatum*. Leaves irregularly and shortly lobed, crimped, dark-green.

10. Var. *columnare*. Of erect columnar habit, with small leaves. Raised¹ by Simon Louis at Metz in 1855 and first sent out in 1879.

11. Var. *globosum*. With a dense, compact, rounded head of foliage.

12. *Acer Dieckii*, Pax, a supposed hybrid between this species and *A. pictum*, var. *colchicum*, has been described above in the Synopsis, No. 36, p. 637.

DISTRIBUTION

The Norway maple has a wide distribution, as it inhabits the greater part of Europe, and extends eastwards into the Caucasus and North Persia.

In Norway, where it is called *Lon* (in Swedish *Lönn*), it is indigenous, according to Schübeler, from the extreme south to Romsdal on the west coast and Elvedal in Osterdal, but has been planted and exists as a shrub as far north as Tromsö, lat. 69° 40'; and in Sweden it is met with growing wild as far north as lat. 63° 10' on the east coast. Elwes has never seen any large trees in Norway; but Schübeler figures one (his fig. 129) at Triset in Laurdal, which was 60 feet high by 9 feet 8 inches in girth, and had very much the appearance of a sycamore. He mentions a tree at Lid at 1000 feet elevation which was 120 years old; and says that the largest known to him were at Drobak on the Christiania fjord, 60 feet high by 14 feet in girth, and at Mollendorf near Drammen, a tree which was called the great Lon, and was 70 feet high by 11 feet in girth. In former times the peasants used to tap this maple, and make a sort of beer with the sap; and Loudon states that in Germany the sap has been found to contain more saccharine matter than that of the sugar maple.

¹ *Gard. Chron.* xv. 564 (1881).

² *Dendrologie*, i. 530 (1869). Koch could throw no light on the name of this variety, the origin of which is unknown.

³ *Gartenflora*, 163, t. 545 (1867).

⁴ *Gard. Chron.* xxxiv. 24 (1903).

⁵ Var. *aureo-variegatum*, a form in which the leaves are mottled green and white, is described in *Gard. Chron.* xiv. 241 (1880).

It grows wild in Finland as far north as 62° lat. on the west coast; and the northern limit of the species as a tree extends from Lake Ladoga, through Central Russia, where it is, with birch and aspen, the commonest deciduous tree, to Orenburg, where it reaches, but does not cross the Ural, in lat. 54°. To the north of this limit it is often met with as a shrub in the pine forests, and has been found even on the west coast of Onega Bay. Southward it grows in the Crimea, and is common in the Caucasus, at 2000 to 6000 feet altitude, extending into Armenia and North Persia.

It is common throughout Germany, especially in the north, where it grows mainly in the plains, valleys, and low hills; and extends southwards through Austria and the Balkan States to Epirus. It occurs in Northern Italy. In Switzerland¹ the tree is only met with in the lower part of the beech forests, ascending to about 3300 feet. In France it is spread throughout the forests of the low hills and mountains, as far south as the Cevennes, Auvergne, and the Central Pyrenees, where it crosses into Northern Spain.

The Norway maple is not a native of the British Isles, where it has not yet been found in the fossil state.

It always grows in company with other trees, never forming pure forest, and generally solitary or in small groups. It is often associated with the sycamore, and like it thrives best on soils rich in soluble mineral matter. It does not ascend in mountainous regions as high as the sycamore; but succeeds better than that species in wet situations. It bears a great degree of cold and is entirely unaffected by late frosts.

Mistletoe² is occasionally found on the Norway maple. (A. H.)

CULTIVATION

Though the tree has been known in England for a very long period—Loudon says it was introduced in 1683—and is one of the hardiest trees in cultivation, it is seldom seen of any size, and is not nearly so commonly planted as it deserves to be. It will grow on the driest and poorest soil, and on my own land there are many trees over 50 feet high by 6 to 7 feet in girth which have not been planted more than fifty years.

It ripens seed abundantly almost every year, and is as easy to raise as the sycamore, and though it does not attain nearly the size and age of that tree, is far more ornamental both in spring, when covered with pale-yellow flowers, before the leaves come out, and in autumn when they turn a brilliant red or yellow colour.

REMARKABLE TREES

The largest tree of this maple that we know of in England is not far from the stables at Cassiobury Park, the seat of the Earl of Essex, and measures over 90 feet, perhaps as much as 95 feet high, by 13 feet 9 inches in girth. But it is not

¹ Christ, *Flore de la Suisse*, 181 (1907).

² Cf. *Gard. Chron.* xxxix. 238 (1906).

so handsome or well-shaped a tree as the one figured (Plate 186), from a photograph for which I am indebted to Mr. W. M. Christy, who tells me that this tree, growing at Watergate, near Emsworth, Hants, is no less than 14 feet 4 inches in girth at 4½ feet from the ground, the branches spreading over an area about 102 to 105 paces round.

Another very fine tree grows in a wood at Park Place near Henley-on-Thames, by the side of the drive from Templecombe, on loamy soil overlying chalk, and this in 1905 measured 80 feet by 9 feet 9 inches, with a bole about 12 feet long (Plate 187).

At Syon there is a healthy vigorous tree, 68 feet by 7 feet 3 inches, with a bole 10 feet long. At Colesborne there are several of about this size, and some younger trees, one of which was photographed when covered with hoar-frost in winter, and shows the habit of branching which this tree sometimes assumes (Plate 188).

There are many handsome specimens in the park and woods at Highclere, which produce a beautiful effect when in flower. The largest that I measured is about 80 feet by 7 feet 2 inches, with a trunk 40 feet high.

At Arley Castle there is a tree, which in 1906 measured 70 feet high by 6½ feet in girth, dividing into two stems at 6 feet from the ground; and self-sown seedlings are growing near it. At Croome Court, Worcestershire, a tree in 1905 was 50 feet high by 4 feet 8 inches in girth. Sir Hugh Beevor measured in 1906 a tree at Newnham Paddox, Worcestershire, which was 63 feet high by 12½ feet in girth at two feet from the ground, dividing above into three stems, girthing each about 6 to 7 feet; and another at the Cranleigh Cottage Hospital, Surrey, 70 feet high by 8½ feet in girth.

At Pampisford Hall, Cambridgeshire, there is a group of four trees, the largest of which was in 1906 65 feet by 4½ feet; but the specimen at Kew, which in Loudon's time was 76 feet high at 70 years old, no longer exists.

In Scotland the largest record we have is of a tree at Bowhill, near Selkirk, one of the Duke of Buccleuch's properties, which Col. H. Thynne tells me is no less than 84 feet high by 7 feet in girth, having been drawn up by surrounding trees. At Smeaton-Hepburn, East Lothian, Henry saw in 1905 two more, one 58 feet by 6 feet, the other 50 feet by 7 feet 2 inches. Another in the Edinburgh Botanic Gardens measured in the same year 48 feet by 4 feet 11 inches.

In Ireland, Henry has seen no Norway Maples of considerable size; but Loudon mentions one at Charleville which was 78 feet high.

The timber of this species is very similar to that of the Sycamore and may be used for the same purposes. (H. J. E.)

ACER LOBELII

Acer Lobelii, Tenore, *Cat. Hort. Neap.* append. 2, p. 69 (1819), and *Fl. Nap.* v. 291 (1835).
Acer platanoides, Linnæus, var. *Lobelii*, Loudon, *Arb. et Frut. Brit.* i. 409 (1838).

A tree attaining about 50 feet in height, forming a narrow pyramid with ascending branches. Bark striped longitudinally. Young branchlets glaucous,

glabrous, remaining green throughout the first and second years. Leaves (Plate 205, Fig. 8) about 5 inches long by $5\frac{1}{2}$ inches wide; lobes five or three, with their apices pointing away from the base of the leaf and ending in long sharp points; margin repand, non-ciliate; upper surface dark green, shining, glabrous; lower surface light green, dull, glabrous except for pubescent tufts in the axils of the nerves; petiole with milky sap.

Flowers smaller than those of *A. platanoides*, in corymbs. Fruit, glabrous, with horizontally spreading wings, each key about an inch long.

A variety with deeply-cut leaves is described by Tenore; but it is not apparently in cultivation.

This species is readily distinguished by the pyramidal habit, striped bark, and glaucous shoots. It grows in woods in the mountains around the Bay of Naples, and according to Spach¹ is also found in the mountains of Calabria. (A. H.)

Acer Lobelii, which Loudon treats as a variety of the Norway maple, is so distinct in its habit of growth and in its bark that it is well worth cultivation. The largest we have seen in England is at Grayswood, a handsome tree with erect branches about 40 feet high. It is quite hardy as far north as Yorkshire, where Sir Charles Strickland has planted a good many which are now from 25 to 40 feet high and growing vigorously. They all have an erect, fastigate habit. There are two good specimens in Kew Gardens. A large tree was reported² to be growing in 1839 at Croome Court, near Worcester; but when this place was visited by us in 1905, it could not be found.

At Verrières, near Paris, in M. P. de Vilmorin's grounds, this tree has attained 55 feet in height by 5 feet in girth. (H. J. E.)

ACER PICTUM

Acer pictum, Thunberg, *Fl. Jap.* 162 (1784); Shirasawa, *Icon. Ess. Forest. Japon*, text 105, t. 65, ff 1-12 (1900); Brandis, *Forest Flora N.W. India*, 112 (1874), and *Indian Trees*, 183, 705 (1906).

Acer latum, C. A. Meyer, *Verz. Kaukas. Pflanz.* 206 (1831).

Acer cultratum, Wallich, *Pl. As. Rar.* ii. 4 (1831).

Acer colchicum, Booth, in Loudon, *Gard. Mag.* 1840, p. 632.

Acer Mono, Maximowicz, *Bull. Acad. St. Péters.* xv. 126 (1857), and *Prim. Fl. Annur.* 68 (1859).

Acer Mayri, von Schwerin, *Mitt. Deut. Dendr. Ges.* 1901, p. 58; Mayr, *Fremdländ. Wald- u. Parkbäume*, 460, f. 161 (1906).

A tree attaining 60 feet in height; bark smooth, usually striped with white lines or bands. Young branchlets green, glabrous, not glaucous except in one variety, remaining green and smooth in the second year in some varieties, becoming grey or brown with irregular fissures in others. Leaves (Plate 205, Fig. 9), averaging 4 inches long and $4\frac{1}{2}$ inches broad, cordate at the base, entire in margin; lobes long, cuspidate or caudate-acuminate, bristle-pointed, five or seven in number

¹ *Ann. Soc. Nat.* 2 sér. ii. 168 (1834). Cf. also Tenore, *Essai Géog. Roy. Naples*, 81 (1827).

² Loudon, *Gard. Mag.* 1840, p. 44.

in the latter case, with the two basal lobes very small and directed downwards; membranous; shining, green, and glabrous on both surfaces, except for pubescent tufts in the basal axils beneath; petiole containing latex.

Flowers in corymbs, appearing with the leaves, yellow or greenish-yellow, variable as regards the pubescence of the calyx and the relative length of the petals and sepals. Fruit, variable as regards the length and divergence of the wings.

Acer pictum is the representative in Asia of *A. platanoides*, and is very uniform in foliage, though it extends over a wide area. Owing, however, to the remarkable variation in the characters of the fruit, it has been usually divided into two species, which cannot be maintained,¹ as there are numerous connecting links; and the different forms are best treated as geographical varieties.

* *Branchlets remaining smooth and greenish in the second year. Wings of the fruit two to three times as long as the carpels.*

1. Var. *colchicum* (*A. latum*, C. A. Meyer). Asia Minor, Caucasus.

Leaves, five- to seven-lobed, light green in colour, thin in texture. Fruit-wings usually spreading at a wide angle. In the ordinary form of this variety, the leaves are green on opening. This was introduced² in 1838 by Messrs. Booth of Hamburg, plants being in cultivation in the London Horticultural Society's garden in 1840.

In var. *colchicum rubrum*, introduced³ in 1846, the young leaves and young branchlets are deep red in colour.

2. Var. *cultratum* (*A. cultratum*, Wallich). Persia, Himalayas, Central China.

Leaves thicker in texture than the last, usually five-lobed, more truncate at the base. Fruit usually with horizontally spreading wings.

This was introduced⁴ from China in 1901 by E. H. Wilson, and is in cultivation at Coombe Wood, where there are plants now 10 feet in height.

3. Var. *tricaudatum*, Rehder.⁵ Central China.

Leaves, three- to four-lobed; basal lobes small or obsolete. This is a peculiar form, with leaves smaller than in the type, scarcely exceeding two inches long by three inches wide; and was introduced⁶ by Wilson in 1901. Young plants at Coombe Wood are already 14 feet high and are growing very vigorously.

4. Var. *tomentosulum*, Rehder.⁵ Central China. A rare form with the young leaves covered beneath with dense whitish tomentum.

** *Branchlets⁷ becoming grey or brown and fissured in the second year. Wings of the fruit about $1\frac{1}{2}$ times as long as the carpels.*

5. Var. *eu-pictum* (*A. pictum*, Thunberg). Japan.

Leaves darker green and thicker in texture than in var. *colchicum*; lobes

¹ Cf. Rehder, in Sargent, *Trees and Shrubs*, i. 178 (1905).

² Cf. Loudon, *Gard. Mag.* 1840, p. 632.

³ Nicholson, *Gard. Chron.* xvi. 375 (1881).

⁴ *Journ. Roy. Hort. Soc.* xxix. 354, f. 101 (1904).

⁵ In Sargent, *Trees and Shrubs*, i. 178 (1905).

⁶ *Journ. Roy. Hort. Soc.* xxix. 354, ff. 100, 102 (1904).

⁷ Rehder, *loc. cit.*, points out that this character is inconstant, as he has found in several Japanese specimens the bark of the branchlets similar in colour to that of var. *colchicum*.

occasionally short and broad. Fruit-wings erect and parallel or diverging only at an acute angle. Introduced by Maries in 1881.

6. Var. *Mono* (*A. Mono*, Maximowicz). Japan, Saghalien, Amurland, Manchuria, Northern and Central China.

Differs from the last in the wings of the fruit diverging at about a right angle. Introduced¹ from Central China by Wilson in 1901. Plants at Coombe Wood are about 6 feet high.

*** *Young branchlets glaucous.*

7. Var. *Mayri* (*A. Mayri*, von Schwerin). Yezo. This differs from var. *eu-pictum* in the young branchlets being glaucous. Mayr, who discovered the tree in 1886, says that the bark is almost white in colour and hard and smooth. Apparently not yet introduced.

Acer pictum is widely distributed, occurring from Asia Minor through the Caucasus and the Himalayas to China, Manchuria, and Japan. In Asia Minor it is met with in the mountains near Trebizond, where, as in the Caucasus, it grows in mixed forests and beech woods, ascending from sea-level to 5600 feet. It has been collected in Armenia and in the Elburz Mountains of Northern Persia. According to Gamble,² it is the commonest maple in the Western Himalaya, but extends throughout the middle and outer ranges from the Indus to Assam, where it grows as a moderate-sized tree with thin grey bark at elevations ranging from 4000 to 9000 feet. The wood is used in India for construction, ploughs, bedsteads, and carrying-poles; and the Tibetan drinking cups are turned from the knotty excrescences which are often found on this tree.³ Further east the tree is spread throughout the mountains of Western China in the provinces of Yunnan, Szechwan, and Hupeh; and it is found northward in the province of Chihli and throughout Manchuria. It also grows in the island of Saghalien, and is the most common and largest species of maple in Japan, where, according to Sargent,⁴ it is one of the most abundant trees in Hokkaido, occasionally attaining a height of 50 feet and a girth of 5 feet. Elwes, however, saw none as large as this. The tree is beautiful in May, when the flowers are just opening, as the large lengthened inner scales of the winter buds are then bright orange-yellow, and very showy. The autumnal colour of the leaves is described as yellow and red.

This species is usually seen in England as a small tree in botanic gardens and public parks, var. *colchicum rubrum* appearing to be the commonest variety in cultivation, the form from Japan being very rare. The finest trees we have seen are two at Tortworth, one of which is 49 feet high, and 5½ feet in girth, with a very spreading top 45 to 50 paces round, and many suckers from the roots with reddish leaves. Another in the park, is grafted on *A. platanoides*, and has very

¹ *Journ. Roy. Hort. Soc.* xxix, 348, ff. 87, 89 (1904.)

² *Indian Timbers*, 202 (1902).

³ Hooker in *Himalayan Journals*, i. 132, 133, says that some of these cups are supposed to be antidotes against poison, and fetch a very high price. The knotty excrescences are produced on the roots of oaks, maples, and other mountain forest trees in the Himalaya by a parasitical plant known as *Balanophora*.

⁴ *Forest Flora of Japan*, 29 (1894).

handsome bark with purple and green streaks, smoother than that of the stock. At Park Place, Henley, there is a tree 51 feet high, and 4½ feet in girth at 4 feet from the ground, dividing above this into several stems. The bark is smooth and grey, and close to the trunk are several suckers about 4 feet high. (A. H.)

ACER OPALUS, ITALIAN MAPLE

Acer Opalus, Miller, *Dict.* ed. 8, No. 8 (1768); Aiton, *Hort. Kew.* iii. 436 (1789); Loudon, *Arb. et Frut. Brit.* i. 420 (1838).

Acer italum, Lauth, *De Acere*, 32 (1781); Willkomm, *Forstliche Flora*, 762 (1887).

Acer opulifolium, Villar, *Hist. Pl. Dauph.* i. 333 (1786); Loudon, *Arb. et Frut. Brit.* i. 421 (1838); Mathieu, *Flore Forestière*, 40 (1897).

Acer rotundifolium, Lamarck, *Encycl.* iii. 382 (1789).

A tree attaining about 50 feet in height, often met with in the wild state as a mere shrub. Bark smooth and grey on young trees, fissured and darker in colour on old trees. Young branchlets glabrous, becoming dark red in their first autumn. Leaves (Plate 206, Fig. 14), variable in size and shape, usually about 2½ inches long by 3 inches wide, cordate at the base, five-lobed; lobes short, ovate-triangular, acute at the apex, irregularly toothed; sinuses shallow, usually rounded at the base; upper surface dark green, shining; lower surface dull, pale, with scattered pubescence, denser on the nerves and forming axil-tufts, in some forms glabrescent; petiole without milky sap.

Flowers appearing very early, before the leaves, in sessile corymbs, yellow; pedicels long, glabrous or pubescent. Fruit, ripening in autumn, brown, glabrous; keys about an inch long; wings more or less divergent, only slightly narrowed at the base.

In winter the twigs are shining, glabrous. Buds conical, obtuse at the apex; outer scales about twelve, pubescent and ciliate. Lateral buds shortly stalked, arising from the twigs at an acute angle. Leaf-scars very slender, crescentic, three-dotted, and fringed on their upper margins with white hairs; opposite pairs of leaf-scars often joined around the stem.

VARIETIES

This species is very variable as regards the foliage. *A. hispanicum*, Pourret, which grows in Spain, and *Acer Martini*, Jordan, a rare tree in Savoy and Basses-Alpes in France, are connecting links between *A. Opalus* and *A. hyrcanum*.

1. Var. *obtusatum*.

Acer obtusatum, Kitaibel, in Willdenow, *Sp. Pl.* iv. 984 (1805); Loudon, *Arb. et Frut. Brit.* i. 420 (1838); Willkomm, *Forstliche Flora*, 763 (1887).

Leaves (Plate 206, Fig. 16) larger, 4 inches or more in width, more rounded in outline, more coriaceous, more densely pubescent beneath; lobes short, broad, slightly and crenately toothed; basal lobes very short.

This is kept up as a distinct species by Pax and Schneider; but intermediate forms are common, and there are no distinctive characters in the flowers or fruit.

2. Var. *neapolitanum*.

Acer neapolitanum, Tenore, *Fl. Napol.* ii. 372 (1820).

This variety differs from the last in the lobes being still shorter, with the basal lobes often obsolete; and the lower surface of the leaves (Plate 206, Fig. 15) is covered with dense whitish tomentum.

DISTRIBUTION

This species is widely distributed in Southern Europe, extends eastwards into the Caucasus, and also occurs in Algeria and Morocco. The typical form is found in the mountain forests of the south and south-east of France, ascending as high as the silver fir, and is recorded¹ from the Jura, Burgundy, Lyonnais, Dauphiné, Savoy, Alpes Maritimes, Provence, Aveyron, Pyrenees, and Corsica. It rarely attains a height of more than 30 feet, and is often only a bushy small tree. It also grows in South-western Switzerland, extending along the Jura as far north as Neuchâtel, and is also found in the Apennines of Northern and Central Italy.

Var. *neapolitanum* is found in wooded regions in the mountains around Naples, ascending as high as the beech, and attains, according to Tenore,² large dimensions in the Basilicata and Calabria.

Var. *obtusatum* is widely spread through Italy, as far south as Calabria and Sicily, and is common in the Balkan peninsula, extending from Croatia, through Istria, Dalmatia, Bosnia, Servia, and Herzegovina to Roumelia, reaching its most southerly point in the Pindus range. In the Caucasus, according to Radde,³ it is confined to the province of Talysch, where it grows at elevations between 1500 and 5000 feet. It is also found in Algeria and Morocco. (A. H.)

CULTIVATION

This species was introduced, according to Loudon, from Corsica in 1752, and though little known in general cultivation and rarely found in nurseries, has apparently a first-rate constitution, and is perfectly hardy. It ripens fruit in this country; and I have raised plants from seed sent me in 1901 by the Earl of Ducie, which grew the first season as fast as a sycamore, and are now about 10 feet high. It is one of the first of the maples to come into flower, early in March at Kew; and when in full flower the tree has a most handsome appearance. Its leaves colour nicely in autumn; and this maple is well worth a place in pleasure grounds, where it is not particular about soil, if this is well drained.

³ *Pflanzenverh. Kaukasusland*, 184 (1889).

REMARKABLE TREES

The only trees which we know to exceed 50 feet in height are two at Arley Castle, which Mr. Woodward measured in 1905—one 57 feet by 5 feet 1 inch at 5 feet from the ground, and the other 56 feet by 7 feet near the base, where it divides into two stems. The one which I figure (Plate 189) is growing in Sir Hugh Beevor's park at Hargham, Norfolk, and when I saw it in 1905 was 45 feet by 7½ feet with a bole of about 7 feet. There is a tree in Kew Gardens, not far from the Director's office, which is 45 feet high, by 5 feet 10 inches in girth at two feet from the ground, dividing at four feet up into four or five stems. Lord Ducie's tree at Tortworth, not more than forty or fifty years old, is 40 feet by 6 feet. There is a younger one almost as large at Grayswood.

In Scotland the only large one we know is at Smeaton-Hepburn, East Lothian, measured by Henry in 1905 as 45 feet high by 6 feet 3 inches in girth.

At Glasnevin, Dublin, a tree measures 46 feet by 7½ feet; and another at Glenstal, near Limerick, was 47 feet by 4 feet in 1905.

TIMBER

The wood is said by Mouillefert¹ to be like that of the sycamore, but pinkish or pale red in colour, closer in the grain, heavier, and more lustrous, and is esteemed in France by turners, cabinetmakers, and wheelwrights. (H. J. E.)

ACER MONSPESSULANUM, MONTPELLIER MAPLE

Acer monspessulanum, Linnæus, *Sp. Pl.* 1056 (1753); Loudon, *Arb. et Frut. Brit.* i. 427 (1838);

Willkomm, *Forstliche Flora*, 769 (1887); Mathieu, *Flore Forestière*, 43 (1897).

Acer trifolium, Duhamel, *Traité des Arbres*, i. t. 10 (1755).

Acer trilobatum, Lamarck, *Encycl.* ii. 382 (1786).

Acer trilobum, Moench, *Meth.* 56 (1794).

Acer rectangulum, Dulac, *Fl. Haut. Pyr.* 242 (1867).

A small tree, in the wild state rarely attaining 40 feet, and often only a shrub. Bark smooth on young trees, ultimately fissuring. Young branchlets glabrous, green, becoming dark brown in the first autumn. Leaves (Plate 207, Fig. 31) coriaceous, small, averaging 1½ inch long and 2¼ inches broad, cordate at the base, three lobed; lobes ovate, obtuse; sinuses wide, acute at the base; margin non-ciliate, usually entire, rarely toothed; upper surface dark green, shining, glabrous; lower surface pale or greyish, with tufts of pubescence in the axils at the base, elsewhere glabrous; petiole without milky sap.

Flowers, appearing before or with the leaves, in small corymbs, at first erect, afterwards pendulous, yellowish-green; pedicels long. Fruit, ripening in

¹ *Essences Forestières*, 206 (1903).

autumn; keys, $\frac{3}{4}$ inch long, erect, convergent; carpels glabrous; wings brownish or reddish.

The Montpellier maple in the wild state varies in the amount of pubescence on the leaf, the apex of which may be sharp or rounded; and the margin, usually entire, is occasionally toothed. The keys of the fruit are occasionally so convergent as to cross each other in their upper part (var. *rumelicum*, Grisb.).

A hybrid between this species and *A. Opalus*, known as *A. Peronai*, von Schwerin,¹ has been found in the Apennines at Vallombrosa. Another hybrid, *A. rotundilobum*, von Schwerin,² occurs between this species and *A. Opalus*, var. *obtusatum*, and is mentioned in the synopsis, p. 634.

The Montpellier maple is widely spread throughout Southern Europe, from Portugal to Turkey. It occurs also in the mountainous regions of Algeria and Morocco, and extends eastwards through Asia Minor to the Caucasus,³ where it grows at elevations between 3000 and 5000 feet, and to Turkestan. In France, it is common in the south in dry, rocky situations; and ascends on the west as far north as Poitiers and Niort, and on the east to Gap, Lyons, Grenoble, and Chambéry; and, according to Christ,⁴ grows at two spots near Bugey, in the southern Jura. It is found in Germany in the mountains of Rhineland, as far north as Coblenz and in the valleys of the Moselle and Nahe rivers; and also grows at Würzburg in Bavaria. In Switzerland, it is wild near Geneva, in the Jura, at Fort de l'Ecluse.⁵ In Austria, its northern limit extends from the Southern Tyrol, through Carinthia, Carniola, Istria, and Croatia to Banat; and the tree is spread southward through the Balkan peninsula to Greece.

This species has been found⁶ in the fossil state in England, in interglacial deposits at Stone, Hants, and Selsey, Sussex.

It was introduced into England, according to Loudon, in 1739, and in the southern counties thrives very well, ripening its fruit perfectly, and attaining a larger size than any wild trees recorded in Southern Europe.

There are two fine trees in Rickmansworth Park, Herts, growing in a good loamy soil overlying chalk, which, in 1904, measured 50 feet in height by 8 feet 3 inches (Plate 190) and 45 feet by 8 feet 1 inch. There are two good specimens in the grounds behind the Herbarium at Kew, which were covered with flowers on April 1, 1907. These are about 45 feet high, and girth respectively 5 feet 10 inches and 5 feet. There are also trees of a considerable size at Oxford, Fulham Palace, and Bicton. At Ewelme Rectory, Wallingford, there is a wide-spreading tree, which the Rev. Canon Cruttwell informs us is 36 feet high, and 9 feet in girth near the base. At Arley Castle, near Bewdley, there is a tree 35 feet high, by 6 feet 9 inches in girth at one foot from the ground, above which it divides into two limbs.

In the Edinburgh Botanic Garden a tree measures 34 feet by 4 feet 2 inches.

In the Jardin des Plantes at Paris there is a fine specimen, which I measured

in 1904 as 60 feet by 8 feet. At Grignon,¹ a tree resisted without injury the low temperature of -23° cent. in the winter of 1870-1871; and in 1879-1880, when the thermometer fell to -26° cent., it only lost a few of its branches. (A. H.)

ACER INSIGNE

Acer insigne, Boissier et Buhse, *Aufzähl. Transkaukas.*, 46 (1860); Boissier, *Flora Orientalis*, i. 947 (1867); Masters, *Gard. Chron.* x. 189, f. 24 (1891).

A large tree; bark of young stems dark grey, smooth, and marked with longitudinal whitish lines. Young branchlets glabrous, green, becoming dark reddish in autumn. Leaves (Plate 206, Fig. 18) resembling those of *A. Pseudoplatanus* in form and size, scarcely exceeding 6 inches wide and 7 inches long, but usually with somewhat shorter lobes, acute or acuminate; serrations and teeth more rounded than in the sycamore; under surface pale in colour, scarcely glaucous, with loose white or brown pubescence, dense along the sides of the primary and secondary nerves, forming tufts in the axils, and scattered over the surface between the nerves.

Flowers, very distinct from those of *A. Pseudoplatanus*, in erect many-flowered terminal corymbs, appearing with the leaves, small, greenish; bracteoles minute, about $\frac{1}{50}$ inch; filaments glabrous. Fruit, ripening in autumn; keys $1\frac{1}{2}$ to 2 inches long; carpels brown, pubescent on the upper side; wings broad, divergent at an angle of 45° .

In the absence of flowers or fruit, this species is best distinguishable from the sycamore by the buds, which are long and sharp-pointed, with eight to ten external scales, ciliate in margin and with a tuft of pubescence at the tip; lateral buds plainly stalked, arising from the twigs at an acute angle; opposite leaf-scars not joined round the twig, which is glabrous throughout.

Boissier considered that there were two forms of the species growing wild:—var. *velutina*, with leaves velvety pubescent beneath; and var. *glabrescens*, with glabrous leaves. Bornmüller,² who studied the tree, while collecting in Persia, is of opinion that these varieties are unstable, as the amount of pubescence is variable; and all the specimens in the Kew herbarium are more or less pubescent.

(A. H.)

Acer insigne was discovered by Buhse in the eastern Caucasus, in the mountains of Talysch, where, according to Radde,³ it is common in the forests from sea-level to 2000 feet altitude, and grows to a large size, developing a wide crown of foliage on good soil, and thriving best in moist situations. It is also recorded by Radde from the valley of the Alasan river in the central Caucasus. It grows

¹ Mouillefert, *Essences Forestières*, 214 (1903). Cf. also *Actes Premier Congrès Internat. Bot.* 385 (1900), where it is stated that this species sustained at Paris without injury the severe winters of 1879-1880 and 1890-1891.

² *Bull. Herb. Boissier*, v. 643 (1905). Bornmüller recognises three varieties, based on the shape of the leaf:—*typica*, Bornmüller, lobes of the leaf acute or acuminate; *obtusiloba*, Freyn et Sint., *Bull. Herb. Boissier*, iii. 843 (1902), lobes obtuse; and *longiloba*, Bornmüller, lobes three, elongated, acuminate.

³ *Pflanzenverb. Kaukasusland*. 184 (1899).

wild in woods in the provinces of Ghilan and Astrabad in Northern Persia, and is often planted along roads; and in Teheran is cultivated in gardens.

This species was introduced by van Volxem, at the same time as *A. Volxemi*. Dr. Masters received in 1877 from van Volxem three plants, one each of *A. insigne*, *A. Volxemi*, and *A. Trautvetteri*, which he planted in his garden at 9 Mount Avenue, Ealing. His specimen of *A. insigne* first flowered in 1889 and 1890, and is now a very fine tree, 43 feet high and 3 feet 7 inches in girth, as measured by Henry in October 1907. It has a good straight bole, with slender ascending branches, and produces fruit regularly. Two seedlings near it are about three feet high. There are two small trees of *A. insigne* in the collection at Kew, which are less striking in appearance than *A. Volxemi*; but are apparently growing as fast.

At Colesborne, plants raised from seed, received from Lagodechi in the central Caucasus, under the name of *A. Trautvetteri*, and sown in December 1902, are now about 5 feet high. (H. J. E.)

ACER VOLXEMI

Acer Volxemi, Masters, *Gard. Chron.* x. p. 18, figs. 1, 2, and p. 188 (1891).

Acer Van Volxemi, Masters, *Gard. Chron.* vii. 72, fig. 10 (1877).

Acer insigne, Boissier et Buhse, var. *Van Volxemi*, Pax, in Engler, *Jahrb.* xvi. 395 (1892).

This tree is referred by Schneider and von Schwerin to *A. insigne*, var. *glabrescens*, Boissier; but it differs considerably from *A. insigne*, and is either a distinct species or is possibly a hybrid between *A. insigne* and *A. Trautvetteri*, resembling the former more in the shape of the leaves and the latter in the structure of the flowers.

In this species, the leaves are extremely large, often 10 inches wide and 9 inches long, resembling those of the sycamore on a large scale, pale and glaucous beneath, with white pubescence along the sides of the primary and secondary nerves, forming axil-tufts, but not scattered over the surface. The buds resemble those of *A. insigne*; but the twigs differ in being pubescent at the nodes and on the upper edges of the leaf-scars. The flowers resemble those of *A. Trautvetteri*, having long bracts and bracteoles.

This tree is little known in the wild state, the only account¹ being that of van Volxem, who collected seed of it some years before 1877, in the valley² of a tributary of the Kura, above the military station of Lagodechi, on the southern slope of the central Caucasian chain. According to van Volxem, "it is a very large tree, very distinct from *A. Pseudoplatanus* in its larger size and its paler green colour, by which it is recognisable hundreds of yards away. The winged fruits are also smaller. It grows intermixed with *A. Pseudoplatanus* in the same forests, but with no intermediate forms, hence it is not a local form, nor would a mere variety remain distinct

¹ *Gard. Chron.* vii. 72 (1877). Van Volxem's specimens from the Caucasus, from which Dr. Masters drew up his description, cannot now be found; and the species has apparently not been collected by any one except van Volxem.

² Van Volxem names this tributary the Yora (or Jora); but this river lies much to the southward of Lagodechi, the Alasan river intervening.

in the wild state. It does not grow at so great a height on the Caucasus by at least 1000 or 1500 feet, so far as I was able to observe. The form of the tree is more columnar. The light green colour of the leaves makes the difference between the two conspicuous and remarkable. The colour of the bark and the shape of the buds are different." (A. H.)

Introduced from seeds collected by van Volxem in the locality mentioned above, a tree, sent to Dr. Masters in 1877 and planted in his garden at Ealing, grew very rapidly, producing splendid large foliage, silvery white on the lower surface. This tree is still living, but has been headed down, as there was no room for it to develop, and is now only about 15 feet high and 1 foot 10 inches in girth. It has not borne fruit. Dr. Masters told me that all efforts to propagate it by grafts, cuttings or layers failed, though tried by some of the leading nurserymen; and he considered this tree, which he watched from 1877, to be the fastest-growing and the noblest of the maples.

A. Volxemi flowered for the first time in 1891, in Belgium; and its distinctness from the sycamore was then clearly established. A small tree at Kew, now about 20 feet in height, has flowered several times and produced fruit. There are also healthy young trees at Frensham Hall, and in the garden of Mr. Chambers at Grayswood, both of which places are near Haslemere.

M. E. Louis, of Simon Louis Frères, the well-known nurserymen at Metz, informed me in a letter dated October 1902, that he cultivates the true *A. Volxemi*, which is sometimes erroneously called *A. Trautvetteri*.

In November 1902, through the kindness of the Grand Duke Nicholas Mikhailovitch of Russia, I obtained a quantity of fresh seed of this species, as well as of *A. insigne*, from Lagodechi, the original locality; and have raised a number of plants from them. These grow rapidly, but have not as yet ripened their autumnal growths well, and in consequence are rather bushy. The tree may, however, be considered perfectly hardy, and is well worth growing on account of its rapid growth and splendid foliage.

Acer insigne, var. *Wolff*, von Schwerin,¹ raised from seeds sent from the Caucasus by Herr Wolf of St. Petersburg, is apparently, from the description, a variety of *A. Volxemi*, distinguished by the very large leaves, perfectly glabrous and deep purple in colour beneath. (H. J. E.)

ACER TRAUTVETTERI

Acer Trautvetteri, Medwedjeff, ex Trautvetter, *Act. Hort. Petrop.* vii. 428 (1880); Wolf, *Gartenflora*, xl. 263, figs. 58-61 (1891).

Acer insigne, Nicholson, *Gard. Chron.* xvi. 75, f. 14 (1881), and J. D. Hooker, *Bot. Mag.* 6697 (1883). (Not Boissier and Buhse.)

A tree attaining, in the Caucasus, 50 feet in height and 6 feet in girth; bark grey, smooth. Young branchlets glabrous, green, becoming dark red in the first

¹ *Mitt. Deut. Dendr. Ges.* 1905, p. 210.

autumn or winter. Leaves (Plate 206, Fig. 19), about 6 inches long and 8 inches wide, cordate at the base, deeply five-lobed; lobes, oblong or ovate, acuminate at the apex, each with three or four small teeth on the margin, which is neither serrate nor ciliate; sinuses, reaching two-thirds the length of the leaf, acute at the base; upper surface dark green, shining, glabrous; lower surface light green, glabrous, except for conspicuous tufts of reddish-brown pubescence in the axils of the primary and secondary nerves; petioles without milky sap.

Flowers, appearing with the leaves, in erect, long-stalked corymbs; bracts and bracteoles conspicuous, $\frac{1}{8}$ inch long; filaments glabrous, ovary pubescent. Fruit, ripening in autumn; keys $1\frac{3}{4}$ inch long, narrowly divergent; carpels scurfy pubescent when young, glabrous when mature; wings broad.

The leaves are variable as regards the depth of the sinuses, being described by Medwedjeff as either five-lobed or five-partite; and the description above applies to the deeply-cut form, which is in cultivation.

The foliage resembles in size and shape some forms of the sycamore, but can be readily distinguished by the margin being simply dentate and not serrate. The buds are also different. In winter the terminal buds are ovoid, obtuse, with six outer scales, the lower pair of which are shining, dark red and glabrous, with the middle and upper parts ciliate; lateral buds distinctly stalked, arising at an acute angle; twigs polished, dark red, glabrous.

This species was discovered by Radde¹ in 1864 in the Caucasus at an elevation of 6000 feet, and was at first identified by Trautvetter with *A. platanoides*, which it resembles in no respect. It is allied to *A. insigne*, and has a more westerly distribution than that species, growing on both sides of the main chain of the Caucasus, but not extending into Talysch or Persia. It is a tree of high elevations, growing at 6000 to 8000 feet altitude in company with birch and subalpine shrubs, or mixed with *Abies Nordmanniana* on the edges of alpine meadows, and flowers in May. It ascends in many places to the timber line, and at lower levels is replaced in the forests by the Norway maple.² According to Wolf the tree attains 50 feet in height and 6 feet in girth; but Radde¹ gives the measurement of a tree, probably of this species, which was 120 years old and 62 cubic feet in volume.

This species was raised in van Volxem's nursery from seeds collected in 1866 by Balansa in Lazistan, and for a long time was confused with *A. insigne*,³ being described and figured under that name in the *Botanical Magazine*. Van Volxem informed Sir J. Hooker that it was the hardiest of the eighty species and varieties of maple cultivated by him, having withstood without injury the disastrous winters of 1879-80 and 1880-81; and being a late grower, it had never even been nipped by spring frosts. At Kew, where there are two healthy trees, it is one of the latest maples to come into leaf. The tree sent by van Volxem to Dr. Masters flowered

¹ *Pflanzenverh. Kaukasusland*, 108, 175, 225, 310 (1899).

² *Ibid.* 245. Radde speaks of *A. platanoides* and *A. Trautvetteri* growing together in impassable thickets, which are beaten down by the heavy snow.

³ *A. Trautvetteri* has also been confused with *A. Volxemi*, as in *Gard. Chron.* x. 188, note, and 189 (1891). Rehder, in *Cycl. Am. Hort.* 15 (1890), agrees with me that the tree, figured in *Bot. Mag.* 6697, is the true *A. Trautvetteri*, though it differs from wild specimens preserved in the Kew herbarium, in having the leaves more deeply cut.

at Ealing on May 23, 1882, but never throve, and has been dead for some years. This species is very rare in cultivation. I saw a young tree, about 20 feet high, in 1906, at Grignon in France, where it exceeds the sycamore in rate of growth.

(A. H.)

ACER RUBRUM, RED MAPLE

Acer rubrum, Linnæus, *Sp. Pl.* 1055 (1753); Loudon, *Arb. et Frut. Brit.* i. 424 (1838); Sargent,

Silva N. Amer. ii. 107, tt. 94, 95 (1892), and *Trees N. Amer.* 639 (1905).

Acer coccineum, Michaux f., *Hist. Arb. Am.* ii. 203 (1810).

Acer sanguineum, Spach, *Ann. Sc. Nat.* ser. 2, ii. 176 (1834).

A tree attaining in America 120 feet in height and 15 feet in girth; with ascending branches. Bark of young stems smooth and light grey, becoming on old trunks darker, ridged, and separating on the surface into plate-like scales. Young branchlets green or red, slightly pubescent towards the tip. Leaves (Plate 207, Fig. 27) very variable in size, averaging 3 inches long and broad; either five-lobed, with two very small basal lobes, or three-lobed, the middle lobe the longest; lobes short, triangular, acute or acuminate at the apex; sinuses very shallow, acute at the base; base of the leaf truncate, slightly cordate or shortly cuneate; margin non-ciliate, irregularly toothed, or doubly serrate; upper surface dark green, glabrous; lower surface silvery white, scattered pubescent, without axil-tufts; petioles without milky sap. The leaves turn scarlet or orange in autumn.

Flowers appearing early in spring before the leaves, in few-flowered, umbel-like clusters encircling the branchlets of the previous year; dioecious or monoecious; reddish; pedicels long; petals present; ovary glabrous. Fruit hanging on drooping stalks, ripening in June, and germinating as soon as it falls upon the ground; keys glabrous, about an inch long, at first convergent, afterwards divergent, brown or reddish in colour.

The red maple can only be confused with the silver maple, from which it differs in the ascending branches and in the shape of the leaves, which are usually only three-lobed, always have very shallow acute sinuses, and are less cordate (often truncate) at the base than in *A. dasycarpum*. In winter the twigs are glabrous, reddish; leaf scars very narrow, three-dotted, opposite pairs not united around the stem. Buds small, shortly stalked, reddish; external scales, six to eight, fringed with whitish cilia; lateral buds arising from the twigs at an angle of 45°.

VARIETIES

In addition to the typical form, above described, Sargent admits two well-marked varieties, occurring wild in America.

1. Var. *Drummondii*, Sargent. (*Acer Drummondii*, Hooker and Arnott, *Journ. Bot.* i. 200 (1834).) Leaves three-lobed, with short broad lobes, and covered on

the under surface, like the young branchlets and petioles, with hoary tomentum. Flowers and fruit bright scarlet. The variety is found in deep river swamps of Southern Arkansas, Eastern Texas and Western Louisiana.

2. Var. *tridens*, Wood.¹ Leaves three-lobed at the apex, rounded or cuneate at the base, thick and firm in texture, serrate except towards the base with remote incurved glandular teeth. Flowers sometimes yellow; fruit usually much smaller and rarely also yellow. This variety occurs in the coast region from Southern New Jersey to Southern Florida, and along the Gulf Coast to Eastern Texas.

A large number of varieties, based on trivial characters, are given by Pax and von Schwerin as occurring in cultivation, the most noteworthy of which is var. *sanguineum*, with the leaves deeper green above, bluish-white beneath, and turning a brilliant red in autumn. In cultivated trees in England there are marked differences in the size and shape of the leaves and in the amount of pubescence on their under surface; but these differences are not worth naming. Columnar and bushy rounded forms are known; and a pendulous form is also mentioned in the Kew Hand List, which seems, however, to be a form of *A. dasycarpum*.

(A. H.)

DISTRIBUTION

In America this tree is one of the commonest and most widely distributed, extending from about lat. 49° N. in Quebec and Ontario, south to Florida and west to Wisconsin, Iowa, and the Trinity river in Texas; abundant in the Mississippi valley, and attaining its largest size on the lower Ohio and in the Wabash valley, where Ridgway measured a tree 108 feet by 15 feet, with a clean bole 60 feet long, and says that larger trees could be found. In New England it grows abundantly in swamps and low ground, and is usually a tree of no great size, so far as I have seen. Emerson records no large trees, while Michaux says that he nowhere saw it larger than in the swamps of New Jersey and Pennsylvania, where it is often 70 feet high and 3 to 4 feet in diameter. It is the earliest tree in flower and was nearly over in the middle of May, near Boston, when the leaves were partly developed. Emerson says that they vary remarkably in size and shape, being sometimes broad and five-lobed, sometimes long and narrow, and are liable to become of a scarlet, crimson, or orange colour at all seasons, sometimes at midsummer, long before other trees have changed colour. He thinks that the frost has little to do with the autumnal coloration of leaves, and that the greater intensity of the light and transparency of the air is the reason why the leaves of trees usually turn so much more brilliant in colour in America than in Europe.

A fastigate tree of this species is illustrated in *Garden and Forest*, vii. 65 (1894), where it is erroneously² called a sugar maple. It grows in the grounds of Mrs. Leavitt at Flushing, New York, and is 80 feet high. Sargent adds that only two other American trees, the tulip tree and the Robinia, are known to have produced forms with fastigate branches.

¹ Cf. Rehder, in *Rhodora*, ix. 116 (1907).

² Mr. W. A. Stiles, in a letter to Kew, dated March 28, 1894, corrects this error.

CULTIVATION

This is the commonest in cultivation of all the American maples, except *A. Negundo*, and was the first to be introduced, having been cultivated by Tradescant as long ago as 1656. Miller says that a tree produced seed in his time from which plants were raised in the Bishop's garden at Fulham; and, according to Loudon, one of these in 1793 was 40 feet by 4 feet 3 inches, but was dead before 1809. It was often confused with the silver maple, and even Loudon says that they are only varieties of one species, though he treats them under separate names. No one, however, who has seen them in their native country could doubt their distinction, which was first established by Linnæus.

The red maple is perfectly hardy everywhere in Great Britain, but requires considerable summer heat and a good soil to bring it to any size. On dry sandy soils it is a stunted tree of no beauty. Its seed, like that of the silver maple, ripens early and must be sown at once, but Loudon says that in his time it was propagated by layers, which, coupled with insufficiency of moisture in the soil, may account for the rarity of fine specimens.

I have raised seedlings this year from seeds sent me from Arley by Mr. R. Woodward in July, when he found them germinating freely below the parent tree; and Mr. Knowles, gardener to H.R.H. the Duke of Connaught, tells me that he has found self-sown seedlings at Bagshot Park.

REMARKABLE TREES

At no place in England, so far as we know, are there so many fine red maples as at Bagshot Park, the seat of H.R.H. the Duke of Connaught. When I visited this place on May 22, 1907, the fruit was so abundant on trees in an open wood that it gave them quite a red appearance. The largest of these that I measured was 82 feet by 9½ feet, with a bole about 20 feet long (Plate 177). There is another on the bank of the lake at Claremont which measures about 75 feet by 9½ feet.

At Whitton, near Hounslow, there is a large tree, probably 150 years old, near the group of *Taxodium distichum*, in ground which has moisture beneath, and in 1904 it measured 80 feet by 8 feet 5 inches, but as this tree is not mentioned by Loudon, it may not be so old as we think, though decay has already commenced (Plate 192). At Walcot there is a tree which in March 1904 was in flower, and measured 68 feet by 6½ feet. At Arley Castle there is a fine tree with mistletoe growing on it, which produced seed freely in 1907, and measures about 60 feet by 7½ feet.

In a wood south of Virginia Water in Windsor Park, Henry measured, in 1906, a tree 80 feet by 6 feet 2 inches; and at South Lodge, Enfield Chase, there is a tree which was 50 feet by 6 feet 7 inches in 1904.

A variety under the name of *globosum*, which I saw growing in an ornamental

plantation in Silk Wood, Westonbirt, Gloucestershire, was conspicuous among all other trees for its brilliant scarlet leaves and upright habit, in October 1907.

In Scotland it grows well as far north as Brahan Castle, Ross-shire, the seat of Col. Stewart Mackenzie of Seaforth, where in 1907 I measured a tree about 50 feet by 12 feet 2 inches; and at Gordon Castle an old tree at the west end of the holly bank, was in the same year 55 feet by 6 feet 2 inches. There is also a good-sized tree close to the lodge at Moncreiffe House, near Perth, which I believe to be a red maple.

In Ireland Loudon mentions one at Woodstock, which at 60 years old was 50 feet high, but Henry could not find it now living. (H. J. E.)

ACER DASYCARPUM, SILVER MAPLE

Acer dasycarpum, Ehrhart, *Beit.* iv. 24 (1789).

Acer saccharinum,¹ Linnæus, *Sp. Pl.* 1055 (1753); Sargent, *Silva N. Amer.* ii. 103, t. 93 (1892), and *Trees N. Amer.* 638 (1905).

Acer eriocarpum, Michaux, *Fl. Bor. Am.* ii. 203 (1803); Loudon, *Arb. et Frut. Brit.* i. 423 (1838).

A tree attaining in America 120 feet in height and 12 feet in girth, the stem usually dividing at a short distance from the ground; ultimate branches pendulous, long, and slender. Bark of young trees smooth and grey, on old trunks dark in colour, ridged, and separating on the surface into thin loose scales. Young branchlets glabrous, green, becoming shining brown in the first autumn. Leaves (Plate 207, Fig. 28) about 5 inches long, 6 inches wide, usually cordate at the base, five-lobed; basal lobes well developed; lobes long acuminate at the apex, with serrated triangular teeth or lobules; sinuses rounded at the base and concave on the sides, extending halfway or more to the base of the blade; upper surface glabrous, shining green; lower surface silvery white, scattered pubescent, without axil-tufts; petiole without milky sap. The leaves turn yellow in autumn.

Flowers appearing before the leaves, earlier even than those of *A. rubrum*, greenish yellow, diœcious or monœcious, in crowded fascicles on the branchlets of the previous year; pedicels very short, petals absent, ovary pubescent. Fruit on slender drooping stalks, ripening in America in May or June, earlier than that of *A. rubrum*, and germinating as soon as it falls; keys woolly when young, ultimately glabrous, widely divergent, pale brown, $\frac{3}{4}$ to $1\frac{1}{2}$ inch long.

The silver maple can only be confused with the red maple, and the marks of distinction are given under the latter species. In winter, the twigs are indistinguishable from those of *A. rubrum*.

¹ This name, which was first given to the silver maple by Linnæus, was subsequently transferred to the sugar maple by Wangerheim and remained in universal use for the latter species during many years. In 1889, Sargent, in *Garden and Forest*, ii. 364, re-established it as the name for the silver maple, and he has been followed in this by most American botanists and foresters. The usage, however, of *A. saccharinum* for the silver maple, and of *A. saccharum* for the sugar maple, is confusing; and we have adopted *A. dasycarpum* for the former, as being a name long in use, and one which has never been applied to any other species.

VARIETIES

The most remarkable are:—var. *laciniatum*, leaves deeply divided into narrow lobes; and var. *tripartitum*, in which the division of the leaves is carried to the midrib. Various intermediate forms, as regards the shape of the leaf, have also received names, which are not worth recognition. Variegated forms are also known in cultivation. (A. H.)

DISTRIBUTION

The silver maple extends from New Brunswick through Southern Ontario to Eastern Dakota, Nebraska, Kansas, and Indian Territory on the west, and southward to Florida; but is rare near the Atlantic coast and on the higher Alleghany Mountains. Sargent gives an excellent article¹ on this species, with an illustration of a tree growing in the open near Boston, and says that it is an inhabitant of low sandy river banks, and grows to its greatest size on the tributaries of the lower Ohio, where it sometimes attains 120 feet in height and 9 to 12 feet in girth. Ridgway measured one in the lower Wabash Valley, which was 118 feet by 14 feet. Michaux says that near Pittsburg, trees of 12 to 15 feet in girth were common on the bank of the river, sometimes alone and sometimes mixed with the willow. Emerson states that in Massachusetts he measured a tree² $12\frac{1}{2}$ feet in girth in a meadow near Northampton, and that another near Lancaster was 16 feet 8 inches round at 6 feet from the ground.

In Canada, where I saw it on the sandy banks of the Gatineau River, near Ottawa, close to its northern limit, it was no larger than in England, but the colour of the leaves was more beautiful than it ever becomes in cultivated trees with us, as is usual in the case of deciduous trees in America. In the open situations which it usually frequents, it is a wide-spreading tree; and Michaux says that it forms a more spacious head than any other tree that he knew.

The fruit, if not destroyed by spring frost, which often happens, ripens in a few weeks after the time of flowering; and if it falls on moist open ground, germinates at once, and sometimes produces plants nearly a foot high before winter. Sargent suggests that this rapid ripening, which is peculiar to the red and silver maples, is a provision of nature for their preservation in situations where the seed, if it ripened in autumn, like other maples, would be water-logged by floods and lose its vitality.

Sargent considers it a valuable tree for ornamental planting, only in deep moist meadow land, or by the banks of streams, where it can spread its long and graceful branches and show its brilliant foliage. This is quite borne out by the specimens which I have seen in England. It is one of the favourite trees for planting in many of the northern cities of the United States.

¹ *Garden and Forest*, iv. 133 (1891).

² Fifty-two years later, in 1890, we learn from a note in *Garden and Forest*, iii. 36, that this tree was 17 feet 4 inches in girth at the same height, having made an annual increase in girth of more than an inch. Though the trunk was partly hollow and some of the branches were gone, the tree was still growing vigorously and might live for many years more.

CULTIVATION

This tree was introduced by Sir Charles Wager in 1725, and is still known in some catalogues and gardens as Wager's maple. It was formerly commoner in cultivation than now, and deserves a place in every garden where a suitable situation can be found; being perfectly hardy at least in the southern half of England, and one of the most beautiful-leaved trees we have both in spring and autumn. The seed is difficult to procure, as it ripens so early in the season—though Loudon says it ripens in England, I have never seen any,—and according to Dawson¹ should be sown directly it is ripe, and shaded and watered during the first summer. It is, however, easy to procure young trees by post from America in autumn, and such will I believe make better trees than the grafted ones which are usually sold in Europe.

Dr. Masters² says that this is one of the best and most elegant trees for planting in towns; but that he never saw a tree of the kind of such proportions as one on the ramparts at Ypres in Belgium.

REMARKABLE TREES

The tallest tree of this species I have seen in England is in a shrubbery at Cobham Hall, Kent, where, however, it has been too much crowded to develop its natural habit and beauty. It is about 77 feet by 9 feet, with a clean bole of nearly 30 feet. There are some trees on Ashampstead Common, Berks, of which the largest is about 65 feet by 8 feet.

At Rickmansworth Park, I measured a tree 60 feet by 12 feet which grows on the banks of the stream and spreads to a diameter of 30 paces. At Barton, Suffolk, there is a very spreading tree on a lawn, forked close to the ground, and 68 feet high, with two main stems 9 feet 3 inches and 6 feet 3 inches in girth. At Hampton Court, Herefordshire, there is an old tree in the lower park on rich alluvial soil, which, when measured by Mr. Hogg in 1881, was 65 feet by 11 feet 5 inches. When I saw it in 1905 it had lost its top and was decaying, though it had increased in girth to 12 feet 3 inches. At Woburn, in rich damp soil near a pond, there is a handsome spreading tree, with a short bole, 53 feet high by 9 feet 5 inches; and at Syon a tall slender tree, 58 feet high and only 3 feet 3 inches round, has smooth bark like that of a beech. At Arley Castle there is a fine tree 61 feet by 4 feet which, according to Mr. R. Woodward, was only planted in 1877. Smaller and younger trees are found in many gardens; but in the North and West of England we have seen none worthy of record, and Loudon mentions no trees equal to those above mentioned.

In Scotland, Mr. W. Middleton Campbell has measured a tree at Camis Eskin, near Helensburgh, which is 58 feet by 11 feet 1 inch.

In Ireland, Henry has seen no large silver maples, and one at Glasnevin, 45 feet high by 6½ feet in girth, is badly shaped and not thriving.

¹ *Trans. Mass. Hort. Soc.* 1885, p. 153.

² *Gard. Chron.* xxxvi. 267 (1904).

TIMBER

All accounts agree in stating that the timber is softer, lighter, and weaker than that of the red or sugar maples, and in consequence is only used as an inferior substitute for these or other similar woods.

The sap of the silver maple is sometimes used to produce sugar in places where the sugar maple is not found, and Michaux says that though the quantity is only half as much, yet the unrefined sugar is whiter and more agreeable to the taste than common maple sugar. (H. J. E.)

ACER SACCHARUM, SUGAR MAPLE

Acer saccharum,¹ Marshall, *Arbust. Am.* 4 (1785); Sargent, *Trees N. Amer.* 632 (1905); Trelease, *Missouri Bot. Garden Report*, v. 88 (1894).
Acer saccharinum, Wangenheim, *Nordam. Holz.* 26 (1787) (Not Linnæus); Loudon, *Arb. et Frut. Brit.* i. 411 (1838).
Acer barbatum, Michaux, *Fl. Bor. Am.* ii. 252 (1803); Sargent, *Silva N. Amer.* ii. 97, t. 90 (1892).

A tree attaining in America 120 feet in height and 12 feet in girth. Bark grey and smooth on young stems, deeply furrowed on old trunks. Young branchlets glabrous, becoming brown in their first summer. Leaves (Plate 206, Fig. 12), about 5 inches long by 6 inches wide, usually five-, rarely three-lobed, cordate at the base; lobes triangular, acuminate, with one or two pairs of sinuate teeth; sinuses rounded and shallow, reaching about one-third the length of the blade; margin non-ciliate; upper surface dark green, glabrous; lower surface pale, dull, with pubescent tufts in the primary and secondary axils, elsewhere either glabrous or more or less pubescent; petiole without milky sap. Leafy stipules,² with bases adnate to the petiole, are occasionally developed in var. *nigra* of this species.

Flowers, monœcious or diœcious, appearing with the leaves, arising from terminal leaf-buds and from lateral leafless buds, in nearly sessile corymbs, greenish-yellow; pedicels long, thread-like, pubescent; petals absent; ovary with long scattered hairs. Fruit, ripening in autumn, glabrous; keys about an inch long; wings broad, thin, usually divergent.

This species in the form of the foliage somewhat resembles the Norway maple; but is readily distinguishable by the pale colour of the leaves beneath, and the absence of milky sap in the petioles. In winter, the buds are conical, sharp-pointed, and pubescent, showing externally 8 to 14 scales; lateral buds shortly stalked; opposite pairs of leaf-scars not united around the stem, their upper margins fringed with yellowish hairs.

¹ This is the name now adopted by Sargent, by Sudworth, *Check List of Forest Trees of U.S.* 91 (1898), and by other American botanists and foresters. *Acer saccharinum*, Wangenheim, is a later name, and must be dropped, especially as *Acer saccharinum*, Linnæus, is now commonly used in America for another species, the silver maple.

² Gray, *Amer. Naturalist*, vi. 767 (1872), and vii. 422 (1873); and Sargent, *Garden and Forest*, iv. 148 f. 27 (1891).

VARIETIES

The sugar maple is very variable in the wild state, and certain varieties of it are now recognised as distinct species by Sargent in his latest book on American trees. Two of these—*Acer floridanum*, Pax, a moderate-sized tree, growing in the Southern States and in Texas and Mexico, and *Acer leucoderme*, Small, a low tree ranging from North Carolina to Arkansas—would probably not be hardy if introduced, and need not be further mentioned by us. *Acer nigrum*, Michaux, now considered by Sargent to be a distinct species, is best treated as a variety of *A. saccharum*, and is to be carefully distinguished from var. *Rugelii*, with which it has been confused.

1. Var. *nigrum*, Britton, *Trans. N.Y. Acad. Sci.* ix. 10 (1889).

Acer nigrum, Michaux f. *Hist. Arb. Am.* ii. 238, t. 16 (1810); Sargent, *Garden and Forest*, 1891, p. 148, f. 27, and *Trees N. Amer.* 634 (1905).

Leaves green beneath, cordate at the base, with the basal sinus closed by the approximation or overlapping of the lobes; sides of the blade drooping; lobes usually three, occasionally five; acute, entire or obtusely toothed. Bark of old trees deeply furrowed, sometimes almost black. Young branchlets orange-coloured.

This variety, according to Sargent, is widely distributed, extending from Ontario and the valley of the St. Lawrence, near Montreal, southward to Virginia and Kentucky, and westward through Michigan, Indiana, Illinois, Iowa, and Missouri to South Dakota and Kansas. It is comparatively rare near Montreal and Vermont, becoming more abundant farther west, almost replacing the type in Iowa, and the only form in South Dakota. It was first noticed by the younger Michaux on the banks of the Genesee River in New York, where it still forms a forest of considerable size.

Loudon states that the black sugar maple was introduced in 1812; but it is now very rare in cultivation. Var. *monumentale*, Temple, a tree of upright columnar habit, occasionally seen in botanic gardens, is a form of var. *nigrum*.

2. Var. *Rugelii*, Rehder, in Sargent, *Trees N. Amer.* 633 (1905).

Acer barbatum, Michaux, *Pl. Bor. Am.* ii. 252 (1803).

Acer barbatum, var. *nigrum*, Sargent, *Silva N. Amer.* ii. 99, t. 91 (1892).

Acer Rugelii, Pax, in Engler, *Bot. Jahrb.* vii. 243 (1886).

Leaves pale beneath, papery in texture, three-lobed, entire or with short obtuse teeth. This is the common and frequently the only form of the sugar maple in the region from North Carolina and Georgia to Missouri; and is occasionally met with as far north as Michigan and Prince Edward's Island, leaves of this form sometimes appearing on the upper branches of trees, which bear on their lower branches typical leaves of the ordinary form of the species. This variety does not appear to be in cultivation in England. (A. H.)

DISTRIBUTION

The sugar maple is one of the most widely and generally distributed trees in Eastern North America. The northern limit of its range on the Atlantic coast is Southern Newfoundland. It extends through Canada and the Northern States southwards along the Alleghany Mountains to Northern Georgia and West Florida, and westward along the valleys of the St. Lawrence and the Saguenay, by the shores of Lake St. John and the northern borders of the Great Lakes to the Lake of the Woods, and in the United States to Minnesota, Nebraska, Eastern Kansas, and Eastern Texas. It is common in all these regions, growing especially on rich uplands mixed with ashes and hickories, white oak, wild cherry, black birch, yellow birch, and hemlock, and often in the north forming the principal part of extensive forests. The undergrowth in some of the forests near the northern border of the United States is often composed almost entirely of young sugar maples, which grow readily under the dense shade of other trees. The type is more prevalent in the north—var. *Rugelii* and var. *nigra* in the central States, while var. *leucoderme* and var. *floridanum* appear to be the only forms found in the south.

Much of the splendour of the northern forest in early autumn is due to the abundance of the sugar maple, which is then unsurpassed by any other tree in brilliancy of colouring, the foliage turning to shades of deep red, scarlet, orange, or clear yellow.

A figure of an unusually large tree, showing the habit which it assumes when in the open, is given in *Garden and Forest*, v. 380 (1892). It grows on the farm of Mr. L. Parker, forty-five miles east of Cleveland, Ohio, and measures 13½ feet in girth at 2 feet from the ground, with very large limbs spreading over an area 100 feet in diameter. It has been tapped annually without any apparent ill-effects, and yields each year three gallons of syrup. Another illustration in *Garden and Forest*, iii. 167 (1890), of a tree exposed on a stony hillside in New Hampshire is of a very different type, and shows the habit of an adult tree which has lost the narrow upright form of growth it usually has when young.¹

REMARKABLE TREES

Though introduced at a very early period (the date is given by Loudon as 1735, on whose authority we know not), the sugar maple has rarely thriven in England, or, so far as we know, in Europe. The reasons for its failure to grow in this country are as mysterious as in the case of the white oak, the American beech, and other trees of the Eastern States; but it seems a short-lived tree, and seldom attains any considerable size. Loudon mentions several trees of no great age 20 to 40 feet high, and one at Purser's Cross which was 45 feet. But none of these, so far as we can learn, are now living, and some maples which have been reported under this name turn out to belong to other species. We know,

¹ The fastigate tree, supposed to be of this species, is really *A. rubrum*. Cf. p. 672.

however, of several worthy of mention, of which the largest is growing at Park Place, near Henley-on-Thames, in the grounds of Mrs. Noble. This tree is in a thick wood on loamy soil overlying chalk, and if upright would be probably over 60 feet high. It leans, however, very much to one side, where the branches extend as much as twenty paces from the trunk. It has a short bole of 8 feet, which girthed 9 feet 2 inches when I measured it in 1905. There were a few fruits on it, which, however, seemed unlikely to ripen. (Plate 191.)

Sir Hugh Beevor has lately discovered a tree in the grounds of Sir Robert Dashwood at West Wycombe, which is 83 feet high by 5 feet 11 inches in girth. It is nearly dead, being probably killed by mistletoe, as many of the branches show large spindle-shaped swellings, caused by this parasite.

At Arley Castle there is a tree which measured, in 1907, 64 feet high by 4 feet 8 inches in girth. At Dropmore one in a wood is 45 feet by 4 feet 10 inches. There are also small trees at Cornbury Park and at Tortworth. There is a healthy specimen at Syon 55 feet by 5 feet 1 inch, which had some seed in 1905. At Barton, Suffolk, there is an ill-shaped tree much crowded by others, which measures about 50 feet by 4 feet 6 inches.

Mr. Bartlett reports that there are five trees of this species at Pencarrow, and that another at Tredethy, Cornwall, is 50 feet high by 3 feet 5 inches in girth.

The Hon. Vicary Gibbs informs us that at Tyntesfield, Somersetshire, a number of sugar maples are growing, which are about fifty years old. The soil being shallow they have made low heads with very stout lateral branches. He has raised some seedlings from them at Aldenham. Young trees, which I raised from seed gathered near Boston in September 1904, have grown fairly well at Colesborne, and are now about 3 feet high.

TIMBER

The wood of the sugar maple has been well known in commerce for a long period, and at one time the variety of it which is known as bird's-eye maple was very fashionable for furniture and cabinet-making, though it is now little used for first-class work in England.

The best account I know of the varieties of maple wood is in Hough's *American Woods*, i. 50-51, where he says that there are peculiar freaks in the growth of timber as yet unexplained, but of which this is one of the most important from a commercial point of view, as well as one of the most beautiful. They are known as "blister," "bird's-eye"¹ or "pin," and "curly" figures. The first two are almost peculiar to the "hard" or sugar maple. The last is found even more commonly in the red and silver or "soft" maples as they are called in the United States and Canada. The three varieties of figure are often found more or less mixed in the same tree, and it requires much experience to detect their presence in the growing tree.

The blister variety, which is much the rarest, usually has a massive trunk in

¹ In bird's-eye maple there is a succession of elevations and depressions in the annual layers of the wood, and Hopkins considers that this is probably due to punctures made in the bark by woodpeckers. Cf. *Garden and Forest*, vii. 373 (1894).

proportion to its top, and on removing a piece of bark the surface of the wood is found to be covered with wart-like swellings. The figure is best on the outside, falling off as the heart is approached. In order to show it, the log is cut on a lathe, which slices off a thin shaving all round, producing what is called a knife-cut veneer. The bird's-eye variety may be detected by small pits in the bark, usually inconspicuous, which correspond to small pits all over the wood, and, like the other, has a head usually small as compared with the trunk.

Maple wood also shows when cut radially a very fine silver grain, which to my eye is almost as beautiful as the other figures. The colour is normally white, but when the trees are old assumes a pink or reddish tint. It is also very much used in its plain form for shipbuilding, flooring, and all purposes where strength, durability, and close texture are required, and is largely imported in the form of prepared blocks, which, when properly fitted and laid, make a durable good floor.

Maple sugar, usually, though not always, the produce of *Acer saccharum*, is derived, by boiling, from the sap which flows from the tree in spring. Though it is in the opinion of most people one of the best kinds of sugar known, and, especially in the form of syrup eaten with buckwheat cakes, is one of the most favourite of American table delicacies; it is so little known to English readers that we do not think it necessary to describe the process of manufacture, which has been given at length by Loudon, Michaux, and other writers on American trees.¹ An article on this subject was published in *Kew Bull.*, 1895, p. 127; and an interesting letter on the domestic uses of maple sugar and maple syrup, by Miss Boyle of Maywood, New Jersey, appeared in *The Garden*, lxxv. 152 (1904). (H. J. E.)

ACER MACROPHYLLUM, OREGON MAPLE

Acer macrophyllum, Pursh, *Fl. Amer. Sept.* i. 267 (1814); Loudon, *Arb. et Frut. Brit.* i. 408 (1838); Sargent, *Silva N. Amer.* ii. 89, tt. 86, 87 (1892), and *Trees N. Amer.* 628 (1905).

A tree attaining in America 130 feet in height and 15 feet in girth. Bark of old trees thick, rough, deeply furrowed, and broken on the surface into small plate-like scales. Young branchlets glabrous, green, remaining green or becoming dark red in their first winter. Leaves (Plate 205, Fig. 3) very large, averaging 9 inches in breadth and length, deeply and usually narrowly cordate at the base; lobes five, with acute or acuminate apex, and large triangular lobules or teeth; sinuses deep, extending more than half-way the length of the blade, rounded at the base; margin ciliate; upper surface dark green, shining, scattered pubescent; lower surface light green, glabrescent between the nerves, with tufts of white pubescence in the axils; petiole with milky sap.

¹ The most complete account is given in *U.S. Dept. Agric., Forestry Bulletin No. 59; The Maple Sugar Industry*, by Fox and Hubbard, Washington, 1905. Cf. also *U.S. Dept. Agric., Forest Service, Circular 95* (1907), which gives notes on the cultivation and economic uses of the sugar maple.

Flowers, staminate and pistillate together, in pendulous racemes, appearing when the leaves are fully grown, bright yellow, fragrant; pedicels slender, pubescent, often branched; stamens nine or ten, filaments pubescent; ovary tomentose. Fruit, ripening in autumn, brown, the carpels covered with long, pale hairs, which extend along the thickened edge of the wing; keys slightly divergent, about 2 inches long.

(A. H.)

DISTRIBUTION

This species, which is the largest of the American maples, is confined to the Pacific coast, where it extends from about 55° N. in Alaska to the San Bernardino Mountains of Southern California, but never, according to Sargent, far from the coast or ascending the mountains higher than about 2000 feet. It is the largest deciduous tree in Vancouver Island except *Populus trichocarpa*, and I believe also in Washington and Oregon, though surpassed by some of the oaks in California. It attains its maximum size in the wet and mild climate of Puget Sound, especially in the Olympic Mountains, and grows with the luxuriance of a tropical tree covered with ferns, moss, and climbing plants. The beautiful photograph (Plate 193), for which I am indebted to Mrs. Browne of Tacoma, was taken near Lake Cushman in the Olympic Mountains. I cannot give exact measurements of these trees, but the height was estimated at 130 feet.¹ On Capt. Barkley's farm, north of Duncans, Vancouver Island, I measured several trees of 110 to 120 feet high, and on Swallowfield farm two trees on the banks of a river, of about the same height, one being 12 feet, the other 13 feet in girth. A gigantic spreading tree on the same farm had a swelling butt, no less than 15 paces round at the ground, but of no great height. It grows as a rule in flat meadows with Douglas fir, *Abies grandis*, and *Thuja plicata*, and likes a fairly damp soil. Farther south in the drier country of Oregon, it is smaller; Sheldon says 50 to 90 feet high by 6 to 15 feet in girth. In the dry country of Northern California about Lake Tahoe it becomes a low crooked tree only 8 to 20 inches in diameter. Its large keys are produced very abundantly, and when ripe add to the ornamental appearance of the tree.

CULTIVATION

Discovered by Menzies during Vancouver's voyage to British Columbia, it was introduced into England in 1812. Douglas sent home seeds to the Royal Horticultural Society about 1827, from which we believe the oldest trees in England have grown. But though very easy to raise and a very rapid grower when young, it does not ripen its young wood when quite young, this being often killed back by the frosts of winter, sometimes to the ground; but as the trees get older this failing decreases. Though the tree is hardy, at least as far north as East Lothian,

¹ Mr. F. R. S. Balfour of Dawick tells me that in the deep alluvial soil of the valley above Lake Cushman, this tree attains an immense size, being well sheltered by the steep mountains around. The maples grow here mixed with *Abies oregona*, *Populus trichocarpa*, and *Thuja plicata*; and though overtopped by the last two, he estimated the maples at over 150 feet high. He also saw it of great size in the Puyallup Valley, and at the mouth of the Nisqually River in Washington; and adds that it is being extensively planted as a shade tree in the towns of the Pacific coast.

it has never become common, and is not often to be had from nurserymen. It is well worth cultivation on account of its large and beautiful foliage, and should be planted in deep moist soil in a warm aspect where it is sheltered by other trees at first. It ripens seeds in England, and I have raised plants from some sent me by the Earl of Ducie in 1900, which are now over 8 feet high.

It does fairly well as a planted tree in the lighter alkali lands of the San Joaquin valley in California, where only a few species will thrive, owing to the nature of the soil.¹

REMARKABLE TREES

The largest specimen I know of the Oregon Maple is one at Boynton, Yorkshire, which Sir Charles Strickland to the best of his recollection planted himself about sixty years ago. It is not a well-shaped tree, as it is rather crowded, but measures 70 feet high by 6 feet in girth. There is another at Hildenley, probably of the same age, which measures 50 feet by 5 feet and bears fruit. There are several trees in Kew Gardens, the largest of which, near the entrance to the nursery, is 49 feet high by 3 feet 8 inches in girth. At Tortworth there is a tree in a rather exposed situation which is 45 feet by 5 feet 6 inches. At Syon a grafted tree is 50 feet high but only 3 feet in girth, and bore some fruit in 1905. In the Royal Avenue at Bath there is a tree 50 feet by 6 feet 2 inches, but it is not in a thriving condition, the soil being too dry to suit it. At Bicton, now the property of Lord Clinton, one of the most thriving young trees which I have seen grows near the house; and was in 1906 about 50 feet high but only 2 feet 9 inches in girth.

At Smeaton-Hepburn, East Lothian, there is a wide-spreading tree, with a bole of 6 feet, which Henry measured in 1905 as 50 feet high by 7 feet in girth.

At Glasnevin, Dublin, there is a fine tree, which in 1907 measured 51 feet high by 5 feet 4 inches in girth. There are two others about 40 feet high, with wide-spreading branches, growing in the quadrangle inside the main gate of Trinity College, Dublin.

TIMBER

This wood, though unknown in Europe, is equal in beauty, and similar in character to that of the eastern maples, and is more valued than any other native hardwood in British Columbia and Washington. In old trees it is often very well figured, though the figure is larger, bolder, and less regular than in the sugar maple, and the colour not so uniform; some parts of the heartwood being of a rich red brown. Some of the best houses in Victoria are decorated with this wood, that of the Hon. J. Dunsmuir, Lieutenant-Governor of British Columbia, being a good example. If carefully selected and well seasoned it is fit for the finest cabinet-maker's work. I had a bedstead made from it by Messrs. Weiler of Victoria which shows the beauty of the wood very well; and it could be procured in fair quantity if desired, as there are many large trees still standing in accessible places.

(H. J. E.)

¹ Hilyard, *Soils*, 481 (1906).

ACER NEGUNDO, ASH-LEAVED MAPLE, BOX ELDER

Acer Negundo, Linnæus, *Sp. Pl.* 1056 (1753); Sargent, *Silva N. Amer.* ii. 111, t. 96 (1892), and *Trees N. Amer.* 641 (1905).
Negundo aceroides, Moench, *Meth.* 334 (1794).
Negundo fraxinifolium, Nuttall, *Gen. Amer.* i. 253 (1818); Loudon, *Arb. et Frut. Brit.* i. 460 (1838).

A tree attaining in America 70 feet in height and 12 feet in girth; bark deeply fissured into broad rounded ridges. Young branchlets green or glaucous, glabrous. Leaves (Plate 205, Fig. 2) pinnate, turning yellow in autumn. Leaflets, three or five, stalked, ovate or oval, rounded or cuneate at the base, acuminate at the apex, serrate or toothed above the middle, often three-lobed; upper surface bright green and glabrous; lower surface pale green and with slight pubescence on the midrib and nerves; rachis glabrous.

Flowers dioecious, without petals, appearing with the leaves, from buds in the axils of the leaf-scars of the previous season, staminate flowers in fascicles, pistillate in narrow pendulous racemes. Fruit, with narrow acute nutlets, diverging at an acute angle, and thin reticulate, straight or falcate wings.

In winter, the terminal buds are about $\frac{1}{8}$ inch long, acute, with four tomentose ciliate external scales; lateral buds appressed to the twigs, with two outer visible scales; opposite leaf-scars united around the twig, narrowly crescentic, three-dotted, fringed with hairs on the margin.

VARIETIES

The species, extending over a vast territory, varies considerably in the wild state, the typical form described above occurring in the eastern part of its distribution. Farther west, in Colorado, Utah, and New Mexico, the branchlets and leaves become pubescent; and in California, an extreme form is met with, which is often considered to be a distinct species:—

1. Var. *californicum*, Wesmael, *Bull. Bot. Soc. Belg.* 43 (1890); Sargent, *Garden and Forest*, iv. 481 (1891), *Silva N. Amer.* ii. 112, t. 97 (1892), and *Trees N. Amer.* 643 (1905).

Acer californicum, Dietrich, *Syn.* ii. 1283 (1840).
Negundo californicum, Torrey and Gray, *Fl. N. Amer.* i. 250, 684 (1838).

This is distinguished, according to Sargent, by its darker-coloured bark; buds covered with dense tomentum; short pale persistent pubescence on the branchlets and ripe fruit; leaflets three, larger, more coarsely serrate, and more frequently lobed than in the type, and coated beneath with pale pubescence. As seen in cultivation at Kew, the leaflets are usually five and not three; and in the wild state, 5-foliolate leaves are occasionally met with, as in a specimen in the Kew herbarium collected by Lobb in California. The pubescence on the leaflets beneath is most strongly marked on the midrib and nerves, is whitish in colour, and forms prominent

axil-tufts. Cf. Plate 205, Fig. 1. There are specimens of this variety at Kew; and a tree at Grayswood, near Haselmere, was about 30 feet high in 1906, and appeared to be very vigorous and thriving.

A considerable number of horticultural varieties are known:—

2. Var. *variegatum*.¹ Leaves with broad white margin. One of the most popular and most largely grown of all variegated trees. It originated as a chance branch sport in the nursery of M. Fromant at Toulouse in 1845; but remained almost unknown, till 1853, when it was awarded, at a horticultural show at Toulouse, a medal given by the Empress Eugenie.

3. Several other coloured forms are known, as var. *aureo-maculatum*, leaves spotted with yellow; var. *aureo-marginatum*, leaves with yellow margin; and var. *auratum*, leaves yellow.

4. Var. *violaceum*.² Young branchlets covered with a glaucous violet bloom.

5. Var. *crispum*.³ Leaves variously cut and curled. According to Nicholson, this is not nearly so vigorous a grower as the type. (A. H.)

DISTRIBUTION

This species is the most widely distributed of North American maples, extending in its typical form from Western Vermont and Central New York, southward to Northern Florida, and westward to the Rocky Mountains. According to Sargent, it is rare east of the Alleghany Mountains, and is commonest in the basin of the Mississippi, attaining its largest size in the valley of the lower Ohio. The biggest recorded, so far as we know, is one measured by Ridgway in the Wabash Valley, which was 60 feet high by 12 feet in girth. It is one of the few eastern trees, which is quite at home in the dry prairie region, and is found on most of the rivers of the great plains, and on the foot-hills of the Rocky Mountains, where it is usually a stunted and ill-shaped tree or bush, and rarely has a clean or straight stem. Slightly modified, as regards the amount of pubescence on the leaves and branchlets, it occurs in Utah, Colorado, New Mexico, and Eastern Arizona. Var. *californicum* is met with in California in the valley of the lower Sacramento river, in the interior valleys of the coast ranges from San Francisco Bay to about lat. 35°, and in the high cañons of the San Bernardino Mountains; and has been planted, with successful results, on the alkaline lands of the San Joaquin valley.⁴

In Western America it is largely planted for shelter belts.⁵ Mr. W. T. Macoun states in a recent number of the *Canadian Forestry Journal*, p. 80 (1907), that in the prairie provinces it is used largely in plantations. It grows rapidly during the first twenty years, and produces a very dense cover, which makes it a bad neighbour for slow-growing trees, but a good nurse for those which, like birch, ash, and American elm, can hold their own in its company.

⁵ Cf. *U.S. Dept. Agric. Forest Service, Circular* 86 (1907), which gives an elaborate account of the economic uses of this tree in the United States, with notes on its propagation and cultivation.

CULTIVATION

Acer Negundo was very early introduced into England, being cultivated in the garden at Fulham by Bishop Compton in 1688. According to Loudon, this tree was about 45 feet high and 7 feet 1 inch in girth in 1835.

It is by far the commonest of American maples in cultivation, the variegated form being grown in every nursery and planted extensively in shrubberies and town gardens for the sake of its colour. It grows from seed with extraordinary rapidity, attaining 5 or 6 feet high in 3 years, is apparently at home in every kind of soil, and resists all the extremes of our climate without injury. Though Loudon says that the seed must be sown in autumn, I have found that it will germinate readily when sown as late as June. Trees which came up in a bed of American ash in my nursery in June 1901, are already 15 feet high, and bearing seed freely when only seven years old.

REMARKABLE TREES

Though not often seen as a tree, yet on good soil it seems to attain almost as great size in England as in America. Loudon mentions a tree at Kenwood which was 47 feet high, 35 years after being planted. A tree at Botley, Hants, probably planted by Cobbett, was recorded¹ in 1884 as being 70 feet high by 6 feet 4 inches, but I did not find this when I visited Botley in 1906. The largest, however, that we have seen is at the Mote, near Maidstone, which I found in 1902 to be 53 feet high by 8 feet 4 inches. Henry measured one at Shiplake House, near Henley, 50 feet by 6 feet 3 inches, with a clean bole 16 feet long; and there is a large wide-spreading tree in Kew Gardens near the Director's Office which is about 40 feet high, and measures 6 feet 8 inches in girth. Another in the Oxford Botanic Garden is 4 feet in girth; and a very old tree, with a short trunk and wide-spreading branches, in Mortlock's Garden, behind the Corn Exchange at Cambridge, probably on the site of the old Botanic Garden, is about 30 feet in height and 5 feet 8 inches in girth. Miss Woolward, in 1905, measured a tree in the grounds of the Knowle Hotel at Sidmouth, 38 feet in height and 3 feet 10 inches in girth.

TIMBER

Its timber is very unlike that of other maples, for though in young trees it is whitish, the heartwood of old trees is of a most peculiar colour, purplish red with dark veins.² I have never seen it of sufficient size to be useful, though Michaux says it was in his time sometimes used by cabinetmakers in the west; and Sargent states that it is sometimes used for the interior finish of houses, wooden-ware, cooperage, and paper pulp. Small quantities of maple sugar are occasionally made from this tree.

(H. J. E.)

¹ *Woods and Forests*, 1884, p. 316.

² I made this note from specimens shown as "Box Elder" at the St. Louis Exhibition, but do not find any confirmation of this in Sargent's or Hough's works.

SEQUOIA

Sequoia, Endlicher, *Syn. Conif.* 197 (1847); Bentham et Hooker, *Gen. Pl.* iii. 429 (1880); Masters, *Journ. Linn. Soc. (Bot.)* xxx. 22 (1892).
Wellingtonia, Lindley, *Gard. Chron.* 1853, p. 823.
Washingtonia, Winslow, *Calif. Farmer*, 1854, ex Hooker, *Kew Journ.* vii. 29 (1855).
Gigantabies, Nelson (*Senilis*), *Pinaceæ*, 77 (1886).
Athrotaxis, Baillon, *Hist. Pl.* xii. 39 (1892).
Steinhauera, Kuntze, *Lexic. Gen. Phan.* 533 (1904).

TALL evergreen trees, belonging to the tribe Taxodineæ of the order Coniferae. Bark thick, of two layers, the outer thick, spongy and fibrous, the inner thin, close, and firm. Branches short and stout; lateral branchlets slender, terete, and deciduous. Buds and leaves different in the two species, the leaves having an undivided fibro-vascular bundle, with a single resin canal beneath it.

Flowers monœcious, solitary, minute, appearing in early spring from buds formed in the previous autumn. Male flowers terminal or in the axils of the uppermost leaves, surrounded at the base by imbricated, ovate, acute, apiculate, involucre bracts; stamens numerous, spirally arranged on an axis; filaments short, dilated into ovate incurved sub-peltate connectives, which bear on their inner surface two to five (usually three) pendulous globose two-valved anther-cells, opening below on the back; pollen simple. Female flowers terminal, the leaves gradually passing into the bracts, which are numerous, spirally imbricated, ovate, keeled on the back, acuminate with either long or short points, and adnate to short thick rounded ovuliferous scales which bear five to seven ovules, at first erect, ultimately becoming inverted.

Cones pendulous, persistent after the fall of the seeds. Scales, formed by the enlargement of the united bracts and ovuliferous scales of the flowers, woody, with deciduous resin-glands, spirally arranged, wedge-shaped at the base, widening at the apex into oblong wrinkled discs, showing a transverse median depression, sometimes tipped by a small spine. Seeds, 5 to 7 under each scale, pendulous, oblong-ovate, compressed, with two lateral wings. Seedlings with four to six cotyledons; primary leaves linear-lanceolate, short-pointed, thin, spreading.

Several fossil species of *Sequoia* are known, occurring earliest in the Cretaceous period in the holarctic region, becoming very widely spread over Europe, Northern Asia, and North America in Tertiary times. Two living species, inhabiting California, are distinguished.

1. *Sequoia sempervirens*, Endlicher. Coast range of California, and crossing

the boundary line into Oregon. Buds scaly. Leaves on lateral branches linear and in two ranks in one plane. Bracts of pistillate flowers about twenty, usually with short points. Cones ripening in the first season; scales abruptly enlarged into terminal discs.

2. *Sequoia gigantea*, Decaisne. Western slopes of the Sierra Nevada in California. Buds without scales. Leaves all radially arranged, spreading or slightly appressed, ovate or lanceolate. Bracts of pistillate flowers 25 to 30, with long points. Cones ripening in the second year; scales gradually thickening from the base to the apex.

Sequoia gigantea, Endlicher, *Syn. Conif.* 198 (1847).

Sequoia religiosa, Presl, *Epimel. Bot.* 237 (1849).

Taxodium sempervirens, Lambert, *Pinus*, ii. 24 t. 7 (1824); Loudon, *Arb. et Frut. Brit.* iv. 2487 (1838).

Abies religiosa, Hooker and Arnott, *Bot. Voy. Beechey*, 160 (1841). (Not Lindley.)

Schubertia sempervirens, Spach, *Hist. Vég.* xi. 353 (1842).

A tree attaining 340 feet in height, with a slightly tapering and irregularly lobed trunk, occasionally 50 to 75 feet in girth above the enlarged and buttressed base. Bark six to twelve inches thick, divided into rounded ridges two or three feet in width, separating on the surface into long narrow fibrous scales, which on falling display the reddish-brown soft spongy fibro-cellular middle bark. Young trees pyramidal, with slender branches to near the base. Older trees in the forest with stems clean to 75 or 100 feet, the stout horizontal branches above forming an irregular narrow crown. Branchlets slender, green in the first year, gradually becoming afterwards brownish with a thin scaly bark, spreading in two ranks more or less in one plane. Buds solitary, both terminal and in the axils of two or three of the uppermost leaves, surrounded by loosely imbricated ovate acute scales, which remain persistent, dry, and brown at the base of the branchlets.

Leaves of two kinds: (1) on normal lateral branchlets, spreading in one plane in two ranks by a twist on their bases, $\frac{1}{4}$ to $\frac{3}{4}$ inch long, linear or lanceolate, ending in short cartilaginous points, slightly thickened on the revolute margins, narrowed at the base, where they become decurrent on the branchlets; upper surface dark green, with a median furrow; lower surface with a green midrib and two conspicuous whitish stomatic bands: (2) on leading branchlets, radially arranged in several ranks, appressed or spreading, about $\frac{1}{2}$ inch long, ovate or ovate-oblong, with incurved cartilaginous points; upper surface concave with a prominent green midrib and two whitish stomatic bands; lower surface rounded, indistinctly stomatiferous. Lateral branchlets with leaves of the latter kind may exceptionally occur on any part of the tree, and usually cover entire branches at the summit of

large trees; while in the case of trees growing at high altitudes they are sometimes spread over the whole of the branches.

Male flowers, $\frac{1}{16}$ inch long, with rounded connectives. Female flowers with about twenty broadly ovate bracts, tipped usually with short points. Cones ellipsoidal, $\frac{3}{4}$ to 1 inch long, $\frac{1}{2}$ inch broad; scales with slender stalks, which enlarge abruptly into discs $\frac{1}{3}$ inch in breadth. Seeds light brown, $\frac{1}{16}$ inch long; wings narrower than in *S. gigantea*.

The cones ripen at the end of the first season, and are freely produced in most parts of the South of England and in Ireland, the first recorded¹ being in 1862 on a tree at Barton, Suffolk, which had been planted in 1847. Fertile seed, however, is very rare, the only instance known to us being on a large tree at Huntley Manor, Gloucestershire, from which Prof. Somerville raised seedlings in 1904. Proliferous cones² occur occasionally; and a cone³ with the upper part ovulate and the lower part staminate has been observed.

The tree suckers from the root,⁴ and sends up, when cut, numerous shoots⁵ from the stool. Fasciation⁶ has been observed in the suckers in the redwood forest in California. Dr. Masters⁷ described and figured the peculiar woody excrescences, which are sometimes formed at the base of the stem of young trees, which have been raised from cuttings.

VARIETIES

In the wild state there is some variation, as noticed above, in the occasional occurrence of lateral branches with foliage like that of the leading shoots. Several varieties have been obtained in cultivation:—

1. Var. *albospica* (var. *adpressa*). Tips of young shoots creamy white in colour. Leaves small and dense upon the twigs, resembling those of *Taxus baccata adpressa*.
 2. Var. *glauca*. Leaves linear, acute, $\frac{1}{4}$ inch long, glaucous, loosely imbricated, appressed or spreading.
 3. Var. *taxifolia*. Leaves broader than in the type.
- A tree, pendulous in habit, is growing at Dropmore.

DISTRIBUTION

The redwood occurs on the western slopes, valleys, and alluvial flats of the coast range, from the Chetco river in Oregon to Salmon Creek Cañon, twelve miles south of Punta Gorda in Monterey county, California, and ascends from sea-level to 2000 or rarely 3000 feet. It occupies a narrow strip of country along the sea coast, about 500 miles in length from north to south, and is not found inland beyond

¹ Bunbury, *Arboretum Notes*, 166 (1889).

² *Bot. Gazette*, xxxviii. 2 (1904).

³ Two suckers are growing beside a tree, 60 feet high, at Shiplake House, near Henley.

⁴ In *Journ. Roy. Hort. Soc.* xix. 432 (1896), it is stated that redwood coppice shoots are believed to have been used for producing hop-poles in Kent; but this must have been an experiment on a small scale, and without any practical value. At Arley, shoots from the stool of a tree, which was felled, made a growth of 4 feet in their first year.

⁵ Pierce, in *Proc. Calif. Acad. Sc.* ii. 83 (1901), who also gives an account of peculiar white-coloured suckers, which are often seen in California.

⁶ *Gard. Chron.* xi. 372, fig. 53 (1879).

the influence of the sea fogs. A large portion of the area, originally covered by the tree, has of late years been destroyed by fires and by felling for lumber. In ancient times the redwood grew considerably to the southward of its present limit, as is proved by logs being found by well-borers in various parts of the coast range, where it does not now exist, as far south as Los Angeles and San Diego.

In Oregon there are only about 2000 acres of redwood, in two small forests, on the Chetco river, six miles from its mouth, and on the Winchuck river. The redwood belt, properly so called, which is a continuous forest of the species, begins on the northern boundary of California, and ends in Mendocino county, where it attains its maximum width, about thirty-five miles. Farther north the belt narrows, being only ten miles broad in Del Norte county. South of Mendocino county the redwood is only met with in small isolated forests.

In Monterey county¹ the groves are small, the most southerly forest of any importance being in the Santa Cruz Mountains, where the tree is common. The State of California appropriated in 1901 \$250,000 for the purchase of the redwood forest of the Big Basin in Santa Cruz county, and this is now known as the California Redwood Park.² Prof. Jepson tells me that the area of the park is about 3800 acres, 2500 acres of which are covered with timber, consisting of Redwood mixed with Tan Oak, Madroña, and Douglas Fir. A fine grove, known as the Santa Cruz "Big Trees," is famous. A small grove, now practically destroyed, existed fifty years ago on the east side of the bay of San Francisco in Alameda county. At present the tree grows in the Mount Diablo range in only one limited locality, Redwood Peak, in the Oakland Hills, directly opposite the Golden Gate. In Napa valley the tree is rather common; and crossing over the summit of Howell Mountain it descends the slope towards Pope valley. This is the point where the redwood grows farthest from the ocean, and the only locality where it is found to the east of the divide of the coast range. In Marin county there are only a few isolated groves, mainly used as picnic grounds; and in Sonoma county a few scattered claims still remain uncut.

The redwood belt, which I visited in 1906, near its northern limit at Crescent City, is the most impressive of all forests, being remarkable not only for the immense size³ of the trees, but also for their extraordinary density upon the ground. A single acre has yielded 100,000 cubic feet of merchantable timber. The favourable conditions of the soil and climate account in great measure for this extreme productivity; but I am inclined to think that the mode of reproduction by suckers and by coppice shoots, explains in part the density with which the trunks stand upon the ground. A large proportion of the old trees are sprouts from ancient

¹ Cf. Jepson, *Flora W. Mid. California*, 24 (1901); and C. H. Shinn, *Cycl. Am. Hort.* iv. 1660 (1902).

² Prof. Jepson in a recent letter says that there is practically no Redwood in the National Forest Reserves; but a few groves in private hands are as safe as if under State or National control, namely:—Redwood Cañon by Mount Tamalpais, near San Francisco; Bohemian Club Grove in Sonoma county; and Armstrong Grove in the same county. These comprise 500 to 1000 acres each.

³ Mr. J. H. Maiden, Director of the Sydney Botanic Garden, in an article in the *Sydney Morning Herald*, quoted in the *London Pharmaceutical Journal*, April 30, 1904, states that the excessive heights claimed for eucalyptus trees in Australia are unreliable, and considers that the redwood, accurately measured by Sargent as 340 feet, is the tallest tree in the world. Von Mueller, in *Eucalyptographia*, Decade 5 (1879-1884), gives, on the authority of Mr. D. Boyle, the measurement of a fallen *Eucalyptus amygdalina* as 420 feet, and states that Mr. G. Robinson, a competent surveyor, measured another tree of this species as 471 feet; and it is unknown to me on what grounds Mr. Maiden has questioned these measurements.

trees, as is readily seen by the way in which one-sided stems are often grouped around a hollow, from which the old stump has rotted away. At the present day reproduction is mainly effected by suckers, the proportion of these to seedlings being as 100 to 1. Seeds do not germinate except in open places, and young seedlings, requiring plenty of light to grow, are usually suppressed by the shade of the suckers, which, being well nourished by the roots of the parent tree, grow fast in dense shade.

The habit of the tree perpetuating itself by suckers seems to have impaired the vitality of the seed, as only 15 to 25 per cent of it proved fertile in experiments made by Mr. P. Rock of Golden Gate Park.

The topography of the redwood belt is uneven, and the character of the forest in consequence is very varied. The mountains of the coast range rise to altitudes of 1000 to 2000 feet, and consist of two or three ridges parallel to the coast, through which rivers and streams have cut deep valleys in some places, and formed wide alluvial flats in others. On the steep slopes and at the higher elevations, where the soil is shallow and dry, the redwood is always mixed with Douglas, hemlock, *Abies grandis*, and two or three other species, and is comparatively small in size and less dense upon the ground. It is only at low altitudes, in the deep soil of alluvial flats and in ravines, where the water-supply is great, that the redwood grows as practically pure forest, and attains a great size and density; but even here a few trees of Sitka spruce and hemlock are usually associated with it. Absolutely pure stands, however, occur on flat tracts near streams, and in these the shade is so great that nothing grows upon the ground but *Oxalis* and a few tufts of *Aspidium munitum*. I saw a stand of this kind close to the Smith River, where the trees were of enormous size and of incredible density upon the ground. One tree measured 51 feet in girth. The river bank was fringed with *Alnus oregona* 50 to 60 feet high, behind which were two or three rows of taller *Umbellularia*; and a single Lawson cypress, 200 feet high, had taken refuge on the river bank. Behind this screen there were only redwoods towering far above the other trees. On the slopes the ground cover was dense and impenetrable, consisting mainly of *Aspidium* attaining an immense size, *Acer circinatum*, *Rhamnus Purshiana*, *Gaultheria Shallon*, *Rubus*, etc. According to R. T. Fisher, of the U.S. Forestry Service, of whose paper¹ I have made use in this account, the redwood slopes, where the tree is mixed in varying proportions, cover fifty times as large an area as the redwood flats, where the tree is pure or nearly so.

Near Crescent City the flat which extends for about three miles in width from the ocean to the first hill of the coast range was originally covered with a mixture of redwood, Sitka spruce, and hemlock, most of which is now cut away. On the bluffs of the sea-shore a few small trees of *Pinus contorta* take refuge, while behind them and inland there are scattered groves of second-growth spruce, about 50 feet high. The first slope, exposed to the south-west and rising to 500 feet, is a dense stand of virgin spruce and hemlock, the trees attaining 200 feet high by 15 feet in girth. Crossing the hill to the north-east slope the first redwoods are seen, and from here inland for about eight miles over rolling country the redwood is the dominant tree, enormous in size and thick upon the ground. Afterwards, ascending the gorge of

¹ "The Redwood": *U.S. Forestry Bulletin*, No. 38 (1903).

the Smith River, Douglas fir begins to prevail, the redwoods becoming gradually fewer and smaller; and the last ones were seen twelve miles inland at about 1000 feet elevation.

The prevailing formation in the redwood belt is sandstone; and the tree attains its maximum either on deep sandy loam or on gravel full of moisture. The climate is remarkably even and moderate, with warm days, cool nights, and scarcely any frost even in winter; while the air is charged with humidity, and the annual rainfall amounts to from 60 to 80 inches. The following observations, taken in 1900 at Crescent City, show the nature of the climate in which the redwood thrives:—

	Rainfall in Inches.	Temperature, Fahrenheit.	
		Maximum.	Minimum.
January	11	64°	32°
February	10	61°	33°
March	6	63°	36°
April	6	70°	32°
May	5	63°	39°
June	2	67°	41°
July	67°	40°
August	0.3	71°	40°
September	0.6	76°	41°
October	11	70°	37°
November	6	72°	33°
December	8	61°	27°
Total rainfall	65.9		

The tree is not found in the interior valleys to the east of the coast range, where the summer is comparatively hot and dry, and only a moderate amount of rain falls in winter.

Dr. Mayr,¹ reproduces a sketch of the largest redwood he saw in December 1885 near Santa Cruz. The mean of three measurements made it 308 feet high by 46 feet in girth at 6½ feet from the ground, above the swollen base. The first large green branches were at 230 feet up. This tree was still standing in 1903. He also gives an excellent illustration² of the appearance of a redwood forest after lumbering and fire have devastated it, which reminds me strongly of similar scenes in the Douglas fir forests of Oregon and Washington.

Fisher gives several tables showing the composition of the species and the size of the trees in the redwood belt. At Scotia, on an alluvial flat, there are 100 redwoods to the acre, no other species being present, and of these thirty-six were over 20 inches, and averaged 76 inches in diameter. Mayr² gives the following figures for the best pure stand which he measured:—57 trees to the acre, averaging 275 feet in timber height and 23 feet in girth; total cubic contents, exclusive of branches, 199,000 cubic feet per acre. The tallest redwood recorded³ was measured in 1896 by Professor Sargent. This tree grew on the Eel River, and was 662

¹ *Fremdländ. Wald- u. Parkbäume*, tt. 19, 20 (1906); cf. also *Waldungen*, p. 268 and frontispiece.
² *Waldungen von Nordamerika*, 267 (1900). ³ *Garden and Forest*, 1897, p. 42.

years old, 340 feet in total height, 230 feet to the first branch, and 10 feet 5 inches in diameter at 6 feet from the ground. I found it impossible to obtain in the dense forests accurate heights; but I saw lying on the ground a tree blown down many years ago which measured 240 feet, the top having been broken off at a point where the stem was still 3 feet in diameter. In the logging camp near Crescent City a tree which had just been felled measured 45 feet in girth at 6 feet from the base, and 24 feet in girth at 144 feet up; the top, knotty and full of branches, had smashed in the fall, and was rejected as being useless as timber.

Most of the trees cut are from 400 to 800 years old. After 500 years it usually begins to die at the top and to fall off in growth. The oldest redwood found by Fisher was 1373 years of age.

Isolated trees are occasionally blown down by the wind; but no considerable tracts are ever overthrown. There is no tap-root; but the lateral roots, numerous and stout, strike downwards, usually at a sharp angle, and form a compact mass, in shape like an inverted funnel. Such roots both anchor the tree securely and provide it with a large supply of moisture.

Fires are of rare occurrence in the damp northern part of the redwood belt; but farther south, where the climate is drier, they are frequent in August and September. Usually, however, only young trees and undergrowth are burned, the larger trees remaining unharmed. Injuries by fire or by the fracture of the branches by the wind, which involve the sapwood, are supposed to be the cause of the curious burrs and protuberances which are found on many trees.

Where the forests have been cut down, the better land has been permanently put under fruit, grain, or pasture; but on the worse lands the tree will survive and is in no danger of extinction, owing to its astonishing power of reproduction by sprouts. There are many fine stands of second-growth redwood; as in Mendocino county, where young trees, only 45 years old, are nearly 100 feet high and 20 to 30 inches in diameter. In Sonoma county, second-growth timber is being cut commercially, and though sappy, makes good boards for boxes.

The Spaniards, near San Francisco Bay, were the first to cut the redwood forests; but their operations were on a very small scale. Regular felling only began in 1850, and at first, as redwood timber was little valued, only Douglas fir and Sitka spruce were taken out of the redwood belt. Of late years, redwood timber has greatly increased in value, and the introduction of machinery has made lumbering more easy and profitable. Only big companies, however, can work with profit, as the outfit is very expensive, consisting of sawmills, many miles of railroad in the forest, locomotives of a special type for ascending steep gradients, waggons, donkey-engines, and logging camps, with a large staff of workmen.

No cutting is being done at the present time in the southern counties. The largest sawmills are in Mendocino county; and they had cleared, by the year 1900, 150,000 acres, or a quarter of the total acreage, including the largest and best stands. In the same year the mills had cleared in Humboldt county 65,000 acres and in Del Norte county 2000 acres. Since that year cutting has been going on at an accelerated pace, and the quantity now felled annually is enormous. (A. H.)

INTRODUCTION

It is stated by Kent in Veitch's *Coniferae* that Hartweg, who collected in California and Mexico for the Royal Horticultural Society in 1846 and 1847, was the introducer, but there is no evidence to confirm this statement, either in Hartweg's letters, which are printed in the Journal of the Society, or in Gordon's account of the conifers of which he sent home seeds.

The first mention I can find of the tree in the *Gardeners' Chronicle* is on March 17, 1849, when James Duncan, gardener at Basing Park, wrote that he had planted out in July 1847 a plant 9 inches high, which had stood two winters without protection. In the same journal for 1851, p. 246, it is stated that in 1845 there was a plant 2 feet 7 inches high at Holker, near Ulverston;¹ and on the authority of Mr. Frost that a grafted tree planted at Dropmore in 1845 was 18 feet high in 1851. It is evident that all of these must have been raised earlier than 1848, when Hartweg returned to England, and in his letter, received by the Society on November 4, 1846,² though he speaks of having seen the tree on the mountains of Santa Cruz, he says nothing about having collected or sent home seeds.

In *A Synopsis of the Coniferous Plants grown in Great Britain and Sold by Knight and Perry, at Chelsea*, published by Longmans, London, without date, but probably about 1850, it is stated on pp. 45, 46, that the redwood was introduced in 1843, when plants were sent to Knight and Perry by Dr. Fischer of St. Petersburg, who received seeds of it from America. I have inquired of M. Fischer de Waldheim, Director of the Botanic Gardens at St. Petersburg, whether he knew who was the actual collector, but he replies that there is nothing in the archives which will give this information.

CULTIVATION

I have never seen a plant raised from seed grown in this country, though I believe it will ripen in the south-west. Imported seed, so far as I have tried it, germinates badly, and the seedlings are tender at first, and should not be planted without protection till they are two or three years old, as the young growth will usually suffer from frost.

I am inclined to think that many of the plants sold by nurserymen are raised from cuttings, and purchased plants certainly seem hardier than the seedlings I have raised, most of which were killed to the ground in 1905 and 1907, though they shot up many suckers the following year. I have no evidence to show whether trees raised from cuttings will grow into tall, straight trees, as in the case of *Cryptomeria*.

According to a note³ by Mr. Frost in 1851, the first plants sent out by Knight and Perry were grafted, but this seems very unlikely, as there is no stock except that of the *Wellingtonia* which would seem at all suitable.

¹ Mr. Fenner tells me that this tree is now only 65 feet high by 6 feet in girth, and has been damaged by wind at the top. Suckers are growing from roots two feet from the main stem.

² *Journ. Hort. Soc.* ii. 124 (1847).

³ *Gard. Chron.* 1851, p. 246.

Though in this country the tree has proved fairly hardy in most localities, it is certainly more susceptible to frost in spring and autumn, especially when young, than *Wellingtonia*, and cannot be looked on as a really hardy tree except in well-drained soils, and in situations where it is well sheltered from dry frosty winds. All the really fine specimens I have seen are in unusually favourable places, and I should not recommend the tree for planting largely except in the south-west and west of England and Scotland, though in Ireland it seems to be more generally flourishing.

It does not dislike lime in the soil, and though the top is always killed back in hard winters, grows fast even at Colesborne, a tree planted on the site of the old house here about 1855, being now no less than 11 feet in girth though only about 55 feet high. Another planted later on thin dry soil is only about 35 feet by 4 feet.

Its long feathering branches, which droop to the ground and sometimes take root, make it a very ornamental tree, but as a timber tree its value remains doubtful. Whilst young it is very liable to be barked at the ground by mice, which have destroyed more than half of those which I have planted, and Sir W. Thiselton-Dyer tells me that squirrels¹ attack the bark at Kew.

Specimens of its timber grown in England are very inferior to the imported wood, on account of the rapid increase in girth which the tree makes unless crowded; and the only places I have seen where it seemed at all likely to be profitable are at Whitfield and Penllergare, though in Ireland there may be better hopes of its economic value, in favourable situations.

The following opinions, taken from the reports² published by the Conifer Conference, express very well the condition of this tree in twenty selected places:—

ENGLAND

Pampisford, Cambridge	Often injured by frost.
Golden Grove, Caermarthen	Leader sometimes frosted.
Scorrier, Cornwall	Requires shelter from wind.
Tortworth, Gloucester	In a shady place.
Linton, Kent	Lost 3 feet of top last winter.
Howick, Northumberland	Not thriving well.

SCOTLAND

Inveraray, Argyllshire	Often loses its leader.
Whittinghame, East Lothian	Vigorous; well sheltered.
Fordell, Fife	Very fine specimens.
Murthly, Perth	Fine in damp places.
Scone, Perth	In fine health; grows well.
The Cairnies, Perth	Doing well in shelter.
Castle Leod, Ross	Fine specimen.

¹ Squirrels are fond of making their nests out of the bark, but do no injury to trees, which have attained a considerable size. Cf. *Gard. Chron.* 1866, p. 413.

² *Journ. Roy. Hort. Soc.* xiv. pp. 483 seq. (1892). Cf. also *Gard. Chron.* 1866, p. 1043, where an abstract is given of Mr. Palmer's statistics of the effects of the severe winter of 1860-1861 on this tree, planted in 113 different places in England, Scotland, and Ireland.

IRELAND

Shane's Castle, Antrim	Grows rapidly here.
Fota, Cork	Free-growing, fine tree.
Woodstock, Kilkenny	A handsome tree.
Birr Castle, King's County . .	Thriving well.
Adare Manor, Limerick	Thriving; gales break leader.
Baron's Court, Tyrone	Fine rapid grower.
Coollattin, Wicklow	Very fine specimen.

REMARKABLE TREES

Among the great number of large redwoods I have seen at various places in England, I think the finest is one at Claremont, growing near the borders of the lake in a very sheltered position (Plate 194), which in 1903 measured 95 feet by 12 feet and in 1907 98 feet by 12 feet 9 inches. At Melbury there is a tree not so tall but thicker, which in 1906 was 85 feet by 15 feet 1 inch. At Fonthill Abbey there is a remarkable twin tree which grows in a damp hollow, dividing at the ground into two trunks which are 98 to 100 feet high by 10 feet and 9 feet 3 inches in girth respectively. At Boconnoc in Cornwall there is a tree which in 1851 was already 16 feet high, and in 1891 was reported as measuring 75 feet by 13 feet, but when I measured it in 1905 it had lost its top, and was then only 68 feet by 14½ feet. At Dropmore, Buckinghamshire, a tree,¹ remarkable for its pendulous branches and branchlets, is 94 feet high and 11 feet in girth. Three years ago, according to Mr. Page, the gardener, it was 10 feet 6 inches in girth, so that it is still making rapid growth. This tree was planted in 1845, when it was a foot high, having been bought for five guineas at Knight and Perry's nursery. It is bearing this year an immense number of cones; but no attempt has ever been made to raise seedlings.

In a sheltered dell known as the Wilderness, at Cuffnells, near Lyndhurst, the seat of R. Hargreaves, Esq., are three splendid redwoods, which were planted about the year 1855 by his father. These measure 102 feet by 10 feet 8 inches, 98 feet by 15 feet, and 105 feet by 10 feet 10 inches respectively, the last being equal or superior to the one at Claremont, and growing close to a magnificent tree of *Pinus insignis*, which will be figured in our next volume.

At Beauport, Sussex, there is a tree with very pendulous branches bearing cones on the ends of the twigs, 73 feet by 9 feet 6 inches, and a larger one of the ordinary form, 85 feet by 11 feet 5 inches; and at Hemstead in Kent there is a tree not quite so tall as the *Cryptomeria* growing by its side (see Plate 42), and of about the same age. In the eastern counties the best we have seen are at Hardwicke House, Suffolk, where a tree in 1905 was 74 feet by 11 feet 10 inches, and at Barton, where in an exposed situation on the lawn there is one of 71 feet by 8 feet. This seems to be the only survivor of four which Sir Charles J. F. Bunbury²

¹ Erroneously reported to have been 114 feet in height in 1903 in *Journ. Board of Agriculture*, x. 345 (1904).

² *Arboretum Notes*, 166 (1889).

planted in 1847 and 1848, one of which bore cones in 1862. In Fulmodestone Wood, Norfolk, a tree planted in 1855 was 67 feet by 8½ feet when Henry measured it in 1904. At The Coppice, Henley, at 300 feet elevation, a tree planted in 1864 was 73 feet high by 9 feet 5 inches in girth in 1905. At Bayfordbury, Herts, the best specimen is 74 feet by 10 feet 2 inches. At St. George's Hill, near Byfleet, a tree growing on Bagshot sand was in 1904 75 feet by 8 feet 3 inches.

In Gloucestershire there are good trees at Tortworth, at Highnam, at Williamstrip Park, and at Huntley Manor, where Prof. Somerville measured one in 1904 76 feet by 13 feet.

At Whitfield, Herefordshire, there is a group of eleven very fine trees on an area of only 25 yards square, of which the tallest is about 95 feet by 12 feet, and the others would average 80 to 90 feet in height, by about 9 feet in girth, and contain from 100 to 120 cubic feet per tree. An acre of such trees, as thickly grown as this, would produce from 8000 to 10,000 cubic feet, which, considering that their age is not more than about fifty years, is a very remarkable yield of timber.

At Penllergare, near Swansea, there is another somewhat similar group of twelve trees on a triangle of which the sides are only about twenty yards, in which the best tree was about 75 feet by 10 feet, and the others from 4 feet to 8 feet in girth; only one of these was a really bad tree, and two of them were forked.

At Penrhyn Castle there are several very fine trees, of which the best that I measured in 1906 was about 90 feet by 12 feet 3 inches, but others may be larger. At Coed Coch, Abergele, there is a splendid tree which Mr. A. Hunter, the gardener at this place, measured in 1905, when it was 90 feet in height and 12½ feet in girth.

In Scotland the redwood seems to grow best in Perthshire, where all the largest that I have seen are found, namely, one at Castle Menzies, which in 1892 was 74 feet by 4 feet 6 inches; and at Moncrieffe, where a tree, mentioned by Hunter as 42 feet by 4 feet 11 inches in 1883, was in 1907 about 65 feet by 9 feet, and though healthy looks as though it had lost its top more than once.

A tree at Falkland Palace, Fifeshire, said to be then one of the finest in Scotland, was in 1892 65 to 70 feet by 9 feet. At Smeaton-Hepburn, East Lothian, in 1902, there was a tree 57 feet by 9 feet, planted in 1844, which had lost its top on several occasions. At Castle Kennedy the wind is evidently too severe for it, as the largest measured by Henry in 1904 was only 39 feet by 7 feet.

In Ireland the redwood has attained large dimensions in those districts which have a mild climate and a heavy rainfall. In Queen's County, where the rainfall is only moderate and sharp frosts occur, it has done badly, and is in marked contrast to the splendid *Wellingtonias* which are growing beside it in several places.

At Castlemartyr, Cork, there are several large specimens, one, about 70 feet in height, being in 1907 16½ feet in girth at 5 feet from the ground. At Fota, in the same county, a tree in 1903 measured 90 feet high by 10 feet in girth. This was reported¹ in 1891 to be 75 feet by 7½ feet. At Coollattin, in Wicklow, there

¹ *Journ. Roy. Hort. Soc.* xiv. 549 (1892).

are three trees, nearly equal in size, one of which measured in 1906 77 feet by 11 feet 5 inches. This¹ was 55 feet by 8½ feet in 1891. At Hamwood, Co. Meath, a tree, said to have been planted in 1847, was 59 feet high by 11 feet in girth in 1905. At Woodstock, in Kilkenny, there is a tree, which in 1904 was 91 feet by 13 feet 3 inches. This¹ was 68 feet by 10 feet 4 inches in 1891. At Churchill, Armagh, a tree,² planted in a bog in 1862, was 60 feet high by 6½ feet in 1884; but had lost its leader several times. Henry did not see this tree on his visit to Churchill in 1904. At the Conifer Conference of 1891 good trees were also reported to be growing at Shane's Castle in Antrim, Clonbrock in Galway, Courtown in Wexford, and Powerscourt in Wicklow.

The largest tree of this species that I have seen in Europe is a well-shaped one, branching to the ground, on the Isola Madre in Lake Maggiore, which in 1906 was no less than 104 feet high by 14 feet 8 inches in girth.

Pardé³ says that the trees at Les Barres were mostly killed to the ground in the winter of 1879-80, but have thrown up vigorous shoots which produce cones every year; and at Segrez I saw a tree which was killed in the winter of 1870-71 and afterwards threw up six or seven straight stems from the stool, which are now over 50 feet high.

TIMBER

The best timber, as a rule, is produced by trees growing on alluvial flats, that from trees growing on the slopes being hard and flinty. The sapwood, which is of no service, is whitish in colour and 1 or 2 inches in thickness. The heartwood varies in colour from light pink to dark mahogany, and is esteemed for many purposes. It is light in weight, soft, straight-grained, is easily worked; and although it requires much filling, is capable of taking a fine polish. Its durability is attested by the fact that trees which have lain for centuries in the forest have been taken to the sawmill and converted into useful lumber. Mr. D. N. M'Chesney says⁴ that in Manila the wood has been found proof against the attacks of the white ant, together with that of *Tsuga Albertiana* and *Libocedrus decurrens*, while the timber of *Pinus ponderosa*, *Picea Engelmanni*, and the Douglas fir suffered badly from these destructive insects.

In Europe the Californian redwood has established a market for itself, but supplies have been steadily falling off for some years. It is, however, still shipped in considerable quantities to China, Japan, Honolulu, and Australia. In its native country it is employed for both exterior and interior fittings of houses, sleepers, electric light and telephone poles, shingles, tanks, and vats. Very frequently the grain is bold, wavy, and very handsome; and is in demand for ceilings and large panels. Some splendid examples were used for the decoration of the Californian Court at the St. Louis Exhibition of 1904. The large burrs which are not uncommon in some districts, when cut into slabs, make very fine table tops showing a mass of close small eyes of a deep red colour. A very large plank of the wood was exhibited at the World's Fair, Chicago, 1903, which measured

¹ *Journ. Roy. Hort. Soc.* xiv. 556, 565 (1892).

² *Woods and Forests*, 1884, p. 624.

³ *Arbor. Nat. des Barres*, 52 (1906).

⁴ *Bull. Nos. 30 and 33, New Series, Division of Entomology; U.S. Department of Agriculture* (1901), p. 95.

16½ feet wide, 12¾ feet long, and 5 inches thick. The tree from which this extraordinary plank was cut was felled in Humboldt County, and was said to be 300 feet in height by 35 feet in diameter. Planks of 5 feet in width are imported, and I have myself purchased boards 4 feet in width absolutely free from knots and defects. In England this wood is chiefly used for the inside linings of furniture, and it is said to be one of the finest woods in the world for large signboards, as it maintains a remarkable consistency of shape under the most trying conditions of climate and exposure. The value in Liverpool in 1907 was from 2s. 2d. to 2s. 6d. per cubic foot, a price which cannot be said to encourage shipments that have to pay the cost of so long a sea carriage. The wood is usually of slow growth, and the annual rings are from thirty to fifty to the inch. The cells are so large that they can be seen by unaided vision. Resin ducts are almost entirely absent in both species of *Sequoia* but have been found by Jeffrey¹ in the flowering shoot and in the first annual ring of vigorous branches of adult *S. gigantea*, and in the wood of the shoot and root of redwood as the result of injury. (H. J. E.)

SEQUOIA GIGANTEA, WELLINGTONIA, BIG TREE

Sequoia gigantea,² Decaisne, *Bull. Bot. Soc. France*, i. 70 (1854), and *Rev. Hort.* 1855, p. 9, f. 1 (not Endlicher); Masters, *Gard. Chron.* xix. 556, f. 85 (1896); Sargent, *Bot. Gazette*, xlv. 226 (1907).

Sequoia Wellingtonia, Seemann, *Bonplandia*, iii. 27 (1855); Lawson, *Pinet. Brit.* iii. 299, tt. 37, 51, 53 (1884); Sargent, *Silva N. Amer.* x. 145, t. 536 (1896), and *Trees N. Amer.* 69 (1905); Kent, *Veitch's Man. Conifera*, 274 (1900).

Sequoia Washingtoniana, Sudworth, *Check List Forest Trees, U.S.* 28 (1898).

Wellingtonia gigantea, Lindley, *Gard. Chron.* 1853, pp. 820, 823; W. J. Hooker, *Bot. Mag.* 4777, 4778 (1854).

Taxodium Washingtonianum, Winslow, *Calif. Farmer*, 1854, ex Hooker, *Kew Journ.* vii. 29 (1855).

Taxodium giganteum, Kellogg and Behr, *Proc. Cal. Acad.* i. 151 (1855).

Washingtonia Californica, Winslow, *loc. cit.*

A tree attaining 320 feet in height, with a tapering stem, occasionally 90 feet in girth above the much enlarged and buttressed base. Young trees narrowly pyramidal. Old trees free of branches to 100 or 150 feet, with an irregular crown of short thickened branches. Trunk fluted with broad, low, rounded ridges; bark 1 to 2 feet thick divided into lobes 4 to 5 feet wide, corresponding to those of the trunk, separating into loose reddish fibrous scales, which expose the spongy middle bark. Branchlets pendulous, not distichously arranged but in dense masses, green in the first year, afterwards gradually becoming brownish with a thin scaly bark. Buds minute, without scales.

Leaves persistent for four years, arranged on the branchlets in approximately three ranks; on the main axes ovate acuminate, up to ½ inch long; on the lateral axes lanceolate, acute, ⅓ to ¼ inch long; appressed and decurrent at the base, free

¹ *Mem. Boston Soc. Nat. Hist.* v. 441 (1903).

² The tree was first described by Lindley, who called it *Wellingtonia gigantea*. *Wellingtonia* cannot be maintained as a distinct genus. *Sequoia gigantea* is the correct name, according to the rules of botanical nomenclature promulgated by the Vienna Congress of 1905, and is now adopted by Sargent.

and spreading from beyond the middle, rigid, ending in sharp cartilaginous points; lower surface green, rounded or keeled; upper surface with green midrib and two inconspicuous bands of stomata.

Staminate flowers, $\frac{1}{8}$ to $\frac{1}{3}$ inch long, with acute or acuminate connectives. Pistillate flowers with twenty-five to forty pale yellow bracts gradually narrowed into long slender points. Cones ripening in the second year, ovoid-oblong, 2 to 3 inches long by $1\frac{1}{2}$ to 2 inches wide, brownish; scales gradually thickening from the base to the dilated disc, which is $\frac{3}{4}$ to 1 inch broad, and often bears a reflexed spine in the centre of the transverse depression. Seeds, $\frac{1}{8}$ to $\frac{1}{4}$ inch long, light-brown, apiculate at the apex, surrounded by laterally united, often unequal wings, which are broader than the body of the seed. Proliferous cones have been observed.¹

Wellingtonia produces cones freely in many parts of the British Isles, but these are smaller in size as a rule than those of the wild tree and rarely contain mature seed. Mr. Richards informed me that he had sown a large quantity of seed, produced by a tree growing at Penrhyn on the lawn in an isolated sunny position, and only obtained eight seedlings. Barnes² raised young plants from seeds produced by a tree at Bicton. At Orton Longueville, Mr. Harding³ succeeded in raising six seedlings out of 100 seeds. The tree cones well at Dropmore, but has seldom if ever produced fertile seed there.

Wellingtonia differs markedly from the redwood, in not reproducing itself either by suckers from the root or by coppice shoots. In its native forests, seed is produced in great abundance, and numerous seedlings occur everywhere in the southern part of the area of distribution of the species; but in the northern groves seedlings are said to be totally wanting.

VARIETIES

None have been noticed in the wild state. Several have appeared in cultivation in Europe.

1. Var. *pendula*. Branches bent downwards at the base, and hanging for their whole length close to the stem, forming in young plants a slender pyramid and in older examples a tall narrow column. This remarkable variety was obtained out of the seed-bed by Lalande of Nantes in 1863, and was put upon the market in 1873 by Paillet of Châtenay-les-Sceaux, near Paris. The best tree⁴ of this kind is growing at M. Allard's arboretum at Angers, in France, and when measured by Elwes in 1907 was 44 feet high by 3 feet in girth, but only 13 feet round the branches. At Bicton,⁵ this variety is represented by a tree which in 1902 was 33 feet high by 26 inches in girth at 2 feet from the ground. At Brettargh Holt,⁵ Kendal, the residence of Charles Walker, Esq., a weeping Wellingtonia was reported to be 22 feet high in the same year. Another example, aged 26 years, growing at Dalkeith Palace and reported to be $19\frac{1}{2}$ feet high in 1902, was figured in the *Gardeners' Chronicle*.⁵ A specimen

¹ Carrière, *Rev. Hort.* 1887, p. 509, f. 103. Cf. *Gard. Chron.* ii. 649 (1887).
² *Gard. Chron.* 1868, p. 872. ³ *Ibid.* xxix. 55 (1901).
⁴ Described and figured by Rehder in Möller's *Deutsche Gärtner Zeitung*, March 22, 1902.
⁵ *Gard. Chron.* xxxi. p. 388, fig. 136, and p. 435; and xxxiii. p. 23 (1902).

30 feet in height at Berkhamstead, Herts, is mentioned by Webster.¹ In the *Revue Horticole*, 1906, p. 395, f. 157, a curious weeping Wellingtonia, growing at the Trianon, is figured. The stem, which is 42 feet in length, bends over and is supported on one side by a prop. Barron also obtained a weeping form, which was sold as *S. gigantea Barroni pendula*.²

2. Var. *aurea* (var. *aureo-variegata*). The young shoots are amber-coloured at first, but speedily become deep yellow, the colour being pretty uniform over the whole tree. The original plant was a seedling, which Hartland³ of the Lough Nurseries, Cork, received in 1856. It began to show colour when it was about a foot high, and after it had attained 8 feet, a large number of golden Wellingtonias were propagated from it by grafting. A specimen 20 feet high was growing⁴ in the public garden at Denbigh in 1887. We have seen no trees of this variety of a considerable size.

3. Several other varieties, which I have not seen, are mentioned by Beissner⁵ as *glauca*, *argentea*, *Holmsii*, and *pygmaea*. (A. H.)

DISTRIBUTION

Wellingtonia has a restricted distribution, being confined to the western slopes of the Sierra Nevada of California, in an interrupted belt at elevations of from 5000 to 8400 feet above sea-level, extending from the middle fork of the American River (lat. 39°) to the head of Deer Creek, just south of lat. 36°.

I am indebted to Mr. Gifford Pinchot for the most recent account which has been officially published of the big trees of California,⁶ illustrated by some excellent photographs; from which it appears that John Bidwell in 1841 was really the first to discover this tree in the Calaveras Grove, Prof. Brewer of Yale having been the first scientific visitor in 1864 to this and the Mariposa Grove. Mr. Whitney, in the *Yosemite Guide Book* (1870) described eight of the then known groves, namely:—

1. The North Grove in Placer county is on a tributary of the middle fork of the

¹ *Hardy Coniferous Trees*, 113 (1896).
² Another weeping form is said to have originated in Little and Ballantyne's nursery at Carlisle; but the original tree died in 1877. Cf. *Journal of Forestry*, iii. 260 (1879). ³ Letter to Kew.
⁴ *Gard. Chron.* ii. 276 (1887). ⁵ *Nadelholzkunde*, 165 (1891).
⁶ A "Report on the Stanislaus and Lake Tahoe Forest Reserves, by G. B. Sudworth," *Bulletin No. 28*; U.S. Dept. of Agriculture, Division of Forestry, published at Washington in 1900, which gives the following table of measurements of thirty of the big trees in the Calaveras Grove:—

Tree No.	Diameter 6 feet above Ground.	Height.	Tree No.	Diameter 6 feet above Ground.	Height.	Tree No.	Diameter 6 feet above Ground.	Height.
1	Feet. 9.0	Feet. 235	11	Feet. 12.5	Feet. 250	21	Feet. 15.0	Feet. 325
2	9.0	251	12	12.5	266	22	15.5	268
3	9.5	260	13	13.0	286	23	15.5	272
4	10.0	237	14	13.5	320	24	15.5	289
5	10.0	243	15	14.0	259	25	16.0	262
6	10.0	261	16	14.0	265	26	16.0	275
7	10.5	248	17	14.0	269	27	16.5	266
8	11.0	255	18	14.5	278	28	16.5	268
9	11.0	260	19	15.0	285	29	16.5	288
10	12.0	248	20	15.0	307	30	19.5	315

American river, at an elevation of 5100 feet, and 70 miles north of the Calaveras Grove. It now contains only six trees, of which the two largest are 240 and 220 feet high.

2. The Calaveras Grove¹ is at an elevation of 4750 feet, occupying a belt only 3200 by 700 feet in extent, and containing 90 to 100 trees of large size, besides a considerable number of small ones. The largest tree standing here was barked up to 116 feet high, and the bark set up in the Crystal Palace at Sydenham, where it was afterwards destroyed by fire. This tree was 302 feet high and 96 feet in girth at the ground. It was felled by boring holes all round the trunk with pump augers, which occupied five men for twenty-two days. An even larger tree in this grove was the "Father of the Forest," cut down in 1853, and now lying on the ground; it has been hollowed out by fire so that a man can ride through it on horseback for a distance of 82 feet. Its extreme length, so far as could be judged from the remains, was 365 feet, and its circumference at the base is said to have been 110 feet.

The largest living trees in this grove were as follows, only nine being, according to Whitney, over 300 feet:—

"The two Sentinels,"	over 300 feet high by 23 feet in diameter.
"The Pride of the Forest,"	300 " 23 "

"Daniel Webster,"	307 " " " 15 feet

3. The Stanislaus or South Calaveras Grove is about six miles south-east of the last, and is said to have contained, when Mr. Sterry owned it, 1380 trees from 1 foot to 34 feet in diameter, but the number now existing is much less. The largest standing trees mentioned were as follows:—

"Columbus."	
"New York,"	over 300 feet high by 104 feet in girth.
"Ohio,"	" 311 " 103 "
"Massachusetts,"	" 307 " 98 "

Besides these, "Smith's Cabin," a hollow tree in which a hunter is said to have lived for three years, 21 feet by 16 feet in size inside, and "Old Goliath," a fallen tree said to be 100 feet or more in circumference, were remarkable for their size.

About 25 miles south-east of this is a grove called the Crane Flat Grove, most of the trees in which are said to be rather smaller than those in the Calaveras Groves.

¹ Cf. note 6 on p. 701.

4. The Mariposa Grove is the one best known to English travellers, and is usually visited from Clark's ranch on the road to the Yosemite Valley. It consists of two nearly distinct groves, the upper one being compact, on an area of 3700 by 2300 feet and containing 365 trees over 1 foot in diameter, besides a great number of small ones. The southern division or lower grove is said to contain only half as many Sequoias, and these are more mixed with other trees, such as Douglas fir, sugar pine (*Pinus Lambertiana*), *Abies concolor*, and *Libocedrus decurrens*. Many of the trees in both of them have been much injured by fire, which has destroyed many of the younger ones within the groves; but there are on the outskirts several small natural groups of young trees up to 6 or 8 inches in diameter. The largest tree here is the "Grizzly Giant," whose photograph is well known in many English houses, and which is 93 feet in girth at the ground, and 64 feet at eleven feet up; some of its branches are fully 6 feet in diameter. The tallest tree in this grove, according to Whitney, is 272 feet, and another is 270 feet by 26 feet in diameter at the base; only six in all are over 250 feet high.

5. The Fresno Grove is about 14 miles south-east of Clark's ranch, and is about 2½ miles long by 1 to 2 miles wide. It contains 500 to 600 trees, of which the largest is 81 feet in girth at 3 feet from the ground.

6. About 50 miles south-east of the Fresno Grove, along the slope of the sierra between the King's and Kaweah rivers, is by far the most extensive forest that has been found. It is about 30 miles north-east of Visalia, and is scattered over an area 8 to 10 miles long and 4 to 5 wide, at an elevation of about 4500 to 7000 feet. The average size of these trees is much smaller, only 10 to 12 feet in diameter, the largest measured, near Thomas's Mill, being 106 feet in girth near the ground, where a considerable portion has been burnt off. At 12 feet from the ground this tree was 75 feet in girth, its height being 276 feet, though the top was dead.

7. There are two other groves on the Tule river, of which the most northerly is 30 miles from the King's River Grove. These were discovered in 1867 by Mr. D'Heureuse when exploring for the Geological Survey. They extend over an area of several square miles and contain a considerable number of trees, of which no measurements are given.

8. Besides these there are small and little known groves on Dinkey Creek, a tributary of King's river, and on the headwaters of the Merced river, the last said to contain less than 100 trees.

Prof. W. L. Jepson of the University of California has been good enough to send us the following enumeration¹ of the existing groves of Wellingtonia, most of which he has visited this year:—

¹ This list will be published in Prof. Jepson's forthcoming work on the Trees of California.

TABLE OF BIG TREE GROVES AND FORESTS. BY WILLIS L. JEPSON.

Groves.	Locality.	Area in Acres.	Altitude.	No. of Trees.
NORTH GROVES.

* Blanks in this column indicate that the trees are so numerous that they have not been counted.

One of the best accounts of the Wellingtonias and their surroundings is in Muir's *Mountains of California*. He states that the young trees have slender branches growing with great regularity down to the ground, as we see them on an English lawn; but when the tree attains 500 or 600 years old, the spiry, feathery, juvenile habit merges into the firm rounded dome-like habit of middle age, which in its turn takes on the eccentric picturesqueness of old age. The foliage of the saplings is dark bluish-green, while that of the older trees ripens to a warm brownish-yellow tint like that of Libocedrus. The bark is rich cinnamon brown, purplish in young trees and in shaded portions of the old ones. In winter the trees break out into bloom, myriads of small four-sided staminate flowers crowding the ends of the smaller sprays, colouring the whole tree, and when ripe dusting the air and the ground with golden pollen. The fertile cones are bright grass green, about 2 inches long by $1\frac{1}{2}$ inch wide, and are composed of about forty firm scales densely packed, with three to eight seeds at the base of each, a single cone thus containing 200 to 300 seeds, which are about $\frac{1}{4}$ inch long by $\frac{3}{16}$ inch wide, with a thin flat margin. The cones are very freely produced; and on two branches, $1\frac{1}{2}$ to 2 feet in diameter, Mr. Muir counted no less than 480. But of the millions of seeds produced, very few germinate; and of these not one in ten thousand lives through the vicissitudes of storm, drought, fire, and crushing by snow, to which they are exposed in youth.

Natural reproduction in the groves, when they have been protected from fire and grazing, is said to be at a standstill, owing to the dry humus beneath the trees forming an unsuitable seed bed; and it is only in the forests on the south fork of the Kaweah, and on the Tule river, where young trees of all ages can be found in abundance.

The damage, waste, and loss which has occurred in those groves which have been partially cut for timber is said to be enormous. When a large tree is felled its immense weight breaks a great part of the top into useless fragments, and crushes many other trees in its fall; whilst the usual means adopted to break up the logs into pieces which can be handled is by blasting; and this destroys another large part of the timber. When the best is removed, a mass of broken branches, timber, and bark, often 5 or 6 feet in depth, is left on the ground, which is later destroyed by fire; leaving complete devastation in place of the most beautiful forest; and it is said that owing to various causes, the lumbering of these forests has often been quite unprofitable to their owners.

Mayr¹ estimates the age of the largest tree which he measured, 33 feet in diameter at 13 feet above the ground, to be 4250 years. Sir Joseph Hooker² told Bunbury that, as the Wellingtonia makes repeated growths in the year, it is more difficult than is the case in other conifers to distinguish the shoot of one year from that of the preceding year; and he suspected that more than one ring of growth is formed in each year, and that in consequence the estimates of enormous age of this species are probably fallacious.

¹ *Waldungen Nordamerika*, 343 (1890).² Lyell, *Life of Sir C. J. F. Bunbury*, ii. 227 (1906).

INTRODUCTION

The Wellingtonia was introduced by Mr. J. D. Matthew, who visited the Calaveras Grove in July 1853, and sent home seeds immediately afterwards. In *Pinetum Britannicum*, p. 318, eleven trees of this origin are traced, namely, two each at Gourdiehill, Megginch Castle, and Ballendean, near Inchtute, and one each at the Kinnoul Nursery near Perth, Newburgh, Balbirnie, Inchry House, and Eglinton Castle; but none of these were so large when he wrote as those raised from later consignments. Lobb visited the Calaveras Grove in the autumn of the same year, and returned¹ to England in December 1853, bringing with him a large quantity of seed and two living plants. The latter were planted out in Veitch's nursery at Exeter, but only survived three or four years.

CULTIVATION²

The culture of the Wellingtonia presents no difficulty if care is taken to have the roots thoroughly spread out when planted out. They are often kept too long in pots, which causes their main root to curl round, and when this has assumed a corkscrew shape it never loses it. If the tree is transplanted every year or so while young, it may safely be removed when 4 or 5 feet high. As regards soil and situation it is more accommodating than the redwood, and even in heavy soil is rarely injured by spring frosts. It grows very fast in most places up to 40 or 50 feet high, and then, unless the soil is deep and well drained, often becomes stunted and increases more in girth than height. If planted in a park or field pastured by stock, it must be very carefully fenced, as horses and cattle will gnaw its bark persistently and do it much injury. I noticed a good instance of this in the park at Mark's Hall, Essex, where some Wellingtonias had been so much bitten by cattle that they resembled the trees in a toy Noah's Ark, one about 35 years old being only 12 feet high by 3 feet in girth. When surrounded by other trees, where it cannot extend its branches laterally, the girth is much less in proportion. A tree that I saw in a plantation at Powis Castle, which was growing extremely well, was 75 feet high and only 7 feet 3 inches in girth, whilst one in the lower park at the same place was 81 feet by 16 feet.

REMARKABLE TREES

When first introduced this tree made such a sensation in the horticultural world, that it was planted almost everywhere, and there are specimens at every place of importance in the United Kingdom, many of which are very nearly equal in size. The tallest at Windsor Castle was already 21 feet high in 1865, and is now, as I am

¹ *Hortus Veitchii*, 39, 346 (1906).

² An interesting article on the causes of success or failure in plantations on a large scale of this tree in South Hampshire appeared in *Gard. Chron.* ix. 794 (1878).

told by Mr. A. MacKellar, 85½ feet high and 12½ feet in girth at 3 feet from the ground.

The largest and finest tree I have measured myself is in an open but well sheltered glade near the lake at Fonthill Abbey, and was, in November 1906, certainly over 100 feet and probably 105 feet high, by 17 feet in girth (Plate 106).¹⁹⁶ This tree was raised at Eaton Hall from seed sent to Lord Stalbridge in 1861, and is not so old by seven years as many others in this country.

There are two very fine trees at Poltimore Park, Devonshire, the seat of Lord Poltimore, one of which I measured in August 1906, and found to be 98 feet by 16 feet 9 inches, but the gardener, Mr. Slade,¹ thinks it is taller. Near the Temple, at Highclere, there is a tree which I saw in 1903, of which the size is given by Mr. Storie, the forester, as 97 feet by 13 feet, but I could not verify this measurement myself.

One of the largest in girth that I know, is an ugly tree at Powderham whose top has long been broken, and which has formed immense branches, so thickly crowded that I could only get the tape round it with assistance. In 1906 it was no less than 17 feet 8 inches; but I must observe that the exact girth of such trees is of little importance, as it depends very much on the height at which the measurement is taken.

At Beauport, Sussex, there are two fine trees, one of which, planted in 1856, was, in 1904, 86 feet high by 13 feet 8 inches in girth. The other, a younger tree, measured 83 feet by 11 feet 11 inches. Sir Hugh Beevor measured in 1904 a tree at Hardwicke, Suffolk, 80 feet by 12 feet 4 inches, and another at Wooton, 85 feet by 14 feet 6 inches. Mr. R. Woodward, jun., reports in 1906 two trees at Wexham Place, Stoke Pogis, the residence of E. H. Wilding, Esq., which measured 79 feet by 9 feet 6 inches and 78 feet by 10 feet 8 inches. Canon Ellacombe² planted a tree at Bitton in 1855, which had attained 70 feet in height in 1888. A tree³ at Wrest Park, Bedfordshire, planted in 1856, was, in 1900, 74 feet high by 15 feet 3 inches in girth.

At Strathfieldsaye there is a fine large tree,⁴ planted in 1857, which I measured in 1903, and found to be 85 feet by about 12 feet. In 1907 it was 90 feet high, but the branches were so thick that I could not get the girth with sufficient accuracy to say how much increase it had made. A number of branches have become layered—a not uncommon occurrence in damp and sheltered situations—but when they have been allowed to remain long after taking root, it is perhaps better not to take them off, as this disfigures the tree for some time. There is also a fine avenue of this tree at Strathfieldsaye, which is more regular and satisfactory in growth than some others which I have seen. Another at Orton Longueville is no less than 700 yards from east to west, but some of the trees when I saw them seemed to be suffering from the wetness of the subsoil, the tops of many being stunted. There is also a fine

¹ Cf. Mr. Slade's remarks on this tree in *Gard. Chron.* xxvii. 406 (1900).

² *Gard. Chron.* iii. 801 (1888).

³ *Ibid.* xxvii. 373, fig. 121 (1900).

⁴ In 1868, this tree was 24½ feet high; in 1872, 30 feet high; in 1895, 71 feet high; and in 1899, 79 feet. A cutting from it was struck, and planted out in 1875, when about 2 feet high, and had attained, in 1896, 30 feet in height and 6 feet in girth, at 4 feet from the ground. Cf. *Gard. Chron.* xix. 8 (1896) and xxvi. 162 (1899).

avenue at Luton Park, in which most of the trees are good specimens, but unless the soil is good and uniform throughout, and the trees are selected with great care, I should not recommend this tree for avenues.

By far the best avenue of this tree that I have seen is one near Wellington College, which was planted in the year 1869 by the late John Walter, Esq., of Bear Wood, Berks, on a light, sandy soil which, however, seems to have suited the trees remarkably well, and on which the symmetry of their tops and uniformity of the growth is remarkable. It is about 1200 yards long, running about north and south, and is 25 yards in width. The trees are planted at 18 yards apart, which is about the right distance for this tree. The average height of the trees is 75 to 80 feet, and the largest that I measured on the west side near the top was 87 feet by 21 feet. Plate 198, taken specially for this work, gives a very good impression of its appearance. Mr. C. E. Salmon tells me that there is another avenue of this tree which was planted in 1871 by the late Mr. J. Walter in front of Bear Wood House.

At Aston Clinton, Bucks, the residence of Lady A. de Rothschild, there is a group of closely planted Wellingtonias with tall clean stems, tapering only slightly, and carrying timber size to 50 or 60 feet. The ground, which is a circular area 120 feet in diameter, is covered with decayed leaves and is free from herbaceous vegetation. On it there are seventy-two trees in all, ranging in height from 60 to 75 feet, and in girth from 4 feet 4 inches to 8 feet 2 inches at 6 feet from the ground, above the swollen base. This clump was planted in 1869, according to Mr. W. H. Warren, who has kindly sent us a photograph, reproduced in Plate 197. This beautiful grove, which was seen by Henry in 1906, shows how well the tree succeeds when planted densely on good land.

At Brickendon Grange, Hertford, the property of John Trotter, Esq., in a wood, composed of a mixture of common spruce, Wellingtonia, *Cupressus macrocarpa*, *Abies Lowiana*, and *Pinus ponderosa*, all planted at the same time, in 1861, the comparative girths of trees, measured by Mr. H. Clinton Baker, in December 1907, without selection, at 5 feet from the ground, are as follows:—

Wellingtonia: 3 feet, 5 feet, 5 feet, 5 feet 2 inches, 5 feet 3 inches, 5 feet 10 inches.

Cupressus macrocarpa: 4 feet, 4 feet 2 inches, 4 feet 8 inches, 4 feet 9 inches, 5 feet 3 inches, 5 feet 6 inches, 5 feet 7 inches, 5 feet 10 inches, 5 feet 10 inches.

Abies Lowiana: 4 feet, 4 feet 10 inches.

Pinus ponderosa: 5 feet 2 inches, 5 feet 3 inches.

Common Spruce: 2 feet 2 inches, 2 feet 5 inches, 2 feet 6 inches, 2 feet 7 inches, 2 feet 8 inches, 2 feet 8 inches, 2 feet 10 inches, 3 feet 1 inch, 3 feet 3 inches.

Sir John Stirling Maxwell sends me the following measurements of some Wellingtonias planted in 1864 or 1865 at Cloverley Hall, Shropshire, the seat of Capt. Heywood Lonsdale, in mixture with spruce and larch.

No.	Height.	Quarter-girth at 5 Feet.	No.	Height.	Quarter-girth at 5 Feet.
1.	64 feet	26 inches	12.	68 feet	24 inches
2.	66 "	24 "	13.	61 "	19 "
3.	67 "	30 "	14.	65 "	23 "
4.	66 "	24 "	15.	71 "	24 "
5.	61 "	24 "	16.	69 "	27 "
6.	73 "	34 "	17.	66 "	29 "
7.	62 "	23 "	18.	72 "	27 "
8.	60 "	19½ "	19.	68 "	27½ "
9.	63 "	20 "	20.	62 "	21 "
10.	65 "	18½ "	21.	70 "	23½ "
11.	58 "	23 "			

He also measured some at 3 and 6 feet to show their rate of growth as compared with other trees, as follows:—

	Girth at 3 Feet.		Girth at 6 Feet.		These trees were not selected with care, but were all good specimens of their kind.
	Feet.	Inches.	Feet.	Inches.	
Wellingtonia, 1	8	0½	6	3	} These trees were not selected with care, but were all good specimens of their kind.
" 2	8	7	7	2	
" 3	9	2	7	2½	
" 4	9	5½	7	9	
Common spruce, 1	5	7	4	5	
" 2	3	9	3	4½	
Larch	5	6½	4	10	
Austrian pine	6	0½	5	8½	

A tree planted in the pleasure ground at Cloverley by the late Mr. W. E. Gladstone in 1872, now measures 56 by 8½ feet; another planted Jan. 1, 1864, is now 65 by 11 feet.

In Scotland, the Wellingtonia has not attained as great a height as in England, but seems to grow well in many places. The finest I have seen is at Murthly, planted in 1857; this in 1891 measured 66½ feet by 9 feet 3 inches, and when I measured it in September 1906, had increased to 86 feet by 12 feet 5 inches. There is one at Castle Menzies which Hunter says was planted out of a pot in 1858, when it cost three guineas, and in 1883 measured 44 feet by 9 feet 3 inches. This has not grown much taller, though it had attained the immense girth of 21 feet when I last saw it in 1907. At Smeaton-Hepburn, East Lothian, a tree, planted in 1855, was measured in 1905 by Henry as 78 feet by 12 feet 9 inches. At Keir, Perthshire, there are several trees, the tallest of which measured, in the same year, 71 feet by 9 feet. At Haddo House, Aberdeenshire, a tree planted in 1857 and reported¹ to be 50 feet by 8 feet 4 inches in 1891, was, in 1904, 68 feet by 11 feet.

The largest trees, reported² by Renwick and M'Kay, are one at Buchanan Castle, Stirlingshire, which was 71 feet high by 9 feet 3 inches in girth in 1900,

¹ Journ. Roy. Hort. Soc. xiv. 501 (1892).

² Brit. Assoc. Glasgow, 1901, Fauna, Flora, and Geology, 144.

and another at Glendoune, Ayrshire, which was 9 feet 4 inches in girth in 1898.

In Ireland there are many fine trees, the tallest in the British Isles in 1891, of those reported at the Conifer Conference,¹ being one at Shanbally in Tipperary, which was then 80 feet in height by 8½ feet in girth.

The finest seen by Henry is growing at Ballykilcavan, Queen's County, the seat of Sir Hunt H. A. Johnson-Walsh, Bart., and measures 95 feet in height and 10 inches in girth. At Brockley Park, a few miles distant, the seat of W. Young, Esq., a tree measures 73 feet by 10 feet 9 inches. At Emo Park, in the same county, there is a fine avenue, though the trees are growing on poor shallow limestone soil. They are planted about 35 yards apart, and average 70 feet high by 10 feet in girth. On the lawn at this place there is a finer tree, 81 feet high by 10 feet 4 inches; and beside it, a redwood, planted at the same time, is only 50 feet high and doing badly.

At Coollattin, Wicklow, a tree measured, in 1906, 78 feet by 12 feet. It produces fruit freely, but the seed does not mature and when sown has never produced seedlings. At Churchill, Armagh, a tree, planted in a bog, was in 1905 67 feet by 12 feet, and looked very healthy. Two trees, 77 feet and 73 feet high, were reported² to be growing in 1897 at Fassaroe, near Bray, in Wicklow.

The largest Wellingtonia of which I have heard on the Continent is a tree near the Hotel Bonnemaison at Bagnères de Luchon (Haute Garonne), of which a large photograph has been kindly sent me by the Hon. W. Rothschild. This splendid tree measures rather over 91 high by 25 feet in girth at the ground. A tree at Locarno,³ on the northern end of Lake Maggiore, has attained, in 17 years after planting, a height of 72 feet and a girth of 9 feet 2 inches. The species appears to be quite hardy in the severe climate of Munich, as Dr. Mayr says that at Grafrath one only 10 years old was nearly 19 feet high, and had endured a frost of -25° Cent. without any injury; though in the winter of 1902-1903, when the thermometer fell to -28° Cent., the branches on the sunny side of the tree were somewhat browned. Trees, however, at Berlin,⁴ which had attained 30 to 40 feet in height, succumbed to the severe cold of the winter 1893-1894.

TIMBER

The timber is very light, soft, weak, and brittle, varying in colour from pale yellowish-brown to rich red-brown, with whitish sapwood, which occupies one to two hundred rings. In native specimens these are extremely close, fifteen or twenty to the inch in some cases.

The wood is said to be very durable in contact with the ground, and is largely used for making vine stakes and for shingles, also to some extent for building, fencing, and box-making. So far as I know it is never imported to Europe, and has no commercial value except locally.

² *Gard. Chron.* xxii. 385 (1897).

⁴ Bolle, in *Garden and Forest*, 1894, p. 95.

In the British Museum of Natural History there is a section taken at about 18 feet from the ground, of a tree felled in 1892 at Fresno. The annual rings show that it was 1335 years old.

In *Garden and Forest*, v. 541-547, there is an account, with two excellent photographs, of the felling of a large Sequoia from which a specimen was taken for the Jesup Timber Collection in the Natural History Museum at New York. One of the pictures shows the tree in the act of falling; the other shows the stump, which at ground level was 90 feet in girth, and on its bark and outer edge fifty men are standing, and there is room for a hundred more. Mr. Moore, the Superintendent of the King's River Lumber Company, on whose land the tree was cut, estimated its contents at 400,000 feet, board measure, equal to about 40,000 cubic feet.

ABIES

Abies, Linnæus, *Gen. Pl.* 294 (in part) (1737); Bentham et Hooker, *Gen. Pl.* iii. 441 (1880); Masters, *Journ. Linn. Soc. (Bot.)* xxx. 34 (1893); Hickel, *Bull. Soc. Dendr. France*, 1907, pp. 5, 41, and 82; 1908, pp. 5 and 179.
Picea, D. Don, in Loudon, *Arb. et Frut. Brit.* iv. 2293 (1838).

EVERGREEN trees belonging to the order Coniferæ; bark containing numerous resin-vesicles; branches whorled. Buds, with numerous imbricated scales, with or without resin, usually two to five at the ends of the branchlets, the central bud terminal and largest, the others surrounding it in a circle on upright shoots, whilst on lateral branchlets those on the upper side are not developed; buds also occur rarely and few in number in the axils of the leaves on the branchlets below. Branchlets of one kind, usually smooth, but in certain species grooved, with raised pulvini; each season's shoot¹ marked by a sheath at the base, composed of the persistent bud-scales of the previous spring.

Leaves on fertile and barren branchlets, often different in length and thickness and in the nature of the apex; arising from the branchlets in spiral order, radially disposed on vertical shoots, but variously arranged according to the species on lateral branchlets; persisting for many years and giving the tree a dense mass of foliage; leaving as they fall circular scars on the branchlets; sessile, but usually narrowed just above the expanded circular base; linear, flattened and thin in most species, quadrangular in section in a few species; ventral surface always with two greyish or white stomatic bands, one on each side of the raised green midrib; dorsal surface with or without stomata, which when present are either in continuous lines, as in the quadrangular-leaved species, or are confined to near the tip of the leaf in the middle line, as in some flat-leaved species; apex acute, acuminate, or obtuse, notched or entire, spine-pointed in one or two species; resin-canals² two, constant in position for each species in the leaves on lateral branchlets, but in some species³ differing in position in the leaves on the upright or fertile branchlets, either *median*,

¹ In *A. bracteata*, all the bud-scales usually fall off, leaving ring-like scars at the base of the shoot.

² The position of the resin-canals is easily seen on examining a thin section with a lens; and can often be made out by squeezing the leaf, after it is cut across, when the resin will be observed exuding from the two canals.

³ In *A. pectinata*, *A. cephalonica*, and *A. Nordmanniana*, the resin-canals are marginal in the leaves of lateral branches, and are median in the leaves of cone-bearing branches. Cf. Gninier and Maire, in *Bull. Soc. Bot. France*, lv. 189 (1908).

when situated in the substance of the leaf about equidistant between its upper and lower surfaces, or *marginal* or *sub-epidermal*, when placed in the lower part of the leaf close to the epidermis; fibro-vascular bundle simple in some species, divided into two parts in other species.

Flowers monœcious, the two sexes on separate branchlets; male flowers usually abundant and on the lower side of the branchlets over the upper half of the tree; female cones on the upper side of the branchlets, usually only near the top of the tree, but in some species borne all over the upper half of the tree. Staminate flowers,¹ solitary in the axils of the leaves of the preceding year's shoot; stamens spirally crowded on a central axis, anthers surmounted by a knob-like projection and dehiscing transversely. Female cones,¹ arising as short shoots, composed of numerous imbricated fan-shaped ovuliferous scales, and an equal number of much longer mucronate bracts; ovules inverted, two on each scale.

Mature cones erect on the branchlets, composed of closely imbricated woody scales, more or less fan-shaped with short stalks. Bracts adnate to the outer surface of the scales at the base; either concealed between the scales or with their tips exerted and then often reflexed over the margin of the scale next below; dilated at the apex, entire or two-lobed, prolonged into a triangular mucro. Seeds two on the inner surface of each scale, winged, and with resin-vesicles. The cones ripen in one season; and the scales, bracts, and seeds fall away from the central spindle-like axis of the cone, which persists for a long time on the tree. The seedling has four to ten cotyledons, stomatiferous on their upper surface.

The species of *Abies* are distinguishable from all other conifers by the circular base of the leaves, which on falling leave circular scars on the branchlets.

The species of *Abies* have been variously divided into sections by different authors, but no satisfactory arrangement has yet been made out. Mayr proposed three sections based on the colour of the cones; but, as Sargent² points out, colour is not a constant character in several species. The cones are of value in the discrimination of the species, by taking into account their age, general appearance, and characters as a whole; but the scales are often very variable in shape in the same species, and the bracts, while more constant in form, often show considerable variation in their length. It is most convenient, in practice, especially as cones are in most cases not available for examination, to group the species, according to the characters of the buds, branchlets, and foliage, which are, as a rule, very constant in the same species. Hickel³ proposes three sections, based on the characters of the branchlets and buds; but his division is artificial, as it separates species closely allied by the characters of their cones.

Some notes on the genus *Abies*, for which we are indebted to Mr. J. D. Crozier, forester to H. R. Baird, Esq. of Durris, Kincardineshire, are inserted. Mr. Crozier's long experience in the east of Scotland gives a special value to his opinion on their respective qualities for planting in Scotland, which our own

¹ Both the staminate flowers and the young female cones are surrounded at the base by involucre of bud-scales.
² *Silva N. Amer.* xii. 97, *adnot.* (1898). Sargent proposes three sections, based on the characters of the leaves.

³ *Bull. Soc. Dendr. France*, 1907, p. 11.

could not have, though in almost every case he confirms the conclusions at which we had already arrived.

About thirty species are known, of which twenty-six have been introduced and are distinguished below. The silver firs are natives of the temperate parts of the northern hemisphere, usually occurring in mountainous regions; attaining high elevations towards the south, as in Guatemala, Algeria, Himalayas, and Formosa; and descending to low levels in the extreme north, as Alaska, Labrador, and Siberia.

The following table is based upon characters taken from the foliage, buds, and shoots of lateral branches, occurring on the lower part of the tree. As regards the leaves, their arrangement upon the branchlets, the position of the resin-canals, and whether the apex is entire or bifid must be noted. The presence of stomata on the upper surface of the leaf is peculiar to certain species. The young shoots are either smooth or deeply grooved with prominent pulvini; and are glabrous in some species, pubescent in others, the pubescence when present being either confined to the grooves or spread over the whole branchlet. The buds vary in size and shape and also in the quantity of resin, which in some cases is so slight that they may be described as non-resinous; whilst in other species the scales are covered with or deeply immersed in resin.

Certain species are distinguishable at a glance by some prominent character. *A. bracteata* has a bud entirely different from that of any other species. *A. Pinsapo*, with its short, thick, rigid leaves, standing out radially from the shoot, is unmistakable. *A. cephalonica*, with a more imperfect radial arrangement, is distinguished by its long flattened leaves ending in a single sharp cartilaginous point. *A. firma* is peculiar in its remarkably broad very coriaceous leaves, which end in two sharp unequal points. *A. grandis* has the leaves quite pectinate in the horizontal plane, those of the upper rank about half the size of those below. *A. Mariesii* is distinguished by the shoot being densely covered with a ferruginous tomentum. *A. brachyphylla* and *A. Webbiana* have deeply-furrowed shoots with prominent pulvini, which become more marked in the second year; and the bark begins to scale very early on the branches and trunk of the tree. *A. nobilis* and *A. magnifica* are peculiar in the upper median leaves curving up from the shoot after being appressed to it for some distance. *A. Pindrow* has long pale green leaves very irregularly arranged.

I. *Leaves radially arranged on the branchlets; apex of the leaf not bifid.*

1. *Abies Pinsapo*, Boissier. Spain. See p. 732.
Leaves rigid, short, less than $\frac{3}{4}$ inch long, thick, acute at the apex; resin-canals median. Shoots glabrous. Buds resinous.
2. *Abies cephalonica*, Loudon. Greece. See p. 739.
Leaves thin, flattened, about 1 inch long, ending in a sharp cartilaginous point; resin-canals marginal. Shoots glabrous. Buds resinous.
In var. *Apollinis*, the radial arrangement is imperfect, and the leaves end in a short point.

II. *Leaves on the lateral branches pectinate in arrangement; the two lateral sets either in one plane, or with their upper ranks directed upwards as well as outwards, showing a V-shaped depression, as seen from above, between the two sets.*

* *Resin-canals marginal.*¹

3. *Abies bracteata*, Nuttall. California. See p. 796.
Leaves long, 2 inches or more, rigid, ending in a spine-like point. Shoots glabrous. Buds peculiar in the genus, elongated, fusiform, membranous, non-resinous.
4. *Abies grandis*, Lindley. Western N. America. See p. 773.
Leaves all in one plane, those in the upper rank about half the length of those below, up to 2 inches long, bifid at the apex; upper surface grooved and without stomata. Shoots minutely pubescent. Buds small, resinous.
5. *Abies Lowiana*, Murray. California. See p. 779.
Leaves in a V-shaped arrangement, $1\frac{1}{2}$ to $2\frac{1}{2}$ inches long, bifid at the apex; upper surface grooved and with eight lines of stomata. Shoots and buds as in *A. grandis*.
6. *Abies firma*, Siebold and Zuccarini. Japan. See p. 762.
Leaves in a V-shaped arrangement, rigid, very coriaceous, broad, up to $1\frac{1}{2}$ inch long, ending in two sharp cartilaginous points. Shoots pubescent in the furrows between the slightly raised pulvini. Buds small, ovoid, only slightly resinous.
7. *Abies homolepis*, Siebold and Zuccarini. Japan. See p. 764.
Leaves in arrangement and appearance like *A. firma*; but shorter, less coriaceous, narrower, and whiter beneath. Shoots with prominent pulvini, glabrous. Buds ovoid, resinous, larger than in *A. firma*.
8. *Abies pectinata*, De Candolle. Europe. See p. 720.
Leaves pectinate in one plane or tending to a V-shaped arrangement, about an inch long, slightly bifid at the apex. Shoot grey, with short pubescence. Buds ovoid, non-resinous.
9. *Abies Webbiana*, Lindley. Himalayas. See p. 750.
Leaves V-shaped in arrangement, up to $2\frac{1}{2}$ inches long, bifid, silvery white beneath. Shoots with prominent pulvini and deep grooves, with a reddish pubescence confined to the grooves. Buds large, globose, resinous.

** *Resin-canals median.*²

10. *Abies balsamea*, Miller. Eastern N. America. See p. 803.
Leaves slender, scarcely 1 inch long, bifid at the apex, with six to eight lines of stomata in each band on the lower surface. Shoots, smooth, grey, with scattered short erect grey pubescence. Buds globose, resinous.
11. *Abies Fraseri*, Poiret. Alleghany Mountains. See p. 806.
Leaves as in *A. balsamea*, but shorter and whiter beneath, with eight to

¹ *A. cilicica* and *A. numidica*, with weak shoots, come in this section. See Nos. 22 and 23.

² *Abies lasiocarpa*, Nuttall, often has the leaves more or less pectinate, and might be sought for here. See No. 26.

twelve lines of stomata in each band beneath. Shoots smooth, yellowish, with dense reddish curved or twisted pubescence. Buds globose, resinous.

12. *Abies brachyphylla*, Maximowicz.¹ Japan. See p. 765.

Leaves in a V-shaped arrangement, short, scarcely exceeding $\frac{7}{8}$ inch, slightly bifid, white beneath. Shoots glabrous, with prominent pulvini and deep grooves. Buds conical, resinous.

III. *Leaves on lateral branches not pectinate above, but densely crowded, those in the middle line directed forwards in imbricated ranks, their bases not being appressed to the branchlet. On the lower side of the shoot the leaves are in two lateral sets.*

* *Resin-canals marginal.*²

13. *Abies Nordmanniana*, Spach.³ Caucasus, Northern Asia Minor. See p. 746.
Leaves up to $1\frac{1}{4}$ inch long, with rounded bifid apex. Shoots smooth, with short scattered erect pubescence. Buds ovoid, brown, non-resinous.
14. *Abies amabilis*, Forbes. Western N. America. See p. 782.
Leaves in arrangement and size like those of *A. Nordmanniana*, but much darker shining green, and with a truncate bifid apex; they emit a fragrant odour when bruised. Shoots smooth, with short wavy pubescence. Buds small, globose, resinous.
15. *Abies religiosa*, Schlechtendal. Mexico, Guatemala. See p. 808.
Leaves about 1 inch long, gradually narrowing from the middle to the usually entire apex, which is occasionally slightly emarginate. Shoots with prominent pulvini and dense minute erect pubescence. Buds shortly cylindrical, resinous.
The median upper leaves are much less numerous than in the two preceding species.
16. *Abies Mariessii*, Masters. Japan, Formosa. See p. 771.
Leaves shorter and broader than in *Abies Veitchii*, widest in their upper third, with a rounded and bifid apex. Shoot densely covered with a ferruginous tomentum. Buds small, globose, resinous.

** *Resin-canals median.*

17. *Abies Veitchii*, Lindley. Japan. See p. 768.
Leaves up to 1 inch long, truncate and bifid at the apex, uniform in width, very white beneath, with nine to ten lines of stomata in each band. Shoots smooth, covered with dense short erect pubescence. Buds small, globose, resinous.
The upper median leaves, pointing forwards, stand off from the shoot at a wider angle than in *A. Nordmanniana*.

¹ *Abies umbellata*, Mayr, is said to be very similar in foliage to this species. See the description of this species, p. 768.

² *A. numidica* with strong shoots, is distinguished from all these species by the leaves of the upper side being directed backwards. See No. 23.

³ *A. cilicica*, with strong shoots, resembles a weak *A. Nordmanniana*. See No. 22.

18. *Abies sachalinensis*, Masters. Saghalien, Yezo, Kurile Isles. See p. 760.
Leaves long and slender, up to $1\frac{3}{4}$ inch, uniform in width, with a rounded and bifid apex, white beneath, seven to eight lines in each stomatic band. Shoots with prominent pulvini, and a dense short pubescence confined to the grooves. Buds small, globose, resinous.
19. *Abies sibirica*, Ledebour. N. E. Russia, Siberia, Turkestan. See p. 758.
Leaves long and slender, up to $1\frac{1}{2}$ inch, uniform in width; apex rounded and either slightly bifid or entire; four to five lines in each stomatic band beneath. Shoots ashy grey, quite smooth, with a scattered minute pubescence. Buds small, globose, resinous.

IV. *Leaves on lateral branches not pectinate above; those in the middle line covering the branchlet, and curving upwards after being appressed to the shoot for some distance at their base. The leaves are in two lateral sets on the lower side of the branchlet. Resin-canals marginal.*

20. *Abies nobilis*, Lindley. Washington, Oregon, California. See p. 786.
Leaves above closely appressed by their bases to the branchlet, which they completely conceal; about 1 inch long, entire at the apex, flattened, grooved on the upper surface in the middle line; stomata usually present on both surfaces. Shoots with a dense, short brown pubescence. Terminal buds girt at the base by a ring of acute or subulately-pointed pubescent scales.
21. *Abies magnifica*, Murray. Oregon, California. See p. 792.
Leaves above appressed at their bases, for a short distance only, to the branchlet, which they do not completely conceal; longer than in *A. nobilis*, up to $1\frac{3}{4}$ inch, entire at the apex, quadrangular in section, not grooved on the upper surface; stomata always present on both surfaces. Shoots and buds as in *A. nobilis*.

V. *Leaves on lateral branches arranged in two ways, which are often observable on the same tree, and depend upon the vigour of the shoots.*

22. *Abies cilicica*, Carrière. Asia Minor. See p. 744.
Leaves either (A) pectinate above with a V-shaped depression between the lateral sets, or (B) with the median leaves above crowded and covering the branchlet, as in *A. Nordmanniana*. The leaves are slender, up to $1\frac{1}{4}$ inch long, not conspicuously white below, slightly bifid at the rounded or acute apex; resin-canals marginal. Shoots smooth, with scattered short erect pubescence. Buds small, ovoid, non-resinous.
Vigorous shoots of this species resemble a weak *A. Nordmanniana*; but with the leaves shorter, more slender, and less white beneath, the buds being much smaller.
23. *A. numidica*, De Lannoy. Algeria. See p. 737.
Leaves either (A) pectinate above with a V-shaped depression; or (B) crowded and covering the upper side of the branchlet, but different from

all other species in the median leaves above, in that case, being directed backwards and not forwards. Leaves short, up to $\frac{3}{4}$ inch long, broad, rounded at the entire or slightly bifid apex; in most cases with four to six broken lines of stomata on their upper surface near the tip; resin-canals marginal. Shoots brown, shining, glabrous. Buds large, ovoid, non-resinous.

VI. *Leaves irregularly arranged; those on the lower side of the branches not truly pectinate.*

24. *Abies Pindrow*, Spach. W. Himalayas. See p. 755.
Leaves all directed more or less forwards; those above irregularly and imperfectly covering the branchlet; those below mostly pectinate, but with some directed downwards and forwards. Leaves soft, pale green, up to $2\frac{1}{2}$ inches long, bifid at the apex with two sharp cartilaginous points; resin-canals marginal. Shoots grey, glabrous. Buds large, globose, resinous.
25. *Abies concolor*, Lindley and Gordon. Colorado, Utah, Arizona, New Mexico, Northern Mexico, Southern California. See p. 777.
Leaves imperfectly pectinate both above and below, some in the middle line being always directed forwards and not laterally outwards; up to 2 to 3 inches long; apex entire; upper surface convex and not grooved, bearing fifteen to sixteen lines of stomata; resin-canals marginal. Shoots smooth, olive-green, glabrous. Bud large, conical, resinous.
26. *Abies lasiocarpa*, Nuttall. Western N. America. See p. 800.
Leaves either (A) in an imperfect pectinate arrangement, or (B) with most of the leaves directed upwards, those in the middle line above crowded, and standing edgeways; $1\frac{1}{2}$ inches long, narrow, usually entire, with conspicuous lines of stomata on the upper surface, especially in its anterior half. Resin-canals median. Shoots smooth, with a moderately dense, short wavy pubescence. Buds small, conical, resinous.

Four species, *A. Delavayi*, Franchet;¹ *A. Fargesii*, Franchet;² *A. squamata*, Masters;³ and *A. recurvata*, Masters;⁴ occur in the mountains of western China and are not included in the above list. The two first species are reported by Masters to have been introduced by Wilson; but, on inquiry, we find that only one species of *Abies* from China is now growing in the Coombe Wood nursery. It is probably *A. Fargesii*; but, as the plants are still very young, we are uncertain of this identification, and think it best to leave this species undescribed for the present.

(A. H.)

ABIES PECTINATA, COMMON SILVER FIR

Abies pectinata, De Candolle, in Lamarck, *Flore Franç.* iii. 276 (1805); Willkomm, *Forstliche Flora*, 112 (1887); Mathieu, *Flore Forestière*, 525 (1897); Kent, Veitch's *Man. Coniferae*, 530 (1900).
Abies alba,¹ Miller, *Dict.* ed. 8, No. 1 (1768); Kirchner, *Lebengesch. Blüthenpfl. Mitteleuropas*, i. 78 (1904).

Abies vulgaris, Poiret, in Lamarck, *Dict.* vi. 514 (1804).

Abies Picea, Lindley, *Penny Cycl.* i. 29 (not Miller) (1833).

Pinus Picea, Linnæus, *Sp. Pl.* 1001 (1753).

Pinus Abies, Du Roi, *Obs. Bot.* 39 (1771).

Pinus pectinata, Lamarck, *Fl. Franç.* ii. 202 (1778).

Picea pectinata, Loudon, *Arb. et Frut. Brit.* iv. 2329 (1838).

A tree attaining under favourable conditions about 150 feet in height and 20 feet or more in girth. Bark on young trees, smooth, greyish; ultimately fissuring and becoming rough and scaly. Buds small, ovoid, non-resinous; scales few, brownish, rounded at the apex. Young shoots grey, smooth, with a scattered short erect pubescence, which is retained in the second year.

Leaves on lateral branches pectinately arranged in two lateral sets; those below the longest and directed outwards and slightly forwards in the horizontal plane; those above directed upwards and outwards, forming between the two sets a shallow V-shaped depression. Leaves about 1 inch long, $\frac{1}{2}$ inch broad, linear, flattened, narrowed at the base, tapering slightly to the rounded, bifid apex; upper surface dark green, shining, with a continuous median groove and without stomata; lower surface with two white bands of stomata, each of seven to eight lines; resin-canals marginal.

On leading shoots the leaves are radially arranged, and differ considerably from those on lateral branches; they are thicker, with median resin-canals, acute and not bifid at the apex, and often show lines of stomata on their upper surface towards the tip. Leaves on cone-bearing branches are nearly all directed upwards, very sharp-pointed, and almost tetragonal in section.

Trees, standing in an isolated position, usually begin to flower at about thirty years old; when crowded in dense forests, much later, usually not before sixty years old.

Staminate flowers, surrounded at the base by numerous imbricated scales, cylindrical, about 1 inch long, with greenish-yellow stamens. Female cones, appearing in August of the previous year as large rounded buds, enclosed in brown scales, and situated just behind the apex of the shoot; in spring, when developed, erect, cone-shaped, about 1 inch long, surrounded at the base by fringed scales; bracts numerous, imbricated, denticulate, ending in long, acuminate points, and completely concealing the much smaller ovate, rounded ovuliferous scales.

¹ *Abies alba*, the oldest name under the correct genus, was never in use until lately, when it has been resuscitated by Sargent and some continental botanists. This is one of the cases where adherence to strict priority would lead to great confusion; and hence we have adopted the name *Abies pectinata*, by which the tree is generally known.

Cones on short stout stalks, cylindrical, slightly narrowed at both ends, obtuse at the apex, about 6 inches long, 2 inches in diameter, greenish when growing, dull brown when mature, with the points of the bracts exerted and reflexed. Scales tomentose externally, fan-shaped, about 1 inch broad and long; upper margin slightly uneven; lateral margins denticulate, each usually with a sinus, below the slight wings on the outer side of the scale; claw clavate. Bract with an oblong claw, extending up three-quarters the height of the scale, and expanding above into a lozenge-shaped denticulate lamina, which ends in a sharp long triangular mucro. Seed with wing about an inch long; wing about twice as long as the body of the seed.

SEEDLING

Seed sown in spring germinates in three or four weeks. The cotyledons, usually five in number, are at first enveloped, as with a cap, by the albumen of the seed; but speedily casting this off, they spread radially in a whorl at the summit of the short caulicle, and remain green on the plant for several years; about an inch in length, linear, obtuse at the apex, flat beneath, and slightly ridged on the upper surface, which shows two whitish bands of stomata. In the first year only a single whorl of true leaves, arising immediately above the cotyledons and alternating with them, is produced. Primary leaves short, acute, or obtuse, but not emarginate at the apex, and with the stomatic bands on the lower surface. A terminal bud closes the first season's growth, the plant scarcely attaining two inches high. In the second year ordinary leaves, arranged spirally on the stem, are produced. The growth of the plant in the first two or three years is mainly concentrated in the root, which descends deep into the soil, the increase in height of the stem above ground being trifling. The stem branches in the third or fourth year, and produces annually for some years one or two lateral branches, making no great growth in height, reaching in the ninth year an average of two feet. About the tenth year normal verticillate branching begins; and from this onwards the plant makes rapid growth.

VARIETIES

Dr. Klein gives in *Vegetationsbilder* illustrations of some remarkable forms¹ which the silver fir assumes at high elevations in Central Europe, and which he calls "Wettertanne" or "Schirmtanne." These trees have lost their main leader through lightning, wind, or otherwise, and have developed immense side branches which spread and then ascend, sometimes forming a candelabra-like shape. The finest of this type known to him is at St. Cerques in Switzerland, and measures at breast height no less than 7.40 metres in girth, about the same as the largest of the Roseneath² trees.

Other varieties, distinguished by their peculiar habit, occur in the wild state.

¹ These forms are also described by Dr. Christ in *Garden and Forest*, ix. 273 (1896).

² One of the trees at Roseneath, Dumbartonshire, has a similar growth of erect branches, like leaders from some of the horizontal limbs. This is figured, from a photograph by Vernon Heath, in *Gard. Chron.* xxii. 8, fig. 1 (1884). At Powerscourt there is also a large tree, 13 feet 3 inches in girth, with branches prostrate on the ground and sending up several upright stems.

Var. *pendula*,¹ with weeping branches, has been found in the Vosges and in East Friesland.

Var. *virgata*,² found in Alsace and Bohemia, has long pendulous branches, only giving off branchlets near their apices, and densely covered with leaves.

Var. *pyramidalis*.³ This form, which in habit resembles the cypress or a Lombardy poplar, was found growing wild in the department of Isère in France. A very fine example, about 35 feet high in 1904, is growing in the arboretum of Segrez.

Var. *columnaris*,⁴ very slender in habit, with numerous short branches, all of equal length, and with leaves shorter and broader than in the type.

Var. *tortuosa*, a dwarf form, with twisted branches, and bent, irregularly-arranged leaves.

Var. *brevifolia*, another dwarf form, distinguished by its short broad leaves.

Remarkable variations in the cones have also been observed. A tree, discovered by Purkyne⁵ in Bohemia, bore cones, umbonate at the apex, and with short and non-reflexed bracts. Beissner⁶ mentions a tree, growing in the park at Wörlitz near Dessau, which produced cones a foot in length.

DISTRIBUTION

The common silver fir is a native of the mountainous regions of central and southern Europe. The northern limit of its area of distribution begins in the western Pyrenees about lat. 43° in the neighbourhood of Roncesvalles in Navarre; and crossing the chain it extends along its northern slope as far as St. Béal; from here it bends northwards to the mountains of Auvergne, whence it is continued in a north-easterly direction through Burgundy and French Lorraine, crossing the eastern slope of the Vosges about the latitude of Strasburg. From here it curves for some distance westward, and reaching Luxemburg, is continued through Trier and Bonn to southern Westphalia. Across the rest of Germany, according to Drude, who gives a map of the distribution of the species, the northern limit extends as an irregular line about lat. 51°, which touches Hersfeld, Eisenach, the northern edge of the Thuringian forest, Glauchau, Rochlitz, Dresden, Bautzen, and Görlitz; and ends in the southern point of the province of Posen. Around Spremberg to the north of the limit just traced, it is found wild in a small isolated territory.

The eastern limit, beginning in Posen, extends through Poland along the River Wartha to Kolo, crosses to Warsaw, and descending through Galicia west of Lemberg, reaches the Carpathians in Bukowina; and is continued along the mountains of Transylvania to Orsova on the Danube.

The southern limit is not clearly known as regards the Balkan peninsula, as the silver fir, which occurs in the mountains of Roumelia, Macedonia, and Thrace,

¹ Kottmeier found peculiar weeping silver firs in the Friedeberg forest, near Wittmund in East Friesland, in 1882. Cf. Wittmack's *Gartenzeitung*, 1882, p. 406, and Conwentz, *Seltene Waldbäume in Westpreussen*, 161 (1895).

⁴ Carrière, *Rev. Hort.* 1859, p. 39.

⁶ *Nadelholzkunde*, 433 (1891).

supposed to be *A. pectinata*, is more probably a form of *A. Apollinis*. In Italy the common silver fir reaches its most southerly point on the Nebroden and Madonia Mountains of Sicily at lat. 38°. From here the limit follows the Apennines up through Italy, crosses into Corsica, and from there passes into Spain, where it extends from Monseny, near the Mediterranean coast in lat. 41° 25', parallel to the Pyrenees, through the mountains of Catalonia and northern Aragon to Navarre. In Spain the silver fir also occurs westwards on a few points of the northern littoral in the Basque provinces and Asturias.

Within the extensive territory just delimited, the silver fir is very irregularly distributed, being totally absent in many parts, as on the plains and lower mountains of southern Europe. In the eastern part of its area it occurs only as isolated trees or in small groups in the beech and spruce forests; whereas, in the western part, as in France and in parts of Germany, it forms forests of great extent, either pure or in which it is the dominant species.

In France the largest forests of the silver fir are in the Vosges and in the Jura. Important forests also occur in the eastern parts of the Pyrenees, the Cevennes, the mountains of Auvergne, and the Alps of Dauphiné. It is rare on the hills of Burgundy, and does not occur in the Ardennes. There are small woods of this species on some of the hills in Normandy, which are, however, supposed to be planted and not indigenous. The great forest of the Vosges¹ is about 50 miles long by 5 to 10 miles in width, and contains about 200,000 acres, situated mainly between 1100 and 3300 feet elevation. This forest consists chiefly of silver fir, though, in some parts, there is a considerable mixture of beech, spruce, and common pine. The most productive woods are on siliceous soil, and only contain 10 per cent of beech and pine; their mean annual production being about 100 cubic feet per acre, the volume of timber standing on each acre averaging 4500 cubic feet.

In the Jura there are even richer and more homogeneous forests than in the Vosges, being according to Huffel the finest in Europe. Here the soil is limestone. One of these forests, which covers Mount La Joux, between 2100 and 3000 feet altitude, contains 10,600 acres, and consists of about 90 per cent silver fir and 10 per cent of spruce. The annual yield per acre is 170 cubic feet of timber. The total volume of standing timber, including only trees over 2 feet in girth, is 6000 cubic feet per acre. The net revenue is thirty-two shillings an acre. There are several other forests equally valuable in this region.

One of the finest silver firs¹ in France, a tree called "Le Président," is growing in the forest of La Joux. It is 163 feet high, with a clean stem of 93 feet, and a girth of 15 feet; and contains 1600 cubic feet of timber. In the forest² of Gérardmer, in the Vosges, there are two fine trees. One, the *Beau Sapin*, has a height of 144 feet and a girth of 13 feet 8 inches; it contains 777 cubic feet of timber, and is valued at £16. The other, the *Géant Sapin*, has a height of 157 feet and a girth of 14 feet 5 inches; it contains 1095 cubic feet of timber, and is valued at £27. In the Pyrenees the silver fir occurs between 4500 and 6500 feet elevation, and trees

¹ See Huffel, *Économie Forestière*, i. 349, 350, 353 (1904).

² Cf. *Trans. R. Scot. Arb. Soc.* xviii. 131 (1905).

of great age, about 800 years old, are said¹ to have existed there at the beginning of the 19th century.

In Corsica the silver fir occurs in the great forests of *Pinus Laricio*, but is not abundant, as it only grows, as a rule, in scattered groups in the gullies, where the soil is deeper and richer than elsewhere; and at Valdoniello I only saw a few trees, none of which were of large size. M. Rotges, of the Forest Service, informed me that it occurs in greatest quantity in the forest of Pietropiano, near Corte.

In Italy the silver fir is unquestionably wild on the Apennines, and considerable forests exist at Vallombrosa and Camaldoli, which are now owned by the government. That at Camaldoli is particularly fine, the total area covered by the silver fir being about 1600 acres. The trees are dense on the ground and very vigorous in growth; and this is easily explained by the heavy rainfall, which, as measured at St. Eremo, in the middle of the forest, at 3600 feet altitude, averages about 80 inches annually. I saw, when I visited Camaldoli, in December 1906, no trees of great size; but one was cut down in 1884, and a log of it shown at the National Exhibition at Turin in that year, which measured 140 feet in height and 17 feet in girth.

The silver fir also occurs in Sicily in small quantity, on the higher mountains, and specimens without cones, which I saw in the museum at Florence, are peculiar in the foliage, and form possibly a connecting link between *A. pectinata* and *A. numidica*.

In Germany, towards the northern part of its area of distribution, the silver fir is met with growing wild on the plains, as in Saxony, Silesia, and Thuringia. Towards the south it is entirely a tree of the mountains, occupying a definite zone of altitude, which, in the Bavarian forest, lies between 950 and 4000 feet. The largest forests, which are nearly pure, occur in the Black Forest and in Franconia; those in Bavaria, Bohemia, Thuringia, and Saxony being smaller in extent.

In Switzerland small forests occur at Zurich, Payerne, and on Mount Torat; the silver fir ascending in the Swiss Alps to 5300 feet altitude. (A. H.)

As to the size² which the silver fir attains in its native forests, many particulars are given by French and German foresters, some of which have been quoted above. None exceed, however, what I have seen in the virgin forests of Bosnia, where I measured near Han Semec, at an elevation of about 3000 feet, a fallen tree over 180 feet long, whose decayed top must have been at least 15 to 20 feet more. Loudon states that he saw, in the museum at Strasburg, a section of a tree of the estimated age of 360 years, cut in 1816 at Barr, in the Hochwald, which was 8 feet in diameter at the base and 150 feet high.

The virgin forests of Silesia and Bohemia contain silver firs of immense size, of which very interesting particulars are given by Göppert,³ who states that, in Prince Schwarzenberg's forest of Krummau, there existed many silver firs of from

¹ Willkomm, *Forstliche Flora*, 116, note (1887).

² Kerner, *Nat. Hist. Plants*, Eng. trans. i. 722, gives the "certified height" of *Abies pectinata* as 75 metres, or 250 feet; but this is not confirmed by other authorities.

³ H. R. Göppert, *Skizzen zur Kenntniss der Urwälder Schlesiens und Böhmens*, 18 (1868).

120 to 200 feet high, free from branches up to 80 to 120 feet, and as much as 6 to 8 feet in diameter. He quotes Hochstetter,¹ who measured in the Greinerwald, near Unter-Waldau, at an elevation of 2563 feet, a silver fir blown down by a storm, which was 9½ feet in diameter at breast height and 200 feet long, and produced 30 klafter of firewood.

The silver fir is planted outside the area of its natural distribution in most parts of France, in Belgium, and in western and northern Germany, but not beyond lat. 51° in eastern Prussia. It is occasionally planted in Norway, and at Christiania has attained 68 feet in length by 3½ feet in girth. At Thlebjergene, near Trondhjem, where, on the side of a hill, sloping down to the sea, with an easterly exposure, a fine plantation,² mainly of spruce and Scots pine, was made in 1872 and subsequent years,—there are some splendid groups of silver fir, 30 to 40 feet in height, apparently exceeding in rapidity of growth the native spruce beside it. It is met with in gardens in the Baltic provinces of Russia, as in Lithuania where there is a small wood near Grodno, and in Courland and Livonia; here, however, it always remains a small tree, never bears cones, and is much injured by severe winters.

One of the most remarkable plantations in Europe is the one made by the Hanoverian Oberforster, J. G. von Langen, in the Royal Park of Jægersborg, near Copenhagen, about 1765. I visited this place in 1908, and measured some of the trees. I found that the largest now standing near the entrance at Klampenborg was 125 feet by 12 feet 10 inches. This tree is figured in a work³ kindly sent me by Skovrider H. Mundt. There are, however, many taller trees on the south side of the main drive, two of which I found to be 140 feet by 9 feet, and 140 feet by 8 feet in girth, respectively. I measured the girth of twenty trees out of sixty-two which are growing on an area of 100 by 30 paces, and believe them to average over 130 feet high, with an average girth of 7½ feet. In Lütken's work full details are given of the measurements of these trees taken in 1893, and confirmed in 1898 by Oppermann, who found 432 trees, averaging 38.9 metres in height and containing 1400 cubic metres per hectare; which is equal to 20,000 cubic feet per acre in the round, or 15,700 feet English quarter-girth measure. My own hasty estimate on the spot was about 12,000 feet English quarter-girth measure per acre. These wonderful silver firs grow on a deep, sandy loam, on level ground near the sea, and seem to have passed their prime. Some of their timber has been used as rafters in the Secretariat hall of the new Raadhus at Copenhagen.

*A. pectinata*⁴ was brought to the eastern United States early in the nineteenth century; but it is not hardy even in the middle states.

Witches' brooms and cankered swellings, due to the fungus *Æcidium elatinum*, De Bary, are common on the silver fir in the continental forests; and are often seen in Ireland and the south-west of Scotland,⁵ though apparently rare in England, where they have been noticed in Norfolk⁶ and at Haslemere.⁷

¹ Hochstetter, *Aus dem Böhmerwalde*, *Allg. Augsb. Zeit.* 1855, No. 182. Cf. Sendtner, *Die Vegetations-Verhältnisse des Bayerischen Waldes* (1860).

⁶ *Trans. Norfolk and Norwich Naturalists' Soc.* vii. p. 255.

⁷ Specimens at Kew.

The swellings which affect the trunk or branches are due to the irritation of the fungus mycelium, which is perennial and stimulates the wood and bark to abnormal growth. These swellings become fissured and are entered by the spores of other fungi, which rot the wood; and the tree, if the stem is affected, is often broken off at the weakened spot by storms or falls of snow. The witches' brooms begin as young shoots, bearing small yellowish leaves, on the under surface of which two rows of *aecidia* are developed in August. These shed their spores at the end of that month and the leaves soon afterwards die and fall off. The affected shoots keep on growing, and develop into peculiar growths, set upright generally on the branches, and consisting of numerous twigs anastomosed together. The fungus passes one stage of its life on various species of *Stellaria*, *Cerastium*, and their allies, and Fischer¹ recommends the extirpation of these plants from nurseries in which the silver fir is raised.

The silver fir is very liable in its native forests to be attacked by the mistletoe. Modified roots, the so-called sinkers of the parasite, have been found in the wood enclosed in forty annual rings and as much as 4 inches long, showing that mistletoe may live on the tree for forty years. When the mistletoe dies the rootlets and sinkers survive for a time, but finally moulder and fall to pieces. The affected parts of the wood show numerous perforations, and exactly resemble the wood of a target that has been penetrated by shot or small bullets.²

The bark of the silver fir remains alive on the surface to an advanced age; and, on this account, when branches, stems, or roots of adjoining trees get into contact, they often become grafted together. This is the explanation of the curious phenomenon of the vitality of the stumps of certain trees in forests. After the stem is cut down, these stumps continue to increase in size and produce a callosity, which eventually covers the stump in the form of a hemispherical cap. Such a stump procures its nourishment from an adjoining tree, with which its roots have become grafted.³

CULTIVATION

The silver fir⁴ was introduced into England about the beginning of the seventeenth century; but the exact date is uncertain. The earliest trees recorded are two mentioned by Evelyn,⁵ which were planted in 1603 by Serjeant Newdigate in Harefield Park in Middlesex. These had attained about 80 feet high in 1679, but from inquiries made by the late Dr. Masters, there is no doubt that they have long since been cut down.

Though in its own country the silver fir is a tree of the mountains, yet it attains its greatest perfection in the south and west of England, Scotland, and

¹ Abstract of Fischer's paper in *Journ. Roy. Hort. Soc.* xxvii. 272 (1902).

² See Kerner, *Nat. Hist. Plants*, Eng. trans. i. 210, fig. 48 (1898). We have never seen or heard of mistletoe on the silver fir in this country.

³ See Mathieu, *Flore Forestière*, 529 (1897).

⁴ Staves were found, in 1900, lining the ancient wells in the Roman city of Silchester, Hants; and the wood was identified by Marshall Ward with *A. pectinata*. The casks, from which the staves had been taken, were probably imported from the region of the Pyrenees, and had either contained wine or Samian ware. Cf. Clement Reid, in *Archæologia*, lvii. 253, 256 (1901).

⁵ *Sylva*, 106 (1679).

Ireland, under conditions of soil and climate very unlike those of its native forests. Though it will endure the severest winter frosts without injury, yet unless under the cover of other trees, or in very sheltered situations, it is often injured by spring frost, on account of its tendency to grow early. As regards soil it is somewhat critical, for though Boutcher¹ says that he has seen the largest and most flourishing silver firs on sour, heavy, obstinate clay, yet I have never myself seen fine trees on any but deep, moist, sandy soils, or on hillsides where the subsoil was deep and fertile. He also says it is vain to plant them in hot, dry, rocky situations, and this is my own experience on oolite formations, where I have never seen a large or well-developed silver fir. In the east and midland counties they usually become ragged at the top before attaining maturity, and in this country rarely attain a great age without suffering from drought and wind.

Though foresters of continental experience recommend this tree for underplanting, on account of its ability to grow under dense shade, yet from an economical point of view it cannot be recommended here; and I do not know of any place in England where the financial results of planting the silver fir are, or seem likely to be, such as would justify growing it on a large scale; partly because of its very slow growth when young, and partly because its timber is not valued as it is in France and Germany. Mr. Crozier's experience² is very noteworthy.

The silver fir seeds itself very freely in some parts of England, Scotland, and Ireland,³ but the seedlings are so slow in growth and so delicate for the first few years, that few survive the risk of frost, rabbits, and smothering. Sir Charles Strickland tells me that in a wood of silver firs at Boynton, Yorkshire, which were mostly blown down in 1839, he remembers that a few years afterwards the growth of young seedlings was in places so dense that he could hardly force his way through them. Some of these self-sown trees are now 6 feet in girth and 60 to 70 feet high, but many are stunted from want of space. Their parents are rough and branchy, dying at the top, and 10 to 12 feet in girth.

REMARKABLE TREES

Though the silver fir will probably be in time surpassed in height and girth by some of the conifers of the Pacific coast of America, yet at present it has no rival in size among coniferous trees in Great Britain. Perhaps the tallest which I have seen in England is the magnificent tree (Plate 208) which grows in Oates Wood, at the top of Cowdray Park, Sussex, at an elevation of 500 to 600 feet, and now owing to its being deprived of the shelter of the surrounding trees, likely to be blown down

¹ Boutcher, *A Treatise on Forest Trees*, 146 (1775).

² Formerly one of our most reliable trees, but now hopelessly unreliable as a timber crop, owing to its susceptibility to attack by Chermes. Like the larch, our old trees are practically immune to attack, but the difficulty in getting up young stock—experienced throughout the greater part of the country—is likely to lead to its extinction altogether as an economic species. Has been much recommended by continental trained foresters—even of late years—for the purpose of underplanting in our Scotch woods, and some of those experiments I saw lately. The result is a hopeless failure in all of them.—(J. D. CROZIER.)

³ At Auchendrane, near Ayr, according to Mr. J. A. Campbell, there are several acres of self-sown seedlings; and in County Wexford I have also seen great numbers.

by the first severe gale. I measured this tree in 1906 in company with Mr. Roberts, forester to the Earl of Egmont, as carefully as the nature of the ground would allow, and believe it to be still over 130 feet in height; when I first saw it in 1903 it was taller. It is clear of branches to at least 90 feet and 10 feet 2 inches in girth. In the background some spruce which are even taller may be seen in our illustration.

I am informed by Mr. F. H. Jervoise, of Herriard Park, Hants, that there was a silver fir there which probably exceeded this height before its top was broken off about sixteen years ago. A photograph, taken in 1851, shows the height to have been then at least double what it now is, namely 70 feet, and another tree standing not far off measures approximately 140 feet.

In the Shrubbery at Knole Park, Kent, a very large silver fir is now about 110 feet high, with a clean bole about 80 feet by 12 feet; but its top is broken off, and it looks as if it might have been much taller.

At Longleat there are a great number of very fine silver firs near the Gardens, and also in the valley at Shearwater, the largest of which I measured in 1903, and found to be about 130 feet by 16 feet 5 inches in girth.¹ Mr. A. C. Forbes estimated the contents of this tree at 550 feet, and in the *Trans. Eng. Arb. Soc.* v. 399, gives the measurements of a group of twenty-seven trees, 120 years old, growing on an area of $\frac{1}{3}$ of an acre at the same place as follows:—Average height, 130 feet; average girth at 5 feet, 9 feet; average contents, 180 cubic feet. Total, 5000 cubic feet. I doubt whether any similar area of ground in England carries so much timber, except, perhaps, a group of chestnut and oak in Lord Clinton's park at Bicton. Silver fir requires unusually good soil to attain these dimensions. Plate 209 shows a part of this grove which stands at an elevation of about 500 feet on a greensand formation.

There is a row of very fine silver firs by the road on Breakneck hill in Windsor Park, one of which I measured as 130 feet by 11 feet, and no doubt many as large, or nearly so, can be found in other parts of the south and west of England; but, as a rule, when the tree attains about 100 to 110 feet its top ceases to grow and becomes ragged.

Near the great cedar at Stratton Strawless (see Plate 133) there are some tall silver firs, one of which in 1907 was 131 feet by 9 feet 7 inches; and Mr. Birkbeck informed me that another, believed to be the tallest tree in Norfolk, and measuring 135 feet, had been blown down in 1895 at the same place.

There are some very fine silver firs still standing at Eslington Park, Northumberland, which were planted about 1760, though Mr. Wightman, the gardener, informs me that the largest, which could be seen standing above all the other trees, was blown down in a gale in December 1894. It measured 122 feet by 21 feet at five feet from the ground, and at fifty feet from the ground was still 9 feet in girth.

Almost equal to these are the trees in the Ladieswell Drive, near Alnwick Castle, Northumberland, which I saw in 1907; though not much exceeding 100 feet

¹ Loudon states that the tallest silver fir known in England in his time was believed to be at Longleat, and measured 138 feet high by 17 feet in girth; but this tree cannot now be identified.

in height, they measure from 14 feet to 16 feet in girth, the largest being estimated by Mr. A. T. Gillanders, forester to the Duke of Northumberland, to contain about 600 cubic feet each.

At Rydal Park, Cumberland, Mr. W. F. Rawnsley informs me that a silver fir was felled which contained 420 cubic feet, and doubtless there are others in the north-west of England as large.¹

In Wales, however, I have seen none remarkable for size, though there are many places which seem as suitable as those I have mentioned.

In Scotland the silver fir attains its maximum of size in the south-west, and in a district where the climate is most unlike that of central Europe; being much warmer in winter, cooler in summer, and with a rainfall of 60 to 80 inches and even more in exceptional years.

On the Duke of Argyll's property at Roseneath are the champion silver firs of Great Britain, both as regards age and girth. Strutt figures them in *Silva Scotica* (plate 6), and states that the largest was then about 90 feet by 17 feet 5 inches. Loudon, twenty years later, gave the height as 124 feet, the age as 138 years, and the diameter of the trunk as 6 feet; but this height is almost certainly an error, as when I visited Roseneath in September 1906, a careful measurement made the largest about 110 feet by 22 feet 7 inches, and the other, which stands close by it, 105 feet by 22 feet 1 inch.² Plate 210, from a negative for which I have to thank Mr. Renwick, is the best I have been able to obtain of these noble trees, which grow close to sea-level in deep sandy soil. The Duke of Argyll believes them to have been planted about 1620 or 1630.

Near Inveraray Castle, on the lower slopes of Dun-y-Cuagh, Mr. D. Campbell, the Duke's forester, showed me some splendid silver firs, over 120 feet high and 15 feet in girth, and assured me that in his younger days he had helped to measure some which were much larger; one he believed to have been 24 feet in girth, containing over 800 feet of timber. On the Dalmally road, a little above the stables at Inveraray, are the tallest trees of the species that I have seen in Scotland; one measures 135 feet, or perhaps as much as 140 feet, by 16 $\frac{1}{2}$ feet; another about 135 feet by 14 feet 3 inches; and there may be even taller ones here which I could not measure. These splendid trees were, as the Duke of Argyll informs me, probably planted by Duke Archibald in 1750, but their timber is so coarse that it is of little value, and is principally used by Glasgow shipbuilders for keel blocks.

Some of the most remarkable silver firs which I have seen in any country are at Ardkinglas, now the property of Sir Andrew Noble, near the head of Loch Fyne. They are described by J. Wilkie, and well illustrated in the *Trans. Scot. Arb. Soc.* ix. 174, and show a tendency, which I cannot explain, to throw out immense branches, which, after growing horizontally 10 to 15 feet from the main trunk, turn up and form an erect secondary stem. The largest of these (*op. cit.* plate 11), according to Wilkie's careful measurement in 1881, was 114 feet high by 18 feet in girth at

¹ Sir Richard Graham of Netherby Hall, Cumberland, showed me a very remarkable tree in a wood called Hog Knowe, which has large spreading branches, 80 paces in circumference, and measures 98 feet by 14 $\frac{1}{2}$ feet. Mr. Watt of Carlisle has been good enough to send me a photograph of this tree, taken by his sister.

² See *Gard. Chron.* xxii. 8, fig. 1 (1884), and xxvii. 166, fig. 39 (1887), where good illustrations of these trees are given.

2½ feet. I made it in 1905 about 21 feet at the same height and 14 yards round the roots. Wilkie computed that the main stem contained 557 cubic feet and the branches 692 cubic feet, including bark, which exceeds the largest tree of the species recorded in this country. I certainly have never seen anything surpassing it in bulk, even in the virgin forests of Bosnia, though I have measured a fallen silver fir there which was at least 200 feet high. Another of these trees figured on plate 12 of the same volume, was estimated at 437 feet in the stem, and 449 feet in the ten principal limbs. At the same place is a very fine tree which Mrs. Henry Callender, who showed it to me, called "The Three Sisters," 115 feet high according to Wilkie,—I made it, twenty-four years later, 120 feet,—with a bole only 8 feet long, where it divides into three tall stems nearly equal in height and measuring just above where they separate, 8 feet 4 inches, 8 feet 5½ inches, and 8 feet 7 inches respectively.

The Union trees,¹ in the avenue at Auchendrane, Ayrshire, planted in 1707, are six in number, the largest being, in 1902, 97 feet high and 16 feet 1 inch in girth. Another tree in the flower garden here, planted at the same time, was 110 feet by 16 feet in 1902.

In the island of Bute, James Kay describes, in *Trans. Scot. Arb. Soc.* ix. p. 75, some fine silver firs which grew in a clump north-east of the circle walk in the woods of Mountstuart, the seat of the Marquess of Bute. They were of immense height (120 feet), and could be seen for miles standing out like an island among this forest of sylvan beauty. There were nineteen silver firs, five spruce, one Scots pine, and two birches, all standing on a space of 60 yards square, where they were healthy and not overcrowded. They were very uniform in size, and ran from 10 to 12 feet in girth, ten being straight to the top and nine forked at 30 feet to 60 feet up.²

In other parts of Scotland the silver fir usually attains smaller dimensions, the largest that I have seen being on the banks of the Tay, near Dunkeld, and at Dupplin Castle, where I measured a tree over 100 feet high by 17½ feet in girth. But Mr. W. J. Bean, in *Kew Bulletin*, 1906, p. 266, mentions an immense tree, which was blown down on November 17, 1893, near Drummond Castle, when 210 years old. The stump of this tree was 6½ feet in diameter, and the cubic contents are said to have been 1010 cubic feet.

At Dawyck, near Peebles, in a cold situation at about 500 feet above the sea, Mr. F. R. S. Balfour showed me some large silver firs which far surpass the larches growing near them, which are believed to have been planted about 1730. The largest of the firs is 112 feet by 15½ feet.

In most parts of Ireland the silver fir is a thriving tree wherever planted, and seems to be well suited to the climate. It was probably introduced early in the eighteenth century, as, according to Hayes, there were trees 100 feet high and 12 feet in girth in 1794 at Mount Usher, in Co. Wicklow. The largest silver fir in Ireland that we know of is at Tullymore Park, Co. Down, the seat of the Earl of Roden, growing in a sheltered valley below the house. Col. the Hon. R. Jocelyn, who showed me

¹ Cf. Renwick, in *Trans. Nat. Hist. Soc. Glasgow*, vii. 265 (1905).

² Mr. Kay informs me that many of the trees described by him thirty years ago have since been blown down, and I could not identify these silver firs when I visited Bute recently.

this tree in 1908, informed me that it was marked on a plan about 200 years old, and though still vigorous in appearance, it seems to be hollow for some way up. It measures from 115 to 120 feet high, with a girth of 18 feet 10 inches; and at about 20 feet from the ground throws out four large branches, which become erect, and form a tree of the candelabra type. (Plate 211.) At Carton, the seat of the Duke of Leinster, a tree was 16 feet 1 inch in girth in 1904, but the top had been blown off by the great gale of 1903. The finest silver firs in Ireland are probably those growing at Woodstock, Co. Kilkenny, where the biggest tree was in 1904 over 120 feet high by 15 feet 4 inches in girth. There are also here four trees standing so close together that they can be encircled by a tape of 30 feet; one of these is 133 feet high by 10 feet 10 inches in girth. At Avondale, Co. Wicklow, Mr. A. C. Forbes measured a tree in 1908, 125 feet in height and 15 feet 4 inches in girth. At Tykillen, Co. Wexford, the silver fir grows well and seeds itself freely, but does not attain anything like the dimensions above noted. There are fine trees at Castlemartyr, Co. Cork, one of which measures 114 feet by 14 feet 8 inches.

TIMBER

Though on the Continent the wood of the silver fir is in some districts, and for purposes where strength combined with lightness is required,¹ valued more highly than that of the spruce or pine, yet in England it is little appreciated, because it seldom comes to market in any quantity, and the trees are rarely clean enough to make good boards. But I am assured by Dr. Watney that, when slowly and closely grown, it is distinctly superior in quality to that of the spruce, and that he uses it in preference on his own property for estate building; and Mr. H. E. Asprey, agent to the Earl of Portsmouth at Eggesford, Devonshire, where this tree grows very well, tells me that he finds the timber quite equal to that of spruce for all estate purposes. The Marquess of Bath informs me that a lot of 22 trees, averaging 140 feet each, were sold privately at 5½d. per foot, and used at Trowbridge for making tin-plate boxes; but most of his silver fir timber goes to the Radstock coal pits, where it is used underground.

Laslett says² that "the pinkish white and scarcely resinous wood works up well, with a bright silky lustre, and is of excellent quality for carpentry and ship-work. It is light and stiff, and like spruce takes glue well. Nevertheless it is as yet far less in request than the latter, though it is employed in the making of paper pulp, as well as for boards, rafters, etc."³ So little is it known, however, to the English timber merchant that the author of *English Timber* does not even mention it, and I am not aware that it is imported to England as an article of commerce.

Strasburg turpentine, which was formerly extracted from the resinous glands found on its bark and largely used for the preparation of clear varnishes and at one time used as medicine, is now apparently superseded by other resins, though, according to Flückiger and Hanbury,⁴ it was still collected to a small extent in the Vosges in 1873.

ABIES PINSAPO, SPANISH FIR

Abies Pinsapo, Boissier, *Biblioth. Univ. Genève*, xiii. 167 (1838), and *Voyage Espagne*, ii. 584, tt. 167-169 (1845); Masters, *Gard. Chron.* xxiv. 468, f. 99 (1885), xxvi. 8, f. 1 (1886), and iii. 140, f. 22 (1888); Kent, *Veitch's Man. Coniferae*, 534 (1900).

Pinus Pinsapo, Antoine, *Conif.* 65, t. 26, f. 2 (1842-1847).

Picea Pinsapo, Loudon, *Encycl. Trees*, 1041 (1842).

A tree attaining about 100 feet in height and 15 feet in girth. Bark smooth in young trees, becoming rugged and fissured on old trunks. Buds ovoid, obtuse at the apex, resinous. Young shoots glabrous, brownish, with slightly raised pulvini.

Leaves on lateral branchlets radially arranged, linear, flattened, but thick, rigid, short, $\frac{1}{2}$ to $\frac{3}{4}$ inch long by about $\frac{1}{10}$ inch wide, gradually narrowing in the upper third to the acute apex; upper surface convex without a median furrow and with eight to fourteen lines of stomata; lower surface with two bands of stomata, each of six or seven lines; resin-canals usually median.¹ In young plants the leaves are longer and end in sharp cartilaginous points. On cone-bearing branches the leaves are short and thick, lozenge-shaped in section, with twenty or more lines of stomata on the upper surface, and two bands of stomata of about ten lines each on the lower surface, which has a prominent keeled midrib.

Staminate flowers crimson, cylindrical, $\frac{1}{2}$ inch long, surrounded at the base by two series of broadly ovate obtuse scales.

Cones sessile or subsessile, brownish when mature, pubescent, cylindrical, tapering to an obtuse apex; 4 to 5 inches long by $1\frac{1}{4}$ to $1\frac{3}{4}$ inches in diameter. Scales: lamina three-sided, 1 inch wide by $\frac{7}{8}$ inch long, upper margin almost entire, lateral margins nearly straight, lacinate; claw short, obcuneate. Bract minute, situated at the base of the scale, ovate, orbicular or rectangular, denticulate, emarginate with a short mucro. Seed with wing $1\frac{1}{4}$ inch long; wing two to three times as long as the body of the seed. In cultivated specimens the cones and scales are usually considerably smaller than in wild trees.

Cotyledons² six, convex and stomatiferous on the upper surface, flattish and green on the lower surface.

HYBRIDS

A series of hybrids have been obtained between *A. Pinsapo* and two other species, *A. cephalonica* and *A. Nordmanniana*, of which a full account is given by Dr. Masters in his valuable paper on hybrid conifers.³

1. *Abies Vilmorini*, Masters.⁴ This is a tree growing at Verrières near Paris, which has the following history. In 1867, M. de Vilmorin placed some pollen of *A. cephalonica* on the female flowers of a tree of *A. Pinsapo*. A single fertile seed was produced, which was sown in the following year; germination ensued and the

¹ The resin-canals in this species are variable in position. Cf. Guinier and Maire, in *Bull. Soc. Bot. France*, lv. 190 (1908).

² Masters, *in litt.*

³ *Journ. Roy. Hort. Soc.* xxvi. 99 seq. (1901).

⁴ *Ibid.* 109.

seedling was planted out in 1868. M. Phillipe L. de Vilmorin¹ states that the tree was in 1905, 50 feet high by 5 feet in girth; and has three main stems, one of which, however, was broken by a storm two years ago. In its habit and foliage it resembles *A. Pinsapo* more than the other parent. The leaves, however, are longer and less rigid than in *A. Pinsapo*, and bear stomata only on their lower surface; moreover their radial arrangement on the branchlets is imperfect. The cones, which are produced in abundance and contain fertile seeds, resemble those of *A. cephalonica*, being fusiform in shape; they have longer bracts than in *A. Pinsapo*, in some years exserted, in other years shorter and concealed between the scales. Seedlings raised from this tree, now four years old, have acuminate sharp leaves like those of *A. cephalonica*.

2. *Abies insignis*, Carrière, *Rev. Hort.* 1890, p. 230. This hybrid was obtained in 1848 or 1849 in the nursery of M. Renault at Bulgnéville in the Vosges. A branch of *A. Pinsapo* was grafted on a stock of the common silver fir (*A. pectinata*); and after some years the grafted plant produced cones. Seeds from these were sown; and of the seedlings raised one-half were like *A. Pinsapo*, the remainder being intermediate in character, it was supposed, between *A. Pinsapo* and *A. pectinata*; and the variation was considered to be the result of graft hybridisation. However, at no great distance there was growing a tree of *A. Nordmanniana*; and it is more probable that the hybrid character of the seedlings was the result of a cross from *A. Pinsapo* fertilised by the pollen of *A. Nordmanniana*. A complete account of these seedlings is given by M. Bailly.²

3. *Abies Nordmanniana speciosa*, Hort.² This hybrid was raised in 1871-1872 by M. Croux in his nurseries near Sceaux, the cross being effected by placing pollen from *A. Pinsapo* on female flowers of *A. Nordmanniana*. A full account of this hybrid is given by M. Bailly.²

4. *Moser's hybrids*. Four different forms, all raised from *A. Pinsapo*, fertilised by the pollen of *A. Nordmanniana*, which were obtained in 1878 by M. Moser at Versailles. Full details are given in Dr. Master's paper, to which we refer our readers.

DISTRIBUTION

A. Pinsapo has a restricted distribution, being confined to the Serrania de Ronda, a name given to the mountainous region around Ronda in the south of Spain. The late Lord Lilford informed Bunbury³ in 1870 that he had seen it growing on the Sierra d'Estrella in Portugal; but we have not been able to confirm the statement.

There are three main forests of this species, none of considerable extent, occurring in localities at considerable distances apart. I visited these forests in December 1906, and explain the rare occurrence of the tree as due to the fact, that in the dry climate of the south of Spain, it can only exist on the northern slopes of mountain

¹ *Hortus Vilmorinianus*, 69, plate xii. (1906). See also *Gard. Chron.* 1878, p. 438; *Rev. Hort.* 1889, p. 115, and 1902, p. 162, fig. 66.

² *Rev. Hort.* 1890, pp. 230, 231.

³ *Arboretum Notes*, 147 (1889).

chains running due east and west; and these are seldom met with. In such situations the soil is never exposed to the direct rays of the noonday sun, and preserves in consequence a great deal of moisture. The tree never grows even on north-west or north-east slopes, and is strictly limited to aspects looking due north.

The most important forest is in the Sierra de la Nieve, a few miles to the east of Ronda. Here the tree extends for several miles in scattered groves on the north slope of the range, growing on dolomitic limestone soil, usually in gullies or under the shade of the cliffs. It occurs mainly at elevations of 4000 to 5900 feet, though it occasionally descends to 3600 feet. In shaded situations and where the soil is deep, there are dense groves of thriving trees, without any admixture of other species; but at the lower elevations, where there is more sun, the trees are scattered and mixed with oak and juniper. In exposed situations, at high elevations, the trees are windswept, stunted, and more or less broken. Seedlings are numerous in many places. The largest trees, seen by me, were a group, on the road across the mountain from Ronda to Tolox, at a spot called *Puerta de las animas*. One of these (Plate 212) was 106 feet in height and 13 feet 8 inches in girth; and another with a double stem, not so tall, girthed 16 feet 3 inches. This group is overhung by a precipice, and is at 4700 feet altitude. The stump of a tree, which had been cut down, showed 240 annual rings and was 32 inches in diameter.

The second forest, and by far the most picturesque, lies to the west of Ronda, on the northern slope of the precipitous peak, Cerro S. Cristoval or Sierra del Pinar, close to the mediæval town of Grazalema. The fir grows here on a talus, composed of sharp angular white limestone stones; and the contrast between the dense mass of green foliage of the tree and the pure white ground from which it springs, is remarkably beautiful. The stones and pebbles are loosely aggregated; and beneath the surface they are mixed with a mass of black mould, in which the roots of the tree freely spread. The fir extends along the precipitous side of the mountain for about two miles, forming a band of continuous forest, which reaches nearly to the summit of the peak, attaining about 5800 feet altitude, and descending generally to 4000 feet, reaching in one gully to 3600 feet. Seedlings are numerous. There is no undergrowth, except an occasional daphne; but climbers like ivy and clematis are common. None of the trees are so tall as those in the Sierra de la Nieve; but many have gigantic short trunks, in one case girthing 25 feet, and are extremely old. In this forest, trees with glaucous foliage, not seen elsewhere, are not at all uncommon.

The third wood of *A. Pinsapo* occurs on the Sierra de Bermeja, which overhangs the town of Estepona and the Mediterranean coast. This wood, which covers only a small area, is most accessible from Gaucin, a station on the railway between Gibraltar and Ronda. Here the soil is disintegrated serpentine rock, and the tree grows on the northern slope, between 4100 and 4900 feet, though stunted specimens occur up to 5400 feet. The fir is pure on the precipitous upper part of the mountain; but lower down is mixed with *Pinus Pinaster*. The largest tree, which I measured, was 90 feet high by 13 feet 5 inches in girth.

Isolated groups of a few trees, the remains of former forests, are reported to be growing on the Sierra de Alcaparain, near Carratraca, north-east of Ronda, and at Zahara and Ubrique, not far from Grazalema. Mr. Mosley of Gibraltar, who gave me valuable help and information, saw *A. Pinsapo* also growing on the Sierra Blanca de Ojen near Marbella.

HISTORY AND CULTIVATION

This species was discovered by Edmond Boissier in 1837. He sent about half-a-dozen seeds to M. de Vilmorin in the same year, and from one of these was raised the very fine tree, which is now growing at Verrières¹ near Paris, and which is certainly the oldest cultivated specimen. This tree was in 1905, 70 feet high by 7 feet 3 inches in girth. *Abies Pinsapo* was introduced into England in 1839 by Captain Widdrington,² who was the first to obtain information about the existence of a new species of *Abies* in Spain, though he was anticipated in its discovery by Boissier. (A. H.)

In cultivation this has proved to be, all over the southern, midland, and eastern counties, one of the most ornamental of its genus, and is perfectly hardy on dry soils throughout Britain, ripening seed at least as far north as Yorkshire. It is one of the few silver firs that seems to require lime to bring it to perfection, and though it will grow fairly well on sandy soils, it will not thrive without perfect drainage, or on heavy clay. It seems to have a great tendency to divide into several leaders and often forms a bushy rather than a clean trunk, unless carefully pruned. It is not often injured by spring frost, and, though not likely to have any economic value, is a tree that should be planted in all pleasure grounds on well-drained soil, and in a sunny situation.

The seedlings which I have raised grow at least as fast as those of *A. pectinata*, and are hardier when young, but require five or six years' nursery cultivation before they are fit to plant out.

The wood is soft and knotty like that of most of the silver firs when grown singly in cultivation.

REMARKABLE TREES

Though specimens of this tree of from 50 to 60 feet high are found in many places all over England, we have not measured any which are specially remarkable. The largest recorded at the Conifer Conference in 1891 was a tree reported to be 62 feet high by 9 feet in girth, at Pampisford in Cambridgeshire; but these measurements were erroneous, as it now is only 56 feet high by 7 feet 3 inches in girth. Here there is a remarkable dwarf form³ of this species, which is only a foot in height, with branches prostrate on the ground for 6 or 7 feet.

The largest tree we know of is growing in a sheltered position in moist soil, at Coed Coch, near Abergele in North Wales, the residence of the Hon. Mrs. Brodrick.

¹ *Hortus Vilmorinianus*, 69, pl. 7 (1906).

² *Sketches in Spain*, ii, 239.

³ This is var. *Hammondi*, Veitch, *Conifers*, ed. i. p. 105.

The gardener, Mr. Hunter, informs us that it is 82 feet high by 10 feet 2 inches in girth; but has never coned. There is a fine tree at Oakly Park, Ludlow, measuring 70 feet by 5 feet 8 inches in 1908.

At Hardwicke, Bury St. Edmunds, Sir Hugh Beevor measured a tree in 1904, which was 63 feet high and 8 feet 11 inches in girth. At Fornham Park, also in Suffolk, he found a tree, which was planted in 1866, 50 feet by 6 feet 7 inches; and says that its growth kept pace with that of an Atlantic Cedar close by. Col. Thynne has taken a photograph of a narrow, pyramidal, symmetrical tree at Longleat, which was 65 feet high by 7 feet 9 inches in 1906 (Plate 213). At Dogmersfield Park, Hants, the seat of Sir H. Mildmay, I measured a well-shaped tree, 65 feet high by 6 feet 10 inches.

There are several good trees at Lilford Park, Oundle, growing on oolitic limestone; but Lord Lilford informed Henry that these were not raised from seed brought home by his father, and could give no confirmation of Bunbury's statement that the latter found the tree growing wild in Portugal.

At Essendon Place, Hertford, a slender tree was 68 feet high by 5 feet 1 inch in 1907. At Merton Hall, near Thetford, Norfolk, there is a tall tree, 75 feet by 5 feet 10 inches, the stem being bare of branches for 30 feet.

At Highnam, Gloucestershire, Major Gambier Parry reports a fine specimen, growing in the pinetum, which measured 60 feet by 6 feet 8 inches in 1906.

At the Rookery, Down, Kent, the gardener, Mr. E. S. Wiles, reported in 1906 a fine specimen, 70 feet by 9 feet, which is growing on stiff yellow loam, intermingled with flint and clay, resting on chalk.

In Wales the best that I have seen is a tree at Bodorgan, Anglesey, the seat of Sir G. E. Meyrick, which in 1906 was about 70 feet high, and had some large witches' brooms growing on it.

In Scotland, we have seen none of more than average size, a tree at Scone being about the best, and, generally speaking, the climate seems too cold for this tree. Sir Archibald Buchan-Hepburn, however, reports one at Smeaton-Hepburn, East Lothian, which was 60 feet by 7 feet 9 inches in 1908.

In Ireland, there is a tree at Curraghmore, Co. Waterford, which the gardener, Mr. D. Crombie, reported in 1905 to be 65 feet high by 8 feet in girth. At Carton, the seat of the Duke of Leinster, there is a good tree, 54 feet high by 8 feet in girth in 1903. At Coollattin, Wicklow, another was 55 feet by 4 feet 10 inches in 1906.

Prof. Hansen states¹ that fine trees of 50 feet high or more may be seen in several Danish gardens, where it has produced cones; and that the tree exists in the south of Sweden and Norway.

In the eastern United States it² never really flourishes, although it is possible to keep it alive for many years in favourable situations, even as far north as eastern Massachusetts.

ABIES NUMIDICA, ALGERIAN FIR

Abies numidica, De Lannoy, ex Carrière, *Rev. Hort.* 1866, pp. 106, 203; Van Houtte, *Flore des Serres*, xvii. 9, t. 1717 (1867); Masters, *Gard. Chron.* iii. 140 (in part and excluding figures) (1888); Trabut, *Rev. Gén. Bot.* i. 405, ff. 17, 18 (1889); Kent, Veitch's *Man. Coniferae*, 529 (1900).
Abies Pinsapo, Boissier, var. *baborensis*, Cosson, *Bull. Soc. Bot. France*, viii. 607 (1861).
Abies baborensis, Letourneux, *Cat. Arb. et Arbust. d'Algérie* (1888).
Pinus Pinsapo, Parlature, DC. *Prod.* xvi. 2, p. 423 (in part) (1868).
Picea numidica, Gordon, *Pinet.* 220 (1875).

A tree attaining 70 feet in height and 8 feet in girth. Bark grey, smooth in young trees, becoming scaly and fissured on old trunks. Buds large, ovoid, acute at the apex, non-resinous; scales ovate, acute, with white scarious margins, usually free at the apex. Young shoots brown, shining, glabrous, with slightly raised pulvini but without grooves.

Leaves on lateral branches pectinate below, the two lateral sets directed outwards in the horizontal plane; those above shorter, crowded, directed upwards, and either, as on weak shoots, forming a narrow V-shaped pectinate arrangement, or, on strong shoots, with the median leaves directed backwards (not seen in any other species) and covering the upper side of the branchlet. Leaves short, $\frac{1}{2}$ to $\frac{3}{4}$ inch long, $\frac{1}{2}$ inch broad, linear, flattened, gradually tapering to the base, broadest above the middle or uniform in width in the upper three-fourths, rounded at the apex, which is sometimes entire but usually slightly bifid; upper surface dark green, shining, with the median groove often faint and rarely continued to the apex, in many leaves with four to six broken lines of stomata in the middle line near the apex; under surface with two white bands of stomata, each of about eight to nine lines; resin-canals marginal. Leaves on cone-bearing branches all more or less upturned, those of the middle ranks also directed slightly backwards, short, rigid, rounded and entire at the apex.

Cones on short stout stalks, brownish, cylindrical with an obtuse apex and tapering base, about 5 inches long by $1\frac{1}{2}$ inch in diameter, with the bracts entirely concealed. Scales; lamina fan-shaped, $1\frac{1}{4}$ inch wide, $\frac{3}{4}$ inch long, upper margin almost entire, lateral margins denticulate and either straight or with a wing on each side above; claw short, obcuneate. Bracts, scarcely reaching half the height of the scales, with a broad oblong claw and an expanded ovate denticulate lamina, which is acuminate or cuspidate at the mucronate apex. Seed with wing about an inch long; wing about $1\frac{1}{2}$ times as long as the body of seed. Cones of cultivated trees have smaller scales with more developed lateral wings; and shorter bracts, scarcely reaching $\frac{1}{4}$ the height of the scale.

The seedlings of this species have been fully described by Fliche.¹

¹ In *Bull. Soc. Forest. Franche-Comté et Belfort*, 1903, p. 168.

IDENTIFICATION

The short broad leaves, which have usually four to six broken lines of stomata on their upper surface near the apex in the middle line, are a good mark of this species. On strong shoots the backward direction of the median leaves, which densely cover the upper side of the branchlet, is also very characteristic.

DISTRIBUTION

Abies numidica is very restricted in its distribution, being, so far as is known, confined to a small area towards the summit of the northern slope of Mount Babor, in the Kabylie range in Algeria. It grows between 5000 and 6600 feet altitude in a climate where snow lies upon the ground from December to April. In January, 1907, I visited Kerrata, at the head of the famous gorge of Chaba-el-Akra; and found that the ascent of the mountain, only a few miles distant, was impracticable. M. Bernard, Inspector of Forests at Bougie, who has charge of the forest of Mt. Babor, informed me that the northern slope contains an area of 4000 acres, and is clothed with a dense forest, composed mainly of cedar and *Quercus Mirbeckii* in the upper zone between 4700 and 6600 feet, and of *Q. Mirbeckii*, *Q. castaneaefolia*, and *Acer obtusatum*, in the lower zone below 4700 feet. The total number of trees of *Abies numidica* scarcely exceeds 3000; and they only grow towards the summit, where they occur scattered amongst the cedars and oaks. None of the trees are more than 70 feet high, and the largest is only 8 feet in girth. The small size is due to their exposed position, and possibly to the destruction of larger trees by the natives in former times. Seedlings are rare; and according to M. Bernard, this is accounted for by the poor germinating quality of the seed, as only 4 to 15 per cent of it produced plants with him. The soil on which the tree grows is limestone, its surface being composed of stones and pebbles, underneath which there is a considerable mixture of mould.¹

Abies marocana, Trabut,² discovered in January 1906 by M. Joly, in the mountains south of Tetuan, in Morocco, is intermediate in the characters of the foliage between *A. numidica* and *A. Pinsapo*. M. Trabut showed me a branchlet, when I was in Algiers in 1907; but in the absence of cones, it is impossible to decide whether it deserves to rank as a new species. Seeds of this should be readily procurable; and the attention of travellers is directed to the possibility of introducing a new silver fir. (A. H.)

HISTORY AND CULTIVATION

The Algerian fir was discovered in 1861 by Captain de Guibert. The first seeds were sent to France in 1862 by M. Davout, a forest officer; and another supply and six young plants were forwarded in 1864 by M. de Lannoy.

¹ M. Maurice de Vilmorin, in *Arbres Forestiers Etrangers*, 33 (1900) gives an account of *Abies numidica* on Mount Babor. He noticed that many of the trees had short stout trunks, free of branches to 10 or 12 feet, occasionally more or less twisted, and often dividing into several stems.

² In *Bull. Soc. Bot. France*, liii. 154, t. 3 (1906). In the plate, the name *Picea marocana*, Trabut, appears by mistake.

The tree is rare in cultivation in England. There are two or three young specimens at Kew; and Kent, writing in 1900, mentions small trees, about 20 feet high, growing at Bicton, and Streatham Hall in Devonshire.

At Pampisford, Cambridgeshire, there are two trees with fine healthy foliage, the larger of which, 37 feet high and 3 feet 2 inches in girth, bore cones in 1907. There is also a specimen at Highnam 35 feet by 3 feet 2 inches. Though we have not identified any specimens in Scotland Mr. Crozier speaks of it as a handsome and free-growing tree which bore cones in 1906 and seems quite at home at Durris.

In Ireland the finest we know of is at Fota, where a tree 39 feet by 6 feet was bearing cones in 1908. Lord Barrymore informs us that it was planted in 1878. There is a good specimen at Glasnevin, 38 feet by 3 feet 7 inches in 1906; and one at Castlewellan measured, in the same year, 25 feet by 3 feet.

At Verrières¹ near Paris, two trees, dating from the original introduction in 1862, were, in 1905, 46 feet in height by 4 feet 3 inches in girth. (H. J. E.)

ABIES CEPHALONICA, GREEK FIR

Abies cephalonica, Loudon, *Arb. et Frut. Brit.* iv. 2325 (1838); Masters, *Gard. Chron.* xxii. 592, f. 105 (1884); Kent, *Veitch's Man. Coniferae*, 498 (1900); Halácsy, *Consp. Fl. Græcæ*, iii. 450 (1904).

Abies Apollinis, Link, *Linnaea*, xv. 528 (1841).

Abies Regina Amalia, Heldreich, *Gartenflora*, ix. 313 (1860).

Abies Panachaica, Heldreich, *Gartenflora*, x. 286 (1861).

Picea cephalonica, Loudon, *Gard. Mag.* xv. 238 (1839).

Pinus cephalonica, Endlicher, *Cat. Hort. Vindob.* i. 218 (1842).

A tree attaining about 100 feet in height. Bark greyish brown, smooth in young trees, in old trees fissuring into small oblong plates. Buds conical or ovoid, obtuse at the apex, composed of thick ovate acute keeled scales, with prominent tips, and covered with a layer of resin. Young shoots smooth, light brown, shining, glabrous.

Leaves on lateral branches radially arranged, but not so regularly as in *A. Pinsapo*, their apices pointing outwards and slightly forwards, those of the upper ranks shorter than those beneath. Leaves linear, flattened, curved, about 1 inch long, $\frac{1}{8}$ to $\frac{1}{2}$ inch broad, abruptly tapering at the base, narrowing gradually in the anterior two-thirds, and ending in a long cartilaginous point; upper surface dark green, shining, with the median furrow not continued to the apex, and usually with several broken lines of stomata; lower surface with two white bands of stomata, each of seven or eight lines; resin-canals marginal. Leaves on cone-bearing branches all upturned, curved, rigid, broad, with the apex simply acute and not prolonged into a fine cartilaginous point.

Cones, on short stout stalks, about 6 inches long by $1\frac{1}{2}$ inch in diameter, cylindrical, slightly tapering at both ends, brownish, with the bracts golden brown, exposed, and reflexed. Scales: lamina narrowly fan-shaped, almost triangular;

¹ *Hortus Vilmorinianus*, 69, pl. 1 (1906).

upper margin convex, undulate or entire; lateral margins with two short denticulate wings; base curving but not auricled on each side of the oblong claw. Bracts: claw oblong, $\frac{1}{8}$ inch wide, extending $\frac{3}{4}$ the length of the scale; lamina lozenge-shaped, $\frac{1}{4}$ inch wide, denticulate, ending in a triangular mucro, exerted and reflexed over the edge of the scale next below. Seed-wing about twice as long as the seed; seed with wing about 1 inch long.

Seedling;¹ caulicle tapering upwards, reddish brown, erect, stout. Cotyledons, five or six, acute not mucronate, about $1\frac{1}{4}$ inch long; upper surface dotted irregularly with stomata and grooved in the middle line. Primary leaves half the length of the cotyledons, not mucronate; lower surface with stomata.

Var. *Apollinis*, Beissner, *Nadelholzkunde*, 440 (1891).

Abies Apollinis, Link, *Linnaea*, xv. 528 (1841).

This variety differs from the type in the arrangement and shape of the leaves. On lateral branchlets the radial arrangement is imperfect, most of the leaves standing crowded on the upper side of the branchlet, with their apices directed upwards, those in the middle line straight and vertical, those on the sides curved and bending upwards; on the lower side of the branchlet a few leaves are directed downwards and forwards. Leaves thicker and broader than in the type, about $1\frac{1}{4}$ inch long by $\frac{1}{10}$ to $\frac{1}{12}$ inch broad, ending in a short acute point, bevelled off from behind; upper surface with a continuous median groove and two to three short lines of stomata near the tip; lower surface with two bands of stomata, each of ten lines.

The cones do not differ in any essential characters from those of the type; and the differences noted by Murray² in the broader bract and expanded wing of the seed are trifling and inconstant.

Halácsy considers *Abies Reginae Amalie* and *Abies panachariaca* to be mere synonyms of *Abies cephalonica*; and only allows the variety *Apollinis*, distinguished, according to him, by its acute leaves, those in the type ending in an acuminate or very sharp spine-like point. According to other authorities, *A. Reginae Amalie* is more akin to var. *Apollinis* than to the type. In all probability there is a series of intermediate forms connecting the type and var. *Apollinis*.³

DISTRIBUTION

According to Halácsy this species occurs in the sub-alpine region of almost all the higher mountains of Greece, between 2700 and 5700 feet elevation. The type is met with in the island of Cephalonia on Mount Enos; and on the mainland—in Doris on Mount Kiona, in Attica on Mount Parnes, and in Arcadia on

¹ Masters, in MS., who states that in var. *Apollinis* the cotyledons are seven in number, sub-acute at the apex, and about 1 inch long; primary leaves shorter and more pointed than the cotyledons.

² *Proc. Roy. Hort. Soc.* iii. 141 (1863).

³ Guinier and Maire, in *Bull. Soc. Bot. France*, lv. 187, figs. 2 and 3 (1908), describe a variety, with leaves like those of *A. cilicica*, which grows on Mount Pindus in Thessaly.

Mounts Mænalus, Madara, Thaumasion, and Rhudia. Var. *Apollinis* occurs, in Epirus on Mounts Tsumerka, Strungula, Peristeri; in Thessaly, on Pindus and Olympus; in Eubœa on Mount Dirphys. It has also been found in Hellas on Mounts Ceta, Tymphrestus, Parnassus, Helicon, Cithæron, Pateras, and Parnes; and in Peloponnesus on Mounts Chelmos, Olenos, Malevo, Taygetos.

As Halácsy considers *Abies Reginae Amalie* to be the same as the type, and not the var. *Apollinis*, his account of the distribution differs from that generally adopted, in which the view taken is that the type is confined to the island of Cephalonia, and that all the continental forms are referable to the var. *Apollinis*.¹

In Cephalonia the forest of this species occurs on Mount Enos, along a ridge 4000 to 5000 feet above sea-level and about 12 to 15 miles in length. It was 36 miles in circumference in 1793; but its area was considerably reduced by disastrous fires in 1798. No recent account of this forest, of which full details were given by General Napier in 1833, has come under our notice.

The form which occurs in the mountains of Arcadia, distinguished as var. *Reginae Amalie*² by some authors, is remarkable for its capacity of producing coppice shoots, when the trunk is felled; and the main stem, even when untouched, is said often to produce secondary stems and branches from the old wood. (A. H.)

CULTIVATION

Seeds³ were first sent from Cephalonia to England by General Sir Charles Napier in 1824; and the first plants, few in number, were raised by Mr. C. Hoare of Luscombe Castle, who distributed them to various places.⁴ Some time afterwards Mr. Charlwood⁵ sold seeds to the public, having received a cask of cones from General Napier.

The form *Reginae Amalie* was first noticed in 1856 by Schmidt of Athens, who found a forest of this tree near Tripolitza in Central Arcadia; its seeds have recently been introduced abundantly.

A. cephalonica seems to be quite hardy over the greater part of Great Britain, but it is rather more susceptible to spring frosts than *A. Pinsapo*, because it starts earlier into growth, and on this account should not be planted in low, damp, or exposed places. It seems to grow on limestone, but not to be so distinctly a lime-loving tree as *A. Pinsapo*. It ripens seeds in good years in the south of England, but the seedlings which I have raised do not grow so fast as those of *A. Pinsapo*.⁶

¹ With regard to the occurrence of this variety in Roumelia, Macedonia, and Thrace, see our remarks on p. 722 concerning the distribution of *A. pectinata* in the Balkan peninsula.

² See Regel, *Gartenflora*, ix. 299, fig. (1860); and Seemann, *Gard. Chron.* 1861, p. 755 fig.

³ Loudon, *loc. cit.*

⁴ A list of these places is given in Loudon, *Gard. Mag.* 1838, p. 31, and in *Pinetum Britannicum*, ii. p. 179.

⁵ Loudon, *Gard. Mag.* 1839, p. 238.

⁶ Owing to its susceptibility to late frosts and to attack by Chermes, it is now nearly impossible to grow this tree up to a planting size. Its timber, when closely grown and of some age, is, in my opinion, the best of the European silver firs, being hard, close in texture, and heavier in a dry state than any I have yet handled. Var. *Apollinis* is less subject to injury by frosts and attack by Chermes than the above, and seems well adapted for planting in the north of Scotland. In cultivation it maintains a more conical outline, and is easily distinguished from the type.—(J. D. CROZIER.)

REMARKABLE TREES

Probably the finest tree in the British Isles is the one growing at Barton, Bury St. Edmunds, which in 1908 was 95 feet in height by 13 feet 3 inches in girth. This tree (Plate 214) is very symmetrical, branched to the ground, and in full vigour, though probably it has nearly attained its limit of height, as the top of the crown of foliage is flattened. This is one of the original plants raised at Luscombe, and was planted at Barton in 1838, being then about thirteen or fourteen years old. According to Bunbury,¹ it did not suffer in the slightest degree from the severe winter of 1860. In 1857, it was 35 feet in height; and in 1858 began to bear cones, which are confined to the topmost of the lateral branchlets. In 1867, the height had increased to 58 feet, and the trunk at three feet from the ground was 7 feet in girth. Seedlings have been frequently raised from its seed. One of these seedlings, which was sent many years ago to Lord Rayleigh, is now growing at Terling Place, Essex, and measures 53 feet high and 3 feet 3 inches in girth.

Another of the original trees is now growing at Luscombe Castle, near Dawlish, in a rather exposed place, about 200 feet above sea level; when I saw it, in April 1908, it was a healthy and well-shaped tree, 75 feet by 11 feet.

There is a very fine healthy tree at Blount's Court, Oxfordshire, which Henry measured in 1907, as 87 feet in height by 10 feet 8 inches in girth. Another planted at the Coppice, Henley, in 1860, measured in 1905, 62 feet high by 8½ feet in girth. At Pampisford, Cambridgeshire, there are two trees, the larger of which was, in 1908, 55 feet by 6 feet 1 inch. The Cephalonian fir has been largely planted on Lord Walsingham's estate at Merton, Norfolk, the largest specimen, 52 feet by 9 feet 7 inches, dating from 1852. On the Thetford road there is an avenue of these trees, growing in loose, shallow sand, which have attained at forty-eight years old an average girth of 8½ feet. The growth of the tap-root is stopped by the compact chalk sub-soil, wide-spreading horizontal roots being formed, which have no great hold in the shifting sand; and several trees have been uprooted by storms.

At Heron Court, near Christchurch, I measured in 1906 a very large tree with ragged top, 82 feet by 10 feet 8 inches. At Beauport, Sussex, there is a good tree, which in 1904 was about 80 feet high by 10 feet 3 inches in girth.

At Powderham there is a very large and spreading, but ill-shaped tree, which appears as though in the mild, soft climate of south Devon it would not be long lived. In 1892 it was recorded as the largest in Great Britain, being then 77 feet by 11 feet at 3 feet from the ground.

At Killerton there is a large tree which measured in 1903 80 feet by 11 feet 9 inches. It forks at about 25 feet. At Highclere another, in the same year, measured 75 feet by 11 feet. At High Canons, Herts, Mr. H. Clinton Baker measured a tree in 1908, which was 58 feet by 8 feet 3 inches. At Bayfordbury, a tree planted in 1847 was 70 feet by 6 feet 11 inches in 1905.

At Castle Kennedy there is a very wide-spreading tree, which in 1904 measured

¹ *Arboretum Notes*, 144.

59 feet by 9 feet 8 inches. Around it were several natural seedlings, from 1 foot to 5 feet in height. At Smeaton-Hepburn another measured, in 1905, 53 feet high by 10 feet in girth. A number of Cephalonian firs were planted at Blairadam, the seat of Sir Charles Adam, Bart., in Kinross-shire, by his ancestor Sir Frederick Adam, who was governor of the Ionian Islands in 1824, and who was censured by General Napier for not sufficiently protecting the forests in Cephalonia. Several of these trees still survive at Blairadam, the largest in the garden near the entrance gate being 49 feet high, and 8 feet 2 inches in girth at 4 feet. It divides into several stems at about 25 feet. Another measures 42 by 5½ feet, and there are several smaller ones, but the tops in most cases have been at various times injured by wind and frost. In other parts of Scotland the tree grows fairly well, but not so fast as in the south, the best I have heard of being at Abercairney, where Mr. Bean¹ records one 75 feet high in 1906. As this, however, was in 1892 only reported as 50 feet high there may be a mistake. Other good trees are growing at Whittingehame, East Lothian, at Haddo House, Aberdeenshire, and at Ochtertyre,¹ Perthshire.

In Ireland, the largest Cephalonian Fir known to us, is growing at Adare Manor, Co. Limerick, the seat of the Earl of Dunraven; and, in 1903, was 86 feet high by 9 feet 4 inches in girth.

At Powerscourt, Co. Wicklow, a tree measured, in 1903, 55 feet by 8 feet 9 inches; and at Hamwood, Co. Meath, there is a fair specimen which in 1904 was 50 feet by 9 feet 6 inches.

At Cahir Park, Co. Tipperary, there are four trees of nearly equal size, one measuring 46 feet by 6 feet 2 inches. Specimens sent in 1906 by Mr. Austin Mackenzie show that these trees belong to var. *Apollinis*.

In the Botanic Garden at Bergielund, near Stockholm, a tree, planted in 1890, was, when seen by Henry in August 1908, 30 feet in height and 1 foot in diameter, and exceeds in rapidity of growth all the other conifers in the garden. In the Botanic Garden, at Christiania, there is a tree, about 25 feet in height, which is, however, not quite hardy, being slightly browned by frost. Hansen² says that this species had attained in 1891 a height of 44 feet and a girth of 6 feet, at 40 years old, in the gardens at Carlsberg, near Copenhagen.

A. cephalonica has proved hardy³ in eastern Massachusetts, where it has already borne cones.

Though General Napier stated that the wood of this tree in Cephalonia is very hard and durable, yet as grown in this country it is not likely to have any economic value, as it is too knotty and coarse for any but the commonest purposes.

(H. J. E.)

¹ *Kew Bulletin*, 1906, pp. 266, 267.

² *Journ. Roy. Hort. Soc.* xiv. 463 (1892).

³ Sargent, *Silva N. Amer.* xii. 99, *adnot.* (1898). Sargent, however, states in his account of the *Pinetum at Wellesley* in 1905, p. 12, that the tree here, which is 51 feet by 6 feet, was considerably injured in the severe winter of 1903-4.

ABIES CILICICA, CILICIAN FIR

Abies cilicica, Carrière, *Conif.* 229 (1855), and *Flore des Serres*, xi. 67, t. 1108 (1856); Tchihatcheff, *Asie Mineure*, ii. 494 (1860); Heuzé in *Rev. Hort.* 1856, p. 81, f. 14; Kent, Veitch's *Man. Conifera*, 500 (1900); Hickel, in *Bull. Soc. Dend. France*, 1908, p. 183.
Abies selinusia, Carrière, *Flore des Serres*, xi. 69 (1856).
Pinus cilicica, Kotschy, *Oestr. Bot. Wochenbl.* iii. 409 (1853).
Picea cilicica, Gordon, *Pin. Suppl.* 50 (1862).

A tree attaining in Asia Minor 100 feet in height and 7 feet in girth. Bark ashy-grey in colour, smooth in young trees, deeply fissured and scaly in old trees. Buds¹ small, non-resinous, ovoid, acute at the apex; scales few, keeled, with their tips more or less free and not appressed. Young shoots smooth, greyish-brown, with scattered short erect pubescence; bark fissuring slightly on the second year's shoot.

Leaves on lateral branches usually pectinately arranged, the upper ranks pointing outwards and upwards, thus forming a V-shaped depression above between the two lateral sets; on vigorous shoots, the median leaves on the upper side are directed forwards and upwards, and cover the branchlet, the V-shaped depression being obliterated. Leaves thin and slender, 1 to 1½ inch long, ⅙ inch wide, linear, flattened, uniform in width except at the tapering base, apex rounded or acute and slightly bifid; upper surface light green with a continuous median groove and usually without stomata, rarely with two to three short lines in the groove near the apex; under surface with two narrow greyish bands of stomata, each of six to seven lines; resin-canals marginal. Leaves on cone-bearing branches, upturned, curved, more rigid and broader than those on barren branches, minutely bifid at the truncate or obtuse apex.

Cones of wild trees subsessile or on short stout stalks, cylindrical, tapering to an acute apex, 6 to 9 inches long by 2 to 2½ inches in diameter, brownish when ripe. Scales² larger than in any other species; lamina 1¾ inch wide, ⅞ inch long, fan-shaped, upper margin thin and entire, lateral margins convex, denticulate, with a sinus on each side; claw short, obcuneate. Bract with an oblong claw, expanding above into an ovate or quadrangular denticulate lamina, tipped with a short mucro, extending to ⅓ or ½ the height of the scale. Seed-wing about 1½ times as long as the seed; seed with wing about 1¼ inch long. In cultivated specimens, scales smaller, 1½ inch wide by ¾ inch long; bracts with a very short claw and a lamina not reaching more than ¼ the height of the scale; seed with wing about 1 inch long.

DISTRIBUTION

This species is confined to Asia Minor and northern Syria, occurring on the Lebanon and the Antitaurus, and forming, in company with the cedar, great forests

¹ The buds are characteristic; and, as Hickel points out, distinguish this species from all the others.

² The peculiar hook-like processes of the scales which occur in some specimens are probably abnormal.

in the Cilician Taurus. It was first discovered by Kotschy¹ in the Cilician Taurus in August 1853, in the valley of Agatsch Kisse, at an elevation of 4000 to 5000 feet. It is known to the Turks as *Ak Illeden*, white fir, and grows in thick forests sometimes unmixed with other trees, sometimes in company with oaks, cedars, and junipers. Yew and *Pinus Laricio* also occur in these forests, which are protected from woodcutters by their inaccessibility. The climate of these mountains is extremely hot in summer, and cold in winter, with much snow in the upper region.

Post² says that it is found in alpine and subalpine Lebanon, and in the Amanus Mountains in the extreme north of Syria, but does not give any details of its size or the elevation at which it grows.

CULTIVATION

The first seeds, received by the museum at Paris in 1854 from M. Blanch, French Consul at Saida, failed to germinate. Balansa sent a good supply of seed in 1855. From these or from Kotschy's seed the few trees which we have found in England were probably raised.

The Cilician fir is extremely rare in cultivation in this country. The best specimen we have found is a tree, growing at Welford Park, Newbury, which in 1908 was 51 feet by 4 feet 4 inches. Mr. Ross, the gardener, informs us that he found this tree as a small plant in a pot, when he came to Welford Park in May, 1860. The tree has been considered by many people to be *Abies homolepis*, and was figured in the *Garden*, for 1904, under that name. It is unquestionably, however, *Abies cilicica*, of which it has the foliage, and only differs slightly from wild specimens in the smaller size of the cones and scales. Mr. A. B. Jackson has identified two at Bicton, 48 feet by 4 feet and 47 feet by 3½ feet respectively; and another at the Heath, Leighton Buzzard, which is 48 feet by 3 feet 10 inches.

The finest in Scotland is a tree at Durris, which Mr. Crozier reports to be 55 feet high and 5 feet 8 inches in girth. It was incorrectly labelled *A. amabilis*. Another good specimen is growing at Castle Kennedy, which measured in 1904, 48 feet in height by 5 feet 1 inch in girth. A second tree here, not so tall, is very thriving. Kent mentions a tree at Rosdhu in Dumbartonshire.

A tree at Glasnevin was 34 feet by 3 feet 2 inches in 1907; and a specimen, at Powerscourt, 37 feet by 2 feet 8 inches in 1906, did not seem to be very thriving.

There is a good specimen at Verrières, near Paris, of which a figure is given by M. Philippe L. de Vilmorin in *Hortus Vilmorinianus* (plate 1). This tree is about 60 feet high. Another and slightly taller tree is growing in the Parc de Cheverny, in the department of Loir et Cher. Pardé says that at Harcourt (Eure) it reproduces itself naturally.

According to Sargent,³ *Abies cilicica*, with the exception of *Abies concolor*, is the most beautiful of those silver firs, which are perfectly hardy and satisfactory in the north-eastern states of the U.S. Some trees are 40 feet in height, notably at

¹ *Reise in den Cilicischen Taurus* (1858).

² *Flora of Syria*, p. 751.

³ *Silva N. Amer.* xii. 99 adnot. (1898).

Mr. Hunnewell's pinetum, Wellesley, Mass.;¹ Mr. Hall's garden, near Bristol, Rhode Island; and Mr. Hoop's pinetum, West Chester, Pennsylvania. Sargent states that the tree does not thrive in western Europe, as the young shoots, which appear early in the spring, are killed by late frosts; and in consequence it is not propagated by nurserymen. Seeds from wild trees are difficult to procure. (A. H.)

ABIES NORDMANNIANA, CAUCASIAN FIR

Abies Nordmanniana, Spach, *Hist. Vég.* xi. 418 (1842); Regel, in *Gartenflora*, xx. 259, t. 699 (1871); J. D. Hooker, *Bot. Mag.* t. 6992 (1888); Masters, *Gard. Chron.* xxv. 142, f. 30 (1886); Kent, Veitch's *Man. Coniferae*, 526 (1900).
Pinus Nordmanniana, Steven, *Bull. Soc. Nat. Moscow*, xi. 45, t. 2 (1838); Loudon, *Gard. Mag.* xv. 225 (1839).
Picea Nordmanniana, Loudon, *Encycl. Trees*, 1042 (1842).

A tree attaining in the Caucasus over 200 feet in height and 15 feet in girth. Bark in cultivated trees greyish brown, smooth when young, becoming slightly fissured in older trunks. Buds ovoid, acute at the apex, brown, non-resinous, with ovate, acute, slightly keeled scales. Young shoots grey, smooth, with very scattered short erect pubescence.

Leaves on lateral branchlets, pectinately arranged below, the two lateral sets spreading more or less in the horizontal plane; those above shorter, directed forwards and densely covering the branchlet in imbricated ranks. Leaves linear, flattened, about 1 to 1½ inch long, 1/10 to 1/12 inch wide, uniform in width except at the gradually tapering base; apex rounded and bifid; upper surface dark green, shining, with a continuous median groove and without stomata; lower surface with two conspicuously white bands of stomata, each of eight or nine lines; resin-canals marginal. Leaves on cone-bearing branches all curved and upturned.

Staminate flowers ovoid-cylindric, 4/10 inch long, each with three series of involucre bracts.

Cones sub-sessile, cylindrical, tapering at both ends, about 6 inches long by 2 inches in diameter, brown in colour, with the bracts exserted and reflexed. Scales: lamina, about 1½ inch wide by ¾ inch long, either with a denticulate wing on each side or with straight lateral margins; claw obcuneate. Bract with oblong claw, expanding above into an almost orbicular lamina, which is denticulate and tipped with a long triangular mucro. Seed with wing about an inch long, the wing being twice the length of the body of the seed.

VARIETIES AND HYBRIDS

Several varieties are mentioned by Beissner, which are said to differ from the type in foliage, the leaves being shorter, glaucous, or yellow in colour. None of these appear to be in cultivation in England.

¹ Elwes saw this tree in May 1905, and remarked that it was very similar in growth to *A. Nordmanniana*, which has shorter darker leaves and denser habit. It had not suffered from the severe frost of the preceding winter which in some places had injured the Caucasian fir. According to Sargent, *The Pinetum at Wellesley in 1905*, p. 12, this tree is 49 feet high and 5 feet in girth.

Var. *equi-Trojani*, Guinier and Maire.¹ A peculiar form, discovered by Sintenis on Mount Ida in north-west Anatolia. It has reddish-brown glabrous shoots, leaves acute at the apex and only slightly emarginate, and cones with bracts much exserted and almost concealing the scales.

The hybrids, which have been obtained between *A. Nordmanniana* and *A. Pinsapo* are dealt with in our article on the latter species.

DISTRIBUTION

This species is a native of the mountains in the southern and south-eastern shores of the Black Sea, including the western spurs of the Caucasus. According to Radde,² it is entirely absent from the eastern parts of the Caucasus and Talysch, its easterly limit being longitude 42°. It usually grows between 3000 and 6600 feet elevation, and either forms pure forests or is associated with *Picea orientalis*, being occasionally mixed both with that species and *Pinus sylvestris*. It is said to prefer calcareous soil and to be dominant on the limestone formations, which are not so favourable to the growth of the oriental spruce and the common pine. In pure forests, the trees stand very close together; and in their deep shade underwood is absent and no light reaches the ground, which is very dry and covered with a thick layer of brown needles. Such forests are the last hiding-place of the European bison in a truly wild condition.

The largest tree mentioned by Radde, the age of which is not given, grew in the valley of the Labba in the district of Kuban, and measured 213 feet in height and 15 feet in girth at breast height, and the stem alone had a volume of 1236 cubic feet. On an area of about 2½ acres in this forest fifteen trees nearly as large were growing. It thrives best and attains its largest size at high elevations, 5000 to 6000 feet; where stems 150 to 170 feet in height, with a girth of 10 feet, are quite common. The oldest tree, which is recorded by Radde, was 370 years old, and measured 170 feet high by 10 feet in girth.

Abies Nordmanniana was also found by Balansa³ in Lazistan, and by Sintenis⁴ at Kostambul in Paphlagonia. Guinier and Maire⁴ in 1904 found it growing on Mount Olympus in Bithynia, where, on the northern slope between 3700 and 6000 feet, it forms extensive forests, either pure or mixed with *Pinus Laricio*, beech, oak, and chestnut, and constituting the timber line at 6300 feet. These botanists state that on Olympus, as well as in the Caucasus, it is a light-demanding tree, a least in the young stage, as the seeds everywhere germinate in open and unshaded places. The discovery by these authors of *A. Nordmanniana* on Mount Olympus and of the var. *equi-Trojani* on Mount Ida extends the distribution of this species westwards through northern Asia Minor to the borders of the Ægean Sea.

¹ In *Bull. Soc. Bot. France*, lv. 186, fig. 1 (1908). This variety was referred to *A. pectinata* by Boissier, in *Fl. Orientalis*, v. 701 (1881).

² *Pflanzenverb. Kaukasusland*, 184, 222, 244, etc. (1899).

³ Specimens in Kew herbarium.

⁴ In *Bull. Soc. Bot. France*, lv. 185, fig. 1 (1908). The silver fir on Mount Olympus was erroneously identified with *A. pectinata* by Boissier in *Flora Orientalis*, v. 701 (1881).

Abies Nordmanniana was first recognised as a distinct species by the Finnish botanist, Nordmann, Professor at Odessa, whose name it bears. He found it in 1836 in the Caucasian province of Imeretia. Pallas and other early botanists had referred the Caucasian silver fir to *Abies pectinata*. It was introduced¹ into Europe in 1848, when Alexander von Humboldt obtained seeds from the Caucasus, which were sown in the Berlin Botanic Garden. (A. H.)

CULTIVATION

No other silver fir found in the Old World is more thoroughly at home in Great Britain, for it grows luxuriantly on soils where the common silver fir will not thrive; is absolutely uninjured by spring frost, even in a young state, and ripens seed as far north as Perthshire and County Down. It seems equally at home on rich loam in the south-east of England, on oolite gravel in the Cotswold Hills, and in the peaty soil and wet climate of Argyllshire. Out of 102 returns sent to the Conifer Conference from all parts of Great Britain, 78 mention this tree and nearly all speak well of it, though it is said to fail at about thirty years old on strong loam in Worcestershire, and to be liable to aphids at Durriss in Kincardineshire.²

Sir Herbert Maxwell³ states that the Crimean silver fir (a misleading name, as it does not occur wild in the Crimea), after it attains twenty to thirty years of age, frequently succumbs to the attacks of aphids, and gives as an instance in proof of this, that at Benmore, where large numbers were planted thirty to forty years ago, very few now remain. But I do not think that this is a fair example, as the climate of Benmore is very wet, and the soil in many places very shallow. In the warmer and drier parts of Scotland I have seen many flourishing specimens, though not so fine as in England.

Wilkie⁴ says that at Tynninghame, in East Lothian, it is later in starting growth than the common silver fir, grows more freely when young, and either for use or ornament is certainly the more valuable of the two. Webster, also, whose experience was gained in Ireland, North Wales, and Kent, says,⁵ "If *A. nobilis* be the best of the Californian silver firs, this is without doubt the finest of the European or Asiatic species." He expected that at no distant date it would supplant the silver fir for forest planting, the timber being of excellent quality, the tree more ornamental, and less exacting as regards soil. He says that it succeeds well on reclaimed peat bog, stiff loam, decomposed vegetable matter, and light gravelly soils.

¹ Hansen, in *Journ. Roy. Hort. Soc.* xiv. 471 (1892). In the catalogue of the Pinetum at Beernem, in western Flanders, Baron Serret says that he received his specimen in April 1847, from Lawson and Son, Edinburgh; and the earliest introduction would seem from this to have been prior to that stated by Hansen.

² *A. Nordmanniana*, the most susceptible of all silvers to attack by Chermes either in a seedling or older state. For general purposes this tree is doomed, and it is only by repeated spraying with insecticide that it will be possible to preserve even the largest specimens. In growth, it has proved itself much slower than *A. pectinata*, and being densely branched and of a shade-bearing nature, its timber when cut up has generally been coarse and knotty. In Scotland it has never been regarded by foresters as of economic importance.—(J. D. CROZIER.)

³ Green's *Encyclopedia of Agriculture*, ii. 112 (1908). The erroneous statement that this fir occurs wild in the Crimea appears to have been first made in Veitch's *Man. Coniferae*, 1st ed. 102 (1881), and has been repeated by Masters, Hansen, the *Kew Handlist of Conifers*, etc. No species of *Abies* grows wild in the Crimea. Cf. Demidoff, *Voyage Russie Meridionale et la Crimée*, ii. 231, 232, 375, 646 (1842).

⁴ *Trans. Royal Scot. Arb. Soc.* xii. 211 (1889).

⁵ *Ibid.* 257.

As the seed can now be procured in quantity and at a cheap rate, even when home-grown seed is not available, there seems to be no reason why this beautiful tree should not be raised at the same rate as the common silver fir and planted in preference to the latter, for though it has not yet had time to attain its full size in this country it grows quite as fast, and from what little we know of its timber is likely to be at least as valuable. Its average rate of growth is from 1 to 2 feet annually when once established; and though we have as yet no evidence that it will endure dense shade as well as the silver fir, yet the accounts of its growth in the Caucasus lead one to expect that it will do so.

REMARKABLE TREES

Among the numerous specimens that we have measured in various places in England, I have seen none to surpass a very healthy and vigorous tree which grows in a wood facing east on the banks of the river at Eggesford, the property of the Earl of Portsmouth in Devonshire, which in April 1904 measured 84 feet by 5 feet 7 inches, and had produced cones. But a tree growing in a wood called Hook's Grove at Bayfordbury is perhaps taller; it was about 85 feet by 6 feet 10 inches in 1907.

At Strathfieldsaye, in the same year, I measured one as 78 feet by 6 feet 7 inches, and at Hemsted, in Kent, there is a tall but very slender specimen, not over forty years planted, which bids fair to become a very large tree. In 1905 it was 68 feet by only 3 feet 7 inches. At Lynhales, Herefordshire, the seat of S. Robinson, Esq., another is 70 feet by 5½ feet and growing freely.

In Wales it is thriving at Penrhyn; where there are two trees, one with its top broken being about 75 feet by 10 feet; the other even taller measures 6 feet 10 inches in girth; and at Hafodunos, where it does well in plantations, Henry measured one 60 feet by 6 feet 7 inches in 1904.

In Scotland the largest recorded in 1891 was at Poltalloch, and then was said to measure 70 feet by 6 feet, but when measured by Mr. Melville in 1906 he made it only 73½ feet by 7 feet 4 inches.

The finest I have seen myself is one at Moncreiffe which, in 1907, I made to be no less than 79 feet by 6½ feet; a healthy tree from which many seedlings have been raised. This is stated by Hunter to have been planted about 1856, and in 1888 was only 30 feet by 2 feet 2 inches. It is said to have been hybridised by the silver fir, but I could not see anything in the seedlings to distinguish them.

In Ireland it also grows very well. A tree at Carton, the seat of the Duke of Leinster, was 74 feet by 5 feet 4 inches, and one at Fota 68 feet by about 6 feet in 1903. Another at Mount Shannon, Limerick, measured, in 1905, 75 feet by 8 feet 9 inches. A good specimen at Ballykilcavan, Queen's County, measured 68 feet by 5 feet 2 inches in 1907. There are many fine healthy specimens at Dereen in Co. Kerry.

In the University Botanic Garden at Upsala, in Sweden, a tree was seen by Henry in 1908 which was about 40 feet high and branched into three stems near the ground, the result evidently of injury to the leader by severe frost in early youth.

According to Hansen,¹ it is said to thrive at Trondhjem in Norway, but Henry saw no specimens at Trondhjem or Christiania. It is often planted in Danish gardens and forests, and is quite hardy in Denmark.

According to Sargent,² it is very hardy in the eastern United States, as far north, at least, as eastern Massachusetts, but although handsome when young, is apt to become thin and shabby here at an early stage. (H. J. E.)

ABIES WEBBIANA, HIMALAYAN FIR

Abies Webbiana, Lindley, *Penny Cyclop.* i. 30 (1833); Griffith, *Icon. As. Pl.* t. 371 (1854); Masters, *Gard. Chron.* xxii. 467, f. 86 (1884), and x. 395, f. 47 (1891); Hooker, *Gard. Chron.* xxv. 788, ff. 174, 175 (1886), and *Flora Brit. India*, v. 654 (1888); Kent, *Veitch's Man. Coniferae*, 543 (1900); Gamble, *Indian Timbers*, 718 (1902).

Abies spectabilis, Spach, *Hist. Vég.* xi. 422 (1842).

Abies Mariesii, Masters, *Bot. Mag.* t. 8098 (1906) (not Masters, *Gard. Chron.* xii. 788 (1879)).

Pinus Webbiana, Wallich, *ex Lambert, Genus Pinus*, 77, t. 44 (1828).

Pinus spectabilis, D. Don, *Prod. Fl. Nepal.* 55 (1825).

Picea Webbiana, Loudon, *Arb. et Frut. Brit.* iv. 2344 (1838).

A tree, attaining in the Himalayas 150 feet or more in height and 35 feet³ in girth, with thick spreading horizontal branches; bearing a flattened crown of foliage. Bark speedily scaling on young stems; on old trunks, greyish brown, rough, irregularly fissured and very scaly. Buds large, globose, brownish, covered with resin, which conceals the keeled obtuse scales. Young shoots reddish brown with prominent pulvini, separated by deep grooves; pubescence short, erect, reddish, confined to the grooves and not spreading over the pulvini. In the second year's shoot the pulvini and grooves are more marked, the pubescence being retained.

Leaves on lateral branchlets pectinately arranged, in two lateral sets, each of several apparent ranks; the lower ranks on each side extending outwards in the horizontal plane; the upper ranks, with leaves becoming gradually shorter, directed outwards and upwards, and forming a V-shaped depression, in the bottom of which the upper side of the branchlet is plainly visible. Leaves 1 to 2½ inches long, ⅓ to ⅓ inch wide or more, linear, flattened, uniform in width except at the shortly tapering base, rounded and bifid at the apex; upper surface dark green, shining, with a continuous median groove and without stomata; lower surface with two broad conspicuously white bands of stomata; resin-canals marginal. Leaves on cone-bearing branchlets similar to those on barren branchlets.

Cones on short stout stalks, resembling in shape and colour those of *A. Pindrow*; in native specimens both from Sikkim and Kumaon, smaller than those on cultivated trees; scales fan-shaped, about ⅞ inch wide and ⅝ inch long (not including the short obtuse claw); bracts extending to near the upper edge of the scale, with an oblong claw, expanding above into a suborbicular denticulate lamina, tipped with a

¹ In *Journ. Roy. Hort. Soc.* xiv. 472 (1892).

² *Silva N. Amer.* xii. 98, *adnot.* (1898). The trees, however, at Wellesley, one of which is 59 feet by 5 feet, were slightly injured during the severe winter of 1903-4. Cf. Sargent, *The Pinetum at Wellesley in 1905*, p. 12.

³ Hooker, *Him. Journ.* ii. p. 108.

short triangular cusp and without any emargination. In cultivated specimens, cones very large, 6 to 8 inches long, 2 to 3 inches in diameter, bluish when growing, brownish when mature, cylindrical, slightly tapering to an obtuse apex; scales much broader than in wild specimens (1¼ inch); bracts only extending to about half the height of the scale, with a broad rectangular claw, only slightly narrower than the broadly ovate denticulate lamina, which is tipped with a short triangular cusp: seed with wing about an inch long; wing broadly trapezoidal, shining brown, and about 1½ times as long as the seed.

The cones of *Abies Pindrow* are very similar, the main difference being that in the latter the expanded portion of the bract is situated close to the lower edge of the scale, and is oval, less finely denticulate, and emarginate above with a minute mucro in the emargination.

VARIETIES

The above description, which, as regards the leaves and branchlets, applies to ordinary cultivated specimens of *Abies Webbiana*, also fits exactly the form of that species which occurs in Sikkim, and does not differ from the original description which was founded on specimens from Nepal. The high-level silver fir, however, which occurs in the western Himalayas appears to be a much shorter-leaved tree than that which is common in Sikkim; and has been supposed by some to be a form of *Abies Pindrow*. This form, which is apparently the same as specimens collected on the Chor mountain near Simla by Sir George Watt, is met with occasionally in cultivation, and may be distinguished as follows:—

Var. *brevifolia*,¹ a tree with smooth bark on the stem and branches. Young branchlets grey, with only slightly prominent pulvini; pubescence short, erect, brown, confined to the indistinct fine grooves between the pulvini. Leaves much shorter than in the type, not exceeding 1¼ inch in length, greyish beneath with two inconspicuous stomatic bands.

This variety differs in appearance from the type, which has longer leaves, very silvery white beneath; but agrees with it in the arrangement, texture, and shape of the leaves. The grey colour and comparative smoothness of the branchlets, and the smooth bark on the stem and branches, suggest some affinity with *A. Pindrow*; but the long, slender, narrow leaves of the latter species, differently arranged on the glabrous branchlets, are entirely different.

I first received cultivated specimens of this variety from Glasnevin, Kilmacurragh, and Batsford Park, where there are young trees, which have not yet produced cones. The Glasnevin and Kilmacurragh trees were raised from seed, sent from the Himalayas in 1879, but without any record of the precise locality; and they resemble the type in habit. The origin of the Batsford tree is obscure.

¹ Brandis, in *Indian Trees*, 692 (1906), distinguishes two forms of *A. Webbiana*, viz. :—

(a) "*A. Webbiana*, Lindley. High Level Silver Fir of N.W. Himalaya." This is identical with our var. *brevifolia*, and is not the same as *A. Webbiana*, Lindley.

(b) "*A. densa*, Griffith. East Himalayan Silver Fir." This, from a comparison of type specimens in the Kew Herbarium, is identical with *A. Webbiana*, Lindley, which was founded on *Pinus Webbiana*, Wallich, described from Nepal specimens.

A tree of this variety, with smooth bark on the trunk and branches, is growing at Powerscourt, and measured in 1906, 58 feet high by 5 feet 5 inches in girth. It bore numerous cones, similar to those of the type, but smaller in size and not so blue in colour. Another tree, about 40 feet high, also with very smooth bark, is growing at Holker Hall, Cark-in-Cartmel, Lancashire. (A. H.)

DISTRIBUTION

Abies Webbiana occurs in the inner Himalayas from Afghanistan to Bhutan at elevations of 10,000 to 14,000 feet, but rare¹ below 11,000 feet. In its western area, *i.e.* in the north-west Himalaya, it usually commences to grow at 1000 to 2000 feet above the line where *Abies Pindrow* disappears; and Gamble has never seen the two species growing together. It is here usually stunted and gnarled, with very short leaves and short thick cones, and occurs commonly with *Betula utilis* and *Rhododendron campanulatum*. Both it and the birch are the last trees to be seen before the treeless snowy wastes begin in the western Himalayas. In Nepal, according to Don, it occurs on Gosainthan.

In its eastern area, Bhotan and Sikkim, it is apparently a larger and finer tree. Griffith² mentions it, under the temporary name of *Abies densa*, as constituting vast forests in Bhotan, remarkable for their sombre appearance, at 12,000 feet, being rare under 9500 feet.

It is slow in growth, the average rate in Sikkim being about 12 rings per inch of radius, and is of much less economic importance than *Abies Pindrow* is in the north-west. Large quantities of planks, however, are exported from Lachoong to Tibet, and their preparation is an important native industry; but Hooker³ says that the timber of Sikkim conifers is generally soft and inferior to that of European species.

In Sikkim this is the most abundant conifer in the interior; extending from a little above 8000 to 13,000 feet or more; at its lower limits scattered or isolated among other trees at 9000 to 11,000 feet, and forming forests which are sometimes almost pure, or in the Lachen and Lachoong valleys mixed with *Tsuga Brunoniana*. Higher up on drier slopes it occurs scattered among *Larix Griffithi* and many species of shrubs and rhododendrons. On the Singalelah range which divides Sikkim from Nepal it begins to appear shortly before reaching Sandukpho, and on the boundary ridge north of that hill assumes a very wind-swept and often gnarled habit; the tops being often broken and covered with a dense mass of ferns, orchids, *Ribes*, begonias, and climbing plants of many species, and sometimes supporting shrubs and trees, which, favoured by the extremely moist summer climate, and from June to October almost constantly bathed in mist, become epiphytic. One tree which I specially noticed on this ridge at about 11,000 feet, bore on its decaying crown no less than four good-sized shrubs of different species, a *Pyrus*, an

¹ As in the Chor Hills, south of Simla.

² *Notule*, iv. 19 (1854), and *Itin. Notes*, ii. 141 (1848). Griffith subsequently abandoned his name *A. densa* and adopted that of *A. Webbiana*.

³ *Himalayan Journals*, ii. 45, note.

Aralia, a *Rhododendron*, and a birch, some of which had stems as thick as my leg. Plate 215 from photographs taken by my late friend, Mr. C. B. Clarke, at this spot, very well represents the trees I saw. The largest trees which I have found of this species were on the track from Lachoong to the Tunkra Pass, leading into the Chumbi valley, some of which must have been nearly 200 feet high, with stems clean up to 40 feet, and Sir Joseph Hooker measured a tree here no less than 35 feet in girth. Higher up, however, it assumes a stunted form and grows mixed with junipers.

HISTORY AND CULTIVATION

Abies Webbiana was discovered early in the nineteenth century by Captain Webb. Seeds were repeatedly sent to England by Dr. Wallich, which probably came from Nepal, but none appear to have germinated till 1822, when some plants were raised in the Fulham Nursery. It is remarkable that most of the trees of *A. Webbiana* seen in this country resemble more nearly the Sikkim form, than the short-leaved Western form. It is probable that none of the original trees now exist, as they were planted in the vicinity of London, where the tree does not thrive, as it is very liable to be cut by spring frosts.

Though this tree is one of the most beautiful of its genus in the few parts of England where it really succeeds; and will resist severe winter frosts without injury when on well-drained soil, yet its tendency to start into growth before the danger of spring frosts has passed, has caused its death in very many places. If seeds could be procured from the more alpine regions of Kashmir or the trans-Indus mountains, they might endure our climate better, but most of the trees now growing in England were probably raised from seed collected by Sir J. D. Hooker in Sikkim.

It ripens seed, however, in some parts of England and Scotland, and I have raised seedlings in 1901 from cones grown near Exeter, of which a few have survived though now not more than a foot high. A shady, elevated, and yet sheltered situation, is best for this species, and as regards soil a deep sandy loam.

REMARKABLE TREES

The largest specimen of *A. Webbiana* recorded at the Conifer Conference in 1891 was at Howick Hall, Northumberland, the seat of Earl Grey, and was then said to be 51 feet by 8 feet. I am informed by Mr. Lambert that it has lost its leader several times since this date, and now measures about 50 feet by 8½ feet.

The largest we have measured is a double-stemmed tree at Beauport, Sussex, 64 feet by 8½ feet in 1904; but Mr. A. B. Jackson found a tree at Tregothnan in Cornwall which was 74 feet by 8½ feet, and another tree at the same place 66 feet by 9 feet. Both of these bore cones in 1908.

At Menabilly, Cornwall, there is a healthy tree of no great size, which bore large cones in 1907, and these remained in perfect condition on the tree in April 1908, when I visited the place; and at Pencarrow there is one 64 feet by 6½ feet.

At Fulmodestone, Norfolk, in a wood where the Earl of Leicester has planted on a deep moist soil a large number of conifers, close enough to shelter each other, a tree was measured by Henry in 1905 as 69 feet by 6½ feet. It has since been much damaged by snow, but has produced cones from which Capt. R. Coke has raised a few seedlings, and now measures only about 60 feet high.

At Enville Hall, Stourbridge, there is a tree, which now looks as if it were suffering from drought. It measured, in 1904, 68 feet by 5 feet 4 inches.

A large tree, said to have been about 75 feet high, died and was cut down at Penrhyn in North Wales in 1902. The stump, which I saw, was about 7½ feet round. At Hafodunos, in North Wales, Colonel Sandbach states that this species is always nipped by the frost and forms new leaders when the old ones are killed, the growth being quite checked.

At Castle Kennedy there is a short avenue of trees of this species, averaging about 40 feet high by 6 feet in girth; but the tops had been cut off, as they had become bare and unsightly from exposure to wind. Here *A. Webbiana* begins to produce cones at an early age; and there is a seedling 20 feet high, with many smaller ones near it.

At Poltalloch, Argyllshire, I measured a fine healthy tree 61 feet by 5 feet 3 inches which in 1906 bore no cones.

At Keir, Perthshire, there are two trees, one with a broken top, the other 57 feet by 4 feet 10 inches, and more narrowly pyramidal than is usually the case. Seedlings were raised from the seed of this tree about ten years ago; but as a rule it bears very small cones (only 3 inches in length) with unfertile seed. A tree at Dunphail, Morayshire, has also produced small cones, which slightly resemble those of *Abies Mariessii*.¹ This tree was probably planted in 1856, and is now only 33 feet in height; but has a double leader.²

In Ireland, *A. Webbiana* thrives well, and there is a good number of fair-sized trees. It is said, however, to be slightly touched by frost at Fota, in the south of Ireland, where the temperature fell to 14° Fahr. during four nights in the winter of 1901-1902. A tree at Fota was in 1903, 47 feet high by 3 feet 7 inches in girth.

At Churchhill, Armagh, the seat of Mr. Harry Verner, there was growing in 1904 a tree laden with cones, even on the lowermost branches; it measured 53 feet by 4 feet 10 inches.

At Courtown, Co. Wexford, a tree was recorded at the Conifer Conference of 1891, as being 52 feet by 6 feet 3 inches. (H. J. E.)

¹ The Dunphail tree has been described and figured by Masters as *Abies Mariessii*, in *Bot. Mag.* t. 8098; but there is no doubt that this is erroneous. Specimens which I have seen show ordinary foliage and branches of *A. Webbiana*; and some of the cones are as large as those usually produced by this species.—(A. H.)

² Thrives at Durrís only in partial shade, when exposed it suffers much from late spring frosts, both top and branch shoots become clubbed and unsightly. Cones at a comparatively early age—about 25 years. Is of no economic value.

(J. D. CROZIER.)

ABIES PINDROW, PINDROW FIR

Abies Pindrow, Spach, *Hist. Vég.* xi. 423 (1842); Masters, *Gard. Chron.* xxv. 691, f. 154 (1886); Kent, Veitch's *Man. Coniferae*, 533 (1900); Gamble, *Indian Timbers*, 719 (1902); Brandis, *Indian Trees*, 692, 720 (1906).

Abies Webbiana, Lindley, var. *Pindrow*, Brandis, *Forest Flora Brit. India*, 528 (1874); Hooker, *Flora Brit. India*, v. 655 (1888).

Pinus Pindrow, Royle, *Illust. Bot. Himalaya*, 354, t. 86 (1839).

Picea Pindrow, Loudon, *Arb. et Frut. Brit.* iv. 2346 (1838).

A tree attaining in the Himalayas over 200 feet in height, with a girth of 25 feet. Narrowly pyramidal in habit, with the branches small and short. Bark smooth and silvery grey when young; greyish brown, deeply and longitudinally fissured on old trunks.

Buds large, globose, covered with white resin. Young shoots quite smooth, grey, glabrous, the bark fissuring slightly in the second year. Leaves on lateral branches mostly pectinate below, pointing forwards and outwards in the horizontal plane, some of the median leaves, however, being directed downwards and forwards; above, covering the shoot, those in the middle line much shorter and directed forwards and slightly upwards. Leaves, soft in texture, up to 2½ inches long, very narrow ($\frac{1}{16}$ inch wide), linear, flattened, shortly tapering at the base and narrowing gradually in the anterior third to the acute apex, which is bifid with sharp unequal cartilaginous points; upper surface dark green, shining, with a continuous median groove and without stomata; lower surface paler with two greyish bands of stomata, each of about eight lines; resin-canals marginal. Leaves on cone-bearing shoots all upturned and more or less directed forwards, covering the shoot in the middle line above, shorter than on barren branches and only slightly bifid at the apex.

Cones on short stout stalks, bluish when growing, brown when mature, cylindrical, about 6 inches long by 3 inches in diameter. Scales; lamina about 1¼ inch wide by ¾ inch long, fan-shaped, variable in form, with two slight wings in cultivated specimens, not winged and with the lateral edges straight or curved in wild specimens, base auricled. Bracts with the expanded portion situated on the scale just above the claw, oval, denticulate, emarginate above with a minute mucro. Seed with wing about 1 inch long, the wing narrowly trapezoidal and about 1½ times as long as the body of the seed.

IDENTIFICATION

Abies Pindrow is remarkably different in most characters from *Abies Webbiana*, with which it has been united by many authors. The trees are very distinct in habit, *A. Pindrow* forming, both in the Himalayas and in cultivation in England, a narrow pyramid with short branches; while *A. Webbiana* is a broader tree with wide-spreading branches. The bark of the former is smooth, that of the latter scaly. The former has smooth, glabrous, grey shoots; the latter has shoots with

prominent pulvini, separated by pubescent furrows. The cones are similar in size and colour; but differ in the shape and position of the bracts. The arrangement and character of the foliage are entirely different.

Var. *intermedia*.

Pinus (Abies) sp. nova (?), M'Nab, in *Proc. Roy. Irish Acad.* ii. 692, f. 19 (1876).

A tree at Eastnor Castle, planted thirty-seven years ago, and about 60 feet in height with a girth of 3 feet 4 inches, is apparently identical with the form described by M'Nab, who mentions two specimens, one collected in the western Himalayas by Hooker and Thomson, and another from a tree, which formerly grew at Castle Kennedy. Mr. Mullins, the gardener at Eastnor Castle, informs me that the tree is narrowly pyramidal in habit, with dark green foliage, and smooth bark on the stem and branches.

Specimens, which I have received, show the following characters:—Branchlets, buds, bark, and habit, as in *A. Pindrow*. Leaves more pectinate than in that species, and arranged on the branchlets as in *A. Webbiana*; about $2\frac{1}{8}$ inch in maximum length, dark shining green above; gradually tapering in the upper third, as in *A. Pindrow*; thicker than in this species; lower surface convex; resin-canals median, in which respect this variety differs from both *A. Pindrow* and *A. Webbiana*. Cones about 4 inches long and 2 to 3 inches in diameter, resembling those of *A. Webbiana* in the position and shape of the bracts.

This variety is intermediate in many respects between *A. Pindrow* and *A. Webbiana*, and is possibly a hybrid. (A. H.)

DISTRIBUTION

Abies Pindrow is more restricted in distribution than *A. Webbiana* and occurs at a lower elevation. It is met with in the outer Himalayas from Chitral to Nepal, at elevations of 7000 to 9000 feet, occasionally ascending to 10,000 feet; and commonly grows in ravines with a northerly or westerly aspect. It is often associated with *Picea Morinda*, *Quercus dilatata*, the deodar, and *Pinus excelsa*; but more often is accompanied by broad-leaved trees, such as the walnut, maples, bird cherry, and Indian horse-chestnut. Madden says that it forms dense forests on all the great spurs of Kumaon and occurs in Kashmir. According to Gamble, it has the same narrowly pyramidal habit with short branches which it assumes in cultivation in England. It grows very tall, but does not attain so great a height as the deodar. The largest trees correctly noted were measured in the Mundali forest in Jaunsar, and had heights varying from 188 to 206 feet with girths of 19 to 25 feet. The rate of growth averages 13 rings per inch of radius. It bears intense shade and its natural reproduction is excellent. The timber is employed indiscriminately with that of *Picea Morinda*, though not quite so good. It is used for planking, tea-boxes, packing-cases, and makes excellent shingles, and would be suitable for railway sleepers if creosoted.

REMARKABLE TREES

The finest trees in Britain are probably two, which I saw in 1906, growing in the grounds of Mr. Victor Marshall at Monk Coniston, the largest of which is now 69 feet high and 4 feet 9 inches in girth. The climate here is mild and damp, but the soil dry and slaty. Mr. S. A. Marshall wrote to Kew that one of these trees coned for the first time in 1902, and in 1904 produced many cones.¹

There is a well-shaped tree at The Coppice, Henley, the seat of Sir Walter Phillimore, Bart. It came from Dropmore as a young plant in 1858, and grew very slowly at first, sustaining some damage from the frost of May 1867. It is now healthy and thriving, and measured, in 1907, 62 feet high by 3 feet 8 inches in girth. At Bury Hill, Dorking, the seat of R. Barclay, Esq., there is a well-grown specimen, which he informed me had been raised from a tree at Denbies in the same neighbourhood, and which in 1908 measured 58 feet by 3 feet 2 inches. It grows, like so many of the best conifers in this country, on greensand. At Dropmore, a tree 48 feet by 3 feet 10 inches in 1905, coned for the first time in 1907. At High Canons, Herts, Mr. H. Clinton Baker measured a tree, which was bearing cones in February 1908, as 48 feet high by 2 feet 8 inches in girth; and in a wood, on his own property at Bayfordbury, there is a thriving young tree, 32 feet high and 1 foot 5 inches in girth. At Cuffnells, near Lyndhurst, a good-sized but badly-grown tree was bearing cones in 1907. At Leighton Hall, near Welshpool, the seat of Mrs. Naylor, there are three, at a considerable elevation, the best of which in 1908 was about 50 feet high. In the pinetum at Lyndon Hall, Oakham, Rutland, Henry measured in 1908 a fine specimen, 58 feet by 3 feet 3 inches, which was planted, according to Mr. E. L. P. Conant, by his father in 1864.

In Scotland I measured a tree at Conon House in Ross-shire, in 1907, which was about 50 feet by only 3 feet 4 inches. At Smeaton-Hepburn, East Lothian, a tree planted in 1844, according to Sir Archibald Buchan-Hepburn, Bart., was, in 1908, 56 feet high by 4 feet 1 inch in girth. Seedlings have been raised from it. At Durris, Mr. Crozier says that it suffers from the same causes as *A. Webbiana*. In Wigtownshire, this species is tender, and a tree at Galloway House, 48 feet by 3 feet 10 inches, as measured by Henry in 1908, has been much injured by frost. Sir Herbert Maxwell reports a good specimen at Stonefield, Loch Fyne; and another, in the Quarry garden at Gordon Castle, which measures 69 feet by 4 feet 9 inches.

In Ireland, the tallest tree is at Charleville, Co. Wicklow, the seat of Viscount Monck. In 1904 it was 60 feet by 5 feet 1 inch. It produced cones in 1903, and since then has been in an unhealthy state. This tree has sent forth from the stem epicormic branches. At Kilmacurragh, Co. Wicklow, the seat of Mr. Thomas Acton, there is a healthy tree, which, in 1904, was 51 feet high by 5 feet 5 inches. At Powerscourt, there are two good trees, one 55 feet by 5 feet in 1904, which bore cones in 1902, 1903, and 1904; the other is 42 feet by 6 feet 3 inches in girth. At Brockley Park, Queen's County, a tree, planted thirty-five years ago, measured in 1907, 51 feet by 5 feet 6 inches. (H. J. E.)

¹ A tree at Kenfield Hall, near Canterbury, produced cones in 1886. Cf. *Gard. Chron.* xxvi. 85 (1886).

ABIES SIBIRICA, SIBERIAN FIR

Abies sibirica, Ledebour, *Fl. Alt.* iv. 202 (1833); Masters, *Journ. Linn. Soc. (Bot.)* xviii. 519 (1881); Kent, *Veitch's Man. Coniferae*, 539 (1900).

Abies Pichta, Forbes, *Pin. Woburn.* 113, t. 39 (1840).

Abies Semenovii, Fedtschenko, *Bot. Centralblatt*, lxiii. 210 (1898), and *Bull. Herb. Boissier*, vii. 191 (1899).

Pinus sibirica, Turczaninow, *Bull. Soc. Nat. Mosc.* xl. 101 (1838).

Pinus Pichta, Endlicher, *Syn. Conif.* 108 (1847).

Picea Pichta, Loudon, *Arb. et Frut. Brit.* iv. 2338 (1838).

A tree attaining about 100 feet in height. Bark smooth, greyish, and covered with resin-blisters, even in old trees. Buds small, globose, brownish, smooth, and covered with resin. Young shoots ashy-grey, with a scattered minute erect pubescence, quite smooth, the pulvini not being at all prominent; in the second year, the bark fissures slightly, and the pubescence is retained.

Leaves on lateral branches resembling in arrangement those of *A. Veitchii*, but more irregular; the lower ones pectinate, and directed outwards and forwards, a few, however, in the middle line with their apices directed forwards and downwards; on the upper side the leaves cover the branchlet and are directed forwards and upwards in the middle line, being about three-fourths the length of the lower leaves. Leaves linear, flattened, slender, up to $1\frac{1}{2}$ inch long, $\frac{1}{20}$ inch wide, uniform in width except at the slightly narrowed base; apex rounded, slightly bifid or entire; upper surface light green, shining, with a continuous median groove and rarely two to three short lines of stomata near the apex in the middle line; lower surface greyish in colour, with two narrow bands of stomata, each of four to five lines; resin-canals median. Leaves on cone-bearing branches all upturned, curved, thick, short ($\frac{3}{4}$ inch long), acute at the apex.

Cones sessile, cylindrical, obtuse at the apex, 2 to 3 inches long, $1\frac{1}{4}$ inch in diameter, bluish when growing, brown when mature, with the bracts concealed. Scales; lamina fan-shaped, thin, $\frac{5}{8}$ to $\frac{3}{4}$ inch wide, $\frac{1}{2}$ inch long; upper and lateral margins denticulate; base with a sinus on each side of the obtuse claw. Bract, at the base of the scale, rectangular or reniform, coarsely denticulate, $\frac{3}{16}$ inch broad, with a short triangular mucro. Seed with wing about $\frac{5}{8}$ inch long; wing broad, purplish, about twice as long as the body of the seed.

The form¹ described by Fedtschenko as a new species (*A. Semenovii*) occurs in Turkestan. Specimens show longer leaves, more pubescent branchlets, and slightly different cone-scales and bracts. Korshinsky, however, in a note in the Kew herbarium, states that the Turkestan tree is identical with *A. sibirica* from the Ural and Altai; and the differences noted would probably disappear if there were more material to examine.

A weeping variety of this species was seen by Conwentz² in 1881 in Regel and Kesselring's nursery at St. Petersburg.

This species, with long slender leaves covering the branchlet above, is best

¹ Cf. Guinier and Maire's remarks on this form in *Bull. Soc. Bot. France*, lv. 184 (1908).

² *Seltene Waldbäume in Westpreussen*, 161 (1895).

distinguished by its ashy-grey smooth shoots which are minutely pubescent, and its small globose resinous buds. It can only be confused with *A. sachalinensis*, which has shoots with prominent pulvini, and leaves with broader and whiter bands of stomata below. *A. lasiocarpa*, which has, like this species, median resin-canals, is distinguished by the peculiar arrangement of the leaves, which have conspicuous lines of stomata on their upper surface.

DISTRIBUTION AND CULTIVATION

This species is the most widely distributed of all the silver firs, occupying large areas of both the plains and mountains of north-eastern Russia and Siberia. In European Russia it forms forests in company with spruce and larch, or rarely with birch and aspen; and occurs through the governments of Archangel, Vologda, Kostroma, Perm, Ufa, Kazan, and Orenburg. On the mountains it does not go as high as the timber line, and does not extend so far south in European Russia as the spruce. It is common in the Ural range, and attains perhaps its maximum development in the Altai,¹ where it forms vast forests between 2000 and 4500 feet elevation. In Turkestan it is found in the Thianshan mountains, and is reported by Korshinsky to form forests at low altitudes in the province of Ferghana, where it grows in mixture with *Picea Schrenkiana*. Its distribution in Siberia is not clearly known, but it appears to be widely spread from west to east, its northern limit on the Yenisei being 66° lat. and on the Lena 60° lat. It occurs on the high lands of Dahuria, and, according to Komarov, reaches its most easterly point in the Yablonoi mountains, being replaced in Kamtschatka, by *A. gracilis*, Komarov; and on the borders of the sea of Okhotsk and in Manchuria by *A. nephrolepis*, Maximowicz.

According to Loudon this species was introduced from the Altai into England in 1820. It is very rare in cultivation, and does not grow for any length of time in the south of England, where the climate is unsuitable to it. Even at Durris, Mr. Crozier describes it as "a slow-growing, many-headed, and evidently short-lived tree." There is an unhealthy specimen, about 15 feet high, at Ochtertyre in Perthshire. At Pampisford, Cambridgeshire, there is a small tree, 30 feet high by 13 inches in girth in 1907, narrowly pyramidal in habit, with the lower branches layering and producing five independent stems about six feet in height. This tree has been badly damaged by the snowstorm of April 1908. Another at Bicton measured 28 feet by 1 foot 8 inches in 1908.

In August 1908 I saw a fine specimen in the University Botanic Garden, Upsala, Sweden, which was 70 feet high and 1 foot in diameter, forming a very narrow pyramid, closely resembling the habit of *A. Pindrow*. Hansen² says that specimens, forty years old, have attained a height of about 40 feet in Denmark; and that there are beautiful examples in the Botanic Gardens at Helsingfors, Finland (lat. 60°), where many seedlings have sprung up around the old trees. (A. H.)

¹ I saw this tree in the forests on the north slopes of the Altai, where the climate was damp, but it did not strike me as a fine or large tree, and was not seen in the drier valleys towards Mongolia.—(H. J. E.)

² *Journ. Roy. Hort. Soc.* xiv. 477 (1892).

ABIES SACHALINENSIS, SAGHALIEN FIR

Abies sachalinensis, Masters, *Gard. Chron.* xii. 588, f. 97 (1879), and *Journ. Linn. Soc. (Bot.)* xviii. 517 (1881); Mayr, *Abiet. jap. Reiches*, 42, t. 3, f. 6 (1890); Sargent, *Forest Flora of Japan*, 83 (1894); Kent, *Veitch's Man. Coniferae*, 537 (1900).

Abies Veitchii, Lindley, var. *sachalinensis*, F. Schmidt, *Mém. Acad. St. Pétersbourg*, sér. 7, xii. 175, t. 4, ff. 13-17 (1868).

A tree attaining in Yezo 130 feet in height. Bark smooth, grey in colour. Buds small, ovoid-globose, rounded at the apex, covered with white resin. Young shoots grey, with prominent pulvini and grooves; pubescence, short, dense, and confined to the grooves. In the second year the pulvini, grooves, and pubescence are well-marked.

Leaves on lateral shoots arranged similarly to those of *A. Nordmanniana*; those below longest, pectinate in two sets in the horizontal plane, directed outwards and forwards; those above covering the branchlet in imbricated ranks, the median leaves shortest, directed forwards and appressed to the shoot. Leaves linear, flattened, slender, very thin, about $1\frac{1}{2}$ inch long, $\frac{1}{20}$ inch wide, uniform in width except at the shortly tapering base; apex rounded and shortly bifid; upper surface grass-green, shining, with a continuous median groove and without stomata; lower surface with two narrow bands of stomata, each of seven to eight lines; resin-canals median. Leaves on cone-bearing shoots up-turned, acute or rounded at the minutely bifid apex.

Cones, $3\frac{1}{2}$ inches long, $1\frac{1}{4}$ inch in diameter, cylindrical, tapering to an obtuse or slightly acute apex, conspicuously marked externally by the reflexed greenish bracts, which leave little of the surface of the scales visible. Scales crescentic, small; lamina, $\frac{1}{2}$ to $\frac{5}{8}$ inch wide, nearly $\frac{1}{4}$ inch long, deeply auricled by two basal sinuses, the denticulate wings ending in a sharp point on each side of the sinus; upper margin entire; outer surface densely tomentose. Bract with a broad cuneate claw, expanding above into an almost orbicular lamina, emarginate and mucronate on its upper margin. Seed with wing $\frac{3}{8}$ inch long; wing broader than long and shorter than the body of the seed.

VARIETIES

Var. *nemorensis*, Mayr, *loc. cit.* This variety is met with in north-eastern Yezo and the Kurile Isles, and is distinguished by its smaller cones, about $2\frac{1}{2}$ inches in length, with minute concealed bracts. In the cones this variety resembles *A. Veitchii*.

Sargent mentions a curious variety found by Miyabe in central Yezo, in which the bark, wood, and bracts of the cone are red in colour.

IDENTIFICATION

Abies sachalinensis agrees in many technical characters with *A. Veitchii*, but owing to its longer and more slender leaves looks different from that species, and would

not in practice be confused with it. The prominent pulvini of the young branchlets, which are only pubescent in the grooves, will distinguish it at once from *Abies sibirica*, which it resembles in general appearance. The latter species has quite smooth branchlets, provided with a scattered minute pubescence. (A. H.)

DISTRIBUTION AND CULTIVATION

This species was discovered in the Island of Saghalien by Schmidt in 1866, and was subsequently found, in 1878, in Yezo by Maries, who sent home seeds in the following year.¹ The tree is known in Japan as *Todo-matsu*.

It is a native of the Kurile Islands, Saghalien, and the northern island of Japan.² In Saghalien it either forms pure woods or is mixed with one or both of the spruces (*Picea ajanensis* and *Picea Glehnii*) which occur in that island.

This is the common, and perhaps the only, silver fir of Hokkaido, where it extends from nearly sea-level up to 4000 or 5000 feet altitude, and all over the island in suitable places; in the south usually as a scattered tree in mixed forests of deciduous trees; in the north and some parts of the west central districts in dense pure forests, or with a mixture of birch and poplar. The finest areas of this species are in the Imperial domains at Tarunai, Uryu, Kushiro, and in the State forests at Shari, and Kunajiri. I endeavoured to visit some of these under the guidance of Mr. Shirasawa, but owing to the torrential rains which flooded the country in the middle of July and broke the railway in many places, I was unable to do so. The country where these forests occur is much like parts of eastern Siberia, having a hot, moist summer, a warm autumn, and a very heavy snowfall which lies for four to five months; the climatic conditions, therefore, are such that the tree is not likely to be a success in Great Britain, and, so far as I could see, it has no special beauty to recommend it. The largest that I saw were about 100 feet by 9 feet, but it grows taller in some places.

The timber is of fair quality, and is used in house- and ship-building, also for furniture and paper-making; and is worth at Tokyo about 10d. per cubic foot.

The Saghalien fir is rare in cultivation, the largest specimen we have seen being one at Fota, in the south of Ireland, which was about 25 feet high in 1907. It looks healthy, but begins to grow early in the season, and is said to be frequently hurt by spring frost. We have measured no specimens in Scotland, but one at Murthly Castle, about 16 feet high, is reported by Mr. Bean³ as not looking healthy. According to Kent, the tree is, like most of the conifers coming from similar climates, unable to thrive in England. In New England, however, it grows much better, and I saw healthy young trees at Mr. Hunnewell's place at Wellesley, Massachusetts. (H. J. E.)

¹ *Hortus Veitchii*, 337 (1906).

² It was reported by Matsumura (*Tokyo Bot. Mag.* xv. (1901), p. 141), to occur in Formosa, on Mt. Morrison; but this was a mistaken identification, as the silver fir in this locality is *A. Mariesii*, according to Hayata, in *Tokyo Bot. Mag.* xix. (1905), p. 45.

³ *Gard. Chron.* xli. 117 (1907).

ABIES FIRMA, JAPANESE FIR

Abies firma, Siebold et Zuccarini, *Fl. Jap.* ii. 15, t. 107 (1844); Masters, *Gard. Chron.* xii. 198, 199 (1879), and *Journ. Linn. Soc. (Bot.)* xviii. 514 (1881); Mayr, *Abiet. Jap. Reiches*, 31, t. 1, f. 1 (1890); Shirasawa, *Icon. Ess. Forest. Japon.*, text 17, t. 6, ff. 1-21 (1900); Kent, Veitch's *Man. Coniferae*, 506 (1900).

Abies bifida, Siebold et Zuccarini, *Fl. Jap.* ii. 18, t. 109 (1844).

Abies Momi,¹ Siebold, *Verhand. Batav. Gen.* xii. 101 (1830) (*nomen nudum*).

Pinus firma and *Pinus bifida*, Antoine, *Conif.* 70, 79 (1846).

Picea firma, Gordon, *Pinet.* 147 (1858).

A tree, attaining 150 feet in height and 16 feet in girth. Bark of branches and trunk early becoming scaly, in old trees fissuring into small plates. Buds small, ovoid, obtuse at the apex, brown, glabrous, slightly resinous. Young shoots brownish grey, with the pulvini slightly raised and separated by grooves; pubescence short, erect, scattered, confined to the grooves. Older shoots retaining the pubescence and fissuring between the pulvini, which are not very prominent.

Leaves on lateral branches pectinately arranged; those below extending laterally outwards in the horizontal plane; those on the upper side gradually shortening to nearly one-third of the length of the lower leaves, and directed in two sets laterally outwards and slightly upwards, forming a shallow V-shaped arrangement.² Leaves up to $1\frac{1}{2}$ inch long, linear, flattened, very coriaceous, shortly tapering to the base, broadest about the middle ($\frac{1}{8}$ inch or more), gradually narrowing to the acute apex, which ends in two sharp cartilaginous points, unequal in size; upper surface dark green, shining, with a continuous median groove and without stomata; lower surface with broad greyish bands of stomata, each of about ten to twelve lines; resin-canals close to the epidermis of the lower surface. Leaves on cone-bearing branches upturned, rounded and entire or only minutely bifid at the apex.

Staminate flowers, $\frac{1}{2}$ inch long, ovoid-conic, surrounded at the base by two to three series of broadly ovate scales.

Cones on stout short stalks, cylindrical, tapering shortly at the base, and obtuse or flattened at the slightly narrowed apex, yellowish-green before ripening, brown when mature, 4 to 5 inches long by $1\frac{1}{2}$ to $1\frac{3}{4}$ inches in diameter, with the tips of the bracts exerted between the scales but not reflexed. Scales: lamina $1\frac{1}{16}$ inches wide by $\frac{5}{8}$ inch long, broadly trapezoidal; upper margin thin, minutely denticulate; lateral margins convex, denticulate; base broad with a sinus on each side of the obtuse claw. Bract extending either nearly up to the edge of the scale or beyond it, always visible externally between the scales, oblong in the lower half, expanding above into an oval lamina, which ends in a triangular cusp. Seed-wing broadly trapezoidal, about twice the length of the body of the seed. Seed with wing nearly $\frac{7}{8}$ inch long. Cotyledons four.

¹ This name, which has been adopted by Sargent, *Silva N. Amer.* xii. 101, *adnot.*, was published without any description, and cannot be maintained. Cf. Masters, *Gard. Chron. loc. cit.*

² On vigorous shoots, the leaves are directed more upwards so that the V-shaped depression is very acute.

The broad coriaceous leaves, ending in two cartilaginous points of unequal size, and pectinately arranged, are characteristic of this species, which when once seen, can scarcely be confused with any other.

Abies holophylla, Maximowicz,¹ which has been identified by Dr. Masters with *A. firma*, is considered by Komarov,² the latest observer, to be a distinct species. It differs in the leaves not being bifid, and also in the bracts of the cone, which are short, scarcely extending more than one-third the length of the scale. This species, according to Komarov, attains 150 feet high, and grows in mountain woods at elevations not exceeding 1800 feet above sea-level, in the Manchurian provinces of Ussuri, Kirin, and Mukden, and also in northern Korea. It was introduced into cultivation in Russia by Komarov, who sent seeds in 1898.

Other specimens of *Abies* from the Chinese provinces of Hupeh, Shensi, and Yunnan³ have also been considered by Dr. Masters to be *A. firma*; but this identification is doubtful. (A. H.)

DISTRIBUTION

This, the best known fir in Japan, is widely distributed in the south, and, according to Mayr, does not extend north of lat. 40°, and attains perfection in the warm sub-tropical provinces of Kii, Shikoku, and Kiusiu. It is very commonly planted in temple grounds and parks, but few of these specimens looked as if the isolated situation agreed with them; and wherever I saw the tree growing naturally, it was scattered among deciduous trees and other conifers in more or less shady places in the forest. It grows to a great size in the sheltered valleys and moist, deep soils of the central and southern provinces. I measured one at Myanohara, on the Nakasendo road near Wada, which was 135 feet by 16 feet, but this tree was dying at the top, and may have been planted or have been a natural seedling in a temple grove. Another in the forest near the entrance to Koyasan was about 120 feet high by 15 feet 9 inches in girth, but the average size of the mature trees that I saw was not over 100 feet by 9 feet. A third, growing close to a temple at Narai (Plate 216), measured 125 feet by $11\frac{1}{2}$ feet. As the timber is of little value except for packing-cases, tea-boxes, and pulp-wood, the tree is not much planted at the present time except for ornament. It reproduces itself freely from seed whenever the conditions are suitable, and its large greenish-yellow cones are fully formed in August.

According to Rein⁴ its natural habitat is from 1000 to 1500 metres, but though this may be the case in the southern island, I should say it was too high for the central provinces, as in Kisogawa I saw it much lower, and I do not think it there reaches 4000 feet.

This species was introduced into Europe in 1861 by J. Gould Veitch,⁵ but has never become common in cultivation, though it seems to be hardy even in some parts of Scotland. It undoubtedly requires a warm, moist climate to bring it to

¹ *Mél. Biol.* vi. 22 (1866).

² *Flora Manchuria*, 204 (1901).

³ *Journ. Linn. Soc. (Bot.)* xxvi. 557 (1902); and *Journ. Bot.* 1903, p. 270.

⁴ *Industries of Japan*, 235 (1889). Mayr says that it ascends to 700 feet in the north and to nearly 7000 feet in the south.

⁵ *Hortus Veitchii*, 335 (1906), where it is stated that it was also sent in 1878 by Maries.

perfection, and seems to be in most places a slow grower. The seedlings which I have raised from Japanese seed will not grow on my soil, from which I infer that lime is distasteful to them.

REMARKABLE TREES

The largest tree that we know of is at Carclew in Cornwall. This was reported in 1891 to be 45 feet by 2 feet 8 inches, and when I measured it in 1902 had increased to about 60 feet by 4 feet. Another at Pencarrow, in the same county, was about 59 feet by 6 feet 5 inches in 1908. At High Canons in Herts, Mr. Clinton Baker showed me a specimen which bore cones in 1907 and measured 47 feet by 3½ feet.

There is a good-sized tree at Grayswood, with longer and less sharp-pointed leaves than usual, and another at Tortworth which in 1905 was 30 feet by 3 feet 9 inches. A tree planted at Bagshot Park by the late Emperor of Germany on July 10, 1880, was, when I saw it in 1907, 36 feet by 3 feet 11 inches.

In Scotland¹ the best that we have seen is at Castle Kennedy, which, in 1904, Henry found to be 44 feet by 5 feet 5 inches. Another in a wood at Munches, Dalbeattie, was 30 feet by 2½ feet. Trees were reported to be growing in 1891² at Balmoral, and at Haddo House in Aberdeenshire, but we have not identified them.

In Ireland there were thriving trees at Fota 25 feet high, and bearing cones in 1907; at Hamwood, Co. Meath, 36 feet by 2 feet 10 inches in 1904; and at Powerscourt, which in 1906 was bearing cones, and measured 39 feet by 3 feet 11 inches.

(H. J. E.)

ABIES HOMOLEPIS

Abies homolepis, Siebold et Zuccarini, *Fl. Jap.* ii. 17, t. 108 (1844); Masters, *Gard. Chron.* 1879, p. 823, and *Journ. Linn. Soc. (Bot.)* xviii. 518 (1881).

Abies Tschonoskiana, Regel, in *Index Sem. Hort. Petrop.* 32 (1865).

Pinus Harryana, M'Nab, *Proc. R. Irish Acad.* ii. 689, Pl. 47, f. 16 (1876).

This species, imperfectly described by Siebold and Zuccarini, is considered by Mayr to be a form of *A. brachyphylla*. It is different in the pulvini of the branchlets, in the shape and arrangement of the leaves, and in the position of the resin-canals in the latter. Specimens in cultivation, described below, agree with the type of Siebold and Zuccarini's species in the Leyden Museum. The cones are unknown; and it is possible that it may be a juvenile form or variety of *A. brachyphylla*; but in the present state of our knowledge, it is best kept distinct.

¹ Has been tried at Durrus repeatedly, but does not live beyond a year or two. Quite unfitted for our climate.—(J. D. CROZIER.)

² *Gard. Chron.* x. 458 (1891).

As seen in cultivation at Kew, it is a small tree, resembling in bark and habit *A. brachyphylla*. The foliage, however, is rather like that of *A. firma*, and the tree is occasionally cultivated under that name.¹

Buds ovoid, obtuse at the apex, whitened with resin, much larger than those of *A. firma*. Young shoots grey, glabrous, with prominent pulvini and grooves, which become less marked in the second year.

Leaves on lateral branches arranged as in *A. firma*, those of the upper rank about half the length of those of the lower rank, linear, flattened, rigid and slightly coriaceous, up to about 1¼ inch long, 1½ inch wide (much narrower than in *A. firma*), tapering gradually to the base, and narrowing near the rounded or acute apex, which is bifid with two short unequal cartilaginous points; upper surface dark green, shining, with a continuous median groove and without stomata; lower surface with two raised narrow white bands of stomata, each of about eight lines; resin-canals marginal.

Though this species has been in cultivation² since 1876 or earlier, we have seen no large specimens; and are ignorant as to whether it changes in character as it grows older or is short-lived. Its distribution in Japan is not known.

(A. H.)

ABIES BRACHYPHYLLA, NIKKO FIR

Abies brachyphylla,³ Maximowicz, *Mél. Biol.* vi. 23 (1866); Masters, *Gard. Chron.* xii. 556 (1879), and *Journ. Linn. Soc. (Bot.)* xviii. 515 (1881); Hooker, *Bot. Mag.* t. 7114 (1890).

Abies homolepis,¹ Mayr, *Abiet. Jap. Reiches*, 35, t. 2 f. 3 (1890); Shirasawa, *Icon. Ess. Forest. Japon.* text 14, t. 3, ff. 1-12 (1900); and Kent, Veitch's *Man. Coniferae*, 513 (1900) (not Siebold et Zuccarini, *Fl. Jap.* ii. 17, t. 108 (1844)).

Pinus brachyphylla, Parlatore, in D.C. *Prod.* xvi. 2, p. 424 (1868).

Picea brachyphylla, Gordon, *Pinetum*, 201 (1875).

A tree attaining in Japan over 100 feet in height and 16 feet in girth. Bark fissuring and scaly on young branches and on the stems of young trees, becoming like that of a spruce on old trees. Buds ellipsoid or broadly conical, obtuse at the apex, smooth, brownish, resinous. Young shoots greyish, glabrous, with prominent pulvini, separated by deep grooves, the pulvini and grooves becoming more marked in older shoots.

Leaves on lateral branches pectinate; those below extending laterally outwards in the horizontal plane, with a few in the middle line directed forwards and downwards; those on the upper side of the branchlet directed upwards and outwards, in

¹ It is readily distinguishable from *A. firma* by its glabrous shoots, larger buds, and much less coriaceous and narrower leaves.

² M'Nab, *loc. cit.* mentions plants of this species, which were growing under the name of *A. Veitchii* in several nurseries.

³ The following description applies to the tree, described by Maximowicz, which is, in my opinion and that of Dr. Masters, very different from *Abies homolepis*, S. et Z., which is treated by us as a distinct species.

two lateral sets, separated by an acute V-shaped depression. Lower ranks with the longest leaves (about $\frac{7}{8}$ inch), those in the other ranks gradually diminishing in size as they approach nearer the middle line above. Leaves linear, flattened, uniform in width except at the gradually tapering base, about $\frac{1}{15}$ inch, rounded and slightly bifid at the apex; upper surface dark green, shining, with a continuous median groove and without stomata; lower surface with two broad conspicuously white bands of stomata, each of ten to twelve lines; resin-canals median.

Leaves on cone-bearing branches shorter than on barren branches, those on the upper side of the shoot crowded and directed upwards, so that the V-shaped depression between the lateral sets is scarcely visible.

Cones on short stalks, cylindrical, slightly narrowed at the base and apex, 4 inches long, $1\frac{1}{2}$ inch in diameter, purple when growing, brown when mature. Scales very thin and flat; lamina fan-shaped, $1\frac{1}{8}$ inch long by $\frac{3}{4}$ inch wide, upper margin entire, lateral margins with denticulate short wings; claw short and obtuse. Bract short, not extending half-way up the scale; with a sub-orbicular finely denticulate lamina, tipped by a minute mucro, and a short obtuse claw. Seed with wing about $\frac{3}{4}$ inch long, the wing about $1\frac{1}{2}$ times as long as the body of the seed. In cultivated specimens, the scales of the cone and the seeds are smaller than in wild specimens. The very thin flat scales with the short minutely denticulate bract distinguish well this species.

IDENTIFICATION

This species has short leaves very white underneath, with an acute V-shaped depression between the lateral sets on the upper side of the branchlet, and is best distinguished by the very prominent pulvini and grooves on the branchlets. The bark of the branches and young stems begins to scale very early, an unusual character in the silver firs, and conspicuous in this species, in *A. homolepis*, and in *A. Webbiana*. The resinous buds, glabrous shoots, and leaves with median resin-canals are additional points in the discrimination of *A. brachyphylla*.

(A. H.)

DISTRIBUTION

According to Mayr this tree occurs on the main island of Japan, between lat. 36° and 38° , in the interior of the mountainous provinces; where it attains its maximum development in the zone of the beech forests, some trees attaining as much as 130 feet in height. The Japanese informed Mayr that it was also present on the highest peaks of Shikoku; but Shirasawa limits its distribution to the central chain of Honshu above 3000 feet elevation, and says that it grows in mixture with broad-leaved trees.

To most Europeans it is the best known of the Japanese silver firs, as it grows abundantly at Chuzenji, a favourite tourist resort. Here at 4000 to 5000 feet it is

scattered through the forest of deciduous trees and attains a height of 100 feet or more, the largest that I measured being 105 feet high by 16 feet in girth, and 95 feet by 11 feet. Higher up the mountains it becomes mixed with *Abies Veitchii* and diminishes in size. Its range of distribution is not accurately known, for though Japanese botanists distinguish it from the other species, as *Dake-momi*, the foresters and woodmen, who call all silver firs *momi*, do not seem, so far as I could learn, to distinguish it from *A. Veitchii* and *A. Mariesii*.

CULTIVATION

The date of introduction of this tree is not certainly known. Kent gives it as about 1870, and Mr. H. J. Veitch tells me that he believes that the first seeds were sent by Dr. Regel from St. Petersburg, but it was at first grown under other names.

It seems to thrive in most parts of England as well as or better than the other Japanese firs, but neither the trees I have planted, nor the seedlings I have raised from Japanese seed, will live long on the calcareous soil at Colesborne; a moist climate in summer, and a deep sandy soil free from lime being apparently the most favourable conditions for its existence. At Kew it seems to grow faster than other firs.

At Pampisford, Cambridge, a narrow conical tree measured in 1907, 44 feet by 3 feet 6 inches. At Grayswood, Haslemere, a tree, obtained from Messrs. Veitch in 1882, measured in 1906, 41 feet by 3 feet 3 inches. Both these trees bear cones freely. A specimen at Bicton is about 47 feet high, and bore cones in 1902. There is a very thriving one on the lawn at Eridge Park, Kent, planted by the Duke of Manchester in 1885, which now measures 30 feet high by 3 feet. At Dropmore there is one which in 1908 was 32 by 2 feet. At Kew, where there are several thriving trees, this species first produced¹ cones in this country in 1887. At Pencarrow,² a tree measured 40 feet by 3 feet 10 inches in 1907.

In Scotland we have seen no specimen of any size.³

Kent figures a handsome tree at Castlewellan, Co. Down, which was about 35 feet high and coning freely in 1907. Henry measured one at Fota, which was, in 1903, 40 feet in height and 2 feet 8 inches in girth. Another at Glasnevin was, in 1906, 38 feet by 2 feet 6 inches.

This species⁴ is very hardy in eastern Massachusetts, U.S., where it has already produced cones. A tree in Mr. Hunnewell's pinetum at Wellesley was 35 feet high in 1905. (H. J. E.)

¹ *Gard. Chron.* ii. 248 (1887).

² This tree is figured under the erroneous name of *A. Veitchii*, in *Hortus Veitchii*, plate opposite p. 83 (1906).

³ *A. brachyphylla* seems in every way adapted for cultivation in the north of Scotland, but too little is yet known of rate of growth to enable an opinion to be formed of its economic value.—(J. D. CROZIER.)

⁴ Sargent, in *Silva, N. Amer.* xii. 102 *adnot.* (1898), and *The Pinetum at Wellesley* in 1905, p. 12.

ABIES UMBELLATA

Abies umbellata, Mayr, *Abiet. Jap. Reiches*, 34, t. 1, f. 2 (1890).

Abies umbilicata, Beissner, ex Mayr, *Fremdländ. Wald- u. Parkbäume*, 258 (1906).

This species is very imperfectly known; and there are no specimens in the Kew herbarium. The plants distributed in England some years ago under the name by Messrs. Veitch are identical with *Abies homolepis*, and, when seen by Mayr, were pronounced by him to be a form of *A. brachyphylla*.

According to Mayr this species is distinguishable with difficulty, when in the young state, from *A. brachyphylla*, with which it agrees in the disposition and form of the leaves, and in the characters of the buds and shoots. Mayr states, however, that the leaves are not so white underneath as in *A. brachyphylla*. I have received from Herr Späth of Berlin, a specimen of reputed *A. umbellata*, which agrees generally in buds, shoots, and foliage with *A. brachyphylla*; but has leaves slightly longer than, and not so conspicuously white beneath, as is usual in that species.

The cones, according to Mayr, resemble those of *A. firma*, and are very different in size, colour, scales, and bracts, from those of *A. brachyphylla*; and are described by him as greenish-yellow when growing, brown when mature, about 4 inches long by $1\frac{1}{2}$ inch in diameter, cylindrical, the flattened apex having in its centre a raised umbo; scales about $1\frac{1}{4}$ inch broad by $1\frac{3}{8}$ inch long; bracts narrowed in the middle, slightly shorter than the scales, only exerted at the base of the cone.

According to Mayr, this species is only found in a few localities in Japan, but grows in considerable quantity on Mount Mutsumine in the province of Musashi, where it occurs with *A. brachyphylla* in the beech forests. It grows also on the Iumonji-toge, leading from Musashi to Shinano, and is also probably not uncommon on the neighbouring mountains of Hida and Kai.

This species has been united by Sargent, Kent, and others with *A. firma*; but it is very different from that species in foliage and shoots. It is possibly a hybrid between *A. brachyphylla*, of which it has the foliage, and *A. firma*, which it resembles in its cones.

(A. H.)

ABIES VEITCHII, VEITCH'S FIR

Abies Veitchii, Lindley, *Gard. Chron.* 1861, p. 23; Masters, *Gard. Chron.* xiii. 275 (1880), and *Journ. Linn. Soc. (Bot.)* xviii. 515, t. 20 (1881); Mayr, *Monog. Abiet. Jap. Reiches*, 38, t. 2, f. 4 (1890); Kent, *Veitch's Man. Coniferæ*, 541 (1900); Shirasawa, *Icon. Ess. Forest. Japon.*, text 16, t. 5, ff. 23-42 (1900).

Abies Eichleri, Lauche, *Berlin. Gartenzeit.* 1882, p. 63.

Pinus selenolepis, Parlato, *DC. Prod.* xvi. 2, p. 427 (1868).

Picea Veitchii, Murray, *Proc. Roy. Hort. Soc.* ii. 347, ff. 52-62 (1862).

A tree, attaining 60 to 70 feet in height. Bark of trunk greyish and remaining smooth even in old trees. Buds small, subglobose, purplish, resinous. Young

branchlets smooth, brown, covered with moderately dense, short, erect pubescence, retained on the older branchlets, the bark of which becomes slightly fissured.

Leaves on lateral branches arranged almost as in *A. Nordmanniana*; those on the under side of the branchlet pectinate; those on the upper side shorter and covering the branchlet, the median ones pointing upwards and forwards, and not appressed so much as in *A. Nordmanniana*. Leaves, about $\frac{1}{2}$ to 1 inch long, $\frac{1}{16}$ inch wide, linear, flattened, gradually tapering to the base, uniform in width in the anterior half, with a truncate bifid apex; upper surface dark green, shining, with a continuous median groove and without stomata; lower surface with two conspicuously white, broad bands of stomata, in nine to ten lines; resin-canals median. On cone-bearing branches, the leaves are more crowded, and less plainly pectinate below, than is the case in barren branches.

Staminate flowers¹ $\frac{1}{4}$ inch long on a stalk of the same length; anthers stalked, connective developed into a saddle-shaped flap, from the back of which projects a horizontal or deflexed spur-like process.

Cones sessile or sub-sessile, cylindrical, flattened at the apex, 2 to $2\frac{1}{2}$ inches long, $\frac{3}{4}$ to 1 inch in diameter, bluish before ripening, brown when mature. Scales small; lamina $\frac{5}{8}$ inch wide, $\frac{3}{8}$ inch long, crescentic, with two lateral denticulate wings, which are separated from the narrow obtuse base by rounded deep sinuses. Bract as long as the scale, obtuse below, dilated above into a two-winged denticulate lamina, ending in a short mucro, slightly exerted and reflexed. Seed-wing very broad and short, scarcely the length of the body of the seed; seed with wing about $\frac{5}{8}$ inch long.

VARIETIES

Mayr distinguishes two forms of cones:—

1. Var. *typica*. Cones large, about $2\frac{1}{2}$ inches long; bracts exerted and reflexed.
2. Var. *Nikkoensis*. Cones small, 2 inches long; bracts scarcely visible, their fine points projecting only slightly between the scales.

Abies nephrolepis, Maximowicz,² has been united with *Abies Veitchii* by Masters, and is perhaps a geographical form of the latter species, occurring in Amurland. According to Maximowicz it differs in the leaves of cone-bearing branchlets being sometimes acute and not bifid, and in the smaller ovoid-cylindrical cones, the scales of which are longer than the bracts and less in size than those of the Japanese tree. This Manchurian tree has not apparently been introduced into cultivation and is still imperfectly known.

Abies Eichleri, Lauche, was supposed to have been raised from seeds sent from Tiflis to Potsdam; and was considered to be a new species from the Caucasus. Some error, however, had arisen, as the plants turned out to be identical with *Abies Veitchii*.

Abies Veitchii has been collected according to Beissner³ by Père Giraldi at

¹ Masters, *loc. cit.*
IV

² *Mtl. Biol.* vi. 22 (1866).

³ See *Journ. Linn. Soc. (Bot.)* xxvi. 557 (1902).
I

9800 feet elevation in the Peling Mountains in the province of Kansu in China. The identification of herbarium specimens of *Abies* is difficult, and the Kansu plant will probably turn out to be a new and distinct species.

IDENTIFICATION

This species, with leaves covering the branchlet on the upper side, which are very white beneath, truncate and bifid at the apex, and less appressed than is the case in *A. Nordmanniana*, is further characterised by its small resinous buds, median resin-canals in the leaves, and smooth branchlets with short erect pubescence. The distinctions between it and *A. Mariesii* are given under the latter species.

(A. H.)

HISTORY AND DISTRIBUTION

Abies Veitchii was discovered on Fuji-yama by J. Gould Veitch in 1860. According to Sargent¹ it was introduced by Mr. T. Hogg into Parson's nurseries in Flushing, New York, in 1876, and a plant raised there was 16 feet high in 1889. It was cultivated in the United States for a time under the name of *Abies japonica*. It was not known in England or on the continent until 1879, when seeds were sent home² to Messrs. Veitch by their collector Maries.

The best account of the distribution is given by Mayr, who considers the tree to be the typical silver fir of the cold region of Japan, a zone which does not occur in Kiushu, where there are no mountains high enough. In Shikoku, *A. Veitchii* is very rare, only about 200 trees being known, which grow on the summit (6600 feet elevation) of Ishituchi-yama. It extends in the main island of Japan over the central mountain chain, from Fuji-yama to lat. 39°, growing at elevations of 6600 feet and upwards. Mayr denies its occurrence beyond lat. 39°; and states that north of this line it is replaced by *Abies Mariesii*,³ which thus intervenes over three degrees of latitude between the southern region, occupied by *A. Veitchii*, and the northern region, occupied by *A. sachalinensis*, these two species not meeting at any point, and having no transitional forms. *A. Veitchii* either forms pure woods or is associated with *Picea hondoensis* and *Picea Alcockiana*, but never with *Picea polita*. Sometimes it is mixed with *Tsuga diversifolia* or with *A. Mariesii*.

Shirasawa gives its lower limit of altitude in the main island as 5000 feet, and states that it attains about 70 feet in height by 7 feet in girth.

According to Mayr and Matsumura, the Japanese name, which is exclusively applied to this species, is *Shirabiso*. *Shiramomi* is also another name for the tree.

So far as I could learn the tree is of no special economic value in Japan.

¹ *Garden and Forest*, ii. 589 (1889). In this journal, x. 511 (1897) the statement is made that Mr. Hogg introduced it some forty years earlier, evidently a mistake for twenty years. *A. Veitchii* is very hardy in the United States, where it has produced cones.

² *Hortus Veitchii*, 337 (1906).

³ Prof. Miyabe showed me, in his herbarium, a barren specimen with small leaves, from Samani, near Cape Erimo, in eastern Hokkaido, which he believed to be *A. Veitchii*. This was *A. sachalinensis*, Masters, var. *nemorensis*, Mayr.

CULTIVATION

It seems to grow fairly well though rather slowly on soils which contain no lime; but it will not live on the calcareous soil at Colesborne.

We have seen no trees of considerable size. One at Tregrehan near St. Austell, measured 27 feet by 2 feet in 1908; and another at Ochtertyre, Perthshire, measured 30 feet by 2 feet in the same year. Mr. Bean¹ noticed in 1906 a specimen 31 feet high at Murthly Castle, and another 20 feet high at Dalkeith Palace. Small specimens will be found in most collections of conifers; and the young trees at Kew at present appear to thrive better than most species of *Abies*.

(H. J. E.)

ABIES MARIESII, MARIES' FIR

Abies Mariesii, Masters,² *Gard. Chron.* xii. 788, f. 129 (1879), and *Journ. Linn. Soc. (Bot.)* xviii. 519 (1881); Mayr, *Abiet. Japan. Reiches*, 40, t. 2, f. 5 (1890); Shirasawa, *Icon. Essences Forest. Japon.*, text 15, t. 4, ff. 15-28 (1900); Kent, Veitch's *Man. Coniferae*, 520 (1900).

A tree, attaining in Japan about 80 feet in height and 6 feet in girth. Buds small, globose, resinous; terminal buds on strong shoots are girt at the base by a ring of ovate, acuminate, rusty-red pubescent scales. Young shoots densely covered with a rusty-red tomentum, retained more or less in older shoots, the bark slightly fissuring in the third year.

Leaves on lateral branches arranged as in *Abies Nordmanniana*, the median leaves on the upper side almost appressed to the stem in imbricating ranks, and about $\frac{1}{2}$ to $\frac{2}{3}$ the length of the lower leaves, which spread pectinately outwards and slightly forwards in the horizontal plane. Leaves linear, flattened, tapering at the base and gradually widening beyond the middle, so that their broadest part is in the upper third; about $\frac{3}{4}$ inch in maximum length, $\frac{1}{10}$ to $\frac{1}{12}$ inch wide; apex rounded and bifid; upper surface yellowish green, shining, with a continuous median groove and without stomata; lower surface with two white bands of stomata, each of eight or nine lines; resin-canals marginal. Leaves on cone-bearing branches all appressed more or less to the shoot, upturned, and shorter than on barren branches.

Cones sessile, deep blue with a velvety lustre before ripening, dark brown when mature, ellipsoid, with an obtuse apex, about 4 inches long by 2 inches in diameter. Scales fan-shaped; lamina 1 inch wide, $\frac{7}{8}$ inch long, upper margin undulate, lateral margins with two denticulate wings; claw broadly obtuse. Bract with a broad obtuse claw, expanding just above the base of the scale, into a broadly oval lamina, which is emarginate at the apex with a short mucro. Seed-wing nearly twice the length of the body of the seed; seed with wing about $\frac{7}{8}$ inch long.

The cones show that the tree is nearly related to *Abies Webbiana*; but it differs entirely from that species in the characters of the branchlets and foliage.

¹ Cf. *Kew Bulletin*, 1906, pp. 260, 268.

² *Abies Mariesii*, Masters, *Bot. Mag.* t. 8098 (1906), described from a tree at Dunphail, Morayshire, is referable to *A. Webbiana*, as mentioned in our account of the latter species.

IDENTIFICATION

This species is similar in the arrangement and size of the leaves to *A. Veitchii*; but is distinguishable from that and from all other species of *Abies*, by the rusty-red or chocolate colour of the densely tomentose branchlets. The leaves are shorter and broader in proportion than those of *A. Veitchii*, being widest in their upper third, with their apex rounded and not truncate as in that species. The two species differ also in the position of the resin-canals.

(A. H.)

HISTORY AND DISTRIBUTION

This species was discovered¹ in 1878, by Charles Maries, when collecting for Messrs. Veitch, on Mount Hakkoda near Aomori in northern Hondo; and for some years it was supposed to occur only in the main island of Japan, where Mayr gives its distribution as from lat. 36° to the extreme northerly point of the island. It has since been found, according to Sargent,² by Tokubuchi in 1892 in one place on the shores of southern Yezo;³ and Dr. Honda lately discovered it in Formosa on Mount Morrison at 10,000 feet elevation.

Sargent saw it on Mount Hakkoda, and says that it is common at about 5000 feet, scattered amongst deciduous trees, and is the only species of *Abies* in this locality, where it forms a compact pyramid, 40 to 50 feet high, with crowded branches and many large dark purple cones. Maries also found it on Nantai above Nikko, which I had not time to ascend; Mr. Tome Shirasawa, who was my companion in North Japan, says that it grows here in company with *Abies Veitchii* on the upper zone of the mountain at 7000 to 8000 feet. The tree according to Mayr is the smallest of all the Japanese silver firs, its maximum height being 80 feet, with a girth of about 6 feet. It is known in Japan as *Aomori-todo-matsu*, and, so far as I could learn, has no economic value.

CULTIVATION

Seeds were sent home by Maries in 1879, but gave poor results; and we have not found anywhere in this country a single tree of any size; but Mr. Bean⁴ has seen a small but healthy tree at Scone Palace in Perthshire. As seen in the nursery at Kew and Coombe Wood, it is very slow and feeble in growth, and apparently is not suited to the English climate, young plants usually having very small leaves and short shoots. There are, however, three flourishing young trees at Bayfordbury, which were obtained from Hesse's nursery at Weener, in Hanover. It seems to do very much better in America, where I saw a vigorous tree⁵ growing at Mr. Hunnewell's pinetum at Wellesley, Massachusetts. Reputed trees of *Abies Mariesii* usually turn out on examination to be *Abies Veitchii*.

(H. J. E.)

¹ *Hortus Veitchii*, 336 (1906).² But Prof. Miyabe told me in 1904 that he had seen no specimens from this place, and doubted its occurrence in Hokkaido. He had specimens in his herbarium from Nambu near Morioka.³ *Forest Flora of Japan*, 82 (1894).⁴ *Gard. Chron.* xli. 117 (1907).⁵ Reported to be 9 feet high, by Sargent, in *The Pinetum at Wellesley in 1905*, p. 13.

ABIES GRANDIS, GIANT FIR

Abies grandis, Lindley, *Penny Cycl.* i. 30 (1833); Masters, *Gard. Chron.* xv. 179, ff. 33-36 (1881) xvii. 400 (1882), and xxiv. 563, ff. 128-131 (1885), and *Journ. Linn. Soc. (Bot.)*, xxii. 174 (1886); Sargent, *Silva N. Amer.* xii. 117, t. 612 (1898), and *Trees N. Amer.* 60 (1905); Kent, *Veitch's Man. Coniferae*, 510 (1900).

Abies Gordoniana, Carrière, *Conif.* 298 (1867).*Abies amabilis*, Murray, *Proc. Roy. Hort. Soc.* iii. 310 (1863) (not Forbes).*Pinus grandis*, Hooker, *Fl. Bor. Amer.* ii. 163 (1839).*Picea grandis*, Loudon, *Arb. et Frut. Brit.* 2341 (in part) (1838).

A tree attaining in America in the coast regions 300 feet in height and 16 feet in girth; but on the mountains of the interior rarely more than 100 feet high by 6 feet in girth; often smaller and stunted at high elevations. Bark of young trees smooth, thin, and pale; of older trees in America, brownish, divided by shallow fissures into low flat ridges roughened by thick appressed scales; in cultivated trees fissuring into thin irregular plates, exposing the reddish brown cortex. Buds small, conical, obtuse at the apex, resinous, roughened by the raised tips of the scales. Young shoots olive-green, smooth, with a minute, erect, not dense pubescence.

Leaves on lateral branchlets pectinate, in two lateral sets in the horizontal plane, each set of apparently two ranks, the upper rank with leaves about half the length of those below. Leaves linear, flattened, up to about 1½ to 2 inches long, 1/10 to 1/12 inch in width, narrowed at the base, uniform in breadth elsewhere, with a rounded and bifid apex; upper surface dark green, shining, with a continuous median groove and without stomata; lower surface with two white bands of stomata, each of about eight lines; resin-canals marginal. Leaves on cone-bearing branches crowded, less spreading or nearly erect, blunt or bifid at the apex, shorter than on sterile branches.

Cones 2 to 4 inches long by 1 to 1½ inch in diameter, cylindrical, slightly narrowed towards the rounded or retuse apex, bright green in colour, with the bracts concealed. Scales resembling those of *Abies Lowiana*, but smaller. Bract situated a little above the base of the scale, quadrangular; upper margin broad, denticulate, deeply emarginate, and with a minute mucro. Seeds 3/8 inch long, light brown, with pale shining wings about 5/8 inch long.

IDENTIFICATION

Abies grandis is readily distinguished by the very flat pectinate arrangement of the leaves; those of the upper rank being about half the length of those in the lower rank. *Abies Lowiana*, when growing feebly, resembles it somewhat in arrangement; but in this species the upper surface of the leaves has stomatic lines, absent in *A. grandis*, and the leaves in the upper rank are only slightly shorter than those in the lower rank.

(A. H.)

DISTRIBUTION

On the north-west coast of America this magnificent tree has a wide range, from Vancouver Island, where it grows at low levels and is not, so far as I saw, a conspicuous feature in the forest; through Washington and Oregon as far south as Mendocino County in California, where it does not extend far from the coast, and grows in company with *Sequoia sempervirens* and *Picea sitchensis*.

Inland it is less abundant on the eastern slopes of the Cascade Mountains, but extends to the Cœur d'Alene and Bitter-root Mountains of Idaho and Montana. In the Flathead Lake Country it is a comparatively small tree, attaining only 12 to 15 inches in diameter, and ascending to about 3500 feet.

It reaches its maximum development in a damp climate and in sheltered valleys, where I have measured trees much over 200 feet in height, and where, according to Sargent and Sheldon, it sometimes reaches as much as 300 feet. So far as I saw, and Sargent confirms this observation, it never grows gregariously, but scattered among other species; and rarely forms an important element in the timber.

It is easy to recognise when young by the flat arrangement of the leaves, but when its branches are far above one's head I could not distinguish it from *A. amabilis* in the Cascade mountains, or from *A. Lowiana* which seems to take its place in southern Oregon and northern California.

It grows very fast in its own country, a specimen measured at 2500 feet altitude on the Cascade Mountains being 140 feet by 16 feet on the stump, at only 106 years old. Though the timber is not much valued by lumbermen, it is used for various purposes locally, and, according to Sheldon, makes the most durable shakes—a name used for large shingles cleft with the axe—used in Oregon.

The tree figured (Plate 218) was growing in 1904 on Swallowfield farm, about fifty miles north of Victoria, in Vancouver Island, and when I measured it, was 215 feet by 19 feet.

Abies grandis was discovered on the Columbia river by Douglas in 1825, though he does not seem to have sent seeds to the Horticultural Society until 1831 or 1832. Very few of these germinated, and it is doubtful if any of the original seedlings are still living.¹ The next consignment² of seed was sent by William Lobb in 1851 to Messrs. Veitch at Exeter; and about the same time seeds were received by the Scottish Oregon Association from their collector Jeffrey.

REMARKABLE TREES

There are many fine trees of this species in the warmer and moister parts of England, Scotland, and Ireland; and, with *A. nobilis* and *A. Lowiana*, it seems best suited of all the American firs to our climate.³

¹ Murray, *Proc. Roy. Hort. Soc.* 311 (1863), states that there were then living no authentic seedling specimens of *A. grandis* raised from the seeds sent by Douglas, but a multitude of young plants existed which had been raised from cuttings.

² *Hortus Veitchii*, 336 (1906).

³ The most vigorous of all the genus. Thrives admirably on gneiss, free from all trace of disease, is not susceptible to frosts or Chermes, and as a shade bearer has no equal amongst silver firs. Produces timber, which is white and

The tallest that I have seen in England grows in Oakly Park near Ludlow, the property of Lord Plymouth, on the rich flat by the river Teme, and measured 102 feet by 8½ feet in 1908. Other fine trees are at Fonthill Abbey, which was 98 feet by 8 feet in 1906; and at Madresfield Court¹ and Eastnor Castle, both of which are over 95 feet high and 7½ feet in girth. The latter is figured (Plate 217). I have seen several others over 90 feet, of which perhaps the one at Heanton Satchville is the largest, though it is too spreading to be a typical specimen. In 1903 it was about 94 feet by 9 feet 7 inches, and 56 yards in circumference of the branches. At Castlehill there are some fine trees, one of which measured 92 feet by 7 feet 10 inches in 1904. At Petworth there is a very tall but not a well-grown tree, 94 feet by 6 feet 6 inches. At Eridge Park a very handsome tree, planted by Mr. Disraeli in 1868, measures 76 feet by 6½ feet. At Youngsbury, Ware, in Herts, Mr. H. Clinton Baker measured a tree in 1907, which was 91 feet in height and 9 feet 8 inches in girth; and at his own place, Bayfordbury, there is another, 73 feet by 5 feet 9 inches in 1905. He also reports two good trees at The Heath, Leighton Buzzard, 98 feet by 8 feet 6 inches, and 88 feet by 7 feet 10 inches respectively. There is also a very large tree in a belt by the road at Flitwick Manor, near Ampthill, Bedfordshire, the seat of Miss Brooks, which is 95 feet by 10 feet. At Welford Park there are two trees which though only planted in 1878, are now about 90 feet high by 7 feet in girth.

At Barton a thriving tree, 68 feet by 4 feet 3 inches, is the best we know in the eastern counties, and this is sheltered and drawn up by tall trees around it.

At Golden Grove, Carmarthenshire, there is a fine tree which in 1892 was 60 feet by 7 feet 8 inches, and when I saw it in 1905 had increased to 80 feet.

In Scotland there are many fine specimens, of which one at Riccarton, in Midlothian, was reported at the Conifer Conference in 1891 to have been 83 feet 3 inches high and only 3 feet 8½ inches in girth, as carefully measured by the owner, Sir James Gibson Craig; and stated by him to have grown 53 feet in twelve years. Soon after this it was attacked by Chermes and was cut down.

At Glenlee, near New Galloway, Mr. T. R. Bruce informs me that there is a tree, planted by Mrs. Melville in 1864, which in 1905 measured no less than 95 feet by 10 feet, though, having lost its leader four years previously, it has now three leads. At Castle Kennedy this species grows much faster than any of the other numerous firs planted there. In 1904, one of two trees, nearly equal in size, was 78 feet high by 6 feet in girth. This tree² was only twelve years old in 1891, when it measured 30 feet by 1 foot 7 inches.

At Benmore, in Argyllshire, one of the wettest places in Scotland, a tree said to be only thirty-five years planted was, in 1907, 80 feet by 7 feet 4 inches; but the trunk was infested with scale and did not seem to be healthy when I saw it. At Poltalloch, there is a fine specimen over 80 feet high, and at Inveraray and somewhat soft, in great volume, and which is found useful in connection with box-making and other industries in Aberdeen. Specially adapted for cultivation for profit where a large volume of timber is a desideratum.—(J. D. CROZIER.)

¹ A note signed J. N. in the *Trans. Scot. Arb. Soc.* xx. 126 (1907) states that this tree, in Sept. 1906, was 114 feet by 8 feet 4 inches. When I measured it in 1904, I made it 96 feet by 7½ feet; and though owing to the ground I could not get a level base line, I can hardly believe that it is now so tall as stated.

² *Journ. Roy. Hort. Soc.* xiv. 547 (1892).

Ardkinglas, in the same county, are trees over 70 feet, which in that wet climate flourish exceedingly.

In the Keillour Pinetum, near Balgowan, in Perthshire, a tree growing in boggy soil was, in 1904, 90 feet high by 7 feet 3 inches. It is not well furnished above, and is perhaps beginning to suffer from the nature of the soil. At Keir, Dunblane, there is a tree which in 1904 measured 82 feet high by 9 feet 3 inches in girth. This tree¹ was twenty-eight years old in 1891, and then measured 55 feet by 4 feet 2 inches. At Abercairney, Perthshire, there is a fine tree, which in 1904 was 91 feet by 8 feet 4 inches. This tree² was about thirty years old in 1891, and then measured 58 feet by 4 feet 6 inches.

At Durriss, Aberdeenshire, there is a good tree, which Mr. Crozier measured in 1904 as 82 feet high by 9 feet 6 inches in girth. When I saw it in 1907 it had increased to nearly 90 feet.

The largest tree in Ireland was formerly at Carton, which was reported in 1891 to be 80 feet high by 6 feet in girth. The top was blown off by the gale of February 1903, and when seen by Henry in the autumn of that year, the tree measured 67 feet by 9 feet 6 inches. At Kilmacurragh, Co. Wicklow, a fine specimen was, in 1906, 86 feet by 7 feet 2 inches; and at Coollattin, in the same county, another measured 63 feet by 6 feet 4 inches. At Powerscourt I measured one in 1903 which was about 87 feet by 7½ feet.

Abies grandis thrives very well in north-western Germany, and according to Count Von Wilamitz-Möllendorf³ grows at Gadow faster than any other silver fir, a specimen figured being 25 metres by 1.40 metre when only twenty-five years old. It also succeeds in some parts of Denmark, where Hansen⁴ states that a specimen planted in 1864 had attained, in 1891, 53 feet by 6 feet. (H. J. E.)

ABIES CONCOLOR, COLORADO FIR

Abies concolor,¹ Lindley and Gordon, *Journ. Hort. Soc.* v. 210 (1850); Masters, *Journ. Linn. Soc. (Bot.)* xxii. 177, ff. 8-11 (1886), and *Gard. Chron.* viii. 748, ff. 147, 148 (1890); Sargent, *Silva N. Amer.* xii. 121, t. 613 (1898) (in part), and *Trees N. Amer.* 62 (1905) (in part); Kent, Veitch's *Man. Coniferae*, 501 (1900).

Picea concolor, Gordon, *Pinetum*, 155 (1858).

Picea concolor, var. *violacea*, Roehl, ex Murray, *Gard. Chron.* iii. 464 (1875).

Pinus concolor, Engelmann, ex Parlatores, in DC. *Prod.* xvi. 2, p. 427 (1868).

A tree attaining in America 100 to 125 feet in height, with a girth of 9 feet. Bark of old trees fissuring into small irregular plates. Buds, much larger than those of *A. Lowiana*, broadly conical, rounded at the apex, brownish, resinous, and slightly roughened by the raised tips of the scales. Young shoots smooth, yellowish-green, with a minute scattered pubescence, variable in quantity and often absent from the greater part of the branchlet. Second year's shoot greyish and irregularly fissuring.

Leaves on lateral branchlets irregularly arranged and not truly pectinate; most of the leaves extending laterally outwards and curving upwards, a few on the lower side directed downwards and forwards, some on the upper side directed upwards and forwards; those above shorter than those below. Leaves up to 2 to 3 inches long, 1½ inch broad, glaucous on both surfaces, linear, flattened, slightly tapering at the base, uniform in width elsewhere; apex acute or rounded and not bifid, though occasionally a slight emargination is discernible with a lens; upper surface slightly convex, not grooved, with fifteen to sixteen regular lines of stomata; lower surface convex with two bands of stomata, each of about eight irregular lines, not conspicuously white; resin-canals marginal. Leaves on cone-bearing branches shorter, thicker, falcate, all curving upwards.

Cones, 3 to 5 inches long, 1¼ inch in diameter, cylindrical, narrowed at both ends, rounded or obtuse at the apex; greenish or purple before ripening, brown when mature. Scales of native Colorado specimens much broader than long; lamina about 1 inch wide by ½ inch long, upper margin entire, lateral margins rounded and denticulate, gradually passing into the obtuse claw or with a slightly auricled truncate base. Bract, at the base of the scale, rectangular, denticulate, with truncate upper margin and a minute mucro; in some specimens deeply bifid above. Seeds ½ inch long, with broad shining pinkish wings, about ½ inch long. In cultivated specimens, both brown and purple cones occur.

The following varieties have arisen in continental nurseries:—

1. Var. *falcata*, Beissner,² leaves sickle-shaped, curving upwards.

2. Var. *glabosa*, Beissner,² globose in habit, with symmetrical short branches.

¹ According to the view taken here, *Abies concolor* includes only the tree found in Colorado, Utah, and Southern California. Sargent and other American botanists combine with this species the tree found in the Californian Sierras, which is considered by us to be a distinct species, *A. Lowiana*. The two forms differ remarkably in buds and foliage; and it is most convenient to regard them as distinct species.

² *Mitt. Dendr. Ges.* 1905, p. 112.

3. Var. *aurea*, Beissner,¹ young foliage golden yellow, gradually changing to a silvery grey colour.

4. Var. *brevifolia*, Beissner,¹ leaves short, thick, obtuse, twice as broad as in the typical form.

DISTRIBUTION

Abies concolor occurs in the Rocky Mountains of southern Colorado and extends southwards over the mountains of New Mexico and Arizona into northern Mexico, being the only silver fir in the arid regions of the Great Basin and of southern New Mexico and Arizona. It occurs also in Utah in the Wasatch Mountains, and in southern California, in the San Bernardino and San Jacinto Mountains. It is accordingly confined to dry regions, while *Abies Lowiana*, which is in all probability only a geographical form of it, occurs in the more rainy regions of the Sierra Nevada of California and the southern mountains of Oregon. According to some opinions, the three species, *Abies grandis*, *Abies Lowiana*, and *Abies concolor* are only geographical forms of one large species.

Sargent says, of *Abies concolor*, that it endures heat and dryness best of all the silver firs of North America, and its distribution is accordingly more southerly than that of the other species, which occur in the United States.

HISTORY AND CULTIVATION

This species was discovered by Fendler, near Sante Fé, in 1847, and was first clearly described by Parlato, who adopted for it Engelmann's MS. name, *Pinus concolor*. It does not appear to have been introduced² into cultivation until about 1872. Syme mentions³ two-year-old seedlings of it as a new species in 1875. Roehl, apparently in 1874, sent specimens and seeds, which were labelled *Picea concolor violacea*,⁴ from New Mexico to Messrs. Sanders and Co., St. Albans. This species has been much confused with *A. Lowiana*, which was introduced considerably earlier. It is probable that there are no trees of true *A. concolor* in cultivation, older than 1873 or 1874.

Abies concolor, according to Sargent, is the only American silver fir, which is really successful in cultivation in the eastern part of the United States, where it grows better than *A. Lowiana*.

We have seen few trees of large size, though one at Highnam Court, Gloucestershire, of no great age, was 44 feet by 2 feet 9 inches in 1908.

It is less common in cultivation than *A. Lowiana*, which it much excels in beauty of foliage. Mr. Crozier says that young trees growing at Durriss are quite healthy.

(A. H.)

ABIES LOWIANA, CALIFORNIAN FIR

Abies Lowiana, A. Murray, *Proc. Roy. Hort. Soc.* iii. 317 (1863).

Abies lasiocarpa, Masters (not Nuttall or Murray), *Gard. Chron.* xiii. 8, f. 1 (1880).

Abies grandis, Lindley, var. *Lowiana*, Masters, *Journ. Linn. Soc. (Bot.)*, xxii. 175, ff. 6, 7 (1886).

Abies concolor, Sargent, *Silva N. Amer.* xii. 121 (1898), and *Trees N. Amer.* 62 (1905) (in part).

Abies concolor, Lindley and Gordon, var. *lasiocarpa*, Beissner, *Handb. Conif.* 71 (1887).

Abies concolor, Lindley and Gordon, var. *Lowiana*, Lemmon, *W. Amer. Cone-Bearers*, 64 (1895); Kent, Veitch's *Man. Conif.* 502 (1900).

Picea Lowiana, Gordon, *Pinet. Suppl.* 53 (1862).

Picea Parsonsiana, Barron, *Catalogue*, 1859, and *Gard. Chron.* v. 77 (1876).

Pinus Lowiana, M'Nab, *Proc. R. Irish Acad.* ii. 680 (1877).

A tree, attaining on the Californian Sierras 200 to 250 feet in height, with a trunk often 18 feet in girth. Bark in cultivated specimens as in *A. concolor*; in wild trees becoming, near the ground, on old trunks, very thick and deeply divided into broad, rounded, scaly ridges. Buds ovoid, blunt at the apex, brownish, resinous, roughened by the raised tips of the scales. Young shoots yellowish green, smooth, covered with a minute scattered pubescence.

Leaves on lateral branchlets pectinately arranged, each lateral set of about two ranks, directed almost horizontally outwards, or curving upwards and outwards, so as to assume above a V-shaped arrangement. None of the leaves are directed irregularly in the middle line; and those of the upper rank are only slightly shorter than those of the lower rank. Leaves, up to 2½ inches long, about ¼ inch broad, linear, flattened, slightly tapering at the base, uniform in width elsewhere, rounded and bifid at the apex; upper surface with a wide median furrow, usually not continued to the apex, and with eight lines of stomata in the furrow; lower surface with two white bands of stomata, each of eight to nine lines; resin-canals, marginal. Leaves on cone-bearing branches, upturned.

Cones, according to Sargent, not distinguishable from those of *Abies concolor*. Wild specimens, however, from California slightly differ, in having larger scales and broader bracts. Cultivated specimens in England bear cones which are chestnut-brown, and apparently never purple, as is often the case in *Abies concolor*.

IDENTIFICATION

Abies Lowiana is regarded by Sargent and other American botanists as a form of *A. concolor*. As seen in cultivation it is very distinct from that species: moreover, it has a different distribution in the wild state. We have kept it separate, as being more convenient to cultivators.

In practice it can only be confused with *A. grandis*, and true *A. concolor*. The characters distinguishing it from *A. grandis* are given under this species on p. 773.

In *A. concolor* the arrangement of the leaves is irregular, not being truly pectinate. Many of the leaves in the middle line, both above and below, are not

directed outwards, but point forwards parallel to the axis of the branchlet. In *A. concolor* the leaves are entire at the apex, and their convex upper surface shows sixteen lines of stomata, and is without a groove; whereas, in *A. Lowiana*, the apex of the leaves is bifid, and their upper surface is grooved, showing eight lines of stomata. The buds are smaller in the latter species. (A. H.)

DISTRIBUTION

Abies Lowiana is found on the Siskiyou Mountains in southern Oregon, and on Mt. Shasta and the Sierra Nevada ranges in California. Its northern limit is the dry interior of southern Oregon, near the divide between the headwaters of the Umpqua and Rogue rivers, which, according to Sargent, is the real northern boundary of the Californian flora.¹ With *Abies magnifica* it forms in great part one of the principal forest belts on the west slope of the Sierra Nevada Mountains for 450 miles, and extends from 4000 to 9000 feet above sea-level. Here I saw it on my way into the Yosemite Valley in 1888, but did not then measure any trees. I found it in September 1904 in company with *A. magnifica*, *Pinus ponderosa*, and *Pinus Lambertiana* abundant on Mount Shasta, from about 3000 to 6000 feet; and here it was of moderate size, the largest that I measured being 140 feet by 11 feet 8 inches. It attains, however, 200 to 250 feet on the Sierra Nevada, and as much as 200 feet in Oregon.

HISTORY AND CULTIVATION

Abies Lowiana was introduced from the Sierra Nevada of California by William Lobb in 1851; and about the same time seeds were sent from southern Oregon by John Jeffrey, who collected for the Scottish Oregon Association. The plants raised from Lobb's seeds were distributed by Messrs. Veitch of Exeter as *Picea lasiocarpa*, while those raised in Scotland from Jeffrey's seeds were distributed as *Picea grandis*.²

Messrs. Parsons of Flushing, United States, received seeds from California in 1853; and plants raised from these were imported to England in 1855 by Messrs. Low of Clapton. These passed into commerce as *Picea Parsonsiana*, a name which first appeared in Barron's Catalogue in 1859, and as *Picea Lowiana*, the name given by Gordon in 1862.

Of all the western silver firs this seems to be the most accommodating to the varied conditions of England, growing well on soils where *A. nobilis* will not thrive, and in a drier climate than *A. grandis* prefers. It is usually grown under the name of *A. lasiocarpa*, in the pineta which I have visited, and generally seen in good health and with a symmetrical top; as it is not so liable to become stunted by the production of cones as *A. nobilis*.

According to Sargent, the Californian form of *A. concolor* grows in the eastern

¹ The fir named *A. concolor* by Plummer in his Report on the Mt. Rainier Forest Reserve, p. 101 (Washington, 1900), is evidently *A. grandis*, which he does not mention, and all his references to white fir no doubt relate to that species.

² Cf. *Hortus Veitchii*, 39, 335 (1906).

States with less vigour and rapidity than the Colorado form; but is equally hardy, and has attained 40 to 50 feet in height in New England.

REMARKABLE TREES

Among the numerous trees that I have measured I find it difficult to say which is the finest specimen. The one at Linton Park was the largest recorded at the time of the Conifer Conference, when it was 64 feet by 8 feet 7 inches. In 1902 I found it to be 85 feet by 10 feet 6 inches, a great increase in ten years (Plate 219).

There is, however, a tree at Fonthill Abbey which I believe to be *A. Lowiana*, though I could not reach the branches in order to identify it, which, in 1906, measured 90 feet by 6½ feet, and resembled, by its short branches, the typical habit of *A. magnifica*.

At Highnam Court, Gloucester, there is a fine specimen which was figured by Kent; according to Major Gambier Parry, it measured 77 feet by 9 feet 2 inches in 1906. I made it 80 feet by 9½ feet in 1908. Another at Eastnor Castle is about 88 feet by 7 feet 4 inches.

In Herts there are several good trees, one at Essendon Place being 82 feet high by 5 feet 9 inches in 1907; another at Youngsbury, Ware, which was planted in 1866, being 68 feet by 5 feet 6 inches in the same year; and a third at Bayfordbury, which was 69 feet by 6 feet 9 inches in 1905.

A very remarkable specimen, narrow and almost columnar in habit, which was planted twenty-six years ago, was seen by Henry at Crowsley Park, Oxfordshire, the seat of Colonel Baskerville, and measured, in 1907, 71 feet by 6 feet.

In Wales there is a very fine tree at Hafodunos, which Henry measured, in 1904, as 87 feet by 7 feet 9 inches; and I saw one at Glanusk Park in Breconshire, which was over 80 feet high in 1906.

In Scotland this species is not usually so large as in the south, though it grows well even in the west, where I have seen good trees at Inveraray and Poltalloch; and in the reports of the Conifer Conference it is generally described as thriving, and several trees of 40 to 50 feet high are mentioned. The largest we have heard of is at Abercairney, mentioned by Mr. Bean¹ as 65 feet by 5 feet.

In Ireland the tree does not appear to have been often planted, and the largest reported at the Conifer Conference in 1891 was growing at Abbeyleix in Queen's County, and measured 45 feet by 6 feet 10 inches. At Coollattin, Co. Wicklow, another was, in 1906, 52 feet by 4 feet 9 inches; and, in the same year, a fine specimen at Castlewellan, Co. Down, measured 67 feet in height and 9 feet in girth.

(H. J. E.)

¹ *Kew Bulletin*, 1906, p. 258, and *Gard. Chron.* xli. 168 (1907), where it is named through inadvertence *A. concolor*.

ABIES AMABILIS, LOVELY FIR

- Abies amabilis*, Forbes, *Pinet. Woburn.* 125, t. 44 (1840); Masters, *Journ. Linn. Soc. (Bot.)* xxii. 171, t. 2 (1886), and *Gard. Chron.* iii. 754, f. 102 (1888); Sargent, *Silva N. Amer.* xii. 125, t. 614 (1898), and *Trees N. Amer.* 59 (1905); Kent, Veitch's *Man. Conif.* 489 (1900).
Abies grandis, Murray, *Proc. Roy. Hort. Soc.* iii. 308 (1863) (not Lindley).
Pinus amabilis, Douglas, *Comp. Bot. Mag.* ii. 93 (name only) (1836); Antoine, *Conif.* 63 (1846).
Pinus grandis, Don, in Lambert, *Pinus*, iii. t. (1837).
Picea amabilis, Loudon, *Arb. et Frut. Brit.* iv. 2342 (in part) (1838).

A tree sometimes attaining in America 250 feet in height and 18 feet in girth, but at high altitudes and in the north usually not more than 80 feet. Bark thin, smooth, pale or silvery white; becoming, on very old trunks, thick near the ground and irregularly divided into small scaly plates. Buds small, globose, resinous, smooth, with purple scales all immersed in the resin, except occasionally two or three, small and keeled, at the base of the bud. Young shoots grey, smooth, densely covered with short, loose, wavy pubescence.

Leaves on lateral branches arranged as in *A. Nordmanniana*, up to $1\frac{1}{4}$ to $1\frac{1}{2}$ inch long by $\frac{1}{4}$ inch broad, fragrant, linear, flattened, gradually tapering from the middle to the base, slightly broader in the anterior half, with a truncate and bifid apex; upper surface very dark green and lustrous, with a continuous median groove and without stomata; lower surface with two broad white bands of stomata, each of eight to ten lines; resin-canals marginal. Leaves on vigorous leading shoots acute with long rigid points, closely appressed or recurved near the middle. Leaves on cone-bearing branches upturned, acute or acuminate.

Cones ovoid-cylindric, slightly narrowing to the rounded apex, dark purple when growing, brown when mature; $3\frac{1}{2}$ to 6 inches long by 2 to $2\frac{1}{2}$ inches in diameter. Scales, 1 to $1\frac{1}{8}$ inch wide, nearly as long as broad, inflexed at the upper rounded margin, gradually narrowing towards the base. Bracts rhombic or obovate-oblong; lamina situated just above the base of the scale and ending in a long acuminate tip, which reaches half the height of the scale. Seeds light yellowish brown, $\frac{1}{2}$ inch long, with oblique pale brown shining wings about $\frac{3}{4}$ inch long.

Abies amabilis resembles *A. Nordmanniana* in the arrangement and size of the leaves; but is readily distinguished from it by the small globose resinous buds. The leaves are also much darker, shining above, more truncate at the apex; and emit, especially when bruised, a strong fragrant odour which resembles that of mandarin orange peel.

(A. H.)

DISTRIBUTION AND HISTORY

Abies amabilis occurs on mountain slopes and terraces from British Columbia southward along the Cascade Mountains to northern Oregon, and on the coast ranges of Oregon and Washington. According to Sargent, it attains its largest size on the Olympic Mountains, where it is the most common silver fir,

extending from 1200 feet up to timber line at about 4500 feet, and forming, with the Western Hemlock, a large part of the forest between 3000 and 4000 feet. In the Cascade Mountains it extends south to about 20 miles north of Crater Lake where Mr. Coville found it on the east side of Diamond Mountain. It occurs¹ in the extreme south-eastern end of Alaska, at the Boca de Quatre inlet, ranging from sea-level to 1000 feet altitude; but has not yet been found between this point and the northern end of Vancouver Island. It is the common fir² in south-western Vancouver Island, where it grows abundantly from sea-level up to the summits of the highest mountains. Near the sea it often forms groves of almost pure growth, the trees standing close together and having very tall slender trunks, about 3 feet in diameter at the base, and often unbranched to a height of 100 feet or more. At an altitude of 3000 feet it is a comparatively small tree, often clothed with branches to the base. Plate 220, taken from a photograph, for which I am indebted to Mr. J. M. Macoun of the Geological Survey of Canada, shows the tree as growing near Kamloops, in British Columbia.

Sargent says, "unsurpassed among fir trees in the beauty of its snowy bark, dark green lustrous foliage, and great purple cones, *Abies amabilis* can never be forgotten by those who have seen it in the alpine meadows covered with lilies, dog's-tooth violets, heaths, and other flowers which make the valleys of the northern Cascade Mountains the most charming natural gardens of the continent."

Engelmann in a letter, dated "Portland, Or., August 6," 1880, and quoted in *Gardeners' Chronicle* of December 4, 1880, says of it:—" *A. amabilis*, on the same mountain where Douglas discovered it, just south of the Cascades of the Columbia, is a magnificent tree, at about 4000 feet, attaining 150 to 200 feet high with a trunk 4 feet in diameter, branching to the ground and forming a perfect cone. The bark of old trees is $1\frac{1}{2}$ to 2 inches thick, furrowed and reddish grey, that of younger trees, less than 100 years, is quite thin and smooth, light grey or almost white. It is certainly very closely allied to *A. grandis*, but readily distinguished by its very crowded dark green foliage and its large dark purple cones. It has the purple cones and sharp-pointed leaves (on fertile branches) of *A. subalpina*, but this latter has much smaller cones, and not such crowded leaves."

Though I saw this tree in abundance on Mount Rainier I cannot say that I know how to distinguish it in the forest from *A. nobilis* without the leaves and cones. It has, according to Plummer, a wider range of elevation than that species, and grows from 800 up to 5500 feet. The cone is as large as that of *A. nobilis*, but without the projecting bracts. From *A. lasiocarpa*,³ with which it was mixed in the upper part of its range, it is distinguished by its habit, which is much less slender and spiry, by its greater size, and by its cones, which are nearly twice as large. Plummer says that it attains 200 feet in height by 15 feet in girth, but I saw none so large as this that I could identify. It is a slow-growing tree, one 20 inches in diameter having 288 rings.

¹ U.S. Forest Service, *Sylvical Leaflet*, 22, p. 1 (1908). Its most southerly point in the coast range is Saddle Mountain, 25 miles south of the mouth of the Columbia River.

² Cf. Butters, *Conifers of Vancouver Island*, in *Postelsia*, 187 (St. Paul, Minn., 1906).

³ Sargent, *Silva*, xii. 126, *adnot.*, mentions the occurrence in a wild state of a hybrid between these two species.

As there were no cones on any of the firs on this side of Mount Rainier in 1904 I was unable to procure seed of either of these species, though Prof. Allen sent me both of them in 1905.

The wood is yellowish and can, according to Plummer, be distinguished from that of *A. lasiocarpa*, by its darker colour. It is soft and perishable, and of no commercial importance at the present time.

Abies amabilis was discovered in 1825 by Douglas on a high mountain south of the Grand Rapids of the Columbia River; but it was not until 1830 that he succeeded in sending to England seed, from which a few plants were raised in the garden of the Horticultural Society at Chiswick; and of these original trees hardly any now survive. For many years afterwards the tree was not seen by any traveller or collector; and seeds of reputed *A. amabilis* sent to Europe invariably turned out to be some other species; and much confusion resulted in the nomenclature of the western American silver firs. In 1880 the tree was re-discovered by Sargent in company with Engelmann and Parry, who found it on Silver Mountain near Fort Hope on the Fraser River; and a few days later Sargent himself observed it on the mountain where it had first been seen by Douglas. Large supplies of seed were sent from Oregon in 1882, and young trees are not now uncommon.

REMARKABLE TREES

Of the original trees, those raised from seed sent home by Douglas, Kent knew only of two surviving in 1900, one at Dropmore and another at Orton Longueville. The latter, as I was told by Mr. Harding, was cut down in 1905, when it measured 5 feet 9 inches in girth.

The tree at Dropmore, which was received from the Royal Horticultural Society, and planted in 1835, was cut down four years ago. Mr. Page informs us that the trunk in the timber yard measured 36 feet long by 8 feet 4 inches in girth at 5 feet from the lower end. A cutting from the tree was raised in 1847 by the late Mr. Frost, and is now growing at Dropmore, and measures 50 feet high by 7 feet 3 inches. For a time, up to 1873, it promised to be a better tree than its parent; but it is now a miserable object, being badly affected by "knotty" disease.¹ This disease has attacked also all the young trees of this species at Dropmore, some fourteen or fifteen in number, which were planted a few years ago.

¹ Dr. Masters, in *Gard. Chron.* xvii. 812, xviii. 109, figs. 19, 20 (1882) states that Mr. Barron had proved the gouty swellings on branchlets of *A. amabilis* and *A. nobilis* to be due to a woolly aphid, and had succeeded in killing the pest, in his nursery at Borrowash, by applications of fir-tree oil. A petroleum emulsion is recommended in *Gard. Chron.* xxvii. 190 (1900). I am indebted to Prof. Borthwick of Edinburgh for a paper on the subject (in *Nat. Zeitschr. Forst. u. Landwirthschaft*, 1908, p. 151, figs. 1-4) by Dr. E. Wolz, who states that these swellings are caused by a Chermes which Cholodkovsky has named *C. piceæ*, var. *Bowvieri*. The life-history of this insect does not seem to have been fully worked out; and it may not be identical with the *Chermes piceæ*, which attacks the bark of silver firs, and is said by Gillanders (*Forest Entomology*, 333) to be common in the nursery on young plants of *A. pectinata* and of *A. Nordmanniana*. The figures given by Wolz, however, of *Abies nobilis*, attacked by the disease, represent exactly the swellings which I have seen on that species at Carlisle, and which is present on most of the trees of *A. amabilis* in England. E. R. Burdon, in *Journal of Economic Biology*, 1908, ii. 132, states that Cholodkovsky's drawing looks more like the effect attributed to *Aecidium elatinum*. Cf. Hartig, *Diseases of Trees*, 180, fig. 109 (1894), who states that no formation of spores ever takes place on these swellings.

We have, however, found several other old trees, none of which are fine specimens, and may have been planted later.

A tree at Bayfordbury, with a broken top, is about 20 feet high. At Brickendon Grange, Herts, there is a remarkable specimen, only a foot in height, with long branches spreading over the ground for about 12 feet. This curiosity is probably very old; and its peculiar form is possibly due to the leader having been repeatedly bitten by animals.

At Pencarrow, Cornwall, a tree is growing, which I made in 1905 47 feet high by 7 feet 10 inches in girth. Mr. Bartlett, in a letter dated February, 1906, gives the following interesting particulars concerning this tree:—"According to Sir W. Molesworth's catalogue of the trees at Pencarrow, the *Abies amabilis* was planted in 1843. The soil is well-drained loam, and the tree stands in a sheltered position. For many years it was a strikingly beautiful specimen, quite symmetrical and feathered to the ground. A few years ago it was attacked by Chermes, and is now in a poor state and likely to be completely ruined by the disease in a few years. The tree bore a few cones near the top, four years ago; but these contained no good seeds. The cones were resinous, dark blue in colour when growing, fading to a dull brown towards autumn. The bark of the trunk and branches is covered with resin-blisters, which exude a liquid resembling golden syrup in colour and consistency. The buds are late in unfolding." Mr. Bartlett states that there is, at Lamellan, in north Cornwall, a perfectly healthy but stunted example of *Abies amabilis*, growing on very poor soil on the edge of a quarry. This tree was probably raised from a cutting of the Pencarrow tree. At Menabilly, in the same county, there is another tree, the flowers of which have been figured.¹ In 1908 it measured 37 feet by 3 feet 7 inches.

At Brocklesby Park, Lincolnshire, Henry measured in 1908 a tree, 50 feet by 4 feet, the date of planting of which is unknown. Though very healthy in general appearance, some of the lower branches are beginning to suffer from knotty disease. The bark is very smooth and covered with numerous resin blisters, differing markedly from the rough bark of an *A. Nordmanniana*, of the same size, growing beside it.

At Smeaton-Hepburn, in East Lothian, there is a tree,² which was planted in 1843; but its top was blown off in 1859, and it is now only 31 feet high, but has a girth of 8 feet 10 inches. It produced staminate flowers in 1886.

At Castle Kennedy, *Abies amabilis* takes on a low creeping bushy habit, possibly due to the plants being raised from cuttings, and I saw a similar dwarf stunted plant at Moncreiffe, which I believe to be *A. amabilis*.

On the whole this species appears to be a failure in cultivation, in Europe; and does not succeed any better in New England, where, according to Sargent,³ it has proved rather tender and grows very slowly. (H. J. E.)

¹ *Gard. Chron.* iii. 755, f. 102 (1888).

² Cf. Sir Archibald Buchan-Hepburn's account in *Proc. Berwickshire Naturalists' Club*, xviii. 207, 210 (1904). It was 8 inches high at the time of planting, when it was supposed to be *A. grandis*.

³ Sargent, in *The Pinetum at Wellesley in 1905*, p. 12, mentions a small healthy specimen, which was raised in the Veitchian nurseries near London, from seeds collected in Oregon by C. S. Pringle in 1882.

ABIES NOBILIS, NOBLE FIR

Abies nobilis, Lindley, *Penny Cycl.* i. 30 (1833); Masters, *Gard. Chron.* xxiv. 652, f. 146 (1885), and *Journ. Linn. Soc. (Bot.)* xxii. 188 (excl. habitat Mt. Shasta, and var. *magnifica*) (1886); Sargent, *Silva N. Amer.* xii. 133, t. 617 (1898), and *Trees N. Amer.* 65 (1905); Kent, Veitch's *Man. Coniferae*, 521 (1900).

Pinus nobilis, Douglas, in *Comp. Bot. Mag.* ii. 147 (1836).

Picea nobilis, Loudon, *Arb. et Frut. Brit.* iv. 2342 (1838).

A tree, attaining in America occasionally 250 feet in height with a girth up to 24 feet, but more usually 150 to 200 feet high. Bark smooth on young trees, becoming on old trunks reddish-brown and deeply divided by broad flat ridges, irregularly broken by cross fissures and covered with thick closely appressed scales.

Buds concealed by the leaves at the tips of the branchlets, ovoid-globose; terminal bud resinous above and surrounded at the base by a ring of lanceolate acuminate or subulately pointed pubescent brown scales; lateral buds with ovate basal scales. Young shoots smooth, densely covered with minute rusty brown tomentum, which is retained in the second year.

Leaves on lateral branches pectinate below, extending outwards in the horizontal plane in two lateral sets; above, the leaves in the middle line, much shorter, completely cover the shoot, from which they arise curving upwards, after being appressed to the branchlet for a short distance near their bases, their tips usually having a slight inclination forwards. Leaves up to about $1\frac{1}{4}$ inch long, $\frac{1}{16}$ inch wide, linear, flattened, narrowed at the base, uniform in width elsewhere, rounded and entire at the apex; upper surface with a continuous median groove and variable as regards the stomata, which are sometimes in two definite bands each of six to eight lines or sometimes present as a few irregular lines, or rarely absent; lower surface with two narrow bands of stomata, each of five to six lines; resin-canals marginal.

Leaves on cone-bearing branches all upturned, thickened, and with sharp cartilaginous points.

Staminate flowers reddish. Pistillate flowers with broad rounded scales, much shorter than the nearly orbicular bracts, which are erose in margin and contracted above into slender elongated reflexed tips.

Cones cylindrical, but narrowing towards the full and rounded apex; 4 to 5 inches long by 2 inches in diameter on wild trees, 6 to 10 inches long by 3 to 4 inches in diameter on cultivated trees; pubescent, purplish-brown with green bracts when growing, the bracts becoming bright chestnut brown in the mature fruit. Scales: lamina, $1\frac{1}{4}$ to $1\frac{1}{2}$ inch broad, 1 inch long, variable in shape; gradually narrowing to the base with straight lateral margins, or rounded and denticulate on the sides above the middle and contracted below; claw short, clavate. Bracts exerted and strongly reflexed, covering the greater part of the scale next below; lamina, broad, full and rounded above, fimbriate in margin, and with a conspicuous midrib prolonged into a mucro about $\frac{1}{2}$ inch long; claw long and cuneate. Seeds pale brown, about $\frac{1}{2}$ inch

long, with similarly coloured obovate-cuneate wings, which in cultivated specimens are considerably longer than the body of the seed.

This tree can only be confused with *A. magnifica*, which has a different habit. The difference between these two trees in the shape and disposition of the leaves is given in the Key, p. 718. (A. H.)

DISTRIBUTION

According to Sargent, this species forms extensive forests on the Cascade Mountains in Washington, extending southwards to the valley of the Mackenzie River, Oregon. It also occurs on the coast ranges of Washington, and the Siskiyou Mountains of California. It is most abundant on the western slopes of the Cascade Mountains, and ranges from 2500 to 5000 feet above sea level, attaining its largest size at 3000 to 4000 feet. It is less abundant and of smaller size on the northern and eastern slopes of these mountains. It commonly attains 200 feet in height; and often grows to 250 feet; Sheldon says, even to 300 feet.

In the Cascade Range Forest Reserve¹ the noble fir forms about 6 per cent of the total, and is an important element in the mixed forests of the middle zone on the western slope, where it often comprises 15 or 20 per cent of the forest. It crosses the summit in lat. 45° where a moist climate prevails, but cannot compete with pine and larch in the drier areas. It is closely associated with the lovely fir, and among lumbermen both species are called larch. Some individuals attain as much as 8 feet in diameter, but the average size is about 150 feet high by 12 feet in girth at the base. Langille states² that this tree cannot hold its own against the lovely fir (*A. amabilis*) and hemlock, which are superseding it, and that a sapling is seldom seen. A tree growing at 6000 feet elevation was 163 years old and 125 feet in height, with a diameter of 4 feet 5 inches at the base.

In the forests of Mt. Rainier in Washington, Plummer says that the noble fir is the finest timber tree and is found from 1800 to 5200 feet. The largest that he measured was 225 feet by 18 feet. But when I ascended this mountain from Longmire's Springs I did not see it, or perhaps I did not distinguish it in the absence of cones from *Abies amabilis*. In the watershed of the Washougal and Rock Creek rivers, however, which are very heavily timbered, it forms, according to Plummer, 25 per cent of the timber. The cones here measure about $4\frac{1}{2}$ inches long by $2\frac{1}{4}$ inches wide, not so large as some I have seen in England.

I saw this tree at its best in the Cascade Mountains above Bridal Veil in northern Oregon in June 1904. In this district the tree is known to the lumbermen as larch, and grows in thick forest, more or less mixed with Douglas fir and hemlock; with *Acer circinatum* and other shrubs as underwood, where there is light enough for any to exist. The largest trees I saw here were above 200 feet in height, and were clear of branches for at least two-thirds of their height, as in the illustration, which was taken from a tree at this place which measured 210 feet by 13

¹ *Forest Conditions of the Cascade Range Forest Reserve, U.S. Geological Survey, Washington, 1903.*

² *Ibid.* p. 35.

feet. (Plate 221.) A stump close by showed 360 rings on a diameter of 4 feet, the first fifty being twice as wide as any of the later ones. I could find no seedlings of the noble fir in this part of the forest, and my guide said that he had seen none except at higher elevations.

The wood of this tree, though not of equal value to that of Douglas fir, is beginning to be more appreciated, and I saw it being cut up at the mill at Bridal Veil where the owner, Mr. Bradley, told me it was worth twenty to twenty-five dollars per 1000 feet, and was sent east to be used for the same purposes as white pine.

HISTORY

This tree was discovered by David Douglas on the south side of the Columbia river in September 1825, and introduced by him five years later on his second journey. Ravenscroft,¹ after quoting Douglas's account of the collection of the seeds, which was published in the *Companion to the Botanical Magazine*, vol. ii. p. 130, says that the seeds arrived in good condition, and were successfully grown and distributed among the Fellows of the Royal Horticultural Society for whom at that time Douglas was working. "Extravagant prices were paid for the plants, fifteen and twenty guineas being then no unusual price." As it usually does, the demand called forth a supply, but for a long time this supply was in a great measure obtained by making grafts and cuttings from the older plants. Plants grown from this source, however, seldom have the same beauty as seedling trees.

The next importation was a small package of seed sent by Mr. Peter Banks, who was drowned soon after. After him Jeffrey sent a quantity to the Oregon Association, but not a plant came up, as the seeds had been destroyed in the cone by the larva of a hymenopterous insect, *Megastigmus pini*, and the same thing happened to the greater part of the seeds sent by William Murray and Beardsley. Afterwards Lobb and Bridges sent more consignments.

Ravenscroft says that plants raised from home-grown seeds are not so strong and healthy as those from imported seed, and have often died from a fungoid attack.

CULTIVATION

Among the silver firs of North America none has had a greater success as an ornamental tree than this, but it is only after many years of cultivation that we are able to say with confidence, what are the conditions of soil under which it will preserve its beauty.

When first introduced it became so popular that seedlings could not be procured in sufficient quantity to supply the demand, and grafting was resorted to by nurserymen; the silver fir being usually the stock selected. These trees grew well for a good many years, and some grafted trees are still thriving; but the majority of

¹ In Lawson, *Pinet. Brit.* ii. 184.

them have shown a tendency to produce cones in such quantity and so prematurely, that the trees have ceased to produce a straight leader, and have often become unsightly and ragged. This applies specially to those which were planted on lawns or on pleasure-grounds, without much shelter.

An avenue of this tree was planted in 1868 at Madresfield Court, Worcestershire, with grafted trees of the glaucous variety from the Worcester nurseries. It was figured in Veitch's *Manual of Coniferae*, ed. 2, p. 524. Though every care has been taken by top-dressing, and removing the cones to keep these healthy, they do not seem likely to remain so, as the lateral branches are, in many cases, covered with the knotty swellings described under *Abies amabilis*, p. 784, note 1.

Mr. W. E. Gumbleton of Belgrove, near Queenstown, tells me that many years ago when *Abies nobilis* was still scarce, the Duke of Leinster, whose tree was one of the first to produce cones, sold the seed of it for £40. The cones were artificially fertilised by shaking out the pollen from the male catkins at the foot of the tree, and dusting it from a ladder on the female flowers at the top.

It is often stated that this is one of the few silver firs which grows well on limestone, but my own experience disproves this, and I have never seen a really fine tree where there was much lime in the soil. A deep sand resting on rock or a hill-side, where good drainage is combined with plenty of humus, seem to be the best conditions for the noble fir; and if the glaucous variety, of which seedlings are difficult to obtain, is desired, I would graft it on *A. Nordmanniana*, which is usually a most vigorous grower, and endures spring frosts better than the common silver fir.

In woods the noble fir is often healthier than in the open, and in some cases has reproduced itself, though not abundantly. I have raised numbers of seedlings from grafted trees, but they were always sickly and died young on my soil, and in any case their growth is slow at first, six to ten years being required to produce trees fit to plant out. But in Scotland seedlings raised from home-grown seed are healthy and vigorous.

The tree is quite hardy in all parts of the country, even in the severe climate of upper Deeside, where at Balmoral it thrives well, and has endured several degrees below zero without injury.¹ It enjoys a fairly wet climate, but will also grow well in the drier parts of England if the soil is deep and cool.

REMARKABLE TREES

The largest noble fir that I know of in England is at Tortworth, where, on a deep bed of sand sloping down to the lake, it had attained in 1901 a height of about 100 feet and 9 feet 6 inches in girth in forty-seven years from the date of planting.

¹ *A. nobilis*, one of the hardiest and best wind-resisting conifers in cultivation, thrives well on gneiss or granite, and may be planted on the most exposed sites. It is the most prolific of all silvers in seed bearing, and readily reproduces itself. Commercially it may be placed next to *A. grandis* amongst exotic firs. The timber, like all the west North American trees of the genus, is white, soft, and light, but closer in texture than *A. grandis*. Root formation ruined by frequent transplanting.—(J. D. CROZIER.)

This tree has suffered to some extent from an attack of Chermes, with which the trunk was covered in 1903, but when I last saw it this had mostly disappeared. Lord Ducie had the tree accurately measured by a man climbing it in May 1908, and informs me that it was then 103 feet 9 inches high, by 9 feet 11 inches in girth. It was planted in 1854, and was 7 feet high in 1855 and 23 feet in 1864.

At Highnam Court, Gloucestershire, there is also a fine specimen in the pinetum, measuring 75 feet by 8 feet, but the trees here seem, as they do in many other places, to have nearly exhausted the soil they grow in, and are beginning to go off. At Miserden Park, the seat of A. Leatham, Esq., in the same county, there is an avenue of grafted trees on dry oolite soil, which were so laden with cones in the year 1900 that they have suffered much in consequence, though hitherto they have borne the exposed situation well.

At Chatsworth Mr. Robertson has measured a tree 85 feet by 8 feet 5 inches with a fine clean stem containing 195 cubic feet. At Walcot, the seat of the Earl of Powis, in Shropshire, I measured in 1906 a very fine glaucous specimen which, though grafted, was 86 feet by 10 feet 9 inches. At Beauport, Sussex, there is a tree, also grafted, 86 feet by 8 feet 1 inch in 1905. At Linton, Kent, there is a tree 90 feet by 8 feet 6 inches in 1902. At Barton there is a tree 80 feet by 7 feet, sheltered in a high wood, and growing fast.

In Fulmodestone Wood, on the Earl of Leicester's property, there is a tree 74 feet by 9 feet 6 inches, from which a self-sown seedling has sprung up, which at eleven to twelve years old was, in 1903, 3 feet 6 inches high; another self-sown seedling in the same place was 20 feet high at about 23 to 25 years old.

At Sandringham there are two fine trees in a shrubbery near York House, the largest of which, in October 1907, measured 85 to 90 feet by 8 feet 10 inches.

At Twizell, Northumberland, once the property of Selby, the author of *British Forest Trees*, I saw in 1906 a tree 80 feet by 8 feet, the top of which, however, was damaged by wind.

In Wales it seems to thrive well both at Penrhyn and Hafodunos, in the north; and at Dinas Mawddwy in Merionethshire, where in 1906 I measured a very flourishing tree 75 feet by 5 feet 8 inches.

In Scotland¹ it generally succeeds better than in England, and where it has sufficient shelter seems likely to attain a great size and age. By far the finest that I have seen, are some trees growing at the foot of a sheltered bank on deep sandy soil, in the Dolphin walk at Murthly, four of which certainly exceed 100 feet in height, and the tallest was, as nearly as I could measure it, from 105 feet to 110 feet by 7 feet 11 inches in September 1906.

A tree growing at Ballindalloch Castle, Banffshire, the seat of Sir J. Macpherson-Grant, is said to be the finest in the north of Scotland, and is stated to have measured in August 1907, 94 feet by 9 feet 11½ inches, and to be only forty-seven years planted.¹

The next largest we have seen is at Keir,² Perthshire, which was, in 1905, 99

¹ *Trans. Roy. Scot. Arb. Soc.* xxi. 98 (1908).

² This tree was reported to be forty years old in 1891, and then measured 82 feet by 5 feet 8 inches (*Journ. Roy. Hort. Soc.* xiv. 531 (1892)).

feet high by 7 feet 5 inches in girth, remarkable for its clean stem and short branches occurring only on the upper half of the tree. Another tree at Keillour, in the same county, was 91 feet by 7 feet 1 inch in 1904; and at Castle Kennedy, Wigtonshire, another measured in the same year 80 feet by 7 feet 10 inches. Sir Archibald Buchan-Hepburn reports one at Smeaton-Hepburn, East Lothian, which measured, in 1908, 84 feet by 8 feet 10 inches. It was planted in 1843.

At Blair Castle, a tree planted by the Duke of Atholl about forty-two years ago was, in 1904, 70 feet by 5 feet; and at Balmoral, though of no great size, it seems to be the best of the silver firs, and has endured a temperature of -15° without injury.

In Ireland, *Abies nobilis* thrives well. At Churchill, Armagh, there is a magnificent specimen, which in 1904 was covered with cones, and measured 73 feet by 8 feet 4 inches. At Curraghmore, Co. Waterford, a tree measured, in 1907, 75 feet in height by 10 feet in girth. At Powerscourt, a tree in 1903 was 59 feet by 6½ feet. At Carton, in the same year, a tree measured 61 feet by 6 feet. At Birr Castle, King's County, there is a very tall tree, which was reported¹ in 1891 to be 83 feet high and 6 feet in girth. There is an avenue of this species at Woodstock, Kilkenny; and good specimens are growing at Castlewellan in Down. In a plantation behind the old deer park at Castle Martyr, Co. Cork, there is a very large tree of the glaucous variety, which, though I could not measure the height accurately, seems to be about 75 feet high and is 10 feet 4 inches in girth. (H. J. E.)

ABIES MAGNIFICA, RED FIR, SHASTA FIR

Abies magnifica, A. Murray, *Proc. R. Hort. Soc.* iii. 318, ff. 25-33 (1863); Masters, *Gard. Chron.* xxiv. 652, f. 148 (1885); Sargent, *Silva N. Amer.* xii. 137, tt. 618, 619 (1898), and *Trees N. Amer.* 66 (1905); Kent, *Veitch's Man. Coniferae*, 516 (1900).

Abies nobilis, Lindley, var. *magnifica*, Kellogg, *Trees of California*, 28 (1882); Masters, *Journ. Linn. Soc. (Bot.)* xxii. 189, t. 5, ff. 19-21 (1886).

Abies shastensis, Lemmon, *Garden and Forest*, x. 184 (1897).

Picea magnifica, Gordon, *Pinctum*, 219 (1875).

Pinus magnifica, M'Nab, *Proc. R. I. Acad.* ii. 700 (1876).

Pinus amabilis, Parlatores, in *DC. Prod.* xvi. 2, p. 426 (in part) (1868).

A tree, attaining in America 200 feet in height and 30 feet in girth. Bark, buds, and branchlets similar in all respects to those of *Abies nobilis*.

Leaves on lateral branchlets arranged as in *A. nobilis*; but with the median leaves above not so densely crowded as in that species, portions of the branchlet being visible from above, whereas in *A. nobilis* the branchlet is completely concealed; moreover, these median leaves are appressed to the branchlet at their bases for a shorter distance than in the other species. Leaves longer than in *A. nobilis*, up to about $1\frac{3}{4}$ inch long, $\frac{1}{16}$ inch wide, tapering gradually to the base, uniform in width elsewhere; apex rounded, entire; obscurely quadrangular in section; upper surface with a central ridge and several (often eight) rows of stomata; lower surface with two bands of stomata, each of four to six lines; resin-canals marginal. Leaves on leading shoots erect and acuminate, with long rigid points pressed against the stem. Leaves on fertile branches much thickened, crowded, upturned, acute with short callous tips.

Staminate flowers dark reddish. Pistillate flowers with rounded scales much shorter than their oblong pale green bracts, which end in elongated slender tips.

Cones very large, 6 to 9 inches long, 3 to 5 inches in diameter, cylindrical, but slightly narrowing to the rounded, truncate or retuse apex; purplish-violet when growing, brown when mature, pubescent. Scales fan-shaped; lamina, $1\frac{1}{4}$ to $1\frac{1}{2}$ inch broad, 1 inch long, upper margin rounded and incurved, the sides gradually narrowing to a cordate base; claw nearly $\frac{1}{2}$ inch long, narrowly obcuneate. Bracts, in the usual form of the species, about two-thirds as long as the scale and not exserted; variable in shape; upper expanded part oval, acute or acuminate, terminated by a mucro; claw sharply contracted below the lamina. Seeds brownish, more than $\frac{1}{2}$ inch long, slightly shorter than their pink obovate-cuneate wings.

Var. *shastensis*, Lemmon, *West. Amer. Cone-bearers*, 62 (1895); Sargent, *Silva N. Amer.* xii. 138, t. 620 (1898), and *Trees N. Amer.* 67 (1905).

Var. *xanthocarpa*, Lemmon, *Third Report*, ex Masters, *Journ. Roy. Hort. Soc.* xiv. 193 (1892), and *Gard. Chron.* xli. 114, figs. 51, 52, 53 (1907).

Abies shastensis, Lemmon, *Garden and Forest*, x. 184 (1897); Coville, *Garden and Forest*, x. 516 (1897).

Abies nobilis robusta, Masters, *Gard. Chron.* xxiv. 652, f. 147 (1885) (not Carrière).

Abies nobilis, Lindley, var. *magnifica*, Masters, *Journ. Linn. Soc. (Bot.)* xxii. 193, Pl. 5 (1886).

This differs from the type only in the cones, which have much longer bracts, yellow in colour, rounded or obtusely pointed (not acute), exserted, usually reflexed, and covering about half the outer surface of the scales.

This variety, which is known as the Shasta Fir, occurs on the mountains of southern Oregon, in the cross and coast ranges of northern California and on the southern Sierra Nevada. In Oregon it is met with in the lower parts of the mountains; but in the other localities it only occurs at very high elevations.

It is rare in cultivation in England, or at any rate has been rarely noticed. A tree at the Cranston Nursery, near Hereford, produced cones¹ of this kind in 1878, which were figured² by Dr. Masters. Another is growing at Durris Castle, Aberdeenshire, where Mr. Crozier states that intermediate forms between this and *A. nobilis* exist.

IDENTIFICATION

This species is only liable to be confused with *A. nobilis*; but in large trees, as seen in cultivation, the difference in habit between the two species is remarkable. The formal arrangement of the branches in *A. magnifica*, though difficult to describe, when once seen can seldom be mistaken. The differences in the foliage are given in the Key, p. 718. (A. H.)

DISTRIBUTION

The most northerly point at which this tree has been found is on the mountains east of Odell Lake in about lat. 44° N. in southern Oregon, where Dr. Coville collected it in 1897, many miles south of where *A. nobilis* occurs; and it is not mentioned among the trees of the Cascade Forest Reserve, so that it really belongs to the Californian rather than to the North Pacific flora. It becomes common on the Trinity Mountains, and on Mt. Shasta is the only fir besides *A. Lowiana*. The tree extends along the entire length of the western slope of the Sierra Nevada, from 6000 to 9000 feet above the sea, and extends to the eastern slope at high elevations.

The northern form has been separated by Lemmon under the name of *A. shastensis*, on account of the bracts which protrude from the scales; being in this respect, as in its geographical distribution, midway between *A. nobilis* and *A. magnifica*;

¹ *Gard. Chron.* 1878, p. 343.

² *Journ. Linn. Soc. (Bot.)* xxii. 193, plate v. (1886).

but this character is variable, and I judged from the specimens shown me by Miss A. Eastwood, that the two forms cannot always be defined.

On the west slopes of Mount Shasta the tree occurs higher up than *A. Lowiana*, mixing with it at about 6000 feet, and at 8000 feet it is the only species of fir. It is not on Mount Shasta a very large tree, the biggest that I measured being not much over 100 feet in height, and 15½ feet in girth, the average being 80 to 100 feet high, by 6 to 8 feet in girth. I could not see very much difference in the bark; though *A. magnifica* is known as the red, and *A. Lowiana* as the white fir, but the very much larger cones of the former distinguish it at once. These were borne only near the summit of the trees, and could only be procured by shooting them off with a rifle, or by felling trees on purpose. They were fully formed but unripe in the first week of September. The soil here was very rocky, and drier than that of any mountain which I have ascended in this latitude; and there was little herbaceous vegetation, though the snow is said to lie deep from November until May or June.

INTRODUCTION

This species was introduced in 1851 by John Jeffrey, who believed it to be *A. amabilis*; and the seedlings were distributed under this name amongst the members of the Scottish Oregon Association. The tree in Scotland is frequently labelled *A. amabilis*, in consequence of this error.

W. Lobb¹ sent seed in 1852, also under the name of *A. amabilis*; but later on the plants were found to differ from that species, and were distributed by Messrs. Veitch as *A. nobilis robusta*.

REMARKABLE TREES

Though it is quite possible that larger trees exist, which have been mistaken for *A. nobilis*, yet we have identified none in England which at all approach that species in size, and all the best we have seen are in the eastern and southern counties. The largest perhaps is one at Fulmodestone, Norfolk, a handsome and well-shaped tree growing in a damp soil and well sheltered situation, which in 1905 was 61 feet by 5 feet 9 inches, and bore cones near the summit.

At Bayfordbury, on a much drier soil, it has flourished better than *A. nobilis*, and in 1905 was 56 feet by 5 feet 9 inches (Plate 222). Mr. H. Clinton Baker recently measured a good specimen, 61 feet by 4 feet 4 inches, at Flitwick Manor; and another, 60 feet by 4 feet 9 inches at High Leigh, near Hoddesdon. At Grayswood, Haslemere, a tree planted as recently as 1881, measured in 1906 56 feet by 4 feet 11 inches; and at Petworth, in 1905, there was a slender and less vigorous tree 47 feet by 3 feet 1 inch.

At Eridge Park, Kent, a tree planted in 1880 by Count Gleichen was, in 1905, 34 feet by 3½ feet.

In a pinetum close to Presteign, Radnorshire, planted about fifty years ago,

¹ *Hortus Veitchii*, 336 (1906).

now the property of Mr. J. H. Wall, I saw a good specimen of *Abies magnifica* in 1906, which measured 53 feet by 5 feet 7 inches.

The largest reported¹ at the Conifer Conference in 1891 was at Revesby Abbey, Lincolnshire, and then measured only 40 feet by 5 feet.

In Scotland it is more numerous and larger. The late Malcolm Dunn, who had an exceptionally wide experience in the cultivation of conifers in Great Britain, wrote of it as follows in a paper² which he sent to the Conifer Conference:—"It is in truth a stately tree and one of the handsomest of all the taller-growing conifers for ornamental purposes. It is one of the very hardiest of the firs, and is seldom affected by spring frost, and the timber being straight, clean-grained, and of good quality, it will no doubt be a useful forest tree." But this latter opinion has not so far received any proof so far as we know, for the tree is, and seems likely to remain, difficult to obtain, and like most of its congeners is slow and costly to raise from seed.

Probably the finest trees in Scotland are one at Durris,³ Aberdeenshire, which was, in 1904, 80 feet high by 6 feet 6 inches in girth, and when I measured it in 1907 had increased to about 85 feet; and another (Plate 223) at Bonskeid, near Pitlochry, of which Mr. J. Forgan has been good enough to send me a photograph, and which measured, in 1908, 87 feet by 8 feet. When he first knew it thirty-five years ago it was about 12 feet high; it has not produced cones. Mr. Bean⁴ noticed in 1906 a tree at Abercairney 70 feet high, and another at Blair Castle 60 feet high.

At Farthingbank, Drumlanrig, there is, growing on clay loam at 650 feet above sea-level, a tree 50 feet by 5 feet 3 inches in 1905, which was planted, according to Mr. Menzies, the forester, thirty-one years previously.

The tree is rare in Ireland, but there is a specimen⁵ at Castlewella, which was 47 feet by 6 feet in 1906; and at Powerscourt, a tree, planted thirty-five years ago, was 57 feet by 6 feet 8 inches in 1906, and is said to bear cones nearly every year.

(H. J. E.)

¹ *Journ. Roy. Hort. Soc.* xiv. 568 (1892).

² *Journ. Roy. Hort. Soc.* xiv. 83 (1892).

³ *A. magnifica* closely resembles *A. nobilis*, but in strong contrast as regards seed-bearing. It does not seem as if the tree is likely to become acclimatised in this respect as, although planted in considerable numbers throughout the policy grounds and plantations, and most of those trees now between fifty and sixty years of age, cones have been produced only on one occasion, and that on only a few trees. The timber when closely grown is closer in texture, richer in colour, and better in quality than *A. nobilis*. Like that species it is impatient of side shade and sheds its branches freely. Constitutionally it is less robust than its near relative, and also less accommodating in its demands on site and soil.—(J. D. CROZIER.)

ABIES BRACTEATA, BRISTLE-CONE FIR

Abies bracteata, Nuttall, *Sylva N. Amer.* iii. 137, t. 118 (1849); Hooker, *Bot. Mag.* t. 4740 (1853); Masters, *Gard. Chron.* v. 242, f. 44 (1889), and vii. 672, f. 112 (1890); Kent, Veitch's *Man. Conifera*, 493 (1900).

Abies venusta, Koch, *Dendrol.* ii. 210 (1873); Sargent, *Silva N. Amer.* xii. 129, tt. 615, 616 (1898), and *Trees N. Amer.* 63 (1905).

Pinus venusta, Douglas, *Comp. Bot. Mag.* ii. 152 (1836).

Pinus bracteata, Don, *Trans. Linn. Soc.* xvii. 442 (1837).

Picea bracteata, Loudon, *Arb. et Frut. Brit.* iv. 2348 (1838); Coleman, *Garden*, xxxv. 12, with fig. (1889).

A tree attaining in America 150 feet in height and 9 feet in girth. Bark brown, smooth; becoming, near the base in old trees, slightly fissured and broken into thick appressed scales. Buds unique in the genus, elongated, fusiform, broadest near the base, and gradually tapering to a sharp point, about $\frac{1}{2}$ to $\frac{3}{4}$ inch long, brown in colour, non-resinous; scales thin, membranous, glabrous, loosely imbricated, obtuse at the apex, shorter at the base of the bud, gradually lengthening above. Young shoots glabrous, greenish, with slightly raised pulvini and inconspicuous furrows. Base of the shoots usually ringed with the scars of the previous season's bud-scales, which in most cases all fall off and do not persist in part, as is usual in other species.

Leaves on lateral branches pectinately arranged, those below spreading outwards in two sets in the horizontal plane; those above slightly shorter, falcate, directed outwards and slightly upwards and forwards, forming a shallow V-shaped depression on the upper side of the branchlet. Leaves, up to 2 inches long, $\frac{1}{10}$ inch wide, rigid, thin, flat, linear, ending in long spine-like cartilaginous points, never bifid; widest in the lower third, gradually tapering to the apex, and abruptly narrowed close to the base; upper surface dark-green, shining, slightly concave in the lower half and flat near the apex, no definite median groove being formed; lower surface with two wide white bands of stomata, each of 10 to 12 lines; resin-canals marginal. Leaves on cone-bearing branches upturned, falcate.

Male flowers, $1\frac{1}{4}$ to $1\frac{1}{2}$ inch long, cylindric, shortly-stalked, surrounded at the base by numerous lanceolate, fawn-coloured parchment-like scales, similar to those of the leaf-buds. Pistillate flowers, with oblong scales rounded above and nearly as long as the cuneate obcordate yellow-green bracts, which end in slender elongated awns.

Cones, remarkable for the long spiny rigid tips to the bracts, ovoid, rounded and full at the apex, 3 to 4 inches long, about 2 inches in diameter, glabrous,¹ resinous, purplish brown. Scales, about 1 inch broad by $\frac{1}{2}$ inch long, almost reniform; upper margin incurved, with a short obtuse denticulate cusp; claw obcuneate. Bracts oblong-obovate, adnate to the scale to beyond the middle and

¹ Remarkable, as all the other species of *Abies* have the scales of the cones pubescent.

deciduous with it, terminating in linear, rigid spines, 1 to 2 inches long, which in the upper half of the cone point towards its apex, and in the lower half are spreading and often recurved. Seeds dark reddish-brown, about $\frac{3}{8}$ inch long and nearly as long as their pale reddish-brown shining wings. (A. H.)

DISTRIBUTION AND HISTORY

Abies bracteata has perhaps the most restricted distribution of all the silver firs, as, according to Sargent, it only occurs in a few isolated groves along the moist bottoms of cañons at about 3000 feet elevation on both slopes of the western ridge of the Santa Lucia Mountains in Monterey County, California. The most northerly point where it is now known to grow is in Bear Cañon, twenty-five miles south of the Los Burros mines; the other localities mentioned by Sargent are in the San Miguel Cañon and in a gorge at the head of the Nacimiento river.

The discovery of this tree is assigned by Don, Sir W. J. Hooker,¹ and Sargent to Dr. T. Coulter, who, according to a letter² of Douglas to Hooker dated November 23, 1831, arrived at Monterey after he began the letter in question. Douglas also, in a letter³ dated October 1832, states⁴ that he found the tree, which he called *Pinus venusta*, in the preceding March "on the high mountains of California," and that it is never seen at a lower elevation than 6000 feet above sea-level, in lat. 36°, where it is not uncommon.

But Kent says,⁵ in a note, that a comparison of the dates shows that Douglas was the first discoverer, which, however, is not proved; as, according to Douglas's own showing, Coulter was at Monterey, near to the place where the tree grows, three months before Douglas found the tree himself. Prof. Hansen⁶ also has incorrectly stated the date of Douglas's discovery of this tree as March 1831 instead of March 1832.

William Lobb, when collecting for Messrs. Veitch in 1853, introduced it to cultivation, and in a letter in *Gardeners' Chronicle*, 1853, p. 435, describes it as "the most conspicuous ornament of the arborescent vegetation. On the western slopes, towards the sea, it occupies the deep ravines, and attains the height of from 120 to 150 feet, and from 1 to 2 feet in diameter, the trunk as straight as an arrow, the lower branches decumbent. The branches above are numerous, short, and thickly set, forming a long tapering pyramid or spire, which gives to the tree that peculiar appearance not seen in any other kind of the *Pinus* tribe. Along the summit of the central ridges, and about the highest peaks, in the most exposed and coldest places imaginable, where no other pine makes its appearance, it stands the severity of the climate without the slightest perceptible injury, growing in slaty rubbish, which to all appearance is incapable of supporting vegetation. In such situations it becomes stunted and bushy. The cones are quite as singular as the growth of the tree is beautiful; when fully developed the scales, as well as

⁴ *Ibid.* 152.

⁶ *Journ. Roy. Hort. Soc.* xiv. 459 (1892).

the long leaf-like bracts, are covered with globules of thin transparent resin. Douglas was mistaken in saying that this tree does not occur below 6000 feet elevation; on the contrary, it is found as low as 3000 feet, where it meets *Taxodium sempervirens*."

In 1856 another expedition to collect seeds was made by W. Beardsley, who gives a good account of his journey, which is quoted from by Murray.¹ In the middle of October the seeds were already shed, and Murray says that Mr. W. Peebles, who went for the same purpose on September 17, 1858, found the cones so ripe that when the tree was felled they fell to pieces.

According to Beardsley, the soil on which it grows is "exclusively the calcareous districts, abounding with ledges of white, veined, and grey marble."

CULTIVATION

A. bracteata has never been a common tree in English gardens and, owing to the difficulty of procuring seeds in California, it is rarely to be had from nurseries. It seems to be quite hardy as regards winter cold, but susceptible to spring frosts; and all the good specimens I have seen are in sheltered and rather elevated situations on well drained soil.

The seedlings which I have raised from English-grown seeds have not thriven on my soil, though the tree does not appear to dislike a moderate amount of lime. All the best specimens we know of are in the south and west of England, and in Ireland. A list of them is given by Kent,² and they all are probably of about the same age, being raised from William Lobb's seeds by Messrs. Veitch in 1854.

REMARKABLE TREES

The finest trees in England are in the valley of the Severn, the largest being at Eastnor Castle (Plate 224), where two are growing. They were stated³ by the late Mr. Coleman to have been planted in 1865, and the best of them was 40 feet high in 1889. It first bore cones in 1888; when I measured it last in 1908, I found it to be 78 feet by 9 feet, and though very healthy and handsome in appearance, the top had become forked. It bore cones freely in 1900, from which I raised numerous seedlings, but these have grown very slowly, and do not seem able to make roots freely on my soil.

At Highnam Court, Gloucester, the seat of Sir Hubert Parry, there is another fine tree, difficult to measure on account of its situation, but, in 1908, I made it 64 feet by 6 feet 5 inches. It has several times produced cones, four being borne in 1907, from which seedlings were raised.

At Tortworth Court there is a tree which Lord Ducie believes to have been planted between 1858 and 1862, and in 1908 was 63 feet by 6 feet. It is growing on old red sandstone, about 250 feet above sea level in a situation much exposed to the south-west wind.

¹ *Edin. New Phil. Journ.* x. 1, pls. 1 and 2 (1859).

² Veitch's *Man. Conifera*, loc. cit.

³ *Garden*, 1889, xxxv. 12.

At Nevill Court, near Tunbridge Wells, I measured a tree which, though only 48 by 4½ feet in 1906, is one of the best shaped I have seen, with a very slender spire, as described by Lobb in California.

At Fonthill Abbey there is a tree about 72 feet by 5½ feet, in a sheltered though elevated situation on greensand. At Osborne, in the Isle of Wight, a tree was 60 feet by 5 feet 9 inches in 1908, but this does not appear to be thriving, on account perhaps, of the dry soil.

At Ponfield, Hertford, the seat of P. Bosanquet, Esq., Henry saw in 1906 a tree, very thriving and about 25 feet in height; and in the same district, at High Canons, near Shenley, Mr. Clinton Baker showed me a tree 53 feet by 4 feet which bore about twenty cones in 1907. At Pampisford, Cambridgeshire, there is a tree, about 25 feet high, growing in a sheltered position, and very thriving.

At Monk Coniston, in Westmoreland, the seat of Victor Marshall, Esq., I have seen a tree which has borne cones, and which measured, in 1906, 60 feet by 5 feet.

Several others are mentioned by Kent: at Kenfield Hall,¹ near Canterbury; at New Court, and at Streatham, near Exeter; at Upcott, near Barnstaple; and at Warnham Court, near Horsham. A large tree at Orton Hall, Peterborough, was, before it was cut down in 1905, 59 by 6 feet, but became unhealthy owing to the soil being too heavy.

In Wales, where the species should grow well, I have seen no trees of any size.

In Scotland the only specimens I have seen are at Castle Kennedy and at Cawdor Castle, neither of which are large, and the climate of Scotland generally seems to be too cold for it.²

In Ireland Henry has seen specimens at Fota, in the south-west, a fine young tree which, in 1903, was 48 feet by 4 feet; at Castlewellan, in the north-east, another, in 1906, was 35 feet by 3 feet 2 inches; and a smaller one also exists at Glasnevin.

On the continent of Europe this tree is very rare, the only fine one I have seen being a tree at Pallanza in the nursery grounds of Messrs. Rovelli, which, in 1906, was about 70 feet by 7 feet, but not very healthy and bearing no cones.

M. Pardé states that there is a fine specimen in the domain of the National Society of Agriculture at Harcourt (Eure); and I saw a small one in M. Allard's collection at Angers. (H. J. E.)

¹ This tree produced cones in 1886. Cf. *Gard. Chron.* xxvi. 85 (1886).

² The one specimen now remaining at Durris—between forty and fifty years of age—if it can possibly be taken as a fair example of the growth of the tree in this locality, proves it of little use for planting. It is quite healthy, but its growth is slow in proportion to that of *A. pectinata*.—(J. D. CROZIER.)

ABIES LASIOCARPA, ROCKY MOUNTAIN FIR

Abies lasiocarpa, Nuttall, *Sylva*, iii. 138 (1849); Masters, *Gard. Chron.* v. 172, ff. 23-27, 32, (1889), and *Journ. Bot.* xxvii. 129 (1889); Sargent, *Silva N. Amer.* xii. 113, t. 611 (1898), and *Trees N. Amer.* 61 (1905); Kent, Veitch's *Man. Coniferae*, 515 (1900).

Abies bifolia, Murray, *Proc. Roy. Hort. Soc.* iii. 320 (1863).

Abies subalpina, Engelmann, *Am. Nat.* x. 555 (1876).

Abies arizonica, Merriam, *Proc. Biol. Soc. Wash.* x. 115, ff. 24, 25 (1896).

Pinus lasiocarpa, W. J. Hooker, *Fl. Bor. Am.* ii. 163 (1839).

Picea bifolia, Murray, *Gard. Chron.* iii. 106 (1875).

Picea lasiocarpa, Murray, *Gard. Chron.* iv. 135 (1875).

A tree, attaining occasionally 175 feet in height, with a trunk 15 feet in girth, but usually not over 80 to 100 feet high. Bark of young trees smooth and silvery grey; of old trees shallowly fissured and roughened by reddish brown or whitish scales; in some trees becoming corky and white in colour. Buds small, about $\frac{1}{4}$ inch long, ovoid-conical, obtuse at the apex, brownish, resinous; scales embedded in the resin but roughening the surface of the bud by their raised tips. Branchlets swollen at the nodes, those of the first year ashy grey, smooth, and covered with a moderately dense short wavy pubescence. Branchlets of the second year retaining some pubescence, darker grey, smooth, with the bark slightly fissuring.

Leaves on lateral branchlets irregularly arranged; sometimes irregularly pectinate with some of the leaves above and below not directed outwards, but forwards at an angle with the axis of the shoot; usually with most of the leaves directed upwards, those in the middle line above covering the shoot and standing edgeways with their apices almost vertical, a few leaves in the middle line below pointing forwards and downwards. Leaves linear, up to $1\frac{1}{2}$ inch long by $\frac{1}{2}$ inch broad, uniform in width except at the gradually tapering base; apex rounded and either entire or with a slight emargination; upper surface with a shallow continuous median groove, and with four to five lines of stomata on each side of the groove in its anterior half, the lines fewer in number and broken in the basal half; under surface with two bands of stomata, each of six to eight lines; resin-canals median. The stomatic lines above give the foliage a glaucous appearance; the bands below vary very much in whiteness. Leaves on leading shoots closely appressed to the stem with their tips directed forwards, flattened in section, and ending in long slender rigid points. Leaves on cone-bearing branchlets upturned, directed forwards, usually acute and not more than $\frac{1}{2}$ inch long.

Cones sub-sessile, cylindrical; rounded, truncate or depressed at the slightly narrowed apex; 2 to 4 inches long by $1\frac{1}{2}$ inch in diameter, dark purple and tomentose, with the bracts concealed.¹ Scales very variable in size and shape, from $\frac{7}{8}$ inch long by $\frac{3}{4}$ inch wide to $\frac{1}{2}$ inch long by 1 inch wide: lateral margins rounded or with sinuses, usually auricled on each side of the short obtuse claw. Bract situated at the base of the scale or slightly above it, quadrangular or

¹ According to Piper, *Contrib. U.S. Nat. Herb.* xi. 93 (1906), cones on trees growing in the Olympic Mountains have exserted bracts.

orbicular, denticulate, emarginate with a long slender mucro. Seed $\frac{1}{4}$ inch long, with dark purplish shining wings, which vary in length according to the height of the scale which they cover almost completely.

Var. *arizonica*, Lemmon, *Bull. Sierra Club*, ii. 167 (1897); Masters, *Gard. Chron.* xxix. 86, 134, ff. 52, 53 (1901).

Abies arizonica, Merriam, *Proc. Biol. Soc. Wash.* x. 115, ff. 24, 25 (1896); Purpus, *Gartenwelt*, v. 4, 26 (1896).

This form occurs in the San Francisco mountains in Arizona, where it is common between 8500 and 9500 feet elevation, and occasionally ascends to 12,000 feet. It is remarkable for the creamy-white thick corky bark of the trunk. As seen in cultivation, young plants differ from the type, in the leaves being emarginate at the apex, whiter beneath, and more regularly pectinate in arrangement. Sargent¹ states that bark equally corky occurs in trees of *Abies lasiocarpa* in other regions, as in Colorado, Oregon, South Alberta, and British Columbia; and, as there is no difference in the cones, he does not assign even varietal rank to the Arizona tree.

The best account of this variety is by Prof. Purpus in *Mitt. D. D. Ges.*, No. 13, p. 47 (1904), who visited the San Francisco mountains in 1901, and introduced the tree to Europe. It seems to be a strictly alpine tree, growing on basaltic and trachytic rocks, where the soil is never quite dry, either scattered or mixed with *Populus tremuloides*, *Pinus flexilis*, *Pseudotsuga Douglasii*, and *Picea Engelmanni*. It attains a height of 60 to 70 feet with a girth of 6 to 9 feet. The bark is very corky and corrugated, in old trees milk-white or silver-grey in colour. It is replaced in these mountains at 7000 to 8000 feet by *Abies concolor*.

This form has only recently been introduced into cultivation. Plants were for sale in the Pinehurst Nurseries, North Carolina, in 1901; and Dr. Masters saw a stock of young plants in Moser's nursery at Versailles in 1903. It is too soon yet to form any opinion as to the suitability of this variety for ornamental gardening.

IDENTIFICATION

Abies lasiocarpa is perhaps most readily distinguished by the conspicuous bands of stomata on the upper surface of the leaf, which separate it clearly from the other species² with median resin-canals and long narrow leaves. The following points are also noteworthy:—the irregular arrangement of the leaves, which are usually quite entire at the apex; the ashy-grey pubescent shoots; and the resinous obtuse buds.

(A. H.)

DISTRIBUTION

This is essentially the alpine fir of the Rocky Mountains and higher ranges on the west coast of North America, and is the most widely distributed fir of the New World, occurring from about lat. 61° N. in Alaska to Arizona and New Mexico. It does not occur in California.³ In the west it extends to the summits of the Olympic

¹ *Silva*, xii. 113.

² As *A. sibirica* and *A. sachalinensis*, which it somewhat resembles in general appearance.

³ U.S. Forest Service, *Sylvical Leaflet* 1, Alpine Fir.

Mountains in Washington, and in the east to the mountains of Idaho, Montana (Plate 225), Wyoming, Colorado, and Utah. Everywhere it grows up to or very near the timber line, and on the shores of Lake Bennett in northern British Columbia descends to 2500 feet. In Colorado it reaches 10,000 feet.

Macoun states that it crosses the Rocky Mountains into the Peace River region, and the country between the Little Slave Lake and the Athabasca River; and that in the Rocky Mountains of Alberta it occurs with *Picea Engelmanni*, but is less common; and in a letter states that it is an enormous tree at Glacier, but becomes dwarfed at higher elevations, ascending to 7000 feet in that region.

Wilcox¹ writes of it as follows:—

“The balsam fir has about the same range as the white spruce (*Picea Engelmanni*) but is less common. At a distance it is hardly to be distinguished from the spruce, but the bark on branches and young trees is raised in blisters which contain a drop or two of balsam. This balsam exudes from the bark wherever it is bruised. At first it is a very clear liquid, regarded by old trappers and woodsmen as a certain cure, when brewed with hot water, for colds and throat troubles. On exposure to the air it hardens into a brittle resin, which the woodsman melts into pitch to seal boxes or mend leaky canvas. The camper-out makes his bed from balsam boughs, as they are more springy and less rigid than those of the spruce.”

I saw this tree in perfection in the Paradise valley on the south-west slopes of Mount Rainier in August 1904. An excellent illustration of this locality is given by C. O. Piper in *Garden and Forest*, vol. iv. p. 382, which shows the tall slender spiry habit of the fir. Here it lives in company with *A. amabilis* in the lower part of its range, and with *Tsuga Pattoniana*, and *Cupressus nootkatensis* higher up; growing in small clumps and groves, as shown in the illustration referred to. It seems to be a very slow grower, a tree felled by Plummer being only 15 inches in diameter at 125 years old. The tallest that I measured here was 77 feet by 5 feet 8 inches, but Sargent says that it occasionally attains 175 feet in height (probably in the Olympic Mountains). The seedlings, which I usually found growing on rotten logs, were very slow in growth, and must be often eight to ten years old before their roots reach the soil.

HISTORY AND CULTIVATION

Abies lasiocarpa was discovered by Douglas in 1832, and his specimen, which is the type of *Pinus lasiocarpa* of W. J. Hooker, the first name applied to the species, is preserved in the herbarium at Kew.

Seeds were first collected about 1863, by Dr. Parry in Colorado; but it is not known if any plants raised from these still survive. The first plants raised in the Arnold Arboretum date from 1873, the largest of them being now only 10 to 12 feet in height. Roehl collected seeds in 1874 in Colorado.² According to Syme,³ a small

¹ *The Rockies of Canada*, 62 (1900).

² Masters, *Journ. Bot.* xxvii. 135 (1889), refers these seeds doubtfully to New Mexico; but there is no doubt that they were collected in Colorado. Cf. Lavallée's article on *Nouveaux Conifères du Colorado et de la Californie*, in *Journ. Soc. Cent. Hort. France*, 1875.

³ *Gard. Chron.* iii. 586 (1888).

plant of this origin was alive in Perthshire in 1888; but it was only 2½ feet in height, forming a wide spreading bush, though it was growing in rich black loam.

No trees of this species are recorded by Kent; nor were any specimens sent to the Conifer Conference in 1891. It appears to be unsuitable for cultivation in this country. Young trees at Kew, a few feet in height, are stunted and dying. Waterer had a large stock of plants in 1889 in the nursery at Bagshot; but they all did badly and were thrown away, only one or two surviving and showing the same wretched appearance as the young trees at Kew. Plants cultivated some years ago at Glasnevin have since died. Henry, however, lately saw in the Pinetum at Hatfield, Herts, a tree, planted in 1893 when it was about 3 feet high, which is now 20 feet in height and 15 inches in girth. It has thriven well hitherto, but is slightly attacked by knotty disease. The best specimen we have seen is one at Bayfordbury, about 14 feet high, and fairly thriving. A small tree at Ochertyre bore cones in 1906. The tree appears to succeed better in Germany. I have raised seedlings from cones sent by Prof. Allen in 1905 from Mount Rainier. (H. J. E.)

ABIES BALSAMEA, BALSAM FIR

Abies balsamea, Miller, *Dict.* No. 3 (1768); Sargent, *Silva N. Amer.* xii. 107, t. 610 (1898), and *Trees N. Amer.* 58 (1905); Masters, *Gard. Chron.* xvii. 422, figs. 57-60 (1895); Kent, *Veitch's Man. Coniferae*, 492 (1900).

Abies balsamifera, Michaux, *Fl. Bor. Am.* ii. 207 (1803) (in part).

Pinus balsamea, Linnæus, *Sp. Pl.* 1002 (1753).

Picea balsamea, Loudon, *Arb. et Frut. Brit.* iv. 2339 (1838).

A tree, commonly 50 to 60 feet in height and 3 to 5 feet in girth, but sometimes larger, with spreading branches, usually forming an open broad-based pyramid. Bark, greyish brown and with numerous blisters; on old trees broken on the surface into small scaly plates. Buds small, globose or occasionally dome-shaped, reddish, shining and resinous. Young shoots smooth, ashy grey, with very short scattered pubescence; on the shoots of the second year some of the pubescence is retained, and the bark fissures slightly between the pulvini. The branchlets when cut have a very resinous odour.

Leaves on lateral branches pectinately arranged, in two sets directed outwards in the horizontal plane; upper leaves of each set shorter than the others, and directed also slightly upwards, thus forming a shallow V-shaped arrangement. Leaves linear, flattened, uniform in width except at the tapering base; rounded and slightly bifid at the apex, up to about 1 inch long and ½ to ⅓ inch wide; upper surface dark green, shining, with a median continuous groove, and with two or three broken rows of stomata in the middle line towards the apex; lower surface with two narrow, greyish bands of stomata, composed of six to eight lines; resin-canals median. Leaves on cone-bearing branches more or less upturned, stouter and broader than those on barren shoots, acute and not bifid at the apex.

Staminate flowers yellow, tinged with purple. Pistillate flowers with nearly orbicular purple scales, shorter than the serrulate greenish-yellow bracts, which are emarginate above and end in long, recurved tips.

Cones sub-sessile, ovoid-cylindrical, tapering both at the base and towards the round or flattened apex; purple¹ in colour, 2 to 4 inches long, about an inch in diameter. Scales, about $\frac{5}{8}$ inch wide and long; lamina fan-shaped, rounded and undulate above, lateral margins denticulate and curving to the truncate or auricled base; claw wedge-shaped. Bracts variable in length, exserted or concealed between the scales; claw oblong; lamina trapezoidal and denticulate, ending in a mucro. Seeds purplish, about $\frac{1}{2}$ inch long; wing about as long as the body of the seed.

In the wild state considerable variation occurs in the habit of the tree, which becomes a mere shrub at high altitudes. The cones vary both in size and in the length of the bracts, which are either slightly exserted, or quite concealed between the scales. Prof. Balfour found on the same tree at Keillour cones both with long and with short bracts.

Var. *Hudsonia*, Engelmann, *Trans. St. Louis Acad.* iii. 597 (1878).

Abies Hudsonia, Bosc. ex Carrière, *Conif.* i. 200 (1855).

According to Engelmann this is a sterile dwarf form which occurs above the timber line on the White Mountains in New Hampshire. Whether this is identical with the *A. Hudsonia*, which occurs in cultivation, is uncertain. The latter, according to Sargent,² is of unknown origin, but is probably, though it has never produced cones, a depauperate form of *A. balsamea*. It has densely crowded branches, short numerous branchlets, and small broad leaves, about $\frac{1}{4}$ inch in length; and is a dwarf spreading shrub, only a foot or two in height. It differs from *A. balsamea* in having marginal resin-canals.

Var. *macrocarpa*.³ This was discovered near the Wolf River, Wisconsin, and raised by Robert Douglas at Waukegan nursery; it is said to be a distinct and beautiful form with longer leaves and larger cones than the type.

DISTRIBUTION

The balsam fir extends far to the northward in the Dominion of Canada, its northerly limit being a line drawn from the interior of Labrador north-westward to the shores of the Lesser Slave Lake. It occurs in Newfoundland and in the provinces of Quebec and Ontario, and descends in the United States in the west through northern Michigan and Minnesota to northern and central Iowa, and in the east extends through New England and New York, along the Catskill and Alleghany mountains to south-western Virginia. It is common and often forms a considerable part of the forest on low swampy ground, while on well-drained hill-sides it is met with as single trees or small groves chiefly in the spruce forests. It ascends to 5000 feet on the Adirondacks. (A. H.)

¹ In cultivated specimens the cones are occasionally olive-green in colour, and rarely exceed 2 inches in length.

² *Garden and Forest*, x. 510 (1897).

³ *Ibid.* v. 274 (1892) and x. 510 (1897).

REMARKABLE TREES

The most noted trees of this species in cultivation were those growing in the Keillour Pinetum, Perthshire, now the property of Captain Black of Balgowan. This pinetum was visited by Prof. Balfour¹ in 1895, who found about 30 trees still living out of 200, which were planted in 1831. The largest tree was about 60 feet high with a girth of 5 feet 1 inch at three feet from the ground. There were several others over 4 feet in girth. In 1904, when Henry made a hurried visit to the Keillour Pinetum, where there was much of interest to be seen, he only saw one tree of *A. balsamea*, with the top broken and in a dying state. Mr. W. Causand informed him that in 1903 there was a tree 68 feet by 5 feet.

The finest specimen of which we have any account in Great Britain is recorded in the *Conifer Conference Report, Journ. Roy. Hort. Soc.* xiv. 511, as having grown at Saltoun Hall, East Lothian, the seat of A. Fletcher, Esq., until 1891, when it was swept away by a flood on the river Tyne. This tree was supposed to have been given by Bishop Compton, who introduced the species in 1697, to Bishop Burnet, formerly incumbent of the parish of Pencaitland, and was thus something like 190 years old. It was 68 feet high though it had lost its top, and at ten feet from the ground no less than 7 feet 10 inches in girth, and was said to have been healthy and growing vigorously up till the time of its destruction.

In England we have never seen a tree of any great size or age, the largest being at Bicton, 52 feet by 4 feet 4 inches in 1908; and this species seems to have been neglected and forgotten by modern planters, as it is only twice mentioned in the numerous reports sent to the Conifer Conference.

Loudon states that it arrives at maturity in twenty to twenty-five years, after which it soon dies, though he mentions trees of 30 to 40 feet high as then existing at Syon, Whitton, and Chiswick.

It appears therefore to be of no horticultural value in this country, though if the Saltoun report was correct it may be grown successfully in some parts of Scotland.²

In Norway, according to Schübeler, the Balsam fir succeeds better than here. He mentions three at Bogstad near Christiania, planted about 1772, of which the largest was 55 feet by 6 feet 4 inches, and another 8 feet 2 inches in girth; but when I visited this place in 1904 I could not find these trees, and do not know whether they are still living. Hansen³ states that specimens, about 50 years old and 40 feet high, are to be met with in Danish Gardens.

TIMBER, RESIN

Sargent describes the wood⁴ as being light, soft, coarse-grained, and perishable, and only used for cheap lumber. From the blisters on the bark, a straw-coloured

¹ See *Gard. Chron.* xvii. 422 (1895), which gives an interesting account of this remarkable pinetum.

² *A. balsamea* was planted at Durris freely about fifty years ago, the largest trees now being from 40 to 45 feet in height. Timber of good quality, and contains an exceptionally small percentage of water in a green state. I have seen no account taken of the latter fact, but it has been a continual surprise to me in handling timber in a green state.—(J. D. CROZIER.)

³ *Journ. Roy. Hort. Soc.* xiv. 458 (1892).

⁴ H. von Schrenk, in *Missouri Bot. Garden Report*, 1905, p. 117, describes and figures logs of this timber, felled in Maine for pulpwood, which show on cross-section irregular areas, perfectly smooth and shining as if they had been planed.

transparent resin, known as Canada balsam, is collected by Indians and poor whites in the province of Quebec. This resin, which was formerly largely used in medicine on account of its stimulating action on the mucous membrane, is now chiefly used for mounting objects to be examined under the microscope, for which, and kindred purposes, it is specially suitable by reason of its transparency. (H. J. E.)

ABIES FRASERI, SOUTHERN BALSAM FIR

Abies Fraseri, Poiret, in Lamarck, *Dict. Suppl.* v. 35 (1817); Forbes, *Pinetum Woburnense*, 111, t. 38 (1840); Sargent, *Silva N. Amer.* xii. 105, t. 609 (1898), and *Trees N. Amer.* 57 (1905); Masters, *Gard. Chron.* viii. 684, fig. 132 (1890); Kent, Veitch's *Man. Coniferae*, 509 (1900).
Pinus Fraseri, Lambert, *Genus Pinus*, ii. t. 42 (1837).
Picea Fraseri, Loudon, *Arb. et Frut. Brit.* iv. 2340 (1838).

A tree attaining in America 70 feet in height and 7 feet in girth, with rather rigid branches, forming an open symmetrical pyramid. Bark smooth and with numerous blisters in young trees, becoming on older trunks covered with thin appressed reddish scales. Buds small, broadly ovoid or globose, reddish, resinous. Young shoots smooth, yellowish grey, densely covered with reddish, short, twisted or curved hairs, the pubescence being retained on the older branchlets.

Leaves on lateral branches pectinately arranged, as in *A. balsamea*; linear, flattened, shorter than in that species, rarely exceeding $\frac{3}{4}$ inch long and $\frac{1}{10}$ inch broad, uniform in width except at the shortly tapering base, rounded and bifid at the apex; upper surface dark green, shining, with a continuous median groove and without stomata; lower surface with two broad conspicuously white bands of stomata, each of eight to twelve lines; resin-canals median. Leaves on cone-bearing shoots upturned, crowded, broader than on barren shoots, rounded and entire at the apex.

Staminate flowers yellow tinged with red. Pistillate flowers, with rounded scales, shorter than the oblong bracts, which are broad and rounded above, ending in long slender tips.

Cones sub-sessile, ovoid, cylindrical, slightly tapering at the base and towards the rounded or flattened apex, purple, about 2 inches long by $1\frac{1}{4}$ inch in diameter, with the bracts conspicuously exserted and reflected. Scales as in *A. balsamea*, but wider in proportion to their length. Bracts; claw oblong; lamina broad, trapezoidal, denticulate in margin and bifid above with a mucro in the emargination. Seed with wing about $\frac{1}{2}$ inch long; wing purplish, broadly trapezoidal, denticulate in the upper margin, about twice as long as the body of the seed.

IDENTIFICATION

This species can readily be distinguished from *Abies balsamea* by the different pubescence on the young branchlets and the shorter, more coriaceous leaves, which

Logs with this so-called "glassy" appearance are occasionally rejected; but examination showed that this peculiarity was simply due to the presence of ice, which follows the radial lines on the healed-over branches of the logs.

have broader bands of stomata than in that species—eight to twelve lines in *A. Fraseri*, usually only six lines in *A. balsamea*. The cones differ mainly in the larger bracts, which are much exserted and reflexed over the edges of the scales next below; whereas in *A. balsamea* the bracts are either concealed, or, if slightly exserted, are never reflexed. (A. H.)

DISTRIBUTION

Abies Fraseri is very restricted in its range of distribution, being only found in the Alleghany Mountains of south-western Virginia, North Carolina, and eastern Tennessee, where it often forms forests of considerable extent at elevations of 4000 to 6000 feet above sea-level. These forests are usually pure; but occasionally this species grows mixed with black spruce, birch, and beech. The tree averages about 40 feet in height; it only rarely attains 70 feet.

Sargent in an article¹ on this species gives a good illustration of a forest, at about 5000 feet altitude on the Black Mountain range, a spur of the Blue Ridge in North Carolina; which is very like some forests that I saw when I visited this most interesting region in 1895.

HISTORY AND CULTIVATION

Abies Fraseri was discovered by the Scotch traveller and botanist whose name it bears, John Fraser, in the first decade of the nineteenth century; and plants of it were first distributed from Messrs. Lee's nursery, at Hammersmith, in 1811. The excellent figure in *Pinetum Woburnense*, was taken from the original tree in this nursery, where it had then attained 16 feet in height, at about twenty-eight years of age.

The tree is short-lived, and the plants of the first introduction are probably all long since dead. According to Sargent,¹ seeds of *A. balsamea*, collected in Pennsylvania and Canada, where specimens are occasionally found, in which the tips of the bracts of the cone are slightly exserted, have been very generally sold as *A. Fraseri*. Seedlings of the Carolina tree were, however, distributed by the Arnold Arboretum a few years prior to 1889. We know of no trees of any size now living in this country. Some seedlings which I brought from N. Carolina in 1895 soon died.

(H. J. E.)

Pinus hirtella, Humboldt, Bonpland et Kunth, *loc. cit.* (1817).

Picea religiosa, Loudon, *Arb. et Frut. Brit.* iv. 2349 (1838).

Picea hirtella, Loudon, *loc. cit.* (1838).

A tree, attaining in Mexico 150 feet in height and 18 feet in girth. Bark¹ greyish-white, rough, divided into small roundish plates.

Buds shortly cylindrical, rounded at the apex, covered with white resin. Young shoots brown on the upper surface, olive green beneath, covered with minute erect pubescence; pulvini prominent. Second year's shoots reddish-brown, smooth, and striate between the pulvini, which are no longer raised.

Leaves on lateral branches, arranged as in *A. Nordmanniana*; but with the median upper leaves much fewer than in that species, covering the upper side of the branchlet, and pointing forwards and slightly upwards; lower leaves in two lateral sets, spreading outwards and slightly forwards in the horizontal plane. Leaves twisted above the base, linear, flattened, gradually narrowing in the anterior half to an obtuse apex, which is usually entire or rarely minutely bifid; upper surface dark green, shining, with a median groove (usually not continued to the apex) and without stomata;² lower surface with two greyish bands of stomata, each of eight to ten lines; resin-canals marginal. The upper leaves are about half the length of those below, the latter about an inch in length and about $\frac{1}{16}$ inch broad. Leaves on cone-bearing branches similar to those on barren branches.

Cones on short stout stalks, 4 inches long, 2 inches in diameter, conical, broadest near the base and gradually tapering to an obtuse and narrowed apex, bluish before ripening, dark brown when mature, the large reflexed bracts being then of a chestnut brown colour. Scales broadly fan-shaped, nearly $\frac{1}{4}$ inch wide by $\frac{5}{8}$ inch long; upper margin almost entire; lateral margins lacinate and denticulate; base broad with a sinus on each side of the short obtuse claw. Bract: claw wide, obtuse; lamina quadrangular, denticulate, emarginate with a short triangular cusp. Seed with wing about $\frac{3}{4}$ inch long; wing broad and $1\frac{1}{2}$ times the length of the body of the seed.

DISTRIBUTION

This species extends throughout the mountains of Mexico, from near Durango in the Sierra Madre range (lat. 24°), where it was collected by Seemann,³ to the

¹ In this tree, as in the other species with prominent pulvini on the branchlets, the bark of the trunk speedily becomes scaly and like that of a spruce, not remaining smooth for a considerable period, as in the common species of silver fir.

² On leaves towards the tip of the shoot, short irregular lines of stomata are present on their upper surface near the apex. Some of these leaves turn their ventral surfaces upwards towards the light.

³ *Bot. Voy. Herald*, 335 (1852).

mountains of northern Guatemala (lat. 15°), where it was observed by Hartweg¹ and collected by Skinner. It is known to the natives as Oyamel, and occurs mainly in forests at 8000 to 10,000 feet, though it occasionally descends to 4000 feet. It apparently reaches its best development on the Campanario, the highest point of the mountains of Anganguero, a range about 100 miles west of the city of Mexico. Here Hartweg found trees 150 feet in height and 5 to 6 feet in diameter. Parry and Palmer collected it in the province of San Luis Potosi in Central Mexico, and gave its range as from 6000 to 8000 feet. Linden found it on the peak of Orizaba, inland from Vera Cruz, growing between 9000 and 10,000 feet elevation.

Stahl, in Karsten and Schenk's *Vegetationsbilder*, 2 Reihe, Heft 3, gives a good account of this tree, which he found growing near Orizaba between 2600 and 3500 metres above sea-level, and in the higher mountains round the valley of Mexico, in pure forests or mixed with pines, oaks, and alders. He gives no dimensions, and the two excellent figures 17 and 18 taken in the Sierra de Ajusco, near Salazar, at about 9500 feet, show the trees to be smaller there than those which Elwes saw on Popocatepetl.²

Dr. Gadow³ found it growing in the mountains of Omilteme, at 8000 feet; and describes the trees as "veritable giants, from 5 to 6 feet in diameter, as straight as a mast, and may be 100 feet high."

Humboldt supposed that there were two species, one with glabrous and the other with pubescent branchlets; but Seemann and Hartweg were convinced that this distinction is unfounded; and the type specimen of *Pinus religiosa*, the supposed glabrous form, according to Bolle, has pubescent branchlets.

The branches of the tree, which are very elegant, are used in Mexico for decorating churches at the times of religious festivals.

This species was discovered in 1799 by Humboldt, who saw it near the city of Mexico in two localities, at 4000 feet elevation between Masantla and Chilpancingo, and near El Guardia at 8400 feet. It was introduced into cultivation in 1838 by Hartweg, who collected for the Horticultural Society of London.

REMARKABLE TREES

Abies religiosa is tender and will not live, except in the warmer parts of these islands, close to the sea coast, where the temperature never falls much below freezing point. Trees planted long ago at Kew and Bayfordbury, do not now survive. Murray mentions⁴ in 1876 specimens growing at Woodstock in Kilkenny, Highnam

¹ *Trans. Hort. Soc.* iii. 123, 138 (1848).

² I believe that this was the silver fir which clothes the lower slopes of the volcano of Popocatepetl, in Mexico, which I ascended to the limit of vegetation, about 13,000 feet, in March 1888, with my wife and Mr. F. D. Godman. The trees formed in some places dense forests at an elevation of 9000 to 10,000 feet, but though my recollection is that they grew to a great size, we took no measurements, being at the time engaged in collecting birds and insects. In the dry volcanic soil in which they grow we found abundantly *Pinguicula rosea*, one of the most charming ornaments of our greenhouses; and higher up lupins and pentstemons were the most conspicuous plants.—(H. J. E.)

³ *Through Southern Mexico*, 378 (1908).

⁴ *Gard. Chron.* v. 560 (1876).

810 The Trees of Great Britain and Ireland

Court in Gloucestershire, Munches in Kirkcudbright, and Hafodunos in Denbighshire, places which we have visited; but none of these trees can now be found.

There are several trees in Cornwall. Specimens with cones were sent to Kew in 1899 from Trevince, near Redruth, the residence of Mr. E. B. Beauchamp. There is also a tree¹ in Mr. Boscawen's garden at Lamorran, which produced cones in 1890.² There is a small tree at Mr. Rashleigh's garden, Menabilly, which was figured in the *Gardeners' Chronicle*;¹ and at Tregothnan, the seat of Viscount Falmouth, there is a large tree which Elwes measured in 1905 as 56 feet by 6½ feet. Though bearing cones, this tree did not seem healthy, and its top was broken by the wind.

A tree at Castle Kennedy is fairly large in size; but it was blown down some years ago, and then replaced in position. It is in consequence very irregular in shape. It produces cones freely, but the seeds are never fertile.

There were formerly two trees at Fota, which differed somewhat in colour of the foliage and hardihood; one³ has since been blown down. The surviving tree (Plate 226) is a handsome one, though its trunk was broken at about thirty-six feet up, and it has now four leaders: when measured by Elwes, in 1908, it was 66 feet high by 7 feet 3 inches in girth. It is branched to the ground, one very large branch coming off near the base. The foliage is variable in colour, being bluish-green towards the ends of the branchlets, and elsewhere of a light or dark green colour, so that there are three tints visible on the tree. It was bearing in August 1904 numerous cones and male flowers, scattered all over the tree. The cones exude a white resin; and are peculiar, as the scales do not all fall at the same time, some remaining at the base and apex of the axis for two or three years.

The tree does remarkably well on the shores of the Italian Lakes.⁴ Carrière says it is killed by frost at Paris; but at Cherbourg⁵ there was a tree 30 feet high in 1867. It seems, however, to be very rare if at all existing in France.

(A. H.)

¹ *Gard. Chron.* ix. 304, figs. 69, 70 (1891).

² This tree was the first in Britain to produce cones, which were exhibited at the Royal Horticultural Society in 1876.

³ This tree was much more tender than the other, and had the top and some lateral branches killed by frost in the winter of 1880-1881. See Osborne, in *Gard. Chron.* xxiii. 56 (1885).

⁴ Sargent, *Silva N. Amer.* xii. 97, adnot. (1898). But Elwes saw none that he could identify in the neighbourhood of Pallanza.

⁵ Hickel and Pardé, in *Bull. Soc. Dendr. France*, 1908, pp. 206, 224, state that the trees of this species in the neighbourhood of Cherbourg died in the severe winter of 1879-1880; and believe that there are now no living specimens in France.

PSEUDOTSUGA

Pseudotsuga, Carrière, *Conif.* 256 (1867); Bentham et Hooker, *Gen. Pl.* iii. 441 (1880); Masters, *Journ. Linn. Soc. (Bot.)* xxx. 35 (1893).

Abies, section *Peuceoides*, Spach, *Hist. Vég.* xi. 423 (1842).

Pinus, section *Tsuga*, Endlicher, *Gen. Pl. Suppl.* iv. Pt. ii. 6 (1847).

Tsuga, section *Peuceoides*, Engelmann, *Trans. St. Louis Acad.* ii. 211 (1863).

Abietia, Kent, Veitch's *Man. Coniferae*, 474 (1900).

EVERGREEN trees belonging to the tribe Abietineæ of the order Coniferae. Branches irregularly whorled. Branchlets of one kind; pulvini slightly projecting, persistent, and showing, when the leaves have fallen, an oval scar at their apex. Buds spindle-shaped, acute at the apex, brownish, shining, glabrous; one terminal larger, and one to four lateral and smaller in the axils of the uppermost leaves; scales numerous, imbricated, rounded and entire at the upper margin, increasing in size from below upwards; some of the scales persistent for three or four years at the base of the branchlets, ultimately falling and leaving ring-like scars. Leaves arising in spiral order; but on lateral branches, thrown by a twist of their bases into two spreading ranks; persistent for four to eight years; linear, flat, narrowed at the base; upper surface green and longitudinally furrowed; lower surface with a prominent midrib and two stomatic bands; fibro-vascular bundle single, resin-canals two on the under surface next the epidermis.

Flowers, arising from buds formed in the previous summer, erect, solitary, surrounded at the base by involucre scales. Male flowers axillary, scattered along the branchlets, cylindrical; pedicel short at first, ultimately elongated; composed of numerous spirally arranged short-stalked globose anthers, opening obliquely: connective surmounted by a short spur; pollen-grains globose, without air-sacs. Pistillate flowers, terminal or in the axils of the uppermost leaves, composed of numerous spirally imbricated rounded scales, much shorter than the acutely three-lobed bracts; ovules two on each scale, inverted. Fruit, a woody pendulous cone, ripening in the first season, ovoid-oblong, acute at the apex, rounded and narrowed at the base; peduncle short and stout; scales persistent on the axis after the fall of the seeds, small and sterile towards the base and apex of the cone, rounded, concave, rigid; bracts conspicuous, exserted, oblong, three-lobed at the apex, the middle lobe awn-like and longer than the two lateral lobes. Seeds, two in shallow depressions, which occupy about half the surface of the scale, triangular, without resin-vesicles, winged. Cotyledons, six to twelve, linear; with a prominent midrib and stomatiferous on the upper surface.

The genus comprises three species, two inhabiting western North America, and the third restricted to small areas in Japan and Formosa.

In the absence of cones, they are distinguishable as follows:—

1. *Pseudotsuga Douglasii*, Carrière. Western North America.
Branchlets usually pubescent, occasionally glabrous. Leaves straight, undivided at the apex.
2. *Pseudotsuga macrocarpa*, Mayr. Southern California.
Branchlets covered with short, stiff pubescence. Leaves curved, undivided at the apex.
3. *Pseudotsuga japonica*, Sargent. Japan, Formosa.
Branchlets glabrous. Leaves straight or curved, bifid at the apex.

The latter two species, not being yet introduced into England, will now be briefly dealt with.

PSEUDOTSUGA MACROCARPA, Mayr, *Wald. Nordamer.* 278 (1890); Sargent, *Silva N. Amer.* xii. 93, t. 608 (1898), and *Trees N. America*, 54 (1905).

Abies Douglasii, var. *macrocarpa*, Torrey, *Ives' Rep.* pt. iv. 28 (1861).

Abies macrocarpa, Vasey, *Gardeners' Monthly*, xviii. 21 (1876).

Tsuga macrocarpa, Lemmon, *Pacific Rural Press*, xvii. No. 5, p. 75 (1879).

Abietia Douglasii, var. *macrocarpa*, Kent, *Veitch's Man. Conifera*, 478 (1900).

A tree usually 50, rarely 80 feet high, with a trunk 3 to 4 feet in diameter. It differs from the common species in the following characters:—Branches comparatively larger and more remotely placed. Branchlets covered with a short, stiff, white pubescence. Leaves, $\frac{3}{4}$ to 1 inch long, resembling those of *P. Douglasii*, except that they are distinctly curved. Buds short and broad, usually not more than $\frac{1}{8}$ inch long. Cones very large, $4\frac{1}{2}$ to 6 inches long; scales $1\frac{1}{2}$ to 2 inches wide, thick, very concave, puberulous on the outer surface; bracts, only slightly exerted, short, narrow, with broad midribs produced into short flattened flexible tips. Seeds, $\frac{1}{2}$ inch long, dark brown or nearly black and shining above, pale brown below; wing $\frac{1}{2}$ inch long.

This species¹ occupies an isolated area in the arid mountains of southern California, at 3000 to 5000 feet elevation, forming open groves or growing in mixture with oak and pines on western and southern slopes. Its distribution extends from the Santa Inez Mountains near Santa Barbara on the coast to the Cuyamaca Mountains on the southern border of California.

PSEUDOTSUGA JAPONICA, Sargent, *Silva N. Amer.* xii. 84, adnot. 2 (1898); Shirasawa, *Icon. Ess. Forest. Japon.* text 21, t. 7 (1900).

Tsuga japonica, Shirasawa, *Tokyo Bot. Mag.* ix. 86, t. 3 (1895).

This species is not represented by dried material in European herbaria; but I have seen a specimen² recently sent from Japan by Capt. L. Clinton Baker, R.N.

¹ A view of a forest of this species is given in *Garden and Forest*, x. 24, f. 5 (1897).

² The buds on this specimen were not developed; but the scales of the previous season's buds remained persistent at the base of the branchlets, and resembled those of *P. Douglasii*.

It is distinguished from the other species by its glabrous branchlets and by its leaves bifid at the apex. The leaves are pectinately arranged, $\frac{3}{4}$ to 1 inch long, $\frac{1}{2}$ to $\frac{1}{10}$ inch wide, straight or curved, yellowish green above, conspicuously white beneath, broadest near the contracted base, and gradually tapering to an acute apex, which is minutely bifid. The cones are small, $1\frac{1}{2}$ to $1\frac{3}{4}$ inch long, 1 inch in diameter; scales few, about twenty in number, more woody in consistence than those of *P. Douglasii*, glabrous externally; bracts strongly reflexed, the central awn-like lobe only slightly larger than the lateral lobes. According to Shirasawa, its discoverer,¹ the tree attains a height of 100 feet and a diameter of 3 feet, and occurs at 1000 to 3000 feet elevation in the mountains of the provinces of Ise, Yamato, and Kii in Japan. It grows in mixed forests, composed mainly of *Tsuga*, Oak, Beech, Magnolia, and other broad-leaved species. Elwes, when at Koyasan, endeavoured to reach the habitat of this species, but owing to the distance, the heavy rain, and inability to find a guide, was unsuccessful. According to Hayata,² this species occurs also on Mount Morrison in Formosa. Its Japanese name is *Togasawara*.

Young plants are reported by Beissner³ to be in cultivation in Ansoerge's nursery, at Flottbeck near Altona, and in the Botanic Garden at Hamburg. Two small branches, recently sent to Kew from Flottbeck and from Herr Langen's nursery at Grevenbroich, are only distinguishable from those of the American species by some of the leaves being bifid at the apex. Apparently in the young stage, the leaves are acute or mucronate and entire, the bifid character only being assumed after two or three years.

Except for its botanical interest this species does not seem likely to have any value in this country.⁴ (A. H.)

¹ Shirasawa discovered this species in July 1893, on the road between Owashi (in Kii province) and Yoshino (Yamato province), about 10 miles from the coast. He states that the forests in which it occurs are small in area and very inaccessible.

² *Tokyo Bot. Mag.* xix. 45 (1905).

³ *Mitt. Deut. Dendr. Gesell.* 1902, p. 53, and 1906, pp. 84 and 144. Mayr, in *Fremdländ. Wald- u. Parkbäume*, 406 (1906), states that seeds of the Japanese species have never germinated in Europe. The young plants, however, referred to above, are unquestionably this species.

⁴ While the above was passing through the press, Mr. H. Clinton Baker writes that he had just received from Pallanza four plants of *P. japonica*, about 2 feet high, which are being planted at Bayfordbury. The buds on these plants are about $\frac{1}{4}$ inch long, shining brown, and without resin; and the leaves are nearly all bifid at the apex.

Abietia Douglasii, Kent, Veitch's *Man. Conif.* 476 (1900).

A tree, attaining in the moist climate of the Pacific coast 250 to 300 feet in height and 40 feet in girth; but in the dry regions of the interior and at high altitudes rarely more than 100 feet high and 10 feet in girth. Bark of young stems thin, smooth, shining, grey; on older trunks, 2 to 12 inches in thickness, corky, divided by deep longitudinal furrows into broad oblong scaly ridges. Young branchlets usually pubescent, occasionally glabrous. Buds $\frac{1}{4}$ to $\frac{5}{8}$ inch long. Leaves $\frac{3}{4}$ to $1\frac{1}{4}$ inch long, straight, rounded or obtuse, rarely acute at the apex; variable in colour, the stomatic bands beneath either dull grey or conspicuously white.

Cones, 2 to $4\frac{1}{2}$ inches long; scales thin, slightly concave, rounded or slightly prolonged at the apex, about $\frac{3}{4}$ inch wide; pubescent on both surfaces; before ripening bluish below, purple towards the apex and bright red on the closely appressed margins, the bracts being pale green; scales and bracts brown when ripe. Bracts variable in length; the three-pointed apex always, however, extending beyond the scale, usually appressed, but occasionally reflexed. Seeds, about $\frac{1}{4}$ inch long, reddish brown and shining above, paler and with whitish spots below; wings longer than the body of the seed, dark brown, rounded at the apex.

VARIETIES

1. Var. *glauca*, Beissner, *Nadelholzkunde* 419 (1891), Colorado Douglas fir.

In the interior of the continent, the Douglas fir, growing in a dry climate at

¹ According to the rules of botanical nomenclature adopted by the Vienna Congress of 1905, *P. taxifolia* is the correct name for the species, as pointed out by Sargent, in *Bot. Gaz.* xlv. 226 (1907); but we prefer to use *P. Douglasii*, the name which is universally in use amongst foresters and arboriculturists.

high elevations in the Rocky Mountains, through Montana, Colorado, Utah, Arizona, New Mexico, and Mexico, is a smaller tree than the form which occurs in the moist climate of the Pacific coast region. It bears small cones, 2 to 3 inches in length, which in rare cases have the bracts reflexed, but resemble in all essential characters, except size, the cones of the coast form. The leaves are usually thicker in texture and are very glaucous beneath; but the bluish tint visible on the upper surface of the leaves, which is supposed to be characteristic, while common in certain localities, and in others occurring on scattered individual trees, is no more constant than the similar coloured variation which is met with in trees like *Picea pungens* and *Cedrus atlantica*. Mayr has separated the Rocky Mountain form as a distinct species, *P. glauca*; but the differences, being rather physiological than morphological, do not entitle it to rank as more than a variety. The main difference lies in the rate of growth and the hardiness of the tree, when seeds of it are raised in countries remote from its native habitat.

Dr. C. C. Parry discovered this variety of the Douglas fir in the outer ranges of the Rocky Mountains in 1862; and in the following year seeds were sent to the Botanic Garden of Harvard College, from which plants were raised, that have proved perfectly hardy and vigorous in growth in New England. In the north-eastern States the Pacific Coast form, whether introduced by seeds collected in Oregon or produced by trees growing in England, has not proved hardy.

The exact date of the introduction of the Colorado Douglas into Europe is uncertain; but it appears to have been unknown in 1884, when the first edition of Veitch's *Manual* was published, and was described as a distinct variety by Beissner in 1891. Seeds were apparently sent from Mexico by Roehl in 1856, and plants¹ raised from these on the continent do not seem to differ from the Colorado Douglas.

According to the experiments of Johannes Rafn, of Copenhagen, the germination of the seed of Douglas fir from Colorado is quicker and much better than that from the Pacific coast.²

In England young plants of the Colorado Douglas³ have ascending branches, and are more narrowly pyramidal in habit than the Oregon Douglas, which has wide-spreading horizontal branches. Owing to its slowness of growth, the Colorado variety has short internodes between the branches, which give it a bushy appearance. The blue tint of the foliage can scarcely be relied on as a distinctive character, as it is variable in intensity and often disappears with age. The leaves are usually thicker, but do not differ in length or shape from those of the Oregon Douglas, the sharp-pointed apex being characteristic of both forms in the young stage. The young branchlets of the Colorado variety are often either quite glabrous or show only a few minute hairs under the lens, whereas those of the other form are distinctly pubescent. In wild trees, judging from herbarium specimens, this distinction does not occur.

¹ *Pseudotsuga Lindleyana*, Carrière, raised from Mexican seed sent by Roehl, and *P. glaucescens*, Bailly, also probably from Mexican seed, belong to var. *glauca*, and bear cones with strongly reflexed bracts.

² *Trans. Roy. Scot. Arbor. Soc.*, xvi. 408 (1901).

³ The Colorado Douglas in cultivation in England has been supposed by Schwappach (cf. Richardson in *Trans. Roy. Scot. Arbor. Soc.* xviii. 195, with figure) to be *Pseudotsuga macrocarpa*; but there is no evidence to support this opinion.

The Colorado Douglas displays in cultivation well-marked peculiarities, which are mentioned in detail on pages 825, 826.

2. Lemmon¹ has described several other wild varieties, as var. *suberosa* from Arizona and New Mexico, var. *elongata* from the base of Mount Hood in Oregon, and var. *palustris* from swamps in the Lower Columbia Valley.

3. A considerable number of cultivated varieties have been distinguished by Carrière and Beissner, most of which are not worth mentioning, as their distinctive characters are trifling and inconstant. Fastigate and pendulous forms are known, but are rarely met with.

Var. *Stairii*, with yellowish foliage, originated² at Castle Kennedy.

Var. *Fretsi*, Beissner,³ is very peculiar in the foliage, as the leaves are short and broad, only $\frac{1}{2}$ inch in length, very obtuse at the apex, and resembling those of *Tsuga Sieboldii*. This originated in the seed-bed, and was sent out by Messrs. Frets & Sons of Boskoop, Holland. (A. H.)

Other varieties occur in cultivation which, though very distinct in habit, are not, in my opinion, worth naming. Among the best of the pendulous forms is one at Bury Hill, Dorking, the seat of R. Barclay, Esq., which in 1908 was 88 feet high.

I noticed in October 1907, near Boldrewood in the New Forest, on the north side of the drive, two trees, one of which was a typical Oregon Douglas fir with drooping branches, and leaves very silvery on the under side. Another close by had much narrower, stiffer, and darker foliage, and denser branches, the leaves much less silvery, and the cones closely packed near the summit of the tree in a manner unusual in this species. The former tree measured 70 feet by 6 feet 10 inches, the latter 66 feet by 5 feet 2 inches. Others of the latter type, standing near the gate leading into Mark Ash, bore no cones at all.

Near Eggesford House, in the higher walk, I saw a Douglas fir tree, so distinct in habit that it might be easily mistaken for another species. It had thin greyish foliage, pendulous branchlets, and very few cones, and measured 80 feet by 5 feet 7 inches, whilst ordinary Douglas firs planted close by were much thicker in proportion. I believe that by selecting such trees as seed-bearers we may ultimately succeed in obtaining distinct races which, for economic planting, will be much more valuable than trees of unknown origin. (H. J. E.)

DISTRIBUTION

The Douglas fir has an extremely wide distribution in western North America, extending from north to south over 33° of latitude, between the parallels of 55° and 22°, and ranging from the Pacific coast to east of the Rocky Mountains. It occupies practically all of this vast territory except the higher elevations of the mountains and the desert and prairie regions of lower altitudes, where the rainfall is slight. It is the dominant tree of the great western forest, always growing in mixture with other

¹ *West American Conebearers*, 57 (1895).

² This variety is fully described in *Gard. Chron.* 1871, p. 1481. I have seen the original, which is now a small unhealthy looking tree; as are all those we have seen elsewhere. The best, perhaps, is a large dense bush rather than a tree, growing in Wood's nursery, near Buxsted, Sussex.—(H. J. E.)

³ *Mitt. Deut. Dend. Gesell.* 1905, p. 74, f. 8.

conifers, which have a much more restricted distribution. In Montana it is associated with the western larch: in California it encroaches on the redwood belt; in southwestern Oregon it is mixed with the Lawson cypress; while in the rest of the great forest of this state, and of Washington and northern Idaho, *Thuja plicata* is usually its constant companion. The various silver firs, hemlocks, and the Sitka spruce also take part, in different localities, in the mixture of coniferous trees in the Douglas forest. Towards the edges of the prairie regions and in the drier parts of the mountains, the Douglas fir gradually gives place to *Pinus ponderosa*, which is the characteristic tree of dry soils, where a very moderate rainfall prevails.

The northern limit of the Douglas fir extends from near the head of the Skeena River, latitude 54°, in the coast range of British Columbia to Lake Tacla in the Rocky Mountains, latitude 55°, reaching its most easterly point near Calgary in Alberta. In the coast range, the tree grows at some distance inland north of latitude 51°; while south of this line it is common on the coast of the mainland and in the island of Vancouver; and in this region, and in Washington and Oregon, between the western foothills of the Cascades and the sea, it is most abundant and of its largest size. It attains its maximum development, 300 feet in height, in Vancouver Island and on the northern slopes of the Olympic Mountains in Washington, where the rainfall is excessive; whereas, on the Cascades and in the interior of the continent, it rarely exceeds 150 feet in height. It is common, but only of moderate size, in the forests of northern Idaho and of western Montana,¹ ascending to 6000 feet.

The Douglas fir extends southwards along the Rocky Mountains, in the Yellowstone Park in Colorado, where it grows between 6000 and 11,000 feet altitude; in Utah, to the east of the Wasatch range; in northern and central New Mexico and northern Arizona, where it is common between 8200 and 9000 feet, being rare and of small size in the southern parts of these two states, where it ascends to 6000 or 7000 feet; in the Guadalupe Mountains of western Texas, where it is abundant; and it spreads into Mexico, along the Sierra Madre range of Chihuahua and the mountains of Nuevo Leon, reaching its most southerly point near the city of San Luis Potosi.

In California it extends southward in the coast mountains² as far as Punta Gorda in Monterey county, but is not abundant, and is rarely over 150 feet in height; inland it extends to the Sierra Nevada,³ where it grows to a large size and ascends to 7000 feet. It does not occur in the arid tracts of Nevada and Utah, which lie between the Sierra Nevada and the Wasatch ranges. (A. H.)

So little seems to be known by British foresters as to the conditions under which the tree grows in America, that though I quite agree with the preceding account, it may be as well to add some of my personal experience of the tree as I saw it on my last journey in 1904. In the Blackfoot valley of Montana it is associated

¹ At Whitefish, Montana, an average tree, growing with the western larch, was 140 feet in height and 8 feet in girth, and showed 245 annual rings; the sapwood, $\frac{3}{8}$ inch wide, containing 45 rings; the bark was $2\frac{1}{2}$ inches in thickness.

² Jepson, in *Flora Western Mid. California*, 19 (1901) says that it is frequent in the Santa Cruz mountains; but is not known in the Mt. Diablo and Mt. Hamilton ranges, or in the Oakland hills.

³ Sargent in *Garden and Forest*, x. 25 (1897), says that it does not extend in the Sierras, south of the head of King's river, or within 100 miles of the territory occupied by *P. macrocarpa*. Jepson (*op. cit.* 20), makes its southern limit on the Sierras, about the head-waters of Stevenson Creek, which is not far from the head of King's river.

with *Larix occidentalis*, on the damper and shadier slopes of the mountains, at 4000 to 6000 feet, giving place to *Pinus ponderosa* in drier and sunnier situations, and never attains, so far as I could see or learn, more than 140 to 150 feet in height.

In Washington and British Columbia it is not seen in the dry country east of the Cascade range, but appears as soon as the forest begins to thicken near the watershed; and on the western slopes of the mountains, from about 6000 feet downwards, is almost everywhere, except in swampy land, the dominant tree of the forest, attaining 200 to 300 feet in height from sea level to about 2000 feet.

It grows usually in mixture with *Thuja plicata*, *Tsuga Albertiana*, *Picea sitchensis*, and *Abies grandis*; sometimes with a smaller proportion of *Pinus monticola*, and in drier situations with *Pinus ponderosa*;³ but in all the coast forests which I saw in Oregon, Washington, and British Columbia, including Vancouver Island, it outnumbered all the other conifers, except where forest fires have destroyed it, and its place is being to some extent taken by the hemlock, whose seeds seem able to germinate and grow in denser shade and in deeper humus than the young plants of the Douglas fir can endure. Wherever the soil becomes too dry and rocky for hemlock and *Thuja*, the Douglas fir is able to grow, climbing up to the dry ridges and sunny slopes until it meets the more alpine species of conifers. Its habit and size vary according to the soil and situation; but I never observed any trees even in the most open situations, whose branches extended so far from the trunk as they do in English parks and gardens, and it does not attain anything like its full size unless it has a deep soil, a sheltered situation, and has been drawn up in youth by the struggle for existence, which prevails everywhere in the forest.

I saw a section of bark in the Washington State exhibit at the St. Louis Exhibition, taken from a tree cut at M'Cormick in Lewis Co., Washington, in the spring of 1904; which was said by Mr. Baker, who was in charge of it, to have been 390 feet high. The same tree was recorded, however, in a Washington newspaper as having been 340 feet high and 42 feet in circumference (probably at three to four feet from the ground), and above 300 years old. The tree is said to have contained 79,218 feet board measure, equal to above 8000 cubic feet, quarter-girth measure. The discrepancy in the account of the height and that given me by Mr. Baker may arise, in part, from the tree in falling, having jumped some distance from its stump.

Another tree even more remarkable, though not so large, was cut by Mr. Angus M'Dougall of Tacoma for the Chicago Exhibition in 1893. This grew in Snohomish Co., Washington, and measured on the stump only 4 feet in diameter. In falling it broke off at a height of 238 feet, where it measured 17½ inches in diameter, and was nearly free from branches to a height of 216 feet, which length was sent to Chicago.

The largest tree I have ever seen myself, which is said to be perhaps the largest known in Vancouver Island, grows by the roadside at Mr. P. Barkley's farm at Westholme, about 40 miles north of Victoria and 4 miles south of Chemainus Station.

³ In the Bow river of Alberta it grows mixed with aspen (*Populus tremuloides*), and cottonwood (*P. balsamifera*).—Wilcox, *The Rockies of Canada*, p. 65.

What its height may originally have been is impossible to say, as it is broken off at about 175 feet. This tree has a very swelling base, which does not show so well as I could wish in the photograph (Plate 227). At the ground it measures 21 paces in circumference. Above the swelling, at about 6½ feet, I made it 41 feet 5 inches in girth. Assuming this tree to be 24 feet in girth at 100 feet high, and to have had a top at all in proportion to its girth, it must have contained 7000 to 8000 cubic feet of timber, or even more. The soil in which it grows is a deep fertile loam, and the timber standing in the valley is some of the finest in the island. Plate 228, from a photograph also taken in Vancouver Island, gives an idea of the forest, and shows on the right the trunk of a typical Douglas Fir; on the left, a trunk of *Thuja plicata*.

In the eastern part of the Washington Forest Reserve, Mr. Martin W. Gorman found this species up to 6000 feet, and measured a tree growing at 5500 feet, 132 years old, which was 18¾ inches diameter on the stump, with the bark 3 inches thick. Another tree at 1200 feet elevation, 244 years old, was 43 inches in diameter, with bark 6 inches thick. In the dry region the tree ranges from 70 to 120 feet high and from 20 to 50 inches diameter. He remarks that the species resists fire better than any other conifer of this region, and bears fertile cones at an earlier age than any other, a tree of only twelve years old having well developed cones.

Observations on the rapid growth of Douglas fir at various ages in its own country are given by Mayr.¹ In southern Oregon, on the best sandy loam, with a rich humus, he measured Douglas firs 130 feet high at eighty years old; a fallen stem, 100 feet high, contained 135 cubic feet.

The wood of the Douglas fir is known in the European, South African, and Australian markets as Oregon pine or Oregon fir, on the Pacific coast of North America as red fir or yellow fir, in Utah, Idaho, and Colorado as red pine, and in California is sometimes incorrectly called spruce or hemlock. It produces probably a larger quantity of commercial lumber than any other conifer in the new world, or at least on the Pacific coast; and is likely to continue the principal source of supply for most purposes, as the white pine (*P. Strobus*) of the New England states and Canada, and the long-leaved or pitch pine of the southern states become scarcer; and as its timber is likely in the future to become an important article of trade in Europe, both as an imported and home-grown product, I think it may be useful to give some particulars of the way in which the immense sawmills of Oregon, Washington, and British Columbia are managed.

First, as regards the growth of the timber, Prof. Sheldon, the Oregon State forestry expert, has published in the *Oregon Timberman*, May 1904, a valuable paper, which entirely confirms my own much more limited observations, and goes to show that the two forms locally known as red and yellow fir are not in any way distinct, but are simply the result of different conditions of growth.

When the trees grow in an open space, and have the annual rings, as is usually the case in youth, pretty far apart, they may attain at the butt 16 to 18 inches diameter at forty years. In such trees the thickness of the sap-wood is from 2 to 3

¹ *Fremdländ. Wald- u. Parkbäume*, 398 (1906).

inches, and the thickness of the bark, which under such conditions is comparatively smooth and greyish in colour, is about $\frac{1}{2}$ inch. The timber of such trees would be known as red fir. When the tree, however, becomes crowded by its neighbours, and its girth increment is much slower, all the energy of the tree being devoted to upward growth, the rings become much closer, and trees of fifty to sixty years of age may be only 1 foot in diameter. The bark in such cases is much thinner, and the quality of the timber from the point at which the slower growth began much better, so that it would be classed as yellow fir when sawn up. Prof. Sheldon gives figures showing sections of such trees, his Plate 6 showing the influence of light, room, and nourishment on the growing tree. The tree from which this section was made was 143 years old with a diameter of only $16\frac{1}{2}$ inches. For 116 years it had stood in a crowded forest with large trees 4 and 5 feet in diameter all round it. Twenty-seven years ago the large trees were felled, and the growth immediately became much more rapid. The sap-wood in this case is $3\frac{1}{2}$ to 4 inches and the bark $1\frac{1}{2}$ inch thick. He says, "The result of this study is to conclude that the rapid growth of Oregon fir in the open produces red fir, and the subsequent growth when the trees begin to crowd each other produces yellow fir. Trees grown in dense clumps crowded all their life produce solid yellow fir. The growth of the upper portion of the tree may show larger annual growths in the centre than are found near the butt of the same tree. This is of interest in accounting for the immense height of the Oregon fir in many places, as trees 300 to 350 feet high are found in the forests of Oregon and Washington."

I asked experienced loggers whether they could distinguish red from yellow fir as they grew, and my impression was that they could not, though they said a very few blows of the axe would soon show the difference in the hardness of the wood. With the object of finding out the age at which the tree comes to maturity, I measured the rings of several trees recently felled at the logging camps which I visited. I am much indebted to the managers of these mills, for the facilities which they gave me to see the whole operations of a modern west coast lumberman. Among them Mr. Bradley of the Bridal Veil Company, Oregon; Mr. Browne, president of the St. Paul and Tacoma Sawmills, Tacoma, Washington, and his logging contractor, Mr. M'Dougall; Mr. Palmer of the Chemainus Mills, Vancouver Island; and Mr. Kenneth Ross, manager of the Big Blackfoot Lumber Company, Montana, were all most obliging and hospitable.

I found that the average age of mature trees 4 to 6 feet in diameter on the stump is 300 to 500 years. At an age of from 400 to 500 years, and possibly much sooner in some cases, the trees begin to decline in health, and some of those felled are more or less hollow. In all cases the annual rings for the first fifty to seventy years are very much thicker than for the next 300 years, the best trees having from four to five rings to the inch at first, and afterwards as many as fifteen to twenty. The better class trees are clear of branches up to about 120 to 150 feet, and in such cases produce wood free from knots, or "clear lumber" as it is called in the trade. Such clear lumber, however, even when a large number of trees are rejected by the fellers, does not exceed 15 to 30 per cent of the total

product, and is worth a much higher price than the more or less knotty lumber known as "merchantable."

The business of lumbering which has been carried on for many years on a very large scale is, on the Pacific coast, as in most parts of North America, conducted in a way which, though perhaps necessary in order to meet the severe competition for price which everywhere prevails, would shock the feelings of any European forester, on account of its wastefulness and the absolute disregard which is paid to the future of the forest; which is in most cases abandoned to fire, as soon as the soundest, cleanest, and most accessible trees have been extracted.

A tract of land having been first surveyed, and its probable contents roughly estimated by the "cruiser," on whose judgment in selecting the best field of operations much of the success of the business depends, is purchased or leased from the owner on the basis of so much per thousand feet board measure. This estimate runs in most cases from 20,000 to 70,000 feet per acre, and as far as I could judge is rarely more than half, and often much less than half, of the actual contents, which in favourable situations amounts to as much as 300,000 to 500,000 feet per acre.

Unless the timber to be felled is near the sea,—in which case it is on Puget Sound often slid direct into the salt water, made up into rafts, and towed by steamers to the sawmill,—the next operation is to build a railroad up the valley to bring the logs from the forest to the sawmill. Sometimes the mill is in the forest itself, and a wooden flume of many miles in length is built, by which the sawn boards can be floated down to the nearest railway station. Sometimes the logs themselves are floated to the mill, where a large enough river exists; or a combination of railway, river, and flume may have to be adopted as the distance from the mill or station increases. The cost of extracting the logs from the forest and bringing them to their shipping point, governs the value of the growing timber, which is rapidly becoming less and less accessible as the best areas are cut over.

When the means of transport are completed, a "skid road" or a temporary tramway is built right up to where the trees grow, and powerful movable donkey engines are used, which are able, with a steel-wire rope, to drag logs of 40 to 50 feet long to a distance of 1000 yards or more from where they fall. Felling then commences and is managed as follows:—The most experienced man in the gang, having marked the trees to be felled, cuts a deep notch into one side at 4 to 6 feet from the ground, after carefully considering which way the tree should fall, so as to run least risk of lodging, or of breaking in falling. Both the undercutting and the sawing which follows, are done on spring boards fixed into a notch cut into the butt at 3 to 4 feet from the ground. When the two fellers, who sometimes make the notch themselves, have got within 5 to 6 inches of it, they insert large iron wedges in the sawcut, carefully watching the top of the tree to see where the wedges should be driven, so as to fell the tree with least danger to themselves and the log. After a few blows on the wedges the tree begins to lean and the men jump clear, calling out to warn others who may be near. There is some risk of large branches being torn off the falling tree or adjacent trees, and many accidents occur.

When the tree comes down, it is cross-cut by other men paid at a lower rate than the fellers, into such lengths as seem best. The smaller end of the log is then bevelled off and two deep notches cut, into which a pair of iron claws are fixed, and attached to the wire rope of the donkey engine. A signal is then given by wire from the men in charge of the log to the engineer, who commences winding up the rope, and with frequent stoppages caused by the log being jammed among stumps and other obstructions, it is at last dragged either to a prepared skid road, where another donkey engine hauls it to the loading point, or direct to where the trucks are able to load it. The loading is managed by building a rolling stage of heavy timbers down which the logs can be slid, or up which they are rolled by a donkey engine on to the trucks. Sometimes a dam is built and a pond formed, into which all the logs are dragged and rolled out on to the trucks. In fact there is no end to the ingenuity of the logging contractor in devising mechanical means for handling these great logs, often 4, 5, and 6 feet in diameter, with the least expense and trouble. Many logs which to an inexperienced eye would be thought valuable, are left either because they would cost more than they are worth to get out, or because they are more or less faulty; and in all cases that I saw, the work is done without the least regard to the younger trees, or to the future. Sometimes half the trees are left standing and as much is left after felling as is taken. The price per 1000 feet at the sawmill is the one governing idea.

When the logs reach the sawmill they usually go into a pond, from which they are hauled as required up an inclined plane to the saw bench. In the largest and modern mills the band-saw has replaced the gang-saws formerly used, and works at an incredible speed, saving a great deal of wood which was formerly eaten up by the saw. Some of the band-saws are double-edged; and after taking off the slabs and squaring the log, it is then converted into whatever sized lumber is wanted; the best quality being cut into vertical grained decking or flooring, 4 to 6 inches wide.

The ingenious arrangements by which everything in these great mills is arranged so as to save manual labour, must be seen to be appreciated. I found many of the men employed were Japanese, who are said to be excellent workmen and to possess both nerve and pluck.

When the boards are cut, the best are sorted out and sent to the drying kiln where they are dried for four or six days in order to prepare them for planing, tonguing, and grooving; which is usually done in another part of the same establishment by machinery, before the finished wood is put in cars for transport to the interior.

Much of it now goes to the middle states, and a great deal to South Africa, China, and Australia; but whenever very large-sized balks, masts, or piles are wanted, the Puget Sound mills are called on to fill the order, because no others in the world can supply timbers of such great size at so cheap a rate. Logs of 24 inches square and up to 100 feet long are regularly quoted.

The Douglas Flagstaff,¹ in Kew Gardens, came from Vancouver Island, and was

¹ Cf. *Journ. R. Hort. Soc.* xiv. 452 (1892).

presented in 1861 by Mr. Edward Stamp. It is 159 feet high, about 12 feet being underground, and is about $4\frac{1}{2}$ feet in girth at ground-level. It weighed 4 tons 8 cwt., and was about 250 years old. In the British Museum of Natural History there is a section cut in 1885, 7 feet 7 inches in diameter, including bark, on which 533 annual rings may be counted. There is also in the Timbers Museum at Kew a fine section, 8 feet in diameter, cut from a tree on Puget Sound.

A technical report on the strength, weight, and structural value of Douglas timber is given by Hatt in *U.S. Bureau of Forestry*, Circular No. 32 (1904), from which it appears that the possibility of obtaining long and large pieces, combined with the exceptional strength and stiffness of the material, compared with its very moderate weight, renders it an ideal timber for structural purposes, and durable on exposure to weather.

In a report on the Forest Products of the United States for 1906 (issued March 1908)¹ I find that this species now comes second in the quantity of timber produced, being only surpassed by "yellow pine," under which heading are included all the various pines of the south and east except white and Norway pine (*P. Strobus* and *P. resinosa*). The quantity cut in 1906 was estimated at 5 billion feet, valued at 70 million dollars, of which the state of Washington yielded 68.5 per cent, Oregon 27.2 per cent, and all the other states together less than 5 per cent. The increase in production was very rapid in the last few years, and the average value had increased from 8.67 dollars per 1000 in 1899 to 14.20 dollars in 1906.

I am informed by Mr. R. S. Kellogg of the United States Forestry Bureau, Washington, that on the Pacific coast all masts except the smallest, and on the east coast the largest masts, are made of Douglas fir, which is transported overland from the Pacific coast.

It is the opinion of Lieut.-Commander Williams of the Bureau of Construction and Repair, U.S. Navy Dept., that there is practically no difference in the strength of Douglas fir and long-leaf pine (*P. palustris*); the latter, however, is considerably heavier. This appears to be now generally recognised by yacht-builders in Europe who use Douglas fir in preference to any other timber for the masts of racing yachts.

A letter on the timber of this tree in *Gardeners' Chronicle*, 1862, p. 452, gives the results of experiments made at Cherbourg by M. Serres on twelve specimens of squared mast timber sent from Vancouver, which showed that in strength it was almost equal to Florida pitch pine, and stronger than Baltic or Canadian pine. The weight of a compound mast made up of pitch pine in the centre and Baltic or Canada pine on the outside was about 12,200 kilos., whilst a solid mast of the same dimensions, made of Douglas fir, weighed only 8900 kilos. The cost of material and workmanship of the latter was very much less.

Mayr's comparison² of the wood as grown in various parts of Europe, with that grown in America, and also with that of silver fir, spruce, and larch, is well worth studying; but the age of the trees was insufficient to make the comparison conclusive.

¹ *U.S. Dept. Agr. Forest Service Bull.* 77.

² *Fremdländ. Wald- u. Parkbäume*, 399, 400 (1906).

With regard to the future of the Douglas fir forests it is very hard to say to what extent or for what period the present supply will last. Axe and fire are certainly destroying them at a great rate, but the reproduction all over the coast region is so good, and the danger of fire in dense young growths of trees so small, that many places cleared twenty to forty years ago are already covered with healthy young trees; and though the size and quality of these will probably never equal those of the virgin forests, yet there is no reason why, with reasonable care, the forests should be devastated as they are now. On the drier mountains of the interior, the danger of destruction is greater; and it seems to me that whilst Douglas pine is the dominant tree of the coast region, *Pinus ponderosa*, owing to its thicker bark and greater adaptability to dry soils and climates, will replace it in the interior.

INTRODUCTION

The Douglas fir was discovered by Menzies at Nootka Sound in 1797. Seeds were, however, first sent home by Douglas in 1827, from which plants were raised by the Horticultural Society of London and distributed throughout the country. According to a note by Mr. Frost¹ the tree at Dropmore, which is usually considered to be the oldest in England, was raised from seed sown by himself in the winter of 1827-1828.

CULTIVATION

The best account² of the cultivation of Douglas fir yet written is by Mr. Crozier, forester on the Durris estate in Kincardineshire, who has paid special attention to this tree, and is one of the most experienced foresters in Scotland. He prefers to collect home-grown seed, and considers that much may be done to improve the type of the tree commercially, by selection of the best varieties as seed-bearers; and states that the production of seed in good years is enormous, no less than 15,000 cones having been counted on an outlying specimen tree about 40 years old.

The seed ripens about the beginning of October, when the cones should be gathered without delay before the seed escapes. After storage in a dry loft through the winter, the cones are exposed to sun heat, which causes them to shed the seed. In the beginning of May the seed is sown in beds 3 to 3½ feet wide, one pound being allowed to every 8 or 10 yards. The seedlings are transplanted at two years old, and Mr. Crozier prefers to plant them out in the month of April one year later by notching, or if the ground is liable to be covered with bracken or herbage, by pitting in plants a year older.

So far as my own observations go this tree will not grow well on clay or on the oolite formation, but it thrives on greensand, and on sandstone of the Llandovery group at Tortworth. If desired to grow to a large size, it should be planted in a well-sheltered situation, where the soil is of sufficient depth and fertility to keep the trees growing for a long period, but in exposed situations the tops are ruined by the

¹ *Gard. Chron.* 1871, p. 1360.

² *Trans. Roy. Scot. Arb. Soc.* xxi. 31 (1908).

wind. All attempts to grow this tree into timber on bare, exposed, or barren downs and hillsides will, I believe, prove futile.¹

The Colorado or glaucous variety has been so much spoken of, and is recognised so universally in cultivation as a distinct form, that we must speak of its peculiarities in full. It is usually supposed to be known by its colour, which is variable in all races of the tree; and I know of a case in which colour alone was considered by a forestry expert, to be sufficient to condemn as seed-bearing parents, a large number of vigorous healthy trees of great size, which were certainly of Pacific coast origin.

The Rocky Mountain forms, of which the Colorado one may be taken as typical, are constitutionally able to endure a continental climate; namely, one characterised by extremes of summer heat and winter cold; whilst the coast form is less hardy, though it will endure the extremes of climate in most parts of Great Britain, and is a very much larger, faster-growing, and, from a forester's point of view, more valuable tree.

They are at Colesborne equally liable to suffer from late spring frost after growth has commenced; but Mayr, whose experience of both is considerable, says that the Colorado form in Germany, does not suffer like the other, from the freezing of the immature shoots in autumn and early winter; and wherever this is a common cause of injury to the coast form, the mountain form should be tried instead. Such places, however, are rare in England; and on this subject I cannot do better than quote the opinion of Mr. Crozier. In a letter to me he says, "That there are two well-defined forms no one with practical experience of the tree will deny, but whether that known as 'Colorado' is confined to the state of that name seems doubtful. As a timber tree, however, my experience convinces me that in the north of Scotland at least it is a failure, and whatever advantages it may possess over the Oregon variety in its nursery stages, is really of no moment, as after a trial of between thirty and forty years, under the most favourable conditions of soil, shelter, etc., it has failed to make timber on this estate; while the Oregon variety, under much less favourable conditions, has never failed to make good headway. The cone² also differs from that of the Oregon variety in some important respects, being much smaller, with the bracts a great deal longer and reflexed."

"I made a further experiment with this tree some years ago, and may give you the dimensions of average specimens at the present time of Oregon and Colorado Douglas and Norway spruce, grown under exactly similar conditions side by side. The age of the Colorado Douglas and Norway spruce is twelve years, while the Oregon Douglas is ten years from sowing.

	Height.	Three last years' growth.	Girth at 6 inches high.
Oregon Douglas	15 feet 6 inches	8 feet 10 inches	9½ inches
Colorado Douglas	10 „ 11 „	5 „ 5 „	6¼ „
Spruce	8 „ 10 „	4 „ 5 „	5¼ „

¹ According to Mr. Bean, in *Kew Bulletin*, 1906, p. 268, this species is used as a hedge plant at Monzie Castle, and answers the purpose very well, being dense and well-furnished.

² The cones on cultivated trees are very variable. Cf. *Gard. Chron.* xxviii. 12 (1900).

These have been planted seven years, and though for a time the Colorado held their own with the spruce they are now being left behind."

"We have raised some millions of the Oregon variety and find it sufficiently hardy for all practical purposes. It does frequently make a second growth in the nursery stages, and these may be killed back, but the damage done in this respect is not serious. After being planted out and established in the plantation, they are capable of bearing a greater degree of exposure than the Norway spruce, and may be seen on the lower spurs of the Grampians easily beating the latter. In the treeless district of Buchan it does not do well, but neither does any other tree; but for general planting in Scotland, and with ordinary precautions, it is quite valuable."

"A member of an old firm of nurserymen informed me that it is about fifteen years since the Colorado variety first began to be sent to this country in quantity, and they only found out the mistake after the seedlings came up. To speak of the Colorado as 'glaucous' and the Oregon as the green variety would be incorrect, as both vary in colour. The Colorado may be found of all shades from green to a rich glaucous, while the Oregon runs from a dark bluish tint to a light green."

A most striking instance of the different rate of growth of the two trees may be seen in Dr. Watney's avenue at Buckhold in Berkshire, where Oregon Douglas about $3\frac{1}{2}$ feet high were planted in the winter of 1882-83, in trenched ground on a gravelly soil with some clay, underlaid at a depth of 10 to 12 feet by chalk. Five of the best of these average in 1908 59 feet 8 inches in height by 4 feet in girth. The largest was 65 feet by 5 feet 3 inches, showing $2\frac{1}{2}$ feet of annual height increase for twenty-four years. Colorado Douglas (so-called) planted on the same land at the same time, were, when I saw them, not above half this size.

In the Great Bear plantation, on the same estate, planted October 1895, and steam cultivated 15 inches deep, Dr. Watney has measured six average Colorado Douglas, planted about 3 feet high, now 13 feet by $6\frac{2}{3}$ inches; six average Scots pine, planted about $1\frac{1}{2}$ feet high, now 18 feet by 12 inches; six average larch, planted about 2 feet high, now 19 feet 7 inches by $9\frac{1}{4}$ inches. According to his experience the Colorado have many small branches which extend but a short distance from the stem, whilst the Oregon are distinguished by wide-spreading branches set much farther apart on the stem. He says that the latter is the fastest-growing tree he knows, whilst the former is probably the most useless of all the common conifers he has grown; and yet he is told by a leading nurseryman that about one-third of the seed he buys produces plants which are apparently of the Colorado variety. These trees are sold and planted somewhere, to the great ultimate loss and disappointment of the unwary planter.

The Douglas fir is usually healthy and little liable to insect or fungus attacks. However, of late years, a fungus, *Botrytis Douglasii*, Tubeuf, which is known as the Douglas fir blight,¹ has caused considerable danger to young trees growing in nurseries. The leaves, especially those on the upper shoots, wilt and fall off; and

¹ Fisher, Schlich's *Man. Forestry*, iv. 461 (1907).

the plants frequently die. There is an illustrated article on this fungus in the *Journal of the Board of Agriculture* for June 1903.

I am informed by Capt. the Hon. R. Coke that in January 1907 there was a bad attack of this fungus, on two-year-old plants in the nurseries at Weasenham, Norfolk, and on some trees of the same age which were planted out in the previous autumn. He was advised at Kew to burn all the affected plants, and spray the remainder with "Violet Mixture."¹ About 25 per cent of the infected plants died or were removed as worthless; the remainder outgrew the disease, and are now (June 1908) looking well, though the fungus has not entirely disappeared. Capt. Coke adds that, after trying the so-called Colorado variety, he will plant no more of them; and that as seedlings of the Oregon variety vary a good deal, he prefers those which show a tendency to stop growing in time to ripen their leader.

The seeds are liable to be destroyed by the larva of an insect,² *Megastigmus spermotrophus*, which has been introduced into Europe from Oregon. The eggs are laid by the insect in the young cones, and one larva develops in each seed and destroys it. This pest has been observed at Mariabrunn, and has done great damage in Denmark; and during 1905 and 1906 was so serious at Durriss in Aberdeenshire, that no seed was worth collecting there.

REMARKABLE TREES AND PLANTATIONS

The largest tree that we have heard of in Europe, is at Eggesford, in Devonshire (Plate 229). This tree must be as old as any existing, for it was reported³ in 1865 to be then about forty years old and 100 feet high. This, however, was an exaggeration, as three years later it was recorded⁴ by Mr. A. Spreadbury, as being 93 feet by 12 feet at three feet from the ground. I measured it carefully in company with Mr. Asprey, agent to the Earl of Portsmouth, in April 1908, and found it, by the mean of two measurements from opposite sides, to be 128 feet by $18\frac{1}{2}$ feet. About four feet from the ground two very large spreading branches come off, which at two feet from the trunk are 6 feet 9 inches and 5 feet in girth. At 30 feet from the ground, the stem is still 13 feet 5 inches round, and at 100 feet it girths 3 feet 3 inches; so that it must contain about 700 feet of timber. It grows on a lawn facing east, a little above the river Exe, on a soil which is evidently deep and fertile; and if the top is not broken may become a much larger tree, though it has only increased 35 feet in height in forty years.

The largest tree in the grounds at Endsleigh was reported by Mr. R. G. Forbes to be, in 1906, 100 feet high, with a quarter-girth of 26 inches in the middle; but in remeasuring it by climbing in 1908, he informs me that it is only measurable to a height of 87 feet. The quarter-girth over bark at $43\frac{1}{2}$ feet is $26\frac{1}{2}$ inches. Allowing

¹ This is composed of sulphate of copper, 2 lbs.; carbonate of copper, 3 lbs.; permanganate of potash, 3 oz.; soft soap, $\frac{1}{2}$ lb.; rain water, 18 gallons.

² Cf. *Gard. Chron.* xxxix. 57 (1906), *Trans. R. Scot. Arb. Soc.* xix. 52 (1906), and *Journ. Board Agriculture*, xii. 615 (1906), where an article on the insect with figures is given by Dr. R. Stewart MacDougall.

³ *Trans. Scot. Arb. Soc.* iii. 80.

⁴ *Gard. Chron.* 1868, p. 1189.

2½ inches for bark, its contents are therefore 87 feet by 24¼ inches, making 355 cubic feet, instead of 469, as stated in *Quarterly Journal of Forestry*, i. 107 (1907).

At the time of the Conifer Conference in 1891, a tree¹ at Dropmore was stated to have been then 120 feet by 11 feet; but I measured this tree in 1905 and could not make it more than 107 feet by 11½ feet, a considerable part of the top having been, as I was told, broken off by the wind. I measured it again carefully in June 1908, when it was 110 feet by 12 feet in girth.

At Walcot there is a very large tree planted in 1842, of which the Earl of Powis gave me a series of measurements. The first taken in 1860 was 74 feet by 7 feet; the second in 1872, 85 feet by 8 feet 10 inches; the third in 1892, 107 feet by 12 feet 9 inches; the fourth in April 1906, taken with a theodolite, was given as 122 feet by 15 feet 6 inches; all the girths taken at 4 feet. The cubic contents were 393 feet. I measured what I believed to be the same tree carefully from both sides, in March 1906, and made it 114 feet by 14 feet 2 inches at 5 feet, and noticed that the top had been somewhat broken. Thus it is evident in both these trees that after they had attained about sixty years old, the height increased much more slowly.

There are two trees at Powis Castle, one of which on the rabbit bank, near the park gate, I made from 112 to 115 feet by 11 feet 10 inches (this is the mean of two measurements from opposite sides as the tree² leans a good deal), and the other in a thick plantation, close to a pond, which, though I cannot, owing to its position, be confident that it is over 130 feet, may be 5 feet or more higher, and is more likely to increase in height than any Douglas fir that I have seen. It is only 9 feet 5 inches in girth and quite the finest timber tree of the sort I know in England.³

There is a tree at Highclere which, in 1903, was about 100 feet by 13 feet 8 inches. At Barton, Suffolk, a tree planted in 1831 measured in 1904, 107 feet high by 10 feet 1 inch in girth, and, while beautifully clothed to the base, was rather thin at the top with a divided leader. At Bury Hill, near Dorking, are perhaps the oldest and largest trees in Surrey, which, as Mr. R. Barclay told me, were planted by his father about 1832. The largest in 1908 measured 104 feet by 12 feet 2 inches, and appeared to have lost its leader recently.

At Albury, Sussex, there are two trees, which in 1904 measured 95 feet by 6 feet 2 inches and 82 feet by 8 feet 3 inches. At Cassiobury, Herts, there is another, which, according to the label, was planted in 1830, and had attained in 1904, 99 feet in height and 11 feet 3 inches in girth. This has now lost its leader, and has remarkably pendent branches, with leaves conspicuously white

¹ The tree at Dropmore, raised from seed, sown in the mid-winter of 1827, was planted out in 1829, and has shown the following growth:—

Measured	1837	1843	1846	1851	1853	1860	1862	1867	1868	1871
Height in feet	18	40	48½	62½	65	78	85	93	95	100

Cf. *Gard. Chron.* 1843, p. 808; 1846, p. 661; 1851, p. 246; 1853, p. 343; 1860, p. 854; 1867, p. 808; 1868, p. 465; 1871, p. 1360.

² Lord Powis had this tree measured in 1908, by a man climbing, as 127 feet by 12 feet 1 inch. I cannot account for the difference.

³ I measured this tree again in July 1908, and having found a spot from which I could see the top, am confident that it is more than 130 feet high. It had increased 5 inches in girth in two years.

beneath. At Fulmodestone, Norfolk, Sir Hugh Beevor measured, in 1904, a tree 98 feet high by 8½ feet in girth. Henry saw a tree there in 1905, which was 82 feet by 9 feet 4 inches.

Many other trees which approach if they do not exceed 100 feet in height, may be found in the southern and western counties.

At Endsleigh, in Devonshire, which was visited by the English Arboricultural Society¹ in August 1906, there is a very fine plantation of Douglas fir in Gunoak Wood, of which careful measurements were made by Mr. R. G. Forbes, forester to the Duke of Bedford, in November 1906, from which it appears that the three largest trees in this plantation measure as follows:—

No. 16.	120 feet high by 11 inches quarter-girth = 100 cubic feet.
No. 23.	100 " 13 " = 117 "
No. 30.	110 " 13 " = 129 "

Mr. E. C. Rundle, agent for the property, writes to me as follows: "The forester says that the trees must not be taken as a full crop, for there is space on the ¼ acre for forty trees instead of thirty-two. As to their age I believe they must be over fifty years, probably fifty-five, though an old man remembers their being planted. The quarter-girth was taken over bark at half the length of the tree, and an inch to the foot would be sufficient allowance. They are growing in an exposed position, but in the middle of a wood on high ground, and the soil is not at all good." The total contents of the thirty-two trees is 2857 cubic feet, an average of rather over 89 feet per tree. If 357 feet is deducted from the total for bark and small tops, it will leave a result of 10,000 feet per acre.

At Woburn, in a plantation called "The Evergreens," on a very light sandy soil, Mr. Mitchell, forester to the Duke of Bedford, showed me a plantation made in 1882, well sheltered by surrounding trees, and wrote me the following particulars:—

"The number of trees planted was 160, of which 132 are now left. I thinned them a few years ago, taking out only dead and suppressed trees. The area of land is as nearly as possible 2 chains square, and includes a few old Scotch and spruce fir. I measured the trees in three classes, as follows:—

72 trees:	50 feet by 6 inches quarter-girth = 900 cubic feet.
40 "	55 " 6½ " " 645 "
20 "	50 " 4 " " 111 "
	1656 "
	Deduct for bark at 8 per cent . 136 "
	Total contents of timber . 1520 "

This works out at 3800 cubic feet per acre at twenty-six years after planting," say thirty years from seed. I may add that though these trees were planted close enough to kill all their lower branches, yet none of these had fallen, and a good many of the stems showed the same want of straightness which is so often evident in this

¹ *Quarterly Journal of Forestry*, i. 64 (1907).

species in England, and which I attribute to the unripeness of their sappy leaders before winter.

In 1904 the Earl of Ducie showed me a plantation of Douglas fir on a steep bank called Ironmill Wood near Tortworth, which, though of insufficient area to give the best results, is a good illustration of the growth of this tree on sandstone (Plate 231). The plantation was made in 1868, and was therefore thirty-six years old when I saw it. The area, as measured by Mr. Harle, agent to Lord Ducie, was 1 acre 28 perches; the number of trees standing was 238; their average height was about 80 feet; and their average cubic contents I estimated at slightly over 20 feet, making a total of about 5000 feet per acre. Mr. A. P. Grenfell, who visited the same place in the same year, made a more careful estimate based on the measurements of the trees standing on $\frac{1}{10}$ of an acre, and came to the conclusion that the total volume, with allowance for bark, was 5250 feet, which gives an annual average increase of 150 cubic feet per acre, no allowance being made for thinnings.

Mr. G. F. Luttrell of Dunster Castle, Somersetshire, showed me, in August 1906, a plantation of Douglas fir which he made in 1880 on a piece of waste land, which was growing only furze, on gravelly soil close to the rock, which is on the Old Red Sandstone formation. In the following December he had this carefully measured, with the following result:—Broom Ball Wood, area 3 roods 10 perches, planted entirely with Douglas fir at about 10 feet apart. Number of trees now standing, 264. Total contents, allowing half an inch for bark, 2491 cubic feet. Of these, 158 trees contain less than 10 cubic feet each, and only 7 contain above 20 cubic feet, the largest tree measuring 42 feet timber length and 10 inches quarter-girth, equal to a volume of 29 cubic feet. The actual height of the tallest was 73 feet, of the shortest 48 feet.

The trees are valued as timber by Mr. Luttrell's forester at 6d. a foot, which amounts on the estimated quantity to £62:6s., equal to £76:13:6 per acre. Deducting from this sum, the expenses of planting and fencing, £6 an acre in 1880, equivalent in 1906, at 4 per cent. interest, to £16 12 6 and the annual deferred rent at 5s. an acre, from 1880 to 1906, equivalent to 11 0 0

£27 12 6

the balance, £49:1s., represents the actual profit per acre 49 1 0

£76 13 6

It seems to me that the price of 6d. per foot for trees of this size is somewhat excessive, as those of less than 10 feet are hardly fit for anything but pitwood or rough fencing; but the value of the trees over 10 feet might be somewhat higher.

From the appearance of this plantation, in which many of the smaller trees were already suppressed and not likely to grow much more, it seemed to me that either a heavy thinning or clean felling was the proper thing to do, but this must depend on the local demand for timber of this size and quality. And if the small area, exposed position, and inferior agricultural quality of the land be taken into

consideration, there can be no doubt that this has been an unusually profitable investment, and one which would fully justify planting Douglas fir on a large scale in this district. Mr. Luttrell states that where there is sufficient room and light the trees reproduce freely from seed.

In Scotland there are many Douglas firs exceeding 100 feet in height, but we cannot say which is actually the largest; and if we did, it would not hold good for many years to come. The tallest recorded at the Conifer Conference¹ in 1891 was at Lynedoch, on Lord Mansfield's property in Perthshire, which was then reported to be 92 feet by 12 feet, but had a fork at 60 feet from the ground² (Plate 230). Another tree at the same place, is the parent of the seedlings planted at Scone and Taymount, and was only 72½ feet by 11 feet 2 inches, though planted in 1834.

One of the oldest trees is in the grounds of Scone Palace, and bears the inscription "raised from the first seed, brought by David Douglas in 1827, planted 1834." In 1850 it was transplanted to its present position, and this has doubtless checked its growth. It measured, in 1904, 96 feet high by 10 feet in girth. Its foliage is conspicuously white beneath.

At Drumlanrig, in Dumfriesshire, there is also an original tree, which was sent by David Douglas to his brother, who was clerk of works at Drumlanrig about 1832. It is growing in shallow gravelly soil near the top of a hill, overlooking a glen, and in 1904 measured 90 feet high by 11 feet 4 inches in girth.

Mr. R. Macleod of Cadboll sends me the measurements of four trees taken in 1907 by Mr. C. E. Cranstoun at Corehouse, near Lanark, as follows:—

No.	Height.	Girth at 5 feet.
1.	70½ feet.	12 feet 5 inches.
2.	83 "	10 " 7 "
3.	85 "	12 " 4 "
4.	92 "	7 " 6 "

He adds that these were raised from the first seed sent to Scotland by Douglas; and that he finds by repeated measurements of several trees, that their rate of girth increase is about 2 inches per annum.

At Durris, in Kincardineshire, the original and largest tree, planted about seventy-two years ago, has now reached 114 feet by 12½ feet, and contains over 300 feet of timber. At Buchanan Castle, Stirlingshire, Mr. Renwick measured³ in 1900 an original tree 85 feet by 13 feet 2 inches. He informs us that the girth in 1908 is 14 feet 2½ inches.

At Murthly Castle there are probably more large trees of this species than anywhere in Scotland, the plantation below the castle being especially fine, and also the avenue called the Dolphin Walk, where the trees, planted about 8 yards apart,

¹ *Journ. Roy. Hort. Soc.* xiv. 537 (1892).

² An accurate measurement of this tree, made in January 1908 by Mr. A. T. Kinnear, makes it 108 feet high by 13 feet 9 inches at 5 feet. The main stem up to the fork, 60 feet from the ground, contains 415 feet, and the two tops together, 48 feet, making the whole 463 cubic feet.

³ *Trans. Nat. Hist. Soc. Glasgow*, vi. 256 (1900).

average about 90 feet by 8 feet, and grow at the foot of a bank, in deep sand with pebbles in it, which looks like an old bank of the Tay, which is not far off. In *The Garden* for 19th May 1900, some particulars are given of the trees here. One, planted in 1847, measured on 11th August 1892, 86½ feet by 8 feet 10 inches, and on 24th March 1900, 97 feet 4 inches by 9 feet 10 inches. A great many others were of about the same size. This proves the diminishing rate of increase, both in height and girth, after forty to fifty years' growth, even when the lower branches remain. Mr. Fotheringham states that all these measurements were taken by sending men or boys up the trees, and not with a dendrometer. He adds that the temperature¹ in February 1895 was for several days below zero, and on one night went down to -11°.

There is probably no plantation in Great Britain about which so much has been written as the Taymount plantation on the estate of the Earl of Mansfield, in Perthshire. It lies about seven miles north of Perth, one mile from Stanley Station, and may be seen from the Highland Railway, which passes close to the east of it. The plantation covers eight acres of flat land, which is locally known as "till," two feet of light loam over red clay, and which may be worth for agricultural purposes 12s. to 15s. per acre. This plantation was first fully described in the *Gardeners' Chronicle* of 10th, 17th, and 24th November 1888, by Dr. Schlich, than whom there can be no higher authority. It was planted by the late W. M'Corquodale in the spring of 1860, with Douglas firs, two-year seedlings, two years transplanted, at 9 feet by 9 feet apart, with larch four years old, between every two firs, and an additional line of larch between every two rows, so that the trees stood 4½ feet apart, and each acre contained 538 Douglas and 1613 larch. The latter were gradually thinned out, and were all removed by 1880. The first thinning of Douglas took place in 1887, when about half the trees had already disappeared, 277 per acre only remaining. Of these 75 per acre were cut, leaving 202 per acre.

Dr. Schlich made a careful estimate of a sample plot measuring $\frac{1}{10}$ of an acre of average appearance, and had a tree felled to ascertain its actual contents; and from these data came to the conclusion that the total per acre was 3738 cubic feet of wood over 3 inches diameter, exclusive of top and branches, which gives an annual increment of 133 cubic feet per acre. But this estimate being the gross volume, when reduced by about one-fourth, makes the quarter-girth measurement, as adopted in English practice, to be 2934 cubic feet.

After inspecting a sample area of Scots pine in the same district, Dr. Schlich goes on to say, "If grown in a well-stocked, overcrowded wood, and in localities of equal quality, Douglas fir is not likely to produce more solid wood, during the first thirty or forty years, than the larch, and probably also not more than Scotch pine." He then goes into careful estimates of the probable future increase of the Douglas, based on data taken from America, where Dr. Mayr found that in the most favourable localities in the Cascade Mountains the average height of mature Douglas

¹ At Balmoral, where there are 25,000 to 30,000 trees, planted in the 'eighties, on a northern aspect at 1000 to 1200 feet altitude, Mr. Michie informs me in a letter that this severe frost, when the temperature fell to -17½°, did no harm to the Douglas fir.

firs on the best soil was 213 feet, with a diameter of 6½ feet, whilst in Montana it only reached an average height of 148 feet, with a diameter of 2.6 feet, thus showing what an immense influence the soil and rainfall have on the growth of this tree.

From a cross section of Douglas fir grown in Washington and then in the museum at Cooper's Hill, Dr. Schlich remarks "that the rate of growth indicated in this section, up to thirty years old, resembles that of an average tree in the Taymount plantation in a striking degree, as follows: diameter of average tree at Taymount at 4½ feet, 12 inches; diameter of thirty years' growth on the section from America, 11.9 inches.

After visiting a second growth area of pure Douglas fir on Ladds farm, about four miles from Portland, Oregon, which was believed to be of about fifty years' growth; I came to precisely the same conclusion, and though I had not then seen Dr. Schlich's article, I wrote in my journal at the time, that the trees in Oregon were very similar in density to those at Taymount, but decidedly cleaner and better grown, and having regard to their greater age and better soil, they might average 100 feet by 4 feet, and I estimated their cubic contents at something like 6000 feet per acre.

When I first visited Taymount, in April 1904, I determined to estimate it for myself, without regard to what others had done. I therefore paced an area of 100 yards long by 50 yards wide in what I thought a fair average of the whole plantation, and found that there were on it ninety-nine trees of the first size, and fifty trees of the second. I did not reckon a number of other trees, which were so small, crooked, or poor, that they could not have been sold profitably with the better ones; and, judging from a fallen tree which I was able to measure accurately, which was 55 feet long by 10 inches quarter-girth, equal to 38 cubic feet, came to the conclusion that the total volume of saleable timber at forty-four years after planting, or forty-eight years from the seed, did not much exceed 5000 feet per acre.

Sir Hugh Beevor visited Taymount in the autumn after I was there, and made an estimate in a different way by taking three different areas of $\frac{1}{4}$ acre each, and measuring everything on those areas. He found 96 trees of 12 inches quarter-girth and upwards at six feet from ground; 44 of 10 and 11 inches; 44 of below 10 inches; and estimated the total contents per acre at 6226 cubic feet.

I revisited Taymount in September 1906 in order to compare it again with what I had seen since in America and in England. I measured twenty trees in the fifth row and twenty in the tenth row from the bank on the east side of the plantation nearest to the high road. I found that their average girth over bark at 5 feet was slightly under 4 feet, the largest being 7 feet 10 inches and the smallest 2 feet 3 inches. I estimated the average timber length of these trees at 60 feet, and the quarter-girth, under bark at half this length, at 8 inches. If this is approximately correct, their average contents would be 26 feet 8 inches, and their total per acre something like 5400 feet, which very closely agrees with my previous estimate, allowing for the increase of two years.

A very different estimate was made by Dr. Somerville in a paper on "Exotic Conifers in Britain," which was printed in the *Journal of the Board of Agricul-*

ture, December 1903, and of which an abstract appeared in *Transactions of Royal Scottish Arboricultural Society*, xvii. 269. This was based on measurements made in June 1903, by the late Mr. Pitcaithley, forester to the late Earl of Mansfield, who selected two typical areas of $\frac{1}{10}$ acre each, on which he counted and measured the trees, of which he found eighteen on one and twenty-five on the other area, and accurately measured the cubic contents of two trees, one of which contained 46.76 cubic feet and the other 39.49 cubic feet measured down to 3 inches diameter. Dr. Somerville, assuming Mr. Pitcaithley's measured trees to be average ones, brings out the total cubic contents per acre by quarter-girth measure as 7977 cubic feet, and comparing this with Dr. Schlich's estimate of 2934 cubic feet made fifteen years previously, comes to the conclusion that the average increase per acre in that period was no less than 336 cubic feet per annum.

This in my opinion is a mistaken calculation, and if compared with the annual increment of 150 feet per acre per annum in Lord Ducie's plantation and the results of the measurement of Gunoak wood, both on better land than that at Taymount, we must hesitate to accept it as even approximately correct.¹

The important point to consider is how long these trees will continue to maintain their rapidity of growth, and what will be the value of the timber? My own belief is that they fall off in their rate of increase; that the larger ones will continue to suppress and starve out the weaker ones, as they have already done to a great extent; and that the timber of Douglas fir grown in the country will never compare in quality or value with the imported timber, which, it must always be remembered, is from 200 to 300 years old, and selected both in the forest and the mill from a very much larger quantity.

Dr. Schlich writes me as follows:—"As to the quality of the Douglas fir timber, I merely quoted what the late Mr. M'Corquodale told me. Since then I have paid some attention to the subject and noticed that in timber from young Douglas firs there is a considerable difference between spring wood and summer wood; hence I am sure, and in this I agree with you, that only trees of considerable age will yield timber equal in quality to that of larch, if at all."

There are other causes, which tend to make the production of clean, straight timber difficult, in many situations and on many soils in this country, and which should be considered by all who contemplate planting this species largely for profit.

The first is its tendency to form large and spreading branches, which it shows in a very marked degree. In order to prevent this, the trees must be crowded to an extent which is only possible with success on soils of unusual depth, or on slopes composed of rock which is sufficiently disintegrated to allow the roots to penetrate deeply; in which case they may clean themselves when they attain a height of 60 to 80 feet; though I have never seen any in England which have naturally cleaned

¹ After this was in print I sent it to the Earl of Mansfield for his opinion, and am informed that in 1908 a careful measurement was made by his forester, Mr. A. T. Kinnear, of the whole of Taymount plantation, which now contains 1536 Douglas firs on the whole area=192 trees to the acre. These contain 51,456 cubic feet (under bark) or 6432 cubic feet per acre, being an increase of 3498 cubic feet per acre since it was measured by Dr. Schlich in 1888, equal to about 134 feet per acre per annum since it was planted, the rate of increase from 1888 to 1908 being about 175 feet. The largest tree is 93 feet high, and contains 118 cubic feet.

their trunks. In default of these conditions recourse must be had to pruning, which entails considerable expense, and must be repeated at frequent intervals.

The second is the tendency which I have observed in so many places for the trees to ripen their leading shoot prematurely in dry summers, and to make a fresh start in the autumn when wet warm weather sets in. The result is that the second shoot is weak, immature, and usually becomes crooked either from frost, wind, or the settling of birds on it. A double lead is then often produced, and the result is seen in many plantations, in the more or less crooked stems,¹ or in forks, which must seriously depreciate the value of the timber when brought to the sawmill.

A third is the effect of gales on the leading shoots, which owing to their great length and weakness, seems greater than on any other conifer, especially as owing to the rapid growth of the tree it overtops other species with which it may be mixed. Even if the tops are not broken they become crooked, and often forked, in places exposed to wind, and the taller the trees become the more they are liable to this source of injury.

For these reasons it seems to me that the most profitable way of utilising Douglas fir, is to cut it at a comparatively early age, and utilise the wood for pit timber and estate purposes, for which purposes I am disposed to class it as superior to spruce or silver fir and inferior to larch.

In Ireland the Douglas fir grows very fast, and has attained in many places a large size. The late Lord Powerscourt planted at Powerscourt in 1865, with his own hands a tree which measured in 1904 100 feet in height and $9\frac{1}{2}$ feet in girth. There are good trees at Fota, Queenstown, 84 feet by $9\frac{1}{2}$ feet in 1903; at Carton, 81 feet by $7\frac{1}{2}$ feet in the same year; at Stradbally Hall, Queen's County, 86 feet by 8 feet 3 inches in 1907; at Coollattin, Wicklow, 85 feet by 9 feet in 1906. At Coollattin there are a few natural seedlings,² and several trees bear cones profusely; but the forester has not been able to raise plants from their seeds, doubtless owing to the cones being attacked by the insect which has done so much damage at Durrish in Kincardineshire. At Castlewella, Co. Down, there are fine trees, about 80 feet in height, which I could not measure on account of heavy rain when I was there in 1908. One measured by the Earl of Annesley in August 1908 is 79 feet by 10 feet, but lost 12 feet of its top in a gale in 1902.

The late Mr. John Booth of Berlin was a great admirer of this tree, and for many years advocated its planting in Germany, where it is now beginning to be looked upon as one of the most valuable forest trees. The result³ of an experiment made by the late Prince Bismarck, on his estates at Sachsenwald near Hamburg, was sent me by Mr. Booth just before his death, and may be summarised as follows:—

An area of 1.16 acre, the soil being a coarse, somewhat loamy, diluvial sand, was planted in 1881, half with four-year old Douglas, 5 feet apart, and half with spruce, 4 feet apart. In 1906, the Douglas plot consisted of 869 trees, measuring 3300 cubic feet of timber; while the spruce plot, 1335 trees, only

¹ This defect is clearly seen in the Taymount plantation.

² Natural seedlings were seen by Henry, also at Dereen and at Powerscourt.

³ Published in detail in *Zeitschrift für Forst- und Jagdwesen*, 1906, p. 8, of which a translation appeared in *Trans. Roy. Scot. Arbor. Soc.* xx. 104 (1907).

836 The Trees of Great Britain and Ireland

measured 1700 cubic feet. The market value of the timber, which could be used for poles and pit-props, worked out at about 1000 marks for the Douglas, and about 360 marks for the spruce. Thus, growing on the same soil, the Douglas, as compared with the spruce, had yielded about twice the amount of timber, with about three times the value. I visited this plantation in August 1908, and measured two of the largest trees, which were 74 feet high by 3 feet 8 inches, and 2 feet 7 inches; but the average was considerably less. I noticed that the lower branches, though dead for several years, were not falling off; and that many of the trees showed the same irregularity in straightness that I have noticed elsewhere. My impression was that unless heavily thinned, a large proportion of the trees would soon be suppressed by their more vigorous neighbours, and that such close planting was neither economic nor desirable.

TIMBER

I have said so much about the timber of this tree in its own country that it only remains to speak of its probable future value here, and as this subject has been ably dealt with in a recent paper by Mr. J. D. Crozier,¹ I cannot do better than summarise his opinions.

He agrees with me that we cannot hope to compete with the imported timber in size, age, or quality, and thinks that in a young state it is not so dense in fibre or so tough as larch of the same age. "For standing in contact with soil, and for such purposes as gate-making, fencing, etc., where the ability to stand wear and tear is a desideratum, it is inferior to larch, but there are many other purposes for which it is infinitely superior, and for the supply of which an infinitely greater volume of timber is required. For constructive purposes of all kinds it is especially suited, and owing to the beauty of its grain and the ease with which it can be worked, it is valuable for the finished work of interiors. The timber stains well, and when varnished, takes on and retains a beautiful gloss. Outlying and badly-grown trees, when sawn up are liable to warp, but this defect is not apparent when dealing with trees of clean straight growth; and with home timber more freedom may be used in regard to nailing. In a younger state it has been tried and found useful as curing-barrel staves and headings, and for box wood, for which in this locality there is an unlimited demand."

"What the most profitable length of rotation may be is a question which will have to be determined by trade demands, but to provide timber of a class fitted for house construction, any period short of 100 years need not, I feel convinced, be contemplated, and on deep rich soils, probably other ten or twenty years will require to be added to that period."

"As a pitwood tree the Douglas fir is well adapted, and is deserving of consideration wherever crops cultivated for that purpose are found to pay. Crowded together in pure plantation, by the time they have reached their thirtieth year, they will be found capable of yielding an amount of pitwood almost incredible to those who have not seen the tree so grown. For this purpose the planting should not be done at more than 3 feet apart."
(H. J. E.)

CASTANEA

Castanea, Adanson, *Fam. Pl.* ii. 375 (1763); Bentham et Hooker, *Gen. Pl.* iii. 409 (1880); Dode, *Bull. Soc. Dendr. France*, 1908, p. 140.
Fagus, Linnæus, *Gen. Pl.* 292 (in part) (1737).
Casanophorum, Necker, *Elem. Bot.* iii. 257 (1790).

TREES or shrubs, belonging to the order Fagaceæ. Bark furrowed. Buds all axillary, no true terminal bud being formed, as the tip of the branchlet falls off in early summer, leaving a small circular scar close to the uppermost axillary bud, which prolongs the branchlet in the following year. Buds alternate, arranged on the long shoots in two ranks; scales numerous, two or three of which are visible externally, lowest pair lateral and each composed of two connate stipules, next pair each corresponding to a stipule and with or without a leaf-rudiment, following pairs of single stipules each covering a young leaf; all the single stipules accrescent and marking in their fall the base of the shoot with ring-like scars.

Leaves deciduous, alternate, simple, stalked, dentate with slender glandular teeth, penninerved, each lateral nerve ending in a tooth. Stipules ovate or lanceolate, scarious, deciduous, their scars visible in winter on each side of the leaf-scars, which show three groups of bundle-dots, and are placed on prominent pulvini, from which decurrent lines descend along the branchlet.

Flowers monœcious, strong-smelling,¹ fertilised by the wind, unisexual, in slender elongated erect catkins, of which those arising in the axils of the lower leaves of the branchlet open early and are entirely composed of male flowers, while the catkins arising in the axils of the upper leaves are shorter and bear female flowers at their base and male flowers on their upper part, the latter not opening until after the female flowers have been fertilised. Staminate flowers three to seven, in a cyme in the axil of a bract, and surrounded by minute bracteoles; calyx campanulate, deeply divided into usually six segments, stamens twice or thrice as many as the calyx lobes; filaments filiform; anthers two-celled, dehiscing longitudinally; ovary aborted. Pistillate flowers, sessile, solitary or two to three together, placed within an involucre of closely imbricated scales, subtended by a bract and two bracteoles; calyx-tube urn-shaped, divided above into six short lobes; ovary adnate to the calyx tube, six-celled, each cell containing two ovules, surmounted by six simple styles, which are exerted out of the involucre.

¹ Cf. Kerner, *Nat. Hist. Plants*, Eng. trans. ii. 200 (1898), concerning the nature of the odour of the flowers.

Fruit, ripening in one season, one to three nuts, ovoid, plano-convex or compressed, enclosed in an involucre, which is tomentose within and is covered externally with branched spines fascicled between deciduous scales, the nuts escaping by the ultimate splitting of the involucre above into two to four valves. Nut crowned by the styles, marked with a scar at the base, its shell lined with tomentum. Seed usually solitary, occasionally two to three in each nut, the aborted ovules, two to eleven in number, remaining at the apex of the seed. Albumen absent. Cotyledons thick, fleshy, undulate, sweet, farinaceous, remaining under ground on germination.

The genus¹ is confined to the warmer parts of the northern temperate zone, and much difference of opinion exists as to the various forms² which are met with. Formerly only two species were recognised, viz. *C. sativa* and *C. pumila*; but the former, widely spread over North America, Europe, and Asia, exists in certain well-marked geographical forms, which it is convenient to treat as distinct species. A small shrub, occurring in North America, near the coast in the South Atlantic states and in Louisiana and Arkansas, is considered by American botanists to be another distinct species, *Castanea alnifolia*, Nuttall, and will not be further alluded to. Four species have been introduced into cultivation and are distinguished as follows:—

I. Leaves without stellate tomentum, acute at the base.

1. *Castanea dentata*, Borkhausen. N. America. See p. 856.

Leaves tapering at the base, long acuminate at the apex, green and glabrous beneath, pendulous. Petiole glabrous.

II. Leaves with stellate tomentum, rounded or cordate at the base.

2. *Castanea sativa*, Miller. Europe, N. Africa, Asia Minor, Caucasus, Persia. See p. 839.

Leaves green beneath, always showing some trace at least of tomentum, not pendulous, coarsely serrate. Petiole and young shoots scurfy pubescent.

3. *Castanea crenata*, Siebold et Zuccarini. China, Japan. See p. 854.

Leaves green beneath, tomentum variable in quantity, shallowly and crenately serrate, the teeth often reduced to bristle-like points. Petiole, young shoots, and midrib densely pubescent with short hairs.

4. *Castanea pumila*, Miller. N. America. See p. 857.

Leaves silvery white and always tomentose beneath. Petiole and young shoots strongly pubescent.

¹ In *Castanea*, the leaves are deciduous, no terminal bud is formed, and the fruits ripen in one season. In *Castanopsis* the leaves are persistent, a terminal bud is present, and the fruits ripen at the end of the second season.

² Dode enumerates twelve species, some of which are alluded to in our accounts of *C. crenata* and *C. pumila*.

CASTANEA SATIVA, SPANISH OR SWEET CHESTNUT

Castanea sativa, Miller, *Dict.* ed. 8, No. 1. (1768).

Castanea vulgaris, Lamarck, *Dict.* i. 708 (1783); Willkomm, *Forstliche Flora*, 428 (1887); Mathieu, *Flore Forestière*, 325 (1897).

Castanea vesca, Gaertner, *Fruct.* i. 181, t. 37 (1788); Loudon, *Arb. et Frut. Brit.* iii. 1983 (1838).

Castanea Castanea, Karsten, *Pharm. Med. Bot.* 495 (1882).

Fagus Castanea, Linnæus, *Sp. Pl.* 997 (1753).

A tree, attaining over 100 feet in height and an immense girth. Bark of very young stems smooth and olive green, soon becoming greyish white, after fifteen to twenty years gradually changing into a thick brown bark, which is deeply and longitudinally fissured. Young branchlets green, covered with a minute scattered pubescence above, and with longer hairs near the base; in the second year grey, glabrous.

Leaves (Plate 202, Fig. 11) not pendulous, oblong-lanceolate; broad, unequal, rounded and often auricled at the base; acuminate at the apex; with about twenty pairs of parallel nerves, raised on the under surface of the blade, each ending in a triangular tooth, which is prolonged into a long fine point; upper surface dark green, shining, covered with minute scattered pubescence; lower surface lighter green, with dense appressed stellate pubescence.¹ Petiole scurfy pubescent, $\frac{1}{2}$ to 1 inch long. Stipules $\frac{3}{8}$ inch long.

Nut, variable in size, abruptly and shortly acuminate at the apex, usually three in each involucre, in wild trees.

An elaborate description of the fruit is given by Lubbock.² The cotyledons are fleshy, occupying nearly the whole of the seed, undulate, and interlocking with each other at the margins. When sown, the pericarp, owing to the swelling of the cotyledons, splits in the soil at the apex, so that the shoot and rootlet emerge, the cotyledons remaining enclosed in the pericarp and being gradually absorbed. The germination thus resembles that of the oak; and the young stem similarly bears several scales (two to six in number) below the primary leaves, which resemble in shape those of the adult plant and bear deciduous stipules.

IDENTIFICATION

In summer the leaves are unmistakable and can only possibly be confused with certain species of oak, like *Quercus serrata* and *Q. castaneaefolia*, which have, however, very different buds. From the other species of the genus, it is distinguished by the characters given in the key.

In winter the following characters (Plate 200, Fig. 1) are available:—Twigs stout, reddish brown or olive green, shining, conspicuously angled, glabrous for the most part but showing remains of glands and pubescence towards the base, which is conspicuously ringed by the fall of the previous season's bud-scales. Leaf-scars

¹ This pubescence often wears off, so that the leaves are glabrescent or even glabrous, when gathered in summer.

² *Seedlings*, ii. 537 (1892).

obcordate or semicircular, with three groups of bundle-dots, and set parallel to the twig on prominent pulvini, distichous on the long shoots. Stipule-scars long, linear. Buds ovoid, slightly rounded and not acute at the apex, those nearest the apex of the twig the largest; three scales visible externally, first scale small and short, second scale longer, both glabrous and ciliate; third scale clothed with appressed pubescence and appearing at the apex of the bud.

The twigs and buds of the chestnut resemble those of the lime tree. The pith affords a good mark of distinction, being greenish and five-rayed in *Castanea*, and whitish and round in *Tilia*.

In France, single trees have been noticed¹ in several localities, which bore catkins entirely formed of pistillate flowers. Such trees, according to Dode,² bear a large quantity of fruit; but the presence in the neighbourhood of a tree with staminate flowers is necessary for fertilisation. Mr. Lynch informs me that an isolated tree in a garden at Cambridge never bore fruit, until branches, with staminate flowers from another tree, were laid upon it; but it is uncertain whether this tree bore only pistillate flowers, or whether its own pollen was ineffective. Dode also mentions² a tree in the department of the Loire which never bore fruit, as its catkins were entirely composed of staminate flowers.

The number of seeds in the nut is also variable; and a single chestnut with three seeds has been known to germinate and produce three plants.¹

VARIETIES

The chestnut varies very little in the wild state, though the amount of pubescence which occurs on the leaf is remarkably different in many specimens. At the Scientific Committee meeting of the Royal Horticultural Society on 6th November 1900, some remarkable leaves were shown, consisting of but little more than the midribs, which had issued from the stump of a tree that had been felled; and it is possible that some of the narrow-leaved varieties originated in this way.

Schelle³ enumerates nineteen varieties, which have been obtained in cultivation. Seven of these are forms with variously coloured and variegated leaves, viz.—*argentea*, *marginata*, *argenteo-marginata*, *argenteo-variegata*, *aureo-maculata*, *aureo-marginata*, and *aureo-variegata*. These are sufficiently explained by their names; and of those we have seen *aureo-marginata* is the best.⁴

Var. *heterophylla*.⁵ Leaves variable in shape, some with irregularly-shaped teeth and occasional deep sinuses, others repand in margin and with few teeth.

Var. *asplenifolia* (var. *laciniata*). Leaves with long narrow teeth, ending in long subulate points.

¹ Clos, in *Bull. Soc. Bot. France*, xiii. 96 (1866).

² Dode, in *Bull. Soc. Dendr. France*, 1908, p. 147.

³ *Laubhols-benennung*, 63 (1903).

⁴ There are small trees of the silver and golden variegated forms at Aldenham which are very handsome and well worth growing. A curious purple-leaved variety is described on p. 852.—(H. J. E.)

⁵ At Verrières, near Paris, there is a tree, 28 feet high and 5 feet in girth, which has a few branches with normal foliage, all the others bearing leaves deeply and irregularly lobed. These two different kinds of branches bear fruit, which reproduces, when sown, seedlings with the form of foliage from which the nuts have been derived. Cf. *Hortus Vilmorinianus*, 56 (1906). There is a fine specimen of this variety at Murthly Castle; and Mr. Renwick has sent us specimens from a large tree at Finlayson, Renfrewshire, a few of the leaves of which are of the *heterophylla* type.

Var. *cochleata*. Leaves small, irregularly cut, hollow or with swellings in the middle.

Var. *prolifera*. Some of the leaves, usually the uppermost ones, remaining whitish tomentose beneath.

Var. *glabra*. Leaves thin and shining.

Var. *rotundifolia*. Leaves small, not exceeding 2½ inches in length, oval in shape.

Var. *pendulifolia*.¹ Branches pendulous.

Many varieties of the fruit, which are propagated by grafting, are cultivated in France and Italy. In France, the name *marron* is given to the best varieties, in which the fruit is large, globular, broader than long, and usually single in the involucre. According to de Candolle,² the Romans in Pliny's time already distinguished eight varieties, but it is impossible to discover from the text of this author whether they possessed the variety with a single kernel. Olivier de Serres³ in the sixteenth century praises the chestnuts, *Sardonne* and *Tuscane*, which produced the single-kernelled fruit called the *marron de Lyons*. He considered that these varieties came from Italy; and Targioni⁴ states that the name *marrone* or *marone* was employed in that country in the Middle Ages (1170). In England, the cultivation⁵ of special varieties of the chestnut for its fruit is so little in vogue that it is not even mentioned in a late and comprehensive book on fruit culture, *The Fruit Garden*,⁶ by Bunyard and Thomas.⁷

DISTRIBUTION

The chestnut occurs wild throughout the whole of southern Europe, in Algeria, Tunis,⁸ Asia Minor, the Caucasus, and northern Persia. It has not been found in the Himalayas where there are several species of *Castanopsis* occasionally known in India⁹ as chestnuts, and is replaced in China and Japan by a closely allied species.¹⁰

Its northern limit in Europe is difficult to trace with accuracy, as the original area of distribution has been much extended by cultivation since the time of the Romans; and it has become naturalised in many parts. According to Willkomm the northern limit runs along the edge of the Jura and is continued through Switzerland to the south Tyrol, Carinthia, Styria, and Hungary, where it reaches Pressburg

² *Origin of Cultivated Plants*, 353 (1886).

³ *Théâtre de l'Agric.* p. 114.

⁴ *Cenni Storici*, p. 180.

⁵ Hogg, in *Fruit Manual*, 224 (1875), says that the chestnuts produced even in the southern counties are so inferior to those imported from Spain and the south of France, that no one would think of planting the chestnut for its fruit alone. He mentions two varieties, *Devonshire Prolific* and *Downton*, which succeed in hot seasons. Lord Ducie, however, informed Sir W. Thiselton-Dyer that he had once sent a sack of chestnuts to Covent Garden market, which realised £3; and was asked to send more, as they were the first on the market.

⁶ In Country Life Library, 1904.

⁷ W. A. Taylor, in Bailey, *Cycl. Amer. Hort.* i. 296 (1900), enumerates and describes seventeen varieties of the European chestnut which are in cultivation in the United States.

⁸ Battandier et Trabut, *Flore de l'Algérie*, 819 (1888); wild in forests of Edough near Bône in Algeria, and in Tunisia near Ain-Drahm. Though cultivated near Tangiers and Tetuan it has not yet been found wild in Morocco. Cf. Ball, in *Journ. Linn. Soc. (Bot.)* xvi. 666 (1878).

⁹ The chestnut has been planted at Bashahr, in the Punjab, where trees fifteen years old are 30 feet high and 4 feet in girth. *Kew Bull.* 1897, p. 113.

¹⁰ The chestnut has been erroneously supposed, mainly on philological grounds, not to be a native of Europe, but to have been introduced at an early period from Asia Minor. The best discussion on this subject is by De Candolle, in *Geog. Bot.* ii. 688 (1855). A learned paper on the classical names of the oak and chestnut by H. L. Long appeared in Loudon, *Gard. Mag.* 1839, pp. 9-20. Dr. Bettelini's excellent account of this tree in *Flora Legnosa del Sottoceneri*, pp. 83-112 (1904), should also be consulted. He describes sixteen varieties, cultivated for their fruit in Switzerland and Italy.

in the west and the Bihar Mountains in Transylvania. According, however, to Fliche,¹ it is not truly wild in any part of France nor even in Corsica, as it never forms part of the real forests and is generally found either as coppice or as isolated trees planted by man rather than as a true forest tree.

In France it is common in Provence, Dauphiné, the Cevennes, Perigord, Limousin, and all the central plateau, and it fruits abundantly in the environs of Paris. As in England, it was long supposed that there were large forests of chestnut in ancient times, and it is popularly believed that the severe winter of 1709 caused their destruction in the region of the Loire. This is, however, an error, and the wood supposed to be chestnut, occurring in ancient churches and other buildings at Troyes, Reims, Sens, Chartres, and in Notre Dame at Paris has been conclusively proved to be oak.² The chestnut in France is rarely cultivated in high forest, as the timber is very liable to shake and to rot at the heart, so that sound pieces of considerable size are rarely obtained. It is, however, often cultivated as coppice, for use as vine props and hoops for casks. Mathieu mentions a tree growing near Sancerre in the department of Cher, which is 30 feet in girth and appears to be perfectly sound. Mr. Chaumette³ saw a chestnut in 1851 near Evian in Savoy, which had a girth of 54 feet, was 85 feet high, wide-spreading and well-shaped, but the trunk was perfectly hollow.

The chestnut is truly wild in Spain,⁴ and appears to attain there a greater development than in any other country. In the north, as in the provinces of Galicia, Asturias, and Biscaya, it constitutes forests of great extent, growing in company with *Quercus Toza*, *Q. sessiliflora* and *Q. pedunculata* or occasionally with the beech, and ascends from sea-level up to 2500 feet. It abounds in the mountains near Avila; and between Baños and Bejar there are vast woods in which it occurs mixed with *Quercus Suber*. It also occurs in the mountains of Toledo and of Estremadura and in the Sierra Morena. In the northern parts of Navarre and Aragon, it ascends in the Pyrenees to 3000 feet. In the extreme south of Spain, it no longer descends to sea-level, but forms a zone between 2700 and 5400 feet altitude in the Serrania de Ronda and the Sierra Nevada; and small woods also occur on the Alpujarras. The chestnut is also common in Portugal, and various localities are mentioned for it by Colmeiro.

In Italy the chestnut occurs throughout the Apennines and also in Sicily, rising to 3000 or 4000 feet elevation; and pure woods are found, especially in Tuscany. The most celebrated tree of this species, the *Castagno di Cento Cavalli*, growing on Mount Etna, was visited by Brydone⁵ in 1770, who found it to be a hollow shell, which looked rather like a group of five trees growing together than a single tree. Brydone made its girth 204 feet. This ruin has lately been seen by Mr. Druce⁶ of Oxford, who found four distinct parts still remaining, three of which

¹ Cf. Fliche, in *Bull. Soc. Bot. France*, liv. 132 (1907), concerning the recent discovery of chestnut charcoal at a prehistoric station in the department of Dordogne. Dr. Christ, in *Flore de la Suisse*, snpl. 48 (1907), discusses the question of the distribution of the chestnut, and now agrees with Engler (*Ber. Schweiz. Bot. Ges.* xi. 81) that it is not truly wild in Switzerland, either in the Jura or in the Alps.

⁶ Cf. *Pharmac. Journ.* Feb. 27, 1904, p. 258.

looked like mighty trees, though not over 70 feet in height. It still fruits freely, and bears on its branches several bunches of the southern species¹ of mistletoe. Besides this great tree, there are four other enormous trees on Mount Etna, mentioned by Parlatore and Tornabene, viz. the *Castagno della Nave*, 22 metres in girth; the *C. della Navota*, 18.7 metres; and the two *C. di Santa Agata*, 22.6 and 26.3 metres, all sound and much more beautiful than the *C. di Cento Cavalli*.

The chestnut forms a part of the forests in the south of Germany, but is not indigenous, being introduced, it is supposed, by the Romans, as in Alsace, where it forms large woods, ascending to 2000 feet, on the slopes of the Vosges, and in the plain, as around Sulzmatt and Rohrbach. Along the foot of the Vosges in Alsace, chestnut coppice, treated on a fifteen years' rotation, is very common, the wood being used for vine-props. The chestnut is cultivated largely in southern Germany as a fruit tree, and as an ornamental tree in parts of north Germany, where in favourable situations, as near Brunswick and at Blankenburg, it ripens its fruit perfectly.

It is planted in southern Sweden and on the coast of Norway between Christiania and Christiansand, and occasionally ripens its fruit. According to Schübeler, it exists in Norway as a bush as far north on the coast as lat. 63°.

In Austria it is commonly planted, as in Bohemia and Moravia, while farther south it is supposed to be often wild. There is a remarkable wood of chestnut, on the domain of Mokritz in lower Carniola, which lies between 500 and 1500 feet elevation. In Carinthia, the chestnut constitutes 10 per cent of the mixed forest on the Neuhaus estate, ascending to 1800 feet; and at Bleiburg it is still a fine tree at 3100 feet elevation.

On the eastern side of the Adriatic,² from Fiume to Castelnuova, the chestnut forms a part of the forest, which is composed mainly of oak and laurel; while in the interior it is a considerable element in the oak forests of western Bosnia and Croatia. It occurs also mixed with the beech in Croatia, Bosnia, Herzegovina, and Montenegro. Wilkomm speaks of grand woods of chestnut in southern Hungary, Slavonia, Croatia, and Dalmatia; and mentions large wild forests in the Etsch valley in the Tyrol. Velenovsky³ states that in the western Balkans, not far from the town of Berkovitz, there are extensive woods of chestnut, which are apparently wild, and have an undergrowth of the common hazel. Elsewhere in Bulgaria the chestnut appears to be planted, and is not a common tree.

The chestnut⁴ is very common in the mountains of Greece, and is met with also in the islands of Keos, Naxos, and Crete. It occurs either solitary or gregariously, and in some parts of the mountains forms extensive woods.

In Macedonia,⁵ Thrace, Albania, and Bithynia, the chestnut often forms the lower border of the deciduous forest, at 1200 to 3000 feet, occurring above the region of ever-green shrubs; but here and there it descends to sea-level. Chestnut woods occur on Olympus, in the peninsula of Mount Athos, and on Mount Kortiach near Salonica.

¹ This appears to be, judging from an imperfect specimen kindly sent by Mr. Druce, *Viscum laxum*, Boissier et Reuter. Cf. Nyman, *Consp. Fl. Europ.* i. 320 (1878).

² Cf. Beck von Mannagetta, *Veg. Verh. Illyrischen Ländern*, 147, etc. (1901).

⁴ Halácsy, *Consp. Fl. Græca*, iii. 125 (1904).

⁵ Grisebach, *Fl. Rumelica*, i. 339 (1843).

In Asia Minor the chestnut has been found wild in northern and western Anatolia; but it appears to be absent from the Taurus and Lebanon. In the Caucasus¹ it is found throughout the whole territory, and also in the Talysch, up to 6000 feet elevation; and it extends into north Persia.

A large chestnut grew in Madeira, on the estate of Count Carvalhal, at Achada, 23 kilometres from Funchal, and was reported by M. Joly² to have been about 160 feet in height with a girth at 3 feet 4 inches from the ground of 38 feet 8 inches. It was burnt down three years ago, and no trace of it now exists. The chestnut is not indigenous³ in Madeira, although formerly many large planted woods existed there, most of which have disappeared.

The chestnut was probably introduced into England by the Romans. Charcoal, supposed to be of chestnut, was discovered by Mr. H. N. Ridley⁴ associated with palæolithic implements and the bones of the rhinoceros in a brick-earth pit between Erith and Crayford in Kent. Mr. Clement Reid⁵ has not found any evidence corroborating the possibility of the tree being a native of Britain in prehistoric times, and Mr. Ridley's specimen may be capable of some other explanation.

The tree⁶ is mentioned in Anglo-Saxon literature as the *cisten* or *cyst-beam*. The modern name *chestnut* is a shortened form of *chesten-nut*, the fruit of the *chesten*, the early English name of the tree, representing the old French *chastaigne*, from the Latin *castanea*. King Henry II., in a grant to the Abbey of Flaxley in the Forest of Dean, says:⁷ "*de eadem foresta dedi eis decimam castanearum mearum*"; and it is probable that the chestnuts here referred to were cultivated at this early time for their fruit and not for their timber.

Natural seedlings⁸ are common in the southern counties, as in Kent, Surrey, Sussex, and Hampshire; and the chestnut may be considered to be naturalised in some places. Briggs states that it is naturalised in Cotehele wood near Plymouth; but as Bromfield remarks, it does not spread over waste places in the way that oak and pine commonly do. (A. H.)

CULTIVATION

The Sweet or Spanish Chestnut, as it is usually called, is on soils and situations which suit it one of the largest trees in England, and both from an ornamental and an economic point of view one of the most important of exotic hard-woods.

It is most at home in the southern counties, for though hardy in almost any part of Great Britain, it loves a warm soil and a warm summer climate, but will grow to a large size where the rainfall is as much as 60 inches per annum.

¹ Radde, *Pflanzenverbreit. Kaukasusland*, 182 (1899).

² Cf. Vahl, in Engler, *Bot. Jahrb.* 1905, p. 307.

³ *Origin British Flora*, 146 (1899).

⁴ Cf. Murray, *New English Dictionary*, ii. 329 (1893). The village of Cheshunt does not take its name, as has been supposed by Ducarel and others, from the chestnut. Skeat, in *Place Names of Hertfordshire*, 37 (1904), proves that Cheshunt is a corruption of Cestrehunt, derived from Anglo-Saxon *ceaster*, a camp, and *hunta*, a huntsman.

⁵ Ducarel, in *Phil. Trans.* 1771.

⁶ There are numerous natural seedlings in Windsor Park, especially amongst the tall pines near Virginia Water. They are also common in Norfolk, at Fulmodestone and at Hargham.

⁷ *Note sur un Chataignier Colossal.*

⁸ *Journ. Bot.* 1885, p. 253.

With regard to soil, the chestnut is rather fastidious, as, though it will exist for a time, it rarely thrives on soils of a chalky or limy¹ nature, and will not grow in stiff clay or in peaty soil.

All the largest I have seen are on greensand or old red sandstone; and when cultivated for coppice-wood, which is probably its best economic use, it requires a better soil and climate than any other tree usually so treated. It is propagated by seed, which ripens in the southern counties abundantly in good seasons, though the fruit is inferior in size and quality to what is imported from Spain and France. The largest nuts should be chosen and kept dry in sand until spring, as they are devoured by mice, and if sown in autumn are liable to rot if exposed to much frost and wet. They should be transplanted when one year old and kept rather crowded in the nursery until they are 5 to 6 feet high, as they are liable to become very bushy if they have room to spread. They are not difficult to transplant, if grown in light soil, but must not be left more than two years before transplanting.²

A remarkable instance of the grafting of the chestnut on the oak³ was shown me in the Botanic Garden of Dijon in France by M. Genty, the professor of botany there. The history of this tree is given in full by M. A. Baudot, in a pamphlet published at Dijon in 1907, from which I gather that in 1835 some acorns of the pedunculate oak were sown by M. Meline, five of which were grafted in 1839 with scions from the chestnut. Three of the grafts failed to take, another was injured by wind, the fifth pushed a shoot in the first year about 4 feet long, and grew so vigorously that it is now nearly 40 feet high with a girth of 4½ feet. The tree bore small fruit in 1852; and in 1903 some were sown, which germinated and produced three young plants, of which two are now planted out in the garden at Dijon, and a third was sent to M. M. de Vilmorin at Les Barres.

The varieties of the chestnut grown for fruit are usually grafted in French nurseries, but are rarely planted in England at present so far as I have seen.

As coppice-wood the chestnut is principally found in the hop-growing districts of Kent, Sussex, and Hants, where, until wiring was introduced, it was one of the most valuable products of English woodland, being cut at intervals of 8 to 12 years and realising frequently £2 to £3 per acre per annum. But now, though still more valuable than ash or hazel, it has fallen so much in price that these coppices are not as carefully managed as they used to be; and the split poles, which are so largely used for fencing, are said to be imported from France. In such coppices the stools are at 5 to 6 feet apart, because the thinner a hop pole is in proportion to its height the

¹ Fliche and Grandeau (*Ann. Chémie et Physique*, 1874, p. 354) proved by experiments, that the presence of a considerable amount of lime in the soil causes the chestnut to languish or to die, as too little iron is absorbed by the tree, and the normal function of the chlorophyll is deleteriously affected. Alphonse de Candolle, in *Nuovo Giorn. Bot. Ital.* x. 228 (1878), states that the chestnut is never found growing in Switzerland on limestone, and that in places where it is believed to occur on limestone, careful examination shows that the roots are surrounded by siliceous soil. However, he brings forward evidence to show that in the climate of south-eastern Europe, as in Hungary and Istria, the chestnut is occasionally found thriving on pure limestone.

² Sir H. Maxwell recommends sowing the best foreign nuts, but these produce seedlings which in my nursery are much more tender when young, than those raised from smaller English-grown seed, and when required for timber trees I should prefer the latter.

³ M. Trabut, in his pamphlet, *Le chataignier en Algérie*, published as bulletin 37, by the Department of Agriculture in Algeria, states that he saw at the Villa Thuret in Antibes, a fine chestnut, which had been grafted on *Quercus Mirbeckii*.

more valuable it is, the young hop shoots, according to Cobbett, disliking a thick pole to twine round.

At Welbeck the chestnut is considered by Mr. Michie,¹ forester to the Duke of Portland, to be the most profitable tree to grow on sandy soil, as it grows much faster than oak and realises about 1s. 2d. per foot at a much earlier period. He showed me a plantation on Tressless Hill thirty-eight years old in 1903, in which the trees averaged about 65 feet high by 3 feet in girth, and stood about 150 to the acre. He said that they should not be grown without underwood, because in severe winters the unprotected trunks were liable to be cracked by frost near the ground.²

We have no exact records of the amount of timber per acre that may be produced by the chestnut when grown for timber in England, but I think that in the south on good land it would probably be greater than that of any other tree. One very remarkable case is a grove of 34 chestnuts and 9 oaks by the drive leading to Bicton House, Devonshire, which average about 100 feet high, by 6 to 7 feet in girth in the middle of the grove, and 9 to 12 feet on the outside (Plate 232). I estimated that this area was about half an acre, and the cubic contents of the timber on it about 5000 feet. At my request the late Mr. Mark Rolle had it carefully measured and wrote me on December 19, 1903, that the exact area on which the trunks stood was 1 rood 32 poles, though, of course, the branches extended over much more. The cubic contents were 7300 feet and the age of the trees about 150 years. We may therefore take at least 10,000 feet per acre as the result here.

Another very striking instance of the same character is a grove called "The Chestnut Tole"³ in Mr. Ashley Dodd's park at Godinton, Kent, where a great number of fine trees, having clean boles of 50 to 70 feet high by 8 to 10 feet in girth, grow mixed with ash. One of the chestnut trees was 86 feet to the point where the branches began, and I think that the timber in this grove would produce as great

¹ Mr. Michie has sent the following note:—

"Sow seed in March, collected from sound, healthy, straight-growing trees, forty-five to fifty-five years of age, as I find that seeds from trees of that age produce stronger seedlings than seed from younger or older trees, or than foreign seed. At one year old I lift the seedlings, shorten the tap-root, and plant in nursery lines. Care must be taken to plant in fresh, sweet soil, as the root is very liable to malformation if in contact with fresh manure. In the following year cut them down to within one inch of the ground, which will cause them to throw out a strong and straight stem from 2 to 3 feet long; after which, at three years old, they can be planted out with safety. Without this treatment before planting out, they generally require cutting off close to the surface, which is not always desirable in the planted area, owing to rank grass, bracken, etc., which smothers the young shoots.

I am greatly in favour of pure chestnut woods, very little thinning, and the encouraging of as much undergrowth as possible, especially on the outsides of plantations, to prevent cold and frosty winds blowing through. At sixty years of age the trees should stand no more than 16 feet apart, which equals 170 per acre, and taking them at the low average of 50 cubic feet per tree, means £425 (at 1s. per foot) when the crop is realised.

The above crop can be grown on a sandy soil, which is of little value for ordinary agricultural purposes; for instance, in Birklands Wood, adjoining Budly Forest, where the soil is very sandy and light, oaks covering an area of about 100 acres, although from sixty to eighty years of age, are long and slender, and contain on an average not more than 6 cubic feet of timber each; whereas some Spanish chestnuts, planted less than sixty years ago, contain fully eight times as much timber as the oaks.

On this estate the timber is used for making gates, gate-posts, and all kinds of fencing; also for window-sills of farm buildings, etc. Timber merchants buy it to supply the Sheffield trade (strickle handles, etc.), and also to put in the inside of threshing machines, for coffin boards, etc. The timber should be slowly and thoroughly dried before being used.

² The same thing has occurred at Kew; and, as Sir W. Thiselton-Dyer pointed out, the cracks occur on the south side, and are the result of too rapid thawing by the sun.

³ Tole seems to be a local name for a clump of trees standing on the crown of a hill.

a quantity per acre and of better quality, than the grove at Bicton. But, however attractive such plantations may be from an ornamental point of view, there is no doubt that the timber is worth much more if cut young; and, as a matter of fact, most of the old chestnut trees in the south of England are so shaky that a great part of their timber is only fit for firewood or fencing.

The chestnut is a good avenue tree in those parts of England where the soil and climate suit it, and there are fine avenues at several places. One of the best known to me is at Cowdray Park where there is an avenue about a mile long, commencing at the bottom of the hill, where the trees are very large, and running up to an elevation of 500 feet or more. According to Loudon this avenue contained 300 trees. Another very fine one at Thoresby is supposed to have been planted by Evelyn, many of the trees in which are about 20 feet in girth. I noticed here that the spiral twist in the trunk of the chestnut is variable in direction. Of three trees standing together in this avenue, one was twisted from left to right, one from right to left, and one had no twist at all; but this twisting of the trunk is commonest on light sandy soil and usually indicates shaky timber.

Another fine avenue of chestnuts is at Newhouse Park, on the property of Sir Robert Newman, near Mamhead, Exeter. This is 24 yards wide, with the trees 12 yards apart, which seems to be the correct distance for this tree in an avenue, as it requires more room than the lime or elm. These trees average about 15 feet in girth and are 70 to 80 feet high. The largest that I measured was 18 feet 8 inches in girth.

REMARKABLE TREES

The number of large chestnut trees is so great that it is quite possible we may omit some of them, but there is no doubt that the most celebrated, and perhaps the oldest planted tree in England, is the Tortworth chestnut, which has been frequently described, and is figured by Strutt, plate xxix., and by Loudon, p. 1988. Strutt says that in 1766 it measured 50 feet in circumference at 5 feet from the ground, had a stem 10 feet high to the fork, and had three limbs, one of which was at that time 28½ feet in girth. It was said by Sir R. Atkyns, in his *History of Gloucestershire*, p. 413, to have been growing in King John's reign, and to have been "197 yards in compass." It has since been mentioned and described by almost every writer on trees, but I am informed by Lord Ducie that a good deal of its history is more or less mythical. At present it is by no means a beautiful tree, and so much of its original trunk is decayed, that no measurement is of much value. I think that no one would recognise the existing tree as having formed the subject of Strutt's plate; but notwithstanding its age it still produces nuts, from which several trees have been raised and planted.

Another very large and celebrated chestnut, also figured by Strutt, plate xiii., and by Loudon, p. 1989, grew at Cobham Hall,¹ Kent, and must have been a finer tree than the one at Tortworth. It measured in 1822, according to Strutt, 29 feet in

¹ The finest chestnut now existing in this park grows at Ashenbank, and measured, in 1906, 93 feet in height and 13 feet 10 inches in girth, with a good bole 40 feet in length.

girth at the narrowest part 3 feet from the ground, 33 feet at 12 feet up, and 40 feet at the point where the trunk divided. It was "called the four sisters, from its four branching stems closely combined in one massive trunk," though the figure does not show this clearly. It has now entirely decayed.

Another historic tree, the "Monmouth Tree,"¹ at White Lackington, in Somerset, was destroyed by the severe storm of Ash Wednesday in 1897. It was reputed by tradition to have been the tree under which the Duke of Monmouth had a famous banquet in 1680. It was 25 feet in girth with a total height of only 49 feet, and had a very venerable appearance. Lord Petre measured in 1758 in Writtle Park, three miles from Ingatestone in Essex, a chestnut 45 feet in girth at 5 feet from the ground.²

In Waldershare Park, Kent, the seat of the Earl of Guilford, there are some remarkably fine chestnuts, the largest in girth being 23 feet 3 inches, but not a well-shaped or tall tree. The finest, in my opinion, is a tree 112 feet high with a straight and clean bole 50 feet long by 15 feet 2 inches at 5 feet, and carrying its girth well up. I estimated the contents of the first length alone at 50 feet by 36 inches quarter girth, making 450 feet of clean timber.

Fredville Park, the seat of H. W. Plumtre, Esq., in the same district of Kent, contains some splendid chestnuts, the largest of which is about 80 feet by 26 feet 3 inches. Another is called the Crows' Nest, from the fact of its having a platform, with benches and a table large enough to seat about twenty people, built in the crown at about 12 feet from the ground and reached by a ladder.

An immense but very ill-shaped chestnut tree dividing at 5 feet into three main limbs grows at Sunninghill Lodge, near Ascot, the seat of Percy Crutchley, Esq., of which a photograph was shown by him at the Lincoln Exhibition of the Royal Agricultural Society in 1907. This tree was carefully measured in 1816 by T. Luff, who estimated its contents at 716 cubic feet. A measurement made June 15, 1907, by M. C. Squires, gives its contents as 1282 feet, an allowance for bark of 1½ to 2 inches being made.

The finest chestnuts growing near London are those in Kew Gardens, the largest of which measures 75 feet high, and 20 feet 10 inches in girth. These were probably planted early in the eighteenth century.

In Herts, there is a large chestnut at Lockleys Park near Welwyn, which the Hon. Arthur Bligh informs us is 21 feet in girth; and at Broxbournebury, Mr. H. Clinton Baker measured a tree in 1908, 65 feet by 23 feet 9 inches.

At Betchworth Park, part of the Deepdene estate, near Dorking, Surrey, there are many splendid chestnuts,³ the finest though not the largest round, being 21 feet 5 inches in girth and 90 feet in height. For girth alone I know of few trees in England equal to one measured here by Henry, which, though its bole is only 8 feet long, is 26½ feet in girth at the narrowest point.

¹ Cf. H. Norris in *Proc. Somerset Archaeological Society* (1897), where a figure of the tree is given.

² Ducarel, *Phil. Trans.* 1771.

³ An interesting article on the chestnut trees in Betchworth Park appeared in *Gardeners' Chronicle*, 1841, p. 4. At that date there were about 80 trees, all of large dimensions. Dr. Aikin, in *Monthly Magazine* for 1798, mentions the rows of old chestnut trees in this park.

At Petworth Park, Sussex, there are several very fine chestnuts, of which one measured by Sir Hugh Beevor in 1904, was no less than 118 feet high by 19 feet in girth, with a trunk clean to about 70 feet, and estimated to contain 800 feet of timber. It grows on the west side of the drive on the west side of the park, about two miles from the house. Another in a clump close to the house I found to be about 100 feet high by 21 feet 9 inches in girth.

At Steventon, North Devon, there is a very large tree in the garden, which Mr. Barrie measured as follows in 1890:—height 86 feet, bole 22 feet 6 inches, girth 16 feet 11 inches, spread 100 feet in diameter, contents 833 feet.

At Tyberton Court, Herefordshire, near the place where the big oak formerly grew,¹ and on soil heavier than the chestnut usually likes, there is a very fine twin tree, which looks as if two stems had started together from the same root. At the base the two measure 31 feet round and are about 95 feet high, one trunk being 20 feet, the other 17 feet 6 inches in girth.

At Highnam Court, Gloucestershire, there is a chestnut stool, which girths 32 feet at 3 feet from the ground, giving off four great stems 80 to 90 feet in height.

At Croft Castle, Herefordshire, there is a row of fourteen trees which were described in the *Transactions of the Woolhope Society*, 1871, p. 306, where their respective girths are given, and average about 17 feet, the two largest being then 20 feet 3 inches and 20 feet 5 inches. They seemed, when I saw them in 1904, to be long past maturity.

Below Warwick Castle, on the banks of the Avon, there is a chestnut having a large branch resting on the ground, where it has taken root and thrown up a large vertical stem, the only instance of self-layering² I have seen in this tree. The trunk in 1907 measured 16 feet 3 inches in girth. This tree is figured in *Gardeners' Chronicle*, 1873, fig. 222.

In Ashridge Park there are many fine chestnuts, one of which has its trunk covered with great burrs and is 24 feet in girth. At Chatsworth there is a chestnut tree of which Mr. Robertson, forester to the Duke of Devonshire, has been good enough to send me a photograph. He makes it 86 feet high, with a bole 45 feet by 15 feet 10 inches, and the cubic contents about 700 feet.

At Harleston, near Althorp, on Lord Spencer's property, are some immense chestnuts growing in a field near the church, on rich red sandy soil, the survivors of a row of which many were blown down many years ago. The largest measures 90 feet by 22 feet 6 inches, and was estimated by Mr. Mitchell, now forester at Woburn, to contain 1200 feet of timber (Plate 233). Another of about the same height has a bole 27 feet by 21 feet 6 inches and contains about 887 cubic feet.

If the length of clean trunk be considered, I have seen no chestnut equal to one at Thoresby (Plate 234), which has been drawn up in a thick wood of beech trees called Osland, and has a clean bole as straight as possible, 70 feet long by 11 feet 3 inches in girth, and a total height of about 110 feet. This was planted about 1730, and is on a sandy soil overlying the Bunter beds of New Red Sandstone.³

¹ Cf. vol. ii. p. 310.

² Henry saw a self-layering tree at Riccarton. Cf. p. 851.

³ For further particulars of this remarkable plantation see our article on the oak, p. 322.

At Euston Park, Suffolk, the property of the Duke of Grafton, Mr. Marshall showed me, in 1905, in a wood called Barnham Springs, a remarkable growth of chestnut from a stool cut forty-two years previously. Sixteen straight stems about 60 feet high, and $2\frac{1}{2}$ feet in girth, had sprung up from the outer edge of the stump, and collectively measured 30 feet in circumference. This growth seems to show how such trees as the one on Mount Etna have been originally formed, as in another 50 or 100 years these stems will probably seem like one tree. At Merton Hall, Thetford, Norfolk, a chestnut, planted about 1660, is 87 feet high, with a clean bole, 40 feet in length and 11 feet 4 inches in girth.

At Shrubland Park, Ipswich, the property of Lady de Saumarez, there are some very large chestnut trees in the grounds. The largest of these, according to Mr. Taylor, measures at ground line 47 feet; at 3 feet 31 feet; at 6 feet $27\frac{1}{2}$ feet. Having had its top blown off some years ago, it is now only 55 feet high.

The finest existing chestnut, if height and girth together are considered, that I have seen, is a tree in a valley called Mackershaw, near Studley Royal, which seems to be the one figured by Loudon, p. 1986, of which he gives the height as 112 feet and the girth at 1 foot as about 23 feet. When I measured this splendid tree in 1904 I made it 112 feet by 20 feet at 5 feet from the ground, and it seemed to be in perfectly sound condition.

At Rydal Hall, Westmoreland, there is a very fine tree, girthing $26\frac{1}{2}$ feet at 5 feet and 37 feet at the ground, of which the owner, Mr. S. H. le Fleming, has kindly sent me a photograph (Plate 235).

In Wales the finest tree I have seen is one which grows just outside the garden at Dynevor Castle, and measured in 1908 about 113 feet by $16\frac{1}{2}$ feet, with a clean bole about 30 feet high. A photograph which was taken proved unsuccessful owing to its being surrounded by other trees.

Notwithstanding its southern origin, the chestnut grows with great vigour in many parts of Scotland, and, according to Loudon,¹ who quotes from Walker's *Essays*, p. 29, the first exotic tree planted north of the Tweed was a chestnut, of which in 1760 a part of the trunk remained, at Finhaven, an ancient seat of the Earls of Crawford. This was measured in 1744, and, as attested before two justices, was 42 feet $8\frac{1}{2}$ inches in circumference close to the ground.

The largest tree I have seen myself is in the Cherry Park, near the stables at Inveraray Castle, and measures about 77 feet by 20 feet, with a bole about 16 feet long. This tree was said in the *Old and Remarkable Trees of Scotland* to have been in 1867 the largest in Scotland, though one at Tynninghame was as tall; and there are two fine ones, both over 16 feet in girth, at Ardkinglas, in the same neighbourhood. Lord Kesteven informs us that there is a chestnut 25 feet in girth, growing at Stonefield, near Tarbert, Argyllshire. At Kirkconnell, south of Dumfries, Henry measured in 1904 a fine tree, 73 feet high and 18 feet in girth, with a bole of 25 feet. At Kirkmichael House, Ayrshire, a tree measured $18\frac{1}{2}$ feet in girth in 1892; and at the Auld House, near Glasgow, two trees, about 60 feet high in 1904, were 16 feet 3 inches and 14 feet 11 inches in girth respectively.

¹ *Arb. et Frut. Brit.* i. 34, 90 (1838).

At Castle Menzies in Perthshire there are several very large trees, perhaps over 300 years old, one of which, in the washing-green, is about 20 feet in girth. Another in the park at Murthly, though not remarkable for height, has a trunk about 15 feet high and 19 feet 7 inches in girth, twisting from left to right. At Dupplin Castle, Perthshire, there are some very fine trees in a sheltered dell below the castle. One of these has a short bole no less than 21 feet 4 inches in girth; another is about 70 feet high by 17 feet 9 inches in girth. Many other large chestnuts in this county are recorded by Hunter; but as a rule they are remarkable rather for their age and girth than for their height, which rarely exceeds 80 feet in Scotland.

Sir Herbert Maxwell says¹ that the tallest recorded in Scotland is at Marchmont House, Berwickshire, which in 1878 measured 102 feet by $14\frac{1}{2}$ feet, with a bole of 32 feet; but Sir Archibald Buchan-Hepburn tells us that a tree at Yester House, Haddingtonshire, is 112 feet high by 18 feet 8 inches in girth, according to careful measurements, taken in 1908 by Lord Tweeddale's forester.

The chestnut at Riccarton, near Edinburgh,—which was described and figured in 1829 by Monteath, *System of Draining*, 209, as an old tree remarkable for layering, had two stems in 1905, one 17 feet in girth and the other, very decayed, 12 feet in girth, both giving off branches which had layered and become independent trees.

From Castle Leod in Ross-shire Mr. Wotherspoon sends me a photograph of a tree, which is probably the largest of the species existing so far north. It is 76 feet high and girths 28 feet close to the ground, 21 feet 4 inches at 5 feet, with a bole 14 feet long.²

In Ireland the chestnut thrives remarkably well, and, growing fast, might in many places be cultivated for its timber. At Fota the chestnuts in a plantation much exposed to the strong winds from the sea, withstood without injury the severe gale of 1903, when many other species were blown down.

The most remarkable chestnut in Ireland is the famous tree at Rossanagh, Wicklow, which was planted, according to Colonel Tighe, who has the family records, in 1718 (Plate 236). This tree is of the large spreading type with a short bole which divides into three mighty limbs. The girth of the main stem close to the ground was in 1903 49 feet, at 3 feet up $27\frac{1}{2}$ feet, and at 5 feet $29\frac{1}{2}$ feet. The height of the tree is about 80 feet, the spread of the branches being 100 feet in diameter. The three limbs girth respectively 12 feet 8 inches, 11 feet 2 inches, and 10 feet.

A very fine tree is growing at Powerscourt which was 84 feet high in 1905, with a good trunk carrying its full girth up to 18 feet and giving off the first branch at 20 feet up. It was $28\frac{1}{2}$ feet in girth at the ground, and $22\frac{1}{2}$ feet at 5 feet up.

At Clonbrock, Co. Galway, there is a tree growing on limestone, planted in 1801. It was 8 feet 6 inches in girth at 3 feet up in 1871, and 12 feet 9 inches in 1904. The chestnut grows at Clonbrock, where rhododendrons refuse to grow; and in the case of the tree just mentioned there is undoubtedly a large proportion of lime in the forest soil on which it stands. At Shannongrove, near Limerick,

¹ *Green's Encycl. Agric.* i. 373 (1907).

² This is probably the same tree which Loudon mentions, p. 2001, as growing at Castle Send (*sic*) in Cromarty.

there are some large trees, more remarkable for girth than for height, one being $24\frac{1}{2}$ feet round at two feet from the ground.

At Rostrevor House, Co. Down, the seat of Colonel Sir J. Ross of Bladensburg, a chestnut, about 25 feet high, is remarkable for the large size and colour of the young leaves, which were purplish when I saw them in July, and are said to turn copper colour in autumn. This variety is of unknown origin, and I have seen nothing like it at Kew or elsewhere.

TIMBER, MISCELLANEOUS PRODUCTS

A great deal has been written as to the use of chestnut wood for the beams and roofs of ancient buildings, both in England¹ and France, but it is now pretty generally admitted that most of the supposed chestnut wood is really that of the oak, which it slightly resembles.² This subject has been so well discussed by Loudon (pp. 1787, 1989, and 1992) that I need not further allude to it; but the properties and uses of the wood were apparently much better known formerly than now, and Mr. N. Kent, in 1792, wrote an excellent paper on the subject from which Loudon quotes largely (p. 1993). The pith of it all agrees with what I have been able to learn from various practical men—that the wood when young is as good or better than oak (because it has much less sapwood) for fencing, gate-posts, piles, and hop-poles; but that if allowed to become more than 3 to 4 feet in girth it is so apt to be shaky, that its value rapidly diminishes, and very old trees are usually only fit for firewood.

The timber in some cases remains quite sound to a great age and becomes mottled and streaked with dark brown like brown oak. I found the butt of an old tree of this nature, in a small timber yard in Wilts, where it had been lying seventeen years without any use being found for it. I had it cut into boards, from which the stiles and rails of an overmantel, and the frames of some doors have been made; and these, when polished with oil, were both in grain and colour of remarkable beauty. But even after this long period the wood was not dry, and shrank considerably after it was cut up, so that care must be taken not to put such wood together in a hurry.

Mr. T. Roberts, forester to the Earl of Egmont, at Cowdray, informs me that chestnut is used on that estate for joists, window-sills, door-jambes, and other purposes, and is found to last quite as long as oak and to be much easier to work up; he also thinks it less liable to insect attacks than oak (presumably sappy oak). But the trees when a hundred years old are all more or less inclined to be shaky,

¹ Sir George Birdwood in *Reports on the Cultivation of the Spanish Chestnut*, p. 9, note (India Office, 12th March 1892), states that the late Mr. T. Blashill, who was architect to the London County Council, pointed out in a letter to the *Times*, that the only instance he knew of chestnut wood in English mediæval carpentry is that of the chancel screen of the church, formerly of the Knights of St. John, at Rodmersham in Kent. The Rev. A. H. J. Massey, Vicar of Rodmersham, tells me, however, that the chancel screen is a modern one of oak, with portions of an ancient screen of chestnut wood worked into it; but the screen separating the Lady Chapel from the chancel, is composed entirely of chestnut wood.

² Mr. Blashill, in *Sessional Papers of the Royal Institute of Architects*, No. 12 (1877-78), has finally settled any lingering doubts which may exist. On the question of oak or chestnut in old timber roofs, he says that in some specimens of English oak, particularly in the variety called *sessiliflora*, the medullary plates are very thin and wide apart, and such specimens are often mistaken for chestnut, but a very clean transverse section will always render the plates visible. Though usually lighter than the rest of the wood, they are often dark, and such specimens have also been mistaken for chestnut. He goes on to say that the clean grain and pleasant working of chestnut make it very suitable for joinery, and there is no fear of its durability

which prevents their being cut into small scantlings. Mr. Weale tells me that it is used extensively in London for making coffins instead of oak. For making hoops, poles of chestnut are considered the best; and the wood is also largely used for making wine casks in France and Spain.

A section from the butt of a chestnut tree, said to be two hundred years old, was shown by the Marquis of Exeter at the Forestry Exhibition of the Royal Agricultural Society at Lincoln in 1907. This tree measured 7 feet in diameter at the butt and was fairly sound and free from shakes. I am informed by Mr. Danson that this tree was grown on a clay soil overlying ironstone, with a north-west exposure, about 230 feet above sea level.

At Shobdon Court, Herefordshire, the seat of Lord Bateman, I saw the trunk of a large chestnut, measuring $19\frac{1}{2}$ feet in girth, lying on the ground. It was quite sound, with the exception of two small ring-shakes, and by counting the rings I found that it was 207 years old.

Such poles as are too thick for hop-poles make, on account of their durability, one of the best forms of park fencing that I know, of which many instances are quoted by Loudon. It is said that a park fence, erected in 1772 by Mr. Windham of Felbrigg, of oak and chestnut thinnings, was taken down in 1792, when the chestnut was found as sound as when put down, while the oak was so much wasted at the ground level that it could not be used again without support.

The Earl of Ducie exhibited at the Stroud show of the Gloucestershire Agricultural Society in June 1907 specimens of fencing posts made from chestnut, planted by himself in 1855, and cut in 1885, which had been in use for twenty-two years, and were still quite sound.

The walking- and umbrella-sticks, which are known in the trade as "Congo sticks," are saplings of the chestnut, which are easily manipulated when growing, the knots or markings for which these sticks are valued being produced by lacerating the bark through to the wood. They were formerly obtained from the north of France, but are now almost exclusively produced near Carlstadt in Croatia.¹

The fruit of the chestnut is so well known that I need say little about it, and though in the colder parts of England it is often so small as to be of little use for human food, it is eaten by pheasants and deer. The large chestnuts eaten at dessert are imported, and are known under the name of "marrons" in France where they are preserved in sugar and form a very favourite sweetmeat.²

being equal, and probably superior to that of any wood (presumably he meant English wood) except oak. He spoke of a large bridge having been built about 1858 of chestnut timber, over the river Wye at Hoarwithy near Hereford. The bridge after nineteen years was taken down in a crippled condition, which he attributed partly to the design of the bridge, and partly to the decay of the timber at the numerous joints where water could lodge. Yet the great bulk of the wood was perfectly sound; and seemed to show that for ordinary work not subject to damp, the timber may be very useful. Although he could not admit its occurrence in ancient roofs, it might be very suitably used in preference to deal or pitch pine; and in church furniture it would probably, in course of time, take a colour which would be far better than that of the stained woods now so much used.

¹ *Kew Bulletin*, 1899, p. 53.

² In some parts of Spain and Italy, and in the south of France, chestnuts are ground into flour; and in the form of cakes, soup, and porridge, form a considerable part of the food of the poorer classes during winter. Specimens of chestnut flour and cakes are exhibited in the museum at Kew; and in *Kew Bulletin*, 1890, p. 173, an analysis of the flour is given by Professor Church, who considers that it is easily digestible and probably useful as food for children. Further interesting particulars concerning the use of the chestnut are given in *Reports on the Cultivation of the Spanish Chestnut* (India Office, 12th March 1892).

A tanning material,¹ extracted from chestnut bark, is prepared near St. Malo in France, and is largely exported to Belgium and to Glasgow. It is said to be used to modify the colour produced by hemlock extract obtained from *Tsuga canadensis*.²

(H. J. E.)

CASTANEA CRENATA, JAPANESE CHESTNUT

Castanea crenata, Siebold et Zuccarini, *Abh. Akad. Muench.* IV. iii. 224 (1846); Schneider, *Laubholzkunde*, i. 804 (1906).

Castanea japonica, Blume, *Mus. Bot. Lugd. Bat.* i. 284 (1850).

Castanea vesca, Gaertner, var. *pubinervis*, Hasskarl, *Cat. Hort. Bog. Alt.* 73 (1844).

Castanea vulgaris, Lamarck, var. *japonica*, A. DC. *Prod.* xvi. 2, p. 115 (1864); Shirasawa, *Icon Forest. Japon.*, text 63, t. xxxiv. ff. 14-25 (1900).

Castanea vulgaris, Lamarck, var. *yunnanensis*, Franchet, *Journ. de Bot.* 1899, p. 196.

Castanea sativa, Miller, var. *acuminatissima*, von Seeman, in Diels, *Flora von Central China*, 287 (1901).

Castanea pubinervis, Schneider, *Laubholzkunde*, i. 158 (1904).

A tree, usually smaller in size than the European species, but occasionally attaining large dimensions. It is probably only a geographical form of that species, but can readily be distinguished and may be kept separate, as it probably differs in growth and in cultural requirements.

The leaves are borne on shorter petioles, but resemble those of the common chestnut in shape, being rounded or cordate at the base and having about twenty pairs of nerves; but they are smaller in size and have much shallower serrations, with very long and fine spine-like points. The main difference lies in the pubescence,³ which is short and dense on the young branchlets, on the petioles, and on the midrib of both sides of the leaf. In the common chestnut this very distinct pubescence is either absent or replaced by a scurf, very different in appearance. The catkins of the eastern tree are more slender and the fruits of wild trees smaller than in the common species. *Castanea crenata* also comes into flower, when still very young, and often bears fruit when quite a small shrub.

In China *Castanea crenata*⁴ occurs wild, mainly in the mountains of the central provinces, as a tree about 40 feet in height; and is nowhere abundant, and so far as I have seen never forms woods of any extent.

¹ A similar extract, prepared from the wood of the chestnut, is largely manufactured in Corsica. Mr. Southwell, Vice-Consul at Bastia, gave me some interesting particulars about this industry, when I visited Corsica in December 1906. There are four factories near Bastia, which produce about 25,000 tons of extract annually. The bark is not employed in Corsica, as the dark colour of the extract produced from it is objectionable. Four tons of wood yield about one ton of extract. The wood is cut into chips, which are soaked under pressure in hot water, which extracts all the tannin and some of the colouring matter. The resulting liquor is concentrated *in vacuo*. Practically the whole of this extract is used in England and Germany for sole-leather. Mr. Southwell informed me that certain trees in Corsica had brown-coloured wood, which produced an unsaleable extract. He had found by experiment that this brown colour in the wood is due to the presence of iron in the soil.—(A. II.)

² *Kew Bulletin*, 1893, p. 229.

³ The pubescence over the lower surface of the leaf is similar to that of the European tree, and is very variable in quantity and persistence.

⁴ The large chestnut tree occurring wild in China is considered by Dode to be distinct from the Japanese tree, and has been named by him *C. Duclouxii* and *C. Fargesii*, in *Bull. Soc. Dendr. France*, 1908, pp. 150, 158.

The low grassy hills of the Yangtse valley and the hills in Chekiang are often covered in places with a scrubby growth of chestnut bushes, scarcely ever over 5 feet in height. This is a distinct species,¹ and corresponds in many respects to *C. pumila* of America, the branchlets and petioles being covered with a dense, bristly pubescence, and the fruits extremely small, usually three in each involucre. This has been supposed to be *Castanea mollissima*, Blume,² an imperfectly known species.

The Chinese have distinguished from the most ancient times two kinds of chestnut, classically known as the *li* and the *erh*. The former, now known as the *pan-li* is the cultivated tree, the latter, known as the *mao-li*, is the wild form of the species, which produces remarkably sweet small fruit. These have been noticed by many observers, as by Abel³ at Tatung on the Yangtze, by Père David⁴ at Kiukiang, and by Fortune⁵ near Ningpo, who introduced the small-fruited chestnut into England⁶ in 1853; but we are unacquainted with any trees raised at that time. Similar small-fruited chestnuts are known in Japan, and were exhibited in London⁷ in 1873.

(A. H.)

The chestnut is widely distributed in Japan where it is called "kuri," from Kiusiu and Shikoku, through the greater part of the mountain forests of Hondo, and in the plains as far north as central Hokkaido. It is usually mixed with other deciduous trees, but in some places forms pure forests of small area. Its wood is preferred for railway sleepers to any other timber, but is not much valued for building purposes. Though, according to Sargent,⁸ it does not attain any great size, yet I measured an old tree in the Atera valley which was 15 feet in girth (Plate 237).

The tree is commonly seen on dry and barren hillsides in the form of coppice, which is cut every few years for firewood. It is also cultivated for its fruit, and several large-fruited varieties are grown which Sargent⁸ says are equal in size to the best in southern Europe, and are largely consumed as food in the towns, and also exported from Kobé to San Francisco. These varieties are more precocious than the European tree, bearing abundant fruit when only 10 or 12 feet high, and he recommends their introduction from Aomori in the north of Hondo, as being more likely to endure cold winters than the French or Kobé varieties.

The Japanese chestnut was introduced into the United States⁹ about 1891, and Rehder¹⁰ states that it is shrubby and usually begins to fruit when about six years old. It has proved hardy as far north as Massachusetts. So far as we know it has not yet been introduced into England.

(H. J. E.)

¹ The shrubby chestnut of China is considered by Dode, in *Bull. Soc. Dendr. France*, 1908, pp. 151, 152, 153, to constitute three new species, *C. hupehensis*, *C. Seguinii*, and *C. Davidii*.

¹⁰ Cf. W. A. Taylor, in *Cycl. Amer. Hort.* i. 294 (1900), who enumerates nineteen varieties of the Japanese chestnut, which have been introduced of late years into North America, gives the date of the first introduction as 1876.

¹¹ *Cycl. Amer. Hort.* i. 257 (1900).

CASTANEA DENTATA, AMERICAN CHESTNUT

Castanea dentata, Borkhausen, *Handb. Forstbot.* i. 741 (1800); Sargent, *Silva N. Amer.* ix. 13, tt. 440, 441 (1896), and *Man. Trees, N. Amer.* 220 (1905).

Castanea vesca americana, Michaux, *Fl. Bor. Amer.* ii. 193 (1803); Loudon, *Arb. et Frut. Brit.* iii. 1984 (1838).

Castanea americana, Rafinesque, *New Pl.* iii. 82 (1836).

Castanea vulgaris, γ . *americana*, A. De Candolle, *Prod.* xvi. 2, p. 114 (1864).

Castanea sativa, var. *americana*, Sargent, *Garden and Forest*, ii. 484 (1889).

Fagus Castanea dentata, Marshall, *Arbust. Amer.* 46 (1785).

A tree attaining in America 100 feet in height. Bark dark brown, and divided by shallow irregular fissures into broad flat ridges, separating on the surface into small thin appressed scales. Young branchlets with minute scurfy pubescence above, and with long hairs near the base; glabrous and grey in the second year.

Leaves (Plate 202, Fig. 13), pendulous, oblong-lanceolate, gradually tapering and unequal at the base, long acuminate at the apex, with about twenty pairs of parallel nerves, raised on the under surface, each ending in a triangular tooth, which is prolonged into a fine point; upper surface dull, dark green, glabrous; lower surface lighter green, glabrous, or with minute scattered hairs, thin but firm in texture. Petiole, $\frac{1}{2}$ to $\frac{3}{4}$ inch long, glabrous. Stipules, ovate-lanceolate, acute, puberulous, about $\frac{1}{2}$ inch long.

Nut,¹ usually much compressed, $\frac{1}{2}$ to 1 inch wide, gradually acuminate at the apex; two to three fruits together in each involucre.

This species is distinguished from the European one by the leaves being always cuneate and never cordate at the base, and never having any stellate tomentum, the under surface being either glabrous or covered with minute glandular hairs.

In winter it is readily distinguishable from *C. sativa* by the glabrous twigs and the more pointed ovoid buds, which have glabrous ciliate scales as in that species. The buds are smaller than in *C. sativa*, being only about $\frac{3}{16}$ inch long. In the specimens seen the twigs are much more slender, with very minute lenticels and small semicircular leaf-scars. (A. H.)

In America the chestnut is a common tree, and has a wide range from New England and southern Ontario southward along the Alleghany Mountains to central Alabama and Mississippi, and westward to Michigan, Indiana, central Kentucky, and Tennessee. So far as I have seen it does not attain so large a size as the European species, though Sargent says it occasionally reaches 100 feet in height.² The largest I saw was a fine old tree on the lawn of Mr. Nathaniel Thayer's house at Lancaster, Mass., which was 80 feet by 13 feet 6 inches, and though rather decayed at the top, where its branches were supported by iron stays, had produced suckers from the root, 40 feet high.

¹ The seedling of this species is described and figured by Rowlee and Hastings, in *Bot. Gazette*, xxvi. 351, fig. 18 (1898).

² In *U.S. Forest Service, Circ.* 71 (1907), a leaflet on the cultivation of this species, it is stated that the tree has been known in the region of its best development to reach a height of 120 feet. Throughout the greatest part of its range, it is much smaller, with an average height of 80 to 100 feet, and a diameter of from 2 to 4 feet.

Emerson mentions a tree at Bolton, Mass., which in 1840 was 15 $\frac{1}{2}$ feet in girth at 6 feet, with an unbranched trunk 24 feet long; and another, on the road to Sheffield, which was 21 feet in girth at 4 feet from the ground. He states that though near the coast it does not ripen fruit so well, yet that in the interior when growing in sunny places it yields abundance of sweet and delicious nuts; and according to Sargent these, though smaller than European chestnuts, are superior to them in sweetness and flavour, and are sold for food in the eastern cities.

In *Garden and Forest*¹ there are several pictures of the chestnut in America, one representing a large tree at Dauphin in Pennsylvania, which is about 6 feet in diameter. Another represents a young forest in West Virginia about forty years old, showing good natural reproduction. A tree on a farm belonging to D. M. Ridgely, near Dover in Delaware, is noted for its excellent fruit, and it has been propagated, the chestnuts being known as Ridgely or Dupont chestnuts.

In the *United States Bureau of Forestry Bulletin No. 53* (1904), R. Zon gives an interesting account of the chestnut tree in Maryland, where it is an important timber tree, being used for railway sleepers, telegraph poles, and fencing. It is usually coppiced, and Zon states that the sprouts usually come from the root collar, only 10 per cent. arising from the top of the stump. He has never seen any sucker shoots. The capacity of sprouting from the stool is retained to an advanced age, over 100 years. The tree in America usually becomes unsound at about 100 years old.

The American chestnut has rarely been tried in cultivation in Europe, and though not likely to succeed so well as the common species, there are thriving young trees at Kew.

Emerson states that the timber is one of the best native woods on which to lay mahogany veneers; and Mr. Weale informs me that it is now imported into England both in logs and boards; but the demand is not very great. It is used by builders as a substitute for oak, and by cabinetmakers. It carves well, and as it fumes readily, is a favourite wood with makers of antique furniture. In the log its value is from 1s. 6d. to 1s. 9d. per cube foot in Liverpool. In the board it is worth from 2s. to 2s. 6d. After conversion it cannot be distinguished from the English-grown chestnut. Hough states that the wood is rich in tannin, which is extracted and used for tanning purposes. (H. J. E.)

CASTANEA PUMILA, CHINQUAPIN

Castanea pumila, Miller, *Dict.*, ed. 8, No. 2 (1768); Loudon, *Arb. et Frut. Brit.* iii. 2002 (1838);

Sargent, *Silva N. Amer.*, ix. 17, tt. 442, 443 (1896), and *Trees N. Amer.*, 221 (1905).

Fagus pumila, Linnæus, *Sp. Pl.* 998 (1753).

A tree, rarely attaining in America 50 feet in height and 9 feet in girth, usually much smaller. Bark light-brown, slightly furrowed and broken on the surface

¹ *Garden and Forest*, ix. 114, f. 12, 234, f. 34 (1896), and vii. 484 (1894). Cf. also *Ibid.* x. 372, f. 48 (1897).

858 The Trees of Great Britain and Ireland

into loose plate-like scales. Young branchlets covered with numerous long erect hairs, becoming grey and glabrous in the second year.

Leaves (Plate 202, Fig. 12) smaller than in *C. sativa*, rarely as much as 5 inches long, not pendulous, oblong-oval, base unequal and rounded or tapering, apex acute, with about 15 pairs of nerves, which end in triangular serrations, tipped by short spine-like points; upper surface dull dark green, minutely pubescent; lower surface greyish white and densely tomentose. Petioles short, $\frac{1}{4}$ inch long, pubescent. Stipules about $\frac{1}{4}$ inch long, pubescent, those of the two lowest leaves broad, ovate, acute, on the middle leaves ovate-lanceolate, towards the top of the branch linear.

Nut ovoid, rounded at the slightly narrowed base, gradually narrowed and pointed at the apex, $\frac{3}{4}$ to 1 inch long, $\frac{1}{3}$ inch broad; only one fruit in each involucre, which opens generally by two or three valves. The fruit,¹ which is ripe in America in September, is delicious in flavour, and is occasionally gathered for market.

Castanea pumila is distinguished from the other species by its smaller leaves, which remain densely whitish tomentose underneath and have fewer nerves. In winter it is distinguished from the common chestnut by the twigs being slender and having a scattered loose pubescence, especially marked towards their apex. The buds are ovoid, not acute at the apex, minute, about $\frac{1}{8}$ to $\frac{3}{16}$ inch long, with both the first and second scales appressed-pubescent and ciliate. The leaf-scars and stipule-scars are smaller than in *C. sativa*.

Castanea pumila,² according to Sargent, occurs on dry, sandy ridges, rich hill-sides, and the borders of swamps, from southern Pennsylvania to northern Florida and the valley of the Neches River, Texas. It is usually shrubby east of the Alleghany Mountains, becoming a tree west of the Mississippi River, and is most abundant and largest in size in southern Arkansas and eastern Texas.³ The wood⁴ is similar to that of *C. crenata*, with very thin sapwood, and is used for fences, posts, railway sleepers, etc.

According to Loudon it was introduced in 1699 by the Duchess of Beaufort, but it is extremely rare in cultivation, the only specimens which we have seen being small shrubs at Kew, which, however, seem perfectly hardy.

There are two specimens at Verrières,⁵ near Paris, the smaller of which has a curiously twisted stem and resembles in appearance a dwarf Japanese tree. The other has two stems, each about 28 inches in girth and about 18 feet high, and produces fruit regularly and often in great abundance.⁶ (A. H.)

¹ Hough, *Trees of N. States and Canada*, 137 (1907).

² According to Taylor, in Bailey, *Cycl. Amer. Hort.* i. 295 (1900), this species commonly throws up root-suckers.

³ *Castanea neglecta*, Dode, in *Bull. Soc. Dendr. France*, 1908, p. 155, said by Dode to occur in the eastern part of the United States, is apparently only distinguishable from *C. pumila* by its larger and less pubescent leaves. It is possibly, as this author points out, a hybrid between *C. dentata* and *C. pumila*.

⁴ Hough, *loc. cit.*

⁵ *Hortus Vilmorianus*, 55 (1906).

⁶ Since this article was corrected for the press, a leaflet has been issued by the U.S. Forest Service, on Chestnut Bark disease, which is caused by a fungus, known as *Diaporthe parasitica* or *Valsonectria parasitica*. This has recently destroyed an immense number of trees in the north-eastern states, spreading with great rapidity. As the disease, if once introduced, may be equally destructive in Europe, we think it well to warn arboriculturists against importing American chestnuts at present.

FRAXINUS

Fraxinus, Linnæus, *Gen. Pl.* 318 (1737); Bentham et Hooker, *Gen. Pl.* ii. 676 (1876); Wenzig, in Engler, *Bot. Jahrb.*, iv. 165 (1883); Lingelsheim, in Engler, *Bot. Jahrb.* xl. 185 (1907).

TREES or shrubs, belonging to the natural order Oleaceæ; leaves opposite, compound, unequally pinnate, rarely reduced to a single leaflet; stipules absent. Buds, large terminal and small axillary, the former usually with four scales visible externally, the latter with two outer scales; these scales are rudimentary leaf-stalks, often showing at their apex traces of the pinnate leaf, and increase in size after the bud opens, falling off eventually and leaving ring-like scars at the base of the shoots.

Flowers polygamous or diceious, in panicles or fascicled racemes, terminal on leafy shoots of the year, or developed from separate buds either in the axils of the leaf-scars of the previous year, or at the base of the young branchlets. Calyx absent in some species; when present, campanulate and four-lobed. Corolla absent in many species; when present, of two to four (rarely five to six) petals, free or connate in pairs at the base. Stamens two, rarely three or four, affixed to the base of the petals or hypogynous. Ovary, with a style divided above into a two-lobed stigma, two-celled, each cell containing two pendulous ovules. Fruit, a samara, indehiscent, convex or compressed below, with a dry pericarp produced into an elongated terminal and more or less decurrent wing,¹ usually one-celled and one-seeded. Seed pendulous; embryo erect in a fleshy albumen; cotyledons flat.

The genus *Fraxinus* is widely distributed over the temperate regions of the northern hemisphere, three² species, however, occurring within the tropics in Cuba and the Philippines, and south of the equator in Java. The genus consists of nearly sixty species, many of which are imperfectly known and require further study in the field. Even in the case of the Mediterranean species, authorities are at variance. The present account deals only with the species which have been seen in the living state.

The genus is divided into five sections:—

I. *Ornus*, Persoon, *Syn. Pl.* ii. 605 (1807).

Calyx and corolla both present, the calyx persisting under the samara. Panicles terminal on leafy shoots or axillary on the branchlets of the current year. About eighteen species.

¹ Abnormal fruit with three wings, has been observed in several species, as *F. americana*, *F. caroliniana*, *F. Berlandieriana*.

² *F. caroliniana*, a native of the United States, is met with in Cuba. *F. Eedenii*, Boerl et Koord, occurs in Java; and *F. philippinensis*, Merrill, in the Philippine Islands.

II. *Ornaster*, Koehne and Lingelsheim, *Mitt. Deut. Dendr. Gesell.* 1906, p. 66.
Calyx present, persistent under the samara. Corolla absent. Flowers in terminal panicles, appearing with the leaves. Seven species.

III. *Sciadhanthus*, Cosson et Durieu, *Bull. Soc. Bot. France*, ii. 367 (1855).

Calyx present, persistent under the samara. Corolla absent. Flowers in dense fascicled cymes, axillary on the preceding year's shoot. Two species.

IV. *Leptalix*, Rafinesque, *New Flora*, iii. 93 (1836).

Calyx present, persistent under the samara. Corolla absent. Flowers in panicles, axillary on the preceding year's shoot. About fifteen species.

V. *Fraxinaster*, De Candolle, *Prod.* viii. 276 (in part) (1844).

Calyx and corolla both absent. Flowers in panicles or racemes on the preceding year's shoot. About twelve species.

These sections, based on the characters of the flowers, are not available in practice in the determination of living trees, flowering specimens of which are often not obtainable; and the following key groups the species according to the characters of the branchlets and foliage:—

KEY TO THE SPECIES IN CULTIVATION

I. Leaves simple or with two to three leaflets.

* *Branchlets four-angled.*

1. *Fraxinus anomala*, Watson. Colorado, Utah, Nevada. See p. 898.

Leaves usually simple, ovate or obovate, glabrous beneath.

** *Branches terete.*

2. *Fraxinus angustifolia*, Vahl., var. *monophylla*. See p. 880.

Leaves opposite, simple or two- to three-foliolate, lanceolate, glabrous beneath.

3. *Fraxinus excelsior*, Linnæus, var. *monophylla*. See p. 866.

Leaves opposite, simple or two- to three-foliolate, ovate or oval, pubescent beneath at the base.

4. *Fraxinus syriaca*, Boissier. Western Asia. See p. 883.

Leaves in whorls. Leaflets usually three (occasionally five to seven occurring on the same branch), lanceolate, glabrous.

II. Leaves with five or more leaflets.¹

A. Branchlets, leaf-rachis, and leaflets quite glabrous.

* *Leaflets stalked.*

5. *Fraxinus potamophila*, Herder. Turkestan. See p. 885.

Leaflets seven to nine, ovate, serrate.

¹ Cf. *F. syriaca* (No. 4), which has occasionally five to seven leaflets.

** *Leaflets sessile.*

6. *Fraxinus angustifolia*, Vahl. S. France, Spain, Portugal, N. Africa. See p. 879.
Leaflets seven to thirteen, lanceolate. Leaf-rachis strongly winged, the wings meeting above; groove interrupted.

7. *Fraxinus Willdenowiana*, Koehne. Origin unknown. See p. 884.

Leaflets, seven to eleven, ovate or lanceolate, increasing markedly in size from the base to the apex of the leaf. Leaf-rachis with a continuous open groove.

B. Branchlets glabrous; leaflets pubescent on part of the lower surface.

* *Leaf-rachis strongly winged on the upper side, the wings meeting in part above, forming an interrupted open groove.*

8 to 11. *Leaf-rachis not conspicuously bearded at the nodes.*

8. *Fraxinus oxycarpa*, Willdenow. Italy, S.E. Europe, Asia Minor, Caucasus. See p. 882.

Leaflets seven to thirteen, ovate or lanceolate; serrations few, ending in long incurved points.

9. *Fraxinus excelsior*, Linnæus. Europe, Caucasus. See p. 864.

Leaflets, five to eleven, oblong-lanceolate; serrations crenate, numerous, exceeding in number the lateral nerves.

10. *Fraxinus excelsior*, Linnæus, var. *rotundifolia*. See p. 866.

Leaflets nine to thirteen, $1\frac{1}{2}$ to $2\frac{1}{2}$ inches long, ovate, oval, or orbicular, coarsely bi-serrate.

11. *Fraxinus Elonza*, Dippel.¹ Origin unknown. See p. 883.

Leaflets, eleven to thirteen, small, less than $2\frac{1}{2}$ inches long, irregularly serrate, oblong, lanceolate or oval; under surface with brown tomentum near the base.

12, 13. *Leaf-rachis with conspicuous tufts of brownish-red tomentum at the nodes.*

12. *Fraxinus nigra*, Marshall. N. America. See p. 898.

Leaflets, seven to eleven, oblong-lanceolate, rounded or broadly cuneate at the base, sessile.

13. *Fraxinus mandshurica*, Ruprecht. Eastern Asia. See p. 893.

Leaflets seven to thirteen, oblong-lanceolate, gradually tapering at the base, sub-sessile.

** *Leaf-rachis with a continuous open groove on its upper side, which is sometimes almost obsolete.*

† *Some or all of the leaflets distinctly stalked.*

14, 15. *Leaflets white beneath.*

14. *Fraxinus americana*, Linnæus. N. America. See p. 901.

Leaflets seven to nine, 4 to 6 inches long, long-acuminate, dull light green above; rachis with an extremely slight groove.

¹ The groove on the leaf-rachis is variable in this species, sometimes being open its whole length.

15. *Fraxinus texensis*, Sargent. Texas. See p. 907.
Leaflets five to nine, $2\frac{1}{2}$ to $3\frac{1}{2}$ inches long, shortly acuminate, shining bluish-green above; rachis with a very slight groove.
16. *Fraxinus caroliniana*, Miller.² S.E. United States, Cuba. See p. 904.
Leaflets, five to seven, about 3 inches long, shortly acuminate; rachis with a well-defined but shallow groove.
- 17 to 23. *Leaflets green beneath; rachis slightly pubescent at the nodes.*
17. *Fraxinus rhynchophylla*, Hance. N. China, Manchuria. See p. 892.
Leaflets five to seven, 3 to 4 inches long, coriaceous, terminating in an obtuse-tipped acumen, entire or very obscurely serrate.
18. *Fraxinus chinensis*, Roxburgh. Central and Southern China. See p. 895.
Leaflets seven to nine, 3 to 4 inches long, coriaceous, shortly cuspidate at the apex, crenately serrate.
19. *Fraxinus obovata*, Blume. Japan. See p. 895.
Leaflets five to seven, 2 to 3 inches long, membranous, variable in shape, irregularly serrate, with minute curved bristles on the lower surface and petiolules, which are also present on the rachis of the leaf.
20. *Fraxinus longicuspis*, Blume. Japan. See p. 897.
Leaflets five, 3 to 4 inches long, membranous, very pale beneath, abruptly contracted into a long cuspidate apex, crenately serrate.
21. *Fraxinus Ornus*, Linnæus. S. Europe, Asia Minor. See p. 887.
Leaflets five to nine, 2 to 3 inches long, membranous, shortly acuminate, serrate.
22. *Fraxinus floribunda*, Wallich. Himalayas, Upper Burma. See p. 890.
Leaflets seven to nine, 4 to 6 inches long, membranous, apex long-acuminate, serrate; lateral nerves prominent and numerous.
23. *Fraxinus quadrangulata*, Michaux. N. America. See p. 900.
Branchlets quadrangular and four-winged. Leaflets seven to nine, 3 to 5 inches long.
- †† *Leaflets sessile or sub-sessile.*³
24. *Fraxinus Spaethiana*, Lingelsheim. Japan. See p. 897.
Leaflets seven to nine, 4 to 6 inches long, coriaceous, lanceolate, long-acuminate, irregularly and often crenately serrate. Distinguished from all other species in cultivation by the dilated swollen base of the leaf-stalk.
25. *Fraxinus lanceolata*, Borkhausen. N. America. See p. 906.
Leaflets seven to nine, 3 to 6 inches long, lanceolate, long-acuminate. Rachis grooved.
26. *Fraxinus Berlandieriana*, De Candolle. Texas, Mexico. See p. 907, note 1.
Leaflets, five to seven, 2 to 3 inches long, oval or obovate. Rachis grooved.

¹ *Fraxinus lanceolata* (cf. No. 21), has occasionally the leaflets distinctly stalked, and might on that account be sought for here.

² Cf. No. 31A. Two forms of this species occur in cultivation, differing in the absence or presence of pubescence on the branchlets and leaf-rachis.

³ *Fraxinus Elonza* (cf. No. 11), sometimes having an open continuous groove on the rachis, might be sought for here.

27. *Fraxinus dimorpha*, Cosson et Durieu. N. Africa. See p. 884.
Leaflets, seven to nine, about $\frac{3}{4}$ inch long, ovate. Rachis with wide-spreading wings.
- C. *Branchlets minutely pubescent; leaflets glabrous.*
28. *Fraxinus Mariesii*, J. D. Hooker. Central China. See p. 892.
Leaflets five, coriaceous, about $2\frac{1}{2}$ inches long, oval, stalked, crenately serrate.
29. *Fraxinus Bungeana*, De Candolle. North China. See p. 891.
Leaflets five to seven, membranous, about $1\frac{1}{2}$ inch long, mostly stalked, oval or rhomboid, long-acuminate, irregularly serrate.
30. *Fraxinus raibocarpa*, Regel. Turkestan. See p. 886.
Leaflets five to seven, oval, entire, about $1\frac{1}{2}$ inch long; upper leaflets subsessile, lower leaflets stalked.
- D. *Branchlets, leaf-rachis, and leaflets pubescent.*
* *Leaflets distinctly stalked.*
31. *Fraxinus Biltmoreana*, Beadle. United States. See p. 905.
Leaflets seven to nine, oval, about 4 inches long, white beneath; rachis very slightly grooved.
- 31A. *Fraxinus caroliniana*, Miller.¹ S.E. United States, Cuba. See p. 912.
Leaflets five to seven, oval, about 3 inches long, green beneath, rounded or broadly cuneate at the base; rachis with a well-defined but shallow groove.
- ** *Leaflets stalked, sessile, or sub-sessile.*
32. *Fraxinus pennsylvanica*, Marshall. N. America. See p. 908.
Leaflets, seven to nine, lanceolate, 4 to 5 inches long, green beneath, pubescent on both surfaces, long-acuminate, tapering at the base; rachis densely white-pubescent, and with a narrow, shallow groove. Buds reddish pubescent.
33. *Fraxinus pubinervis*, Blume. Japan. See p. 896.
Leaflets five to seven, lanceolate, 3 to 4 inches long, glabrous above, green and pubescent beneath, acuminate, tapering at the base; rachis grooved, with pubescence densest at the nodes. Buds greyish pubescent.
- *** *Leaflets sessile or sub-sessile.*
34. *Fraxinus oregona*, Nuttall. Western United States. See p. 910.
Leaflets seven to nine, oval, 3 to 4 inches long, green beneath, shortly acuminate, entire or obscurely crenate in margin.
35. *Fraxinus velutina*, Torrey. Texas to California. See p. 912.
Leaflets three to five, about $1\frac{1}{2}$ inch long; lateral leaflets variable in shape and serration, terminal leaflet obovate.
36. *Fraxinus xanthoxyloides*, Wallich. Baluchistan, Afghanistan, N.W. Himalayas. See p. 885.
Leaflets, five to nine, about $\frac{3}{4}$ inch long, ovate. Rachis with wide-spreading wings.

¹ Cf. No. 16.

37. *Fraxinus holotricha*, Koehne. Origin unknown. See p. 887.
Leaflets nine to thirteen, lanceolate or ovate-lanceolate, about 2 inches long, sharply serrate. (A. H.)

FRAXINUS EXCELSIOR, COMMON ASH

Fraxinus excelsior, Linnæus, *Sp. Pl.* 1057 (1753); Loudon, *Arb. et Frut. Brit.* ii. 1214 (1838); Willkomm, *Forstliche Flora*, 658 (1897); Mathieu, *Flore Forestière*, 241 (1897).

A large tree, attaining 140 feet in height. Bark smooth and greyish when young, becoming rough and fissured in old trees. Branchlets glabrous. Leaflets (Plate 262, Fig. 4), 9 to 15, sessile and articulate, oval- or oblong-lanceolate, acuminate at the apex, tapering at the base, where the margin is entire, elsewhere crenately serrate, the serrations more numerous than the lateral nerves; upper surface glabrous and green; lower surface paler with pubescence on the midrib, extending over the basal part of the leaflet; venation pinnate, the lateral nerves forming loops near the margin. Rachis glabrous or pubescent, strongly winged, the wings meeting above,¹ except opposite the insertion of the leaflets where there is an open channel, and below the leaflets where the rachis is flattened or broadly grooved.

Flowers,² opening before the leaves appear, fertilised by the wind, in dense axillary panicles, polygamous or occasionally dicecious, without calyx or corolla. Male flowers with two stamens more or less connate below. Female flowers with a two-celled superior ovary, the style being dilated above into two thick stigmas. Perfect flowers with an ovary and two stamens.³

Fruit, of two carpels, joined together to form the body of the samara, which is compressed at right angles to the partition and is produced in front into a veined membranous wing. The samaræ are very variable in shape, but are usually linear-oblong or elliptic, obtuse at both ends, and notched at the tip. They hang in racemes on long stalks, and, ripening in autumn, generally remain on the tree till the following spring; and are ultimately carried by the wind a short distance away from the parent tree.

SEEDLING⁴

The young plant on appearing raises the samara out of the soil, the two cotyledons being united together at first by a cap formed of the albumen. The

¹ Rain collecting on the leaflets drains into the ducts thus formed, inside of which are hairs and peltate groups of cells that gradually absorb the water, which is retained for several days after a fall of rain. See Kerner, *Nat. Hist. Plants*, Eng. Transl. i. 231, fig. 54 (1898).

² Section *Fraxinaster*.
³ Schulz, in *Ber. Deutsch. Bot. Ges.* x. 401 (1892), has shown that trees of the common ash greatly vary in the kind of flowers which they produce. Trees bearing only male flowers are common; while those with only female flowers or with only perfect flowers are rare. In many cases two of the three kinds of flowers are borne on the same tree; and what is very remarkable, a tree is not necessarily of the same sex in successive years. Ash trees do not flower, as a rule, regularly every year; and fruit is much more abundant in some years than in others.

⁴ Figured in Lubbock, *Seedlings*, ii. 214, fig. 512 (1892).

cotyledons, when developed, are about $\frac{3}{4}$ to $1\frac{1}{2}$ inch long, oblong, obtuse, entire, glabrous, pale beneath, tapering at the base into a very short winged petiole. Caulicle terete, 1 to 3 inches long, ending in a long yellow, fleshy, flexuose tap-root. Young stem, green and glabrous, terete below, angled above. First pair of leaves, arising $\frac{1}{4}$ to 1 inch above the cotyledons, simple, ovate, acuminate or acute, irregularly serrate and ciliate, minutely pubescent, on a winged petiole about $\frac{1}{2}$ inch long. Second pair of leaves, three-foliolate, on a petiole about an inch long, the terminal leaflet the largest. Third pair with either three or five leaflets.

IDENTIFICATION

The common ash is only liable to be confused with species like *F. angustifolia* and *F. oxycarpa*; but is readily distinguished by its black buds, and the crenate serrations more numerous than the lateral nerves in the leaflets.

In winter, the twigs are stout, shining-grey or olive green, compressed towards the tip, swollen at the nodes. Leaf-scars, opposite, obliquely set on projecting pulvini, semicircular or almost orbicular, often with lateral projecting horns, and showing an almost circular row of bundle-dots. Terminal buds black, conical, quadrate, with four scales visible externally, but consisting altogether of seven to eight pairs of scales. Lateral buds smaller, given off at a wide angle, with two or three external scales.

VARIETIES

The common ash, though distributed over a wide area, varies little in the wild state; and such varieties, as have been based on the form of the fruit, cannot be considered as well established. Near Perpignan a form with small leaves has been collected, which is var. *australis*, Godron et Grenier, *Flore de France*, ii. 471. In the province of Talysch in the Caucasus, a remarkable form occurs with large leaflets, velvety pubescent underneath; and the shoots, buds, and leaf-rachis are densely pubescent. This variety, which was described by Scheele¹ as a distinct species (*F. coriariifolia*), is said by Koch² to be met with occasionally in cultivation in gardens, where it is known as *Fraxinus expansa*.

A curious variation in the common ash was observed by A. D. Richardson³ in the case of four young plants, found growing in a clump of several hundreds, on the banks of the Boyne near Navan in Co. Meath. The leader shoots had the leaves alternate in a $2/5$ spiral arrangement, instead of the normal opposite and decussate one.

Numerous varieties have been obtained as seedlings in nurseries or as isolated specimens growing wild.

¹ *Linnaea*, xvii. 350 (1843).

² *Dendrologie*, ii. 1, 243 (1872).

³ *Gard. Chron.* xxxvi. 133, fig. 55 (1904).

1. Var. *monophylla*, O. Kuntze, *Flora von Leipzig*, 82 (1867).*Fraxinus monophylla*, Desfontaines, *Tab. de l'École de Bot.* 52 (1804).*Fraxinus heterophylla*, Vahl, *Enum. Pl.* i. 53 (1804); Loudon, *Arb. et Frut. Brit.* ii. 1228 (1838).*Fraxinus simplicifolia*, Willdenow, *Sp. Pl.* iv. 1098 (1805).*Fraxinus excelsior*, var. *diversifolia*, Aiton, *Hort. Kew.* iii. 445 (1789).

This remarkable variety, which is usually known as the laurel-leaved or simple-leaved ash, is met with in the wild state in the forests near Nancy in France, and also rarely in England and Ireland. It appears¹ occasionally when a quantity of ash seeds is sown, and intermediate forms are found with three, five, and seven leaflets. The shoots and buds are identical with those of the common ash. In the ordinary form of the variety, the leaf (Plate 262, Fig. 2) is simple, not being divided into leaflets. Occasionally there is a large leaflet, with one or two small leaflets at its base; and this form is known as var. *monophylla laciniata*. The simple-leaved form or the terminal leaflet in the two- to three-leaflet form, has a stalk about half as long as the blade or a little longer, and is variable in shape, being usually oval in outline with an obtuse, acute, or acuminate apex; margin coarsely serrate; lower surface pubescent except towards the apex; petiole widely grooved on its upper side. A form of the single-leaved ash with variegated leaves, was discovered, according to Loudon, in 1830 at Eglantine, near Hillsborough, Co. Down, Ireland.

The simple-leaved ash is very distinct in appearance and thrives well in towns. It is usually propagated by grafting.

At Beauport, Sussex, there is a tree of this kind, 70 feet by 5 feet 9 inches; and self-sown seedlings reproducing the variety have been observed by us there. Other large specimens occur: at Syon, a tree² 84 feet by 7 feet 6 inches; at Sidmouth, measured by Miss Woolward in 1904, two trees 9 feet 4 inches each in girth, the taller being 86 feet high; also three good trees in the grounds at Woburn growing beside the lake. Lord Kesteven reports one at Stubton Hall, Newark, which was 67 feet high by 8 feet 1 inch in girth in 1906. Elwes has seen others from 50 to 70 feet high at Scampston Hall, Yorkshire; at Sharpham, near Totnes; and at Dodington Park, Gloucestershire. A tree at Oxford, near the east end of the broad walk in Christchurch meadow, mentioned by Walker³ in 1833, is, according to Mr. Druce, about 65 feet high and 4 feet 7 inches in girth. It is crowded by other trees and is not thriving.

On the Pitfour estate near Mintlaw in Aberdeenshire, a tree 55 feet high by 7 feet 9 inches is reported by Mr. Ainslie; and Elwes saw one at Gordon Castle, which in July 1907 was covered with fruit and measured about 60 feet by 9 feet 2 inches in girth.

There is a very good specimen in Stephen's Green, Dublin; one at Beauparc House in Co. Meath measured, in 1905, 40 feet high by 6 feet 2 inches in girth; and another at Curraghmore, Co. Waterford, was 50 feet by 5 feet in 1907.

2. Var. *rotundifolia*. A tree growing in a wood at Strete Ralegh, near Exeter,¹ Cf. Mathieu, *Flore Forestière*, 241 (1897), and *Allgem. Garten-Zeitung*, iii. 6 (cited by Loudon).² This tree in 1849 was 50 feet high by 4 feet in girth; it is now beginning to decay at the top.³ *Flora of Oxfordshire*, 3 (1833). Cf. also Dyer, in *Journ. Bot.* ix. 147 (1871).

the seat of H. Imbert Terry, Esq., who has sent specimens, is remarkably distinct in the shape of the foliage from any ash known to me; but is probably only a variety of the common ash, with which it agrees in bark and in buds. In the absence of flowers and fruit, this identification is not quite certain, and on that account a full description is now given: Leaflets (Plate 266, Fig. 32), nine to thirteen, 1½ to 2½ inches long; terminal leaflet stalked, with a long cuneate base; lateral leaflets, sessile, broadly oval or ovate, unequal at the usually cuneate, but occasionally broad and rounded base, acute or slightly acuminate at the apex, coarsely bi-serrate, slightly scabrous with scattered stiff hairs on the upper surface, pale beneath with dense woolly pubescence on the sides of the midrib and lateral nerves near the base. Leaf-rachis, strongly winged, the wings meeting above in its apical half, but forming a wide open groove towards the base; pubescent on the dorsal side with scattered stiff hairs, densest at the nodes.

This ash resembles in foliage the figure of *F. rotundifolia*, Aiton,¹ which is given by Willdenow.² The latter species, according to Aiton, Willdenow, and Loudon,³ is a small tree of Italy, with flowers and buds like *F. Ormus*; and the Strete Ralegh tree cannot be identified with it, as in all essential characters⁴ it resembles the common ash.

Nothing is known of the origin of the tree at Strete Ralegh, which Miss Woolward found in 1905 to be about 75 feet in height, the bole dividing near the ground into two stems, 3 feet 1 inch and 2 feet 7 inches in girth respectively.

3. Var. *angustifolia*, Schelle. A variety⁵ with small narrow leaves (Plate 262, Fig. 5), which differs in no essential character from the common ash, of which it has the buds and the characteristic serrations and pubescence of the leaflets; and in this way can be readily distinguished from such species as *F. angustifolia*, Vahl, and *F. oxycarpa*, Willd.

4. Var. *crispa*, Loudon (also known in gardens as var. *atrovirens* and var. *cucullata*). Leaflets dark green, curled and twisted. Plant usually rigid and stunted, of very slow growth.

5. Var. *nana*, Loudon (also known in gardens as var. *polemoniifolia* and var. *globosa*). A compact slow-growing dwarf form, with very small leaves.

6. Var. *aurea*, Loudon. With yellow branches. A pendulous form of this is known.

7. Var. *asplenifolia*, Koch. Leaflets very narrow, almost linear.

8. Var. *fungosa*, Loddiges. Bark remarkably wrinkled, with corky ridges.

9. Var. *verticillata*, Loudon. Leaves whorled, not opposite as in the common form.

10. Var. *monstrosa*, Koch. Young branches fasciated.

11. Var. *erosa*, Persoon. Leaflets incised.

¹ *Hort. Kew.* iii. 445 (1789). Cf. our remarks on this species under *F. Ormus*, p. 888.² *Berlin. Baumzucht*, 116, fig. vi. 1 (1796).³ *Arb. et Frut. Brit.* ii. 1244 (1838).⁴ Bark and buds especially. The pale under surface of the leaf, which is thin in texture, is seen in common ash seedlings and in some forms of var. *monophylla*. The strongly-winged rachis of the leaf is characteristic of *F. excelsior* and its near allies.⁵ Var. *elegantissima*, in cultivation at Aldenham, obtained from Simon-Louis, is scarcely to be distinguished from this variety.

12. Var. *verrucosa*, Desfontaines. Branchlets warty.

13. Certain variegated forms are known, as—var. *albo-marginata*, leaflets edged with white, and var. *albo-variegata*, in which the white colour appears as blotches on the leaflets.

Most of the foregoing varieties are of little or no beauty or interest, and do not, so far as we know, become large or shapely trees. (A. H.)

14. Var. *pendula*, Aiton. The weeping ash in some form or other is found in almost every garden, but rarely as a large tree. Loudon describes several forms of it, and says that the original tree was discovered near Wimpole in Cambridgeshire 150 years or more ago, and was decaying in 1835.

Another form, the Cowpen ash, which grew near Morpeth, is figured by Loudon;¹ and I have seen two trees which have naturally assumed a very similar habit. One stands by the road in the village of Ollerton, Notts. The other is in a field at Marsden, in the parish of Rendcombe, Gloucestershire.

A third form, called by Loudon the Kincairney Ash, grew in the parish of Caputh, near Dunkeld, Perthshire, and was distinguished by its alternately pendulous and upright branches. It was propagated at the Perth Nurseries, but I have not noticed any of this variety now in cultivation.

To make an effective tree, the weeping ash should be grafted on a very tall stock, and if the branches are attended to, may be trained into a shady arbour like a great umbrella. But if the stock is also allowed to grow as well as the graft, the effect will be more curious than beautiful; and the weeping ash is not so much admired or planted as it was formerly when trained and clipped trees were more in fashion. At Heanton Satchville, in North Devon, the seat of Lord Clinton, I saw it trained in combination with a trellis of living ashes which were planted all round the central weeping tree, and had their stems woven together when young so as to form the walls of the arbour; but in the course of time this had become ragged; and as the ash does not bear clipping like the beech or hornbeam, I should prefer either of those trees for such a purpose.

By far the finest grafted weeping ash that we know of is growing in the gardens of Elvaston Castle, near Derby, the seat of the Earl of Harrington. It was reported² in 1905 to be 98 feet high, with long weeping branches hanging vertically from the summit of the tree, one of them descending to about 20 feet from the ground; but when I saw it in 1906 I did not think it was more than about 90 feet high, the bole, 6 to 7 feet in girth, being straight and clean. (Plate 238.) This tree was grafted by Barron about 1848. Another larger tree also exists here, which has a bole 50 feet by 12½ feet, and was apparently grafted with weeping ash at the same time, but in this case the branches of the stock have outgrown the grafts.

In Ireland there is a very handsome and well shaped weeping ash at Castlewellan, 41 feet high, with a trunk 5 feet in girth with branches hanging to the ground all round it. (H. J. E.)

¹ *Arb. et Frut. Brit.* ii. 1216, f. 1045 (1838).

² *Garden*, 1905, lxviii. 400, with figure.

DISTRIBUTION

The common ash is spread through almost all Europe, and occurs also in the Caucasus.

The northern limit in Europe passes from the Trondhjem fjord in Norway, about lat. 63° 40', through Sweden at about lat. 61°, and in Finland extends to lat. 62°, descending from there through Russia in a S.E. direction to Riazan, whence it continues N.N.E. to Kazan, its extreme eastern point in Europe. From Kazan, the eastern limit descends in a S.W. direction through Penza, Saratof, and Voronej to Kharkof, and then passes by Ekaterinoslav to the Crimea. In the Caucasus¹ the ash does not occur north of the rivers Kuban and Terek. The southern limit extends from the Transcaucasian province of Talysch through Asia Minor and Turkey to Dalmatia, and across Italy and southern France to the Pyrenees. In the Iberian peninsula² it is met with, according to Willkomm, in the mountains of Catalonia, Aragon, Burgos, Santander, Leon, Asturias, Galicia, and northern Portugal. The western limit takes in the western coast of France and the British Isles. Outside the range mentioned above, it occurs as small scrub in rare situations, as in Norway at Tromsö (lat. 69° 40'), and in the government of St. Petersburg.

An ash occurs in the western Himalayan region which, according to most of the authorities, is *Fraxinus excelsior*. It has been distinguished as a distinct species by Wenzig,³ and, so far as I can judge from dried specimens, is very different indeed from the common ash. Sir George Watt informs me that this ash is always an insignificant tree, never attaining more than 30 feet in height and a foot in girth.

The ash is generally met with growing wild as isolated trees or in small groups in the continental forests, but pure woods of some extent occur in moist situations, as in river valleys subject to flooding, in Hungary, Slavonia, Poland, and Russia. In northern regions it is rather a tree of the plains and valleys than of the mountains; but in southern Europe it is only met with in the mountains. It ascends in south Tyrol to 4000 feet, and in Switzerland to about 4400 feet.

The ash is a true native of the British Isles, and has been found in a fossil state in the interglacial beds at Hitchin in Hertfordshire, and in neolithic deposits at Crossness in Essex.⁴

It may be said to occur wild in every part of the British Isles, except in the northern part of Scotland, where, however, it bears the climate in plantations. In Yorkshire⁵ it ascends to 1250 feet elevation. In Braemar, H. B. Watt⁶ observed it up to 1200 feet. In Ireland⁷ it is frequent in woods, hedges, and rocky places; and ascends in Donegal to 800 feet, in Down to 1000 feet, and in Wicklow to 1300 feet.

¹ It ascends in the Caucasus to 6000 feet, according to Radde, *Pflanzenverbreitung in den Kaukasusländern*, 181 (1899).

² Cf. Captain Widdrington's account of the distribution of the ashes in Spain, given under *Fraxinus angustifolia*, p. 880.

³ *Fraxinus Hookeri*, Wenzig, in Engler, *Bot. Jahrb.* iv. 179 (1883). It differs from the common ash in having fewer leaflets, usually five, rarely seven. The bud is also very distinct, being dark yellow in colour, and covered with minute warts. The leaflets are sessile, oval, broadly cuneate at the base, acuminate at the apex, pale beneath, with pubescence on each side of the midrib, minutely crenulate-serrate. The rachis appears to have a wide open groove above; and the fruit in its lower part is longitudinally and deeply grooved in the middle line.

⁷ *Cybele Hibernica*, 236 (1898).

Ash woods, supposed to be wild, occur on limestone in hilly districts in Yorkshire, Derbyshire, and Somerset. In the latter county, they are very numerous in the Mendip Hills, and have been mapped by Mr. C. E. Moss,¹ who gives an interesting account of their distribution and peculiar features. The ash is often pure, with a dense undergrowth of hazel, or it is mixed with yew and whitebeam. Mr. Moss notices the prevalence of dog's mercury and wood garlic² in many of these ash woods.

The Gaelic name of the ash, according to Sir H. Maxwell,³ is *uinnse* (inshy), and becomes Inshawhill in Wigtonshire, and the plural *uinnsean* (inshan) takes the peculiar form of Inshanks, the name of two places in that county, and Inshewan, near Kirriemuir; while the common alternative form *uinnseog* (inshog) remains as Inshock in Forfarshire, Inshaig in Argyllshire, Inshog near Nairn. Analogous forms,⁴ with the initial letter *f*, appear in names of places in the south and west of Ireland, as the river Funcheon in Co. Cork.

(A. H.)

CULTIVATION

Though the oak will always be looked on as the premier tree of Great Britain, yet now that its most important use has passed away, the ash must be considered as the most economically valuable of all our native trees, and is perhaps the only hardwood from which a quick and certain return can be expected by the planter.

It is almost the only tree whose value has not fallen in consequence of foreign competition, and, though a good deal of American and some Hungarian and Japanese ash is now imported, yet the timber of these is not considered equal for toughness, strength, and elasticity to the best English ash, for which no foreign wood forms an efficient substitute. And as the tree can be grown over all parts of our islands, and attains a great size wherever suitable soil is found, it should be planted more largely in all favourable situations, where it produces timber of good quality.

In considering the requirements of the ash, one must always remember that it is a bad neighbour both to other trees and to crops, and that it is far more valuable as timber when grown in woods where it can be drawn up to a good height, than in hedgerows where it produces many branches. It likes a deep, rich soil, neither too wet nor too dry, and grows very well on limestone formations, even on a shallow soil, if the rock is sufficiently disintegrated for the roots to penetrate the crevices.

It is short-lived on wet or swampy soils, and the timber is inferior on sandy or peaty land. The finest trees are generally in sheltered situations, but though it is the latest of our native trees to come into leaf, none suffers more from late frosts; and therefore when planted in low situations it is often severely injured when young. It will grow up to a great elevation, and in the most exposed situations, though here it becomes stunted and branchy. No hardwood except that of the chestnut becomes valuable at so early an age, but the wood of old trees, even when sound, usually becomes discoloured or "black-hearted," and ash is never

¹ *Geog. Distribution of Vegetation in Somerset*, 41 (Roy. Geog. Soc., 1907).

² Mr. A. C. Forbes, in *Eng. Estate Forestry*, 72 (1904) says:—"We have always noticed that the existence of the wild garlic, *Allium ursinum*, is an almost certain indication of good ash ground."

³ *Scottish Land Names*, 109 (1894).

⁴ Cf. Joyce, *Irish Names of Places*, 488 (1870).

more valuable than when it is from 3 to 6 feet in girth, with a clean stem, a size often attained at fifty to sixty years of age.

In plantations ash is often mixed with other trees, and if allowed to take the lead will do them more harm than oak, but a few ash should be introduced in the best soil of larch or other plantations, because the seedlings, which spring up abundantly, will, when the conifers are cut, renew the plantation naturally, and the parent trees will throw up vigorous shoots from the stool after felling.

In the midland counties, ash is the commonest, and by far the most profitable underwood, being cut at intervals of twelve to twenty years; when the poles are much in demand for many purposes, especially for sheep hurdles. But in most places during the last twenty years ash poles have fallen in value, though larger timber has increased in price; and so much damage has been done to the stools by rabbits that large areas are now becoming very thin, and the crop inferior. No tree except beech suffers more from rabbits than ash, and where they are allowed to increase, and are not killed before winter, the bark of old trees as well as of underwood is sure to be peeled, and the natural reproduction from seed checked. I believe that where the soil is stiff, young ash will pay for some cultivation when young, as their shade is not dense enough to keep down grass and weeds, and if they become stunted, as they often do after planting, it is better, and, indeed, necessary, to cut them down to the ground two to five years later.

Self-sown ash seem to grow more vigorously than planted ones, if not too crowded, and their rate of growth is sometimes extraordinary. An ash self-sown in my nursery, at three years old was 7 to 8 feet high, whilst the transplanted seedlings on the same ground were only 3 feet high at the same age. I have seen shoots 6 to 7 feet long the first year from strong healthy stools, and poles worth £15 to £20 per acre at sixteen years old, on land which for agricultural purposes was not worth 8s. an acre. The stools, however, often become worn out and hollow at the base after five or six cuttings, and these should be replaced with seedling plants every time the crop is cut.

Some years ago, when ash coppice began to fall in price, I left the strongest and straightest pole on every stool at the rate of about 160 per acre, with the object of converting the coppice into timber trees. But though, where the soil is good and the stools young, these poles are likely to make useful trees at fifty to sixty years from the last cutting over, yet where the land is poor they have increased but little, and have a hidebound appearance, owing, no doubt, to the want of shelter and the exposure to the sun and wind. I should advise all intending planters of ash to examine carefully the best local ash plantations, and inquire into the probable demand for poles before adopting this course.

The ash is always raised from seed, except in the case of varieties which are grafted on stocks of the common ash. The keys are ripe in late autumn, and often hang on the tree till the following summer, especially when they are not mature. The best-ripened seed, I believe, usually falls first, and should be gathered before winter, and put in a shallow layer mixed and covered with earth or sand, and kept fairly dry until the following winter, when it should be sown. It is advised in books

that they should be turned over several times during the year before sowing, but I have not found this necessary; and with regard to the time of sowing, it should be put off as long as possible, because the natural germination of the seed takes place six to eight weeks before the tree comes into leaf, and the tender seedlings are thus often injured and killed by late frost. Therefore I advise storing them in a cold place, and not sowing until they begin to germinate. If they come up too thickly and survive the first spring, they may be transplanted in the following March or April, which will tend to check their early leafing, but if thin on the ground they may be allowed to stand two years before transplanting into rows. At three, or at most four, years old, they will be fit to go out permanently, the stronger side branches and double leads, if any, being first pruned. If intended for copsewood, they must be cut over in the month of April, two or three years after planting, and any pruning necessary to older trees should be done in summer or early autumn, so that the wounds may heal as soon as possible. The tree makes an abundance of fibrous roots, and unless these are allowed to become dry, the proportion of loss from transplanting should be very small, and transplanting may be done later than in the case of most hard woods.

For ash coppice, 4 or 5 feet apart is the right distance; for timber trees, they may be alternated with spruce or larch, which will keep them from becoming branchy. The cutting of the stools must be done with a sharp knife or axe as near the ground as possible, and with an upward cut, and the poles removed at latest by the middle of May, as much harm is caused by getting the poles away after the stools have begun to push new growth.

One of the best examples of copse-grown ash that I have seen in England is the Walk Copse near Buckhold, Berks, where a number of tall, slender, clean poles, believed by Dr. Watney to be about sixty years old, have originally sprung up from seed, in a plantation once largely composed of silver firs. Though the soil is a flinty clay, now of little agricultural value, the majority of these trees are 90 to 100 feet high, by 3 to 4 feet in girth, and quite clean to 50 or 60 feet. One of the best was quite straight and clean to 65 feet high, but only about 3 feet in girth. Such poles as these are much sought for by agricultural implement and coach makers, and are worth from 2s. 6d. to 3s. per foot.

REMARKABLE TREES

I do not know of any ash at present alive in England which equals in size a tree mentioned by Loudon as growing near Moccas Court, Herefordshire, on the edge of a dingle. This had immensely large roots, running on the surface for 50 feet or more down the steep hillside, and a clear trunk of 30 feet long, 7 feet in diameter at 15 feet from the ground. This, including three large limbs, was estimated to contain 1003 cubic feet of timber. This ash is remembered as a marvellous tree, though quite decayed, by the Rev. Sir George Cornwall, who told me that not a vestige of it now remains.

The tallest living ash trees I have seen or heard of are in a grove near the

old heronry at Cobham Hall, Kent, the seat of the Earl of Darnley, a place which contains taller and finer ash trees and hornbeams, and more of them, than any that I have seen in England. Strange to say, Strutt, who figured several trees at Cobham, overlooked these; but in Francis Thynne's continuation of Holinshed's *Chronicles*, p. 1512, I find the following, which shows that Cobham was renowned for its trees more than three centuries ago. Speaking of William, the last Lord Cobham but one, he says:—

“ Besides which, overpassing his goodlie buildings at the Blackfriars in London, in the year of Christ 1582, and since that the statelie augmenting of his house at Cobham Hall, with the rare garden there; in which no varietie of strange flowers and trees do want, which praize or price maie obtaine from the farthest part of Europe, or from other strange countries, whereby it is not inferior to the garden of Semiramis.”

The largest ash here, described by Loudon, was a tree 120 feet high, with a trunk 6 feet 8 inches in diameter, straight, and without a branch for a great height. This was perhaps the same whose trunk I saw in July 1905 lying on the ground, where it had fallen several years ago. But those which remain are not only the tallest ash trees, but the tallest trees of any sort with one exception that I have measured in England, and there are so many of them that I can well believe that I did not measure the tallest. The tallest tree, measured in April 1907, by Lord Darnley, is 146 feet high by 12 feet in girth. Another growing by the side of a drive, which he christened Queen Elizabeth's ash, I measured 143 feet high by 12 feet 7 inches in girth. In the grove near it are several, very nearly if not quite, as tall, one of which I made 141 feet by 13 feet 1 inch, with a bole 50 feet high, and a roughly estimated contents of 700 to 800 feet. (Plate 239.) Another, 140 feet by 12 feet 9 inches, with a bole of 48 feet, which, judging from the large mass of fungus growing on its root, is probably decaying. There are many other trees in this grove which are 125 to 130 feet high, and stand pretty close together, growing in a sheltered situation,¹ on what appeared to be a deep but rather sandy loam.

Other remarkable ash trees at Cobham are the Twisted Ash, whose trunk is spiral, and measures 116 feet by 17 feet 9 inches. (Plate 240.) The View Ash, a tree nearer the house, is only about 80 feet high by 17 feet 9 inches at 5 feet, but is 29 feet in girth at the base, and has its trunk and most of its branches covered with green and healthy twigs.

Next to Cobham in respect of its great ash trees is Knole Park, also in Kent, where, in a sheltered valley near the gate from the Sevenoaks Road, called “The Hole in the Wall,” are a number of very fine sound trees, from 125 to 130 feet high or more, and from 13½ to 16 feet in girth, one of which has a bole 35 feet long, and probably contains over 700 feet of timber. Here again the soil is a deep sandy loam, which grows splendid beech, oak, and chestnut, but I cannot guess the age of the ash, though they are probably over 200 years.

One of the most perfect examples, from a timber point of view, is a tree growing in a wood called Poultridge, just outside Ashridge Park (Plate 241), which

¹ This is about 330 feet above sea-level, and is situated between the Medway and the Thantes.

is about 125, perhaps 130 feet high, but difficult to measure on account of the surrounding trees. It had, in 1906, an absolutely straight, clean stem, about 75 feet in height by 11 feet 10 inches in girth, and looked as if it would square 27 to 28 inches halfway up, in which case it contains about 400 feet of faultless timber in one length. It is surrounded by other trees and underwood, and a photograph could not have been taken if Mr. Liberty, forester to Earl Brownlow, had not been obliging enough to clear away the intervening brushwood.

At Chilham Castle, in Kent, the seat of C. S. Hardy, Esq., there are some splendid ash trees. The best of these was recently cut down in the heronry, where I saw its stump in 1907, and counted about 185 rings, the diameter being about 4 feet. The soil here does not appear to be deep, and is on a chalk subsoil, as at Ashridge, but the tree grew in a very sheltered position, was drawn up to a height of 132 feet, and nourished by the beech which surrounded it. The first length contained 236 cubic feet. A tree of very similar character was growing in the park not far off, and measured about 115 feet by 13 feet 6 inches, with a straight, clean bole about 45 feet long. I estimated its contents at 280 feet in the first length.

At Godinton, Kent, there are many very fine tall ash trees in what is called the "Tole," a splendid clump mainly composed of chestnut, which contains as large a quantity of clean, fine timber as I ever saw on the same area in England. I measured an ash here about 110 feet high, and only 6 feet 5 inches in girth, which hardly fell off at all in thickness up to 50 or 60 feet.

At Woburn there was in Strutt's time an immense ash which he figures on Plate 22, and gives the height as 90 feet, the girth at 3 feet, 15 feet 3 inches, the bole 28 feet high, and the diameter of the branches 113 feet. The estimated contents were 872 feet. This tree was still healthy in Loudon's time but I can find no trace of it at present.

At Arley Castle there is a fine ash tree 120 feet by 14 feet as measured in 1904 by Mr. R. Woodward; and at Althorp there was a very fine ash which is now much damaged by wind and old age. When measured in 1890 by Mr. Mitchell, now forester at Woburn Abbey,¹ it had a bole 36 feet high with immense limbs spreading on all sides, was 17 feet 3 inches in girth at 3 feet, and had a cubic content of 800 feet. At Hatfield there is also a very fine ash tree growing near the big elm in a hollow, which I made 104 feet by 15 feet 8 inches. An immense ash butt was bought by Mr. Miles of Stamford in February 1894, and hauled into his yard by eleven horses. I am informed by Mr. C. Richardson that it measured 20 feet long by 50 inches quarter-girth, equal to 435 cubic feet of timber, and that it was the largest he had ever seen or heard of. Mr. A. B. Jackson in 1908 saw some tall trees at Kedleston Park, Derby, one measuring 120 feet by 10 feet 2 inches, and another 125 feet by 8 feet 10 inches. He measured also a tree at Elvaston Hall, 110 feet by 12 feet 7 inches.

At Studley Royal, Yorkshire, there are some tall, straight, and clean ash, the best that I measured being 119 feet by 10 feet 6 inches; and at Castle Howard and other places in the same county, and in parts of Lincolnshire, the ash is a more

¹ *Trans. Roy. Scott. Arb. Soc.* xiii. 88 (1891).

profitable timber tree than any other. The largest that I have seen in the north is one at Lowther Castle, known as Adam's Ash, which is 21 feet 10 inches in girth.

Lees in *Gardeners' Chronicle*, November 7, 1874, figures several curiously split and distorted relics of ash trees which existed in the district he knew so well round Worcester; but does not mention any of extraordinary size. He suggests that such wrecks may often have escaped being converted into firewood, owing to the superstition which formerly prevailed, that rickety children might be cured by passing them through a fissured ash tree; and relates an instance known to him of the curious superstition, that a similar passage through a cleft ash would induce fertility in barren women.

White, in his *Natural History of Selborne* (Ed. Allen, 1900, p. 266), speaks of a row of pollard ashes at Selborne which had been in former times cleft and held open by wedges while ruptured children were pushed through the aperture, in the belief that they would be cured of their infirmity. He also states that there were then several people living in his parish, who in childhood were supposed to be so cured. He describes an old pollard ash which for ages had been looked on with no small veneration as a "shrew-ash," and whose twigs were, when applied to the limbs of cattle, supposed to cure the pains caused by a shrew-mouse having run over the affected part. A "shrew-ash" was made by boring a hole in the trunk and putting a live shrew into the hole, where it was plugged up with several quaint incantations now long forgotten.

In Wales I have not seen or heard of any larger than a tree by the slaughter-house in Dynevor Park. Though not very well shaped and somewhat past its prime, I found it in 1908 to be 104 feet by 22 feet 9 inches.

In Scotland there are also many great ash trees, of which perhaps the largest recorded anywhere has long ago completely decayed. It was described in Walker's *Essays*, p. 17, as growing in a deep, rich soil, in the churchyard of Kilmalie, and was considered to be the largest and most remarkable tree in Scotland; and said to measure in 1764 no less than 58 feet in girth at the ground. Another celebrated old tree is in the hotel garden at Logierait, Perthshire, which Hunter¹ described in 1883 as measuring 47 feet 7 inches at 1 foot from the ground, and 32 feet 5 inches at 5 feet. It was then completely hollow and covered with ivy, with an opening 5 feet 9 inches wide on one side, in which a summer-house had been made. But the late Sir R. Menzies informed me in 1903 that this tree is now very much decayed.

Strutt, *Sylva Scotica*, Plate 8, figures a very fine ash tree, at Carnock, Stirlingshire, then in perfect vigour, and said to have been planted about 1596 by Sir T. Nicholson of Carnock. He gives its measurement as 90 feet high by 19 feet 3 inches at 5 feet. This tree, however, died and was broken up about 40 years ago. The tallest ash that I have myself measured in Scotland is at Gordon Castle, which is a fine healthy tree in the home park, 101 feet high with a bole of 30 feet, which in 1904 girthed 12 feet 6 inches. J. Webster records one at the same place

¹ *Woods, Forests, and Estates of Perthshire*, 545 (1883).

70 feet by 15 feet 8 inches in 1881. Sir Archibald Buchan-Hepburn reports a tree at Smeaton-Hepburn 124 feet by 11 feet in 1908.

But these are much exceeded in height by a tree west of the Beech Walk at Mountstuart in the island of Bute, which James Kay¹ states to have been in 1879 no less than 134 feet high by 9 feet 4 inches, with a bole of 35 feet 6 inches, and if this measurement was correct it must have been the tallest hardwood tree in Scotland. It was estimated to contain 273 feet of timber. I could not, however, identify this tree when I visited Mountstuart in 1906, and fear that, like some of the splendid beech trees which grew there, it has fallen.

At Ochertyre, Perthshire, Hunter² records an ash supposed to be about 400 years old, which measured in 1881 34 feet 10 inches at 1 foot and 20 feet 8 inches at 5 feet, and I am informed by the widow of the late gardener, Mr. Conacher, that the tree still remains in very good condition. At Keir, near the Bridge of Allan, there is a remarkable ash stool, from which four stems proceed, averaging 6 feet 4 inches in girth and 103 feet in height. A tape 16 feet 10 inches long, girths the four stems at 5 feet from the ground. At Dupplin Castle I measured a fine tree about 100 feet high with a stem clean to 45 feet and 10 feet 7 inches in girth. At Dalswinton, Dumfriesshire, Henry measured in 1904, a tree 110 feet by 8 feet 3 inches, with a fine clean stem; and another 93 feet by 13 feet 3 inches.

Near Cawdor Castle, Nairnshire, the property of the Earl of Cawdor, and one of the most beautifully situated of the really old inhabited castles in Scotland, there is a very large, though branchy and ill-shaped ash no less than 21 feet in girth. At Brodie Castle, Morayshire, there is a very large tree, 18 feet 8 inches in girth, of which the owner has kindly sent me a photograph; and at Darnaway, in the same county, an immense tree of great age, much damaged by storms, existed in 1881. Even as far north as Conon House, Ross-shire, the seat of Sir Kenneth MacKenzie of Gairloch, the ash grows extremely well in a low-lying flat. Here I saw a lot of beautifully grown, though not very large trees, which would have been a credit to any woodland in the south.

On the shore of Loch Fyne, a mile north of Minard Castle, a curious ash grows on the beach at high-water mark, which is known as the "Nine Sisters," because nine stems sprang from the same root, the largest of which when I saw them in 1907 were 7 to 9 feet in girth.

In Ireland the ash thrives exceedingly well; and often attains an immense size. In Co. Meath, where the soil is remarkably fertile, it has in many parts expelled all the other trees from the hedgerows; and one may drive long distances on the roads between lines of flourishing ash trees, without seeing a single oak or beech.

In the latter part of the eighteenth century several ash trees of enormous size were still living, of which Hayes gives an account.³ He relates, on the authority of an official of the Dublin Society, that a tree was then standing at Donirey near Clare Castle in Co. Galway, which measured in girth 42 feet at 4 feet and 33 feet at 6 feet. The trunk had long been hollow, having been used 25 years before as a

¹ *Trans. Scot. Arb. Soc.* ix. 75 (1879).

² *Op. cit.* 454.

³ *Practical Treatise on Planting*, 137, 142, 148 (1794).

school. In 1794, it had only a few branches remaining, which were, however, still vigorous. At Curraghmore, the seat of the Marquess of Waterford in the county of that name, there were many enormous ash trees, one of which was 22½ feet in girth at a height of 13 feet 9 inches, the girth of the butt being 33 feet 9 inches. In 1792 Hayes measured the famous ash tree at Leix in Queen's County, which was 40½ feet round at 1 foot, and 25 feet at 6 feet up, where the girth was least. Marsham in a letter to Gilbert White, dated 12th February 1792, says that a print of this tree was then being engraved in London, but we have never been able to see a copy of this, if it was ever published.

An ash at Castledurrow, which Hayes says was the finest he ever saw, in October 1793 measured 18 feet in girth and nearly as large at 14 feet high, the branches extending 45 feet from the stem in every direction. Another at Kennity Church, King's County, was 21 feet 10 inches in girth with a bole of 17 feet. The funeral parties used to stop and say prayers under this tree, after which they threw a stone at its foot.

None of these relics of antiquity now remain; and most of the fine ashes have been cut down. Probably the tallest now left in Ireland is one at Woodstock in Co. Kilkenny, in an alluvial flat beside the river Nore and close to the village of Inistioge (Plate 242). Henry, in 1904, made it 127 feet in height by 16 feet 9 inches in girth; but the forester's records give it as 136½ feet high in 1901. This tree was 11 feet in girth in 1825, 11 feet 8 inches in 1834, 13 feet 2 inches in 1846, and 16 feet 9 inches in 1901, according to the same records. Another tree beside it, which was 9 feet 5 inches in girth in 1825, was 11 feet 9 inches in 1901; and a third tree, 10 feet 5 inches in 1825, had attained 15 feet 3 inches in 1901.

At Mitchellstown, in Co. Cork, there was in 1903 a remarkably fine ash, with a tall clean stem, which was 111 feet high by 9 feet in girth. Another tree, 91 feet high, was 27 feet in girth at 2 feet above the ground, but only 15 feet 2 inches at 6 feet up. At Kilmacurragh in Co. Wicklow there is a good ash, the height of which exceeds 100 feet, but is impossible to measure on account of the situation of the tree; the girth in 1903 was 13 feet at 5 feet above the ground. There are fine trees of great girth (17 to 18 feet), but not remarkable for height, at Doneraile Court, Co. Cork. Henry measured in 1904, on Lord Oranmore's property at Castle Macgarrett, Co. Mayo, a tree 119 feet by 14 feet 2 inches, containing 216 cubic feet of timber. At Castlewellan, Co. Down, there are some very fine ash in the park, one of which near the garden gate is figured on Plate 243. It measured in 1908 about 70 feet high, and 18 feet in girth.

The finest ash that I have seen on the continent is in the Royal park of Jægersborg near Copenhagen, and measured in 1908, 125 feet by 11 feet 8 inches.

ASH DISEASES

The commonest disease in the ash in my own district is a canker which affects trees during most of their life without killing them, though the timber is worthless except for firewood. This disease is described and figured by the late Mr. Wilson

Saunders, F.R.S. ;¹ and Mr. Sidney Webb fully explained the manner in which extensive canker resulted from minute wounds, at a meeting of the Scientific Committee of the Royal Horticultural Society, February 11, 1879. A full account of the disease is given by Dr. Masters in the *Gardeners' Chronicle*, 1879, p. 208, where it is stated that the injury is originated by the larva of a minute moth called *Prays curtisellus*.² Plate 244 shows a bad case of this canker in an ash at Staple, near Colesborne; and there is a tree at least 70 feet high by the roadside, close to the sixth milestone from Cirencester to Cheltenham, which has had this disease from its base to near the summit as long as I can remember.

In *Trans. Scot. Arb.* x. 235, there is a useful paper on the Ash Bark Beetle, *Hylesinus Fraxini*, a pest which seems to be dangerous only where the ash is already unhealthy. As the eggs of this insect are laid in spring only under the bark of felled, dead, or sickly trees, wherever this pest is troublesome, all such should be removed from the neighbourhood of the healthy trees by April, and ash loppings should not be left on the ground. A curious malformation occurs in a tree growing close to Cirencester, on the east side of the Tetbury road nearly opposite the Kennels. Plate 244 shows the remarkable growths on its branches, specimens of which were sent to Kew and found to contain numerous examples of *Hylesinus Fraxini*.

TIMBER

For coach, waggon, and agricultural implement making, and for all purposes in which strength, toughness, and durability are required, ash timber has no equal, and no substitute has been found among foreign trees which can be relied on as well. In consequence, it is now the easiest to sell, if not quite the highest priced, of all English timbers; and its growing scarcity seems to point to a great future for it.

It varies much, however, in strength, toughness, and elasticity, according to the soil on which it is grown, and the age at which it is cut. I am informed by Mr. Clutterbuck of the Gloucester Waggon Works, who has had long experience with English and foreign timber, that there is no better ash in England than that grown on the Cotswold hills; but if left standing too long, it becomes discoloured at the heart, and is probably never worth more per foot than when 60 or 70 years old.

It is now perhaps the only wood worth growing as copsewood, and, when established on good land and cut every ten to fifteen years, still makes as much as a pound per acre per annum. The poles are used for making hurdles, hoops, crates, and many other purposes, and as hop-poles are only second to chestnut. I have found that for the rails of light field-gates in a hunting country, on account of their elasticity nothing is better; and when well made they last thirty years or more. Ash wood takes creosote well, which very much increases its durability; and some sheep-hurdles which I had creosoted thirteen years ago are still sound, though when not so treated, they do not last more than three to five years. Ash, however, soon decays in contact with the soil and is unfit for building purposes, though it was

¹ *Journ. Roy. Hort. Soc.* v. 135 (1879).

² Also known as *Tinea curtisella*, Don. Cf. Schlich's *Man. Forestry*, iv. 344 (1907), where the moth is figured and described.

formerly used for staircases. Loudon says that the staircase at Wroxton Abbey, near Banbury, was made of this wood, and in Hatfield House some of the inside work is made of ash. Slabs from flat-sided trees often show a very ornamental curly grain which makes very handsome panelling, and might be used for door panels with good effect.

The burrs are also cut into beautiful veneers which, when polished, are used in cabinetmaking, and which sometimes in Hungary and south Russia are of great size and perfectly sound, though in England usually small and faulty. I purchased in Manchester, under the name of Circassian ash burr, some splendid veneers of this wood, which measure about 5 feet by 3 feet, and are made up of small, closely crowded knots, which take a fine polish and are of a greyish white or pinkish grey colour.¹ English ash, however, seldom or never assumes the wavy grain which is found in Hungary and Russia, and is one of the most beautiful woods I know. This is known as fiddle-back ash, because wood of this character, usually maple, is selected for the backs of violins. It varies very much in colour, the most valuable being the whitest; and also in the size and character of the figure; but when a combination of small waves with eye-like patches is combined, it is superior to the best American maple. Such wood was formerly much used for decorating railway carriages, and for furniture, but from some reason which I cannot explain is now out of fashion. I believe that the waving rarely extends throughout the tree, the best figure being always near the outside, and the causes which produce it are, so far as I know, as yet without any scientific explanation. (H. J. E.)

FRAXINUS ANGUSTIFOLIA, NARROW-LEAVED ASH

Fraxinus angustifolia, Vahl, *Enum.* i. 52 (1804); Loudon, *Arb. et Frut. Brit.* ii. 1229 (1838).

Fraxinus australis, Gay, ex Koch, *Dendrologie*, ii. 1. 247 (1872).

A tree attaining 70 to 90 feet in height. Shoots glabrous, green, slender. Leaflets (Plate 262, Fig. 6), seven to thirteen, 1½ to 3 inches long, smooth and slightly coriaceous, shining above, usually pretty uniform in size, subsessile, lanceolate, base cuneate, apex acuminate, glabrous on both surfaces; coarsely and sharply serrate except near the base; serrations few, spreading, often with incurved points (occasionally deeply serrate with long bristle points). Rachis of leaf glabrous, strongly winged, the wings meeting above and only showing a groove opposite the insertions of the leaflets. Flowers (section *Fraxinaster*) without calyx or corolla, few in erect racemes, arising from the axils of the leaf-scars of the preceding year's shoot. Fruit lanceolate, obliquely truncate and entire at the apex; but apparently variable.

This species is distinguished from all forms of the common ash by its absolutely glabrous leaflets, which have fewer, sharper, and more spreading serrations than in that species. The terminal buds are also different, being small, dark brown, quadrate,

¹ I have seen in London a fine old cabinet, supposed to be veneered with Amboyna wood, so like the Circassian ash in pattern, though the colour was yellower, that I much doubt whether the two could be distinguished when made up.

conical, usually glabrous, with four outer scales—six external scales, however, occurring in individual trees with leaves in whorls of threes.

VARIETIES

1. Var. *monophylla*¹ (*F. Veltheimi*, Dieck). A form in which the leaves (Plate 262, Fig. 3) are simple, unequally two-foliolate, or three-foliolate; terminal leaflet or single leaf lanceolate, acuminate, coarsely serrate or dentate; lateral leaflets, when present, much smaller but similar in shape; petiole with a wide open groove on the upper side. Shoots green, glabrous, with pink lenticels.

This variety can only be confused with *Fraxinus excelsior*, var. *monophylla*, from which it is readily distinguishable by the glabrous leaflets, different in texture and usually narrower, being lanceolate and not ovate. This tree appears to do well in cultivation, but will probably not attain a large size. We know of no trees of this variety in England except in the collection at Kew.

2. Var. *lentiscifolia* (*F. lentiscifolia*, Desfontaines²?). In the typical form of *F. angustifolia*, both as it occurs wild and under cultivation, the leaflets are set close upon a short rachis and point forwards towards its apex. In this variety, the leaflets are set wide apart upon an elongated rachis, from which they spread out at right angles and are not directed forwards; they also differ slightly in colour and texture from the type.

Willdenow³ considered *F. parvifolia*, Lamarck,⁴ *F. tamariscifolia*, Vahl,⁵ and *F. lentiscifolia*, Desfontaines,⁶ to be identical. I have not been able to follow Koehne or Dippel in their treatment of these forms as distinct. It is not in the least certain what species was intended by Lamarck's *parvifolia*, a name which has been given by some writers to a small-leaved variety of *F. oxycarpa*. In the Kew Herbarium, a garden specimen, collected by Bentham in 1854 and labelled "*F. lentiscifolia*," agrees with our variety of *F. angustifolia*; and a wild specimen from Italy is indistinguishable from it.

Both pendulous and dwarf forms of var. *lentiscifolia* are known in cultivation.

DISTRIBUTION

The narrow-leaved ash, with glabrous leaves, is common in the south of France, and occurs also in Spain, Portugal, Morocco,⁷ and Algeria.

Captain Widdrington⁸ says of this tree: "The ash is extraordinarily rare in the south and central regions of Spain. It is not now cultivated, and the only specimens I saw growing wild were in the wilder parts of Estremadura and the Sierra Morena where they were generally by the side of water-courses. The only species that I have seen in these regions is the *lentiscifolia*. The first year that I was in the

¹ Stated in the *Kew Hand List of Trees*, 545 (1902), to be a cross between *F. parvifolia* and *F. excelsior monophylla*. It shows no evidence of hybrid origin, and is evidently a variety of *F. angustifolia*.

⁴ *Encycl.* ii. 546 (1786).

⁵ *Enum.* i. 52 (1804).

⁶ *Table de l'École de Bot.* 52 (1804).

⁷ This ash, referred to *F. oxyphylla* by Ball, was seen by him in Morocco, between Tangiers and Tetuan, and also at the base of the Atlas mountains. Cf. *Journ. Linn. Soc. (Bot.)* xvi. 564 (1878).

⁸ *Spain and the Spaniards*, i. 390 (1844).

interior of Spain, I picked up the seed of an ash near the Escorial; but the leaves having fallen, I did not ascertain the species, but sending them to England they vegetated, and are now growing in Northumberland. This is the same tree, and I have never seen it farther north than New Castile; at the same time I think it probably may exist as far as Leon, where, the instant you cross the chain, the *Fraxinus excelsior*, our common species, supplies its place; at least, I could make out no difference. The timber of *F. lentiscifolia* is heavy and less elastic than that of our species, but the elegance of the tree, and its perfect hardiness in a dry soil, should make it more common than it is in our ornamental collections."

This species¹ replaces the common ash in Algeria, where it is only found wild in quantity in the forests of the plains and along the banks of streams and rivers; but it ascends as isolated trees occasionally to 6000 feet in the mountains, and is reported to be common in the Djurdjura range. I saw it growing in fields near the forest of Akfadou, inland from Bougie, where the trees have a mutilated appearance, owing to the annual lopping of their branches by the natives, who feed their cattle with the leaves.² In Algeria³ the tree attains a large size, and grows in good soil with great rapidity, reaching a height of 90 feet by 3 feet in diameter at seventy years old. The wood is similar to that of the common ash, though slightly inferior in quality. Dr. Trabut informed me that he had sent seed to Australia, where the tree is said to thrive well, succeeding better than the common ash.

A tree at Chiswick House measured, in 1903, 75 feet by 7 feet 5 inches. Another at Whitton, near Hounslow, in 1905 was 56 feet by 6 feet 2 inches. At Williamstrip Park, Gloucestershire, in 1904 Elwes measured a tree 60 feet by 6 feet 9 inches.

The variety *lentiscifolia* has been identified by us at Syon, 55 feet by 5 feet 6 inches in 1905; at Hardwick, Bury St. Edmunds, a grafted tree, 72 feet by 6 feet 3 inches below the graft and 7 feet 10 inches above it; at Bicton, another grafted tree, over 50 feet by 6 feet; and at Stowe, also a grafted tree, 68 feet by 7 feet 8 inches. From the similarity in appearance of the trees at Hardwick, Stowe, and Bicton, there is little doubt that they were all propagated and planted at the same time. Elwes has also seen at the Hendre, Monmouthshire, a tree of similar appearance, which was 71 feet high by 5 feet 4 inches below, and 6½ feet above the graft. There is also a healthy grafted tree at Ware Park, Herts, growing on sandy soil, which Mr. H. Clinton Baker measured as 78 feet by 6 feet 3 inches in 1908. Another (Plate 245) on the lawn at Rougham Hall, the seat of F. K. North, Esq., is 76 feet high by 8½ feet above the graft, and 7½ feet below it. A third at Ribston Park, Yorkshire, was 68 feet by 6 feet 7 inches.

It is hardy as far north as Denmark, where Elwes measured in the park of Count Friis, in 1908, at Boller near Horsens, a grafted tree about 60 feet by 4 feet 4 inches, which was bearing immature fruit. (A. H.)

¹ The Algerian tree has been distinguished as var. *numidica* (*F. numidica*, Dippel), with broader and larger leaflets; but specimens gathered by me at Akfadou are typical *angustifolia*.

² M. Maurice L. de Vilmorin, in *Bull. Soc. Amis des Arbres*, 1895, states that this ash is much planted around villages in Kabylia, where its leaves, which are stripped off the tree in September, are an indispensable fodder for cattle, sheep, and goats at this season when no grass is available. The foliage of a single tree is usually worth 50 francs; and he was shown a very old wide-spreading tree, the owner of which sold its leaves annually for 300 francs.

³ Cf. Lefebvre, *Forêts de l'Algérie*, 348 (1900).

FRAXINUS OXYCARPA

Fraxinus oxycarpa, Willdenow, *Sp. Pl.* iv. 2, 1100 (1805); Loudon, *Arb. et Frut. Brit.* ii. 1230 (1838).

Fraxinus oxyphylla, M. Bieberstein, *Fl. Taur. Cauc.* ii. 450 (1808); Boissier, *Flora Orientalis*, iv. 40 (1879).

Fraxinus rostrata, Gussone, *Pl. Rar.* 374, t. 63 (1826).

A tree of moderate size. Shoots green, glabrous; lenticels pink. Leaflets (Plate 263, Fig. 11), nine to thirteen, usually small, $1\frac{1}{2}$ to 3 inches long, sessile or subsessile; lanceolate, oval or ovate; base tapering, apex acuminate; serrations few, sharp, spreading and often ending in incurved points; lower surface pubescent on the midrib and veins towards the base. Rachis of the leaf glabrous, winged, the wings meeting above and only forming an open channel opposite the nodes. Flowers (section *Fraxinaster*) without calyx or corolla, in short racemes in the axils of the leaf-scars of the previous year's shoot. Fruit broad, oblanceolate, acute or acuminate at the apex.

This species closely resembles *F. angustifolia*, differing in the leaflets being always pubescent beneath. The terminal buds are conical, quadrate, long and slender, with four outer narrow scales of equal length, dark brown and pubescent.

It is doubtful if the differences in the samaræ relied upon for the separation of this species from *F. angustifolia* are really constant. The fruits in this group of *Fraxinus* are extremely variable, and do not appear to give specific characters.

While *F. angustifolia* seems to be confined to the western part of the Mediterranean region, *Fraxinus oxycarpa* is widely distributed in Italy, Asia Minor, Persia, and the Caucasus.

Var. *parvifolia*, Wenzig.¹ Leaflets small, oval-oblong. Boissier considers this to be rather a bushy or sterile juvenile form of the species than a distinct variety, and records it from various localities in Asia Minor. An ash identified by Mathieu,² with *F. parvifolia*, Lamarck, grows in the neighbourhood of Montpellier in France, as a shrub about 5 to 10 feet high, and belongs to this variety.

At Kew, the ash, cultivated as *F. parvifolia*, Lamarck, is a variety of *F. oxycarpa*, distinguished by having leaflets (Plate 263, Fig. 9) shorter than in the type, broader in proportion to their length, and more closely set upon the rachis.

Fraxinus oxycarpa is much rarer in cultivation in England than *F. angustifolia*; but small trees are growing at Kew, Woburn, Eastnor Castle, Oxford Botanic Garden, and at Grayswood, Haslemere, where it has produced seed, from which plants have been raised by Elwes, and are growing at Colesborne. It does not seem in this country to be so vigorous a tree as *F. angustifolia*. (A. H.)

¹ In Engler, *Bot. Jahrb.* iv. 175 (1883).

² *Flore Forestière*, 245 (1897).

FRAXINUS SYRIACA

Fraxinus syriaca,¹ Boissier, *Diag. Ser. I.* ii. p. 77 (1849).

Fraxinus oxyphylla, M. Bieberstein, var. *oligophylla*, Boissier, *Fl. Orient.* iv. 40 (1879).

A tree attaining 60 feet in height. Shoots glabrous, green, stout, conspicuously marked by very prominent leaf-bases; lenticels white. Leaves (Plate 263, Fig. 10), small, always in whorls of threes or fours. Leaflets usually three, occasionally five to seven on some of the branchlets, sessile, lanceolate to ovate, base cuneate, apex acuminate, sharply and coarsely serrate, the serrations with incurved points, glabrous on both surfaces. Rachis of the leaf narrowly winged, the wings not meeting above, but forming an open groove.

Flowers (section *Fraxinaster*) in short racemes in the axils of the leaf-scars of the preceding year's shoot; without calyx or corolla. Fruit ovate-oblong; apex rounded, truncate or acuminate, ending in a mucro.

This species occurs in Syria, Kurdistan, Persia, Baluchistan, and Afghanistan.

The occurrence always of the leaves in whorls, a phenomenon met with in individual instances in other species, appears to be constant in this species. On strong shoots leaves with five to seven leaflets exceptionally appear; those with three leaflets, however, being by far the most common. Small specimens of this tree are growing at Kew, but it does not seem likely to be worth growing in England. (A. H.)

FRAXINUS ELONZA

Fraxinus Elonza, Dippel, *Laubholzkunde*, i. 87, fig. 46 (1889); Koehne, *Deutsche Dendrologie*, 513 (1893).

A small tree. Branchlets green, glabrous; lenticels few, oval, white. Buds laterally compressed and not quadrangular, narrowed and rounded at the apex; external scales four, densely brown pubescent, inner pair longer than the outer pair. Leaflets (Plate 266, Fig. 27), eleven to thirteen, 1 to $2\frac{1}{2}$ inches long, sessile, oval or lanceolate, with unequal base and acuminate apex, sharply and irregularly serrate, some of the serrations being often triangular and spreading; under surface pubescent near the base with brown tomentum, often occurring only on the inner side of the midrib. Leaf-rachis, with scattered pubescence, densest at the nodes; strongly winged, the wings meeting above in part of their length. Fruit described as broadly linear, with almost parallel sides, truncate and emarginate at the apex.

The native country of this species is unknown; and it is possibly a hybrid, as

¹ *Fraxinus sogdiana*, Bunge, *Mém. Sav. Etrang. Acad. Pétersbourg*, vii. 390 (1851), occurring in Turkestan, formerly supposed to be identical with this species, is considered distinct by Koehne in *Gartenflora*, 1899, p. 288, and by Lingelsheim, in Engler, *Bot. Jahrb.* xl. 222 (1907).

Koehne suggests. It occurs in England in cultivation under the erroneous name of *F. chinensis*,¹ the plants at Kew having been obtained from Sir C. W. Strickland, who tells us that it was sent out by the Royal Horticultural Society some years ago. Plants cultivated as *F. Elonza* are usually *F. oxycarpa*. (A. H.)

FRAXINUS WILLDENOWIANA

Fraxinus Willdenowiana, Koehne, *Deutsche Dendrologie*, 515 (1893).

Fraxinus parvifolia, Willdenow, *Berlinische Baumzucht*, 124, t. 6, f. 2 (1796) (*non* Lamarck); and *Sp. Pl.* iv. 1101 (1805).

A small tree. Shoots glabrous, lenticels white. Leaflets (Plate 265, Fig. 24), seven to eleven, 2 to 3½ inches long, subsessile (except the terminal one, which is much the largest and stalked), ovate, base broad and unequally cuneate, apex acuminate; serrations coarse and sharp with minute incurved points; both surfaces glabrous. The leaflets increase in size from the base to the apex of the leaf, the rachis of which is winged, the wings usually not meeting on the upper side, but forming an open groove. Fruit unknown.

This species was considered by Willdenow to be different from *F. parvifolia*, with which he had first identified it, yet he left it with this name. Koehne has accordingly given it a new name. It is sometimes met with in cultivation under the name of *F. rotundifolia*. It is readily distinguished by the large terminal leaflet and the open-grooved rachis from the other glabrous species. Its native home is uncertain. It is perfectly hardy at Kew and has very distinct foliage. (A. H.)

FRAXINUS DIMORPHA

Fraxinus dimorpha, Cosson et Durieu, *Bull. Soc. Bot. France*, ii. 367 (1855); Mathieu, *Flore Forestière*, 245 (1897).

Fraxinus xanthoxyloides, Wallich, *var. dimorpha*, Wenzig, in Engler, *Bot. Jahrb.* iv. 188 (1883).

A small tree attaining 40 feet in height. Young shoots purple, slender, glabrous, obscurely quadrangular. Leaves (Plate 262, Fig. 1) on barren branchlets with seven to nine small leaflets, which are ½ to ¾ inch long, sessile or subsessile, ovate or oval, crenulate-serrate, and glabrous except for pubescence on the midrib towards the base on the under surface; leaf-rachis usually glabrous, strongly winged, the wings spreading and forming a very open channel. The leaves on flowering shoots are larger, with seven to eleven leaflets, oblong-lanceolate, acute and serrate. Flowers (section *Sciadanthus*) perfect, without a corolla, but with a calyx which persists under the fruit, grouped in fascicled cymes on the previous year's shoot

¹ *F. chinensis*, Roxburgh, a native of China, is entirely distinct from *F. Elonza*, which is closely allied to *F. oxycarpa*, a Mediterranean species. Koch, in *Dendrologie*, ii. pt. 1, 247 (1872), mentions *F. Elonza* as having been in cultivation some years, and considered it to be probably a variety of *F. angustifolia*.

in the axils of the leaf-scars. Fruit oblong; body compressed with a longitudinal furrow on each surface, and many-rayed; wing long and obliquely truncate at the apex. Buds very small, with two outer scales pinnately lobed.

This remarkable ash was observed by Sir Joseph Hooker in South Morocco.¹ It also occurs in the mountainous regions of Algeria in the valleys at 4000 to 6000 feet altitude. In dry situations it remains a bush with very rigid and almost spiny branches, and rarely flowers even when very old. On the banks of streams it grows to be a small tree and produces flowers and fruit. The wood is very hard and heavy, with a satin-like lustre.

This species is rarely seen² except in botanical gardens, where, as at Kew, it grows to be a small tree, remarkable for its diminutive foliage. It has smooth grey bark. (A. H.)

FRAXINUS XANTHOXYLOIDES

Fraxinus xanthoxyloides, Wallich, *List*, 2833; C. B. Clarke, in Hooker, *Fl. Brit. India*, iii. 606 (1882); Brandis, *Indian Trees*, 444 (1906).

This species is probably only a pubescent geographical form of *Fraxinus dimorpha*, which it resembles exactly in habit. The young shoots are covered with a minute dense pubescence. The leaflets only differ from those of *F. dimorpha* in having a scattered pubescence all over the lower surface; the rachis of the leaf is also pubescent.

This species occurs in Baluchistan, Afghanistan, and the north-west Himalayan region, at altitudes of 3000 to 9000 feet, growing mainly in dry valleys, where it is often gregarious. It is reported to attain a height of 25 feet.

It is rare in cultivation, and forms a small tree, scarcely distinguishable in appearance from *F. dimorpha*. (A. H.)

FRAXINUS POTAMOPHILA

Fraxinus potamophila, Herder, in *Bull. Soc. Imp. Mosc.*, xli. 65 (1868); Dippel, *Laubholzkunde*, i. 98, fig. 54 (1889).

A small tree; branchlets glabrous. Leaflets (Plate 262, Fig. 8) small, seven to nine, about 1½ to 3 inches long, stalked (petiolules glabrous, ½ inch or more in length), ovate, tapering unequally at the base, acute at the apex, coarsely serrate, the serrations often ending in long points; glabrous on both surfaces. Rachis of the leaf with angled edges on its upper side, enclosing a shallow groove. Flowers

¹ Hooker and Ball, *Tour in Morocco*, 176 (1878); Ball, in *Journ. Linn. Soc. (Bot.)*, xvi. 564 (1878).

² A tree at Coombe Wood, which had attained almost 25 feet in height, was destroyed in 1907. Mr. A. B. Jackson has seen small specimens at Barron's nursery, Elvaston, where they were erroneously named *E. lentiscifolia*.

unknown. Fruit described as linear-oblong, nearly two inches long, acute, blunt or obliquely truncate.

This ash grows along the banks of rivers in Turkestan and Songaria, occurring in the Ili region at 1000 to 2500 feet elevation. It was introduced into cultivation by the Botanic Garden at St. Petersburg; and small trees are doing fairly well at Kew.

Fraxinus Regelii, Dippel,¹ of which I have seen no authenticated specimen, is said to be also a native of Turkestan, and was considered by Koehne² to be probably identical with *F. potamophila*, Herder. There are young plants in the Kew collection, raised from seed sent in 1900 by M. Scharrer, Director of the Botanic Garden at Tiflis, and named *F. Regelii* on his authority, which are remarkably distinct from any ash known to me, and differ from Dippel's description of *F. Regelii* in the larger size of the leaflets, which are crenate and not dentate in serration. The Tiflis plants have the young branchlets glabrous, purplish; leaflets (Plate 265, Fig. 25), five or seven, about 3 inches long, stalked, the base of the leaflet often decurrent on one side of the petiolule to its insertion; terminal leaflet obovate or rhomboid; lateral leaflets ovate or oval; all shortly acuminate or cuspidate at the apex, unequal at the base, crenately serrate; bluish green and glabrous on the upper surface; pale green and slightly pubescent on the sides of the base of the midrib on the lower surface; rachis elongated, terete, glabrous, with a shallow groove on its upper side. The identification of these plants with *F. Regelii* must be left uncertain.

(A. H.)

FRAXINUS RAIBOCARPA

Fraxinus raibocarpa, Regel, in *Act. Hort. Petrop.* viii. 685 (1884).

A small tree. Branchlets brown, minutely pubescent, glandular. Leaflets (Plate 266, Fig. 29), five, upper subsessile, lower stalked, about $1\frac{1}{2}$ inch long, oval, unequal and rounded at the base, acute or obtuse at the apex, usually entire in margin without cilia; under surface glabrous, with a few minute brown glands. Leaf-rachis slightly glandular, with a wide open groove on its upper side. Fruit in leafy panicles, arising on the current year's shoot; samara surrounded at the base by the persistent calyx, curved, falcate; body terete and rayed; wing terminal, very broad, spathulate-obovate, obtuse.

This species, of which the flowers are unknown, belongs apparently to the section *Ornus*. It was discovered in 1882 by Regel at elevations of 6000 to 7000 feet in the mountain valleys of eastern Bokhara and Turkestan; and was introduced into cultivation shortly afterwards by the St. Petersburg Botanic Garden. Small plants at Kew have grown very slowly, and this species does not seem likely to be worth cultivating in this country.

(A. H.)

¹ *Laubholzkunde*, i. 97, fig. 53 (1889), described from plants sent out by the St. Petersburg Botanic Garden as *F. sogdiana*, an entirely different species, referred to on p. 883, note 1.

² *Deutsche Dendrologie*, 515 (1893).

FRAXINUS HOLOTRICHA

Fraxinus holotricha, Koehne, in *Mitt. Deut. Dendrol. Ges.* 1906, p. 67.

A small tree. Branchlets grey, densely covered with short stiff erect pubescence. Leaflets, nine to thirteen, subsessile, lanceolate or ovate-lanceolate, about 2 inches long, $\frac{1}{2}$ to $\frac{5}{8}$ inch wide; apex prolonged into a sharp-pointed and often curved acumen; base unequal and tapering; margin ciliate, unequally and sharply serrate; both surfaces covered with a scattered grey pubescence. Rachis of the leaf, with pubescence like that of the branchlets, densest at the nodes; narrowly grooved on the upper side.

Flowers (section *Fraxinaster*), without calyx or corolla, in short racemes, perfect in the single specimen seen; ovary pubescent. Fruit unknown.

This species resembles *F. angustifolia* in the shape and size of the leaflets; but differs in the copious pubescence on the branchlets and leaves. The buds are quadrate, with four dark brown scales, very pubescent at the tips.

F. holotricha was discovered by Koehne in Späth's nursery near Berlin, and in the botanic gardens at Berlin and Dresden, where it had received the erroneous name of *F. potamophila*. Its native country is unknown. The specimen, from which I have drawn up the above description, was sent me from Metz by Messrs. Simon-Louis. Three young plants were sent by Späth to Kew in 1908. (A. H.)

FRAXINUS ORNUS, FLOWERING ASH, MANNA ASH

Fraxinus Ornus, Linnæus, *Sp. Pl.* 1057 (1753); Bentley and Trimen, *Medicinal Plants*, iii. 170, fig. 170 (1880); Hanbury, *Science Papers*, 362-368 (1876).

Fraxinus paniculata, Miller, *Dict.* No. 4 (1759).

Fraxinus florifera, Scopoli, *Fl. Carn.* ii. 282 (1772).

Ornus europæa, Persoon, *Syn. Pl.* ii. 605 (1807); Loudon, *Arb. et Frut. Brit.* ii. 1241 (1838).

A tree attaining about 60 feet in height and 6 feet in girth, with smooth ashy-grey bark. Young branchlets slender with white lenticels, usually glabrous, occasionally glandular pubescent, marked with a ring of brown hairs at the base of the shoot. Leaflets (Plate 265, Fig. 26), five to nine, 2 to 3 inches long, the terminal one obovate and stalked, the lateral ones with distinct stalklets, which are about $\frac{1}{4}$ inch long and brownish pubescent; ovate to oblong, base rounded or broadly cuneate, apex shortly acuminate, finely and irregularly serrate, under surface glabrous except for brown woolly pubescence on the midrib. Rachis of the leaf grooved, the groove deepest in the upper part of its length, usually glandular pubescent, with tufts of brown hairs opposite the insertions of the leaflets.

Flowering branches developed from terminal buds, which contain leaves as well as flowers, the inflorescences being usually accompanied by two pairs of leaves and consisting of five panicles, the largest one terminating the branch, four smaller ones arising in the axils of the leaves, the whole forming a drooping compound panicle. Pedicels long and slender. Calyx divided into four triangular acute persistent sepals.

Corolla deeply divided into four strap-shaped wavy wide-spreading petals. Stamens two, hypogynous, the filaments twice as long as the petals. Flowers apparently perfect, but functionally behaving as if distinctly staminate and pistillate. Fruit compressed, with a terminal flat obovate-linear wing, blunt or emarginate at the apex.

IDENTIFICATION

In summer the tree is readily distinguished by its smooth bark and stalked leaflets showing the characters just enumerated. In winter the twigs show a slight pubescence towards the apex and a ring of hairs at the base of the shoot. Leaf-scars parallel to the twig on projecting leaf-cushions, semi-orbicular to crescentic, the ends of the horns truncate, marked on the surface with a curved row of separate bundle scars. Terminal bud large, greyish to greyish brown, ovoid, four-sided, rounded (rarely acute) at the apex, the two outer scales gaping above and densely pubescent. Lateral buds smaller, densely pubescent, arising from the twigs at a wide angle.

VARIETIES

Fraxinus Ornus, occurring over a wide area, both as a wild tree in forests, and cultivated in sunny arid regions, as in Sicily, shows considerable variation in the size, shape, and texture of the leaflets; and several varieties have been established.¹ The only one of those which is truly distinct is var. *argentea*, Grenier et Godron,² a remarkable form, growing wild in the forests of Corsica and Sardinia, distinguished by the leaflets being silvery white beneath, firm in texture, crenulate-serrate, usually smaller than the type, often subsessile, though stalked leaflets also occur on the same branch, ovate or oval in outline, occasionally approximating to an orbicular shape. This singular variety has been made a distinct species;³ but modern French and Italian botanists regard it as only a peculiar geographical variety, which seems to be sporadic in forests where the type is also met with.

Aiton⁴ and Willdenow⁵ described, as the true manna ash, *F. rotundifolia*, with broad ovate or almost orbicular, deeply serrate leaflets. Willdenow's figure of the foliage corresponds with the ash which I have described (p. 866) as *F. excelsior*, var. *rotundifolia*, and it is possible that both he and Aiton were in error in considering their plant to have flowers like those of *F. Ornus*.

Lamarck's⁶ *Fraxinus rotundifolia*, differs, according to the description, from Aiton and Willdenow's species of the same name, and is considered by Wenzig⁷ and Lingelsheim⁸ to be *F. Ornus*, var. *rotundifolia*; but is kept up by Koehne⁹ as a distinct species. Hanbury¹⁰ states that the manna ash cultivated in Sicily shows

¹ Fiori et Paoletti, *Flora Analitica d'Italia*, ii. 341, mention, besides the typical form, var. *rotundifolia* with broad elliptical leaflets, and var. *lanceolata* with lanceolate leaflets.

² *Flore de France*, ii. 473 (1850).

³ *Fraxinus argentea*, Loiseleur, *Flora Gallica*, ii. 697 (1806).

⁴ *Hort. Kew*, iii. 445 (1789).

⁵ *Berlin. Baumzucht*, 116, fig. vi. 1 (1796). The figure was copied by Loudon, *Arb. et Frut. Brit.* ii. 1244 (1838), who merely repeats Willdenow's description, and was probably unacquainted with the tree.

⁶ *Encycl.* ii. 546 (1786).

⁷ In Engler, *Bot. Jahrb.* iv. 169 (1883).

⁸ *Ibid.* xl. 212 (1907).

⁹ *Deutsche Dendrologie*, 508 (1893).

¹⁰ *Science Papers*, 368 (1876).

great variation, but that no special form can be singled out as deserving the name *rotundifolia*; and I have seen no specimens of *F. Ornus*, which could be separated as a var. *rotundifolia*, much less any which could be separated as a distinct species.¹

A variegated form of *F. Ornus*, of which I have seen no specimens, is said to occur in cultivation. A simple-leaved form, var. *diversifolia*, Roch., is of rare occurrence in the wild state, and has been noticed in the canton of Tessin in Switzerland.²

DISTRIBUTION

The manna ash is widely distributed in southern Europe and Asia Minor. In France it only occurs wild in the department of the Maritime Alps; and in Switzerland it is met with in a few places in mountain woods about Lake Lugano in the canton of Tessin.² It grows in the southern Tyrol, where it ascends to 2000 feet elevation, in Carniola, Istria, Dalmatia, Croatia, Slavonia, and Banat, reaching its northern limit in Hungary on the south side of the Carpathian chain. It is common in eastern Spain, Corsica, Sardinia, Italy, Servia, Bosnia, Greece, and Asia Minor.

The wood of the flowering ash is excellent, and the foliage is used as fodder in the southern countries of Europe; but its chief economic importance is due to its being the source of manna. The manna of commerce, according to Hanbury, is exclusively collected in Sicily, where the plantations are known as Frassinetti. However, of late years, attempts have been made to cultivate it on a large scale for manna in the southern parts of the Austrian empire. In Sicily trees begin to produce manna when they are about eight years old; and they are tapped in subsequent years annually until they are about twenty years old, when they are cut down and their place taken by coppice shoots from the stools. During July and August transverse incisions are made in the bark, so as just to reach the wood; and the manna exudes as a clear liquid, which solidifies on the stem of the tree or on pieces of straw or wood that are inserted in the incisions. Manna consists mainly of a peculiar sugar called mannite, which is a mild laxative and is employed as an officinal drug in many countries. (A. H.)

REMARKABLE TREES

The manna ash is said to have been introduced into England by Dr. Uvedale of Enfield about 1710. It is commonly cultivated as an ornamental tree, on account of its beautiful appearance when in flower; and it thrives and attains a large size, especially in the southern parts of England. The largest I have measured is an old

¹ Tenore, in *Syll. Pl. Fl. Neap.* 10 (1831) considers Lamarck's plant to be a variety of *F. Ornus*. Both Tenore and Bertolini, *Fl. Italica*, i. 54 (1833), were of opinion that *F. rotundifolia*, Willdenow, was a distinct species. Lingelsheim, in Engler, *Bot. Jahrb.* xl. 212, 213 (1907), retains *F. rotundifolia*, Tenore, *loc. cit.*, as a distinct species, confined to a small area in south Tyrol, Bosnia, and Dalmatia; and creates a new species, *F. cilicica*, occurring in Cilicia in Asia Minor. These supposed species appear to be glabrous forms of *F. Ornus*.

² Cf. Bettelini, *Flora Legnosa del Sottoceneri*, 145 (1904).

tree in the park at Godinton, Kent, which is about 60 feet high, 10 feet 4 inches in girth below the graft, and 8 feet 8 inches above it.

There is a fine tree growing at Escot, Ottery St. Mary, Devonshire, the residence of Sir John Kennaway, which was in 1905, according to Miss F. H. Woolward, 61 feet in height, with a girth of stem at 5 feet up of 6 feet 9 inches, the circumference at the base being 11 feet 9 inches. This tree flowers abundantly every year. Another at Carclew is 50 feet by $9\frac{1}{2}$ feet.

A tree, about 60 feet high, grows near the stables at Tottenham House, Savernake, the seat of the Marquess of Ailesbury; a photograph of this tree, which was taken in June 1908, from the roof of the stables, shows it in full flower.

There is a good tree at Kew, close to the North Gallery, which measured, in 1907, 42 feet by 5 feet; and another, on the mound, near the Cumberland gate, is 60 feet high and 7 feet 6 inches in girth at three feet from the ground, dividing above into three main stems.

At Syon there is a tree 62 feet by 6 feet 6 inches, and good trees occur at Beauport, Sussex, and Whiteaway, Devon. A very fine one is reported by the Hon. Vicary Gibbs to be growing at Rook's Nest, near Oxted, Surrey. At Brocklesby Park, Lincolnshire, a tree was 50 feet by 7 feet 1 inch in 1904.

In Scotland there is a tree at Gordon Castle about 50 feet high.

In Ireland, a tree at Fota measures 65 feet by 5 feet 6 inches; and trees about 40 feet high are growing at Narrow Water, near Warrenpoint, in Down, and at Glenstal, Limerick.

Henry saw specimens in the botanic gardens at Copenhagen and Christiania, about 40 feet high and 3 feet in girth, in 1908. (H. J. E.)

FRAXINUS FLORIBUNDA

Fraxinus floribunda, Wallich, *List*, 2836, and in Roxburgh, *Fl. Ind.* i. 150 (1820); Hooker, *Fl. Br. India*, iii. 605 (1882); Gamble, *Man. Indian Timbers*, 471 (1902); Brandis, *Indian Trees*, 443 (1906).

Ornus floribunda, A. Dietrich, *Sp. Pl.* i. 1, 249 (1831).

A large tree, attaining in the Himalayas over 100 feet in height. Shoots compressed, purple, glabrous, with scurfy glands; lenticels white and prominent. Leaflets (Plate 264, Fig. 17), seven to nine (rarely five), the upper pair subsessile, the others on glabrous petiolules, 4 to 6 inches long, oblong, except the terminal one which is obovate, base unequal and rounded, apex long-acuminate, midrib and principal veins prominent and pubescent beneath, regularly and sharply serrate. Rachis of the leaf winged, the wings enclosing a broad open groove on the upper side, pubescent in the groove and at the insertions of the leaflets.

Flowers (section *Ornus*) in large panicles; corolla lobes, $\frac{1}{8}$ to $\frac{1}{6}$ inch, linear-oblong. Samaras very narrow, obtuse or emarginate.

This is the largest and finest of the flowering ashes, and attains a great size in its native home, Sir D. Brandis mentioning trees in the Chenab Valley planted near villages and temples, which reach 120 feet in height and 15 feet in girth. It is the only valuable species of ash in the Himalayas, where it grows on rich moist soils, generally on limestone. It is distributed throughout the Himalayas from the Indus to Sikkim, between 5000 and 9000 feet, but is only common locally. It is also met with in Baluchistan, Afghanistan, and in the Shan Hills of Upper Burma.

We have seen no large trees of this species in England; but it appears to do well at Kew, and probably would succeed as an ornamental tree in at any rate the warmer parts of the British Isles. (A. H.)

FRAXINUS BUNGEANA

Fraxinus Bungeana, De Candolle,¹ *Prod.* viii. 275 (1844); Franchet, *Pl. David.* i. 203 (1884); Hemsley, *Journ. Linn. Soc. (Bot.)*, xxvi. 84 (1889); Sargent, *Garden and Forest*, vii. 4, fig. 1 (1894).

Fraxinus parvifolia, Lingelsheim, in Engler, *Bot. Jahrb.* xl. 214 (1907) (not Lamarck).

A shrub about 5 feet high. Branchlets grey, minutely pubescent, with a dense ring of hairs at the base of the shoot. Buds ovoid, with dark puberulous scales. Leaflets (Plate 266, Fig. 31), five to seven, 1 to $1\frac{1}{2}$ inch long, thin, membranous; usually on pubescent stalklets, $\frac{1}{4}$ -inch long, upper pair sometimes subsessile; oval or rhomboid, broadly cuneate or rounded at the base, abruptly contracted into a long acuminate apex, crenately serrate, pale beneath; both surfaces quite glabrous. Leaf-rachis, grooved on the upper side, minutely pubescent, pubescence densest opposite the nodes.

Flowers, in terminal panicles, polygamous; petals 4, linear-obovate; calyx minute, 4-lobed. Fruit with a short slightly flattened many-nerved body, margined to about the middle by the decurrent base of the wing, which is oblong with a rounded, often emarginate apex.

This species is common on the hills near Peking and in the adjacent parts of Mongolia, and is the representative there of the European *F. Ornus*. Dr. Bretschneider sent seeds in 1881 to the Arnold Arboretum, Massachusetts, where plants were raised which are perfectly hardy in New England. They are pretty shrubs with abundant clusters of white flowers. This species does not seem to be in cultivation² in England. (A. H.)

¹ This species was founded by De Candolle on specimens (one of which is at Kew) of a shrub, collected by Lunge in 1831, near Peking, and named by the latter *F. floribunda* in *En. Pl. Chin. Bor.*, 61 (1832). Maximowicz, followed by Koehne and Lingelsheim, have erroneously applied De Candolle's name to *F. rhynchophylla*.

² Plants, sent to Kew by Sargent in 1903, cannot be found, and are supposed to have died. Since this article was corrected for the press, four plants from the Arnold Arboretum have arrived at Kew.

FRAXINUS MARIESII

Fraxinus Mariesii, J. D. Hooker, *Bot. Mag.*, 6678 (1883); Hemsley, *Journ. Linn. Soc. (Bot.)*, xxvi. 86 (1889).

A small tree. Branchlets slender, terete, purple, minutely pubescent, especially towards the tip; lenticels white. Leaflets (Plate 264, Fig. 18) five, $1\frac{1}{2}$ to 3 inches long, coriaceous, oval, acute or acuminate at the apex, base rounded or slightly tapering; regularly and crenately serrate, occasionally entire in margin; glabrous beneath. Petiolules $\frac{3}{4}$ to $\frac{5}{8}$ inch, scurfy pubescent. Rachis of the leaf purple, finely pubescent, grooved on its upper side.

Flowers very showy in erect panicles from the uppermost axils, about as long as the leaves. Calyx minute, four-cleft. Petals five or six, $\frac{1}{4}$ inch long, linear-oblong. Stamens two to four, as long as the petals.

This was discovered by Maries in the Lushan Mountains near Kiukiang in central China; and it has not been found elsewhere by subsequent collectors. Maries sent home seeds in 1879 from which the plant was raised by Messrs. Veitch. It flowered¹ for the first time, at Coombe Wood, as early as 1882.

It appears to be perfectly hardy in England, and is an ornamental small tree or shrub of considerable value, on account of the creamy-white large panicles of flowers, which appear about the end of June, and the bronze tint of the foliage.

(A. H.)

FRAXINUS RHYNCHOPHYLLA

Fraxinus rhyrachophylla, Hance, *Journ. Bot.*, vii. 164 (1869); Franchet, *Pl. Davidiana*, i. 203, t. 17 (1884); Sargent, *Garden and Forest*, vi. 484, fig. 70 (1893); Komarov, *Fl. Manshurica*, iii. 248 (1907).

Fraxinus Bungeana, Maximowicz, *Mél. Biol.* ix. 396 (1874) (not De Candolle).

Fraxinus chinensis, Roxburgh, var. *rhyrachophylla*, Hemsley, *Journ. Linn. Soc. (Bot.)*, xxvi. 86 (1889).

A large tree. Shoots glabrous, lenticels few and scattered. Terminal buds remarkable, obtuse, conical, somewhat four-sided, with four or six outer scales, which are ovate, strongly keeled, with acute points directed outwards, pubescent and grey on the dorsal surface, and densely ferruginous woolly pubescent on their inner surface and edges; lateral buds, ovoid to rounded, small, with two to four outer scales, directed outwards at an open angle.

Leaflets (Plate 265, Fig. 23) five to seven, coriaceous, stalked or sessile, ovate to ovate-lanceolate; base cuneate; apex with a long acumen, which is blunt or rounded and tipped with a short mucro; margin remotely and crenately serrate

¹ *Hortus Veitchii*, 367 (1906).

in its upper half, sometimes almost entire; upper surface glabrous; lower surface glandular and glabrous except for some pubescence along the midrib towards the base. Terminal leaflet largest, basal leaflets smallest. Rachis of the leaf with a wide and open shallow groove on its upper side, pubescent in its whole length and bearded at the insertions of the leaflets, the pubescence being continued on the upper side of the petiolules.

Flowers (section *Ornaster*) in compact terminal panicles, polygamous, without a corolla; calyx persistent at the base of the samaræ, which are long, narrow, and erect on filiform pedicels.

This is the large ash tree¹ which is common in the mountains about Peking; and it also occurs in the adjacent parts of Mongolia, and in Manchuria and in northern Korea. It was discovered¹ by Père D'Incarville in the eighteenth century. Dr. Bretschneider sent seeds to the Arnold Arboretum in 1881, and plants were raised there, which are growing vigorously and promise to become large trees. They had already in 1893 produced flowers and fertile seed.

The species is remarkably distinct, and is very different from *F. chinensis*, Roxburgh, of which it has been supposed to be a variety. It appears to be scarcely known in Europe, the only specimens which I have seen being from Tortworth, where small plants are reported to be growing badly; and from Aldenham, where the foliage of a young tree, growing freely, is remarkable for its large size and glossy appearance. (A. H.)

FRAXINUS MANDSHURICA

Fraxinus mandshurica, Ruprecht, *Bull. Phys. Math. Acad. Sc. Pétersb.*, xv. 371 (1857); Maximowicz, *Prim. Fl. Amurensis*, 194, 390 (1859), and *Mél. Biol.* ix. 395 (1874); Hemsley, *Journ. Linn. Soc. (Bot.)*, xxvi. 86 (1889); Komarov, *Fl. Manshurica*, iii. 248 (1907).

A large tree, attaining 100 feet in height and 12 feet in girth, with bark like that of the European ash. Branchlets glabrous. Leaflets (Plate 266, Fig. 28), seven to thirteen, 3 to 5 inches long, oblong-lanceolate, sessile, or with very short pubescent stalklets, tapering and unequal at the base, long-acuminate at the apex, sharply and irregularly serrate; glabrescent above; under surface with scattered coarse hairs on the sides of the midrib and lateral nerves. Leaf-rachis, with dense tufts of rusty-brown tomentum at the nodes, winged, the wings meeting above in part of its length, elsewhere deeply grooved.²

Flowers (section *Fraxinaster*) dioecious, in panicles in the axils of the leaf-scars of the preceding year, without calyx or corolla. Fruit, in loose clusters, oblong-lanceolate, apiculate or emarginate.

¹ See Bretschneider, *European Bot. Discoveries in China*, 53, 336, 1058 (1898). There are two ashes in the Peking mountains, one a large tree, *F. rhyrachophylla*; the other a small shrub, *F. Bungeana*.

² The rachis of the uppermost two leaves is usually fringed at its insertion, close to the terminal bud of the branchlet, with rusty-brown pubescence.

The Manchurian ash is the representative of the common ash in eastern Asia, and is very similar in appearance to *F. nigra*,¹ being mainly distinguishable by the longer points to the leaflets, which are more tapering at the base, often shortly stalked, and usually more sharply serrate. (A. H.)

F. mandshurica is widely spread throughout Manchuria, Amurland, Korea, Saghalien, and Japan, and is a large tree, Ruprecht having measured specimens at the mouth of the Ussuri 12 feet in girth.

In Japan this fine ash is known as *yachidamo*, and is one of the commonest trees in Hokkaido, but is only known to occur in the north of the main island. I did not see it in Aomori or Akita. It seems to grow best in Hokkaido in the deep rich flats of black alluvial soil which are now being rapidly brought under cultivation by the Japanese settlers, but even here seldom attains the dimensions of the European ash; the average size of the trees in the virgin forests being from 80 to 100 feet high by 6 to 8 feet in girth, though no doubt, if they had room to spread they would grow much thicker than this. The general habit of the tree and of its leaves and seed is very similar to that of *F. excelsior*, and the wood also seems similar, but it is not apparently used for the same purposes as in Europe. A great quantity of it is made into railway sleepers, which are now being exported largely to Korea and China, and which, if I can judge from what I saw on the Hokkaido railroads, will not last very long unless creosoted. There is, however, a particularly handsome variety of this wood, which seems to be found only near the butt and on the outside of old trees growing in damp places, which goes by the name of Tamu, and which, if known in Europe would certainly command a high price for veneers. A large wardrobe, which has been made for me from Japanese woods, is fronted with veneer cut from a billet of this wood, which I brought home in 1904, and is extremely handsome; showing a figure like that of the best Hungarian ash but of a pale pinkish-brown colour. This wood is much used in Japan for veneering railway carriages, for doors, and for the posts used for supporting and for fitting the sliding screens of Japanese houses. It is liable to warp, however, and requires very careful seasoning to prevent cracking.

F. mandshurica was introduced² at Kew in 1891 from the St. Petersburg Botanic Garden; but only one plant now survives, which has a stunted and unhealthy appearance. Like many plants from Manchuria and Amurland, the foliage appears early in the spring, and is badly injured by late frosts every year. I have raised seedlings from seed sent me from Japan by Professor Shirasawa, but they are too young to judge of the probable success of the tree in England.

Sargent, however, says³ that this tree has proved perfectly hardy in the Arnold Arboretum, where it has been introduced for some years. He considers it one of the noblest of all the ashes, and one of the most valuable timber trees of Eastern Asia. None of the other ashes of Japan, so far as I saw, attain any great size, or are likely to have any economic value in Europe. (H. J. E.)

¹ Lingelsheim, in Engler, *Bot. Jahrb.* xl. 223 (1907), unites this species with *F. nigra*, of which he considers the Manchurian tree to be only a geographical variety.

² The St. Petersburg plants were probably raised from seed from Amurland. Cf. *Gartenflora*, xxvii. 13 (1879).

³ *Forest Flora of Japan*, 52 (1894).

FRAXINUS CHINENSIS

Fraxinus chinensis, Roxburgh, *Fl. Ind.* i. 150, Carey's edition (1820); Hanbury, *Science Papers*, 271, fig. 17 (1876); Hance, *Journ. Bot.* xxi. 323 (1883); Hemsley, *Journ. Linn. Soc. (Bot.)* xxvi. 85 (1889); Lingelsheim, in Engler, *Bot. Jahrb.* xl. 216 (1907).

A small tree. Branchlets glabrous. Leaflets seven to nine, 2 to 4 inches long, coriaceous, shortly cuspidate at the apex, crenately serrate; terminal leaflet the largest, obovate-oval, and long-stalked; lateral leaflets oval or elliptic, subsessile or with short pubescent winged stalklets, unequal and broadly rounded or tapering at the base; dark green and glabrous above; under surface pale green and pubescent on the sides of the midrib and lateral nerves. Leaf-rachis deeply channelled throughout, with brownish tufts of tomentum on the upper side of the nodes; base of the rachis of the uppermost two leaves fringed with brown hairs.

Flowers (section *Ornaster*) in terminal and lateral glabrous panicles; calyx 4-toothed; corolla absent. Fruit, about $1\frac{1}{2}$ inch long, $\frac{1}{4}$ inch wide, oblanceolate, acute or rounded at the apex.

This species in the wild state is very variable as regards the shape of the leaves, five varieties being distinguished by Lingelsheim. The above description is drawn up from small specimens cultivated at Kew, which were received in 1891 from St. Petersburg under the name *F. Bungeana*. A distinct variety has been in cultivation at Kew for some years under the erroneous name *F. longicuspis*, which has five or seven leaflets, obovate-lanceolate or narrow-oblong, 2 to $3\frac{1}{2}$ inches long, about 1 inch wide, cuspidate at the apex, cuneate at the base, indistinctly serrate. It agrees exactly with a dried specimen at Kew, gathered in the Ningpo mountains, where the broad leaflet form also occurs.

This species is widely spread throughout the central and southern provinces of China, and is noteworthy as being one of the trees on which the wax insect lives. It is very rare in cultivation, the only specimens we have seen being those at Kew and a small shrub at the Edinburgh Botanic Garden. (A. H.)

FRAXINUS OBOVATA

Fraxinus obovata, Blume, *Mus. Bot. Lugd. Bat.* 311 (1850); Franchet et Savatier, *Enum. Pl. Jap.* i. 310 (1875).

Fraxinus Bungeana, Maximowicz, *Mél. Biol.* ix. 396 (1873) (not De Candolle); Franchet et Savatier, *Enum. Pl. Jap.* ii. 434 (1879); Lingelsheim, in Engler, *Bot. Jahrb.* xl. 214 (1907) (in part).

A small tree. Branchlets glabrous. Leaflets five or seven, 2 to 3 inches long, membranous, terminal one largest and long-stalked; lower pairs shortly-stalked,

obovate or oval; cuneate and unequal at the base; acute, acuminate or rounded at the apex; remotely and irregularly serrate; upper surface shining, smooth, glabrous; lower surface light green, glabrous, but roughened on the midrib and nerves by minute, curved, stiff bristles, which are also present on the petiolules and on the margin of the blade. Rachis of the leaf, grooved throughout, pubescent on the upper side of the nodes, and armed near the nodes and at the base with minute curved bristles, which are also occasionally present towards the apex of the branchlet. Flowers (section *Ornus*), in terminal glabrous panicles, on filiform pedicels; calyx with five long acuminate teeth. Fruit linear, $1\frac{1}{2}$ inch long, $\frac{1}{8}$ inch wide.

This species, of which we have seen the type specimen, preserved at Leyden, and a specimen at Kew, lately received from Tokyo, differs from all the ashes known to me, in the occurrence of characteristic minute curved prickles on the under surface, margin, and petiolules of the leaflets and on the rachis of the leaf. Blume considered it to be only cultivated in Japan, and possibly an introduction from China. It appears to be unknown to Japanese botanists. However the only living specimen which we have seen is a small plant at Aldenham, which was raised from seed obtained from the Imperial Garden at Tokyo. (A. H.)

FRAXINUS PUBINERVIS

Fraxinus pubinervis, Blume, *Mus. Bot. Lugd. Bat.* i. 311 (1850); Franchet et Savatier, *Enum. Pl. Jap.* i. 311 (1875), and ii. 435 (1879); Lingelsheim, in Engler, *Bot. Jahrb.* xl. 214 (1907).
Fraxinus Bungeana, De Candolle, var. *pubinervis*, Wenzig, in Engler, *Bot. Jahrb.* iv. 170 (1883).

A small tree, with smooth bark. Young branchlets densely covered with greyish pubescence, disappearing in the second year. Buds conical, densely covered with a brownish-grey pubescence. Leaflets, five or seven, coriaceous, 3 to 4 inches long, 1 to $1\frac{1}{2}$ inch wide; terminal largest, long-stalked and often broadest in its upper half; lateral, upper pair sessile, lower pairs shortly stalked; lanceolate, cuneate at the base, acuminate at the apex, crenately serrate; upper surface glabrous; lower surface pale green, with dense whitish pubescence on the side of the midrib, spreading to the lateral nerves, and continued on the petiolules. Rachis of the leaf, with a continuous open groove, pubescent throughout, the pubescence densest at the nodes. Flowers (section *Ornus*), in large, terminal glabrous panicles, with early deciduous petals and long pedicels; calyx with long acuminate teeth. Fruit linear-spatulate, acute, $1\frac{1}{2}$ inch long, $\frac{1}{8}$ inch wide.

This species is known to the Japanese as *toneriko*; and in a native book on forest trees, is said to attain 30 feet in height and 3 feet in girth, but no accurate account of its distribution or habitat is given. There is a dried specimen at Kew, lately received from Tokyo. The only tree in cultivation known to me, is one at Aldenham, about 15 feet high, which was received six years ago from the Yokohama Nursery Company, and is growing vigorously.

FRAXINUS SPAETHIANA

Fraxinus Spaethiana, Lingelsheim, in Engler, *Bot. Jahrb.* xl. 215 (1907).
Fraxinus Sieboldiana, Dippel, *Laubholzkunde*, i. 63, t. 27 (1889); Koehne, *Deutsche Dendrologie*, (1893) (not Blume).

A small tree. Branchlets glabrous, grey. Leaflets seven to nine, coriaceous, 4 to 6 inches long, $1\frac{1}{2}$ to $1\frac{3}{4}$ inch wide, sessile or subsessile (terminal leaflet sessile or with a stalk up to $\frac{1}{2}$ inch long); lanceolate-oblong; unequal and tapering at the base; abruptly contracted at the apex into a long, often curved acumen; margin non-ciliate, irregularly and often crenately serrate; lateral nerves fifteen to twenty pairs; glabrous except for slight pubescence along the midrib on the lower surface at the base. Rachis of the leaf, glabrous, with a continuous open groove on its upper side, dilated at its base into a swollen, dark-brown, shining sheath, which partly embraces the branchlet and conceals the glabrous dark-brown buds. Flowers, section *Ornus*. Fruit in large terminal glabrous leafless panicles. Samaræ linear-spatulate, $1\frac{1}{2}$ inch long, $\frac{1}{3}$ inch wide in the broadest part, rounded and entire at the apex; calyx with five short teeth.

This species, which has been a considerable time in cultivation, under the garden name of *F. serratifolia*, is readily distinguishable from all the other species¹ of ash which have been introduced, by the swollen base of the petiole, which somewhat resembles that of the plane tree. It is a native of Japan, where it appears to have been confused with *F. Sieboldiana*, which we consider to be a form of *F. longicuspis*. Specimens lately received at Kew, through the Hon. Vicary Gibbs, from Dr. Fukuba, Director of the Imperial Gardens at Tokyo, enable us to describe the fruit, which has hitherto been unknown.

It is a handsome and striking species, represented at Kew by a tree about 15 feet high, and at Aldenham by small plants. (A. H.)

FRAXINUS LONGICUSPIS

Fraxinus longicuspis, Siebold et Zuccarini, in *Abhand. Baier. Acad. Wissen.* iv. 3, p. 169 (1846); Franchet et Savatier, *Enum. Pl. Jap.* i. 310 (1875); Shirasawa, *Icon. Ess. Forest. Japon*, text 126, t. 81 (1900); Lingelsheim, in Engler, *Bot. Jahrb.* xl. 214 (1907).
Fraxinus Sieboldiana, Blume, in *Mus. Lugd. Bat.* i. 311 (1850).

A tree, attaining, according to Shirasawa, 50 feet in height and 7 feet in girth. Young branchlets grey, glabrous. Leaflets five, occasionally seven; terminal largest, stalked; lateral, upper pair sessile, lower pair stalked; oblong, oblong-lanceolate, or

¹ *F. platypoda*, Oliver, a species, discovered by me in Central China, has a similar swollen base to the petiole; but it has never been introduced.

ovate, cuneate at the base, abruptly contracted above into a long cuspidate apex, crenately serrate; upper surface glabrous; lower surface pale green, slightly pubescent on the side of the midrib, elsewhere glabrous. Rachis of the leaf, grooved on its upper side, pubescent at the nodes, glabrous elsewhere. Buds purplish brown, minutely pubescent. Flowers (section *Ornus*) in terminal and lateral panicles; petals four, narrowly-linear. Fruit about an inch in length, subtended by a 4-toothed calyx, oblanceolate, with a long cuneate base and an obtuse emarginate apex.

This species is variable as regards the shape of the leaflets; and two varieties have been noticed, regarded as distinct species by Blume; one characterised by broad ovate leaflets (terminal leaflet 3 to 3½ inches long and 1½ inch broad), with slight pubescence along the midrib beneath; the other with narrow oblong leaflets (terminal leaflet 3½ to 4 inches long and 1 to 1½ inch wide), glabrous on the under surface; but, as Franchet points out, there are numerous specimens with intermediate characters.

*Fraxinus longicuspis*¹ is a native of the mountainous districts of Japan, attaining, according to Shirasawa, an elevation of 5000 feet in the central chain of Hondo. It is abundant in Nikko, Chichibu, and Kiso; and has been collected near Hakodate by Maximowicz, in Akita by Elwes, in the mountains of Yamagata by Faurie, and in the island of Tsu-sima by Wilford. On account of its small size, it is of no economic importance in Japan. It appears to be extremely rare in cultivation in this country, the only specimen which we have seen being a small plant at Kew, about 2 feet high, which was raised from seed sent by Sargent in 1894. (A. H.)

FRAXINUS NIGRA, BLACK ASH

Fraxinus nigra, Marshall, *Arb. Am.* 51 (1785); Sargent, *Silva N. Amer.* vi. 37, tt. 264, 265 (1894), and *Trees N. Amer.* 764 (1905).

Fraxinus sambucifolia, Lamarck, *Dict.* ii. 549 (1786); Loudon, *Arb. et Frut. Brit.* ii. 1234 (1838).

A tree, attaining in America 90 feet in height and 5 feet in girth of stem, with bark divided into large irregular scaly plates. Shoots glabrous. Leaflets (Plate 264, Fig. 19), seven to eleven, 3 to 5 inches long, terminal one petiolulate, lateral leaflets sessile; oblong to oblong-lanceolate, rounded and unequal at the base, long acuminate at the apex, remotely and finely crenulate-serrate; under surface glabrous, except for long reddish hairs along the nerves and midrib, densest towards the base, where they spread over the surface of the leaflet. Leaf-rachis winged on the upper side, the wings meeting above and not forming a continuous open groove; glabrous except opposite the insertions of the leaflets, where it is bearded all round with dense rufous hairs.

The terminal buds are blackish, broadly ovate and acute, with six scales visible externally, of which the outer pair, slightly puberulous, almost enclose the others.

¹ The Japanese botanists recognise two species:—*F. longicuspis*, called in Japanese *oshida* or *aotago*; and *F. Sieboldiana*, known as *shioji*. The latter name may possibly refer to *F. Spaethiana*. Cf. p. 897.

Flowers (section *Fraxinaster*) polygamous, without calyx or corolla, arising in the axils of the leaf-scars of the preceding year's shoot. Fruit, linear-oblong, with a short flattened faintly nerved body, surrounded by a thin wing very emarginate at the apex.

This is the American representative¹ of the common European ash, and it is easily distinguished from nearly all the other species by the dense ring of rufous pubescence on the leaf-rachis at the nodes. *Fraxinus mandshurica*, which has the rachis similarly bearded, but more deeply grooved, differs in having leaflets with a sharp serrate margin and a tapering base. (A. H.)

Fraxinus nigra is found, according to Sargent, in deep, cold swamps and on the low banks of streams and lakes, from southern Newfoundland and the north shores of the Gulf of St. Lawrence to Lake Winnipeg, and southward to the mountains of Virginia, southern Illinois, and north-west Arkansas. Macoun says that in Canada it is more widely distributed than the white ash, and more abundant than the latter throughout its range, from Anticosti to eastern Manitoba, in swamps and river bottoms. It grows on peat mosses, but remains small in such situations. I saw it in the woods about Ottawa, but of no great size, and Sargent gives 80 to 90 feet as its extreme height. Ridgway found it abundant in Knox County, Indiana, where a tree 83 feet high, of which the bole was 57 feet, only measured 1½ foot in diameter at 5 feet from the ground. He says that it presents so very close a resemblance to the young Pecan tree (*Carya olivæformis*) as not to be readily distinguished except by experts.² In *Carya*, however, the leaves are alternate. Its wood, according to Emerson, is remarkable for toughness, and on this account was preferred to every other by the Indians for making baskets, and is still used for that purpose in preference to every kind of wood except that of a young white oak.

We have seen no specimens of this tree except small plants³ at Kew and Colesborne, although it was probably planted in many places early in the nineteenth century; having been introduced, according to Loudon, in 1800. Like many other trees of the Atlantic side of North America, it is short-lived and does not thrive in our climate. Prof. Sargent informs me in a letter that at the Arnold Arboretum, near Boston, it is one of the most difficult of all trees to grow. At Angers in France, it does badly on its own roots, but succeeds when well grafted; a specimen there having attained 15 feet high in eight years. (H. J. E.)

¹ According to Cobbett, *Woodlands*, Art. 136 (1825), the seeds of this species, like the English ash, do not come up until the second year.

² Mr. G. B. Sudworth, however, tells me that the bark of the two is so distinct that they can readily be distinguished. He adds that other species of ash, hickory, oak, Liquidambar, and Nyssa, are now used for basket-making.

³ These plants were raised from seed sent from Michigan in 1895, and are not thriving, having been repeatedly injured by frost. They are now only 2 feet high.

FRAXINUS ANOMALA, UTAH ASH

Fraxinus anomala, Watson, King's Rep. v. 283 (1871); Sargent, *Silva N. Amer.* vi. 39, t. 266 (1894), and *Trees N. America*, 765 (1905).

A small tree, attaining about 20 feet in height, with bark shallowly fissured by narrow ridges. Branchlets quadrangular, slightly four-winged, glabrous, with inconspicuous reddish lenticels. Leaves (Plate 262, Fig. 7) simple (occasionally two- to three-foliolate), ovate or obovate, acute or rounded at the apex, base cuneate or cordate, slightly crenulate or entire in margin, glabrous beneath. Petiole flattened and grooved above, about half the length of the blade of the leaf.

Flowers (section *Leptalix*) in panicles from the axils of the leaf-scars of the preceding year's shoot, with a calyx, but corolla absent. Fruit oblong, with a rounded wing surrounding the long, flattened, striately nerved body.

This curious tree, so remarkable amongst the ashes, in its usually simple leaves and quadrangular stems, occurs in Colorado, Utah, and Nevada.

It is in cultivation at Kew, where it is perfectly hardy, and is worthy of a place in collections on account of its peculiarities. (A. H.)

FRAXINUS QUADRANGULATA, BLUE ASH

Fraxinus quadrangulata, Michaux, *Fl. Bor. Am.* ii. 255 (1803); Loudon, *Arb. et Frut. Brit.* ii. 1235 (1838); Sargent, *Silva N. Amer.* vi. 35, t. 263 (1894), and *Trees N. Amer.* 761 (1905).

A large tree, attaining 120 feet in height and 9 feet in girth. Bark separating irregularly into large thin plates. Branchlets glabrous, stout, quadrangular; with four wings between the nodes, persisting and becoming corky in the second year; lenticels white. Leaflets (Plate 265, Fig. 22), five to nine, 3 to 5 inches long; on pubescent stalklets, $\frac{1}{8}$ to $\frac{1}{4}$ inch long; ovate or oval, rounded or broadly cuneate at the base, acuminate at the apex, regularly serrate, glabrous above; under surface covered with scattered whitish tomentum, densest towards the base. Leaf-rachis pubescent, with a shallow open channel on its upper side.

Flowers (section *Leptalix*) in panicles from the axils of the leaf-scars of the previous year's shoot, perfect, calyx obsolete, corolla absent. Fruit oblong; body long, flat, with numerous faint rays, surrounded by the base of the broad wing, which is emarginate at the apex.

This species is readily distinguished from all the other species with numerous leaflets by the conspicuous wings on the branchlets. (A. H.)

The blue ash though little known outside of botanic gardens in Europe is, next to the white ash, the largest of its genus found in the United States. It is unknown in New England or Canada, though hardy at Ottawa, where I saw it in the

arboretum of the Experimental Farm. Sargent says that it grows usually on rich limestone hills from southern Michigan to Iowa, central Missouri, and north-eastern Arkansas, and southward to northern Alabama and east Tennessee on the Big Smoky mountains, where it attains a great size. Usually it is from 60 to 70 feet high, with a trunk 2 to 3 feet in diameter; but Ridgway says that four freshly cut trees, in the Wabash valley in Illinois, were 116 to 124 feet high, with clear trunks 51 to 76 feet long, and 2 to 2½ feet diameter on the stump. Here it was common in rich hilly woods, but I saw none standing of anything like these dimensions.

The tree was discovered by the elder Michaux in 1795 and introduced¹ by him into France, and his son speaks of the beautiful stocks that were growing in Europe; but I have seen none of considerable size, the best perhaps in England being a tree at Tortworth, which was 34 feet by 1 foot 10 inches in November 1905, and reported by Lord Ducie to be growing freely. Michaux says that the wood of this species in the western states is extensively used for waggon-building and wheels, and also for flooring houses; but it does not now seem to be known to English importers. Mr. G. B. Sudworth informs me, however, that this timber is still found in considerable quantity in the Ohio valley, and can be obtained in logs as large as 24 to 30 inches in diameter. He adds that for farm tool handles it is preferred to any other ash on account of its superior strength and elasticity. (H. J. E.)

FRAXINUS AMERICANA, WHITE ASH

Fraxinus americana, Linnæus, *Sp. Pl.* 1057 (1753); Loudon, *Arb. et Frut. Brit.* 1232 (1838); Sargent, *Silva N. America*, vi. 43, tt. 268, 269 (1894), and *Trees N. America*, 767 (1905).
Fraxinus alba, Marshall, *Arbust. Am.* 51 (1785).
Fraxinus acuminata, Lamarck, *Dict.* ii. 547 (1786).
Fraxinus juglandifolia, Lamarck, *Dict.* ii. 548 (1786).
Fraxinus epiptera, Michaux, *Fl. Bor. Am.* ii. 256 (1803).

A large tree, attaining in America 120 feet in height and 15 to 20 feet in girth. Bark deeply divided by narrow fissures into broad flattened scaly ridges. Shoots stout, green, glabrous, with white lenticels. Leaflets (Plate 265, Fig. 21), seven to nine, 4 to 6 inches long, distinctly stalked (the petiolules glabrous and $\frac{1}{4}$ to $\frac{1}{2}$ inch long), lanceolate or oval, rounded or broadly cuneate at the base, acuminate at the apex; entire, crenulate, or coarsely serrate; under surface whitish and pubescent along the midrib and nerves, or in some cases throughout. Rachis of the leaf terete and apparently not grooved on the upper side; but usually a slight groove can be made out on close examination.

Flowers (section *Leptalix*) dioecious, in glabrous panicles in the axils of the leaf-scars of the preceding year's shoot; corolla absent. Fruit in crowded clusters, surrounded by the persistent calyx at the base, lanceolate or oblong, with a terete rayed oblong body, much shorter than the terminal wing, which is pointed or emarginate at the apex.

¹ It was introduced, according to Loudon, into England in 1823.

VARIETIES

A form is known with very small fruit, var. *microcarpa*, Gray.¹ In regard to the leaf, two varieties have been described,² viz. :—

Var. *acuminata*, Wesmael. Leaflets dark green above, very white and almost glabrous beneath, nearly entire in margin. This form is more common in the southern states.

Var. *juglandifolia*, Rehder. Leaflets usually broader than in the preceding variety, more or less pubescent beneath, coarsely serrate at least above the middle. This is the northern form of the species.

These two varieties occur in cultivation in England, the leaves of both remaining unchanged in colour until they fall in autumn. A form of var. *acuminata* occurs, in which the leaflets are narrow at the base, and turn reddish brown before they fall.

There is also said to exist a horticultural variety, var. *albo-marginata*, in which the leaflets are edged with white.

IDENTIFICATION

As *Fraxinus americana* may be a valuable tree for economic planting in England, its correct identification is important. Reputed trees of *F. americana* growing slowly usually turn out on examination to be *F. viridis* or some other species. In summer, the leaflets white beneath and distinctly stalked, the rachis terete and practically not grooved, and the glabrous branchlets, will readily distinguish *F. americana*. The only species which closely agrees with it, *F. texensis*, has, when adult, fewer, usually five (rarely seven) leaflets, which are smaller and quite different in shape, being broadly oval with a rounded or acute apex. (A. H.)

DISTRIBUTION

The white ash is one of the best known and most highly valued trees in New England and Canada; where it occurs according to Sargent, from Nova Scotia and New Brunswick through Ontario to northern Minnesota, southward to northern Florida, and westward to Kansas, Indian Territory, and eastern Nebraska, and the valley of the Trinity River, Texas; being less common and smaller west of the Mississippi. It attains in the forest a height of 120 feet with a diameter of 4 feet and upwards, and thrives best in a deep loamy soil near the banks of streams, just as the common ash does in England. When standing alone it assumes a spreading habit with large branches.

Ridgway measured a sound tree in Wabash County, Illinois, which was 144 feet high with a clean stem 83 feet long and 9 feet in girth at the top, and 13 feet at the base, which, according to English measure, would have contained over 500 cubic feet; and Dr. C. Schneck measured a tree in the same county 144 feet high with a stem 90 feet long and 17½ in girth above the swell at the base; and this tree, if it carried its girth up, might have contained 1000 feet of timber.

¹ This variety is common in the Gulf States, the fruit being less than ½ inch long; whereas it usually attains 1½ to 2 inches. Sargent, however, states that both large and small fruit may occur on the same individual, and even on the same branch.

² Cf. Rehder in *Cycl. Amer. Horticulture*, 607 (1900).

I saw no large specimens of this species in New England or Canada where most of the best have been felled. I noticed at Ottawa that in the autumn its leaves assume a rich purplish colour, which the black and red ashes did not show.

Michaux says¹ that on large trees the bark is deeply furrowed, and divided into small squares from 1 to 3 inches in diameter; and that it grows in Maine in company with the white elm, yellow birch, white maple, hemlock, and black spruce, and in New Jersey with red maple, shellbark hickory, and button-wood (*Platanus occidentalis*), in places that are constantly wet or occasionally flooded. Pinchot and Ashe² figure a splendid tall straight forest tree with small head and rough bark resembling that of the common ash, and say that its average height in North Carolina is 50 to 80 feet with a diameter of 2 feet to 3 feet.

Professor Sargent says³ that the white ash when planted with the common ash in the high regions of central Europe comes into leaf still later than that species, and thus escapes the spring frosts; it is less able to resist drought than the green ash, and is usually found on moist soil, though it does not like wet swamps, like the black ash. In the forest it sends up a perfectly straight and slender stem to a great height, ash poles 100 feet high and not over a foot in diameter being often seen. A photograph taken in Chester County, Pennsylvania, shows a tree in the open with a rather spreading head and a trunk 15 feet 10 inches in girth.

CULTIVATION

Fraxinus americana is stated by Aiton⁴ to have been introduced into England in 1724 by Catesby. Sargent, however, points out that the ash described by Catesby is another species.

Though very seldom seen, I believe that the American ash will grow in this country, in some places at least, almost as fast as the native ash. My attention was first called to this fact by the very straight, clean, and rapid growth of a young tree at Kew which stands by the walk not far from the Old Conservatory, now the Museum of Timbers. The date of planting is unknown. It measured in 1907 63 feet by 2 feet 5 inches, while *F. lanceolata*, growing near it is 43 feet by 2 feet 1 inch, and *F. oregona*, 44 feet by 2 feet 8 inches.

Knowing that the wood is considered better for oars than that of the native ash, and used exclusively for the heavy oars of our navy, I thought it worth trying as a timber tree, and raised a large number of plants from seed sent me by Messrs. Meehan of Philadelphia as *F. americana*, but which I found out three years later to be *F. lanceolata*.⁵ Later on I raised seedlings of the true white ash and found that at first they do not grow nearly so fast as *F. lanceolata*. They do not ripen the young

¹ *N. Amer. Sylva*, iii. 49.

² *Garden and Forest*, vii. 402.

³ Mr. G. B. Sudworth informs me that ten or fifteen years ago Messrs. Meehan became aware that they had been selling two or three species of ash seed as *F. americana*, and submitted samples to him for identification. To his great surprise he found that none of it was pure, but contained a mixture of *F. americana*, *F. lanceolata*, and *F. pennsylvanica*. Since then they have been more careful. He adds that continental tree planters have, to his knowledge, been planting green and red ash in mistake for white ash; and it is probable that most of the young trees grown under that name on the continent are incorrectly named.

⁴ *Trees of North Carolina*, p. 71, plate 6.

⁵ *Hort. Kew*, iii. 445 (1789).

wood well until they attain a certain age, but are perfectly hardy and will probably grow best in the east and south-east of England.

The only large trees I know of in England are two at Kew which grow on the mound near the Cumberland gate and which measure 85 feet by 8 feet 6 inches and 85 feet by 8 feet respectively (Plate 246). There is a tall slender white ash at Croome Court, Worcestershire, crowded by other trees, which measures about 80 feet by 4 feet 6 inches, and another¹ at Arley Castle 60 feet by 5 feet 4 inches. There is also a smaller one at Syon. Another at Tortworth was 46 feet by 3 feet in 1907. Loudon says that at St. Anne's Hill in Surrey there was one 33 feet high which had been planted thirty-six years, and that near London young plants are generally injured by spring frost, which I have not found to be the case at Colesborne.

Sir Charles Strickland tells me that he has planted the tree at Hildenley at Yorkshire, but does not find it succeed so well as the Oregon ash.

A tree at Fota, in the south of Ireland, is 50 feet high and 6 feet in girth.

Cobbett says:² "This tree grows much faster than ours. I have abundant proof, for the American white ash plants which I have at Kensington, which were not sown till last April, are now (1825) full as tall again as any of the English ash of the same age that I ever saw. This, therefore, is above all others the ash which I recommend to be put into plantations in England, whether for ornament, for timber, or for under-wood." But Cobbett in this case, as in many others, was rather apt to jump to conclusions after too short experience; for if the tree had continued to grow as it did at first, there must by this time have been many good-sized ones in England.

TIMBER

The timber of the white ash is as highly valued in America as ours is in England for the same purposes, and is largely imported to England where it is used as a substitute for English ash. Laslett in writing of American white ash says: "It is tough, elastic, clean, and straight in the grain, and stands well after seasoning, hence we get from this tree the best material for oars for boats that can be produced. They are much and eagerly sought after by foreign governments as well as our own, and also by the great private steamship companies and mercantile marine. The best quality wood has a clean, bright uniform whitish colour; the second is slightly stained with red and yellow shades alternating; the third and least valuable quality is that in which the red and yellow colours predominate. It is much slower in growth than the English, and is probably not so durable." On visiting the principal importers of this wood in Liverpool, I found large quantities of American oars imported ready-made; and was told that the timber had now become so scarce in the east, that it came from the west side of the Mississippi.³ I have not been able to procure a sample grown in this country for comparison; but I am indebted to

¹ *Catalogue of Hardy Trees, Arley Castle*, No. 43 (1907).

² *Woodlands*, art. 135.

³ A lot of oars which I saw in the Portsmouth Dockyard were stamped on the blade "De Valls Bluff. Ark. U.S.A." I am informed by experienced naval carpenters, and officers, that they believe that English ash, if it can be procured of sufficient straightness and length, would be at least as good, if not better.

Mr. A. Howard for a plank believed to be of this species, which was imported from Canada, and was cut from a log measuring 56 feet long by 24 inches quarter-girth at the top. It cost £66 and was cut into twenty-four boards containing 2763 feet board measure. (H. J. E.)

FRAXINUS TEXENSIS, TEXAN ASH

Fraxinus texensis, Sargent, *Silva N. Amer.* vi. 47, t. 270 (1894), and *Trees N. Amer.* 768 (1905).

Fraxinus albicans, Buckley, *Proc. Philad. Acad.* 1862, p. 4 (in part).

Fraxinus americana, Linnæus, var. *texensis*, Gray, *Syn. Fl. N. Amer.* ii. part i. 75 (1878).

Fraxinus americana, Linnæus, var. *albicans*, Lingelsheim, in Engler, *Bot. Jahrb.* xl. 219 (1907).

A small tree, with a short stem, rarely attaining 50 feet in height and 9 feet in girth. Bark dark grey, deeply divided by narrow fissures into broad scaly ridges. Branchlets glabrous. Leaflets, five to seven, often nine in young plants, 2 to 2½ inches long, distinctly stalked, with glabrous petiolules about ⅛ to ¼ inch long, ovate or oval (the terminal leaflet often obovate), base rounded and unequal, apex acute or rounded (acuminate in young plants), crenate-serrate and non-ciliate in margin; upper surface shining bluish green, glabrous; lower surface whitish, usually pubescent on the sides of the midrib and lateral nerves, the latter being forked near the margin; rachis slender, glabrous, terete, slightly grooved on the upper side.

Flowers (section *Leptalix*) dioecious in glabrous panicles in the axils of the leaf-scars of the preceding year; corolla absent. Fruit, spatulate, with persistent calyx at the base; body short, terete; wing terminal, rounded or emarginate at the apex.

This species, while very close to *F. americana* in technical characters, is distinct in appearance, and differs in the smaller leaflets, which are shining bluish green, and not dull on the upper surface.

It was discovered in 1852 by Dr. J. M. Bigelow, and grows on high dry limestone bluffs and ridges in northern, central, and western Texas, from near Dallas City to the valley of the Devil's River.

Young plants are growing in the nursery at Kew, which are thriving, and about 6 to 8 feet in height, after six years' growth. They were raised from seed sent by Mr. Bush in 1901. These plants have usually 7 to 9 leaflets, while specimens in the Kew Herbarium from Texas have only five leaflets; but this is probably a juvenile character. It is also growing well at Aldenham.

(A. H.)

FRAXINUS BILTMOREANA, BILTMORE ASH

Fraxinus Biltmoreana, Beadle, *Bot. Gazette*, xxv. 358 (1898); Sargent, *Trees N. Amer.* 773, fig. 618 (1905).

Fraxinus catawbiensis, Ashe, *Bot. Gazette*, xxxiii. 230 (1902).

A tree attaining in America, according to Ashe, over 100 feet in height, with a girth of about 7 feet. Young shoots covered with a dense white pubescence, retained in the second year; lenticels few, conspicuous, narrow, long, white. Leaflets (Plate 266, Fig. 30), seven to nine, about 4 inches long, oval or oblong (the terminal one on a long stalk, broadly oval or obovate), abruptly tapering and unequal at the base, acuminate at the apex, remotely serrate (the serrations often obsolete, so that the margin is nearly entire), with occasional scattered cilia; distinctly stalked with pubescent petiolules, $\frac{3}{8}$ to $\frac{1}{2}$ inch long; upper surface dark green, glabrous except for a little pubescence towards the base of the leaflet; lower surface white in colour, with a thin fine short pubescence, densest on the sides of the midrib and nerves. Rachis of the leaf slender, terete, finely pubescent, not grooved or only slightly grooved towards the apex.

Flowers (section *Leptalix*) dioecious in pubescent panicles in the axils of the leaf-scars of the previous year; corolla absent. Fruit girt at the base by the persistent calyx; body, short, elliptical, many-nerved; wing not decurrent, only slightly narrowed at the ends, emarginate at the apex.

Buds shortly ovoid, with four outer visible scales, equal in length, the external pair overlapping the inner pair; scales carinate, obtuse at the apex, orange-coloured, and covered with a scaly pubescence.

This species, as regards leaf-characters, looks like a pubescent *Fraxinus americana*;¹ and is readily distinguished from *F. pennsylvanica* by the leaflet being white in colour beneath, with a finer pubescence, and being more abruptly tapering and unequal at the base, with shallower and remoter serrations, which often become obsolete. The rachis of the leaf is like that of *F. americana*.

According to Sargent, it occurs on the banks of streams from northern West Virginia through the foothills of the Appalachian Mountains to northern Georgia and Alabama, and to middle Tennessee.

This species in the United States has apparently been considered to be a form of *F. pennsylvanica*, and has been in cultivation probably as long. At Fawley Court, Oxfordshire, the residence of W. D. Mackenzie, Esq., there are two fine trees. The largest, in a shrubbery, rather crowded by other trees, is about 80 feet in height by 7 feet 3 inches in girth. The other, standing in the open, is a very well-shaped vigorous tree (Plate 247), measuring 68 feet by 6 feet 6 inches. Both are bearing mistletoe and grow in good alluvial soil. The bark is grey in colour, and fissured like that of the white ash.

(A. H.)

¹ Beadle says that this species bears the same relation to *F. americana* as *F. pennsylvanica* bears to *F. lanceolata*. Lingelsheim, *op. cit.* 191, 222, considers this species to be a hybrid, between *F. americana* and *F. pennsylvanica*; but its wide distribution and abundance in the forest are not favourable to his view.

FRAXINUS LANCEOLATA, GREEN ASH

Fraxinus lanceolata, Borkhausen, *Handb. Forst. Bot.* i. 826 (1800); Sudworth, *Check List Forest Trees U.S.* 107 (1898).

Fraxinus viridis, Michaux, *Hist. Arb. Amer.* iii. 115, t. 10 (excl. fruit), (1813).

Fraxinus juglandifolia, Willdenow, *Sp. Pl.* iv. 1104 (1805) (not Lamarck); Loudon, *Arb. et Frut. Brit.* ii. 1236 (1838).

Fraxinus pennsylvanica, Marshall, var. *lanceolata*, Sargent, *Silva N. America*, vi. 51, t. 272 (1894), and *Trees N. America*, 771 (1905).

A tree rarely attaining more than 60 feet in height, with a girth of stem of 6 feet. Shoots dark green, glabrous, with conspicuous white lenticels. Leaflets (Plate 264, Fig. 16), seven to nine, usually sessile, 3 to 6 inches long, pale green beneath, ovate-lanceolate, tapering and unequal at the base, long-acuminate at the apex, under surface glabrous except for slight pubescence along the midrib, variable in serration. Rachis of the leaf glabrous, distinctly grooved on its upper side.

Flowers and fruit similar to those of *F. pennsylvanica*.

This species¹ is considered by Sargent to be a variety of *F. pennsylvanica* because west of the Mississippi trees occur, which are intermediate in character and can be as readily referred to one species as to the other. As seen in cultivation in England, it is very distinct, and on account of its glabrous shoots, it is very often mistaken for *F. americana*. The green ash is, however, readily distinguished from that species by the usually sessile leaflets, which are pale green and not white beneath.² The rachis is, moreover, more deeply grooved than is ever the case in *F. americana*, and the buds in the two species are different. (A. H.)

This tree was described and figured by the younger Michaux, who says, "The green ash is easily recognised by the brilliant colour of its young shoots and leaves, of which the two surfaces are nearly alike." He found it more common in the western districts of Pennsylvania, Maryland, and Virginia, than anywhere else, and speaks of it as a tree of moderate dimensions, laden with seed when only 25 to 30 feet high.

Sargent, who treats it as a variety of *F. pennsylvanica*, and distinguishes it by the leaves being rather narrower, shorter, and usually with more sharply serrate leaflets, bright green on both surfaces, says that it rarely exceeds 60 feet high, and occurs from the shores of Lake Champlain through the Alleghany mountains to western Florida and west to the valley of the Saskatchewan, the valley of the Colorado river, Texas, the eastern ranges of the Rocky Mountains, the Wasatch range, Utah, and Arizona. It is comparatively rare east of the Alleghany mountains, and most abundant in the Mississippi basin. East of the Mississippi it seems distinct, but westward is connected with the red ash by intermediate forms.

¹ A small tree growing in Kew Gardens and labelled *F. coriacea*, resembles in many respects the green ash. It is apparently the Texan form of the Mexican *F. Berlandieriana*, DC., which was formerly considered to be a variety of *F. lanceolata*. The Kew tree has glabrous shoots like those of the green ash; but the leaflets (Plate 263, Fig. 14) are smaller, more coriaceous and very reticulate, usually three to five in number, the terminal one largest and obovate, the lateral ones oval and acuminate at the apex, all sparingly and irregularly serrate in the upper two-thirds, with the under surface pale green and glabrous except for some pubescence along the midrib. Rachis of the leaf glabrous and slightly grooved. *F. coriacea*, Watson, a tree occurring in desert regions from Utah to California is probably a variety of *F. Berlandieriana*, differing in the pubescent branchlets and leaf-rachis. It is in cultivation at Aldenham, where a young tree, about 10 feet high, obtained from Barbier's nursery at Orleans, is thriving.

² Mr. G. B. Sudworth, adds, that the leaflets are usually sharply serrate, while those of *F. americana* are commonly undulate, entire, or with only a few teeth.

Ridgway, in his *Additional Notes on the Trees of the Wabash*,¹ says that Dr. J. Schneck of Mount Carmel measured a tree 92 feet high and 5 feet in girth; but when I visited the remains of this wonderful forest, in September 1904, I saw no ash trees of considerable size.

Pinchot and Ashe² say that the wood is inferior in quality to that of the white ash, but in North Carolina is not distinguished from it commercially.

Having raised a large quantity of plants from seed sent me as that of *Fraxinus americana*, which I did not identify as the green ash until Mr. F. V. Coville of Washington saw them growing in my nursery in 1904, I have distributed them to many friends as *F. americana*, and it is probable that the tree will thus become common in England under a wrong name, as has happened in so many cases before. For this mistake, which was unavoidable, I now apologise; but as the tree grows faster than any other American ash in a young state, and is likely to make useful poles, if not large trees, I have planted out some thousands of them at Colesborne.

Like all the American ashes which I have raised, the seed germinates quickly after sowing, and though liable to be injured by late frosts is at least as hardy as the common ash. When young the shoots continue to grow late in autumn and do not ripen their young wood, which for three to four years at least is liable to be killed back by winter frosts. Some of these seedlings are now, at four years old, 6 to 7 feet high and growing very vigorously. Michaux says that this species was introduced by his father to France in 1785, but I cannot hear of any surviving under this name.

Loudon says that at Stackpole Court, Pembrokeshire, it had in forty years attained a height of 60 feet, and had ripened seeds from which many plants had been raised and distributed in the plantations, but the Earl of Cawdor tells me that his gardener can find no trees in the woods which resemble the American ash, and that none of the men on the place can remember any peculiar ash trees there. In 1906 I also searched the woods at Stackpole without finding any trace of these trees. Loudon also mentions a tree in the garden of Pope's villa at Twickenham, which no longer exists. There are several young trees in Kew Gardens; and the tallest, about 40 feet high, is widely branching in habit, differing remarkably from a white ash of the same height beside it, which has narrow branches and a straighter stem. Their foliage is also very different in colour. (H. J. E.)

FRAXINUS PENNSYLVANICA, RED ASH

Fraxinus pennsylvanica, Marshall, *Arb. Amer.* 51 (1785); Sargent, *Silva N. Amer.* vi. 49, t. 271 (1894), and *Trees N. Amer.* 770 (1905).

Fraxinus pubescens, Lamarck, *Dict.* ii. 548 (1786); Loudon, *Arb. et Frut. Brit.* ii. 1233 (1838).

A tree, attaining 60 feet in height and 5 feet in girth of stem. Bark brownish red and slightly furrowed, with scaly ridges. Young shoots stout, covered with

¹ *Proc. U.S. Nat. Mus.* xvii. 411 (1894).

² *Timber Trees of North Carolina*, 73.

dense white pubescence, which is retained in the second year; lenticels white, inconspicuous. Leaflets (Plate 263, Fig. 13), seven to nine, occasionally five, 3 to 5 inches long, three times as long as broad, ovate-lanceolate to oblong-lanceolate, tapering at the base, acuminate at the apex, finely serrate and ciliate in margin; upper surface with scattered fine pubescence; lower surface densely pubescent and green in colour. The leaflets are usually distinctly stalked, with pubescent petiolules; but forms occur in which they are sessile, the substance of the leaflet being prolonged to its insertion. Rachis of the leaf densely white pubescent, with a distinct shallow groove on its upper side.

Flowers (section *Leptelix*) dioecious, in tomentose panicles in the axils of the leaf-scars of the preceding year's shoot; corolla absent. Fruit linear-spatulate, surrounded at the base by the persistent calyx; body slender, terete, many-rayed; wing slightly decurrent, narrow, and rounded or acute at the apex.

For the distinctions between this species and the Oregon ash, see under the latter. *Fraxinus Biltmoreana* differs conspicuously in having the leaflets white beneath. *Fraxinus profunda*, Bush,¹ which is remarkably distinct in its fruit, differs also in having the leaflets entire or undulate in margin, their base being usually very asymmetrical.

There are several forms of *F. pennsylvanica* in cultivation, some having the leaflets very firm in texture and set close on the rachis, others having thin leaflets wider apart on the rachis. The leaflets also vary in the length of their stalklets, in the size of the serrations, and in the shape of the base, which may be gradually tapering or abruptly tapering and almost rounded. *F. Richardi*, *F. Boscii*, and *F. glabra*, names given to certain horticultural varieties, are all probably referable to this species.

Var. *aucubæfolia* (*F. aucubæfolia*, Kirchner, *Arb. Musc.* 507 (1864)), in which the leaves are variegated with yellow, is considered by Lingelsheim² to be a hybrid between *F. pennsylvanica* and *F. lanceolata*. At Aldenham³ this forms a handsome tree about 30 feet high. (A. H.)

It is neither so large nor so common a tree as the white ash in the United States where, according to Sargent, it has nearly the same distribution as the latter; being most common and largest in the north Atlantic States, smaller and less abundant west of the Alleghanies. Macoun says⁴ that in Canada it ranges farther west than the white and black ashes, growing along the Assiniboine river and the tributaries of Lake Manitoba. It is usually 40 to 60 feet high, with a diameter rarely exceeding 18 inches to 20 inches; and is here of no value for timber, but makes good firewood, even when green. Emerson measured a tree at Springfield in September 1840 which was 9 feet in girth at 3 feet from the ground; and Ridgway says⁵ that Dr. Schneck measured a tree in the Wabash forests 138 feet high by 16 feet in girth.

¹ See Sargent, *Trees N. America*, 772. This ash, which is probably not yet introduced, grows to a great size in river swamps in Missouri, Arkansas, and Florida. It is considered by Lingelsheim, in Engler, *Bot. Jahrb.* xl. 220 (1907), to be a variety of *F. pennsylvanica*. ² *Op. cit.* 222.

³ It is cultivated here under the erroneous name, *F. americana*, var. *aucubæfolia*, which is given in *Kew Handlist of Trees*, 533 (1902). ⁴ *Forest Wealth of Canada*, p. 23. ⁵ *Proc. U.S. Nat. Mus.* xvii. 411 (1894).

Fraxinus pennsylvanica was introduced into England in 1783¹; and it is often met with in cultivation in public parks and botanic gardens, where it grows well as a small tree. One in the Botanic Garden at Oxford measures about 50 feet by 3 feet, and I have seen smaller trees at Stowe and elsewhere. I have raised it from American seed, and it seems to grow as fast as the white ash, but not so fast as the green ash. It ripens its wood better, and when young loses its leaves earlier than either of these.

Macoun says² that the red ash and the green ash are not separated commercially from the other species, the wood of the latter resembling that of the white ash, while that of the former is more like the black ash. Therefore there is some doubt whether Laslett, who writes of the Canadian ash, whose timber is often confounded with that of the white ash, is speaking of this tree or of the black ash which he does not mention. He says that it was, until recently, imported in considerable quantity in the form of oars, and that it is reddish brown in colour, considerably darker than the wood of the English ash. (H. J. E.)

FRAXINUS OREGONA, OREGON ASH

Fraxinus oregona, Nuttall, *Sylva*, iii. 59, t. 99 (1849); Sargent, *Silva N. Amer.* vi. 57, t. 276 (1894), and *Trees N. Amer.* 776 (1905).

A tree attaining 80 feet in height and a girth of stem of 12 feet. Bark deeply divided by interrupted fissures into broad flat scaly ridges. Young shoots stout, covered with dense white tomentum, which persists in the second year; lenticels white, inconspicuous. Leaflets (Plate 263, Fig. 15), 3 to 4 inches long, subsessile, usually seven, sometimes five or nine, oval, about twice as long as broad, base rounded or abruptly tapering, apex acute or shortly acuminate; margin entire or minutely and remotely crenate, ciliate; upper surface with scattered fine pubescence; lower surface covered with dense white tomentum. Rachis white tomentose, with a distinct shallow groove on its upper side, basal part wide and flattened.

Flowers (section *Leptaliæ*) dioecious in glabrous panicles rising out of the axils of the preceding year's shoot; calyx present, persisting under the fruit, corolla absent. Fruit obovate-oblong; body slightly compressed; wing long, decurrent, many-nerved, and rounded, apiculate or emarginate at the apex.

Fraxinus oregona can only be confused with sessile forms of *F. pennsylvanica*, which has longer serrate leaflets, with more nerves, tapering gradually to the base. In *F. oregona* the leaflets are shorter in proportion to their breadth, and are usually entire in margin; but this last character is not absolutely distinctive, as the leaflets of the two species vary in regard to the presence or absence and size of the serrations.

¹ Aiton, *Hort. Kew.* v. 476 (1813).

² *Forest Wealth of Canada*, p. 23.

This species was discovered by David Douglas in 1825 on the banks of the Lower Columbia river. It is mentioned by Koch¹ as having been in cultivation in the Botanic Garden of Berlin prior to 1872. (A. H.)

This tree is the common ash of north-west America, extending from Puget Sound through western Washington and Oregon and the coast region of California to San Francisco, and along the western foothills of the Sierra Nevada to San Bernardino and San Diego counties. It is an important timber tree in Oregon and Washington, but if it occurs in British Columbia,² is too scarce to be noticed by Macoun. I saw no trees of great size during either of my visits to the Pacific coast, but Sheldon³ says that it attains as much as 100 feet in height and 1 to 4 feet in diameter, and describes the wood as hard, tough, firm, straight-grained, and taking a high polish.

In California, according to Jepson,⁴ *F. oregona* only attains a length of 15 to 30 feet, growing along the Sacramento river, and on the banks of the streams of the coast ranges. The leaflets become glabrous with age; and on this account Lingelsheim⁵ has distinguished the Californian form as var. *glabra*.

In England the tree grows well in a young state; but I know of none of any size, except one at Nuneham Court, Oxfordshire, which in 1907 was 63 feet high and 3 feet 8 inches in girth. A tree of *F. americana* growing near it, and believed to have been planted at the same time, was only 38 feet by 1 foot 8 inches. Sir Charles Strickland has a plantation at Hildenley, Yorkshire, of this species mixed with larch; and as these trees, when I saw them in 1901, were 20 to 30 feet high, and had ripened seed from which I have raised plants, I think their hardiness in this country is abundantly proved; and that the tree is more likely to succeed in the west and north of England than the eastern American ashes. At Tortworth Court Lord Ducie has made a mixed plantation of *F. americana* and this species, which are now 20 to 30 feet high at about fifteen years old; but the soil and situation are not very favourable. In 1908 the Oregon ash were bearing seed freely. (H. J. E.)

¹ *Dendrologie*, ii. 1, p. 260 (1872).

² Piper, *Flora of the State of Washington*, 449 (1906), says its range is "British Columbia to California, in the coast region"; but gives no localities for British Columbia. It is not mentioned as occurring in Vancouver Island by the authors of *Postelsia*, the year-book of the Minnesota Seaside Station for 1906.

³ *Forest Wealth of Oregon*, 32 (1904).

⁴ *Flora W. Mid. California*, 385 (1901).

⁵ In Engler, *Bot. Jahrb.* xl. 220 (1907).

FRAXINUS CAROLINIANA, SWAMP ASH

Fraxinus caroliniana, Miller, *Dict.* No. 6 (1768); Loudon, *Arb. et Frut. Brit.* ii. 1237 (1838); Sargent, *Silva N. Amer.* vi. 55, t. 274, 275 (1894), and *Trees N. Amer.* 762 (1905).
Fraxinus platycarpa, Michaux, *Fl. Bor. Amer.* ii. 256 (1803).
Fraxinus triptera, Nuttall, *Gen.* ii. 232 (1818).
Fraxinus cubensis, Grisebach, *Cat. Pl. Cub.* 170 (1866).

A tree attaining 40 feet in height, with a stem 3 feet in girth; bark marked by irregularly-shaped brown patches, separating on the surface into thin scales. Branchlets glabrous or pubescent, with white minute scattered lenticels. Leaflets (Plate 263, Fig. 12) seven, occasionally five, stalked (petiolule $\frac{1}{4}$ to $\frac{3}{8}$ inch), about 3 inches long, oval; unequal, rounded, or broadly cuneate at the base; apex shortly acuminate; finely and irregularly serrate; green and glabrous on the under surface except for some white pubescence along the sides of the midrib and nerves, or in some forms pubescent throughout. Leaf rachis, glabrous or pubescent, with two slight wings on the upper side, forming a groove.

Flowers (section *Leptaliæ*) diœcious in panicles arising in the axils of leaf-scars of the preceding year's shoot; calyx present, persisting under the fruit; corolla absent. Fruit broad, elliptic or spatulate; body short and compressed, surrounded by a pinnately-veined broad thin wing.

This species grows in river swamps in the coast regions of the Atlantic and Gulf States from southern Virginia to the valley of the Sabine river in Texas, extending through western Louisiana northwards to south-western Arkansas. It also occurs in Cuba.

This species was introduced into England in 1783, according to Loudon, who, however, mentions no trees of any size as growing in England in 1838. We have seen no specimens, except small trees at Kew, which are thriving. (A. H.)

FRAXINUS VELUTINA

Fraxinus velutina, Torrey, *Emory's Report* 149 (1848); Sargent, *Silva N. Amer.* vi. 41, t. 267 (1894), and *Trees N. Amer.* 774 (1905).
Fraxinus pistaciaefolia, Torrey, *Pacific R. Report*, iv. 128 (1856).

A tree, 40 feet high, with a girth of stem of 2 feet. Bark deeply divided into broad flat broken scaly ridges. Shoots purple, covered with dense white pubescence; lenticels white. Leaflets (Plate 265, Fig. 20), small, about $1\frac{1}{2}$ inch long, three or five, occasionally seven or nine, or rarely only one, and variable in shape, margin, and insertion; usually sessile, occasionally stalked, the terminal leaflet often obovate, the lateral leaflets commonly lanceolate with cuneate base and acuminate

apex; coarsely serrate in the upper half or two-thirds, but sometimes entire, ciliate; upper surface pubescent; lower surface densely white pubescent. Rachis of the leaf white pubescent and deeply grooved on its upper side.

Flowers (section *Leptaliæ*) diœcious in short panicles in the axils of the leaf-scars of the preceding year's shoot; calyx present and persisting under the fruit; corolla absent. Fruit spatulate, with terete body and terminal wing.

This species is readily distinguished by the dense white pubescence over the shoot, leaf-rachis, and leaflets, the latter being variable in number and smaller than those of the other pubescent ashes, except *F. xanthoxyloides*, which has still smaller leaflets with a broadly winged rachis and is much less strongly pubescent.

Fraxinus velutina occurs usually in elevated cañons beside streams in Texas, New Mexico, Arizona, southern Nevada, and south-east California.

Young trees are doing well at Kew, where they are of considerable interest from their peculiar foliage, which gives them a neat and elegant appearance. The oldest, planted in 1891, are now about 15 feet high. (A. H.)

ZELKOVA

Zelkova,¹ Spach, in *Ann. Sc. Nat. sér. 2*, xv. 356 (1841); Bentham et Hooker, *Gen. Pl.* iii. 353 (1880); Nicholson, in *Woods and Forests*, 1884, p. 176.

Abelicea, Reichenbach, *Consp. Veg.* 84 (1828); Schneider, *Laubholzkunde*, i. 224 (1904).

Planera, Gmelin, subgenus *Abelicea*, Planchon, in *Ann. Sc. Nat. sér. 3*, x. 261 (1848).

DECIDUOUS trees or shrubs, belonging to the order Ulmaceæ. Branchlets slender, distichous. Leaves alternate, distichous, simple, shortly stalked, penni-nerved, crenately serrate. Stipules in pairs, membranous, lanceolate, caducous.

Flowers monœcious; corolla absent; calyx, four- or five-lobed. Staminate flowers, clustered, two to five together, on the branchlets below the leaves or in the axils of the lowermost leaves; disc absent; stamens, four or five, with short, erect filaments and exserted anthers; ovary rudimentary or absent. Pistillate flowers, solitary in the axils of the uppermost leaves; disc cupular, fleshy; staminodes present or absent; ovary sessile; styles, two, stigmatiferous on the inner side; ovule solitary, pendulous. Fruit, a small drupe, sessile, subtended by the persistent calyx, subglobose, oblique, veined or rugose on the surface, crowned by the remains of the styles, persisting as two minute beaks; with a membranous or slightly fleshy outer covering, and a thin, hard endocarp or stone, containing a compressed, concave, horizontal seed, without albumen. The fruit ripens late in autumn, and persists on the branchlets till the following spring.

In *Zelkova* no true terminal bud is formed, and the tip of the branchlet falls off in early summer, leaving a small circular scar at the apex of the twig. The base of the shoot is ringed with the scars of the inner scales of the previous season's bud, and shows, as a rule, a few of the outer scales persisting dry and membranous. The buds, all axillary, and composed of numerous imbricated scales, are often multiple, two being then developed, side by side, in a single axil. The leaf-scars are narrow, crescentic, and three-dotted; with a linear stipule-scar on each side. In *Ulmus* the buds are single in the axils, and none of the scales persist at the base of the shoot.

Three species of *Zelkova*² are known to exist in the wild state, two of which are large trees well known in cultivation, *Z. acuminata*, Planchon, a native of China and

¹ The name *Zelkova* is sanctioned, and *Abelicea* rejected in *Actes Congrès Internat. Bot. Vienne*, 77 (1906).

² *Hemiptelea Davidii*, Planchon, *Compt. Rend. Acad. Paris*, lxxiv. 1496 (1872), a thorny tree, occurring in northern and central China and Korea, is united with *Zelkova* by Bentham and Hooker, in *Gen. Pl.* iii. p. 353. It differs from that genus in having winged fruit. Cf. Schneider, *Laubholzkunde*, i. 224. This species does not appear to be in cultivation in Europe.

Zelkova

Japan, and *Z. crenata*, Spach, inhabiting the Caucasus and North Persia. The third species, *Z. cretica*, Spach, is a shrub growing in Crete and Cyprus, which has not yet been introduced, and does not come within the scope of our work. The following species, also a shrub, is only known in cultivation:—

Zelkova Verschaffeltii, Nicholson, *Kew Handlist of Trees*, 145 (1896).

Zelkova japonica, Dippel, var. *Verschaffeltii*, Dippel, *Laubholzkunde*, ii. 39, fig. 14 (1892).

A shrub or small tree. Branchlets slender, pubescent, with white hairs. Leaves (Plate 267, Fig. 8), coriaceous, variable in size, from $1\frac{1}{4}$ inch long by $\frac{3}{4}$ inch wide to $2\frac{1}{2}$ inches long by $1\frac{1}{4}$ inch wide, oval, acuminate at the apex, cuneate and unequal at the base, divided by the midrib into unequal halves, the larger half with six to eight nerves, the smaller half with four to seven nerves, each nerve ending in a long triangular tooth, tipped with a short cartilaginous point; margin ciliate; upper surface dark green, with scattered white pubescence; lower surface light green, with downy white pubescence, densest on the midrib and nerves; petiole, $\frac{1}{8}$ inch to $\frac{1}{4}$ inch, pubescent. Buds, often two together in an axil, small, globose, pubescent. Fruit similar to that of *Z. crenata*, but slightly smaller in size.

This species, which resembles an elm in having asymmetrical oblique leaves, was considered by Schneider¹ to be a peculiar variety of *Ulmus glabra*, and is occasionally met with in cultivation, as *Ulmus Verschaffeltii*, and *Ulmus pendula laciniata Pittcursii*.

A tree, 15 feet high, in the nursery of the Paris Municipality, specimens of which have been sent us by M. Vacherot, produced flowers and fruit this year; and the fruit, hitherto unknown, proves to be that of a *Zelkova*. *Z. Verschaffeltii* is not known in the wild state, though Koehne² states that O. Kuntze collected specimens of *Z. crenata* in the Caucasus, which strongly resembled it. It is possibly a hybrid between *Z. crenata* and *Z. cretica*, and was first noticed by Dippel in 1892.

(A. H.)

ZELKOVA CRENATA

Zelkova crenata, Spach, *Ann. Sc. Nat.* xv. 358 (1841); Boissier, *Fl. Orientalis*, iv. 1159 (1879).

Zelkova carpinifolia, Dippel, *Laubholzkunde*, ii. 38 (1892).

Zelkova ulmoides, Schneider, *Laubholzkunde*, i. 806 (1906).

Rhamnus ulmoides, Gleditsch, *Itin.* i. 313 (1787).

Rhamnus carpinifolius, Pallas, *Fl. Rossica*, i. 2, 24 (1788).

Planera Richardi, Michaux, *Fl. Bor. Am.* ii. 248 (1803); Loudon, *Arb. et Frut. Brit.* iii. 1409 (1838).

Planera carpinifolia, Watson, *Dendrol. Brit.* 106, t. 106 (1825); Koch, *Dendrol.* ii. 1. 425 (1872).

Planera crenata, Desfontaines, *Cat. Hort. Paris* (1829).

Abelicea ulmoides, Kuntze, *Rev. Gen.* ii. 621 (1892); Schneider, *Laubholzkunde*, i. 224 (1904).

A tree attaining about 100 feet in height, and 15 feet in girth. Bark thin, smooth, greyish-brown, marked with persistent lenticels; on older trees, scaling off in small

¹ *Laubholzkunde*, i. 226 (1904).

² *Deutsche Dendrologie*, 137 (1893).

irregular plates. Branchlets covered with dense, white pubescence. Leaves (Plate 267, Fig. 6), slightly coriaceous, about 3 inches long and $1\frac{1}{2}$ inch wide, oval-lanceolate, acute at the apex, cordate and unequal at the base, with nine to eleven pairs of nerves, each ending in a crenate serration, the apex of which is minutely pointed; margin ciliate; upper surface dark green, with scattered minute pubescence; lower surface more or less covered with white pubescence, densest on the midrib and nerves; petiole, $\frac{1}{8}$ to $\frac{3}{16}$ inch, pubescent.

Fruit, about $\frac{1}{5}$ inch long, pubescent, with a very slight depression on either side of the prominent ridge on the upper surface.

In winter the twigs are pubescent, and bear elongated conical buds, which are brownish, tinged with white in colour, owing to the scales, which are glabrous on the surface, being fringed with long, white cilia.

This species is readily distinguished by the pubescent oval leaves, acute and not acuminate at the apex, the serrations only showing minute points. *Z. acuminata* has glabrous ovate leaves, with a long acuminate apex, the serrations ending in long, sharp, often recurved points.

DISTRIBUTION

This species occurs in the Russian provinces, lying south of the main range of the Caucasus, and in northern Persia, in the territory bordering on the Caspian Sea, extending as far eastward as Asterabad.

The best account of its distribution in Transcaucasia is given by Scharrer,¹ who states that it grows wild in two distinct areas, one in the government of Kutais and the other in Talysch, while there are a few scattered trees at Araxes, in the Karabagh district. In Kutais it grows in the Mingrelian plain, east of Sennakh, and ascends in the lower mountains of Imeritia to about 1000 feet, occurring at low levels in small groups in the oak forests, and at higher elevations mixed with ash, maple, and beech, and never forming pure woods. In Talysch it is not found on the marshy plains, but is common in river valleys, ascending on the mountains to 5000 feet, and often forming pure and dense woods. Scharrer measured a tree, 100 feet in height, with a stem 8 feet in diameter and free of branches to sixty feet. The climate in which it thrives is humid, with a rainfall of 50 or 60 inches; and it requires a moist, permeable, rich soil to come to perfection. At Tiflis, however, where the rainfall is only $19\frac{1}{2}$ inches, the tree is met with growing on good loamy soil and on rocky mountain slopes, but is slower in growth than in Mingrelia. It has borne without injury a temperature of -24° C.

The elder Michaux,² who travelled in Persia in 1782, and saw the tree growing in the forests of Ghilan, states that it commonly attains a height of 80 feet, with a girth of 9 to 12 feet, with a straight trunk, branching at about thirty feet up, and resembling the hornbeam in its bark, fluted trunk, and mode of branching. Scharrer, however, states that in the forest it produces clean stems, very uniform in thickness

¹ *Gartenflora*, xxxvi. 187 (1887).

² Cf. André Michaux, *Mémoire sur le Zelkova* (Paris, 1831).

and free from branches, except at the summit, excelling in this respect most broad-leaved trees. It grows fast in youth, continuing its growth in height to sixty or eighty years old, afterwards mainly increasing in girth. It is moderate in its demands for light, and gives good coppice shoots.

CULTIVATION

This species was introduced into cultivation in 1760, the oldest known tree in Europe being one¹ in the garden of M. Lemmonier at Petit Montreuil, near Paris, which was cut down in 1820, when it was 72 feet in height and 6 feet 8 inches in girth. It is probable that the elder Michaux, who saw this tree growing in northern Persia in 1782, also introduced seed.¹ Further consignments¹ were sent to France in 1831, by Chevalier Gamba, French Consul at Tiflis. Seeds from this source germinated after lying eighteen months in the ground; but Gay, in a note in the Kew Herbarium, states that this tardy germination was probably accidental, as seeds from Karabagh, which he sowed in the last days of March, produced seedlings, which were peeping out of the ground at the end of May. (A. H.)

This tree is now rarely seen in nurseries, though it is easily propagated by suckers, and seed could be procured without difficulty from its native country. In consequence it is hardly known to modern gardeners, though both from its ornamental habit and valuable timber it would be much better worth planting than many trees of more recent introduction.

The principal point to be attended to is to protect it from frost, and prune it carefully until the main stem has attained the desired height; and to plant it in a deep, rich alluvial soil, and warm, sheltered situation. So far as I have been able to learn, no tree has produced fertile seed in this country.

REMARKABLE TREES

A remarkable tree at Wardour Castle, Tisbury, Wiltshire, is reputed by tradition to have been sent, when quite young, from North America by the second Lord Baltimore, about 1632, and has been supposed² to be *Planera aquatica*, Gmelin,³ a native of swamps in the south-eastern United States. There must be some error in the tradition, as the tree is undoubtedly *Zelkova crenata*. It is known as the Iron tree, and the late Lord Arundell of Wardour assured me that this name, used in America for the Hornbeam and Hop Hornbeam, was a proof of its American origin. He also believed that the tree had been cut down during the siege of Wardour Castle in Cromwell's time, and had afterwards produced from the stool the seventeen

¹ André Michaux, *Mémoire sur le Zelkova* (Paris, 1831).

² See a lengthened correspondence concerning this tree in *Garden*, xxiv. 370 (1883), xxvi. 38 (1884), and xxxii. 92 (1887).

³ This species was introduced into England in 1816, according to Loudon, *Arb. et Frut. Brit.* iii. 1413 (1838); but it appears to be unsuitable for our climate, and no specimens are known to us to exist, except two plants in the Elm collection at Kew, about 8 feet high, which were introduced in 1897, and are thriving so far.

tall stems which it now shows (Plate 248). These measure from 5 to 8 feet in girth, the whole forming a group about 12 feet wide, and some of them reaching nearly 100 feet in height. There are many small suckers, as usual, and some of these have been transplanted to the front of the present mansion, where they were, when I saw them in 1903, about 25 feet high. Lord Arundell was good enough to give me two rooted suckers from the old tree, one of which is now planted at Tortworth Court, and the other at Colesborne.

At Holme Lacy, Hertfordshire, the seat of the Earl of Chesterfield, there is a very fine tree standing on a walled depression near the house. Its bole was until recently surrounded by laurels, which have now been cleared away, so that I was able in October 1908 to measure it carefully. I found it to be about 95 feet high by 19 feet in girth at the smallest point, about 3 feet from the ground. A photograph of this tree is at Kew, and it was reported in 1884 to be 70 feet high.

There are several trees in Kew Gardens, the largest growing in front of the Herbarium, and measuring 60 feet in height and 9 feet 3 inches in girth. A larger specimen was cut down a good many years ago, and a section of the trunk is exhibited in the Timbers Museum.

There are several fine trees at Syon,¹ the largest near the lake being, in 1905, 98 feet in height and 12 feet 7 inches in girth, while another is 89 feet by 13 feet. Both these trees are remarkable for their buttressed stems. Near the bridge there is a slender specimen, crowded by other trees, which is 92 feet high, with a stem 7 feet 2 inches in girth, and free of branches to about 50 feet.

At Albury there is a remarkable specimen, with a bole of only 4 feet in height, but 16 feet in girth, dividing into numerous stems.

In the Wilderness, at Croome Court, Lady Coventry showed me a tree of this species, which was supposed to be a species of hornbeam. It measured, in 1906, 65 feet by 14½ feet, and grew in an angle between two hedges, into which its suckers had spread profusely, and being clipped with the hedge, may eventually form part of it when the original tree dies. Another tree grows in the Temple Shrubberies at the same place, about 70 feet by 7 feet, with a clean trunk about 15 feet long, and was of a better shape, but is now partially decayed.

At Pitt House, near Chudleigh, Devonshire, the seat of Captain Morrison Bell, there are several Zelkovas which seem to thrive well in this climate. The largest is a very well-shaped and healthy tree measuring 80 to 85 feet by 13 feet. Its leaves were beginning to unfold on 15th April 1908. Some trees have thrown up suckers in the hedge by the high road here, but the gardener has not observed any flowers.

At Oxford, in the University Park, on the banks of the Cherwell, there are two, the larger of which, not a well-shaped tree, is about 80 feet by 12½ feet.

At Kyre Park there are two trees on the banks of a pond near the house, both of which have begun to decay, and large pieces of the smooth bark were dropping off them when I visited Kyre in 1904. The largest measured about 75 feet by 16 feet

¹ According to Loudon the largest tree at Syon was in 1834, 54 feet high and 2 feet 3 inches in diameter.

7 inches. Mrs. Childe tells me that in the hot summer of 1905 flowers were produced by this tree.

At Belshill, near Belford, Northumberland, the property of Sir W. Church, Bart., there is a fine tree in a sheltered situation which measures 70 feet by 9 feet 10 inches, and looks healthy, though it is believed to be over 100 years old.

In Scotland we have not seen or heard of any trees, though there is no doubt it would grow well in the south and west, where the climate is much better than at Belshill.

There are two trees at Glasnevin, one 50 feet and the other, a remarkably fine one, 61 feet in girth (Plate 249). Both are 9 feet in girth, and divide at 10 feet up into numerous branches.

A tree¹ at Verrières, near Paris, is 70 feet in height and 8 feet in girth.

There is a large tree in the grounds of the Petit Trianon at Versailles, about 90 feet by 10 to 12 feet, which appears to be grafted on the roots of an elm, and Mr. Hickel informed me that most of the older trees in France were so grown.

This species² is represented in the United States at Woodlands, Philadelphia, where there are growing in a cemetery a few low bushy trees, with short trunks, 4 feet in diameter, and numerous erect branches.

TIMBER

According to Scharrer the wood is homogeneous, prettily veined, very tough and flexible, does not crack and warp, takes a fine polish, and is very durable even when placed in wet situations. It is very suitable for cabinet-work and carriage-building. The native name of the tree, *dzelkwa*, signifies "stone-wood," so-called on account of the hardness of the timber, into which nails are driven with difficulty.

The younger Michaux, who examined a tree cut down at Paris in 1820, states that the sapwood is white, and the heartwood reddish in colour, the latter being heavier and stronger than that of elm, while even the sapwood equalled the ash in strength and elasticity.

A plank of this wood cut from a tree which grew at Boynton, in Yorkshire, was given me by Sir Charles Strickland, and resembles the wood of the Japanese species in texture and colour. Mrs. Baldwyn Childe has also sent me a specimen of it from a branch of her tree. Though unknown in the trade, and, as far as I can learn, never cut for export, I believe that this wood would prove valuable for making furniture if it could be obtained at a reasonable price. (H. J. E.)

A tree attaining in Japan 120 feet in height and 15 feet or more in girth. Bark smooth, greyish, resembling that of a beech, but on old trees dividing on the surface into irregular rounded scaly plates. Branchlets slender, at first with a scattered slight pubescence, but becoming glabrous in summer. Leaves (Plate 267, Fig. 7), membranous, thinner than those of the Caucasian species, about 3 inches long and $1\frac{1}{4}$ inch broad, ovate, with a long acuminate apex, slightly cordate and unequal at the base; nerves, nine to twelve pairs, each ending in the long, sharp, often recurved tip of a serration; margin ciliate at first, the cilia falling off in summer; upper surface dark green, with scattered, short, stiff hairs; lower surface light green, at first slightly pubescent, becoming glabrous in summer; petiole $\frac{3}{8}$ to $\frac{1}{4}$ inch, glabrescent.

Fruit about $\frac{1}{8}$ inch broad, sub-globose, oblique, with a concave depression on either side of a transverse ridge on the upper surface, which bears the remains of the styles; prominently veined, glabrescent.

In winter the twigs are glabrous, and the buds are minute, ovoid, uniformly brown in colour, with glabrous slightly ciliate scales.

DISTRIBUTION

Zelkova acuminata occurs in China and Korea, as well as in Japan, but appears to be only common in China in the Tsin-Ling mountain in Shensi, where it was collected by Père Giraldi.¹ It has also been found² in the province of Chekiang, on the hills near the Taihoo Lake, and on the mountains inland from Ningpo. Carles² collected it near Seoul in Korea.

It is much more widely distributed in Japan, occurring throughout Kiushiu, Shikoku, and Honshu, forming forests in mixture with maple, beech, *Quercus grosseserrata*, and other broad-leaved trees. According to Shirasawa, it is usually of branching habit in the forest, the tallest and stoutest trees being those cultivated

¹ Diels, in Engler, *Jahrb.* xxxvi. No. 5, p. 33 (1905).

² Hemsley, *Journ. Linn. Soc. (Bot.)*, xxvi. 449 (1894).

near houses and temples, which often have clean stems due to pruning. Mayr, however, records a forest tree, 123 feet in height, with a stem 33 inches in diameter, and clean of branches to 57 feet. Dupont,¹ who gives many interesting particulars concerning this species, states that it ascends in Kiushiu to 3000 feet on northern slopes, and in Honshu to 4000 feet on southern slopes; and that it requires for its best development a deep, permeable, and rich soil, such as is found on alluvial tracts. It thrives well also on volcanic soils and sandy loams, but does not succeed on poor sands or on stiff clays. Dupont states that on suitable soils and situations it grows remarkably straight, whether isolated or crowded in the forest, attaining on soil of middling quality at 1600 feet elevation in the latitude of Fuji-yama, 5 feet in girth at 60 years old, 9 feet at 120 years, and $12\frac{1}{2}$ feet at 180 years. The growth of isolated trees on alluvial soil is still more rapid, the annual rings averaging $\frac{1}{8}$ inch in width. He advocates the planting of this tree on account of its rapid growth and the value of its timber, which he considers to be superior to that of oak. (A. H.)

It seems strange that this tree, whose wood is more highly valued by the Japanese than any other hard wood, should be planted on so small a scale in Japan. Probably it requires too many years to come to maturity to induce private persons to plant it when bamboo, Cryptomeria, and pine offer so quick and certain a return. But though I saw no plantations of Keaki,² I believe the Government are making efforts to preserve and increase the area under this species. It is said to be found wild in the south up to about 5000 feet, and in the north up to about 2000 feet. It also grows wild in Hokkaido, but not to so great a size as in the north-eastern districts of the main island which are famous for their large trees. I heard of, but was not able to see, one said to be the largest in Japan at Sendai. Rein³ speaks of one which was felled at Meguro, near Tokio, in 1874, and measured 11.7 metres in girth at one metre high.

The largest I measured myself was growing by the side of the Nakasendo road, at a place called Hideshiwa, near the village of Sooga in Shinano, in a grove of trees just below the road, and may have been wild or planted. It was about 115 feet high and 20 feet in girth, dividing at about 20 feet, into two tall upright limbs, each 10 feet or more in girth, and seemed to contain about 800 to 1000 cubic feet of timber. Close to it was a very large *Æsculus*, and on the other side of the road another Keaki, 113 feet high, by 13 feet 6 inches in girth, clean and straight to about 70 feet high.

Such trees as these are found only where they have been crowded when young, the tendency of the species being to assume a branching and spreading habit, so that most of these which are seen planted singly are thick and spreading rather than tall.

In the forest the Keaki grows scattered among other trees, and is said by the author of the handbook on Japanese forestry to love calcareous soils. I never saw any such soil in Japan, but it seemed to grow equally well on all kinds of soil provided it is deep and moist. As to the age to which the tree attains I cannot speak positively, but it looks like a very long-lived tree. Its bark is smooth and greyish in colour, somewhat like that of the beech. It seeds freely and reproduces itself

¹ *Essences Forest. du Japon*, 45 (1879).

² The Japanese name of this species is *Keyaki*, occasionally spelled *Keaki*.

³ *Industries of Japan*, 225 (1889).

easily, the seedlings being hardy and fast growing and bearing shade well. In appearance the Zelkova is not an ungraceful tree, resembling a beech perhaps more than an elm, but its small leaves make it a poor shade tree, and its habit of growth varies very much according to the situation in which it grows.

CULTIVATION

This species was introduced into cultivation in England by J. Gould Veitch,¹ who sent seeds from Japan in 1862. It was apparently introduced on the Continent a few years earlier by Siebold; and Koch, writing in 1872, mentions that it had been cultivated previously for several years in the Botanic Garden at Berlin, where it had sustained severe frost without injury.

I raised a quantity of seedlings in 1901 from Japanese seed, which grew rapidly at first, and seemed quite hardy; but those which I have planted out grow slowly, and, where not protected from spring frost, have been killed back every winter, so that they produce bushy shrubs. I should, therefore, suppose that it requires more summer heat and moisture than most parts of England afford, and that it should be planted only in rich, deep soil, where it can be shaded and drawn up by other trees. Careful pruning is also evidently necessary to check its tendency to produce lateral branches when young, and I do not anticipate that it will ever attain large dimensions in Great Britain or be worth planting for its timber.

So far as we have ascertained there are no large trees existing in England, the best specimens we have seen at Kew Gardens, at Tortworth, and in Lord Kesteven's woods at Casewick, Lincolnshire, not exceeding 20 to 30 feet in height.

Mr. C. Palmer tells me that in November 1864, he planted a specimen received from Veitch, then 3 feet high, in an exposed situation, at about 500 feet above the sea, near Stukeley Grange, Leighton Buzzard. This tree in 1874 was 18½ feet high by 6 inches only in girth. In 1892 it had increased to 2 feet in girth.

A good-sized and healthy-looking tree, of whose age no record can be found, grows near the pond below the entrance from Woburn village to Woburn Park on the right-hand side of the drive.

At Kilmacurragh, Co. Wicklow, a healthy tree measured, in 1904, 41 feet in height and 3 feet 1 inch in girth.

The oldest and largest tree of this species that we know of in Europe is growing in the Botanic Gardens at Karlsruhe. I am indebted to Herr Max Leichtlin, of Baden-Baden, for a photograph of this tree (Plate 250), and Herr Gräbener has also sent us one. He informs us that it is one of three seedlings which was raised at St. Petersburg (or brought from Leyden). It was planted sometime between 1859 and 1861, and has never suffered from frost, having sustained the severe winter of 1879-1880 without injury.² In 1904 it measured at 1½ metre from the ground 3.10 metres in girth.

¹ *Hortus Veitchii*, 386 (1906). Mr. H. J. Veitch informs me that the plants raised at Coombe Wood only attained 3 to 4 feet in height, and gradually died out, the whole being finally lost during a severe winter.

² Mayr says that at Grafrath it has endured -25° Cent. without injury.

This species¹ has been planted pure in small experimental plots at five different forestry stations in Germany; but the results have not been encouraging. Both Schwappach and Mayr consider that it probably would succeed if planted in mixture with other hardwood trees.

In the Botanic Garden at Copenhagen, Henry saw, in 1908, a fine tree, about 40 feet high, but dividing into three stems at 2 feet from the ground. This tree was planted about 1870, and exceeds considerably in size a *Z. crenata* planted beside it the same year. At Christiania, *Z. acuminata* remains a bush about a foot high, being repeatedly cut by frost.

The largest specimens in the United States are two trees, growing in Dr. Hall's gardens at Warren, Rhode Island, which were raised from seed sent home in 1862. According to Sargent,² who says that this species is probably the only Japanese tree worth introducing into North America, on a large scale for timber, these have received no special care, the soil is not particularly good, and their growth has been checked by overcrowding. They were about 50 feet high in 1893, with trunks about a foot in diameter, and had produced flowers and fruit. There appear³ to be several other trees of this species in the same garden, and hundreds of self-sown seedlings were observed near them in 1893. The only drawback⁴ to the cultivation of this species in America is that it is subject to the attack of the elm-leaf beetle.

TIMBER

The wood⁵ resembles in structure that of the elm, the vessels being disposed in similar broken lines. The sapwood, according to Mayr, about 1½ inch in thickness, and white in colour, is separated from the brown heartwood by a narrow pink zone. According to Dupont,⁶ the wood, while like that of the elm in appearance, is more like the ash in working, as it bends readily, and is of great strength, surpassing even the oak in this quality. It resists exposure to moisture, and is very durable for building purposes. It is much used in Japan for making furniture, an especial kind, cut from burrs, and called *jo-rin-moku*, being especially esteemed. The most beautiful trays and cabinets⁷ which come from Japan are made of dark, irregularly grained, and wavy-lined wood of the Zelkova. Many of these trays are ornamented with the bark of *Pterocarya*. Dupont says that the wood contains an oil, with a disagreeable odour, which prevents it from being made into articles used for containing liquids.

The wood is the most valuable in Japan for building, for furniture, and for all purposes where a strong, tough, durable wood, not liable to warp, crack, or decay, is required; and it is also valuable for carving and lacquering. It is the highest priced wood in Japan, worth in ordinary sizes up to 4s. per cubic foot, and for finely grained or very wide planks much more. I was told that a single large plank of

⁷ Sargent, *Garden and Forest*, x. 40 (1879).

finely grained wood of this tree shown at the Osaka Exhibition in 1903 was priced at 800 yen (over £80); and I saw beautifully figured pieces myself of a peculiar reddish tint which were held for fancy prices, such pieces being much valued for the construction of the dais which is a marked feature in Japanese rooms, and on which is the seat of honour. Most of the pillars, beams, gateways, gates, and carved roofs, which are so striking a feature in Japanese temples, old and new, are made of Keaki wood, which seems indestructible by time or damp when covered in, and I was told that some of these which looked sound, though much weather worn, were 1000 years old. It seemed to me, however, that 1000 years is simply a convenient expression in Japan for anything very old, though no doubt historical evidence could be found if wanted as to the durability of this fine wood. The fancy grained varieties are known as Jorin, Uzura (partridge), Tama (gem), or Botan (peony), and these are used for cabinetmaking and fancy work. The colour, according to Rein, is deepened by long submersion in water. Rein gives the specific gravity of the wood at 0.682. I bought some of the wood in Japan, and have used it in making a large wardrobe; it takes polish well, makes good joints, and seems equal to mahogany for furniture making, but so far as I can learn has not as yet been imported, and is unknown in the trade.

(H. J. E.)

Momisia, F. G. Dietrich, *Lexic. Garten.* v. 128 (1819).
Solenostigma, Endlicher, *Prod. Fl. Norf.* 41 (1833).

THE genus *Celtis*, belonging to the order Ulmaceæ, comprises about sixty species, spread over the temperate and tropical regions of the northern hemisphere; and was divided into four sub-genera by Planchon.¹ In the following account, the characters of one of the sub-genera, *Euceltis*, are given, as all the species in cultivation belong to it.

Deciduous trees, without spines. Leaves stipulate, alternate, distichous, simple, stalked, serrate or entire, usually oblique and three-nerved (rarely four- or five-nerved) at the base, the midrib and basal nerves giving off pinnately secondary nerves.

Flowers minute, pedicellate on the branchlets of the year, polygamo-monoecious. Staminate flowers in few-flowered fascicles from the axils of caducous bud-scales. Perfect flowers solitary or in two- to three-flowered fascicles in the axils of the lower leaves. Calyx four- or five-lobed, imbricate in æstivation, deciduous. Corolla absent. Stamens, four or five, inserted under the margin of a pubescent disc; filaments, subulate, erect and exerted in the staminate flowers, shorter and included, occasionally absent, in the perfect flowers; anthers two-celled, extrorse, opening longitudinally. Ovary sessile, one-celled, crowned with a short style, divided into two divergent, elongated, reflexed lobes, papillo-stigmatic on the inner surface; ovule solitary, suspended. Fruit, a fleshy drupe, with a firm epicarp, a succulent thin mesocarp, and a thick-walled bony stone, containing one seed. Cotyledons emarginate at the apex, raised above ground in germination.

Seven species of *Celtis* are in cultivation in this country, which may be distinguished as follows:—

I. *Leaves ovate.*

* *Leaves quite glabrous.*

1. *Celtis Davidiana*, Carrière. China. See p. 929.

Leaves shining on both surfaces, toothed in the upper third, shortly acuminate, minutely punctate when viewed with a lens.

¹ De Candolle, *Prod.* xvii. 169 (1873).

2. *Celtis glabrata*, Steven. Asia Minor, Caucasus. See p. 929.
Leaves bluish green, serrate except near the base, acute or very shortly acuminate, conspicuously punctate when viewed with a lens.

** *Leaves pubescent.*

3. *Celtis occidentalis*, Linnæus. North America. See p. 930.
Leaves caudate-acuminate, serrate in the upper half or two-thirds, smooth to the touch above, pubescent on the nerves beneath.
4. *Celtis crassifolia*, Lamarck. North America. See p. 932.
Leaves shortly acuminate, serrate in the upper half or two-thirds, scabrous to the touch above, pubescent on the nerves beneath.

II. *Leaves lanceolate.*

* *Leaves usually entire.*

5. *Celtis mississippiensis*, Bosc. North America. See p. 933.
Leaves, entire in margin, rarely dentate at the apex, glabrous except for axil tufts at the base beneath.

** *Leaves serrate.*

6. *Celtis australis*, Linnæus. Southern Europe, North Africa, Caucasus. See below.
Leaves caudate-acuminate, covered beneath throughout with a soft pubescence.
7. *Celtis caucasica*, Willdenow. Caucasus, Persia, Afghanistan, Baluchistan, N. India. See p. 928.
Leaves shortly acuminate, pubescent beneath only on the midrib and nerves.

(A. H.)

CELTIS AUSTRALIS, NETTLE TREE

Celtis australis, Linnæus, *Sp. Pl.* 1043 (1753); Loudon, *Arb. et Frut. Brit.* iii. 1414 (1838); Planchon in DC. *Prodr.* xvii. 169 (1873); Boissier, *Fl. Orientalis*, iv. 1156 (1879); Willkomm, *Forstliche Flora*, 545 (1887); Mathieu, *Flore Forestière*, 293 (1897).

A tree, usually attaining 50 to 70 feet in height, and 10 feet in girth, but in rare cases becoming as much as 20 feet in girth. Bark thin, greyish, smooth, somewhat resembling that of the beech, but on old trunks sometimes covered with warty excrescences. Young branchlets pubescent. Leaves (Plate 267, Fig. 5), about 4 inches long by $1\frac{1}{4}$ inch broad, oval-lanceolate, unequal and cuneate at the base, contracted above into a very long caudate-acuminate apex, serrate except near the base; upper surface dark green, scabrous, shortly-pubescent; lower surface greyish, covered with a soft tomentum; petiole greyish-tomentose, about $\frac{1}{2}$ inch long. Fruit globose, up to $\frac{1}{2}$ inch in diameter, at first whitish, then red, and finally dark-brown; with a scanty sweetish flesh. Fruit pedicel, very slender, an inch or more in length. The seedling¹ is similar to that of *C. occidentalis*; but the cotyledons are wider, rhomboidal in shape, and with a shallower emargination; and the primary leaves are longer, narrower, and more acuminate. The seedling attains about 8 inches in height in the first year.

¹ Lubbock, *Seedlings*, ii. 495 (1892).

In winter, the twigs are slender, tomentose. Leaf-scars crescentic, 3-dotted, on prominent pulvini. Stipule-scars linear, one on each side of each leaf-scar. Terminal bud not formed and scar present at the apex of the twig, as in *C. occidentalis*. Lateral buds, appressed to the twig, compressed, ovoid, acute, with 2 to 3 pairs of loose, tomentose, ciliate, imbricated scales.

No varieties of *C. australis* have been described; but in the eastern part of its area there are forms connecting it with *C. caucasica*, which is a very closely allied species.

Celtis australis is widely distributed throughout the Mediterranean region, and extends into Asia Minor and probably farther eastward, in the Caucasus and north Persia. In France, it is common in Provence and Languedoc, where it is often cultivated as coppice, and is met with as a rare tree as far north as Poitiers and Lyons. It is usually an inhabitant of the plains and low hills, but occasionally ascends to 3000 feet in the mountains. In the north of France, it is scarcely hardy, at least when young. It occurs in Switzerland in the canton of Tessin. Farther east, its northern limit is the southern parts of Tyrol, Styria, and Hungary, whence it extends southward through the Balkan States to Greece and Crete. In Banat, Istria, and Dalmatia it often forms small woods, and ascends to 1600 feet. It is in all these regions extensively planted, and has become naturalised in many districts. It also occurs in Spain and Portugal, Sardinia, Italy, Sicily, Morocco, Algeria, and Tunis; and is said to grow in the Madeira Islands.

Celtis australis attains a great age, and trees of extraordinary size are recorded, there being one¹ in the public square at Aix in Provence, estimated to be 500 years old, which is 19 feet in girth, and higher than any of the adjoining houses. There are fine specimens also in the Botanic Gardens at Montpellier, which are 10 to 12 feet in girth. Willkomm saw very large trees in the Balearic Islands, and says that enormous trees are to be seen in Istria and Dalmatia, one at Pisino being supposed to be 1000 years old.

Celtis australis produces suckers from the roots, and when cut gives good coppice shoots. In the south of France, coppice woods of this species are very valuable, as the shoots² attain about 4 inches in diameter in ten or twelve years, and are worth one to two francs each. The wood resembles much that of the ash, of which it has all the good qualities, and is used in carriage-building, and for making numerous kinds of small articles, as tool-handles, hay-forks, trenails, tent-pegs, etc. Whip handles in France are almost universally made of this wood, and are called "perpignans," because the chief place of manufacture is at Perpignan. The foliage is given to cattle as fodder, the seed contains a sweet oil, and the bark and root yield a yellow colouring matter.

Celtis australis was introduced³ in 1796, according to Loudon, who mentions a

¹ Mouillefert, *Traité des Arbres*, ii. 1207 (1898).

² Jolyet, *Les Forêts*, 226 (1901).

³ In the *London Catalogue of Trees*, 18 (1730), three species of *Celtis* are mentioned as being in cultivation in England:—

"I. Virginian Nettle Tree. Red fruit. In several gardens near London there are large trees.

II. Nettle Tree, with black fruit. European sort, is most rare in England.

III. *Celtis* with large yellow fruit. Has been grown in Devonshire many years, where there are some large trees, which produce ripe fruit, from which many plants have been raised; but we know not where it came from originally."

tree at Mitcham, which was 6 feet 8 inches in girth, and had a spread of 60 feet; and a tree at Kew, 40 feet in height, which no longer exists, there not being at present a single specimen there of this species. It appears to be very rare in cultivation at the present time, the only trees which we have seen being one at Liphook, and another at Hursley Park. The latter is a small unhealthy-looking tree about 20 feet high, though of considerable age. There is also a small tree at Tortworth.

According to Bureau,¹ this species supports at Paris the severest winters without injury; but according to Pardé,² it bears with difficulty severe frosts in the north of France. The seedlings which Elwes raised at Colesborne were killed by 20° of frost, and though the tree may succeed in the warmest and driest parts of the south-east of England, it seems hardly worth planting elsewhere. (A. H.)

CELTIS CAUCASICA

Celtis caucasica, Willdenow, *Sp. Pl.* iv. 994 (1805); Loudon, *Arb. et Frut. Brit.* iii. 1415 (1838); Boissier, *Flora Orientalis*, iv. 1156 (1879).

Celtis australis, Brandis, *Forest Flora of N.W. India*, 428 (1874), and *Indian Trees*, 595 (1906) (not Linnæus); Hooker, *Flora Brit. India*, v. 482 (1888); Gamble, *Indian Timbers*, 629 (1902).

A tree of moderate size, very similar to *C. australis*, of which it is possibly only a geographical form. It differs in the following characters:—Leaves ovate-lanceolate, broader in proportion to their length, and more rhomboidal, with a shorter and non-caudate acuminate apex; upper surface glabrescent, scarcely scabrous; lower surface with slight pubescence, confined to the nerves and midrib. Drupes yellow.³

This species, which is connected with the European species by var. *cuspidata*,⁴ with long-acuminate leaves, is widely spread through the Caucasus, Persia, Afghanistan, Baluchistan, and northern India. In the Caucasus, it is associated with *C. australis*; but farther east the latter species is scarcely met with. In Afghanistan, according to Aitchison,⁵ it is usually a planted tree near shrines and in graveyards; but it is quite wild along the Darban and Shendtoi rivers; and in Baluchistan, its leaves, according to Lace,⁶ are often used, as they are in India, for feeding sheep and goats, the trees being pollarded for this purpose. It occurs in India in the north-west Himalaya, as far east as Nepal ascending to 8000 feet, where it is a common tree, wild in the forests, and around villages. According to Webber,⁷ in Gorakhpur, it reverses the season of casting its leaves, which wither and fall off in the hot weather, and it flowers in the early months of the cold season. The wood is tough and strong, and is used for oars, tool-handles, sticks, and other purposes requiring toughness and elasticity.

This species, though mentioned by Loudon, was not in cultivation in England in his day; and Schneider⁸ doubts if it has yet been introduced on the Continent.

¹ *Nowv. Arch. Mus. Hist. Nat.* vi. 181 (1894).

² Brandis mentions a variety with purplish-black fruit.

³ *Journ. Linn. Soc. (Bot.)* xviii. 93 (1880).

⁴ *Forests of Upper India*, 232 (1902).

⁵ *Arb. Nat. Des Barres*, 242 (1906).

⁶ Planchon, in DC. *Prod.* xvii. 170 (1873).

⁷ *Ibid.* xxviii. 305 (1891).

⁸ *Laubholzkunde*, 231 (1904).

There is, however, a tree of this species in the Kew Collection, which is marked "Aitchison" on the label, and was probably raised from seeds sent by Aitchison from Afghanistan, about the year 1881. (A. H.)

CELTIS GLABRATA

Celtis glabrata, Steven, ex Planchon, in *Ann. Sc. Nat. sér. 3, x.* 285 (1848).

Celtis Tournefortii, Lamarck, var. *glabrata*, Boissier, *Fl. Orient.* iv. 1157 (1879).

A shrub or small tree. Young branchlets with a minute scattered pubescence. Leaves (Plate 267, Fig. 10), about 2 inches long, 1¼ inch broad, quite glabrous, ovate, unequal and rounded or broadly cuneate at the base, acute or very shortly acuminate at the apex, coarsely serrate except near the base; upper surface bluish green, roughened with minute papillæ; lower surface lighter green in colour; punctate with numerous translucent minute dots, when viewed with a lens; petiole glabrous, ⅓ inch. Fruit pedicels about an inch. Drupes globose, reddish brown.

This species occurs in Asia Minor, in Lycia and Cilicia, and in the Caucasus. Schneider doubts if it has been introduced into cultivation; but there is at Kew a small tree, undoubtedly of this species. *C. Tournefortii*, Lamarck, a closely allied species, occurring in Sicily, Greece, and Asia Minor, is mentioned by Loudon, as having been introduced into England in 1739, and cultivated in 1838 in the London Horticultural Society's Garden; but I have seen no specimens in this country. (A. H.)

CELTIS DAVIDIANA

Celtis Davidiana, Carrière, *Rev. Hort.* 1868, p. 300.

Celtis Bungeana, Blume (in part); Hemsley, *Journ. Linn. Soc. (Bot.)* xxvi. 449 (1894).

Celtis sinensis, Persoon (in part); Maximowicz, *Mél. Biol.* ix. 27 (1872); Bretschneider, *Botanicon Sinicum*, i. 117 (1882).

A small tree. Young branchlets slightly pubescent. Leaves (Plate 267, Fig. 11), about 2½ inches long, 1¼ inch broad, ovate or ovate-lanceolate, base rounded, contracted above into a short acuminate apex, rarely entire, usually slightly toothed in the upper third; glabrous and shining on both surfaces, dark green above, light green beneath, punctate when viewed with a lens; petiole ⅓ inch, pubescent. Fruit-pedicels, slender, ¾ inch long. Drupes small, ovoid, black in colour.

This species occurs in north China, in the hills around Peking, and in the mountains of the province of Shingking; and was found by me growing as a small tree, about 20 feet in height, in the mountains of Hupeh. It has been confused with two other Chinese species, *C. Bungeana*¹ and *C. sinensis*,² which do not appear to be in cultivation in Europe. It is readily distinguishable from all the other cultivated species by the very shining glabrous leaves; and is a very distinct and handsome tree.

¹ Blume, *Mus. Bot. Ludg. Bat.* ii. 71 (1852).

² Persoon, *Syn. Pl.* i. 292 (1805).

It was introduced into Kew Gardens, where there is a small tree about 15 feet high, by seeds sent from Peking by Bretschneider in 1882. It had, however, been previously introduced into France by Père David, who sent seeds to Carrière in 1868, from which a tree was raised in the Jardin des Plantes. This tree, according to Franchet¹ had become with age identical in character with *C. Bungeana*; but this is incorrect. It fruited for the first time² at Paris in 1894. Schneider³ mentions trees of this species in the Botanic Gardens at Strassburg and Darmstadt.

(A. H.)

CELTIS OCCIDENTALIS, HACKBERRY

Celtis occidentalis, Linnæus, *Sf. Pl.* 1044 (1753); Michaux, *Hist. Arb. Am.* iii. 225, t. 8 (1813); Loudon, *Arb. et Frut. Brit.* iii. 1417 (1838); Sargent, *Silva N. Amer.* vii. 67 (in part), t. 317 (1895), and *Trees N. Amer.* 299 (1905) (in part).

A tree, attaining in America, 100 feet in height and 9 feet in girth. Bark grey, broken on the surface into appressed scales, and often roughened on old trees with thick discontinuous corky ridges. Young branchlets glabrous or pubescent. Leaves (Plate 267, Fig. 4), uniform in size, about $2\frac{1}{2}$ inches long and $1\frac{1}{4}$ inch wide, ovate, unequal and rounded or shortly cuneate at the base, with a long caudate-acuminate usually non-serrated apex; serrate in the upper half or two-thirds; upper surface smooth to the touch; lower surface pubescent on the nerves; petiole $\frac{1}{4}$ inch or more, glabrous or pubescent. Fruiting pedicels short, about $\frac{3}{8}$ inch. Drupe, purplish-black or orange when ripe, globose or ovoid, about $\frac{2}{5}$ inch in diameter.

In winter the twigs show the following characters:—Branchlets slender, zigzag, reddish-brown, shining, glabrous. Leaf-scars oblique on prominent pulvini, three-dotted. Stipule scars minute, linear, one on each side of each leaf-scar. Terminal bud not formed, the end of the branchlet falling off in summer, and leaving a minute orbicular scar at the apex of the twig. Buds⁴ all axillary, uniform in size, about $\frac{3}{16}$ inch long, alternate, distichous, appressed to the twig, ovoid, acute, compressed, covered by three pairs of pubescent, ciliate, imbricated scales.

Seedling.⁵—Primary root long, tapering, flexuose, with numerous lateral fibres. Caulicle erect, pubescent, about $1\frac{1}{2}$ inch long. Cotyledons oblong, cuneate and three-nerved at the base, emarginate at the apex, green above, pale beneath, about $\frac{3}{4}$ inch long. Stem hispid. First pair of leaves opposite, ovate, acuminate, serrate, three-nerved, covered in the young stage with clear dot-like glands. Succeeding leaves similar, but alternate.

Scarcely any varieties are known, unless *C. crassifolia* be considered a geographical form of this species. *C. pumila*, Pursh,⁶ a low shrub, of xerophytic

¹ *Planta Davidiana*, i. 269 (1884).² *Rev. Hort.* 1894, p. 97.³ *Laubholzkunde*, 228 (1904).⁴ Sometimes in this species, the axil of the leaf produces three buds side by side. The middle bud sends out a shoot in the following year, whilst the lateral ones are left as a reserve. If the shoot happens to die in the year after, one of the two accessory buds develops. Cf. Kerner, *Nat. Hist. Plants*, Eng. transl. ii. 32 (1898).⁵ Cf. Lubbock, *Seedlings*, ii. 493, fig. 646 (1892).⁶ *Fl. Amer. Sept.* i. 200 (1814); Hill, *Bull. Torr. Bot. Club*, xxvii. 496 (1900).

habit, usually growing on sand dunes, rocky places, and dry hills and mountains, and widely distributed in the United States from Delaware and Pennsylvania to Utah and Colorado, is considered by some to be a variety of this species, but is probably distinct.

This species is widely distributed, occurring in the north from Quebec to Manitoba, and extending southward to Louisiana, Missouri, Kansas, and North Carolina. Its exact distribution is not clearly known, as it has been confused with other species; but it appears to be commoner in the north and east, while *C. crassifolia* is most prevalent in the Mississippi valley and west of the Alleghanies. It is replaced by *C. mississippiensis* in the extreme south, and by *C. reticulata* in the dry regions of the far west.

In New England it is a low round-headed tree, and is well depicted by Sargent in *Garden and Forest*, iii. 39, fig. 43 (1890), which represents a tree growing close to the seashore in Massachusetts. It is not common east of the Hudson,¹ but on the banks of this river grows with a slender trunk and long graceful pendulous branches. Amongst North American species none, perhaps, retains its foliage green and fresh so late in the season.

(A. H.)

The American Nettle Tree or Hackberry was introduced into England in 1656 by Tradescant, and the first description of the species, made from a tree cultivated in England, was published in Ray's *Historia Plantarum*, ii. 1917. It seems to be the only species of *Celtis* which bears our climate well enough to be worth planting, but is so rare in cultivation that very few people know it, and it is rarely found in nurseries.

I have found it easy to raise from seed, and though the seedlings grow slowly and are somewhat susceptible to frost when young, it will, as it grows older, endure a greater degree of cold in winter than *C. australis*. The largest tree mentioned by Loudon was one at Syon, which, in 1838, was 54 feet high and 7 feet in girth. This cannot be the same as one which now grows there, which, according to the garden catalogue, was 50 feet by 3 feet 3 inches in 1849, and when I measured it in 1903, was 60 feet by 4 feet 4 inches. There is a fine tree in Kew Gardens, which, owing to its being crowded on one side by an evergreen oak, leans considerably, and is about 45 to 50 feet by 6 feet 4 inches. This is probably one of the original trees of the Kew Arboretum, though not mentioned by Loudon, unless, as is possible, he mistook it for *C. australis*.

The finest and best-shaped tree, however, that we know of, is one at West Dean Park (Plate 251), which is probably the one mentioned by Loudon as then fourteen years planted and 19 feet high. Now it is 50 feet by $5\frac{1}{2}$ feet, and when I saw it in July 1906 was bearing fruit abundantly. This tree evidently lives to a considerable age, as I saw one in the Botanic Gardens at Padua which was planted in 1760, and measures no less than 32 metres high by 2 metres in girth, with a fine clean bole.

Henry saw a good specimen in the Botanic Garden at Copenhagen.

(H. J. E.)

¹ *Garden and Forest*, i. 465 (1888).

CELTIS CRASSIFOLIA, HACKBERRY

Celtis crassifolia, Lamarck, *Encycl.* iv. 138 (1797); Michaux, *Hist. Arb. Amer.* iii. 228, t. 9 (1813); Loudon, *Arb. et Frut. Brit.* iii. 1418 (1838); Britton, *Man. Fl. North. States and Canada*, 339 (1901).

Celtis cordata, Persoon, *Sp. Pl.* i. 292 (1805).

Celtis Audibertiana, Spach, *Ann. Sc. Nat. sér. 2*, xvi. 41 (1841).

Celtis occidentalis, Sargent, *Silva N. Amer.* vii. 67 (1895), and *Trees N. Amer.* 299 (1905). (In part.)

A tree, attaining rarely as much as 130 feet in height, and 10 feet in girth. Bark as in *C. occidentalis*. Young branchlets pubescent. Leaves usually about $2\frac{1}{2}$ inches long by $1\frac{1}{2}$ inch broad, but on isolated branches, commonly found in the inner part of the crown, often 6 inches long and 3 inches broad; ovate, unequal, and shortly cuneate at the base, shortly acuminate at the apex, serrate, as a rule, only in the upper half; upper surface scabrous to the touch; lower surface pubescent on the nerves; petiole, $\frac{1}{4}$ inch or more, pubescent. Fruiting pedicels long, $\frac{3}{4}$ inch or more. Drupe purple, red or black when ripe, globose or ovoid, about $\frac{2}{8}$ inch in diameter.

This species, which is not distinguished by Sargent, even as a variety, from *C. occidentalis*, is remarkably distinct in foliage, and appears to be a more upright and faster-growing tree in cultivation than that species. Michaux states that it is one of the finest species of the genus, remarkable for its great height and straight trunk, and that it is common in the states west of the Alleghanies, especially in Ohio and Kentucky, where, however, its timber was little esteemed on account of its weakness and liability to speedy decay on exposure to the weather. Its distribution has been confused with that of *C. occidentalis*; but, according to Britton, it occurs from New York to South Carolina, Ohio, Illinois, Missouri, and Tennessee.

(A. H.)

Ridgway¹ speaks of this species of Hackberry under the name of *C. occidentalis*, as "a very tall and beautiful tree in rich bottoms, growing frequently 120 to 130 feet high and 3 feet in diameter, with a tall straight trunk of 60 to 70, or even 80 feet to the first limb. When growing to its full perfection in a dense forest, there is an individuality about the aspect of this tree which it is difficult to describe, owing to the extreme slenderness and great length of the trunk, which not unfrequently comprises three-fourths of the total height of the tree; and the smooth grey bark conspicuously clouded on the north side with blackish moss or lichen for its entire length. This striking appearance is sometimes increased by vines of the Virginia creeper ascending to the topmost branches, which are wreathed and matted with its foliage. One tree was seen whose silvery shaft gleamed among the surrounding tree tops, in a wood where the summit level was considerably more than 100 feet aloft, and though only 10 feet in circumference must have been upwards of 90 feet

¹ *Proc. U.S. Nat. Museum*, 1882, p. 72.

to the first limb, which grew not more than 25 feet from the extreme summit of the tree."

Though I was not fortunate enough to find any such trees standing, when I visited the remains of this forest in 1904, yet I saw enough to make me wish that an area of this unique forest could be preserved to show what the virgin forests of the Wabash valley were once like; for there is no other part of the temperate world where so many species of hardwood trees grow to such a size as they formerly did here.

This species appears to have been introduced about the beginning of the nineteenth century; several trees, 10 to 15 feet in height, being mentioned by Loudon.

At Kew it appears to be straighter and more vigorous in growth than *C. occidentalis*; and all the specimens have a few branches mainly in the upper and inner parts of the tree, which bear very large leaves. One of the trees, growing on the walk behind the Aroid House, is 38 feet high by $3\frac{1}{2}$ feet in girth.

(H. J. E.)

CELTIS MISSISSIPPIENSIS

Celtis mississippiensis, Bosc, *Dict. Agric.* x. 41 (1810); Sargent, *Silva N. Amer.* vii. 71, t. 318 (1895), and *Trees N. Amer.* 300 (1905).

Celtis levigata, Willdenow, *Berlin Baumz.* 81 (1811); Loudon, *Arb. et Frut. Brit.* iii. 1420 (1838).

Celtis occidentalis, Linnæus, var. *integrifolia*, Nuttall, *Gen.* i. 202 (1818).

Celtis occidentalis, Sargent, *Forest Trees N. Amer.*, 10th Census U.S. ix. 125 (1884) (in part); and *Garden and Forest*, iii. 39 (in part), ff. 9, 10, 11 (1890).

A tree, attaining in America, 80 feet high and 9 feet in girth. Bark bluish-green, and covered with prominent excrescences. Young branchlets glabrous. Leaves (Plate 267, Fig. 9), up to 3 inches long and $1\frac{1}{4}$ inch wide, ovate-lanceolate or lanceolate, unequal and rounded or broadly cuneate at the base, long-acuminate at the apex; margin usually entire, occasionally irregularly serrate towards the apex; light green and glabrous, except for slight axil tufts at the base beneath; petiole, about $\frac{1}{2}$ inch, glabrous. Fruiting-pedicels, about $\frac{3}{4}$ inch. Drupes, ovoid, $\frac{1}{8}$ to $\frac{1}{4}$ inch, bright orange red, with thin dry flesh and a smooth light brown stone.

This species is distributed from southern Indiana and Illinois, through Kentucky, Tennessee, and Alabama to Florida, and through Missouri, Arkansas, and Texas to Nuevo Leon. It is also a native of the Bermudas. It is very abundant and of its largest size in the basin of the lower Ohio River, a tree measured by Schneck in Richland County, Illinois, being 95 feet high and $5\frac{1}{2}$ feet in girth. Here it is often associated with *C. crassifolia*, from which it may be distinguished¹ by its usually smaller size, shorter trunk, entire leaves, and bright orange-red fruit. It is the most common species in Kentucky and Tennessee; but is rare in the Gulf States. Though apparently found in Texas and Nuevo Leon, it is replaced to the

¹ Elwes noticed that the wrinkled bark of this species easily distinguished it in the forest from *C. crassifolia*.

934 The Trees of Great Britain and Ireland

westward by *Celtis reticulata*, Torrey,¹ which occurs in Texas, New Mexico, Arizona, Utah, Nevada, and Lower California, and has not yet apparently been introduced.

C. mississippiensis was probably introduced, by the elder Michaux, into France, where the species was first described in 1810 from a tree cultivated at Paris. It was not introduced into England in Loudon's time. The only cultivated specimen known to us is a small tree in Kew Gardens.

Alnobetula, Schur, *Verhand. Siebenb. Ver. Naturw.* iv. 68 (1858).

DECIDUOUS trees or shrubs, belonging to the order Betulaceæ. Leaves alternate, simple, stalked, usually serrate or dentate, rarely entire, penninerved. Stipules¹ enclosing the leaf in the bud, caducous or deciduous. Flowers opening either in early spring before or with the unfolding of the leaves, or in two species in autumn, monœcious, unisexual, without petals, in few-flowered cymes in the axils of short-stalked peltate scales of pedunculate catkins. Staminate catkins, at first naked and erect, afterwards pendulous, in the axils of the last leaves or of leafy bracts; scales three-flowered; bracteoles, three to five, adnate to the base of the scale; calyx, four-partite; stamens four, filaments short, undivided; anthers dorsi-fixed, not pilose at the apex. Pistillate catkins erect, solitary or racemose, in the axils of the leaves and produced in autumn, or terminal on a short leafy branch and produced in spring; scales two-flowered; bracteoles, two to four, adnate to the base of the scales; calyx absent; ovary two-celled; styles two, stigmatose at the apex; ovule, solitary in each cell, suspended. Fruit, a strobile or cone, formed by the scales of the pistillate flower becoming, when ripe, thick, woody, obovate, three- to five-lobed or truncate at the thickened apex. Cones persistent on the branch after the opening of the closely imbricated scales and the escape of the nutlets. Nutlet, compressed, minute, bearing at the apex the remains of the styles, marked at the base by a scar, with or without lateral wings. Seed, solitary by abortion, filling up the cavity of the nutlet.

About twenty-five species are distinguished, inhabiting Europe, Algeria, extra-tropical Asia, North America, Central America, and the Andes of South America from Colombia to Peru.

The following key includes all the species in cultivation, with the exception of *Alnus serrulata*, Willdenow, a North American shrub.

I. *Buds sessile, with several (two to six) outer scales, which are unequal in length.*

1. *Alnus firma*, Siebold et Zuccarini. Japan. See p. 952.

¹ Cf. Lubbock, "On Stipules of the Alder," in *Journ. Linn. Soc. (Bot.)*, xxx. 527 (1895).

Leaves ovate-lanceolate, green beneath, with fifteen or more pairs of lateral nerves.

2. *Alnus viridis*, De Candolle.¹ Mountains of Central Europe, plains of Northern Russia, Siberia, Labrador, and Greenland.

Leaves broadly oval, green beneath, with eight to ten pairs of lateral nerves.

This species is a shrub, rarely attaining more than 10 feet in height, and will not be further dealt with by us.

II. *Buds stalked, with two outer scales, almost equal in length.*

A. *Leaves white or grey beneath.*

3. *Alnus incana*, Mœnch.² Europe, Caucasus, North America. See p. 945.
Branchlets pubescent, buds rounded at the apex. Leaves grey beneath, with the lateral nerves running to the tips of serrated lobules; margin not revolute.
4. *Alnus rubra*, Bongard. Western North America. See p. 956.
Branchlets glabrous, buds beaked at the apex. Leaves whitish beneath, with nerves as in *A. incana*; margin revolute.

B. *Leaves green beneath.*

* *Leaves simply serrate, not lobulate, rounded or acute at the apex.*

5. *Alnus elliptica*, Requier. A hybrid between *A. cordata* and *A. glutinosa*, occurring wild in Corsica. See full description under *A. cordata*, p. 949.
Branchlets glabrous and covered with wax glands. Leaves elliptic, rounded at both base and apex, with prominent brown axil-tufts beneath.
6. *Alnus rhombifolia*, Nuttall. Western North America. See p. 958.
Branchlets pubescent. Leaves ovate or oval, rounded at the base, acute or rounded at the apex, pubescent throughout beneath.
- ** *Leaves simply serrate, not lobulate, conspicuously acuminate at the apex.*
7. *Alnus cordata*, Desfontaines. Corsica, Southern Italy. See p. 949.
Branchlets glabrous, covered with wax glands. Leaves broadly ovate, cordate at the base, cuspidate-acuminate at the apex, with conspicuous axil-tufts beneath.
8. *Alnus japonica*, Siebold et Zuccarini. Japan, Manchuria, Korea, Formosa. See p. 953.
Branchlets glabrous. Leaves lanceolate, cuneate at the base, long-acuminate at the apex, with minute axil-tufts beneath.
9. *Alnus maritima*, Nuttall. Delaware, Maryland, Indian Territory. See p. 955.
Branchlets glabrous. Leaves ovate or obovate, cuneate at the base, shortly acuminate at the apex, glabrous beneath.
10. *Alnus nitida*, Endlicher. North-west Himalaya. See p. 954.
Branchlets densely and minutely pubescent. Leaves ovate-elliptical, cuneate

¹ *Fl. Franç.* iii. 304 (1805). *Alnus Alnobetula*, Hartig, *Naturges. Forst. Kulturpfl.* 372 (1851). *Betula Alnobetula*, Ehrhart, *Beil.* ii. 72 (1788).

² *Alnus tinctoria*, Sargent, a closely allied species, occurring in Japan and Manchuria, is distinguished by its large, broadly ovate leaves, acuminate at the apex. *A. incana* has small, narrowly ovate leaves, acute at the apex. Cf. p. 946.

or rounded at the base, short- or long-acuminate, with slight axil-tufts beneath.

*** *Leaves with serrate lobules.*

11. *Alnus glutinosa*, Gærtner. Europe, Siberia, Western Asia, North Africa. See below.
Branchlets usually glabrous. Leaves obovate, cuneate at the base; obtuse, truncate or rounded at the apex; with prominent axil-tufts beneath.
12. *Alnus glutinosa*, Gærtner, var. *barbata*, Ledebour (*Alnus barbata*, C. A. Meyer). Caucasus. See p. 938.
Branchlets pubescent. Leaves elliptical, rounded at the base and apex, covered on both surfaces with pubescence, densest on the midrib and nerves beneath.
13. *Alnus tenuifolia*, Nuttall. Western North America. See p. 957.
Branchlets glabrous. Leaves ovate, broad and rounded at the base, acute or shortly acuminate at the apex, pubescent on the midrib beneath with inconspicuous axil-tufts.
14. *Alnus subcordata*, C. A. Meyer. Caucasus, North Persia. See p. 951.
Branchlets pubescent. Leaves ovate-oblong, unequal and rounded or subcordate at the base, cuspidate-acuminate at the apex, pubescent on the midrib and nerves beneath.

ALNUS GLUTINOSA, COMMON ALDER

Alnus glutinosa, Gaertner, *De Fruct.* ii. 54 (1791); Loudon, *Arb. et Frut. Brit.* iii. 1678 (1838); Willkomm, *Forstliche Flora*, 339 (1887); Mathieu, *Flore Forestière*, 421 (1897); Winkler, *Betulaceæ*, 115 (1904).

Alnus nigra, Gilibert, *Exerc.* ii. 401 (1792).

Alnus communis, Desfontaines, *Tabl. Hort. Paris*, 213 (1804).

Alnus vulgaris, Persoon, *Syn.* ii. 550 (1807).

Betula Alnus glutinosa, Linnæus, *Sp. Pl.* 983 (1753).

Betula Alnus, Scopoli, *Fl. Carn.* ii. 233 (1772).

Betula glutinosa, Lamarck, *Dict.* i. 454 (1783).

Betula palustris, Salisbury, *Prod.* 395 (1796).

A tree, occasionally attaining 100 feet in height and 12 feet or more in girth. Bark of young trees smooth and greenish; after twenty years old becoming brownish-black and divided on the surface into broad flattened plates. Young branchlets, three-angled at the tip, usually glabrous, occasionally pubescent, covered with glands, which secrete a waxy resin, often seen on the dried twigs as a bluish bloom. Leaves (Plate 268, Fig. 6) averaging 3½ inches long and 3 inches broad, variable in shape, but nearly always broadest above the middle, obovate, sub-orbicular or elliptical; cuneate at the base; obtuse, truncate, or retuse at the apex; margin entire in the basal third, elsewhere lobulate, each lobule serrate or dentate; upper surface dark green, shining, glabrous; lower surface light-green, pubescent along the midrib and

nerves, with conspicuous tufts of rusty-brown hairs in the axils; petioles, glabrous or pubescent, $1\frac{1}{2}$ to 1 inch long; stipules conspicuous, deciduous, ovate to lanceolate, obtuse, fringed with glandular hairs. The leaves turn blackish in autumn.

Flowers appearing very early, before the leaves, in February or March. Catkins, three to six in a raceme, at the tip of a branchlet. Staminate catkins, 2 to 4 inches long, at first erect and rigid, afterwards lax and pendent; stamens,¹ four, yellow, opposite the segments of the four-lobed calyx. Pistillate catkins, always erect, at first about $\frac{1}{4}$ inch long, smooth, with reddish-brown stigmas; afterwards $\frac{1}{2}$ inch long, ovoid, cone-like, the scales ending in purple shield-like expansions, each with a central brown point. Cones at first green, ultimately black, persistent on the tree after the escape of the nutlets. Nutlets obovate, blunt-angled, wingless or with a very narrow coriaceous wing.

The nutlets² are gradually shaken out of the cones by the wind during autumn and winter. Their walls are provided with small air-tight cavities, which enable them to float in water, and secrete an oil, which protects them from being wetted. Usually falling into streams and ditches, they float undamaged and unchanged during winter, and germinate in the water in early spring. The young seedlings, drifting to the bank, establish themselves where they happen to be stranded in a suitable place.

In winter, the twigs are glabrous and usually covered with a thin waxy secretion. Leaf-scars pentagonal or rhomboid, parallel to the twig on a projecting cushion, five-dotted, the lowermost three dots coalesced together. Stipule-scars linear, one on each side of a leaf-scar. Terminal bud present, similar to the lateral buds; all conspicuously stalked, ovoid, obtuse, with two external scales, viscid-glandular, and often covered with a purplish bloom. Pith triangular in section.

The common alder coppices freely from the stool; but rarely if ever produces root-suckers.

VARIETIES

The common alder, distributed over a wide area, shows considerable variation in the wild state, and several varieties have been described.

1. Var. *barbata*, Ledebour, *Fl. Rossica*, iii. 657 (1851); Winkler, *Betulaceæ*, 118 (1904). *Alnus barbata*, C. A. Meyer, *Verz. Pfl. Kauk.* 43 (1831).

This variety is remarkably distinct in the foliage, but has the flowers and fruit of typical *A. glutinosa*. Young branchlets pubescent. Leaves, about 3 inches long and 2 inches wide, rounded at the base, rounded or occasionally acute at the apex, margin with serrate lobules, ciliate; nerves eight or nine pairs, running parallel and curved to the margin; upper surface dark green, shining, minutely pubescent; lower surface pubescent, the pubescence densest along the midrib and nerves; petiole $\frac{3}{4}$ inch, pubescent. Buds pubescent.

¹ Kerner, in *Nat. Hist. Plants*, Eng. trans. ii. pp. 119, 133, 135, gives an elaborate account of the way in which pollination is effected by the wind, and of the devices for the protection of the pollen in rainy weather.

² Cf. Miall's account of the fruit of the alder in *Round The Year*, p. 279.

This variety occurs in the Caucasus, and is very similar to var. *denticulata*,¹ occurring in the same region and in north Persia, which is less pubescent. Var. *barbata* is in cultivation at Kew.

2. Var. *quercifolia*, Willdenow, *Berlin Baumz.* 44 (1796). Oak-leaved alder. Leaves obovate, lobed like the common oak. This variety has been found wild in Sweden.

3. Var. *sorbifolia*, Dippel, *Laubholzkunde*, ii. 161 (1892). Service-leaved alder. Leaves oval, lobed like those of *Pyrus intermedia*. This variety has been found wild in Finland.

4. Var. *laciniata*, Willdenow, *loc. cit.* Cut-leaved alder. Leaves (Plate 268, Fig. 7), divided half-way to the midrib into three to six pairs of non-serrated triangular segments; petiole slender, about an inch long.

The cut-leaved alder, according to Duhamel, occurs wild in the north of France, particularly in Normandy, and in the woods of Montmorency near Paris. Thouin states, according to Loudon, that it was first found by Trochereau de la Berlière, and planted by him in his garden near St. Germain, where the stool remained in 1838, from which all the nurseries of Paris were supplied with plants. The largest trees we have seen of this variety are described on p. 942.

5. Var. *imperialis*, Petzold and Kirchner, *Arb. Musc.* 599 (1864). *Alnus imperialis*, Desfossé-Thuillier, *Illust. Hort.* vi. 97, fig. (1859).

Leaves (Plate 268, Fig. 8) oval, divided more than half-way to the midrib, into six or seven pairs of long narrow lanceolate non-serrated curved segments. This variety, so far as we know, does not attain to as large a size as the ordinary form of the cut-leaved alder. A specimen at Ponfield, Hertford, is 25 feet high by 1 foot 8 inches in girth.

6. Var. *incisa*, Willdenow, *Sp. Pl.* iv. 335 (1805) (var. *oxyacanthæfolia*, Loddiges, *Catalogue*, 1836). Thorn-leaved alder. Leaves (Plate 268, Fig. 10) small, deeply incised, resembling those of the common hawthorn. A fine specimen, 44 feet high by 2 feet 8 inches in girth, is growing in the arboretum at Barton, near Bury St. Edmunds.

7. Var. *rubrinervia*, Dippel, *loc. cit.* A tree, pyramidal in habit, with large and shining leaves, furnished with red petioles and nerves, vigorous in growth and handsome in appearance. In cultivation at Aldenham.

8. Var. *pyramidalis*, Dippel, *loc. cit.* Branches erect, leaves as in the type.

9. Var. *aurea*, Verschaffelt, *ex* Dippel, *loc. cit.* Lemaire, *Illust. Hort.* 1866, t. 490. Leaves yellow. Found as a seedling in Vervaene's nursery at Ledebergles-Gand. In cultivation at Aldenham.

10. Var. *maculata*, Winkler, *loc. cit.* Leaves variegated with yellow. There is a small specimen at Aldenham, which is slow in growth.

Hybrids² between *Alnus glutinosa* and *Alnus incana* are common in the wild state, where the two species are growing together, and have been observed in

¹ Ledebour, *loc. cit.* *Alnus denticulata*, C. A. Meyer, *loc. cit.*

² *A. glutinosa* × *incana*; *A. spuria*, Callier. Schneider, *Laubholzkunde*, 130 (1904), distinguishes three forms of this hybrid.

Sweden, Norway, Russia, Denmark, Bosnia, and Montenegro. These hybrids are intermediate in the characters of the leaves and fruit; and so far as we know, are not in cultivation in England.

A hybrid¹ between *A. glutinosa* and *A. serrulata* has also arisen in cultivation in Silesia and Brandenburg.

DISTRIBUTION

The common alder is distributed through nearly the whole of Europe, Siberia, Western Asia, and North Africa. In Europe, its northerly limit extends from lat. 63° 52' in southern Norway at Anderoen, to lat. 63° 20' on the west side of the Gulf of Bothnia in Sweden, reaching Uleaborg in Finland in lat. 65°, where, however, it only exists as a shrub, and is continued through the interior of Finland and Russia along the parallel of 62°. In Siberia, its distribution is not accurately known; but it occurs in the Ural and Altai mountains, and in the district around Lake Baikal. Its southern limit, commencing in the province of Talysch in the Caucasus, between 39° and 40° lat., extends through Asia Minor and Greece to Sicily, where it reaches at Catania, lat. 37° 25', its most southerly point in Europe. It occurs in Spain and Portugal, as far south as the Sierra Morena, about lat. 38°. It is also distributed through the mountains of Algeria and Morocco. A variety,² recorded for Japan, is probably a distinct species.

According to Sir Herbert Maxwell³ the Anglo-Saxon name for alder was *alr*, in Norse *olr* (now, according to Schübeler, *aar*, *older*, and *or*); and the Gaelic name *fearn*, the names surviving in place names such as Allerton, Allerbeck, Ellerslie, Balfarn, Farnie, Glenfarne.

It is generally distributed throughout the British Isles, growing usually on river banks, along the sides of lakes, and in wet or marshy places; and ascends in the Grampians to 1600 feet.

It is common throughout France, in similar situations, and ascends to 5700 feet in the Pyrenees. Although most usual on siliceous soils, it grows on chalk in Champagne; and in Germany, has been shown to be indifferent to the mineral constituents of the soil, provided a sufficient quantity of moisture is present. It is met with as pure woods, on peat-bogs and marshy places, in north Germany, in the Baltic provinces and Lithuania in Russia, and also in Hungary; but more usually is mixed with birch and aspen, and more rarely grows in company with other hardwoods. It ascends in the mountains of Norway to 1100 feet, in the Central Alps in Switzerland to 3200 feet, and in the Carpathians to 3800 feet. The alder is susceptible to late frosts and is injured by cold dry winds, and on this account thrives best in the colder parts of Europe on slopes with a westerly aspect.

It is naturalised in various localities in the eastern United States, particularly in southern New York and in New Jersey. It succeeds well in North America, when

¹ *A. glutinosa* × *serrulata*; *A. silesiaca*, Fiek. Cf. Schneider, *loc. cit.*

² Var. *japonica*, Matsumura, *Journ. Coll. Sci. Tokyo*, xvi, 2, p. 9 (1902).

³ Green's *Encyclopedia of Agriculture*, i. 62.

planted in wet situations; but is not, as a rule, a long-lived tree, and never grows to be so large as it does in England.¹ (A. H.)

PROPAGATION AND CULTURE

Though old writers tell us that the alder was often planted by inserting long cuttings, or by burying pieces of the root in the soil; and though layering is the mode usually adopted by nurserymen for propagating the varieties; yet, as a general rule, it is best raised from seed. The cones ripen in autumn and are freely produced almost every year so far as I have observed. As soon as they begin to open, they should be gathered when quite dry; and though it is said that the seeds will keep for two years or more in the cone, yet, as a rule, they should be sown in autumn or in early spring and lightly covered with earth. Though I have not tried it myself, I believe that the germination is more rapid and regular if the seed is soaked in water before sowing, but seedlings can be procured so cheaply from nurserymen that I have always bought them at one or two years old. They are easy to transplant and grow fast if the soil is moist, being fit to plant out at three or at most four years old; and I have had as good or better success by planting them in spring as in autumn. The alder bears coppicing well, if not cut too near the ground, but the stools have a tendency to decay in the centre and to spread outwardly. True suckers are not produced, though the roots when exposed by running water will throw up shoots. The usual age for coppicing is fifteen to twenty years, and I am informed by Sir Hugh Beevor that he obtained a yield of 1700 poles per acre, which at seventeen years' growth from the stool averaged 20 feet long with a girth of 7 to 11 inches, giving a yield of about 1100 cubic feet per acre. If the trees are allowed to stand for timber they should be cut at fifty to seventy years, when they may average 50 to 70 feet high by 4 to 5 feet in girth. The only lot of alders I ever sold standing, 300 in number, realised £100, being at the rate of 4d. or 5d. per foot. Sir Herbert Maxwell states, that as long as clogs remain in common use, there will be little difficulty in realising £40 per acre for mature alder coppice, and this on land so wet as to be worthless for any other purpose. Except in localities where a good and regular market is assured, I should not recommend the planting of alder except in places too cold, wet, and marshy for willow or poplar to thrive; but Selby,² whose opinion of the tree as an ornamental one was better than my own, states as the result of his own experience, that the nature of the roots of the alder causes the tree to attract and retain the moisture in the soil, to such an extent that it will convert into a morass, land which, if drained and planted with other trees, might be rendered dry and productive. He adds that from experiments he has made he is "fully convinced that a plantation of alders would soon render the ground (even if previously of tolerably sound and dry quality) soft and spongy, and in time convert it into a decided bog." I cannot learn that this observation has been confirmed by others, and am inclined to doubt its being of general application.

¹ Hough, *Trees N. States and Canada*, 131 (1907).

² *British Forest Trees*, p. 218 (1842).

The common alder is rarely planted as an ornamental tree, and only on wet situations or on the banks of ponds and streams is it able to attain its full dimensions. But if desired for ornament in such a situation, I should recommend the cut-leaved alder in preference to the common one; and for drier ground either the grey or the Italian alder.

REMARKABLE TREES

Among the finest trees that we have seen or heard of, those at Pain's Hill take a high place. One of these on an island is probably over 90 feet, but we could not measure it. Another growing by the lake has seventeen stems about 75 feet in height, growing from a stool which is 19 feet in girth. I estimated the contents of these poles at about 200 cubic feet. At Whitton there is a tall slender tree about 90 feet by 6 feet without a branch for 46 feet, and with a clean stem to 70 feet up. At Betchford Park, Surrey, Henry measured a tree 90 feet high by 11 feet 4 inches at 3 feet from the ground, dividing into two stems at 4 feet. At Enville Hall, Stourbridge, he saw one which was 87 feet by 8 feet 2 inches. Sir Hugh Beever tells us of a large one at Shottisham, Norfolk, 70 feet high and 18 feet in girth near the ground, out of the base of which a mountain ash of large size is growing.

At Holme Lacy there is a large tree near the home farm, which has a short bole 6 feet high by 18 feet in girth, dividing into four main stems about 60 feet high; I estimated the contents of this tree to be not far short of 300 cubic feet.

On the banks of the Nene near Lilford Hall, Northamptonshire, there is a fine row of large and picturesque alders, of which Plate 252 gives a good representation, but I was unable to measure them on account of the water.

In Boughton Park, near Kettering, the property of the Duke of Buccleuch, a remarkable alder is growing near the Broad Avenue, in comparatively dry ground. It measures 70 feet by 9½ feet, and has the lower part of the trunk covered with bark so like that of an elm that it was difficult to recognise it as an alder, by the trunk alone.

At Aldermaston Park there is a very large old tree which looks as if it had been pollarded, and which in 1906 was 17 feet 4 inches in girth.

At Elvaston Castle, Derby, Mr. A. B. Jackson has seen a remarkably fine tree, which he estimates at 90 feet by 7½ feet, with a clean bole 60 to 70 feet long.

In Wales the finest alder I have seen is in a wood at Penrhyn Castle which is about 75 feet by 6 feet 9 inches, with a clean bole 40 feet long. The contents of this tree were estimated by me at over 100 feet of timber.

Of the cut-leaved alders the finest I have seen is about 68 feet by 10½ feet on the banks of the lake at Syon. At Melbury there is a tree very similar in size and appearance to that at Syon; and Henry measured, in 1905, one at Cassiobury Park, 85 feet by 11½ feet; and another at Belton, 85 feet by 10 feet 2 inches. Colonel Birch Reynardson sends me a photograph of a tree at

Holywell Hall, Stamford, which is 65 feet high and no less than 17 feet in girth at two and a half feet, dividing into two trunks of equal height. At Audley End, Henry measured, in October 1908, a fine specimen, 65 feet high, and 15 feet in girth at a foot from the ground, dividing above into three great stems, with a spread of branches 80 feet in diameter.

In Scotland the alder attains as large a girth and perhaps a greater age than in England. One of the oldest and largest on record is in the flower gardens at Gordon Castle, and was figured in 1881.¹ It was only 35 feet high but 14 feet 9 inches in girth and with a spread 63 yards in circumference. The late Mr. J. Webster supposed it to be nearly three centuries old, but when I saw it in 1907, nothing remained but a hollow stump 16½ feet in girth. At Fasnakyle, in Strathglass, there is a very large old alder, of which Mr. Stevenson Clarke sends me a photograph, and which in 1904 measured 18 feet in girth at two feet from the ground. It has a rowan tree 2 feet in diameter growing on it.

At Shanbally, near Dumfries, Henry measured an alder in 1904 which was 65 feet by 10 feet 5 inches, dividing at eight feet into two stems; and at Scone he saw a cut-leaved alder, which was 66 feet by 6 feet 3 inches in the same year.

Some of the most remarkable alders in Ireland grow in the old Deer Park at Kilmacurragh on strong wet land covered with tall bracken and rushes. Henry thinks that in former times this park may have been part of the virgin forest of Wicklow. The trees are scattered in groups as if self-sown; and though fully mature, are in most cases sound. They average 55 to 60 feet in height, and in some cases have clean boles 30 to 40 feet high and 8 to 10 feet in girth. The one figured (Plate 253), was about 60 feet by 11 feet 4 inches, and stands near the top of the park.

At Powerscourt, an immense alder was felled in 1902, the butt being 20 feet in girth near the ground. At Churchill, Armagh, a tree growing in peat soil, measured, in 1904, 94 feet in height by 6 feet 4 inches in girth, with a clean stem to 60 or 70 feet.

TIMBER

Alder is now a wood of third-rate importance in the English timber trade, and though still used for making the clogs² which are worn in Lancashire, is so low in value that it will not bear much cost for carriage. On this account it is usually worked up on the ground where it grows into pieces suitable for clog soles by men who travel about from place to place, and this work is carried on by preference in summer.

In Scotland, however, alder is still used for making herring barrels, in districts where it is plentiful, though imported staves as usual are taking its place. The timber is said to be most valuable for piles, and to be certainly durable under water,

¹ *Trans. Scot. Arbor. Soc.* ix. pl. 1 (1881).

² A complete set of specimens, illustrating the manufacture of clog-soles from alder wood, was sent to the Kew Museum, in 1904, from Enniscorthy, Ireland. Cf. *Kew. Bull.* 1904, p. 6, where the clog-sole industry is described.

so that where milldams, weirs, or similar work is being done on an estate, it may be profitable to use it in preference to more costly wood.

It is useless for posts or fencing, as it decays quickly when exposed to wet and dry conditions. It makes very good panelling, and is strong enough for inside work such as window-sills, and may be used for cheap furniture, but is said to be subject to the attacks of wood-boring beetles, unless previously steeped for some time in lime water. The colour is a pale reddish brown; and the large burrs which are commonly found on old trees show a very pretty figure when cut in slices, but are usually too small and full of flaws to have any marketable value, though Sir Thomas Dick Lauder says that handsome tables can be made of them.¹ Loudon quotes Mitchell to the effect that in Dorsetshire the local saying used for willow and poplar in the midland counties, is applied to alder poles when peeled, viz.—

Thatch me well and keep me dry
Heart of oak I will defy;

but, according to Cobbett, the bark must be taken off with a draw knife as soon as possible after the poles are cut, and even then they will only last a year or two as hop poles.

Alder wood which is dug up from peat bogs is said to become as black as ebony, but I have seen none large or sound enough to be used like bog oak. As fuel the wood is little valued in England, though Mouillefert says that in France it is considered specially suitable for heating ovens and glass works, though considerably inferior in heating power to beechwood. The charcoal made from it was at one time in great demand for making gunpowder, but, so far as I can learn, is now little used for that purpose. The wood is said to be used on the continent for making cigar boxes; this may be the case for very cheap cigars, but all the cigar boxes I have seen appear to be made of the wood of the West Indian "cedar," *Cedrela odorata*. The bark was used for tanning in the north, but only contains about 16 per cent of tannin, and Mouillefert says that in France a black dye used for felt is made from the bark and sulphate of iron.

Another use for alder wood which seems to be little known is the making of hat-blocks, an industry carried on in Dunstable, Luton, and other towns near the principal hat factories. For this purpose the larger sized trees are preferred, cut into plank of not less than 10 inches wide and 3 inches in thickness. I am informed that in consequence of the increasing difficulty in procuring this wood in England, it is now imported from the continent, and as much as 1s. 3d. a foot is paid at the ports on the north-east coast.

The following details of the cost of making clog soles from alder were taken on my own estate in 1908:—

About 100 trees, estimated at 56 years old, growing on the bank of a stream at Colesborne, on an area of about one-third of an acre, were sold at 7d. and 8d. a

¹ Alder burrs seem to have been a favourite wood with cabinet-makers in Sweden in former times, as I saw several handsome cabinets veneered with this wood in the Northern Museum at Stockholm.

foot, and as measured down to 3 inches diameter, produced 817 cubic feet and realised	£24 10 0
Deduct expenses of cutting and hauling out	£2 16 0

The maker informed me that the cost of carriage to Oldham was £8, 2s. at the rate of £1 per ton, and that the sum realised was £72, in addition to which he had the whole of the waste and chips to sell for firewood.

ALNUS INCANA, GREY ALDER

Alnus incana, Mœnch, *Meth.* 424 (1794); Willdenow, *Sp. Pl.* iv. 335 (1805); Loudon, *Arb. et Frut. Brit.* iii. 1687 (1838); Willkomm, *Forstliche Flora*, 349 (1887); Mathieu, *Flore Forestière*, 426 (1897); Winkler, *Betulaceæ*, 120 (1904).

Alnus lanuginosa, Gilibert, *Exercit. Phyt.* ii. 402 (1792).

Alnus glauca, Michaux, f., *Hist. Arb. Amer.* iii. 322 (1813).

Betula Alnus incana, Linnæus, *Sp. Pl.* 983 (1753).

Betula incana, Linnæus, f., *Suppl.* 417 (1781).

A tree, attaining about 70 feet in height and 6 feet in girth. Bark smooth and silvery grey, only fissuring slightly at the base of old trunks. Young branchlets greyish pubescent. Leaves (Plate 268, Fig. 1) about 3 inches long and 2 inches wide, ovate or oval, rounded or cuneate at the base, acute or slightly acuminate at the apex; lateral nerves nine to twelve pairs, running straight to the margin, each ending in a short acute lobe, which is finely serrate and ciliate; upper surface dull, dark green, pubescent; lower surface greyish, covered with soft hairs, densest on the midrib and nerves, without axil-tufts; petiole, ¾ inch long, pubescent.

Catkins in number and position like those of *A. glutinosa*; but male catkins looser, with distant shining red-brown scales and yellow anthers. Cones smaller than in *A. glutinosa*, with more numerous scales, thinner and less distinctly five-lobed. Nutlets depressed, pentagonal, reddish-brown, with wing almost as broad as the body.

In winter the twigs are three-angled at the tip, and densely covered with a fine

pubescence. Leaf-scars and stipule-scars as in the common alder. Buds reddish-brown, ovoid, conspicuously stalked, with two external scales, finely pubescent on the surface and only slightly glandular. Pith triangular or three-lobed.

The grey alder exhibits in the wild state considerable variation in the shape and pubescence of the leaves, and the cones may be sessile or shortly stalked. Many varieties are mentioned by Winkler and Schneider, most of which are scarcely worth discriminating; but the following are noteworthy:—

1. Var. *argentata*, Norrlin. Leaves silvery on both surfaces, and covered with a dense silky pubescence. Observed in Finland, Silesia, Saxony, and Switzerland.
2. Var. *glauca*, Regel. Leaves bluish-green and nearly glabrous beneath.
3. Var. *orbicularis*, Callier. Leaves small, almost orbicular, with five pairs of lateral nerves, wild in Silesia. This is occasionally cultivated under the name of var. *parvifolia*; but var. *parvifolia*, Regel, which occurs in Sweden and Finland has still smaller leaves, only $\frac{1}{2}$ inch in length, and ovate in shape.
4. Var. *acuminata*, Regel.¹ Leaves (Plate 268, Fig. 9) divided more than half-way to the midrib, into three to six pairs of long, narrow, triangular, serrate segments. This form has been observed wild in Sweden, and has been much confused with another wild variety in the same country, var. *pinnatifida*, Wahlenberg,² which resembles in the shape of the leaves *A. glutinosa*, var. *incisa*; and has not been seen by us in cultivation. Var. *acuminata* is common in gardens, and is usually known as var. *incisa* or var. *pinnatifida*.
5. Var. *aurea*, Schelle. Leaves and fruit yellow. This variety is growing well at Aldenham, and is striking in appearance.
6. Var. *montrosa*, Dippel. A dwarf shrub, with the tips of the branches ribbon-like and fasciated, which originated in Spath's nursery. In cultivation at Aldenham.

DISTRIBUTION

The grey alder is widely distributed throughout the greater part of Europe and the Caucasus. It is also met with in North America, where, however, it is only a shrub, commonly growing in swamps and on river banks, and forming dense thickets rarely more than 10 or 12 feet high, and is spread throughout British territory from Newfoundland to the eastern base of the Rocky Mountains, descending in the United States to New York, Pennsylvania, Wisconsin, and Nebraska.

Alnus incana is replaced in northern and eastern Asia by two closely allied species: *A. hirsuta*,³ Turczaninow, not in cultivation, a native of Siberia, Kamtschatka, Manchuria, Saghalien, and Japan; and *A. tinctoria*, Sargent,⁴ which is confined to Manchuria and Japan. The latter species differs mainly from *A. incana*, in the larger size and different shape of the leaves, which are broadly

¹ *Mem. Soc. Nat. Mosc.* xiii. 158, t. 17, f. 8 (1861).

² *Bull. Soc. Nat. Mosc.* 1838, p. 101. *Alnus incana*, var. *hirsuta*, Spach.

³ *Bull. Soc. Nat. Mosc.* 1838, p. 101. *Alnus incana*, var. *glauca*, Shirasawa, *Icon. Ess. Forest. Japon*, t. 19, ff. 1-17 (1900). This species is known in Japan as *yama-harinoki*, or mountain alder, and is much used for making small articles in the Hakone mountains. Cf. Rein, *Industries of Japan*, 239, 336 (1889).

⁴ *Fl. Suec.* 622 (1824).

ovate, 4 to 6 inches long, $3\frac{1}{2}$ to 5 inches wide; base broad and rounded or truncate, occasionally cuneate; apex acuminate or cuspidate; pubescent on both surfaces, glaucous or brownish beneath; with 9 to 12 pairs of nerves, each ending in a triangular serrated lobule; petiole an inch or more in length. The amount of pubescence on the branchlets, petioles, and leaves is variable; but the buds appear to be always densely pubescent. The cones are much larger than those of *A. incana*, attaining about $\frac{3}{4}$ inch in length and $\frac{1}{2}$ inch in diameter. *A. tinctoria* grows in Yezo, according to Sargent, on low slopes in rich moist ground, usually at some distance from the banks of streams, which are generally occupied by *A. japonica*. *A. tinctoria* attains in Japan 60 feet in height, and 6 feet in girth; and was collected by Elwes at Asahigawa in Yezo. It was formerly in cultivation at Coombe Wood, where it was probably raised from seed sent by Maries; but no specimens can now be found there; and the only one which we have seen in England is a tree at Aldenham,¹ about 15 feet in height, which is reported to be growing vigorously. There are trees of *A. tinctoria* in the Arnold Arboretum, Massachusetts, which were raised from seed collected by Sargent in Japan in 1892.

The grey alder extends in Europe much farther to the northward than the common alder, its northern limit in Scandinavia being about lat. $70^{\circ} 30'$. In Finmark it reaches the mouth of the river Tana, and following the shore of the Arctic Sea, the northern limit extends throughout Russia along the Arctic Circle. Its distribution is divided into two areas, a northern one extending southward in the plains of Russia to the 55th N. parallel; and a southern area, which comprises the mountain ranges of the Carpathians, Alps, Jura, and Apennines, where the tree grows at high elevations in the mountains, and descends along the river valleys to lower altitudes, as along the Rhone, Isère, Drôme, Durance, and Var in France, and along the Rhine and its tributaries in Germany, and along the Danube in Austria. Its southern limit passes westwards from Russia through Transylvania to Banat and Servia; but the tree is not found in Croatia, Dalmatia, or Istria. In Italy it descends along the Apennines as far south as lat. $43^{\circ} 40'$, and grows as a rule between 4000 and 6000 feet, occasionally as low as 3000 feet. It ascends in the Erz mountains to 2100 feet, in the Swiss Alps and the Tyrol to 5000 feet, and in France thrives at 6000 feet altitude near Barcelonnette and Briançon.

In Scandinavia the grey alder is common in the pine and spruce forests, usually occurring as underwood; but in favourable situations near streams attaining a considerable size. There are many fine specimens in the beautiful natural park, close to Gefle on the Baltic. These trees, many of which are suckers from the roots of old trees that had been felled, are narrowly pyramidal in habit. The largest measured 75 feet in height and 5 feet in girth. In Denmark, Mr. Prytz of the forest service, who has measured trees 65 feet high and $7\frac{1}{2}$ feet in girth, informed me that the wood had been tested, and clogs made of *A. incana* had worn as well as those manufactured from the common alder. I saw several trees in a beech forest near Nykjöbing averaging 60 feet in height and 3 or 4 feet in girth. In Denmark it grows better on dry soil than the common alder.

¹ At Aldenham, and in gardens on the Continent, this species is cultivated under the erroneous name, *A. incana*, var. *hirsuta*. Cf. Schneider, *Laubholzkunde*, i. 134 (1904).

In the Baltic Provinces of Russia it is common as coppice treated with a short revolution; and often takes possession of forests, when the larger trees have been cut away, and succeeds in doing so, as it is able to grow very well on dry soil. In Germany and Austria it grows chiefly on the banks of streams and rivers, but is also met with on hilly ground and on mountain precipices. It is very rarely met with on peat-bogs. In the Alps it is especially common on gravelly soil, and it is the most common species in many places, where the mountain torrents form vast areas of gravel and sand, through which their branches spread in all directions. One of the most remarkable and beautiful of these woods is situated at 2500 feet elevation on the river Romanche near Bourg d'Oisans in Isère. The whole area is about 200 acres, one-half of which is composed of a dense wood of grey alder, mixed with a small number of aspens and ashes, the other half being more open and consisting of a mixture of grey alder and white willow. The dense wood is treated as coppice, with a revolution of thirty years, forty standards per acre being reserved each time of felling. When cut, the grey alder produces vigorous shoots, which grow rapidly till they are thirty-five or forty years old; after which time growth ceases and the shoots begin to die. At Bourg d'Oisans natural seedlings are very numerous.

The grey alder, unlike the common alder, suckers freely from the root, often at a great distance from the parent stem. It layers easily, and can also be propagated by cuttings. This facility of reproduction renders it of great service for the re-forestation of the mountains in France, especially in the difficult work of planting trees on the sides of the torrents, where the soil is easily washed away.

Alnus incana is not a native of the British Isles, and has not yet been discovered in the fossil state there. (A. H.)

CULTIVATION

Though the tree is hardly known to English foresters, I believe that it may become an exceedingly useful one on account of its extreme hardiness, rapidity of growth and ability to thrive in very cold heavy soil, and in places subject to late and early frosts. I have used it with great success as a nurse to trees like *Thuja plicata*, in situations which were too wet and cold for that tree when young, and believe that it might be economically used for quickly suppressing rank herbage which would smother more tender and slower-growing trees in low and damp situations. It can be procured quite cheaply from French nurseries as one- or two-year seedlings, and grows with extraordinary rapidity on any soil, providing a dense cover, and rendering the land fit for planting. It soon overtops other trees, and if left standing requires the branches to be lopped so as to allow their heads to get up. It seems to thrive equally well on wet ground, and to grow much better than the common alder on soil too dry for that tree. I believe that the wood is at least as good, and according to Mouillefert is less brittle, than that of the common alder.

Though Loudon says that it was introduced as long ago as 1780, I have never seen a tree of any size in England; but Sir Hugh Beevor has sent me a photograph of one at Hargham in Norfolk, which measures about 72 feet high by 3 feet

in girth, being drawn up in a wood by other trees. It is growing on good loam over clay, and is the only big pole of the species in the wood; others which have been cut throw up many shoots from the stool, of which the majority die. On Lord Castletown's property at Doneraile, Co. Cork, there is a wood,¹ partly composed of grey alder, which has in places covered the ground with its suckers. (H. J. E.)

ALNUS CORDATA, ITALIAN ALDER

Alnus cordata, Desfontaines, *Tabl. Hort. Paris*, 244 (1815); Winkler, *Betulaceæ*, 110 (1904).
Alnus cordifolia, Tenore, *Flor. Neap.* i. *Prod.* p. lxiv. (1811), and ii. 340 (1820); Loudon, *Arb. et Frut. Brit.* iii. 1689 (1838); Baillon, *Nat. Hist. Plants*, vi. 223, figs. 158-164 (1880); Masters, *Gard. Chron.* xix. 284 f. 42 (1883); Mathieu, *Flore Forestière*, 428 (1897).
Betula cordata, Loiseleur, *Notiz.* 139 (1810), ex Loiseleur, *Fl. Gall.* ii. 317 (1828).

A tree, attaining 80 feet in height. Bark greyish-brown, smooth or slightly warty. Young branchlets, three-angled at the tip, stout, glabrous. Leaves (Plate 268, Fig. 4) about 4 inches long and 3 inches broad, oval or ovate, cordate at the base, shortly and abruptly acuminate at the apex; margin not lobulate, regularly serrate; nerves six to ten pairs, looping before reaching the margin; upper surface dark green, shining, glabrous; lower surface light green, glabrous, except for axil-tufts of rusty brown pubescence; petiole 1 to 2 inches, glabrous. Male catkins, three to four in a terminal raceme. Cones, solitary or two to three in an erect terminal raceme, 1 to 1½ inches long, ovoid. Nutlet, sub-orbicular, with a thin narrow wing.

In winter the twigs are glabrous, with leaf-scars and stipule-scars like those of the common alder. Buds long-stalked, arising from the twigs at a wide angle, ovoid, beaked at the apex, glabrous and covered with wax glands; scales ciliate in margin.

*Seedling*²:—Cotyledons oblong-oval, slightly fleshy, pale green, about ½ inch long, with a very short grooved petiole. Caulicle pubescent, about ½ inch long, ending in a tapering flexuose tap-root. Young stem brown, pubescent. Leaves alternate; first pair broadly ovate, acute or cuspidate, irregularly and acutely serrate, with pubescent petioles; ultimate leaves cordate, cuspidate.

This species shows no variation in the wild state, except that the leaves are occasionally rounded and not acuminate at the apex. It differs considerably from *A. subcordata*, which has been supposed to be a variety of it; and is readily distinguished from all other species by the conspicuous cordate base of the leaves.

Alnus elliptica, Requier, *Ann. Sc. Nat.* v. 381 (1825) is a remarkable natural hybrid between *A. cordata* and *A. glutinosa*, which was originally found growing on the banks of the river Salenzara in Corsica. It has leaves, similar in size to those of *A. cordata*, but thinner in texture, oval or elliptical, rounded at the base and apex; margin not lobulate, finely and equally serrate; glabrous on both surfaces, except for axil-tufts beneath. The fruits are not so large as in *A. cordata*, and are inter-

¹ Described by Prof. Fisher in *Quarterly Journal of Forestry*, ii. 95 (1908).

² Cf. Lubbock, *Seedlings*, ii. 531, f. 666 (1892).

mediate between that species and *A. glutinosa*. The branchlets are glabrous and covered with wax glands. This hybrid, which in general aspect strongly resembles *A. cordata*, but is readily distinguished by the thinner leaves, not cordate at the base, appears to be very vigorous in growth at Kew, where there is a tree growing beside the lake, which is 72 feet in height and 5 feet in girth. The bark is like that of *A. cordata*, being greyish in colour and slightly warty on the surface.

Alnus cordata has a very restricted distribution, being confined to Corsica and southern Italy. In Corsica it ascends to 3000 feet, as at Vizzavona, where I saw it in a beech forest, growing not only beside a stream, but also on the side of the hill at some little distance off. Here the trees were about 70 feet high and 5 feet in girth, with clean timber to 50 feet, and were narrowly pyramidal in habit, with ascending branches. It grows in southern Italy from the Bay of Naples southwards; and according to Tenore occurs both on marshy ground and in the mountains. It forms woods on Mt. Serino.

This elegant species, with foliage somewhat resembling at a distance that of the Caucasian lime, which is retained late in the autumn, was introduced, according to Loudon,¹ in 1820. It flowers in March, before the leaves appear; and seems to grow as fast and to be as hardy as the common alder.

It supports well the climate of the north of France; and at Nancy, where the winters are severe, flowers and fruits regularly, and has attained 7 inches in diameter after twelve years' growth. According to Mouillefert,² it succeeds better on dry soils than either the common or the grey alder; and has been planted on the chalky soil of Champagne, where it is treated as coppice with a short revolution. At Grignon it has borne -4° Fahr. without injury, but suffered in 1880, when the temperature fell to -13° Fahr. Here on poor chalky soil it has attained, at thirty-five years old, 48 feet in height and 2 feet 8 inches in girth; and on better soil, 64 feet by 3 feet 1 inch.

The finest tree that we have seen of this species grows on the lawn at Tottenham House, Savernake, Wilts, and is a well-shaped tree, measuring no less than 69 feet high by 9 feet 3 inches in girth at four feet from the ground (Plate 254). When Elwes found it on April 3, 1908, it was in full flower, and covered with the cones of the previous year. It does not appear to be a very old tree, and is growing in a deep and rather heavy soil overlying chalk, at an elevation of about 400 feet.

In the new park at Merton Hall, Thetford, a tree, growing in a wind-swept situation, on very dry, light, sandy soil, measured in 1908, 50 feet high and 10 feet in girth, with a spread of branches 56 feet in diameter. Lord Walsingham believes that this tree was planted about 1843, as the new park was enclosed in the preceding year. The bark at the base is deeply fissured and scaly.

¹ *Arb. et Frut. Brit.* 1689 (1838); but in Loudon, *Gard. Mag.* 1837, p. 143, and 1839, p. 39, a tree at Britwell House, Bucks, growing on gravelly soil, was reported to be 60 feet high; and this would show that the date of introduction was earlier than 1820. So far as we can learn, this tree no longer exists.

² *Essences Forestières*, 252 (1903). However, two trees at Verrières near Paris, about 80 years old, have only attained 60 feet in height and 5 feet 8 inches in girth; and M. Philippe L. de Vilmorin states (*Hortus Vilmorinianaus*, 54 (1906)), that their growth seems to have come long ago to a standstill.

A specimen is growing at Milford House, near Godalming, which was planted by the famous botanist and traveller, Phillip Barker Webb. The present owner, R. W. Webb, Esq., informed us in 1905 that it was very healthy, measuring 8 feet in girth, and estimated to be about 50 feet in height.

There is a fine tree growing near the pond in front of the palm-house in Kew Gardens, which is 71 feet high by 5 feet 8 inches in girth. At Tortworth, a tree measures 60 feet high by 6 feet in girth; and at Waterer's Nursery, Knaphill, Woking, another is 50 feet by 5 feet 10 inches.

At Nuneham Park, Oxford, a tree, growing on hilly dry ground, on the green-sand formation, measures 51 feet by 5 feet 5 inches, and is very thriving. Elwes has seen a tree at Bicton, measuring 65 feet by 5 feet 10 inches, and another at Melbury, where it grows vigorously and fruits.

In the playing fields at Eton, on the banks of the Thames, there are two trees, the larger of which is 40 feet high by 6 feet 4 inches in girth. These were in full foliage on 17th November 1907, having scarcely lost a leaf, and were bearing fruit. They have not developed tall straight stems, as in the other places where the tree is thriving; and this is probably owing to their position being exposed to easterly and north-easterly winds. At Ponfield, Herts, a young tree 35 feet by 2 feet 4 inches in 1906 is doing well on dry soil; and there is a good specimen in the Cambridge Botanic Garden. Another at Yattendon Court, Berks, is 50 feet by 3 feet 8 inches.

In Scotland it also grows well at the Botanic Gardens, Edinburgh, where there is a tree 60 feet by 5 feet 10 inches; and in the west at Castle Kennedy, and at Monreith, where Elwes saw a tree 30 feet high, bearing cones in September 1906.

There is a fine specimen in the Glasnevin Botanic Garden, which is 64 feet high by 5 feet 4 inches in girth. (A. H.)

ALNUS SUBCORDATA, CAUCASIAN ALDER

Alnus subcordata, C. A. Meyer, *Verz. Pfl. Kauk.* 43 (1831); Winkler, *Betulacea*, 112 (1904).
Alnus cordifolia, Tenore, var. *subcordata*, Regel, in *Mém. Soc. Nat. Mosc.* xiii. 170 (1861), and in DC. *Prod.* xvi. 2, p. 185, (1868).

A tree, attaining about 60 feet in height. Bark grey, warty on the surface, ultimately scaling at the base of old trunks. Young branchlets pubescent. Leaves (Plate 268, Fig. 5) about 4 inches long and $2\frac{1}{2}$ inches broad, ovate-oblong, rounded and unequal or subcordate at the base, cuspidate-acuminate at the apex; coarsely serrate or bi-serrate in the upper half, finely serrate in the lower half; nerves, about eight pairs, running to the margin; upper surface dark green, slightly pubescent; lower surface light green, pubescent throughout, the pubescence densest along the nerves and in the axils; petiole, $\frac{3}{4}$ inch, pubescent. Staminate catkins, three to five in a raceme. Cones solitary or several, ovoid-elliptic, about an inch long; nutlets broadly ovoid, with a very narrow wing.

This is a moderate-sized tree, occurring in the province of Talysch in

the Caucasus, and in the provinces of Asterabad and Ghilan in Persia, where Dr. Stapf informs me that he has seen large trees south of the Caspian Sea.

It is closely allied to, if not identical with *Alnus orientalis*, Decaisne, a native of Asia Minor and Cyprus. The latter has not been introduced, so far as we know, into English or continental gardens.

It was known in cultivation a good many years ago in France, as Gay records¹ a tree 30 feet high growing at Verrières in 1861; but we are unaware of the exact date of its introduction into England. It appears to grow as well and to be as hardy in England as *A. cordata*; and a fine tree, growing near the lake in Kew Gardens, is 52 feet high and 4 feet 10 inches in girth. There is a small specimen at Aldenham.

(A. H.)

ALNUS FIRMA

Alnus firma, Siebold et Zuccarini, *Abh. Akad. München*, iv. 3. p. 230 (1845); Sargent, *Forest Flora Japan*, 63 (1894); Winkler, *Betulaceae*, 102 (1904).

Alnus Sieboldiana, Matsumura, *Journ. Coll. Sci. Tokyo*, xvi. 5, p. 3 (1902).

Alnus yasha, Matsumura, *op. cit.* p. 4 (1902).

Alnus pendula, Matsumura, *op. cit.* p. 6 (1902).

Alnus multinervis, Schneider, *Laubholzkunde*, 123 (1904).

A tree, attaining in Japan a height of 30 feet, but usually smaller. Young branchlets three-angled at the tip, pubescent. Leaves (Plate 268, Fig. 2) about 4 inches long and $1\frac{3}{4}$ inch broad, plicate; nerves deeply immersed above and very prominent beneath, about fifteen to eighteen pairs, running parallel and straight to the margin; ovate-lanceolate, rounded and unequal at the base, acuminate at the apex; upper surface dark green, shining, glabrous; lower surface light green, pubescent, the pubescence strongest on the midrib and nerves; margin finely and regularly serrate, ciliate; petiole $\frac{1}{2}$ inch, pilose; stipules often persistent, ovate-lanceolate, $\frac{1}{2}$ inch long, membranous, glabrous. Buds sessile, conical, long-pointed, curved, green, glabrous, with two external scales.

Flowers appearing in spring. Staminate catkins terminal or lateral, 1 to $2\frac{1}{2}$ inches long. Pistillate catkins, one, two, or three to five, arising from one bud. Cones, solitary or racemose, variable in size, $\frac{1}{2}$ to 1 inch long, in the different varieties. Nutlets, obovate-oblong or sub-rhomboid with a membranous wing.

This alder displays great variation in Japan, no less than three distinct species being recognised by Matsumura and Schneider. These appear to be geographical varieties:—

1. Var. *multinervis*, Regel in *Bull. Soc. Nat. Mosc.* xxxviii. 2. 423 (1865), and in DC. *Prod.* xvi. 2, p. 183 (1868). *Alnus pendula*, Matsumura. *Alnus multinervis* Schneider.

Branchlets pubescent. Leaves with numerous lateral nerves, eighteen pairs or more. Cones in pendulous racemes, $\frac{3}{8}$ inch long. This form is the

¹ Note with a specimen in Kew Herbarium. This tree is not mentioned in *Hortus Vilmorinianus* (1906).

only one in cultivation, and grows on the banks of streams in sub-alpine regions in Yezo and Hondo.

2. Var. *Sieboldiana*, Winkler, *loc. cit.* *Alnus Sieboldiana*, Matsumura.

Branchlets glabrous. Lateral nerves twelve to fifteen pairs. Cones solitary, 1 inch long. A native of the sea-coast in Hondo.

3. Var. *yasha*, Winkler, *loc. cit.* *Alnus yasha*, Matsumura.

Branchlets pubescent. Lateral nerves twelve to fifteen pairs. Cones solitary or racemose, $\frac{3}{4}$ inch long. Occurs in mountain woods in Kiusiu, Shikoku, and Hondo.

According to Sargent, *Alnus firma* is largely planted along the borders of rice-fields near Tokyo, to afford support for the poles on which the freshly cut rice is hung to dry. He observed var. *multinervis* on the mountains of Hondo, where it grows on dry rocky soil and reaches 5000 feet elevation, and describes it as a graceful tree 20 to 30 feet in height. The species, as mentioned above under the varieties, is widely distributed throughout the whole of Japan.

It was introduced by Sargent into New England in 1892; and, according to Winkler, was brought by Zabel into the forest garden of Münden in Germany. There are trees 6 to 10 feet in height in the collection at Kew. It is a remarkably distinct species, with plicate many-nerved leaves, recalling those of two other Japanese trees, viz.: *Carpinus japonica* and *Acer carpinifolium*; and is worthy of a place in collections of shrubs, as it scarcely can be considered to be a tree.

(A. H.)

ALNUS JAPONICA, JAPANESE ALDER

Alnus japonica, Siebold et Zuccarini, *Abh. Akad. München*, iv. 3, p. 320 (1845); Sargent, *Garden and Forest*, vi. 343, f. 53 (1893), and *Forest Flora, Japan*, 63, t. 20 (1894); Shirasawa, *Icon. Ess. Forest. Japon.*, text 38, t. 19, ff. 18-34 (1900); Winkler, *Betulaceae*, 114 (1904).

Alnus maritima, Nuttall, var. *japonica*, Regel, in DC. *Prod.* xvi. 2, p. 186 (1868).

Alnus maritima, Nuttall, var. *formosana*, Burkill, *Journ. Linn. Soc. (Bot.)* xxvi. 500 (1899).

A tree attaining about 80 feet in height. Young branchlets usually glabrous. Leaves (Plate 268, Fig. 12) about 4 inches long and $1\frac{1}{2}$ to $1\frac{3}{4}$ inch wide, lanceolate or narrowly elliptical, cuneate at the base, long-acuminate at the apex; margin not lobulate, finely serrate; nerves, about twelve pairs, mostly running to the margin; upper surface dark green, shining, pubescent on the midrib and nerves; lower surface light green, glabrous except for minute axil-tufts; petiole about $\frac{1}{2}$ inch, slightly pubescent. Buds minute, stalked, glabrous, glandular.

Flowers,¹ appearing in spring, the fruit ripening in autumn; otherwise similar to *Alnus maritima*.

This species occurs in Japan, Manchuria, Korea, and Formosa. In Manchuria² it grows along the sea-coast from St. Olga Bay southwards, and also inland, either solitary or in groups, in sandy soil along the rivers. It has been collected in Korea

¹ In Formosa, according to Burkill, the flowers are produced later, in summer; and he adduces this as a reason for uniting this species with the American *A. maritima*.

² Komarov, *Flora Manchuriae*, ii. 60 (1904).

at Port Chusan; and in Formosa, it grows near Tamsui at the north end of the island. According to Sargent, it is the most beautiful and largest of the alders in Japan, forming a pyramidal tree, often 70 or 80 feet in height, and well furnished to the ground with branches clothed with large dark green lustrous leaves. It differs from *A. maritima* in the larger, differently shaped and coloured leaves, and in the time of flowering.

Sargent states that it is perfectly hardy in New England, where it grows rapidly and promises to become a large and handsome tree. It was introduced, according to Nicholson,¹ in 1886. There are small healthy trees in the collection at Kew; and at Aldenham a specimen is about 14 feet high. (A. H.)

ALNUS NITIDA, HIMALAYAN ALDER

Alnus nitida, Endlicher, *Gen. Pl. Suppl.* IV. ii. 20 (1847); Brandis, *Forest Flora N.-W. India*, 460, t. 57 (1874), and *Indian Trees*, 623 (1906); Hooker, *Flora Brit. India*, v. 600 (1888), and *Bot. Mag.* t. 7654 (1899); Gamble, *Indian Timbers*, 670 (1902); Winkler, *Betulaceae*, 108 (1904).

Clethropsis nitida, Spach, *Ann. Sc. Nat. sér. 2*, xv. 202 (1841); Cambessedes in Jacquemont, *Voy. dans l'Inde, Bot.* 159, t. 159 (1844).

A large tree attaining 100 feet in height and 15 feet in girth. Bark blackish, with thin quadrangular scales. Young branchlets densely and minutely pubescent. Leaves (Plate 268, Fig. 3) about 5 inches long, and 2½ inches broad, ovate-elliptical or elliptical, base rounded or cuneate, apex acuminate; margin entire, obscurely crenate, or remotely and slightly serrate; thin in texture; nerves, nine to twelve pairs, looping before reaching the margin; upper surface dark green, glabrous, shining; lower surface light green, glabrous except for slight axil-tufts; petiole, ¾ to 1 inch, minutely pubescent. Male catkins, 2 inches long, in terminal erect, often leafy racemes. Cones, ¾ to 1½ inch long, three to five in erect lateral racemes; nutlet with a narrow thickened margin. The flowers in this species open in September.

Alnus nitida occurs in the north-western Himalaya, from Kashmir to Kumaon, usually at low elevations, 2000 to 4000 feet, fringing the banks of rivers, and not uncommonly descending with them into the plains. It occasionally, however, ascends as high as 9000 feet; and is common on the Sutlej in the dry region of Kunawar, as far as Spui on the right bank and Namgia on the left bank, according to Brandis, who states that it attains 100 feet high and 15 feet in girth; but Gamble has never seen it so big, and says it is usually crooked and branching. An attempt was made recently to float out the wood from the Tons river forest, but failed, as the timber quickly became waterlogged. The bark is used for tanning and dyeing.

Alnus nitida is one of the few Himalayan broad-leaved trees which have

¹ *Diet. Gardening, Suppl.* 34 (1900).

succeeded in this country, where, however, it is little known, the only trees in cultivation¹ that we know of being three thriving specimens which are growing near the lake in Kew Gardens. The largest of these is now 40 feet by 2 feet 3 inches in girth. They were raised from seed sent by Mr. R. E. Ellis of the Indian Forest Department in 1882. (A. H.)

ALNUS MARITIMA

Alnus maritima, Nuttall, *Sylva*, i. 34 (1842); Sargent, *Garden and Forest*, iv. 268, t. 47 (1891), *Silva N. Amer.* ix. 81, t. 458 (1896), and *Trees N. Amer.* 215 (1905); Winkler, *Betulaceae*, 114 (1904).

Alnus oblongata, Regel, *Mém. Soc. Nat. Mosc.* xiii. 171 (1861) (in part).

Betula-Alnus maritima, Marshall, *Arb. Am.* 20 (1785).

A tree attaining in America 30 feet in height and 1 foot in girth. Bark smooth, greyish-brown. Young branchlets slightly pubescent, three-angled at the tip. Leaves (Plate 268, Fig. 11) in cultivated specimens 2½ inches long, 1¾ inch wide, somewhat larger in wild specimens, ovate or obovate, cuneate at the base; acute, slightly acuminate, or rounded at the apex; nerves, eight to twelve pairs, running to the margin; margin not lobulate, remotely serrate in the upper two-thirds with minute incurved glandular teeth; upper surface dark green, shining, glabrous; lower surface light green, glabrous; petioles ½ inch, slightly pubescent. Buds minute, stalked, ovoid, glabrous, slightly glandular.

Flowers appearing in July on the branches of the year, and opening in September. Staminate catkins in scurfy pubescent racemes in the axils of the upper leaves. Pistillate catkins usually solitary from the axils of the lower leaves. Cones ripening in the following September, so that both flowers and ripe fruit occur simultaneously on the tree, ovoid, ⅝ inch long; nutlet obovate, narrowed and apiculate at the apex, with a thin membranous border.

This alder grows on the banks of streams and ponds in Delaware and Maryland, usually near, but not immediately upon the sea-coast, as its name would seem to imply. However, it abounds on the banks of the Nanticoke and Wicomico rivers in Maryland, near the high-water mark. What appears to be the same species was collected by Hall on the Red River in Indian Territory.

It was introduced into cultivation by Thomas Meehan, who sent it in 1878 to the Arnold Arboretum, where it is tolerably hardy, flowering and fruiting freely, though it was killed to the ground in 1885. There are now two trees, about 6 feet high, growing in the nursery at Kew, which were sent by Prof. Sargent in 1899. These flower in September, and produce fruit in quantity. (A. H.)

¹ Mr. A. B. Jackson has lately seen a tree at Grayswood, Haslemere, which is 18 feet high and 9 inches in girth.

ALNUS RUBRA, OREGON ALDER

Alnus rubra, Bongard, *Mém. Acad. St. Pétersb.* ii. 162 (1833); Winkler, *Betulaceae*, 124 (1904); Sargent, *Bot. Gazette*, xlv. 226 (1907).
Alnus oregona, Nuttall, *Sylva*, i. 28, t. 9 (1842); Sargent, *Silva N. Amer.* ix. 73, t. 454 (1896), and *Trees N. Amer.* 210 (1905).
Alnus incana, Moench, var. *rubra*, Regel, *Mém. Soc. Nat. Mosc.* xiii. 157 (1861).

A tree attaining 80 feet in height and 10 feet in girth. Bark greyish or whitish, thin, roughened by minute wart-like excrescences. Young branchlets glabrous, three-angled at the tip, scarcely viscid except at the beginning of the season. Leaves (Plate 268, Fig. 16) about 4 or 5 inches long and $2\frac{1}{2}$ inches wide, ovate or elliptical, rounded or cuneate at the base, acute at the apex; nerves, about 15 pairs, each running straight and parallel to the apex of a lobule, which is furnished with minute gland-tipped serrations; margin slightly revolute and ciliate; upper surface dark green, slightly pubescent; lower surface whitish or greyish, covered with a minute brown pubescence; petiole, $\frac{3}{4}$ inch, with a few scattered hairs. Buds beaked at the apex, glabrous, stalked. Stipules ovate, acute, tomentose, $\frac{1}{8}$ to $\frac{1}{4}$ inch long.

Flowers opening in spring before the leaves. Staminate catkins, three to six in a raceme, 4 to 6 inches long when fully opened. Cones, three to six in a raceme, $\frac{1}{2}$ to 1 inch long, with truncate scales, much thickened at the apex; nutlet orbicular or obovate, surrounded by a membranous wing.

This species can only be confused with *A. incana*, from which it differs in the glabrous branchlets and the usually larger leaves with revolute margins. The buds also differ, those of *A. rubra* being elongated, pointed, and glabrous, whilst those of *A. incana* are shorter, rounded at the apex, and pubescent.

Alnus rubra, according to Sargent, ranges from Sitka, where it often clothes mountain-sides to elevations of 3000 feet above the sea, southwards through the islands and coast ranges of British Columbia, and through western Washington and Oregon, and the cañons of the Californian coast ranges, to the Santa Inez mountains near Santa Barbara. It grows to its largest size in the neighbourhood of Puget Sound, where it commonly fringes the banks of streams and grows in wet places.¹

This species was introduced into cultivation a few years ago, and there are two trees in Kew Gardens about 15 feet in height. Elwes has raised seedlings from these trees, which grow very rapidly in heavy soil at Colesborne, but being planted in a situation very subject to late frosts, have suffered on several occasions, when the grey and common alders standing near were quite untouched.

The wood is light, soft, brittle, and not strong, but close-grained and takes a fine polish; and is now largely used in Washington and Oregon for making furniture.

(A. H.)

¹ In Vancouver Island, the stem and branches are often covered with *Polypodium falcatum*, the creeping rhizomes of which find anchorage in its moss-covered bark. Cf. *Postelsia*, 1906, p. 76. A figure of the tree, growing in a moist part of the forest and surrounded by devil's club (*Echinopanax horridum*), is given in Piper, *Flora of the State of Washington*, plate vii. (1906).

ALNUS TENUIFOLIA

Alnus tenuifolia, Nuttall, *Sylva*, i. 32 (1842); Sargent, *Silva N. Amer.* ix. 75, t. 455 (1896), and *Trees N. Amer.* 211 (1905); Winkler, *Betulaceae*, 124 (1904); Schneider, *Laubholzkunde*, 133 (1904).
Alnus incana, Moench, var. *glauca*, Regel, *Mém. Soc. Nat. Mosc.* xiii. 154 (1861) (in part).
Alnus incana, Moench, var. *virescens*, Watson, in Brewer and Watson, *Bot. Calif.* ii. 81 (1880).
Alnus occidentalis, Dippel, *Laubholzkunde*, ii. 158 (1892); De Wildeman, *Icon. Select. Hort. Thenensis*, ii. 147, t. 75 (1901).

A tree attaining 30 feet in height and 2 feet in girth. Bark bright red-brown, broken on the surface into small scales. Young branchlets glabrous. Leaves (Plate 268, Fig. 15) about 3 inches long by 2 inches wide, ovate, broad and rounded at the base, acute or shortly acuminate at the apex; nerves, nine or ten pairs, running parallel and straight to the margin, and ending in acute triangular lobes, which are finely serrate; upper surface dark green, pubescent on the midrib and nerves; lower surface yellowish green, glandular, pubescent on the midrib with slight axil-tufts; petioles pubescent, $\frac{3}{4}$ to 1 inch long. Buds stalked, pubescent at the base. Stipules deciduous, lanceolate, acute, pubescent. Staminate catkins, three to four, in slender-stemmed racemes; stamens four. Cones, ovoid-oblong, $\frac{1}{3}$ to $\frac{1}{2}$ inch long, three to four in a raceme; scales thickened, three-lobed and truncate at the apex; nutlets nearly circular, surrounded by a thin membranous border.

This species, distributed over a wide area, shows two well-marked geographical varieties:—

1. Var. *virescens*, Callier. This is the commonest form, and has been described above (Plate 268, Fig. 15).

2. Var. *occidentalis*, Callier. *Alnus occidentalis*, Dippel. Leaves (Plate 268, Fig. 14) larger, 4 to 5 inches long and 3 to 4 inches wide; nerves, twelve pairs; slightly bluish-green and pubescent throughout beneath; stipules ovate, broad, obtuse. This variety is rare, and has only been observed in British Columbia and Oregon.

This species is widely distributed in western North America. It occurs in British Columbia, from Francis Lake in lat. 61° to the valley of the Lower Fraser River, and extends eastward along the Saskatchewan River to Prince Albert. It extends southwards along the Rocky Mountains to northern New Mexico, and is the common species in the northern interior region, east of the divide of the Cascade Mountains, in eastern Washington, Oregon, Idaho, and Montana. It is very abundant on the southern California Sierra, forming great thickets at 6000 to 7000 feet above the sea, along the head-waters of the rivers of southern California flowing to the Pacific Ocean. It is equally abundant and attains its largest size in Colorado and northern New Mexico, and is met with in Nevada and Utah.

This species is rare in cultivation. There are two or three trees of each variety in the alder collection at Kew, which are about 15 feet in height, and show no special beauty or vigour. Var. *virescens* is thriving at Aldenham; and a fine specimen

958 The Trees of Great Britain and Ireland

at Grayswood, Haslemere, planted in 1888, is now about 30 feet in height and 1 foot 8 inches in girth.

According to De Wildeman, var. *occidentalis* was introduced from British Columbia in 1891, by Dieck and Purpus, into the arboretum at Zoschen.

ALNUS RHOMBIFOLIA

Alnus rhombifolia, Nuttall, *Sylva*, i. 33 (1842); Sargent, *Silva N. Amer.* ix. 77, t. 456 (1896), and *Trees N. Amer.* 212 (1905); Winkler, *Betulaceae*, 115 (1904).
Alnus oblongifolia, Watson, in Brewer and Watson, *Bot. Calif.* ii. 80 (1880) (in part).

A tree attaining 80 feet in height and 9 feet in girth. Young branchlets pubescent. Leaves (Plate 268, Fig. 13) on young trees up to 5 inches long and 3 inches broad, on old trees 3 inches long and $1\frac{1}{2}$ inch broad, ovate or oval, rounded and unequal at the base, acute or rounded at the apex; margin slightly thickened and reflexed, finely and irregularly serrate, and ciliate; nerves, ten or eleven pairs, running parallel and slightly curved to the margin; upper surface dark green, shining, glabrous; lower surface light green, pubescent, the pubescence strongest on the midrib and nerves; petiole, $\frac{1}{2}$ inch, pubescent. Buds stalked, pubescent. Staminate catkins, in pubescent racemes, deciduous before the opening of the leaves; stamens, two or three, rarely one. Cones oblong, $\frac{1}{3}$ to $\frac{1}{2}$ inch long, fully grown at midsummer, but remaining closed till the trees flower in the following year; nutlet broadly ovate with a thin, acute margin.

This species grows on the banks of streams from northern Idaho to the eastern slope of the Cascade Mountains in Washington and Oregon, extending southward over the coast ranges and along the western slopes of the Sierra Nevada to the mountains of southern California. It is the common alder of central California, and the only species at low altitudes in the southern part of this state.

It is extremely rare in cultivation, the only specimen which we have seen being a small plant in Lord Aldenham's remarkable collection of shrubs and trees at Aldenham, Herts. According to Nicholson,¹ it was introduced into cultivation in 1888.

¹ *Dict. Gardening, Suppl.* 34 (1900).

BETULA

Betula, Linnæus, *Sp. Pl.* 982 (1753); Bentham et Hooker, *Gen. Pl.* iii. 404 (1880); Winkler, in Engler, *Pflanzenreich*, iv. 61, *Betulaceae*, 56 (1904).
Betulaster, Spach, in *Ann. Sc. Nat. sér. 2*, xv. 198 (1841).
Aptercaryon and *Chamabetula*, Opiz, in *Lotos*, v. 258 (1855).

DECIDUOUS trees or shrubs belonging to the order Betulaceæ. Bark smooth with longitudinal lenticels, often peeling off in papery strips, and becoming on old trunks thick and furrowed near the base. Branchlets of two kinds: long shoots with several leaves and axillary buds, no true terminal bud being formed; and short shoots or dwarf spurs, each with two (rarely one or three) leaves and a terminal bud. Buds viscid, elongated, ovoid, fully grown and green at midsummer, composed of imbricated scales, but with the two basal ones short and lateral, usually only four scales being visible externally; inner scales accrescent, and marking in falling the base of the shoots with ring-like scars. Leaves alternate, simple, stalked, penninerved; serrate, dentate or incised. Stipules lateral, enclosing the leaf in the bud, fugacious. Flowers monœcious, fertilised by the wind, in cylindrical catkins, composed of closely imbricated three-lobed scales, with three flowers on each scale. Male catkins,¹ formed in the preceding autumn, clustered in the axils of the upper leaves of a long shoot, erect and naked during winter, pendulous in spring. Staminate flowers, with a one- to four-lobed calyx; stamens two, with short bifurcated filaments, each of the four branches bearing an erect half-anther, there being thus apparently twelve stamens on each scale. Pistillate catkins, solitary, or two to four in a raceme, terminal on the short shoots, and appearing with the leaves in spring. Pistillate flowers, without a calyx, two-celled, with one ovule in each cell; styles two, stigmatic at the apex. Cones, ripening² usually in autumn, composed of woody three-lobed scales and small fruits, deciduous together; nutlets oval or obovate, compressed, bearing the persistent styles at the apex, and with the outer shell produced into a marginal transparent wing, interrupted at the apex; seed solitary, pendulous, without albumen.³

In winter, species of *Betula* are readily distinguished by the short shoots on the older wood, which end in a terminal bud, and are densely clothed with scars, as each season's growth is very short and marked by two crescentic leaf-scars in addition to the ring-like scars left by the fall of the scales of the bud of the previous spring. The long shoots show similar ring-like scars at the base, and bear axillary buds

¹ In some of the shrubby species the male catkins are solitary on the ends of the short shoots, and remain enclosed in the buds during winter, appearing in spring.

² In *B. nigra* the fruit ripens in May or June.

³ The cones, scales, and fruits shown in Plates 269 and 270, were all drawn by Miss F. H. Woolward, except in the case of Figs. 8 and 16.

arranged alternately. The leaf-scars, semicircular or crescentic, and three-dotted, have on each side a linear stipule-scar. The pith of the twigs is oblong in section.

About thirty species of *Betula* are known, all natives of the northern hemisphere, extending from the Arctic circle to Texas in the New World, and to southern Europe, the Himalayas, China, and Japan in the Old World. A considerable number are shrubs, the treatment of which does not come within the scope of our work. Of the arborescent species, a few, either not introduced or imperfectly known, are not included in the following account.

B. corylifolia, Regel et Maximowicz, though not yet introduced, is included in the key and fully described below, as it is very distinct and has been much confused with other Japanese species.

There are young plants in the nursery at Kew, received from the Arnold Arboretum, as *B. globispica*, Shirai,¹ which appear to be a very distinct species; but, as there is no authentic material in the Kew Herbarium with which to compare them and ascertain if they are correctly named, it is inadvisable to deal with this species at present.

Similarly, young plants of *B. alnoides*, Buchanan-Hamilton, var. *pyrifolia*, Franchet, growing at Coombe Wood, which were raised from seed sent from central China by Wilson in 1901, are left undescribed, as they show considerable variation, and we cannot be certain, until they have borne fruit, of their identification.

KEY TO ARBORESCENT SPECIES OF BETULA IN CULTIVATION

I. Branchlets and leaves quite glabrous.

1. *Betula verrucosa*, Ehrhart. Europe, Northern and Eastern Asia. See p. 966.
Leaves bi-serrate, shortly acuminate.
2. *Betula populifolia*, Marshall. North America. See p. 987.
Leaves lobulate and irregularly serrate, ending in a long caudate acumen.

II. Branchlets or leaves or both pubescent.

- * *Leaves cordate at the base.*
3. *Betula Maximowiczii*, Regel. Japan. See p. 976.
Leaves 5 or 6 inches long, broadly ovate.
 4. *Betula ulmifolia*, Siebold et Zuccarini. Japan. See p. 979.
Leaves, 3 inches long, narrowly ovate.
** *Leaves cuneate at the base.*
 5. *Betula pubescens*, Ehrhart. Europe, Northern Asia, Greenland. See p. 962.
Leaves light green beneath, rhombic-ovate, bi-serrate, with six pairs of nerves.
Branchlets not glandular, clothed with minute dense erect pubescence.
 6. *Betula davurica*, Pallas. Manchuria, Korea, North China. See p. 974.
Leaves light green beneath, narrowly ovate, bi-serrate, with six to eight pairs of nerves. Branchlets glandular, with minute erect pubescence interspersed with a few long hairs.

¹ The Japanese name of this species, according to Matsumura and Goto, is *Jizo-kamba*.

7. *Betula nigra*, Linnæus. North America. See p. 988.

Leaves greyish beneath, ovate, acute, with large serrated teeth, and six to eight pairs of nerves. Branchlets glandular, tomentose.

*** *Leaves rounded or truncate at the base.*

A. Leaves orbicular or oval.

8. *Betula corylifolia*, Regel et Maximowicz. Japan. See p. 975.

Leaves acute, pale beneath with conspicuous silky hairs on the midrib and nerves; nerves twelve to fourteen pairs.

B. Leaves ovate-oblong, considerably longer than broad, and widest near the middle.

9. *Betula lutea*, Michaux. North America. See p. 990.

Leaves, with nine to twelve pairs of nerves, pilose on the midrib and nerves of both surfaces, and on the petiole. Branchlets pilose.

10. *Betula lenta*, Linnæus. North America. See p. 991.

Leaves with nine to twelve pairs of nerves, pilose on the midrib and nerves of both surfaces; petiole glabrescent. Branchlets glabrous, except for a few hairs above the leaf-insertions.

11. *Betula utilis*, Don. Himalayas, China. See p. 980.

Leaves, with nine to twelve pairs of nerves; lower surface with dense axil-tufts of pubescence; petiole tomentose. Branchlets tomentose.

C. Leaves ovate, not much longer than broad, widest near the base.

† *Branchlets very glandular.*

12. *Betula Ermani*, Chamisso. Eastern Siberia, Manchuria, Japan. See p. 977.

Leaves truncate at the base, with ten to twelve pairs of nerves, glabrescent and conspicuously glandular beneath. Branchlets glabrous.

13. *Betula fontinalis*, Sargent. Western North America. See p. 992.

Leaves thin in texture; rounded, truncate, or subcordate at the base, with six pairs of nerves; both surfaces minutely glandular, with scattered long hairs. Branchlets with long pale hairs.

‡ *Branchlets not conspicuously glandular.*

14. *Betula papyrifera*, Marshall. North America. See p. 983.

Leaves about 3 inches long, with six to eight pairs of nerves; lower surface glandular and with conspicuous axil-tufts. Branchlets pubescent or glabrous.

15. *Betula utilis*, Don, var. *Jacquemontii*, Regel. Himalayas. See p. 981.

Leaves about 3 inches long, with seven or eight pairs of nerves; lower surface glandular, with long hairs on the midrib and nerves, and without conspicuous axil-tufts. Branchlets with short, erect, dense pubescence.

16. *Betula luminifera*, Winkler. Central China. See p. 980.

Leaves, 5 or 6 inches long, with ten to fourteen pairs of nerves, pubescent on both surfaces. Branchlets with dense erect pubescence.

(A. H.)

BETULA PUBESCENS, COMMON BIRCH

Betula pubescens, Ehrhart, *Beit. Naturk.* vi. 98 (1793); Mathieu, *Flore Forestière*, 415 (1897); Winkler, *Betulaceæ*, 81 (1904).

Betula tomentosa, Reitter and Abel, *Abbild. Holzart*, i. 17 (1790).

Betula alba, Linnæus, *Sp. Pl.* 982 (1753) (in part); Roth, *Tent. Fl. Germ.* i. 404 (1788); Willkomm, *Forstliche Flora*, 302 (1887); Schneider, *Laubholzkunde*, i. 116 (1904).

Betula alba, Linnæus, var. *pubescens*, Loudon, *Arb. et Frut. Brit.* iii. 1691 (1838).

Betula odorata, Bechstein, *Diana*, i. 74 (1797).

A tree, usually attaining 70 or 80 feet in height, and 5 or 6 feet in girth, occasionally larger. Branches ascending or spreading, branchlets usually not pendulous. Bark smooth, white, and papery, often peeling off in transverse shreds, with black triangular markings below the insertion of the branches; thick and deeply furrowed at the base of old stems. Young branchlets covered with short, erect pubescence, often minute and only discernible with a lens, usually retained in the second year. Leaves (Plate 269, Fig. 1), $1\frac{1}{2}$ inch to 2 inches long, $\frac{3}{4}$ inch to $1\frac{1}{2}$ inch wide, rhomboid-ovate or ovate, usually cuneate at the base, acute or acuminate at the apex; margin ciliate and coarsely serrate; nerves, five or six pairs; upper surface with scattered pubescence; lower surface pubescent on the midrib and nerves; petiole, $\frac{1}{2}$ inch, pubescent and glandular.

Fruiting-catkins (Plate 269, Fig. 1), cylindrical, about 1 inch long, $\frac{1}{3}$ inch wide, at first erect, afterwards pendulous, on long pubescent stalks; scales, puberulous, ciliate, with the central lobe more prolonged than is the case in *B. verrucosa*, and with the lateral lobes angular and usually erect, but occasionally recurved.¹

In winter the twigs are slender, dark brown, densely covered with short, erect pubescence. Buds, $\frac{1}{5}$ inch long, ovoid, rather blunt at the apex, viscid, with glabrous, ciliate scales.

Seedling.²—Cotyledons, about $\frac{1}{6}$ inch long, oblong-ovate, obtuse, glabrous, with pubescent petioles, about $\frac{1}{8}$ inch long. Caulicle short, pubescent, raising the cotyledons above the ground. Stem pubescent and non-glandular, bearing primary leaves, which are alternate, ovate, cordate at the base, simply and coarsely serrate, and pubescent.

The birch,³ under ordinary conditions of growth, does not produce root-suckers; however, when cut down, although coppice shoots are not given off from the stool, the roots give rise to numerous tomentose shoots, which bear leaves larger than those of ordinary branches, cordate at the base, dentate in margin, and pubescent on both surfaces.

¹ When the lateral lobes are recurved, the scales are similar in shape to those of *B. verrucosa*; and in such cases we may suspect a hybrid between the two species or an intermediate form. The pubescent stalks of the catkins and the puberulous scales are, however, apparently characteristic of *B. pubescens*.

² Cf. Lubbock, *Seedlings*, ii. 541, fig. 672 (1892).

³ Cf. Dubard, in *Ann. Sc. Nat.* xvii. 169, plate 2, fig. 4 (1903).

The witches' brooms, which are so common on birch trees, are generally supposed to be due to a fungus, *Exoascus betulinus*, the threads of which penetrate the young growing twigs, causing them to branch repeatedly and thus form large, irregular, nest-like clusters. Miss Ormerod,¹ however, states that these abnormal growths are caused by the development of unhealthy buds, which have been attacked by a gall-mite.² It is possible that in some cases it is the fungus, and in other cases the gall-mite, which is the cause of these witches' brooms.

A large number of birches were killed in 1900 in Epping Forest by a fungus, identified, by Paulson,³ with *Melanconis stilbostoma*, Tulasne, which attacks the young growing branches.

VARIETIES

This species is very variable in the wild state, both as regards the stature of the tree and the shape, size, and pubescence of the foliage. A large number of varieties have been distinguished by Continental botanists, of which the nomenclature is very confused; and as most of these are separated by inconstant characters and are of no value from the cultivator's point of view, it will be sufficient here to refer the reader to the works of Willkomm, Winkler, and Schneider, where the different forms are fully dealt with. The following varieties are, however, worthy of note:—

1. In Alpine and northern localities this species is often met with as a small shrub with twisted branchlets, but with leaves very variable in character. This group of forms may be distinguished as var. *tortuosa*, Koehne, *Deut. Dend.* 109 (1893).

2. Var. *Murithii*, Gremlin, *Excursionsfl. f. d. Schweiz*, 365 (1893).

B. Murithii, Gaudichaud, *Fl. Helv.* vi. 178 (1830); Christ, *Ber. Schweiz. Bot. Ges.* v. 16 (1895).

An Alpine shrub, occurring in the Bagnes valley, near Mauvoisin (Valais), in Fribourg, and in the Joux valley (Vaud) in Switzerland. This has broadly ovate or ovate-triangular leaves, with large simple serrations, and prominent reticulate venation beneath.

3. Var. *denudata*, Grenier et Godron, *Fl. France*, iii. 147 (1855). This name may be given to a series of forms, characterised by rhombic leaves, cuneate at the base, and glabrous beneath or with only slight axil-tufts. This is often cultivated as var. *pontica*,⁴ var. *carpatica*,⁵ var. *odorata*, etc., and is usually a tree of considerable size.

4. Var. *urticifolia*, Spach, in *Ann. Sc. Nat.*, sér. 2, xv. 187 (1841); Schneider, *Laubholzkunde*, i. 117 (1904).

Betula urticifolia, Regel, in *Mém. Soc. Nat. Mosc.* xiii. 115 (1860); Willkomm, *Forstliche Flora*, 313 (1887); Winkler, *Betulaceæ*, 80 (1904).

¹ *Injurious Insects*, 212 (1890).

² Gillanders, *Forest Entomology*, 25 (1908), identifies the gall-mite with *Eriophes rudis*, Canestrini; and gives a figure of swollen buds on the branch of a birch tree. These had been found in close proximity to a witches' broom.

³ *Essex Naturalist*, xi. 1, p. 273 (1901). Cf. also *Nature*, lxxii. 599 (1900). Mr. Massee thinks that root-rot or unsuitable soil conditions, rather than the fungus, were the cause of death of these trees.

⁴ There is a good-sized healthy tree in the Botanic Garden at Glasnevin, under the name of *B. alba*, var. *pontica*, which was mentioned by Loudon as being, in 1838, thirty-five years old and 35 feet high.

⁵ The true var. *carpatica* (*B. carpatica*, Waldstein and Kitaibel, in Willdenow, *Sp. Pl.* iv. 464 (1805)) is a low tree allied to var. *tortuosa*, the distinctive characters of which are given in Schneider, *op. cit.* 119.

This variety, which was long considered to be a distinct species, has been shown by Beissner and Schneider to be an abnormal form of *B. pubescens*. It differs from the type in the longer, more acuminate, slightly lobed leaves; and in the fruiting-catkins, which are very long ($1\frac{1}{2}$ inch or more) and slender, with pubescent ciliate scales, the middle lobe of which is elongated. The leaves and fruit are shown in Plate 269, Fig. 2.

This peculiar form has been found wild in the province of Wermland, in Sweden, and is only a tree of small dimensions. It is often planted in botanical gardens.

5. Some peculiar forms have arisen in cultivation, as var. *aurea*, young foliage tinted with yellow, sent out a few years ago by G. Paul, Cheshunt Nurseries; and var. *nana*, a dwarf form.

HYBRIDS

1. Hybrids have often been observed between this species and *B. verrucosa*, and have received various names, as *B. hybrida*, Bechstein, in *Diana*, i. 80 (1797); *B. aurata*, Borkhausen, *Forstbot.* i. 498 (1800); *B. glutinosa*, Wallroth, *Sched. Crit.* 497 (1822); and *B. ambigua*, Hampe, in Reichenbach, *Fl. Sax.* 120 (1842). These hybrids are intermediate in the characters of the branchlets, foliage, and fruit; and may be suspected in cases where the branchlets are more or less glandular and show slight pubescence.

2. *B. intermedia*, Thomas, in Gaudichaud, *Fl. Helvet.* vi. 176 (1830), a hybrid between *B. pubescens* and *B. nana*, is a shrub about 10 feet high, with small leaves, which is found in the Swiss Jura, Greenland, Iceland, northern Europe, and Siberia. This has been collected¹ in a few localities in the Highlands of Scotland.

DISTRIBUTION

This species is widely distributed through Europe and northern Asia, extending farther northward than *B. verrucosa*, but not descending so far south. It is the most northerly tree in Europe, growing on the shores of the Arctic Sea from North Cape (lat. 71°) to the mouth of the White Sea; its northern limit eastward through north-eastern Russia and Siberia to Kamtschatka being near the Arctic circle, though in some localities it ascends a degree or two higher. Its southern limit in Russia and Siberia appears to be the edge of the steppes, on which the tree does not grow; but it occurs in the Caucasus and Armenia. Farther westward the southern limit is the Carpathians and the Alps; and the tree is not found in the Apennines or in the Pyrenees, its most southerly point in France being near Grenoble. It is also a native of Iceland and of south-western Greenland. The distribution may then be roughly described as the northern hemisphere, from Greenland in the west to Kamtschatka in the east, between the parallels of 45° and 71° .

As compared with *B. verrucosa*, this species is found on the continent of Europe on wetter soils and in moister climates, and is the birch which grows on marshy ground and on undrained peat-mosses.

¹ Cf. E. S. Marshall, in *Journ. Bot.* xxxix. 271 (1901), and *Bot. Exchange Club Report* for 1904, p. 33.

In Norway, Schübeler distinguishes this species as the highland birch, and speaks of *B. verrucosa* as the lowland birch, the latter not being found north of Snaasen in lat. $64^\circ 12'$, or on the fells higher than 1600 to 1800 feet.

In Russia it forms large pure forests in the provinces of Olonetz and Vologda; while in Esthonia, Livonia, and Finland, it is mixed with pine, spruce, and aspen; farther south it is gradually replaced by *B. verrucosa*, with which, however, it is sometimes associated. Von Sivers¹ states that in the Baltic provinces this species is the characteristic tree of the low-lying moors, and on account of its resistance to May frosts, holds its own with the spruce and common alder. On better soils it forms immense forests, where *Betula humilis* and *Rhamnus frangula* are the underwood, and which are the favourite summer resort of the elk. It never attains such large dimensions as *B. verrucosa*, scarcely ever surpassing 100 feet in height.

In northern Germany, large forests, composed mainly of this species and common alder, are common on marshy ground. In France it is usually met with in the moister parts of the forests or on peat-mosses.

It appears to be much more common, as a wild tree, in the British Isles, than *B. verrucosa*, the moist climate being favourable to its development; and the extensive birch forests of the Highlands of Scotland are usually *B. pubescens*. As the two species have not as a rule been distinguished by collectors, and no discrimination has been made between planted and wild trees, it is impossible at present to give an accurate account of the distribution of the two species in this country. (A. H.)

The distinction between the two forms or species of common birch which is almost universally admitted by Continental botanists and foresters appears to have been generally overlooked in Great Britain; and though most local floras admit both, yet, after much inquiry and investigation, I have found it impossible to define their distribution as indigenous trees. In many districts where the birch now reproduces itself by seed abundantly, the original parents were of both forms, which are not distinguished by nurserymen, though the name "silver birch" is supposed to be, and should correctly be used for the rough-twigged form. The bark of this being more silvery—though this character is variable and disappears with age—and the habit more pendulous and graceful, it should be chosen as an ornamental tree. But, where birch is planted on peat bogs or wet moors in order to produce a timber crop, and to prepare the ground for planting other trees, as has been recommended by Mr. G. U. Macdonald,² or to act as a nurse for other trees, it would be preferable to use the downy-twigged form, which is considered to be more naturally at home and to thrive better on wet than on dry rocky soil.³

But both forms as well as their hybrids grow together in many parts of England and Scotland, and my experience in planting them does not justify me in saying that there is a marked difference in their relative growth or size. However,

¹ *Forst. Verhält. Balt. Prov.* 18 (1903).

² "Protection of Young Spruce from Frost," in *Trans. Roy. Scot. Arb. Soc.* xix. 287 (1906).

³ M. Bommer, Director of the Botanic Garden at Brussels, pointed out to me in the Museum there, characters in the bark by which he could distinguish the two common birches. It seems to me, however, that bark is, especially in the birch, so much influenced by climate, soil, and the age and vigour of the trees, that these characters were not reliable.

when visiting the nursery at Balmoral in 1904, I noticed self-sown seedlings of both forms, in which the distinction was very striking, and took some away with me, which I planted on my trial beds at Colesborne. Of these the growth of *B. verrucosa* has been immensely superior; and Mr. J. Michie, Commissioner to His Majesty at Balmoral, writing to me on the subject, says, "I have no doubt about the rough and smooth twigged birches remaining constant through life; they are distinct varieties, and in nature grow side by side frequently. I do not say that the rough-twigged variety always develops a pendulous habit with age, but it grows larger and has a lighter colour of bark. It generally weeps, on the same ground where the other remains rigid, of less size, and with darker bark."

Birch is the most Alpine tree in Great Britain, and ascends in the Highlands to about 3000 feet.

The Gaelic name of the birch is *beith* (pronounced bey), and according to Sir Herbert Maxwell,¹ is found in various forms in Scottish place-names, as Drumbae, the birch-ridge, Auchenvèy and Largvey in Galloway (*achadh-na-beith*, birch field, and *learg-bheith*, birch hill-side). Beòch in Ayrshire, Galloway, and Dumfriesshire is *beitheach* (beyagh), birch-land.

In Ireland, this word² occurs in many names of places, as Ballybay in Monaghan (mouth of the ford of the birch), Kilbehenny, a village in Tipperary (birch-wood), Aghavea in Fermanagh (birch-field). Beagh is also a common place-name in different parts of Ireland.

(H. J. E.)

BETULA VERRUCOSA, SILVER BIRCH

Betula verrucosa, Ehrhart, *Beit. Naturk.* vi. 98 (1791); Willkomm, *Forstliche Flora*, 314 (1887); Mathieu, *Flore Forestière*, 407 (1897); Winkler, *Betulaceae*, 75 (1904).

Betula pendula, Roth, *Tent. Fl. Germ.* i. 405 (1788); Schneider, *Laubholzkunde*, i. 113 (1904).

Betula alba, Linnæus, *Sp. Pl.* 982 (1753) (in part).

Betula alba, Linnæus, var. *pendula*, Aiton, *Hort. Kew*, iii. 336 (1789); Loudon, *Arb. et Frut. Brit.* iii. 1691 (1838).

Betula rhombifolia, Tausch, in *Flora*, xxi. 2, p. 752 (1838).

Betula lobulata, Kanitz, in *Linnaea*, xxxii. 351 (1863).

Betula odorata, Reichenbach, *Icon. Fl. Germ.* xii. 2, t. 626, f. 1288 (1850) (not Bechstein).

A tree, attaining in Russia 120 feet in height and about 12 feet in girth. Bark like that of *B. pubescens*, but more silvery white in colour. Main branches ascending, smaller branches and branchlets pendulous. Young branchlets glabrous, with scattered minute glands, which are persistent in the second year.

Leaves (Plate 270, Fig. 9) about 1½ to 2 inches long, and 1 to 1½ inch broad, deltoid, with a broadly cuneate base and an acuminate apex; margin biserrate; nerves five or six pairs; both surfaces glabrous and glandular; petiole ¾ inch, glabrous, glandular.

Fruiting-catkins (Plate 270, Fig. 9) cylindrical, about 1 inch long and ½ inch wide, directed towards the apex of the branchlet, on a slender, glabrous, glandular

¹ *Scottish Land Names*, 109 (1894).

² Joyce, *Irish Names of Places*, i. 506 (1883).

stalk, about ½ inch long; scales glabrous, ciliate, with rounded, recurved lateral lobes larger than the middle lobe.

The twigs in winter are slender, shining, glabrous, covered with scattered glands and waxy patches. Buds ovoid, acute, ¼ inch long, appressed to the branchlet, with brown glabrous scales.

The shoots, which spring, as in *B. pubescens*, from the roots, after a tree is felled, are covered with numerous glandular warts and layers of wax, and bear large, incised, pubescent leaves. The seedlings of this species have simply serrate, pubescent leaves resembling those of seedlings of *B. pubescens*,¹ but conspicuously glandular on both surfaces; the stem is pubescent, but bears numerous glands.

VARIETIES

1. Var. *dalecarlica*, Linnæus, f., *Suppl.* 416 (1781), Fern-leaved Birch. Leaves (Plate 270, Fig. 10) produced into a long acuminate apex, and with the margin cut into pinnatifid serrated lobes. This variety has been found growing wild in the provinces of Dalecarlia and Wermland in Sweden, and is occasionally seen in cultivation, there being a good specimen in Kew Gardens.² It is sometimes known in nurseries as *var. laciniata*.

2. Shrubby forms, with leaves smaller than in the type, have been distinguished as *var. oycowiensis*, Regel, in DC. *Prod.* xvi. 2, p. 164 (1868), found growing wild in Silesia and Galicia; and *var. arbuscula*, Winkler, observed by Fries in the wild state in Dalecarlia.

3. Var. *japonica*, Rehder, in Bailey, *Cycl. Am. Hort.* i. 159 (1900); Schneider, *Laubholzkunde*, i. 112 (1904).

Betula japonica, Siebold, *Verh. Batav. Gen.* xii. 25 (1830); Winkler, *Betulaceae*, 78 (1904).

Betula latifolia, Tausch, *Fl. Ratisb.* 751 (1838); Komarov, *Act. Hort. Petrop.* xxii. i. p. 38 (1904).

Betula alba, Linnæus, sub-species *latifolia*, Regel, in *Bull. Soc. Nat. Mosc.* xxxviii. 399 (1865), and in DC. *Prod.* xvi. 2, p. 165 (1868).

Betula alba, Linnæus, var. *Tauschii*, Shirai, in *Tokyo Bot. Mag.* viii. 319 (1894).

In eastern Asia, in Manchuria, Saghalien, and Japan, the common birch is represented by a series of forms which have been grouped together by Winkler under the name *B. japonica*, Siebold. In some respects they approach more closely *B. verrucosa* than *B. pubescens*, and are perhaps best treated as a geographical variety of the former species. Trees of Japanese origin cultivated in Kew Gardens show the following characters:—Young branchlets sparingly glandular, glabrous or with a few scattered hairs. Leaves, 2 inches long, 1½ inch wide, ovate, cuneate at the base, acuminate at the apex; margin ciliate, sharply and simply serrate; nerves seven or eight pairs; upper surface with scattered pubescence; lower surface light green, glandular, glabrous except for slight pubescence on the midrib and nerves; petiole, ¾ inch, glabrous, glandular. Fruiting-catkins about 1 inch long, ½ inch wide,

¹ Cf. Watson, *Compendium*, 560 (1870); and Kerner, *Nat. Hist. Plants*, Eng. Trans. ii. 514 (1898).

² According to Schübeler, p. 461, this beautiful variety was first found in 1767 at Lilla Ornäs, about seven English miles south of Falun in Sweden, when it was quite a small tree, 6 feet high, but grew to be in 1878, 64½ feet high, with a trunk 6 feet 8 inches in girth. An excellent illustration of it is given by Schübeler (Fig. 86) with outlines of the leaves (Fig. 87).—(H. J. E.)

cylindrical, on long, slender, minutely pubescent, glandular stalks; scales long-stalked, veined, puberulous, ciliate, with the triangular central lobe slightly longer than the broad, rounded, recurved, lateral lobes; nutlets with rather broad wings.

This variety¹ is distinct in the larger number of nerves in the narrower, longer, slightly pubescent leaves, which are simply serrate in margin; and in the characters of the fruit-scales. The bark of cultivated trees is more like that of *B. Ermani* than the common birch, as it is uniformly white in colour, with raised whitish lenticels, and scales off in transverse shreds. According to Sargent,² it is a slender tree, attaining about 80 feet in height in Yezo.

There are three trees of this variety in Kew Gardens, about 20 to 25 feet in height, which were raised from Japanese seed sent by Sargent in 1891 under the erroneous name *B. ulmifolia*. A similar tree,³ 25 feet high, cultivated at Kew as *B. alba*, var. *latifolia*, was obtained from Madrid in 1887. These trees are narrowly pyramidal in habit, and very ornamental on account of their beautiful white bark; and appear to be fast in growth and very thriving.

4. Several varieties have arisen in cultivation, of which the most noteworthy are:—

Var. *Youngi*, Schneider, Young's weeping birch; and var. *elegans*, Schelle, Bonamy's⁴ weeping birch. Both these forms have long, slender, pendulous branchlets; and are usually grafted on stems 6 to 8 feet high, when they assume the habit of the weeping sophora. A fine specimen is growing in Smith's nursery at Worcester.

Var. *fastigiata*, Schelle, is characterised by its upright branches, the tree resembling in its appearance a Lombardy poplar. According to a writer in *Woods and Forests*, this variety retains its foliage later in autumn than any other form of the silver or common birch.

Var. *purpurea*.⁵ Leaves purple, resembling in colour those of the purple beech, valuable for ornamental planting.

DISTRIBUTION

This species is widely distributed in Europe, and in northern and eastern Asia. The northern limit, beginning in Scotland, crosses Norway in lat. 64°, Sweden in lat. 65°, and ascends in Russian Lapland to Lake Ruanjärvi; and thence, crossing Lake Onega, passes through the province of Vologda to Siberia, where its exact distribution has not been made out. In eastern Asia, var. *japonica* is met with in Manchuria, Saghalien, and Japan. The type occurs in the mountains of north China, and was found near Lake Kokonor (lat. 37° 50') by Przewalski; and it appears to be the common birch in the Altai and Ural mountains. It is not found in Persia or Afghanistan, but occurs on the higher mountains of the Caucasus and in Armenia and Asia Minor. In Europe the southern limit extends from the

¹ The Japanese name for this variety is *Shira-Kamba*.

² *Forest Flora of Japan*, 61 (1894).

³ This tree has broadly ovate leaves, subcordate or rounded at the base, and larger than those of the trees raised from Japanese seed, sent by Sargent; but in other respects is identical, and is probably also of Japanese origin.

⁴ This originated in Bonamy's nursery at Toulouse, and is usually known in gardens as *B. alba pendula elegans*. Cf. *Rev. Hort.*, 1869, p. 135, fig. 33, and *Gard. Chron.*, 1869, p. 1278.

⁵ Probably identical with var. *atrosanguinea*, stated by Schübeler to have originated in France, and to be growing in the Botanic Garden at Christiania.—(H. J. E.)

Rhodope mountains in Bulgaria, through Servia, Bosnia, and Istria to the Venetian Alps; and following the southern limit of the Alps in northern Italy, it extends from the maritime Alps along the Apennines to Aspromonte in Calabria, crossing over to Sicily, where it reaches its extreme southerly point on Mount Etna in lat. 37° 40'. It does not occur in Corsica or Sardinia. It is common in the forests of the plains and lower mountains of France in the north, east, and west; but towards the south only grows at high elevations, as in the mountains of Auvergne and in the Pyrenees. It grows in Portugal in the Sierra de Gerez; and in Spain throughout the northern mountains, in Catalonia, Aragon, Navarre; and also in the Sierra Guadarrama, the mountains of Toledo, and the Sierra de Gata.

The largest forests of the species occur on the plains of the Baltic and central provinces of Russia, where it grows either pure or in mixture with aspen and grey alder, or with the common pine and spruce. Von Sivers¹ points out that the two species of birch occur in the Baltic provinces in different soils and situations. *B. verrucosa* grows on the glacial drifts, where it reaches large dimensions, and often forms pure forests of clean, straight stems, which on the better class of soil, amongst spruce, often reach 100 to 130 feet in height.

There are also extensive pure woods in the plains of northern and central Germany; but farther south the tree is more at home in the mountains, as in the Alps and Carpathians, and only forms small woods, or grows scattered or in groups amidst other trees.

This species is most common in continental Europe on dry soils, thriving best in localities where the common pine does well, as in loamy sands with a moderately moist subsoil; but dwindles and ceases to grow on marshy ground or on undrained peat-mosses. It requires more light than the other species, and in woods of *B. verrucosa* the soil is usually covered with grass; the leaf mould and moss, so common on the ground in woods of *B. pubescens*, being usually absent.

(A. H.)

CULTIVATION OF THE COMMON AND SILVER BIRCH

After the oak, there is perhaps no tree which has been so generally attractive to artists and lovers of the picturesque as the birch, which will grow almost anywhere, and is often looked on by English foresters and woodmen as a weed. This it may be on land fit to grow fine timber; where, however, it is not often so prevalent as on poor dry soils, or on wet, boggy land; but when the question of covering waste land with timber of some sort at a low cost has to be considered, there is no tree that will do it so cheaply and so surely as the birch.

It seeds very profusely, and the seed is so light that it spreads with great rapidity, and germinates in places where hardly any other tree will live. It is absolutely the hardiest tree we have, and though its economic value is low at present, yet probably it will, when our coal gets scarce and dear, be looked on as the cheapest and best of firewood.

¹ *Forst. Verhält. Balt. Prov.* 18 (1903).

In north Russia it is the usual fuel for railway engines, and all over Scandinavia is the principal firewood, but though our climate does not produce the tree as well as that of more northern regions, where the bark is almost the only material used for covering the roofs of common buildings; yet, having regard to the great beauty of the tree in landscape, it should be much more generally grown than it is. All this was well brought out by Loudon many years ago in his great work, and yet the birch remains a neglected tree. But it has another virtue which must appeal to many in these days. It is of all trees the one most distasteful to rabbits, and on my property is the only tree which grows up from self-sown seed, on land which on account of its poverty has been treated as a rabbit warren.

As a nurse for other trees on poor land, whether of a dry and rocky nature, or wet and peaty, the birch seems to me to have a greater value than most writers on forestry have admitted. For wherever the soil is naturally covered by self-sown birch, or a fairly thick crop can be obtained by sowing, the land will be made fit for the planting of more valuable trees, such as larch or Corsican pine, at a lower cost; and after providing shelter for smaller plants than could otherwise be used, it can, when the permanent crop has been established, be cut and sold at an age when spruce or Scots pine of the same age would be worthless.

A very successful instance of its use in this way has been described¹ by G. U. Macdonald, forester at Raith, Fifeshire, the object here having been to plant moorland with spruce, in a locality where the late and early frosts were so severe that the spruce would hardly grow at first without some protection.²

On very dry oolite soil, birch is the only tree which reproduces itself naturally among long coarse grass, which it will, if thick enough, eventually suppress; and, though a large quantity of small birch wood may not be always saleable at as good a price as at Raith (20s. per ton for crate-wood), yet it is such excellent firewood, even when quite small, that having regard to the low cost of its seed, I can suggest no means whereby the desired result could be obtained so cheaply.

If desired to establish a birch covert by sowing, I would advise the careful selection of seed from trees naturally growing on land of similar character, because though foresters in this country have not yet realised the preference shown by the rough twigged birch for dry rocky land, it is universally accepted as a fact in Germany, whilst for wet or boggy land the downy twigged birch is preferable.

To raise birch from seed is not always easy; and whether it is better to sow in autumn directly the seed is ripe, or in spring, is a question which, after trying both plans, I have not yet decided to my own satisfaction. But, as a rule, I would follow nature and sow in autumn, not attempting to cover the seed with earth, but covering with some fir boughs, fern, or leaves, until it began to germinate. So far

¹ *Trans. Roy. Scot. Arb. Soc.* xix, 287 (1906).

² It has been used with great success as a nurse for beech in some of the plantations, which were made by the Danish forester, Ulrich, near Copenhagen, and which were shown to the Royal English Arboricultural Society, in August 1908. The object here was to protect young beech trees from spring frosts, and afford shade during their youth. Birches were planted in lines about 8 feet apart, and the beech planted between the rows of birch eight or ten years later. When the beech are sufficiently tall, the birch are thinned and finally cut out entirely and used as firewood. This system seemed to me to be one well worthy of adoption in England for other trees which require shade in youth.

as I have seen the germination is slow and irregular, and seems to depend a good deal on the maturity and age of the seed. For though birch seed is best sown the first year, I have had fair results from seed which had been kept a year in a bag, whilst I have sometimes obtained poor results from fresh seed sown in spring. I always sow the seed of exotic birches in pots or under glass, and prick out the seedlings at a year old.

As a rule the seedlings grow fast, and must not be left long in the nursery, as they do not transplant well when old, but there is much variation among the different species; and it seems that some of the American birches do not grow well or live long in this country, unless grafted on the roots of the common birch.

As a rule the birches seem to grow best in nature when unmixed with other trees; and in some of the best birch woods I have seen in Norway, Japan, and America are almost pure, but if mixed with conifers or other hardwoods, and not suppressed by their shade, they often attain large dimensions.

REMARKABLE TREES, COMMON AND SILVER BIRCH

Among the numerous birches which I have measured in England, I cannot mention any tree which is equal in height to some that I have seen in Norway and Russia, as the tallest do not exceed about 90 feet. Along the road which passes through Savernake Forest from Marlborough to Andover there are a great number of large and beautiful trees, planted as an avenue on both sides; but of their age I can obtain no record. Near the school is one of the finest (Plate 225), which measured in 1908 about 90 feet high by 8 feet in girth. Another near it was covered with large witches' brooms; and a third, from which a large branch had been recently torn off by the wind, was pouring out sap in such quantity that a pool of it had formed on the ground. In this park a birch, which was considered by the woodman to be the largest, and which like the rest appeared to be *B. pubescens*, measured 77 feet by 10 feet 7 inches.

Plate 256 shows the graceful habit of a fine birch in front of Lord Walsingham's house at Merton, Norfolk. Plate 257 shows a group of self-sown birches in Sherwood forest, close to the Queen oak, described on page 322 of this work.

At Dropmore there is a birch (*B. pubescens*) about 55 feet high, with an immense bole 21 feet in girth at a foot from the ground, and dividing a little way up into three main stems, 9 feet 10 inches, 8 feet 2 inches, and 6 feet 3 inches in girth respectively. One large limb has rested on the ground for many years, but does not seem to have rooted.

In Windsor Park there are numerous fine birches, one of the handsomest of which, growing by Prince Albert's chapel, was in 1904 71 feet by 8 feet 8 inches. At Longleat there is a fine tree of which Colonel Thynne has sent me a photograph, and which measured 76 feet by 9 feet 4 inches in 1906. At Barton there is a tree from 80 to 85 feet high, with a clean stem about 50 feet long and 5 feet 7 inches in girth, and drooping branches. This tree is still young and vigorous, and is one of the finest we have seen anywhere.

At Beauport, Henry saw one dividing at 5 feet into five stems, and girthing below the fork 11 feet. At Arley Castle he measured one 76 feet by 8 feet 1 inch in 1905. At Croome Court there is a tree 77 feet high, of which one large stem has been broken off short. Mr. J. Smith mentions¹ a birch growing at Embley Park, Hants, in 1887, which was 85 feet by 6 feet 7 inches, with a bole of 25 feet.

In Wales the birch, so far as I have seen, does not attain so large a size as in England and Scotland, the finest I know of being at Ogwenbank, near the entrance to the great slate quarry at Penrhyn. This, though only about 50 feet high, spreads over an area 25 paces in diameter, and has two main stems which are 13 feet and 12 feet 2 inches in girth respectively.

In Scotland, Mr. Renwick considers a birch (*B. verrucosa*) at Auchendrane, in Ayrshire, to be the finest in the west of Scotland. He gives an account of this tree, with a photograph, in *Trans. Nat. Hist. Soc. Glasgow*, vii. 262 (1905). It is 67 feet in height, with a bole of 13 feet, girthing 10 feet 8 inches; and was planted, according to Miss Cathcart, by her mother in 1818, having been purchased from Booth's nursery near Hamburg as a cut-leaved weeping birch.

A still larger tree at Newton Don, near Kelso, which was cut down in 1901, measured, in 1893, 80 feet high, with a short bole, 13 feet in girth at 1 foot 7 inches above the ground, and dividing at 3 feet up into two main stems. Captain C. B. Balfour informs us that Jeffrey, in his *History of Roxburghshire*, describes it in 1859 as being then 74 feet high and 14 feet in girth at the base.

At Monzie there are some tall birches, drawn up by other trees, one measuring 90 feet high by 8 feet in girth. At Blair Drummond there are several old birches, all with large boles, some with remarkable burrs, and one with low spreading branches layering. One of these measured 60 feet by 13 feet 10 inches; and another 70 feet high is 10 feet 8 inches in girth.

In Darnaway Forest there are many fine birch trees on the banks of the Findhorn, one of which was stated by Sir Thomas Dick Lauder to girth 13 feet; but I am informed by Mr. D. Scott, forester to the Earl of Moray, that many of these have died, and those remaining are fast decaying. The largest measure 9 to 10 feet in girth, and many of them contain 70 to 75 cubic feet of timber. The rough twigged birch predominates here, but does not as a rule assume a pendulous habit until it is of some age.

At Gordon Castle there is a fine tree in the park, which in 1904 was 68 feet by 9 feet; and at Murthly, in the drive from Dunkeld, I measured in 1906 a very tall and slender birch (*B. verrucosa*) which was 89 feet high and only 3 feet 9 inches in girth.

In the Pass of Killiecrankie and many other Highland glens the birch grows freely mixed with oak on the rocky slopes, and in the wide valley of the Spey there are beautiful open woods of pure birch, covering a large extent of the gravelly flats and terraces which every traveller on the Highland Railway between Kingussie and Grantown must have admired. In the swampy flat at the head of Loch Morlich, in Glenmore, there is an open wood of curiously distorted, twisted, and stunted

¹ *Trans. Scot. Arb. Soc.* xi. 532 (1887).

birches, mixed with alders, in the hollow trunks of which the goosander occasionally breeds, and the goldeneye duck may also sometimes do so (Plate 258).

In no part of Great Britain do the birches assume the same tall, clean growth, or have the same smooth, silvery bark that they do in the forests of Scandinavia, where pure woods of birch are in some districts very prevalent on the lower land, whilst on the fjelds and mountains it ascends as a scrubby and stunted tree to a greater elevation than any other. Schübeler¹ describes and figures some instances of abnormal growths in birch. His figure 88 shows a fallen trunk from which six healthy-looking young trees are growing in a line, and I have a similar though less striking instance in my own woods. The tallest birch he knew in Norway was at Drobak in Sœterdalen, 30 kilometres south of Christiania, and measured 100 feet by 5 feet 9 inches. Another at Sondre Tveten, in Eidanger, was 79 feet by 11 feet. He figures a remarkable tree at Dunserud, in Eker, which divides into six large trunks, and measures 75 feet in height. Perhaps the most shapely and beautiful of those which he figures, are a tree at the farm of Hohls, in south Trondhjem Amt, measuring 80 feet by 11 feet, and another at Gravrok, 18 kilometres south of Trondhjem, which measured 80 feet by 16 feet. It seems from these particulars that the birch is the largest deciduous tree in Norway, and attains greater dimensions than in this country; but though I have spent several months in the forests of north and south Trondhjem in the pursuit of my favourite quarry, the elk, I never saw such trees as those above mentioned, and believe that they all grow in the neighbourhood of farms on unusually fertile soil.

TIMBER AND BARK

The timber of the birch can hardly be said to have any general recognised value in England, though in some districts it can be sold to coopers, chairmakers, and clogmakers;² in others, especially since charcoal burning has ceased in most places to be a profitable industry, it can only be looked on as firewood. It is so perishable in contact with the soil, that it is of no use for fencing unless creosoted; and though in former times,³ according to Sang, the Highlanders made everything that they used of it—rafters, ploughs, harrows, carts, and fences—yet now it would only be used as a makeshift, when other wood could not be had. I have seen large old burry birches, which when cut into boards, were fit for small cabinet panels; but the wood twists a good deal in drying, and is usually inferior, in grain, texture, colour, and figure to the wood of several species of American birch which can be imported in larger size and at a low price. As underwood it has an uncertain value for making brooms and tool handles and is also used for bobbins.

In Sweden and Russia the burrs found on the trunks of this tree are converted into many ornamental articles of great beauty. Beer-pots carved out of these burrs, and hooped with wood or silver, are often heirlooms in Scandinavian houses;

¹ *Viridarium Norvegicum*, 469.

² Birch clog soles are used in the Yorkshire manufacturing towns, whilst in Lancashire alder is preferred.

³ Pennant, *Tour in Scotland*, 112 (1772), says that wine was extracted from the live tree.

and as the wood takes a high polish, it is highly valued in Siberia for work-boxes, cigarette cases, and other small fancy articles.

In northern Sweden and Russia the wood is sometimes found full of undulations, which make it very ornamental for furniture, and some bedroom furniture made by the Nordiska Kompaniet (Lundberg and Laja) of Stockholm, was almost equal in beauty to satinwood. I have also seen it used as veneer with the best effect for decorating cabins in steamers built in Denmark and Sweden. This is known in Sweden as "Flammig björk." Another curious form of birch wood is that known in Finland and Sweden as "Masur." I was informed by Mr. Jacobssen, Swedish Vice-Consul at Åbo, that this variety in Finland is only found in certain places, Karku, Tyrois, and Kalvola. A number of logs which I saw in the works of the Finska Colorit Aktiebolag at Åbo were covered on the outside with small pitted depressions, somewhat similar to those which produce bird's-eye maple, and when cut into veneer, are dyed of various colours, of which French grey seemed to me the most effective; and made up into furniture which commands a high price.

At St. Petersburg this form of birchwood is known as "Karelsky," being supposed to come from the Karelian peninsula; and is largely used both in the solid and as veneer for furniture making. Though not so elegant as the waved form, or as the bird's-eye maple which it somewhat resembles, it is very quaint and striking in appearance, and can be imported at very reasonable prices.

The bark,¹ when taken off in sheets, is used in Scandinavia for covering the roofs of houses, and remains for many years undecayed between the inner boarding and the outer sod of turf. A strong smelling oil, obtained by destructive distillation from birch wood, is, when mixed with alcohol and rubbed on the skin, the best protection I know of against the swarms of midges and mosquitoes which make life almost unbearable in the short summer of the far north. This oil is used as a preservative, and gives the fragrant odour to Russia leather. Birch bark has no equal for lighting fires, and in the dripping forests of the north I have often had good reason to value it when nothing else would start a fire. (H. J. E.)

BETULA DAVURICA

Betula davurica, Pallas, *Fl. Ross*, i. 60, t. 39 (1784); Winkler, *Betulaceae*, 86 (1904).

Betula Maximowiczii, Ruprecht, in *Bull. Phys. Math. Acad. Pétersb.* xv. 139 (1856) (not Regel).

Betula Maackii, Ruprecht, in *Bull. Phys. Math. Acad. Pétersb.* xvi. 380 (1857).

A tree, attaining 60 or 70 feet in height. Bark purplish brown, separating in small, papery scales, which remain attached, curled and ragged, to the trunk, giving the tree a peculiar appearance. Young branchlets glandular, covered with a minute erect pubescence, interspersed with a few long hairs. Leaves, about 3 inches long and 1½ to 2 inches wide, narrowly ovate or ovate-rhombic, cuneate at the base,

¹ Pyrobutulin, obtained by sublimation from the outer bark of birch, is used for depositing films on glass, about to be engraved, and for covering lint with an antiseptic layer. Cf. Wheeler, in *Pharm. Journ.* ix. 494 (1899).

acute or acuminate at the apex; margin ciliate, coarsely and irregularly serrate; nerves, six to eight pairs; upper surface at first pubescent on the midrib and nerves, ultimately glabrescent; lower surface glandular, with scattered pubescence on the midrib and nerves; petiole, ½ inch, slightly pilose.

Fruiting catkins, ¾ to 1 inch long, ovoid-cylindrical, acute at the apex; scales glabrous with scattered glands on the margin and outer surface, middle lobe triangular, lateral lobes broad, rounded and spreading; nutlet obovate, with narrow wings, broadest in their upper part.

This species, which is readily distinguished by its peculiar bark, is widely spread throughout Amurland, Manchuria, Korea, and north China. According to Komarov,¹ it grows throughout the whole of Manchuria, in the drier parts of the valleys and in open places on the mountains, on rocky or sandy soil, occasionally forming small woods, but is never seen in the dense virgin forests.

It is extremely rare in cultivation, the only specimen which we have seen being a small tree in Kew Gardens, about 15 feet high, which was raised from seed sent by Bretschneider from Peking in 1882. (A. H.)

BETULA CORYLIFOLIA

Betula corylifolia, Regel and Maximowicz, in *Bull. Soc. Nat. Mosc.* xxxviii. 417, t. 8 (1865); Regel, in *DC. Prod.* xvi. 2, p. 178 (1868); Winkler, *Betulaceae*, 59, fig. 17 (1904).

A tree, the dimensions of which are not stated. Young branchlets slightly pubescent. Leaves (Plate 270, Fig. 14), 2½ to 3 inches long, about 2 inches wide, oval; rounded or truncate (rarely cuneate) at the base, acute at the apex; coarsely serrate; nerves, twelve to fourteen pairs, impressed above and very prominent beneath; upper surface pilose on the midrib, elsewhere glabrous; lower surface pale in colour, with conspicuous long silky hairs on the midrib and nerves, elsewhere glabrescent; petiole, ¾ inch, at first pilose, later glabrescent. Fruiting catkins (Plate 270, Fig. 14), 1½ to 2 inches long, ¾ inch wide, cylindrical, often curved; scales large, slightly pubescent, ciliate in margin, deeply three-lobed, lobes linear-oblong, the middle one about twice as long as the lateral lobes; seeds with very narrow wings.

This remarkable species,² peculiar in the shape of the leaf and in the stout, long fruiting catkins, was found on the high mountains of the provinces of Senano and Nambu in the main island of Japan, by Tschonoski. Very little is known about it in the wild state, and it has never apparently been introduced into cultivation in Europe. (A. H.)

¹ *Flora Manchuria*, ii. 49 (1903).

² The Japanese name of this species, according to Matsumura and Goto, is *Urajiro-kamba*.

BETULA MAXIMOWICZII

Betula Maximowiczii,¹ Regel, in *Bull. Soc. Nat. Mosc.* xxxviii. 418 (1865); Winkler, *Betulaceae*, 89 (1904).

Betula Maximowicziana, Regel, in DC. *Prod.* xvi. 2, p. 180 (1868); Shirasawa, *Icon. Ess. Forest. Japon.*, text 45, t. 23, ff. 1-8 (1900); Mayr, *Fremdländ. Wald- u. Parkbäume*, 449 (1906).

A tree, attaining in Japan, according to Mayr, 100 feet in height. Bark grey, smooth, peeling off in thin, papery strips. Young branchlets, with scattered glands; glabrous, except for slight pubescence above the insertions of the leaves. Leaves (Plate 269, Fig. 6) about 6 inches long and 4 inches wide, broadly ovate, deeply and narrowly cordate at the base, acuminate at the apex; margin non-ciliate, biserrate; nerves, ten to twelve pairs, each ending in a long-pointed serration; upper surface at first pubescent with erect hairs, later glabrescent; lower surface with scattered pubescence throughout, or glabrous, except for pubescence on the midrib and nerves, gland-dotted; petiole an inch or more in length, pubescent or glabrous.

Fruiting catkins (Plate 269, Fig. 6), two to four in a raceme, about $2\frac{1}{2}$ inches long, and nearly $\frac{1}{2}$ inch in diameter; scales glabrous, shortly three-lobed, the lateral lobes spreading and shorter than the middle lobe; nutlets very small, with broad wings.

A variety of the species is in cultivation in Kew Gardens, distinguished by having smaller leaves, with more shortly pointed serrations, and with their under surface (as well as the young branchlets and petioles) covered with long, soft pubescence.

This species is readily distinguished by its large leaves, deeply and narrowly cordate at the base. In winter the twigs are stout, shining, yellowish, nearly glabrous; buds about $\frac{3}{8}$ inch long, appressed to the branchlet, curved laterally and ending in a sharp beak, with glabrous scales.

B. Maximowiczii occurs in Japan, in the central chain of Hondo, but is more common in Yezo,² where, according to Sargent,³ it is a shapely tree, 80 or 90 feet in height, with a trunk 2 or 3 feet in diameter, covered with pale, smooth, orange-coloured bark. Towards the base of old trees the bark becomes thick and ashy-grey, separating into long, narrow scales.

The largest that Elwes saw in Japan were growing in a mixed forest of maple, poplar, ash, spruce, and silver fir, on volcanic soil, at about 3000 feet elevation, near the Crater Lake, Shikotsu, in Yezo; and one measured 90 feet high by 9 feet 9 inches in girth. The Japanese name⁴ of this species is *Udai-kamba*.

¹ This species, with *B. luminifera*, Winkler, *B. Baumkeri*, Winkler, both natives of central China, and *B. alnoides*, Buchanan-Hamilton, distributed throughout the Himalayas and in central and southern China, constitute the section *Betulaster*, distinguished by elongated fruiting catkins and broad-winged nutlets.

² Mayr, *op. cit.*, plate 31, gives a picture of this tree growing in a forest in Yezo.

³ *Forest Flora of Japan*, 62 (1894).

⁴ According to Matsumura, in *Shokubutsu Mei-I*, 48 (1895). The same name is given in Goto's *Forestry of Japan*.

It was introduced into cultivation in England by J. H. Veitch,¹ who sent home seeds from Yezo in 1888; and a large number of seedlings were raised at the Arnold Arboretum, in 1893, from seed received by Sargent² from the forestry officers of Yezo.

Sargent has spoken highly of the beauty and value of this tree, which, wherever we have seen it in this country, is thriving. It is one of the most beautiful of the young trees in Messrs. Walpole's lovely garden at Mount Usher, County Wicklow.

A tree at Kew, raised from seed obtained in 1893 from the Arnold Arboretum, was 25 feet high and 13 inches in girth in 1907. At Tortworth, a tree, probably of the same age, 30 feet high and 17 inches in girth, is growing vigorously. At Grayswood, Haslemere, a tree obtained as a small plant from Lemoine in 1894, was 29 feet by 21 inches in 1906, and is very healthy.

This species is common on the Continent in botanical gardens, and is very hardy, having borne without injury the severe winter climate of Grafrath, near Munich; and on this account, and because of its rapid growth, it is recommended by Mayr as worth cultivating as a forest tree.

Shirasawa says that the wood is rather hard, showing no difference in the colour of the sap and heart wood, and is used in Japan for house-building. The fishermen of Yezo make torches out of the bark, as it takes fire easily, even when wet. (A. H.)

BETULA ERMANI

Betula Ermani, Chamisso, in *Linnaea*, vi. 537, t. vi. f. 8 (1831); Erman, *Reise*, t. 17 (1835); Komarov, *Flora Manshurica*, ii. 49 (1903); Winkler, *Betulaceae*, 66 (1904).

A tree,³ attaining about 100 feet in height in Manchuria. Bark creamy-white, with raised whitish lenticels, and peeling off in irregular shreds. Young branchlets glabrous, except for a few hairs above the insertions of the leaves, and covered with numerous glands which roughen the shoot in the second year.

Leaves (Plate 270, Fig. 12), about 3 inches long, 2 inches broad, ovate, with a broad truncate or slightly cordate base, acuminate at the apex; margin slightly ciliate at first, coarsely and irregularly serrate; nerves, ten to twelve pairs; upper surface with scattered hairs; lower surface glandular, glabrous except for slight pubescence in the axils and on the midrib and nerves; petiole, $\frac{1}{2}$ inch, glabrescent, glandular.

Fruiting catkins (Plate 270, Fig. 12), ovoid-oblong, about 1 inch long and $\frac{5}{8}$ inch in diameter, sessile or shortly stalked; scales glabrous on the surface, ciliate and glandular in margin, with linear-oblong lobes, the middle lobe longer than the two lateral divergent lobes; nutlets with narrow wings, broadest above.

¹ *Hortus Veitchii*, 357 (1906).

² *Forest Flora of Japan*, 62 (1894).

³ According to Matsumura, *Shokubutsu Mei-I*, 47 (1895), var. *nipponica* of this species is known as *Take-kamba*, while the type is called *Ezo-no-take-kamba*, i.e. *B. Ermani* of Yezo.

Var. *nipponica*,¹ Maximowicz, *Mél. Biol.* xii. 923 (1888). This differs from the type in the branchlets not being so densely glandular, and in the longer, narrower cones, which are cylindrical, $1\frac{1}{2}$ inch long, and $\frac{1}{2}$ inch in diameter. This variety was found by Maximowicz in the Nikko mountains, and is probably the form of the species occurring in the main island of Japan.

B. Ermani is widely distributed in eastern Asia, occurring in Kamtschatka, Manchuria, Korea, Saghalien, Kurile Isles, and Japan. According to Komarov,² it grows in Manchuria, near the sea-coast, from the river Amur to St. Olga Bay, in the Sichote-Alin mountains, in the north-eastern part of the province of Mukden, and in the Korean main range; and is a native of mountain forests at elevations between 2000 and 7000 feet. Komarov informs us that it is the largest of the birches, which he found in Manchuria, attaining a height of 60 to 100 feet.

According to Sargent,³ it is the most common birch in the high mountains of the main island of Japan, where it is scattered through the coniferous forests at 4000 to 6000 feet, and is very conspicuous from the white bark of the trunk, and the bright, orange-coloured bark of the principal branches. It appears to be the birch figured and described by Shirasawa,⁴ as *Betula alba*, var. *communis* (not Regel), which he states to be a tree of vigorous growth, attaining 70 feet in height and 3 feet in diameter, occurring in the central chain of Honshu, especially at Shimotsuke, in Nikko, Musachi, in Chichibu, and Kiso, in Shinano. At Kiso the bark is used as material for writing on, and for envelopes; and also for torches, as it contains a considerable amount of resin. Elwes saw a birch, which he believes to be *B. Ermani*, growing in great abundance in the forest north of Asahigawa, and also on the volcanic cone near Lake Shikotsu, in Hokkaido. Here it seemed to be commoner than, but not so large, a tree as *B. Maximowiczii*.

This species was introduced into cultivation through the agency of the St. Petersburg Botanic Garden; and is not uncommon in gardens both on the Continent and in England, where it is often wrongly named *B. ulmifolia*, *B. corylifolia*, etc. At Kew there are small trees, 20 to 25 feet in height, both of the typical form and of var. *nipponica*. The former⁵ is the first of the birches to come into leaf, the foliage often being fully developed at the end of March; and, in consequence, the trees are usually much injured by spring frosts. The largest tree we have seen of this species is in the arboretum at Westonbirt, and when measured by Elwes in 1908, was 51 feet by $2\frac{1}{2}$ feet. There is a good specimen apparently of the typical form at Benmore, in Argyleshire, which is grafted near the ground, and has yellowish scaly bark like that of *B. lutea*. In 1907 Elwes found it to be about 40 feet by 3 feet. Var. *nipponica* is later in leafing, and is not usually injured by frost. Two trees of this variety at Grayswood, Haslemere, are about 30 feet in height.

(A. H.)

¹ This variety appears to be identical with a specimen in the Kew herbarium collected by Tschonoski on "high mountains not far from Fuji-yama," which is labelled *B. Bhojpattra*, var. *subcordata*, Regel, in DC. *Prod.* xvi. 2, p. 177 (1868).

² *Flora Manshurica*, ii. 50 (1903).

³ *Forest Flora of Japan*, 62 (1894).

⁴ *Icon. Essences Forest. Japon*, text 42, t. 21 ff. 1-15 (1900). *Betula alba*, var. *communis*, Regel, is *B. papyrifera*, an American species, which certainly does not occur wild in Japan.

⁵ The trees of the typical form were raised from seed sent by the Arnold Arboretum in 1893.

BETULA ULMIFOLIA

Betula ulmifolia, Siebold et Zuccarini, in *Abh. Bayer. Akad. Wiss.* iv. 3, 228 (1846); Winkler, *Betulaceae*, 62 (1904) (in part); Schneider, *Laubholzkunde*, i. 101 (1904).

A tree, attaining in Japan 70 feet in height and 8 feet in girth. Bark described as greyish-brown, smooth, shining, not separating into thin layers, and resembling that of *Prunus pseudocerasus*. Young branchlets covered with a white, short, somewhat appressed pubescence. Leaves, about 3 inches long, $1\frac{1}{2}$ inch wide, narrowly ovate or ovate-oblong, unequally cordate¹ at the base, acuminate at the apex; margin ciliate, bi-serrate, with falcate serrations; nerves twelve to fourteen pairs; upper surface with appressed, long, brownish hairs both on the midrib and nerves, and in bands between the nerves; lower surface similarly pilose on the midrib and nerves, gland-dotted and glabrous between the nerves; petiole $\frac{1}{2}$ inch, pilose.

Fruiting catkins, on short pilose peduncles, about $\frac{3}{4}$ inch long and $\frac{1}{2}$ inch in diameter, ovoid; scales pubescent, ciliate, strongly veined, with the central lobe oblong and obtuse, nearly twice as long as the ovate rounded lateral lobes; nutlets with narrow wings.

This species is extremely rare in cultivation, the only specimen which we have seen being a tree, about 8 feet high, in Kew Gardens, which was raised from seed, received under the name *B. grossa*,² S. et Z., from Tokyo in 1896. It is identical with the type specimen of *B. ulmifolia*, S. et Z., preserved in the Munich herbarium, with which we have compared it.

This species, together with *B. grossa*, S. et Z., *B. carpiniifolia*, S. et Z., both natives of Japan, and *B. costata*, Trautvetter, a native of Manchuria, are closely allied; and our knowledge of their exact relationship and distribution is very imperfect. It is possible that *B. grossa* and *B. carpiniifolia* are varieties or hybrids of *B. ulmifolia*, while *B. costata* is the continental geographical form of the same species.

Shirasawa,³ whose figures of *B. grossa* and *B. ulmifolia* do not in either case exactly agree with the type specimen of the latter species, says that both these species are spread throughout the central chain of Hondo, and occur also in Kiushiu and Shikoku. *B. ulmifolia*, which is the representative in Japan of the American *B. lutea*, differs much in bark and other characters from *B. Ermani*, with which it has been confused.

(A. H.)

I saw a very fine birch which my guide and companion, Mr. Mochizuki of the Japanese Forest Service, called *B. grossa*, growing in the forest of central Japan, at Ongawa, about 3000 feet above the sea; and measured specimens 80 to 90 feet high.

¹ The leaves on the lower part of the branchlet and on the short shoots are markedly cordate; those on the upper part of the branchlet are usually truncate or rounded at the base.

² Similarly a dried specimen at Kew, collected in the Etchu province on Mt. Tateyama, and labelled *B. grossa* by the Tokyo University Science College, is identical with *B. ulmifolia*. It bears the Japanese name *Yoguso-minebari*.

³ *Icon. Ess. Forest. Japon*, text, 42, 43, t. 22 (1900).

The timber, of which I brought home a specimen now at Kew, is a hard wood of a bright pinkish brown colour, and is used for flooring. It seems at least as good as the best American birch timber. It was, however, very difficult to identify the species of birch, of which no less than five¹ are said to be found in this district, and the foresters of Japan were not themselves sure of their scientific names.

(H. J. E.)

BETULA LUMINIFERA

Betula luminifera, Winkler, *Betulaceae*, 91, fig. 23 (1904).

A tree, the dimensions of which are not known. Young branchlets covered with dense, erect, pale pubescence, non-glandular. Leaves (Plate 270, Fig. 16), about 5 inches long and $3\frac{1}{2}$ inches wide, broadly ovate, sub-cordate or truncate at the broad base, acuminate at the apex; margin ciliate, irregularly serrate, the serrations ending in cartilaginous points; nerves ten to fourteen pairs; covered more or less on both surfaces with white, short pubescence; petiole $\frac{3}{4}$ inch, pubescent. Fruiting catkins (Plate 270, Fig. 16), solitary, cylindrical, elongated, about 3 inches long and $\frac{2}{3}$ inch in diameter; on a peduncle $\frac{3}{4}$ inch long; scales lanceolate, auricled on each side a little below the middle; nutlets pubescent, with broad wings.

This species, which is the representative in central China of *B. Maximowiczii* of Japan, was discovered by Père Farges in the north-eastern mountains of Szechwan, and was introduced into cultivation in 1901 by E. H. Wilson, who sent seeds from the same locality. A young tree in Veitch's nursery at Coombe Wood is now 16 feet high at seven years old, and is very flourishing. This species is remarkable for its fine foliage, and is worthy of cultivation as an ornamental tree.

(A. H.)

BETULA UTILIS, HIMALAYAN BIRCH

Betula utilis, Don, *Prod. Fl. Nepal.* 58 (1825); Hooker, *Fl. Brit. India*, v. 599 (1888); Gamble, *Indian Timbers*, 668 (1902); Winkler, *Betulaceae*, 61 (1904); Schneider, *Laubholzkunde*, 102 (1904); Brandis, *Indian Trees*, 622 (1906).

Betula Bhojpattra, Wallich, *Pl. As. Rar.* ii. 7 (1832); Brandis, *Forest Flora, N.-W. India*, 457 (1874).

Betula Jacquemontii, Spach, in *Ann. Sc. Nat. sér. 2*, xv. 189 (1841).

A tree, attaining in the Himalayas about 60 feet in height, but becoming a shrub at high elevations. Bark on young trees thin, smooth, brownish red, with

¹ Matsumura, in *Shokubutsu Mei-I.* 47 (1895), enumerates eight distinct species of birch as occurring in Japan; but of these, *B. utilis*, as explained in a note under our account of that species, and *B. grossa*, mentioned above, are doubtful. There remain six distinct species, undoubted natives of Japan, viz.:—*B. Maximowiczii*, *B. corylifolia*, *B. Ermani*, *B. globispica*, *B. ulmiifolia*, and *B. verrucosa*, var. *japonica*; all of which are referred to in this account of the genus *Betula*, and under each species is given its native name.

darker coloured horizontal lenticels, peeling off in transverse rolls; on older trees darkened and thickened at the base. Young branchlets, non-glandular, covered with a dense, greyish tomentum; older branchlets smooth, glabrous. Leaves (Plate 269, Fig. 7) coriaceous, about $3\frac{1}{2}$ inches long and $2\frac{1}{4}$ inches wide, oval or ovate-oblong, rounded at the base, acuminate at the apex; margin slightly ciliate, irregularly serrate; nerves nine to twelve pairs; upper surface shining, dark green, with scattered pubescence; lower surface yellowish green, glandular, glabrous between the nerves, which are slightly pubescent, and with dense axil-tufts of pubescence; petiole $\frac{3}{4}$ inch, tomentose.

Fruiting catkins (Plate 269, Fig. 7),¹ cylindrical, $1\frac{1}{2}$ inch long, $\frac{1}{3}$ inch in diameter, on tomentose peduncles, variable in length; scales with glabrous, ciliate, spatulate lobes, the central lobe dilated above and obtuse at the apex, and often trifid, about twice as long as the erect or slightly divergent lateral lobes; nutlets with narrow wings.

VARIETIES

In addition to the type, described above, which occurs in the Himalayas and China, the following varieties can be recognised:—

1. Var. *sinensis*, Franchet, *Journ. de Bot.* xiii. 207 (1899).

Betula albo-sinensis, Burkill, in *Journ. Linn. Soc. (Bot.)* xxvi. 497 (1899).

Leaves glabrescent beneath. Fruit-scales glabrous, not ciliate; nutlets smaller than in the type. Discovered in north-eastern Szechwan by Père Farges. Not yet introduced.

2. Var. *Prattii*, Burkill, *Journ. Linn. Soc. (Bot.)* xxvi. 499 (1899). Leaves more pubescent than in the type, the pubescence extending over the whole under surface, and very dense in the axils and along the midrib. Fruit-scales strongly ciliate, with spatulate lobes, the lateral lobes spreading and not erect. This variety occurs in western Szechwan, at high elevations (13,500 feet), and has not yet been introduced.

3. Var. *Jacquemontii*, Regel, in DC. *Prod.* xvi. 2, p. 177 (1868).

Betula Jacquemontii, Spach, in *Ann. Sc. Nat. sér. 2*, xv. 189 (1841); Cambessedes, in Jacquemont, *Voyage dans l'Inde, Botanique*, 157, t. 158 (1844); Regel, *op. cit.* 178 (1868).

A tree, with white bark, marked by brownish horizontal lenticels, and peeling off in transverse strips. Young branchlets slightly glandular, and covered with a dense, erect, short pubescence. Leaves (Plate 270, Fig. 15), about $2\frac{1}{2}$ inches long, and $1\frac{3}{4}$ inch broad, ovate, rounded or slightly cuneate at the base, acuminate at the apex, bi-serrate; nerves seven to nine pairs; upper surface with scattered pubescence or glabrescent; lower surface gland-dotted and glabrous except for long hairs on the midrib and nerves; petiole $\frac{3}{4}$ inch, glabrescent, glandular. Fruiting catkins (Plate 270, Fig. 15), $1\frac{1}{2}$ inch long, $\frac{1}{3}$ inch wide, cylindrical, on long pubescent stalks; scales glabrous, ciliate, with an elongated linear central lobe,

¹ In this figure the middle lobe of the scale is represented short and trifid at the apex, as is occasionally the case; but as a rule it is more elongated, and broadened and rounded at the apex.

acute at the apex, and two or three times as long as the divergent short rounded lateral lobes; nutlets with narrow wings.

This variety is represented in Kew Gardens by two trees obtained from St. Petersburg in 1891 and 1894, and 25 feet and 20 feet high respectively. It is very distinct in appearance from the typical form of the species, having white bark; smaller, few-nerved, thinner leaves; and different catkins. Moreover, the branchlets and fruiting peduncles are shortly pubescent in the variety, and tomentose in the type.

This variety,¹ judging from the material in the Kew Herbarium, is common in the Himalayas, and probably constitutes a distinct species, which a careful study in the field may show to occupy a different area of distribution from that of typical *B. utilis*, which is so readily recognisable by its reddish bark and other characters.

DISTRIBUTION

*B. utilis*² is widely distributed in the Himalayas and in China. It occurs in West Tibet, and in the Himalayas from the Kurram valley and Kashmir, to Sikkim and Bhotan, at altitudes usually ranging from 10,000 to 14,000 feet, but descending in the north-west to 7000 feet. It is often gregarious at the upper limit of arborescent vegetation, where it is commonly associated with *Rhododendron campanulatum*. According to Brandis, it attains 50 to 60 feet in height, and sometimes 10 or 12 feet in girth. Gamble's account of the bark includes that of the type and of var. *Jacquemontii*; as he describes it as smooth, shining, reddish white or white, the outer bark consisting of numerous distinct, thin, papery layers, peeling off in broad horizontal rolls; the thicker lower part of the bole becoming rough and dark as in the European birch. He states that the growth is slow, with an average of fifteen rings per inch of radius. The wood is extensively used in the inner arid Himalayan region for building purposes; it is elastic, does not warp, and seasons well. The bark is the most valuable part of the tree, and is used for paper, umbrellas, hookah-tubes, and roofs of houses.

In China it is a moderate-sized tree, growing only at high elevations, between 8000 and 13,500 feet, in the provinces of Szechwan, Hupeh, and Kansu. It was seen in the latter province by Przewalski,³ who describes the bark as reddish, peeling off and hanging from the tree in long festoons.

This species is very rarely seen in cultivation, and the typical form from the Himalayas, like most of the broad-leaved trees from that region, for some unexplained reason, does not appear to have succeeded in this country. At Grays-

¹ Shirai, in *Tokyo Bot. Mag.* viii. 320, ff. 23, 24 (1894), states that this variety occurs in Japan; but the plant figured by him seems to be identical with a specimen gathered by Maximowicz in the province of Shinano, and labelled *B. Bhojpatra*, var. *typica*, Regel, which is certainly not that species, and appears to be *B. ulmifolia*, S. et Z. Shirai's account of the bark of this tree, as not being papery, but greyish brown, smooth, cracking, and falling off in patches, confirms this identification.

² There is no evidence that *B. utilis* occurs in Japan, where it is represented by the closely allied species *B. Ermani*. Shirasawa, in *Icon. Ess. Forest. Japon.* text 44, t. 23, ff. 9-22 (1900), figures a tree as *B. Bhojpatra* which is not this species (*B. utilis*), as is confirmed by his account of the bark, as being hard, compact, and falling off in scaly facets. *B. Ermani*, var. *nipponica*, has also been considered erroneously to be a form of *B. utilis*.

³ Cf. Bretschneider, *Europ. Bot. Discoveries*, 987 (1898).

wood, Hašlemere, a tree planted in 1882, which was obtained from a nursery at Newry, was 30 feet high and 2 feet 1 inch in girth in 1906.

There are three trees about 20 feet high in the Botanic Garden of Trinity College, Dublin, which, according to Burbidge,¹ were raised from seed sent by Sir Joseph Hooker in 1881. At Castlewellan there are some young trees, about 8 feet high, which were obtained by grafting branches of the Dublin trees on the common birch. (A. H.)

BETULA PAPYRIFERA, PAPER BIRCH, CANOE BIRCH

- Betula papyrifera*, Marshall, *Arbust. Am.* 19 (1785); Sargent, *Silva N. Amer.* ix. 57, t. 451 (1896), and *Trees N. Amer.* 202 (1905); Winkler, *Betulaceae*, 83 (1904).
Betula lenta, Wangenheim, *Nordam. Holz.* 45 (1787) (not Linnæus).
Betula papyracea, Aiton, *Hort. Kew.* iii. 337 (1789); Loudon, *Arb. et Frut. Brit.* iii. 1708 (1838).
Betula grandis, Schrader, *Ind. Hort. Bot. Goett.* 2 (1833).
Betula latifolia, Tausch, in *Flora*, xxi. 2 p. 751 (1838).
Betula alba, Linnæus, var. *papyrifera*, Spach, in *Ann. Sc. Nat. sér. 2*, xv. 188 (1841).
Betula cordifolia, Regel, *Monog. Betulaceae*, 86 (1861).
Betula macrophylla, Hort., ex. Schneider, *Laubholzkunde*, i. 115 (1904).

A tree, usually attaining in America, in its typical form, 60 or 70 feet in height and 2 or 3 feet in diameter, the variety found on the lower Fraser River in British Columbia being usually much larger in size. Bark thin, smooth, creamy-white, marked with long, narrow, horizontal lenticels, and separating into thin papery layers; becoming on old trunks near the base $\frac{1}{2}$ inch thick, dull brown or blackish, fissured, and scaly. Young branchlets, with scattered long hairs, mostly falling off in summer; in the second year dark brown and glabrous.

Leaves (Plate 269, Fig. 5), 2 to 3 inches long, $1\frac{1}{2}$ to 2 inches wide, ovate; rounded or slightly cordate at the base, acuminate at the apex; margin ciliate and irregularly bi-serrate; nerves six to eight pairs; upper surface dull green, slightly pilose on the nerves; lower surface paler, with numerous minute brown glands, usually glabrous except for dense axil-tufts of pubescence and a few long hairs on the midrib and nerves, occasionally minutely pubescent between the nerves; petiole at first pilose, ultimately glabrescent.

Fruiting catkins (Plate 269, Fig. 5), cylindrical, about $1\frac{1}{2}$ inch long, $\frac{1}{3}$ inch thick, hanging on slender stalks; scales pubescent or glabrous, ciliate, with the middle lobe longer than broad; lateral lobes rounded, erect, spreading or recurved. Nutlet with broad wings.

In winter the twigs usually show a few scattered long hairs; buds, $\frac{3}{8}$ inch long, appressed to the branchlet, ovoid, acute, with glabrous, ciliate scales, glistening with resin.

VARIETIES AND HYBRIDS

This species, spread over a vast territory in North America, is very variable in the wild state; and the forms occurring on the Rocky Mountains and in the Pacific

¹ *Proc. Roy. Hort. Soc.* 1901, p. xxxviii.

Coast region have not yet been fully studied in the field. The following varieties are noteworthy:—

1. Var. *cordifolia*, Regel, in *Bull. Soc. Nat. Mosc.* xxxviii. 401 (1865); Fernald, in *Rhodora*, iii. 173 (1901); Sargent, *Silva N. Amer.* xiv. 55, t. 724 (1902).

Leaves distinctly cordate at the base, smaller than in the type. An alpine tree, moderate in size, scarcely exceeding 40 feet in height, which occurs on Mount Katahdin in Maine, on the White Mountains in New Hampshire, and in the northern Rocky Mountain region.

2. Var. *kenaica*.

Betula kenaica, Evans, *Bot. Gazette*, xxvii. 481 (1899); Sargent, *Silva N. Amer.* xiv. 53, t. 723 (1902), and *Trees N. Amer.* 205 (1905).

A tree in Kew Gardens, about 20 feet high, obtained from Dieck in 1891, and said to be a native of Alaska, has been identified by Sargent with *B. kenaica*. Judging from this specimen and the description given by Sargent, this species is only a small-leaved variety of *B. papyrifera*, from which it cannot be separated by any characters of importance. The branchlets are minutely pubescent and slightly glandular. The leaves are about 2 inches long, with five to seven pairs of nerves. The fruiting catkins are smaller than in the type, about an inch long, with glabrous ciliate scales, the middle lobe of which is narrow, oblong, not much longer than the rounded broad lateral lobes. The bark is like that of ordinary *B. papyrifera*, but the white colour is slightly tinged with orange.

Betula kenaica was discovered in 1897 by Dr. Evans in Alaska, in the Kenai Peninsula, near Cook Inlet; and was found on Kodiak Island by Coville in 1899. It is described as being a small tree, only reaching 40 feet in height. It is probable¹ that the variety extends south from Alaska through British Columbia; and is a form with small leaves growing on poor soil and in mountainous regions, while var. *Lyalliana*, with large leaves, occurs at nearly sea-level in rich alluvial soil.

3. Var. *Lyalliana*,² Koehne, in Beissner, Schelle, and Zabel, *Laubholz-Benennung*, 55 (1903); Schneider, *Laubholzkunde*, i. 115 (1904).

Betula occidentalis, Lyall, in *Journ. Linn. Soc. (Bot.)*, vii. 134 (1864) (in part) (not Hooker); Sargent, in *Bot. Gazette*, xxxi. 237 (1901), *Silva N. Amer.* xiv. 57, t. 725 (1902), and *Trees N. Amer.* 204 (1905) (not Sargent, in *Silva N. Amer.* ix. 65, t. 453 (1896)).
Betula Lyalliana, Koehne, in *Mitt. Deut. Dend. Ges.* viii. 53 (1899).

This variety, which is considered to be a distinct species by Sargent, differs from the type in the greater size of the tree, in the orange tint of the bark, and in the larger leaves, which are thin and membranous in texture, and not so thick and coriaceous as is usual in this species. The leaves are about 4 inches long and 3 inches broad, with seven to nine pairs of nerves, and are coarsely and doubly serrate, broadly ovate, with a broad, truncate base and a slightly acuminate apex.

¹ Specimens just received from trees cultivated in the Arnold Arboretum, U.S., labelled *B. occidentalis*, Sargent, and *B. kenaica*, Evans, are so similar, that they cannot be distinguished even as varieties. This confirms the opinion that var. *kenaica* and var. *Lyalliana* (*B. occidentalis*, Sargent) are merely geographical forms of *B. papyrifera*, the differences in the size of the leaves and fruiting catkins being due to soil and climate. Under cultivation in this country they maintain these differences.

² This name is preferable to *B. papyracea*, var. *occidentalis*, Dippel, *Laubholzkunde*, ii. 177 (1892), as the plant described there is apparently var. *grandis*, Schneider, a cultivated variety which originated from the eastern form of the species. Cf. our remarks on *B. occidentalis*, Hooker, given in p. 993.

The young branchlets have a minute, dense, erect pubescence, interspersed with long hairs and a few scattered glands. The fruiting-catkins are like those of the type, with slightly thinner scales, the middle lobe of which is triangular and elongated.

This splendid tree, which attains a height of 100 or 120 feet, and a diameter of 3 or 4 feet, on the alluvial banks of the lower Fraser River, appears to be confined to the lower basin of that river in south-western British Columbia and north-western Washington. It was first collected by Lyall in 1859, "in woods by river banks, on the Sumas and Chilukeveyuh prairies and other low grounds to the westward of the Cascade Mountains"; and his specimens preserved in the Kew Herbarium are identical with my own collected near New Westminster.

Piper¹ recognises the typical variety as occurring in north-western Washington, where he says that it is a tree with dark grey bark, occasionally 3 feet in diameter. He mentions a similar tree, smaller in size and often white-barked, which grows in Stevens County and the Blue Mountains of Washington State. This smaller tree, which also occurs in Idaho, is a connecting link between var. *Lyalliana* and the form of the species which occurs in the Rocky Mountains.

I collected seeds of var. *Lyalliana* on October 20, 1906, from two trees, about 60 feet in height, which I found growing near New Burnaby, on the electric tram-line between Vancouver and New Westminster. The virgin forest had been cut down in this neighbourhood, and the few trees which I saw were young and thriving, and growing in open spaces amidst second-growth *Thuja* and *Douglas*. I had no time to descend to the alluvial flats of the Fraser River, where Sargent reports the existence of trees of large size. At the large lumber mills of Vancouver and New Westminster, where I made inquiries, the tree is unknown at the present time; but I was informed that some years ago a small quantity of furniture had been made from large trees cut down near New Westminster.

The seed which I collected has been distributed to various places in Great Britain, and has germinated well. Seedlings raised in a nursery bed at Casewick, Lincolnshire, by Lord Kesteven, are now (August 1908) 12 to 22 inches in height, and for so far have been healthy and vigorous in growth. Some of the seed did not germinate till the following year. At Brocklesby, Mr. Havelock has raised a few plants in a frame, which are 24 to 30 inches high, with fine, large foliage. At Pollokshaws, near Glasgow, Sir John Stirling Maxwell reports that they did better when sown in the open than when grown in a frame, and average 15 inches in height, the tallest being 29 inches. He adds that this variety shows every sign of being a thriving tree.

Elwes has also raised from seeds sent to him from Kaslo, on Lake Kootenay, British Columbia, in 1904, a few young trees which appear to belong to this variety, and others from seed given him by Professor Sargent, and said to be from the lower Fraser Valley. These are growing vigorously at Colesborne.

4. *Betula Andrewsii*, Nelson, in *Bot. Gazette*, xliii. 279, with figure of the tree (1907), is a peculiar form with many branching stems from the base, which has been found in Colorado.

¹ *Contrib. U.S. Nat. Herb.* xi. 218 (1906).

5. A hybrid between *B. papyrifera* and *B. populifolia*, found growing wild in New Hampshire and Massachusetts, is described by Sargent in *Garden and Forest*, viii. 356, fig. 50 (1895).

Several varieties and hybrids have originated in cultivation:—

6. Var. *grandis*, Schneider (*B. macrophylla*, Hort.). Leaves large, cordate, lobulate in margin. Similar leaves appear on coppice shoots and on lower branches of old trees belonging to the typical form of the species.

7. *B. Koehnei*, Schneider, *Laubholzkunde*, i. 114 (1907), a hybrid between *B. papyrifera* and *B. verrucosa*, is identical with *B. cuspidata* of Späth's nursery.

8. *B. excelsa*, Aiton, *Hort. Kew*, iii. 337 (1789), long supposed to be either a distinct species or a cultivated variety of *B. papyrifera*, is considered by Schneider (*op. cit.* 108) to be a hybrid between this species and *B. pumila*, and differs from the former mainly in the smaller size of the leaves.

DISTRIBUTION

The paper birch is the most widely distributed species of *Betula* in North America, the typical form extending northward to Labrador, the southern shores of Hudson's Bay and Great Shore Lake, and southward to Long Island, New York, northern Pennsylvania, central Michigan, central Ohio, northern Nebraska, the Black Hills of Dakota, and northern Montana. In various forms it also occurs west of the Rocky Mountains to the Pacific Coast, in Alaska, British Columbia, Washington, and Idaho.

It usually grows on rich wooded slopes and on the borders of streams, lakes, and swamps; and is common in Canada, New York, and northern New England, becoming rarer to the southward and in the Rocky Mountains. (A. H.)

CULTIVATION

Notwithstanding the rarity of this tree in cultivation, it seems to grow freely at Colesborne, where I have raised it from seed, and planted it out in situations where it is exposed to cold and damp. Here it does not suffer from spring frost, and has attained 15 feet in height in seven years. As an ornamental tree, however, it is not in England superior to the common birch, and has no special merit to justify its being planted except as a curiosity.

The paper birch was introduced into England in 1750, according to Loudon; but is rarely seen except in botanic gardens, as at Kew, where there are several fair-sized specimens, the largest, a tree with ascending branches, near the Victoria gate, being 45 feet high by 3½ feet in girth. Close to it is another nearly equal in size, with markedly drooping branches. In the Cambridge Botanic Garden, a tree, grafted at 1½ foot from the ground, was, in 1906, 47 feet by 4 feet 7 inches.

The largest tree we know of in cultivation is in Mr. Kaufman's garden at White Knights, near Reading, which Henry measured in 1904 as 82 feet by 4 feet 11 inches. Another tall white-barked tree with a clean stem, grafted on common

birch near the ground, grows at Bicton, and measured, in 1906, 75 feet by 7 feet 2 inches (Plate 259). A large tree is growing at Woburn, near the lake on the right of the main entrance from the village. It is on its own roots, and has bark of a brownish-grey colour, quite unlike the trees at White Knights and Bicton. At Arley,¹ a tree measured 41 feet by 4 feet in 1905. There is also an old and sickly tree at Boynton, in Yorkshire, and a young and healthy one on its own roots, about 40 feet high, at Tortworth.

In Scotland and Ireland we have failed to find a single specimen of any size.

The handsomest specimen that I have seen in Europe is at the nursery of Simon-Louis frères at Metz, where on a deep rich loam it has attained 70 feet high by 6 feet 4 inches in girth, and has a fine silvery bark, more beautiful than any that I know in England. (H. J. E.)

BETULA POPULIFOLIA, GREY BIRCH

Betula populifolia, Marshall, *Arbust. Am.* 19 (1785); Loudon, *Arb. et Frut. Brit.* iii. 1707 (1838); Sargent, *Silva N. Amer.* ix. 55, t. 450 (1896), and *Trees N. Amer.* 200 (1905); Winkler, *Betulaceæ*, 79 (1904).

Betula excelsa canadensis, Wangenheim, *Nordam. Holz.* 86 (1787).

Betula acuminata, Ehrhart, *Beit. Naturk.* vi. 98 (1791).

Betula cuspidata, Schrader, *ex Regel*, in DC. *Prod.* xvi. 2, p. 164 (1868).

Betula alba, Linnæus, var. *populifolia*, Spach, in *Ann. Sc. Nat. sér. 2*, xv. 187 (1841).

Betula alba, Linnæus, sub-species *populifolia*, Regel, in *Bull. Soc. Nat. Mosc.* xxxviii. 399 (1865).

A tree, attaining in America 30 or 40 feet in height and 18 inches in diameter. Bark similar to that of *B. verrucosa*, but greyish in colour. Young branchlets glabrous, covered with reddish-brown glands, which persist and roughen the shoot in the second year. Leaves (Plate 269, Fig. 4), 2½ to 3 inches long, 1½ to 2 inches wide, deltoid; broadly cuneate or truncate at the base; prolonged into a long caudate-acuminate apex; margin lobulate, irregularly serrate; nerves five or six pairs; both surfaces shining, glabrous, covered with minute brown glands; petiole reddish, long, slender, glandular, glabrous.

Fruiting-catkins (Plate 269, Fig. 4), cylindrical, ¾ inch long, ¼ inch in diameter, pendent or spreading on slender stalks; scales pubescent and ciliate, with short triangular middle lobe and recurved broad lateral lobes; wings broader than the narrow nutlet.

This species is closely allied² to *B. verrucosa*; but it is a smaller tree, strikingly different in the colour of the bark, and is readily distinguished by the shape of the leaf, the apex of which is very prolonged, and by the pubescent scales of the fruiting-catkins.

Varieties *laciniata* and *pendula* mentioned by Loudon are not known now in

¹ *Hortus Arleyensis*, 45 (1907).

² Sargent, in *Garden and Forest*, ii. 484 (1889), points out the differences between these two species.

cultivation.¹ Var. *purpurea*, with reddish leaves, was sent out in 1892 by Ellwanger and Barry, of Rochester, New York. *B. cærulea*, Blanchard, is apparently a form of this species, with dull bluish-green leaves, ovate rather than deltoid in outline, which is common on hills in northern New England and eastern Canada.

This is the smallest of the arborescent birches of America, and grows usually on dry, gravelly or sandy, barren soil, or on the edges of swamps and lakes. Its area of distribution extends from Nova Scotia and the valley of the St. Lawrence southward to Delaware, and westward through northern New England and New York to the southern shores of Lake Ontario. It is very abundant in the coast region of New England and the middle states, and springs up in abundance after forest fires or on abandoned farm lands.

It was first cultivated in England by Archibald, Duke of Argyll, at Whitton, near Hounslow, in 1750, and is rarely met with now except in botanical gardens. At Kew, the largest specimen, growing near the end of the rhododendron dell, is 35 feet high and about 6 inches in diameter. It produces fruit regularly. Loudon mentions a birch supposed to be of this species at Dodington Park in Gloucestershire, 60 feet high in 1838, but no such tree now survives there. (A. H.)

BETULA NIGRA, RED BIRCH

Betula nigra, Linnæus, *Sp. Pl.* 982 (1753); Loudon, *Arb. et Frut. Brit.* iii. 1710 (1838); Sargent, *Silva N. Amer.* ix. 61, t. 452 (1896), and *Trees N. Amer.* 198 (1905); Winkler, *Betulaceæ*, 58 (1904).

Betula lanulosa, Michaux, *Fl. Bor. Am.* ii. 181 (1803).

Betula rubra, Michaux f., *Hist. Arb. Am.* ii. 142 (1812).

A tree, attaining in America 80 or 90 feet in height, with a trunk occasionally 5 feet in diameter, and usually divided into two or three diverging limbs at 15 or 20 feet above the ground. Bark at first smooth, reddish brown; with age, separating into successive layers, which curl up and persist on the trunk as thin papery scales of various tints of red and brown; ultimately turning black and becoming an inch thick and deeply furrowed at the base of old trunks. Young branchlets tomentose, with numerous glands; older branchlets glabrous and roughened with the remains of the glands. Leaves (Plate 270, Fig. 13), $1\frac{1}{2}$ to 3 inches long, 1 to 2 inches wide, deltoid-ovate, with cuneate base and acute apex; margin non-ciliate, coarsely and irregularly bi-serrate, and often lobulate; nerves seven or eight pairs; upper surface shining, with fine pubescence mainly on the nerves; lower surface greyish, with pubescence chiefly on the midrib and nerves, and with numerous white glands; petiole tomentose and glandular.

Fruiting-catkins (Plate 270, Fig. 13), cylindrical, 1 to $1\frac{1}{2}$ inch long, $\frac{1}{2}$ inch in diameter, erect, on stout tomentose peduncles, about $\frac{1}{2}$ inch long: scales pubescent

¹ There is a var. *laciniata*, and also a var. *purpurea* assigned to *B. verrucosa* in Späth's and Simon-Louis's nurseries, which may be what Loudon referred to.

and ciliate. The fruit ripens in May or June, and Sargent has called attention to the fact that the early ripening of the seeds of this and other trees, as the red and silver maples, growing beside rivers assures their germination, as they fall on the banks at the season of low water, immediately germinate, and grow speedily.

Betula nigra is readily distinguishable by its peculiar bark, the only other species in cultivation which at all resembles it in this respect being *B. dahurica*. It is also very distinct in the greyish colour of the leaves beneath, which are cuneate at the base, acute and not acuminate at the apex, and usually lobulate in margin with sharp double serrations.

In winter the twigs are brown, glandular, and almost glabrous; buds minute, $\frac{1}{8}$ inch long, appressed to the branchlet, with a sharp beak directed inwards; scales ciliate and pubescent.

This species, which is known as the red or water birch,¹ grows usually on the banks of streams and ponds or in swamps, in deep rich soil, liable to inundation. It occurs from Massachusetts, southwards to Florida, east of the Alleghany Mountains; through the Gulf States to Trinity River, Texas; and throughout the Mississippi valley to Indian territory, Kansas, Nebraska, Minnesota, Wisconsin, and Ohio. It attains its largest size in the damp lowlands of Florida, Louisiana, and Texas, being the only birch tree of these warm regions. (A. H.)

Sargent says² that its distribution is peculiar, as though it grows abundantly and luxuriantly on the banks of the Merrimac and Spicket rivers in north-east Massachusetts, it occurs nowhere else in New England, and only becomes common in the south of New Jersey, extending from thence to Iowa in the west, and to Florida and Texas in the south, growing in the south on the banks of almost every stream which has a gravelly bed, and of which the banks are not marshy, and attaining a height of 80 or 90 feet with a trunk 3 to 4 feet in diameter; but in North Carolina, according to Ashe, its average size is 40 to 60 feet high by 1 to 2 feet in diameter.

It was introduced into cultivation in England by Peter Collinson in 1736; but is rarely met with, though it ought to be more suitable for cultivation³ in the warmer parts of England than the more northern species. There are several good specimens in Kew Gardens, the largest, near the rhododendron dell, being 57 feet high and 5 feet in girth. This tree divides at 7 feet from the ground into two main stems; and one or two smaller trees in the collection of birches branch similarly near the ground into two or three stems. A tree near the Victoria gate has a single stem, 48 feet in height and $4\frac{1}{2}$ feet in girth. Some of these trees bore ripe fruit in June 1908.

Though Sargent says that large specimens may be seen in some of the older European parks, neither Pardé nor Correvon mention any trees of this species; but Bean⁴ saw one $7\frac{1}{2}$ feet in girth at Herrenhausen, Hanover. (H. J. E.)

¹ It is also known as the river birch, and though known to botanists as *B. nigra*, it is very seldom called in America black birch, the latter name being very commonly applied to *B. lenta*. ² *Garden and Forest*, ii. 591.

³ In an article on this tree, in *Gard. Chron.* xxv. 21 (1899), Mr. Bean recommends it for ornamental planting on low islands in lakes, and beside water-courses.

⁴ *Kew Bull.*, 1908, p. 392.

BETULA LUTEA, YELLOW BIRCH

Betula lutea, Michaux f., *Hist. Arb. Am.* ii. 152 (1812); Sargent, *Silva N. Amer.* ix. 53, t. 449 (1896), and *Trees N. Amer.* 197 (1905); Winkler, *Betulaceae*, 65 (1904).

Betula lenta, Linnæus, var. *lutea*, Regel, in DC. *Prod.* xvi. 2, p. 179 (1868).

Betula lenta, Linnæus, var. *genuina*, Regel, in *Mém. Soc. Nat. Mosc.* xiii. 126 (1861).

Betula excelsa, Pursh, *Fl. Am. Sept.* ii. 621 (1814) (not Aiton); Loudon, *Arb. et Frut. Brit.* iii. 1711 (1838).

A tree, attaining in America 100 feet in height and 3 or 4 feet in diameter. Bark smooth, shining, silvery or golden grey, breaking into ribbon-like strips and curls, which long remain attached; in old trees, $\frac{1}{2}$ inch thick, reddish brown, and fissured. Young branchlets covered with long pale hairs; in the second year smooth, brown, and usually glabrous.

Leaves (Plate 270, Fig. 11), 3 to $4\frac{1}{2}$ inches long, $1\frac{1}{2}$ to 2 inches wide, ovate-oblong, rounded at the base, acute or slightly acuminate at the apex; margin finely and sharply serrate, ciliate between the teeth; nerves nine to twelve pairs; both surfaces with long silky hairs mainly on the midrib and nerves; pale beneath; petiole pilose.

Fruiting-catkins (Plate 270, Fig. 11) erect, sessile or sub-sessile, ovoid-oblong, 1 to $1\frac{1}{2}$ inch long, $\frac{3}{4}$ inch in diameter; scale lobes nearly equal, ciliate, pubescent.

In winter the slender twigs are more or less pilose; buds fusiform, $\frac{1}{4}$ inch long, rather blunt at the apex, with minutely pubescent, ciliate scales.

This species occurs in Newfoundland and along the northern shores of the Gulf of St. Lawrence, to the valley of the Rainy River, extending southwards to Delaware and Minnesota, and along the Alleghany Mountains to the high peaks of North Carolina and Tennessee. It is one of the largest broad-leaved trees of the eastern provinces of Canada and New England, where it is abundant, usually growing in rich soil on moist uplands, in company with the beech, sugar and red maples, black and white ash, and white elm. The leaves turn a bright yellow in autumn. (A. H.)

The yellow birch was introduced into England, according to Loudon, about 1767, but has never become common.

The finest we know of in England grows in a shrubbery near the kitchen garden at Tortworth, and measured in 1907 about 50 feet by 4 feet. It has borne fruit, from which Lord Ducie has raised seedlings. There are small specimens in Kew Gardens.

At Auchendrane, Ayrshire, Mr. Renwick measured a tree in 1907, 57 feet high, with a bole of 15 feet girthing 5 feet 2 inches.

A very fine tree is growing at Oriel Temple, Co. Louth, the seat of Lord Masserene, which was mentioned by Loudon under the name *B. lenta*. When I saw it in July 1908, it was in perfect health, and measured 58 feet high by 7 feet 4 inches in girth (Plate 260). Loudon states that in his time it was about fifty years planted, and 50 feet high with a diameter of 1 foot 9 inches. (H. J. E.)

BETULA LENTA, CHERRY BIRCH, BLACK BIRCH

Betula lenta, Linnæus, *Sp. Pl.* 983 (1753); Loudon, *Arb. et Frut. Brit.* iii. 1713 (1838); Sargent, *Silva N. Amer.* ix. 50, t. 448 (1896), and *Trees N. Amer.* 196 (1905); Winkler, *Betulaceae*, 64 (1904).

Betula nigra, Du Roi, *Obs.* 30 (1771) (not Linnæus).

Betula carpinifolia, Ehrhart, *Beit. Naturk.* vi. 99 (1791) (not Siebold and Zuccarini).

A tree, attaining in America 80 feet in height and 2 to 5 feet in diameter. Bark smooth, close, dark brown, with pale, elongated, horizontal lenticels, peeling off transversely in thin strips; on old trunks deeply fissured and broken into large, irregular scaly plates. Young branchlets glabrous, except for a few hairs above the leaf-insertions, slightly glandular.

Leaves (Plate 269, Fig. 3), $2\frac{1}{2}$ to 5 inches long, $1\frac{1}{2}$ to 3 inches wide, ovate-oblong, rounded or slightly cordate at the base, acuminate at the apex; margin non-ciliate, bi-serrate; nerves nine to thirteen pairs; upper surface dark green with a few long hairs confined to the midrib and nerves or scattered throughout; lower surface lighter in colour, with silky hairs on the midrib and nerves, forming axil-tufts; petiole pilose at first, ultimately glabrescent.

Fruiting-catkins (Plate 269, Fig. 3) erect, sessile, ovoid-oblong, 1 to $1\frac{1}{2}$ inch long, $\frac{1}{2}$ inch in diameter; scales glabrous, with nearly equal lobes, the lateral lobes being divergent.

This species is characterised by the pleasant aromatic flavour and fragrance of the leaves, twigs, and inner bark; and on that account is sometimes named sweet birch in America. It is, however, more often called, on account of the colour of the bark, cherry birch or black birch. In winter the twigs are shining and almost glabrous; buds fusiform, $\frac{5}{16}$ inch long, ending in a sharp beak, brownish, viscid, shining.

Var. *laciniata*, Rehder, in *Rhodora*, ix. 111 (1907). Leaves with six to nine pairs of sharply serrated lobes. A single tree of this variety, which resembles *B. verrucosa*, var. *dalecarlica*, in the form of the leaves, was found in 1901 at New Boston in New Hampshire.

A hybrid between this species and *B. pumila*, L., has been described by Sargent.¹ (A. H.)

This species is an inhabitant of Newfoundland and Canada from Nova Scotia to Lake Superior, growing in its greatest perfection in central Ontario, Algoma, and Parry Sound, where Macoun says it is often more than 4 feet in diameter. In the United States it extends west to Iowa, and along the Alleghany Mountains to Kentucky and Tennessee, attaining a large size in the valleys of North Carolina. Ashe figures on plate 12 of his work a splendid tree 80 feet in height, with a clean bole 5 feet in diameter. He says the bark is reddish brown and rough on old trees, while on young trees and branches it is smooth and dark, resembling that

¹ *Garden and Forest*, viii. 243, fig. 36 (1895).

of *Prunus serotina*. It produces seed once in three or four years, and does not bear shade well, though young trees will sprout from the stump. The timber is heavy, hard, and strong, dark brown in colour, and takes a good polish.

I saw a very fine tree of this species in a garden at Lancaster, Massachusetts, 62 feet by 10 feet, dividing at 3 feet into four stems, which were covered with a very pretty ragged yellow and grey bark.

Betula lenta was introduced into England in 1759, according to Loudon. We are not aware that it has anywhere attained a large size, except at Oakly Park, near Ludlow, the property of the Earl of Plymouth, where on a rich sheltered flat on the banks of the Teme, I found a tree of considerable age, which in August 1908 measured about 60 feet by 4 feet 9 inches. The trees in Kew Gardens are about 20 feet in height. A specimen at High Canons, Herts, measured 36 feet high by 4 feet 2 inches in girth, and bore fruit in 1907. Another at Bicton, 38 feet by 3 feet 5 inches, is growing in the Arboretum walk, near the Paper Birch.

Beer is sometimes obtained in America by fermenting the sugary sap of this tree. Oil of birch, which is made on a considerable scale in Pennsylvania, is a more important product. This is obtained by distilling the wood,¹ one ton of which yields about 4 lbs. of oil. This oil is nearly identical, both in chemical and physical properties, with oil of winter-green, which is manufactured in the same district; and commercial oil of winter-green is a mixture of the two oils in varying proportions. (H. J. E.)

BETULA FONTINALIS

Betula fontinalis, Sargent, in *Bot. Gazette*, xxxi. 239 (1901), and *Trees N. Amer.* 207 (1905).

Betula occidentalis, Sargent, *Silva N. Amer.* ix. 65, t. 453 (1896) (not Hooker); Winkler, *Betulaceae*, 86 (1904); Schneider, *Laubholzkunde*, i. 114 (1904).

A tree, occasionally attaining 40 feet in height and 3 or 4 feet in girth, more commonly shrubby, with many branching stems. Bark about $\frac{1}{4}$ inch thick, dark brown, shining, not separating into thin layers, marked by pale brown horizontal lenticels. Young branchlets viscid, densely covered with resinous glands, interspersed with long, pale hairs; older branchlets dark in colour and roughened with the persistent glands. Leaves about $1\frac{1}{2}$ inch long, and 1 to $1\frac{1}{2}$ inch broad, thin in texture, broadly or narrowly ovate; rounded, truncate or subcordate, and often unequal at the base; acute at the apex; margin ciliate, sharply and doubly serrate; nerves six to eight pairs; both surfaces glandular with scattered long hairs, at first paler beneath, becoming glabrescent; petiole, $\frac{1}{2}$ inch, glandular, glabrescent.

Fruiting-catkins, about 1 inch long, $\frac{1}{4}$ inch in diameter, cylindrical, on slender glandular stalks; scales pubescent, ciliate, with the three lobes triangular and nearly equal in size, the lateral lobes divergent; nutlets with broad wings.

This species is readily distinguished by its conspicuously glandular branchlets and its small, thin leaves, which are variable in width, and in the form of the base.

¹ Cf. article by H. Trimble in *Garden and Forest*, viii. 303 (1895), where the process is described. The oil of birch is contained in the inner bark only; and on this account the wood used in distillation is obtained from small trees, usually coppice shoots.

B. fontinalis × *B. papyrifera*. There are two small trees in Kew Gardens, with wide-spreading pendulous branches, which were obtained from Dieck in 1891, and were said to be *B. occidentalis* from Alaska. One of these trees has firm, dark-brown, shining bark like that of *B. fontinalis*; while the other has white bark, peeling off in shreds, indistinguishable from that of *B. papyrifera*. The branchlets are exactly similar to those of *B. fontinalis*. The leaves (Plate 269, Fig. 8) are very variable and not precisely the same on both trees; resembling those of *B. fontinalis* in colour, but much larger and much thicker in texture; 2 to 3 inches or more in length, broadly ovate; rounded, truncate, or cuneate at the base, acute at the apex, coarsely serrate or toothed in margin, pubescent and gland-dotted on both surfaces. The fruiting-catkins (Plate 269, Fig. 8) and the scales are as large as those of *B. papyrifera*; but the scales are more like those of *B. fontinalis* in shape, the three lobes being almost triangular, glabrous, and ciliate. In all probability these two trees, with such variable characters in the bark and foliage, are hybrid between *B. fontinalis* and *B. papyrifera*, which occur in the same region.

The small-leaved birch, described above under the name *B. fontinalis*, was identified by Nuttall¹ with *B. occidentalis*, W. J. Hooker, *Fl. Bor. Amer.* ii. 155 (1839); and most botanists, including Sargent² in 1896, Winkler, and Schneider, have followed Nuttall. Sargent,³ however, in 1901 advanced the opinion that the tall, large-leaved birch of the lower Fraser River, considered by us to be *B. papyrifera*, var. *Lyalliana*, is a distinct species, which he identified with Hooker's *B. occidentalis*; and he proposed the name *B. fontinalis* for the small-leaved birch.

The material⁴ in the Kew Herbarium, on which Hooker founded his species, includes no less than three distinct birches, none of which, however, is the large-leaved variety of *B. papyrifera*; and as his description is confused and not confined to a single species, the name *B. occidentalis*, Hooker, must be entirely abandoned; and, in consequence, *B. fontinalis* is rightly adopted for the small-leaved birch, as being the first valid name for this species.

B. fontinalis is a small tree or spreading shrub, widely distributed in western North America, where it usually grows on moist soil near the banks of streams in mountain valleys. It extends from the basin of the upper Fraser and Peace rivers in British Columbia, Alberta, and the valley of the Saskatchewan, southwards to Mount Shasta and the northern Sierra Nevada in California, and through the Rocky Mountains and the interior ranges to Nevada, Utah, and northern New Mexico; extending eastwards in the United States to the Black Hills of Dakota and north-western Nebraska. Mr. M'Innes, of the Canadian Geological Survey, has recently discovered this species in the district north of Lake Superior.⁵

¹ *N. Amer. Sylva*, i. 22 (1842).

² *Silva N. Amer.* ix. 65 (1896).

³ *Bot. Gazette*, xxxi. 237 (1901).

⁴ This material includes:—

I. One specimen collected by Dr. Scouler, labelled "De Fuca Straits"; another, collected by Dr. Tolmie, "N.-W. Coast"; and a third collected by Douglas "west of the Rocky Mountains." These three specimens are a small-leaved variety of *B. papyrifera*, identical with *B. kenaica*, Evans.

II. Two specimens, collected by Dr. Richardson, labelled "Arctic Sea-Coast," one of which is *B. fontinalis*, Sargent; and the other, *B. alaskana*, Sargent.

III. A specimen, with young foliage, collected by Drummond, near Edmonton, which is probably *B. fontinalis*.

⁵ *Canadian Forestry Journal*, 1905, 175.

It was introduced into cultivation in the Arnold Arboretum in 1874; but is rarely met with in Europe, except in Botanic Gardens. Four or five specimens, in the lower nursery at Kew, which were received from Sargent in 1903, are now 8 to 10 feet in height, and are vigorous in growth, promising to become trees of considerable size. Another specimen in the collection at Kew, raised from seed obtained from the Pinehurst Nursery in 1897, is about 10 feet in height and is more shrubby in appearance.

(A. H.)

TIMBER OF THE AMERICAN BIRCHES¹

All American authors agree in saying that the tree which supplies the best wood of commerce is that of the *Betula lenta*, known in New England as black birch, in Canada as cherry birch. Macoun says that the yellow birch is scarcely distinguished in commerce, and judging from the specimens in Hough's *American Woods*, it would be difficult for any one but an expert to do so. Michaux and Macoun both say that the timber of the white birch is less valuable than either of the above; and Sargent says that the wood of the red birch has lately been found suitable for furniture of the best quality. Mr. Weale tells me that large quantities of red and yellow birch are imported into Liverpool, chiefly in the form of hewn logs of 15 to 18 inches square, which are valued in proportion to their size at from 1s. 6d. to 2s. a foot and upwards for logs showing figure. The wood often shows a beautiful undulation called "roll figure," which, when cut into veneers, was a few years ago very fashionable for bedroom furniture, and is sometimes rather difficult to distinguish from satin wood, though its colour is rather pinkish than yellowish and the undulations larger and more open. Mr. C. L. Willey, of Chicago, tells me that this fine "curly birch" is principally found at altitudes of 3000 to 4000 feet in North Carolina, and is very light in colour, having a yellowish tint; whilst other trees produce wood of a reddish colour, resembling that of cherry (*Prunus serotina*).

A large quantity of American birch is also imported in the form of planks 2 inches to 5 inches thick, and averaging 8 inches wide, which are sold in Liverpool at about 1s. per cubic foot, and consumed for chair-making at High Wycombe and elsewhere. At this low price it is the most formidable competitor to the native beech, and in some of the factories which I visited, seemed to be the more popular wood of the two.

The bark of the Paper Birch, and to a less extent that of other species, is as important to the inhabitants of Canada as that of the common birch is to those of northern Europe. Canoes and lodges are covered with large sheets of bark; it is placed on shingled roofs under the shingles to prevent the water from coming through; and very ornamental boxes, baskets, and other articles are made from it by the Indians. It also serves as a writing material, and I have a clearly written letter from Prof. Elrod, sent me by him, when during an expedition in Montana he ran out of paper.

(H. J. E.)

¹ Emerson distinguishes the five common birches of New England as follows:—

1. *B. lenta*, black birch; bark dark coloured.
2. *B. lutea*, yellow birch; bark yellowish, with a silvery lustre.
3. *B. nigra*, red birch; bark reddish or chocolate coloured, very much broken and ragged.
4. *B. papyrifera*, canoe birch; bark white with a pearly lustre.
5. *B. populifolia*, grey or white birch; bark chalky-white, dotted with black.

DIOSPYROS

Diospyros, Linnæus, *Gen. Pl.* 143 (1737); Hiern in *Trans. Camb. Phil. Soc.* xii. 1, 144 (1873);
Bentham et Hooker, *Gen. Pl.* ii. 665 (1876); Gürke in Engler u. Prantl, *Pflanzenfam.* iv. 1,
161 (1890).

Cargillia, R. Brown, *Prod. Fl. Nov. Holl.* 526 (1810).

Leucoxyllum, Blume, *Bijdr. Fl. Ned. Ind.* 1169 (1825).

Noltia, Schumacher, *Dansk. Vidensk. Selsk. Skrift.* iii. 189 (1828).

Rospidius, A. de Candolle, *Prodr.* viii. 220 (1844).

TREES or shrubs, belonging to the order Ebenaceæ. Leaves alternate or rarely sub-opposite, deciduous or persistent, simple, entire, without stipules.

Flowers dioecious or rarely polygamous, monœcious or perfect,¹ in cymes or solitary from the axils of the leaves of the current year, or in a few species arising from the old wood. Calyx, three- to seven-, usually four-lobed, pubescent, and accrescent under the fruit. Corolla urn-shaped, campanulate, tubular, or salver-shaped, three- to seven-, usually four- to five-lobed, pubescent. Male flowers small, usually in cymes; stamens four to sixteen, inserted on the base of the corolla or hypogynous; filaments slender and often united by pairs, forming an outer and inner series; anthers opening longitudinally or by apical pores; ovary aborted or wanting. Female flowers often solitary; staminodes four to eight, sometimes wanting, occasionally with fertile anthers; ovary with four to sixteen cells, which are double the number of the styles and one-ovuled, or rarely of the same number as the styles and two-ovuled. Fruit a berry, with the enlarged and persistent calyx at its base, containing one to ten or more oblong seeds, which have a copious albumen.

The alternate, simple, stalked, entire leaves, without stipules, and the shoots without true terminal buds and with two persistent bud-scales at their base, are distinguishing marks of the genus.

About 180 species of *Diospyros* are known, mostly confined to the subtropical and tropical regions of both hemispheres. The wood is usually hard and close-grained, the heartwood black, the sapwood soft, thick and yellow.

Only three species are in cultivation in this country; and of these *Diospyros Kaki*, Linnæus f., the Chinese Persimmon, a shrub or small tree, usually only met with in England in greenhouses or trained against a wall, does not come within the scope of our work. It ripens its fruit in warm summers in England. (A. H.)

¹ In many species the sexes are unstable; cf. Wright, *Ann. R. Bot. Gard. Peradeniya*, ii. pt. i. 1, 133 (1904).

DIOSPYROS VIRGINIANA, AMERICAN PERSIMMON

Diospyros virginiana, Linnæus, *Sp. Pl.* 1057 (1753); Loudon, *Arb. et Frut. Brit.* ii. 1195 (1838)

Sargent, *Silva N. Amer.* vi. 7, tt. 252, 253 (1894), and *Trees N. Amer.* 749 (1905).

Diospyros guajacana, Romans, *Nat. Hist. Florida*, 20 (1775).

Diospyros concolor, Moench, *Meth.* 471 (1794).

Diospyros pubescens, Pursh, *Fl. Am. Sept.* i. 265 (1814); Loudon, *Arb. et Frut. Brit.* ii. 1196 (1838).

Diospyros caroliniana, Rafinesque, *Fl. Ludovic.* 139 (1817).

Diospyros Persimmon, Wikström, *Jahr. Schwed.* 1830, p. 92 (1834).

A deciduous tree, attaining occasionally in America 115 feet in height and 6 feet in girth, but usually smaller. Bark¹ deeply divided into square corky plates. Young shoots with a minute dense erect pubescence, persistent usually in the second year. Leaves (Plate 199, Fig. 3) oblong or elliptical; rounded and unequal or broadly cuneate at the base; shortly acuminate at the apex; margin entire and ciliate; upper surface dull, light green, and glabrous except for some pubescence on the midrib at the base; lower surface pale, glabrous; veins pinnate, arcuate, and looping near the margin; petiole pubescent, $\frac{1}{2}$ to 1 inch long.

Flowers appearing, when the leaves are more than half-grown, on the current year's shoot, diceious. Staminate flowers in two- to three-flowered pubescent pedunculate cymes; calyx with four broadly ovate acute ciliate lobes; corolla tubular, slightly contracted below the very short acute reflexed lobes; stamens sixteen, in two series, with pubescent filaments. Pistillate flowers, solitary, on short recurved peduncles; stamens eight, usually with aborted anthers; ovary pilose towards the apex, eight-celled; styles four, two-lobed at the apex, pubescent at the base.

Fruit solitary, on short woody peduncles, persistent on the branches during winter; depressed, globose; surrounded at the base by the persistent calyx, which has four broadly ovate pointed recurved lobes. The fruit is variable in size, from that of a small cherry to a large plum; and its flavour is very different in different localities and even on trees growing close together—sometimes sweet without the action of frost, or ripening after frost, or at other times acid and never edible. Seeds oblong, flattened, $\frac{1}{2}$ inch long. Seedless forms occur, and experiments are being made in America with these and other good varieties.

The leaves on trees, growing in the Southern States, are strongly pubescent beneath; and this variety, which we have not seen in cultivation in England, is scarcely to be distinguished by the foliage alone from *D. Lotus*, which has pubescent leaves, and differs in this respect from the ordinary form of *D. virginiana*, with

¹ The bark is well figured in *Gard. Chron.* iv. 504, fig. 71 (1888).

glabrous leaves. The buds and leaf-scars of the two species are very different, and constitute the best marks of distinction.

In winter, the American Persimmon (Plate 200, Fig. 4) shows the following characters:—Twigs slender, covered with a minute dense erect pubescence, with two broadly ovate scales (of the previous season's bud) persisting at the base of the shoot. Leaf-scars, oblique on prominent pulvini, small, semicircular, with a deep transverse lunate depression, showing indistinctly the coalesced cicatrices of the vascular bundles. True terminal bud not formed, the tip of the branchlet dying off in summer and leaving at the apex of the twig a short glabrous stump with a terminal scar, which subtends the uppermost axillary bud. Buds ovoid, slightly compressed, small, brown, shining, glabrous, usually with a minute curved beak tipped by a few hairs; outer scales two, imbricate, ovate, acute, non-ciliate, concave interiorly, pubescent at the tip, glabrous elsewhere.

This species is widely distributed in the United States, its most northerly point being at Newhaven in Connecticut. It is not uncommon in Long Island, and extends southwards to Alabama and Florida, and westwards through Ohio and Iowa to Missouri, Arkansas, Louisiana, eastern Kansas, Indian Territory, and the valley of the Colorado River in Texas. It usually grows on light, sandy, well-drained soil, but attains its largest size in the deep alluvial lands of the Mississippi basin, where it sometimes reaches a height of more than 100 feet, with a slender trunk free from branches for 70 or 80 feet. It is exceedingly common in the south Atlantic and Gulf States, often covering with its suckers abandoned fields, and springing up by the sides of roads and fences. Sargent¹ gives a figure of a tree with wide-spreading branches, not unlike the specimen at Kew in size and appearance, which is growing in an old corn-field near Auburn in Alabama.

Elwes saw a fine tree of this species in a damp river bottom near Mount Carmel, Illinois, in 1904, which measured 100 feet high by 6 feet in girth, with a clean, straight trunk 60 feet high; but the late Dr. Schneck, who showed it to him, measured one as much as 115 feet high, 80 feet to the first limb, and only $5\frac{1}{2}$ feet in girth at the base. When growing in open fields or along road-sides, where it is most frequently seen, it forms a more spreading tree, usually 30 to 40, and rarely more than 60 feet high. (A. H.)

CULTIVATION

This tree is easy to raise from seed, and perfectly hardy in England, but requires a warm, dry soil, and a much hotter summer than usual to make it thrive. The seedlings which I have raised grow very slowly and do not root freely in my soil. Judging from the extreme rarity of the tree in cultivation, it is hardly likely to be worth planting generally, and, so far as we know, has never borne fruit in England. Even in the climate of central France it fruits, according to Pardé,² very rarely, and grows slowly, having only attained about 20 feet in height at Les Barres. Neither

¹ *Garden and Forest*, viii. 262, fig. 38 (1895).

² *Arboretum Nat. des Barres*, 215 (1906).

Mouillefert nor Mayr mention this tree; and I have seen none in Europe worth mentioning, except a fine tree in the Botanic Garden at Padua, which appears to be the pubescent variety of this species, although it is labelled *D. Lotus*. According to Prof. Saccardo, it was planted in 1760, and measured 30 metres high by 2 metres in girth in 1887.

The American Persimmon was introduced into England some time before 1629, when an account of a cultivated tree appeared in Parkinson's *Paradisus* published in that year.

It is extremely rare in this country at the present day, and Loudon in 1838 only mentioned six trees, two of which still survive. One of these, which is a staminate tree, growing in Kew Gardens, now measures 64 feet in height by 5 feet 3 inches in girth, and, according to Sargent,¹ is apparently as thriving as if it were in its native habitat. It is one of the denizens of the original Kew Arboretum, which was laid out by W. Aiton, and in all probability was one of the numerous trees presented in 1762 to the mother of George III. by Archibald, Duke of Argyll, who was a great introducer and cultivator of rare trees at Whitton, near Hounslow.² (Plate 261.)

Another, mentioned by Loudon as being 24 years planted and 18 feet high in 1838, is growing at the Wilderness, White Knights, near Reading, and is now 45 feet high by 4 feet 1 inch in girth. At Barton, Suffolk, another is 40 feet high by 2 feet 1 inch in girth. At Bushey Lodge a tree with a broken top was, in 1904, 30 feet high by 5 feet 8 inches in girth. Suckers are growing from its roots as far away as 50 feet, and one of these, 10 feet high, is said to be about ten years old.

TIMBER

The wood is very hard and heavy, of a pale yellowish-white colour, with black heartwood, which, however, usually shows only in old trees. Hough states that he felled one 14 inches in diameter for the specimens in his work,³ but though there were over sixty rings of sapwood, only two or three in the heart were black. It is used in America for shoe-lasts and shuttles, for which latter purpose it is imported to a small extent to Liverpool. Michaux⁴ states that it was used at Charleston for shafts, and preferred for that purpose to ash or any wood except lancewood, but the quantity available is too small to give this timber much economic importance. The fruit is little valued as human food, though eaten by animals.

DIOSPYROS LOTUS, DATE-PLUM

Diospyros Lotus, Linnæus, *Sp. Pl.* 1057 (1753); Loudon, *Arb. et Frut. Brit.* ii. 1194 (1838); C. B. Clarke, in Hooker, *Fl. Brit. India*, iii. 555 (1882); Hemsley, in *Journ. Linn. Soc. (Bot.)* xxvi. 70 (1889); Shirasawa, *Icon. Ess. Forest. Japon.* 123, t. 79 (1900).
Diospyros microcarpa, Siebold, in *Ann. Soc. Hort. Pays.-Bas.* 1844, p. 28.
Diospyros japonica, Siebold et Zuccarini in *Abh. Bayer. Acad.* iv. 3, p. 136 (1846).

A tree attaining 60 feet in height and 6 feet in girth. Bark remaining a long time smooth, finally rough and with plate-like scales. Young shoots with a moderately long dense pubescence, often persistent in the second year. Leaves (Plate 199, Fig. 4) oblong or elliptical, base rounded or broadly cuneate, apex acuminate or acute; margin entire, ciliate; upper surface dark green, shining, usually becoming glabrous except at the base of the midrib, but often with scattered minute hairs on the veins and veinlets; lower surface pale and pubescent throughout; veins pinnate and looping towards the margin; petiole, $\frac{1}{4}$ to $\frac{1}{2}$ inch, pubescent.

Flowers diœcious. Staminate flowers, two to three together in subsessile cymes; calyx with four short ovate acute ciliate lobes; corolla urceolate, with four short obtuse lobes; stamens sixteen, in pairs in two series; filaments glabrous. Pistillate flowers, solitary, subsessile; staminodes, eight; ovary eight-celled, one ovule in each cell; styles, four. Fruit subsessile, almost globose, yellow or blackish, $\frac{1}{2}$ to $\frac{3}{4}$ inch in diameter; fruiting-calyx spreading, with a ring of short dense silky hairs on the inside beneath the fruit. The fruit varies considerably in size, and is astringent in flavour.

The leaves pubescent beneath, and the different buds and leaf-scars distinguish this species in summer from *D. virginiana*. In winter the following characters (Plate 200, Fig. 3) are available:—Twigs slender, usually with scattered long hairs, occasionally glabrous; two long acuminate scales of the previous season's bud persist at the base of the shoot. Leaf-scars small, nearly parallel to the twig on prominent pulvini, semicircular, marked with a raised transverse crescentic ridge, composed of the coalesced bundle cicatrices. True terminal bud absent, stump at the apex of the twig pubescent. Buds long, ovoid, acuminate, blackish, pubescent; outer scales two, imbricate, long, acuminate, pubescent, ciliate, concave interiorly.

This species has been long in cultivation, and its exact distribution in the wild state is difficult to define. It appears to be indigenous in Asia Minor; in the Caucasus,¹ where it occurs wild throughout the whole territory between sea-level and 3500 feet; in Afghanistan; in the north-west Himalaya² at 2000 to 6000 feet in Hazara and Kashmir; and in central and northern China.

It has been cultivated for centuries in the countries bordering on the Mediterranean, and has become naturalised in many places, as in the south of France and in Dalmatia. It is not wild in Japan, but is often planted there, either for its own

¹ Radde, *Pflanzenverb. Kaukasusländ.* 181 (1889).

² Gamble, *Indian Timbers*, 455 (1902).

1000 The Trees of Great Britain and Ireland

fruit or as a stock on which to graft the persimmon. In China it is largely cultivated, and the fruits, known as *hei-tsao* or "black dates," are an article of commerce. (A. H.)

The date-plum was early introduced into England, being cultivated by Gerard¹ in 1633 or earlier. It grows easily from seed, and, according to Loudon, at the rate of 12 to 18 inches annually, if planted in rich soil,² but requires a warmer climate than ours and never attains a large size, so far as we know, in England; though trees of 20 feet or so in height are sometimes seen in botanic gardens and in parks. It ripens fruit usually every year at Kew.

Mayr³ figures the wood, which is very remarkable on account of the contrast in colour between the black heart-wood and the pale sap-wood. Judging from this and the wood of the Japanese *kaki*, this wood if procurable would be valuable for cabinet-making; but, so far as I know, it is nowhere common enough to have acquired any recognised commercial value. (H. J. E.)

¹ *Herball*, Johnson's edition, 1495 (1633).

² The seedlings which I have raised from seed collected in France, seem liable to injury by frost, and do not ripen their shoots when young.

PINUS

Pinus, Linnæus, *Gen. Pl.* 293 (*ex parte*) (1737); Duhamel, *Traité des Arbres*, ii. 121 (1755); Bentham et Hooker, *Gen. Pl.* iii. 438 (1880); Engelmann, in *Trans. Acad. St. Louis*, iv. 161 (1886); Masters, in *Journ. Linn. Soc. (Bot.)*, xxvii. 236, 248, 258, 269, 309 (1891), xxx. 37 (1893), and xxxv. 560 (1904); Mayr, *Wald. Nordam.* 425 (1890), and *Fremdländ. Wald- u. Parkbäume*, 340 (1906); Shaw, in *Bot. Gaz.* xliii. 205 (1907).

EVERGREEN trees or shrubs, belonging to the division Abietinæ of the order Coniferæ. Bark usually thick, rough, and deeply fissured; but in some species thin and scaly, and in a few others peeling off in thin flakes like a plane tree. Branches arising from the stem in apparent whorls. Shoots of two kinds: short shoots, which are minute spurs of limited growth, bearing the adult leaves in clusters and deciduous with them; and long shoots, the ordinary branchlets, which continue growth.

In the majority¹ of pines, the long shoot produced in spring is a single internode, consisting of (*a*) a leafless base, which bears the staminate flowers, when these are developed; and (*b*) a longer upper portion bearing foliage, and ending in (*c*) a terminal bud, subtended by a whorl of smaller buds, one or more of which may be replaced by pistillate flowers (young cones). The buds and young cones being close to the apex of the shoot, are said to be subterminal. In the second year the mature cones and the branchlets, which have developed from the single whorl of buds of the first year, are situated beneath the base of the new shoot of the year, which has sprung from the terminal bud of the preceding season.

In another group² of pines, the long shoot produced in spring consists of two (rarely three or more) internodes, each with a leafless base, a leaf-bearing portion, and a whorl of buds (with or without young cones). The buds and young cones are in two or more whorls, and are both subterminal and lateral in position. Similarly, in the second year, the branchlets and mature cones are in two or more whorls.

In young or vigorous trees of any species of either group the subterminal whorl of buds and young cones, already formed in spring, is occasionally placed in a lateral position by the development above it of a summer shoot, which is distinguished from

¹ Termed uninodal pines by Shaw.

² Multinodal pines of Shaw, who points out that when the trees are old or diminishing in vigour, they often produce shoots with only one whorl of buds, but recognisable as having two internodes by the presence of two leafless bases; or they may, when very feeble, only develop one internode to each shoot.

the normal spring shoot with long leaves and brown withered scale-leaves, by bearing short leaves with green scale-leaves. In this exceptional case, which is, however, common in certain species, the buds and cones are said to be pseudo-lateral.

Buds, varying in the different species in shape and in the characters of their spirally imbricated scales, which are united together by their fringed margins or matted hairs, or are embedded in resin, their tips being erect, spreading, or reflexed. The buds are compound; their outer scales empty and persistent at the base of the shoot, when the bud unfolds; their inner scales enclosing minute buds, which develop into the short shoots and adult foliage (and when flower-bearing, into the staminate flowers as well). These inner scales persist on the developed branchlets as scale-leaves.

Leaves of three kinds: (a) Primordial leaves, borne on seedling plants, solitary, spirally arranged, spreading, linear-lanceolate, keeled on both surfaces, serrulate. (b) Scale-leaves, containing in their axils the short shoots and adult leaves, triangular-lanceolate, entire or fringed in margin, usually¹ quickly deciduous in part, their basal portion only persisting. (c) Adult leaves, needle-like, persistent two to twenty years, in clusters of one to five (rarely six or seven), at the apex of the short shoot, serrulate or entire in margin; section² plano-convex in two-leaved species, triangular in three- to five-leaved species; fibro-vascular bundle branched or simple; resin-canals, two to twelve, marginal or median. The sheath at the base of each cluster, formed by the scales of the minute buds, is either quickly and entirely deciduous or persistent; in the latter case usually becoming, with age, shortened, blackened, and lacerated, but in certain species dividing into segments, which become reflexed and surround the base of the leaf-bundle as a rosette.

Flowers monœcious. Staminate flowers,³ clustered in a head or spike at the base of the current year's shoot, ovoid or cylindrical, surrounded at the base by an involucre of scale-like bracts, composed of numerous imbricated sessile two-celled anthers; connective crest-like, nearly orbicular; pollen-grains with two lateral air-vesicles. Pistillate flowers or young cones, sub-terminal or lateral, solitary or in clusters, surrounded at the base by sterile bracts; composed of two series of scales, minute carpels becoming obsolete in the ripe cone, and large ovuliferous scales, each of the latter bearing two pendulous ovules. Pollination occurs in the first year, when the scales open to receive the pollen, closing immediately afterwards; but fertilisation, the arrival of the pollen-tube at the embryo-sac, does not occur till May or June in the second year; in consequence the cone remains small in the first year, and increases only in size in the second year.

Fruit a woody cone,⁴ ripening in nearly all the species⁵ at the end of the second

¹ In the species with leaves densely crowded on the branchlets, the scale-leaves persist during the first year.

² In *P. monophylla*, the section of the solitary leaf is terete.

³ Shaw, *Pines of Mexico*, 1 (1909), points out that in the Soft Pines the buds enclosing the staminate flowers are not sufficiently advanced at the end of the growing season to be distinguishable; but in the Hard Pines they are recognisable by their larger size. In the latter, the young staminate flowers are either (a) enclosed in the general outline of the bud, or (b) they form about the nodes of the bud characteristic enlargements, which are constant for each species.

⁴ The subterminal, lateral, or pseudo-lateral position of the cone referred to in descriptions of species is, as already defined above, that of the young cone in the first year.

⁵ In *P. Pinca*, *P. leiophylla*, and *P. chihuahuana* the cones take three years to ripen; and in these the umbo of the scale shows separate growths of the first and second years.

year; symmetrical, or oblique with the scales larger on the outer side of the cone. The exposed part of each scale in the unopened cone, known as the *apophysis*, is thickened and shows the apex of the growth of the first year as a terminal or dorsal protuberance or scar called the *umbo*, which is either unarmed or provided with a sharp prickle or stout spine. The cones in most species open their scales when ripe, allowing the seed to escape; but in *P. Cembra*, *P. pumila*, and *P. albicaulis* the scales are incapable of dehiscence, and the seeds are liberated by the attacks of squirrels and other animals. In other species a large proportion of the cones remain on the trees unopened for many years, the scales ultimately separating when scorched by forest fires. Usually the cones fall through decay at the insertion of their peduncle; but in *P. resinosa*, *P. ponderosa* and *P. palustris* separation occurs near the base of the cone, a few of the lower scales remaining attached by the stalk to the branch.

Seeds, two on each scale, obovate, triangular or cylindrical; wing embracing by its rim-like base the sides and part of the upper surface of the seed, and either separating freely from it as in the Hard Pines, or adhering closely and breaking off from it irregularly as in *P. Strobus* and its allies. In certain species, the seeds of which are edible and distributed by animals, the wing, no longer serving for flight, is either reduced to a mere vestige only visible on the upper surface of the seed, as in *P. Cembra* and its allies, or it is much shortened and reduced to a narrow lateral rim, which usually remains on the scale when the seed falls, as in *P. Pinca*, *P. cembroides*, *P. Bungeana*, and their allies.

In germination the shell of the seed, from which the wing has usually fallen, is raised as a hood on the top of the cotyledons,¹ which vary from three to eighteen in number and are usually triangular, flat, and green below, and keeled and marked with stomata above, entire in margin, acute or mucronate at the apex. The young stem elongating bears primordial leaves, in the axils of which the adult fasciated leaves are usually produced in the second year.

About eighty species of Pinus are known, distributed through the northern hemisphere from the Arctic circle to Central America, the West Indies, Canary Islands, Morocco, Algeria, Syria, Himalayas, Burmah, Philippine Islands, Sumatra, and Borneo. Of these about fifty-two species are in cultivation, which may be arranged as follows:—

I. HAPLOXYLON, Koehne, *Deutsche Dendrologie*, 28 (1893). Soft Pines.²

Leaves with a single fibro-vascular bundle. Scale-leaves subtending the leaf-clusters inserted on prominent bases, which are not decurrent on the branchlets. Cones symmetrical, opening when ripe. Seed-wing present or obsolete, not readily detachable from the seed. Cortex persistent on young trees for many years. Walls of tracheids of medullary rays of the wood not dentate. The wood is usually soft, close-grained, and light in colour; sap wood generally narrow.

¹ The number of cotyledons in each species is variable within narrow limits, and is stated by Dr. Masters in *Journ. Linn. Soc. (Bot.)* xxvii. 236 (1891). Cf. also Hill and de Fraine, in *Ann. Bot.* xxiii. 199 (1909).

² The shoots are always uninodal in the soft pines.

A. LEAF-SHEATH ENTIRELY DECIDUOUS. LEAVES IN FIVES.

§ 1. STROBUS, Spach. White Pines.

Leaves serrate in margin, with marginal resin-canals. Cones sub-terminal, elongated, pendulous, usually long-stalked; scales thin, each with a terminal unarmed umbo. Seeds with long wings, closely adherent and breaking off irregularly.

* *Branchlets glabrous.*

1. *Pinus excelsa*, Wallich. Himalayas. See p. 1011.

Branchlets glaucous, green. Buds conic, shortly acuminate. Leaves 5 to 8 in. long, spreading, slender; some sharply bent as if broken.

2. *Pinus Peuke*, Grisebach. Balkan Peninsula. See p. 1014.

Branchlets shining green. Buds ovoid, shortly acuminate. Leaves about 4 in. long, densely tufted towards the end of the shoot, and not spreading or broken as in *P. excelsa*.

** *Branchlets pubescent. Bud-scales free at their apices.*

3. *Pinus Ayacahuite*, Ehrenberg. Mexico. See p. 1017.

Branchlets covered with a short rusty-brown pubescence. Buds ovoid, acuminate, resinous. Leaves 4 to 6 in. long, spreading, occasionally bent as if broken, as in *P. excelsa*.

*** *Branchlets pubescent. Bud-scales closely appressed.*

4. *Pinus Lambertiana*, Douglas. Oregon, California. See p. 1020.

Branchlets with short brown, partly glandular pubescence. Buds cylindrical, rounded at the apex or sharp-pointed. Leaves about 4 in. long, twisted a complete turn, rigid, ending in a sharp cartilaginous point.

5. *Pinus monticola*, Don. Western North America. See p. 1022.

Branchlets with short brown, partly glandular pubescence. Buds ovoid, acuminate. Leaves 4 in. long, slightly twisted in their upper half, blunt at the apex.

6. *Pinus Strobus*, Linnæus. Eastern North America. See p. 1025.

Branchlets with pubescent tufts below the insertions of the leaf-clusters, elsewhere usually glabrous. Buds ovoid, acuminate. Leaves 3 in. long, very slender, not twisted.

7. *Pinus parviflora*,¹ Siebold et Zuccarini. Japan, Kurile Isles. See p. 1033.

Branchlets greyish, with a scattered minute pubescence. Buds ovoid, not acuminate. Leaves 2 in. long, white on the inner surfaces, blunt at the apex.

§ 2. CEMBRA, Spach. Stone Pines.

Leaves serrate or entire in margin, with median or marginal resin-canals. Cones sub-terminal, short-stalked; scales thickened, each with a terminal unarmed umbo. Seeds large, edible, with rudimentary or obsolete wings.

¹ This species, which is variable in the length of the seed-wing, is intermediate in character, and forms a connecting link between the first two sections.

* *Leaves serrate, with median resin-canals.*

8. *Pinus Cembra*, Linnæus. Alps, Carpathians, North-Eastern Russia, Siberia. See p. 1035.

Branchlets covered with a dense orange-brown shaggy tomentum. Buds ovoid, acuminate, resinous. Leaves 2½ to 3½ in. long, with few serrations at the tip.

9. *Pinus koraiensis*, Siebold et Zuccarini. Amurland, Manchuria, Korea, Japan. See p. 1041.

Branchlets and buds as in *P. Cembra*. Leaves with numerous sharp serrations at the tip, otherwise as in *P. Cembra*.

10. *Pinus Armandi*, Franchet. China. See p. 1043.

Branchlets olive green, glabrous or with minute scattered hairs. Buds with free or appressed scales. Leaves 4 to 6 in. long, spreading, and often bent, as in *P. excelsa*.

** *Leaves entire in margin, with marginal resin-canals.*

11. *Pinus pumila*, Regel. Kamtschatka, Eastern Siberia, Amurland, Saghalien, Kurile Isles, Japan. See p. 1045.

Buds and branchlets as in *P. Cembra*. Leaves¹ also similar, but usually shorter and differing in the position of the resin-canals.

12. *Pinus flexilis*, James. Western North America. See p. 1046.

Branchlets glabrous or covered with a minute brown soft pubescence. Buds ovoid, sharp-pointed, resinous. Leaves 2 to 3 in. long, stout, rigid, curved, sharp-pointed.

13. *Pinus albicaulis*, Engelmann. Western North America. See p. 1048.

Scarcely distinguishable from *P. flexilis* in the absence of cones, though the branchlets apparently differ in their scattered minute stiff pubescence.

B. LEAF-SHEATH ENTIRELY DECIDUOUS. LEAVES IN THREES.

§ 3. GERARDIANÆ, Engelmann. Plane-bark Pines.

Leaves serrulate, with marginal resin-canals. Cones sub-terminal; scales much thickened, each with a dorsal umbo. Seeds large, edible; wing reduced to a narrow deciduous rim, remaining on the scale when the seed falls.

14. *Pinus Bungeana*, Zuccarini. China. See p. 1050.

Branchlets glabrous, green, smooth. Buds spindle-shaped, with scales free at their tips. Leaves 3 in. long, shining green, rigid, with the basal sheaths deciduous in the first year.

15. *Pinus Gerardiana*, Wallich. Western Himalayas. See p. 1052.

Branchlets glabrous, green, smooth. Buds conic, acuminate, resinous. Leaves 3 to 4 in. long, duller in colour and less rigid than in *P. Bungeana*, with the basal sheaths deciduous in the second year.

¹ In the insular form of this species, the leaves are indistinctly serrulate in margin.

C. LEAF-SHEATHS PARTLY DECIDUOUS, THEIR INNER PART PERSISTING AS A ROSETTE OF REFLEXED SCALES AROUND THE BASE OF THE LEAF-BUNDLE. LEAVES ENTIRE IN MARGIN.

* *Leaves in fives.*

§ 4. BALFOURIANÆ, Engelmann. Fox-tail Pines.

Cones sub-terminal, short-stalked, cylindrical; scales each with a dorsal umbo, armed with a slender prickle. Seeds with long wings, easily separable.

16. *Pinus Balfouriana*, Balfour. California. See p. 1054.

Branchlets stout, pubescent. Buds ovoid, acuminate. Leaves $1\frac{1}{2}$ in. long, without stomata on the outer surface, rigid, curved.

17. *Pinus aristata*, Engelmann. Colorado, Utah, Nevada, Arizona, South-eastern California. See p. 1055.

Differs from the preceding species in the numerous resinous exudations on the leaves, and in the cones and seeds.

** *Leaves solitary or in twos, threes, or fours.*

§ 5. CEMBROIDES, Engelmann. Nut Pines.

Cones sub-terminal, sub-sessile, globose; scales few, much thickened, each with a dorsal umbo, unarmed or with a minute prickle. Seed large, edible, with wing reduced to a narrow rim, remaining on the scale.

18. *Pinus monophylla*, Torrey. Utah, Nevada, Arizona, California, Lower California. See p. 1056.

Leaves solitary, rigid, terete, sharp-pointed, $1\frac{1}{2}$ in. long, remotely placed on the branchlets.

19. *Pinus edulis*, Engelmann. Wyoming, Colorado, Utah, New Mexico, Texas, Arizona, Northern Mexico. See p. 1058.

Leaves in twos, rarely in threes, rigid, sharp-pointed, $\frac{3}{4}$ to $1\frac{1}{2}$ in. long, remotely placed on the branchlets.

20. *Pinus cembroides*, Zuccarini. Arizona, Lower California, Northern Mexico. See p. 1059.

Leaves in threes, rarely in twos, softer and more slender than in the other species of the section, and densely crowded on the branchlets.

21. *Pinus Parryana*, Engelmann. Southern California, Lower California. See p. 1060.

Leaves in fours, rarely in fives, $1\frac{1}{2}$ in. long, rigid, sharp-pointed, remotely placed on the branchlets.

II. DIPLOXYLON, Koehne, *Deutsche Dendrologie*, 30 (1893). Hard Pines.

Leaves with a divided fibro-vascular bundle. Bases of the scale-leaves subtending the leaf-clusters, decurrent on the branchlets. Cones sometimes asymmetrical, and often remaining closed for several years after ripening; scales always with dorsal umbos. Seed-wing present, occasionally reduced to a narrow rim; always readily detachable from the seed. Walls of tracheids of the medullary rays of the wood not dentate. The wood is usually heavy, coarse-

grained, and dark-coloured; sapwood thick, and paler in colour than the heart-wood.

D. LEAF-SHEAF PERSISTENT IN ALL THE CULTIVATED SPECIES. LEAVES ALWAYS SERRATE.

a. *Leaves in fives.*

§ 6. PSEUDOSTROBUS, Engelmann. Leaves with median resin-canals. Cones sub-terminal. Shoots uninodal.

22. *Pinus Montezumæ*, Lambert. Mexico, Guatemala. See p. 1061.

Branchlets stout, not glaucous, reddish brown. Buds ovoid, pointed, an inch long, reddish brown, scarcely resinous. Leaves about 9 in. long; basal sheaths $1\frac{1}{4}$ to 2 in. long. Scale-leaves persistent.

22A. *Pinus Montezumæ*, Lambert, var. *Hartwegii*, Engelmann. Cold regions and high altitudes of Mexico. See p. 1062.

Branchlets and buds, as in the type, but the latter smaller, $\frac{1}{2}$ to $\frac{3}{4}$ in. long, usually with resinous appressed scales. Leaves 5 to 6 in. long; basal sheaths 1 in. long. Scale-leaves persistent.

23. *Pinus pseudostrobus*, Lindley. Mexico. See p. 1064.

Branchlets slender, glaucous. Buds, leaves, and scale-leaves as in *P. Montezumæ*.

24. *Pinus Torreyana*, Parry. Coast of California near San Diego, and Santa Rosa island. See p. 1065.

Branchlets glaucous, dull grey in the second year. Buds cylindro-conic, $\frac{1}{2}$ in. long; scales pale brown with appressed points. Leaves 7 to 13 in. long, very stout; basal sheaths an inch long. Scale-leaves deciduous.

β. *Leaves in threes.*

§ 7. TAEDA, Mayr.

Leaves with median resin-canals. Cones variable in size and position. Shoots uninodal or multinodal.

* *Buds resinous; points of bud-scales appressed.*

† *Leaves more than 6 in. long.*

25. *Pinus Coulteri*, Don. California. See p. 1067.

Branchlets stout, glaucous, remaining green in the second year. Buds ovoid, stout, acuminate or cuspidate, 1 to $1\frac{1}{2}$ in. long. Leaves 10 to 14 in. long, dark green, spreading from the upper part of the branchlets of the first and second years.

26. *Pinus Sabiniana*, Douglas. California. See p. 1069.

Branchlets slender, glaucous, remaining green in the second year. Buds narrowly cylindrical, an inch long. Leaves 7 to 12 in. long, greyish green, spreading or drooping from the upper part of the branchlets of the first and second years.

27. *Pinus ponderosa*, Lawson. Western N. America. See p. 1071.

Branchlets stout, reddish, not glaucous, becoming nearly black in the second

and third years. Buds cylindro-conic, an inch long. Leaves 6 to 10 in. long, dark green, densely crowded on the greater part of the branchlets, directed outwards and forwards.

- 27A. *Pinus ponderosa*, Lawson, var. *Jeffreyi*, Vasey. California and Lower California. See p. 1072.

Branchlets stout, glaucous, becoming dark-coloured in the second and third years. Buds stout, cylindro-conic, reddish brown, an inch long, with scales less resinous and their points more free than in the type.

†† Leaves less than 6 in. long.

28. *Pinus tuberculata*, Gordon. Oregon, California. See p. 1077.

Branchlets reddish brown, not glaucous. Buds cylindrical, pointed, an inch long. Leaves 4 to 5 in. long, rigid, dark green; basal sheath $\frac{1}{2}$ in. long.

29. *Pinus radiata*, Don. Coast of California, near Monterey. Islands of Santa Cruz, Santa Rosa, and Guadalupe. See p. 1079.

Branchlets reddish brown, not glaucous. Buds cylindrical, pointed, $\frac{1}{2}$ to $\frac{3}{4}$ in. long. Leaves 4 to 5 in. long, slender, flexible and soft in texture, light green, densely crowded on the branchlets; basal sheath $\frac{1}{2}$ inch long.

** Points of the bud-scales free and slightly spreading, not reflexed.

30. *Pinus patula*, Schlechtendal et Chamisso. Mexico. See p. 1085.

Branchlets glaucous. Buds cylindro-conic, $\frac{1}{2}$ to $\frac{3}{4}$ in. long. Leaves 6 to 9 in. long, filiform, soft and very slender, drooping; basal sheath, 1 in. long.

31. *Pinus Teocote*, Schlechtendal et Chamisso. Mexico. See p. 1086.

Branchlets glaucous, the epidermis of the decurrent pulvini peeling off in the second and third years. Buds cylindro-conic, resinous, $\frac{3}{4}$ in. long. Leaves 4 to 8 in. long, rigid, spreading; basal sheath an inch long.

32. *Pinus rigida*,¹ Miller. Eastern Canada, and North-eastern United States. See p. 1087.

Branchlets not glaucous. Buds cylindro-conic, $\frac{1}{2}$ to $\frac{3}{4}$ in. long. Leaves $3\frac{1}{2}$ to 4 in. long, rigid; basal sheath $\frac{3}{8}$ to $\frac{1}{2}$ in. long.

33. *Pinus serotina*,¹ Michaux. South-eastern and Southern United States. See p. 1090.

Distinguishable from *P. rigida* by the different cones and longer leaves, 6 to 10 in. long; but in cultivated trees in England the leaves are as short as in that species.

*** Buds non-resinous; bud-scales with free, fimbriated, and recurved points. The apex of the second year's branchlet is marked with a conspicuous sheath of the persistent recurved bud-scales.

34. *Pinus palustris*, Miller. South-eastern and Southern United States. See p. 1091.

Branchlets stout, orange brown. Buds $1\frac{1}{2}$ to 2 in. long, with silvery white scales. Leaves 8 to 18 in. long, densely crowded on the branchlets; basal sheath $\frac{3}{4}$ to 1 in. long. Scale-leaves persistent.

¹ Adult trees of both these species are readily recognisable by the adventitious shoots on the old branches and stems. Occasionally the buds in *P. rigida* are very resinous, with closely appressed scales.

35. *Pinus Taeda*, Linnæus. South-eastern and Southern United States. See p. 1094.

Branchlets glaucous. Buds $\frac{1}{2}$ in. long, with brown scales. Leaves 6 to 9 in. long, spreading; basal sheath nearly 1 in. long. Scale-leaves persistent.

36. *Pinus canariensis*, Smith. Canary Islands. See p. 1096.

Branchlets yellow, not glaucous. Buds $\frac{3}{4}$ in. long, with reddish brown scales. Leaves 7 to 12 in. long, densely crowded on the branchlets, slender, flexible.

γ. Leaves in twos; in one species, clusters of three leaves also occur.

See § 8 and § 9.

- § 8. BANKSIA, Mayr.

Cones lateral. Shoots multinodal, a vigorous branch showing a whorl of buds, branchlets, or cones in the middle of each year's shoot, in addition to the subterminal whorl.

* Leaves in twos and in threes, on the same branch.

37. *Pinus echinata*, Miller. South-eastern United States. See p. 1098.

Branchlets slender, brittle, glaucous, with the bark in the third year exfoliating in large flakes. Buds $\frac{1}{4}$ in. long, brownish, shining, with resinous appressed scales. Leaves 3 in. long, resin-canals median; basal sheath $\frac{3}{8}$ in. long.

** Leaves always in pairs.

† Buds non-resinous, with free and recurved points to their scales.

38. *Pinus halepensis*, Miller. Mediterranean region, Caucasus. See p. 1099.

Branchlets glaucous. Leaves $2\frac{1}{2}$ to 4 in. long; resin-canals marginal; basal sheath $\frac{1}{3}$ in. long. In var. *Brutia* the leaves are 4 to 6 in. long.

†† Buds resinous, with appressed scales.

39. *Pinus muricata*, Don. California. See p. 1104.

Branchlets stout, reddish brown. Buds cylindrical, $\frac{3}{4}$ to 1 in. long; scales encrusted with white resin. Leaves 4 to 6 in. long, stout, rigid; resin-canals median; basal sheath $\frac{1}{2}$ in. long.

40. *Pinus pungens*, Michaux. Alleghany Mountains. See p. 1106.

Branchlets shining brown. Buds cylindrical, $\frac{3}{4}$ in. long. Leaves 2 to $2\frac{1}{2}$ in. long, stout, rigid, very sharp-pointed; resin-canals median; basal sheath $\frac{1}{4}$ in. long.

41. *Pinus virginiana*, Miller. Eastern United States. See p. 1107.

Branchlets slender, glaucous violet. Buds cylindrical, $\frac{3}{8}$ in. long. Leaves $1\frac{1}{2}$ to 3 in. long; resin-canals median; basal sheath $\frac{3}{16}$ in. long.

42. *Pinus Banksiana*, Lambert. Canada, east of the Rockies; United States, Minnesota to Maine. See p. 1109.

Branchlets slender, greenish. Buds ovoid, $\frac{1}{2}$ in. long. Leaves 1 in. long; resin-canals median; basal sheath $\frac{1}{8}$ to $\frac{1}{6}$ in. long.

- § 9. PINASTER, Mayr.

Cones subterminal. Shoots uninodal, a branch, even when vigorous, showing only one whorl of branchlets, buds, and cones, in each year's shoot, close to its apex. Leaves always in pairs.

* *Buds non-resinous; bud-scales with free and recurved points.*

43. *Pinus Pinaster*, Solander. Mediterranean region. See p. 1113.
Branchlets stout. Buds stout, spindle-shaped, pointed, $\frac{3}{4}$ to 1 in. long. Leaves 5 to 6 in. long, stout, rigid; resin-canals marginal; basal sheath 1 in. long.
44. *Pinus Pinea*, Linnæus. Mediterranean region. See p. 1119.
Branchlets slender. Buds ovoid, pointed, $\frac{3}{8}$ in. long. Leaves 4 to 5 in. long; resin-canals marginal; basal sheath $\frac{4}{10}$ in. long.
- ** *Buds resinous; bud-scales free at the apex. Bark of upper part of the stem reddish and peeling off in thin papery scales.*
45. *Pinus sylvestris*, Linnæus. Europe, Asia Minor, Caucasus, Siberia. See Vol. III. p. 571.
Branchlets shining, greenish. Leaves 2 to 3 in. long, glaucous blue, broad and flattened; resin-canals marginal; basal sheath $\frac{1}{3}$ in. long.
46. *Pinus densiflora*, Siebold et Zuccarini. Japan. See p. 1125.
Branchlets glaucous. Buds $\frac{1}{2}$ in. long. Leaves 3 to 4 in. long, dull green; resin-canals marginal; basal sheath $\frac{3}{8}$ in. long, often ending in two long narrow filaments.
- *** *Buds resinous; points of the bud-scales appressed.*
- † *Buds cylindric or spindle-shaped. Leaves $1\frac{1}{2}$ to 3 in. long.*
47. *Pinus montana*, Miller. Mountains of central and southern Europe. See p. 1127.
Branchlets brown. Buds $\frac{1}{4}$ to $\frac{1}{2}$ in. long, very resinous. Leaves persistent 5 to 10 years, $1\frac{1}{2}$ to $2\frac{1}{2}$ in. long; resin-canals marginal; basal sheath $\frac{1}{2}$ to $\frac{6}{10}$ in. long.
48. *Pinus contorta*, Loudon. Western North America. See p. 1134.
Branchlets brown. Buds $\frac{1}{2}$ in. long, very resinous. Leaves persistent 3 to 8 years, twisted, $1\frac{1}{2}$ to 3 in. long; resin canals median; basal sheath $\frac{1}{4}$ in. long.
†† *Buds ovoid. Leaves¹ 3 to 6 in. long.*
49. *Pinus resinosa*, Solander. Eastern Canada; United States, Minnesota to Massachussets. See p. 1140.
Branchlets orange-brown. Buds pale brown, $\frac{1}{2}$ to $\frac{3}{4}$ in. long. Leaves 5 to 6 in. long; resin-canals marginal; basal sheath $\frac{7}{8}$ in. long.
50. *Pinus Thunbergii*, Parlatores. Japan. See p. 1143.
Branchlets brown. Buds $\frac{1}{2}$ to $\frac{3}{4}$ in. long, whitish. Leaves 3 to 4 in. long, rigid, sharp-pointed; resin-canals median; basal sheath $\frac{1}{2}$ in. long, ending above in two long filaments.
51. *Pinus Laricio*, Poiret. Southern Europe, Caucasus, Asia Minor. See Vol. II. p. 407.
Branchlets brown. Buds $\frac{1}{2}$ to 1 in. long, light brown, tinged with white. Leaves 4 to 6 in. long; resin-canals median; basal sheath $\frac{1}{2}$ in. long.
52. *Pinus leucodermis*, Antoine. Bosnia, Herzegovina, Montenegro. See Vol. II. p. 424.
Branchlets glaucous. Buds $\frac{1}{2}$ to 1 in. long, dark brown. Leaves 2 to 3 in. long, rigid, sharp-pointed; resin-canals median; basal sheath $\frac{1}{2}$ in. long.

(A. H.)

¹ They are sometimes only 2 in. long in *P. leucodermis*, No. 52.

PINUS EXCELSA, HIMALAYAN BLUE PINE

Pinus excelsa, Wallich, *List* 6059 (1828), and *Pl. As. Rar.* iii. t. 201 (1832); Loudon, *Arb. et Frut. Brit.* iv. 2285 (1838); Forbes, *Pinet. Woburn.* 75, t. 29 (1839); Masters, *Gard. Chron.* xix. 244, figs. 32, 35 (1883), and *Journ. Linn. Soc. (Bot.)*, xxxv. 581 (1904); Lawson, *Pinet. Brit.* i. 27, t. 4 (1884); Hooker, *Fl. Brit. India*, v. 651 (1888); Kent, *Veitch's Man. Coniferae*, 328 (1900); Gamble, *Man. Indian Timbers*, 704 (1902); Brandis, *Indian Trees*, 689 (1906); Clinton-Baker, *Illust. Conif.* i. 20 (1909).

Pinus nepalensis, De Chambray, *Traité Prat. Arb. Rés. Conif.* 312 (1845).

Pinus pendula, Griffith, *Journals*, 211, 237, 239, 264, 265, 287, 293 (1847).

Pinus Griffithii, McClelland, in Griffith, *Notul.* iv. 17 (1854), and *Icon. Pl. Asiat.* iv. t. 365 (1854).

A tree, attaining in the Himalayas 150 ft. in height and 12 ft. in girth. Branches widely spreading; branchlets upturned at their tips. Bark greyish brown, smooth on young trees, ultimately fissuring into small regular plates. Buds conical, elongated, shortly acuminate; the long subulate points of the scales either free or appressed together with resin. Young branchlets glaucous, smooth, glabrous, turning olive green in winter, and dark grey in the second year.

Leaves in fives, persisting for three years, 5 to 8 in. long, spreading, often bent near the base, as if broken; slender, scarcely curved or twisted, serrulate, sharp-pointed, marked with stomatic lines on the three surfaces; resin-canals marginal; basal sheath $\frac{3}{4}$ in. long, early deciduous.

Cones solitary or two to three together, erect when young, pendulous in the second year on stalks $1\frac{1}{4}$ to 2 in. long; cylindrical, 6 to 10 in. long, light brown when mature. Scales elongated-cuneate, about $1\frac{1}{2}$ in. long, 1 in. broad at the widest part; apophysis longitudinally channelled, convex from side to side, and thickened in the centre, with rounded thin upper margin, and short pointed terminal dark coloured umbo. Seed ovoid, brown, $\frac{1}{4}$ to $\frac{5}{16}$ in. long; wing $\frac{7}{8}$ in. long, $\frac{3}{8}$ in. wide, very oblique on the outer side, light brown, streaked with darker brown wavy lines. Cotyledons 8 to 12.

This species is readily distinguishable from all the other pines with five leaves and a deciduous sheath, by its glabrous glaucous branchlets.

Striped¹ and one-leafed² sports, arising in cultivation, have been described; but appear to be unknown in England.

DISTRIBUTION

This species,³ known as the blue pine in India, is a native of the temperate Himalayas, at 6000 to 12,500 feet elevation, extending westward to Afghanistan and Kafirstan, and eastward to Nepal, but has not been seen in central and north-west Kumaon. It has not been found in Sikkim, but is common in Bhutan.⁴ According to

¹ Var. *zebrina*, Croux, in *Rev. Hort.*, 1889, p. 392, fig. 101. Leaves marked an inch below the apex with a cream-coloured band. Originated at Sceaux in France.

² Var. *monophylla*, Carrière, *Conif.* 398 (1867). Each sheath with apparently only one leaf, all the five leaves being welded together.

³ It was first collected by Buchanan-Hamilton near Narainhetty, in Nepal.

⁴ Hooker and Thomson, *Fl. Indica, Introductory Essay*, 178, 181 (1855), and Griffith, *Journ. Mission Bootan in 1837-1838*, p. 129.

Gamble it either forms pure woods or is mixed with other trees, such as the deodar, being accompanied at high levels by birch and silver fir, and at low elevations by *Pinus longifolia*. On the edges of the forest, scrub lands soon become covered with seedlings, which grow up into dense belts. These seedlings, on account of their rapid growth, soon suppress those of the deodar. Mayr¹ refers to the ease with which this pine naturally regenerates itself in the Himalayas, and gives a picture of the forest with numerous seedlings.

It commonly attains a height of 100 to 120 ft., with a girth of 6 to 10 ft., rarely reaching 150 ft. in height and 12 ft. in girth. On good soils at moderate elevations, it grows rapidly, making five rings per inch of radius; while at high elevations on rocky soil its rate sinks to 20 to 25 rings per inch. It prefers sandy or clayey soils, though occasionally met with on limestone. In India, while easy to rear in the nursery, it bears transplanting badly; and Gamble recommends that it should be grown in baskets, which should be used in planting out.

The timber is good, next in value to that of the deodar, and is largely used in construction throughout the western Himalayas, especially in Kashmir and the Punjab. For railway sleepers it is slightly inferior to the deodar; but for planking, doors, windows, and furniture, it is better than the timber of that tree, as it is not so brittle, and is free from the oil, which in the deodar so readily absorbs dirt. In Kangra and Kulu, it is said to be used for making tea-boxes, as it is free from strong scent.²

The wood is highly resinous, and produces turpentine and tar.² The trees are tapped for about three years, then allowed three years' rest, when tapping is recommenced on the other side. The more resinous parts of the wood are much employed for torches, known as *mashâl* in Hindustani.

In dry winter seasons, the leaves and twigs become covered with a copious sweet exudation, which is collected and eaten by the natives. The origin of this manna-like substance is not yet accurately determined.³ (A. H.)

CULTIVATION

P. excelsa was introduced into cultivation⁴ by Lambert, who raised many plants in 1823 at Boyton. Plants were also reared in the Chiswick Garden and in the Glasgow Botanic Garden in 1827 from seeds sent by Wallich.

It is perfectly hardy in all parts of Great Britain, Mr. Palmer's tables showing only five places out of ninety-five in which it was killed by the severe winter of 1860, and in three of these the thermometer fell below zero. Two-year seedlings raised at Colesborne from Himalayan seed were uninjured in my garden in 1908 by a temperature of about zero. But judging from its comparative rarity, and the smaller size of the trees we have seen in the north of England and in Scotland, it requires the full summer heat of our climate to do it justice, nearly all the largest specimens I

¹ *Fremdländ. Wald- u. Parkbäume*, 375, fig. 122 (1906).

² Cf. Watt, *Commercial Products of India*, 888 (1908), who refers to Thurston, *Resin and Turpentine from Indian Pines*, *Imp. Inst. Handbook*, 1893, pp. 7-19; Lawrence, *Valley of Kashmir*, 80 (1895); etc.

³ Cf. Madden, in *Journ. Agri-Hort. Soc. India*, reproduced in *Indian Forester*, i. 55 (1875).

⁴ *Genus Pinus*, ii. 6 (1824).

have seen being in the south and east, not attaining such large dimensions where the winters are very mild. It seems comparatively indifferent to soil, growing best on a good deep loam, and is one of the pines which may be planted on limestone successfully.

As a rule it seems to have a tendency to fork low down, and often develops into large spreading bushy trees with several leaders, and the lower branches resting on the ground. Its growth when young is rapid, but seems to fall off very much after forty or fifty years. It is liable to be injured by wind, and requires a sheltered situation, with full sun. I am not aware that it has anywhere been tried under forest conditions, and it has no special qualities that will justify its being looked on as other than an ornamental tree. It produces seed freely, which sheds early, and in favourable situations reproduces itself naturally.

REMARKABLE TREES

The best specimen as regards height and symmetry that I have seen is at Hewell Grange, near Bewdley, the seat of the Earl of Plymouth, which in 1909 measured 93 ft. by 8 ft. 4 in. There are two fine trees growing on low ground near the lake at Eastnor Castle, with tall oaks and elms near them. Mr. Mullins, the gardener, measured these in 1909, by sending a man up the stems to near the top, and found them to be 90 ft. by 7 ft. 11 in., and 80 ft. by 8½ ft.

A tree at the Hendre, Monmouthshire, is said by Sir H. Maxwell¹ to be 90 ft. high. A well-shaped tree near the mansion at Claremont was 81 ft. by 8 ft. in 1907. A tree at Nuneham Park was 74 ft. by 8 ft. 7 in. in 1907. A large tree forking close to the ground, where some of the branches have layered, about 60 ft. by 8 ft., is growing at Goodwood. At Ampney Crucis, near Cirencester, on the lawn of the house occupied by Mrs. Elwes, a tall slender tree was about 68 ft. by 4 ft. in 1909. At Highnam, Gloucester, a tree measured in 1906, 63 ft. by 8 ft. 5 in. At Wilton House, near Salisbury, a tree was 77 ft. by 8 ft. 3 in. in 1906.

At Merton, Norfolk, there is a tall tree, dividing near the base into four stems which reach a height of 86 ft. This was raised from seed in 1861. At Munden, Watford, a fine tree is 75 ft. high, girthing 9 ft. at two feet from the ground, and dividing above into two stems. There is a very remarkable specimen at The Frythe, Welwyn, which was planted in 1846. It is 60 ft. high and 7 ft. in girth, with extremely wide spreading branches, many layering and sending up erect stems. The total circumference of the branches was 246 ft. in 1906. Mr. H. Clinton-Baker measured a tree at High Canons, Herts, 75 ft. by 7 ft. in 1908.

Another is that at Barton, near Bury St. Edmunds, which measured in 1904, 87 ft. by 9 ft. 5 in. It was raised² from seed given to Lady Napier by Wallich, and was planted out in 1843. It bore the severe winter of 1860-1861 without injury. There is a large tree at Casewick, Stamford, from which Lord Kesteven

¹ Green, *Encycl. Agr.* iii. 280 (1908).

² Bunbury, *Arboretum Notes*, 131 (1889).

has raised numerous seedlings. At Wimpole, near Cambridge, a well-shaped tree measured 63 ft. by 7 ft. 3 in. in 1909.

In Wales the largest I have seen is an ill-grown tree, at Maesllwch Castle, forking at the ground, where it was 10 ft. 10 in. in girth in 1906.

In Scotland the finest tree¹ is probably one at Smeaton-Hepburn, planted in 1839, which was 76 ft. high in 1902, with a trunk 12 ft. in girth at two feet from the ground, dividing above into three stems. At Keir, Perthshire, a fine tree measured 67 ft. by 6 ft. 3 in. in 1903. At Galloway House, Wigtownshire, there is a healthy tree, about 40 ft. in height.

In Ireland, there is a fine wide-spreading tree at Kilruddery, near Bray, which in 1904 measured 65 ft. by 9 ft. 4 in. There are also good specimens at Castle-martyr. At Brockley Park, Queen's County, a tree, dividing into several stems near the base, was 64 ft. high in 1907. At Emo Park, Portarlinton, another measured, in the same year, 66 ft. by 6 ft. 9 in.

Sargent² says that in New England it is hardy though short-lived; but there are large, healthy cone-bearing trees in Central Park, New York, and near many cities of the middle states. (H. J. E.)

PINUS PEUKE, MACEDONIAN PINE

Pinus Peuke, Grisebach, *Spicileg. Flor. Rumel.* ii. 349 (1844); Christ, in *Flora*, xlviii. 257, t. 2 (1865); Boissier, *Flora Orientalis*, v. 698 (1884); Masters, in *Gard. Chron.* xix. 244, figs. 33, 34 (1883), and in *Journ. Linn. Soc. (Bot.)*, xxii. 205, figs. 30, 31 (1887), and xxxv. 581 (1904); Kent, Veitch's *Man. Conif.* 357 (1900); Beck von Mannagetta, *Vegetationsverhält. Illyrischen Ländern*, 363-365 (1901); Clinton-Baker, *Illust. Conif.* i. 42 (1909).

Pinus excelsa, J. D. Hooker, *Journ. Linn. Soc. (Bot.)*, viii. 145 (1864) (not Wallich).

Pinus excelsa, Wallich, var. *Peuce*, Beissner, *Nadelholzkunde*, 286 (1891).

A tree, attaining in Bulgaria 100 ft. in height and 7 ft. in girth, narrowly pyramidal in habit. Bark similar to that of *P. excelsa*. Buds ovoid, shortly acuminate, about $\frac{3}{8}$ in. long, brown, resinous; scales with long subulate free points. Young branchlets smooth, glabrous, shining green, becoming brownish grey in the second year.

Leaves in fives, persistent two or three years, about 4 inches long, directed forwards and slightly outwards, not widely spreading or bent as in *P. excelsa*, slender, straight, not twisted, serrulate, sharp-pointed, marked with stomatic lines on all three surfaces; resin-canals marginal; basal sheath $\frac{3}{4}$ in. long, early deciduous.

Cones on short (less than $\frac{1}{2}$ in.) stalks, subterminal, spreading or pendulous, green before ripening, brown when mature, cylindric, tapering to a blunt apex, 4 to 6 in. long, $1\frac{1}{2}$ to 2 in. in diameter. Scales broadly cuneate, thin, $1\frac{1}{4}$ to $1\frac{1}{2}$ in. long, $\frac{3}{4}$ in. broad; apophysis slightly rounded or almost straight in the thin bevelled upper margin, raised in the centre and marked exteriorly with longitudinal channels, convex from side to side, ending in a small dark-coloured depressed umbo. Seed

¹ Cf. *Hist. Berwickshire Nat. Club*, xviii. 211 (1904).

² *Garden and Forest*, x. 461 (1897).

similar to that of *P. excelsa*, but with a shorter broader wing, which has finer, closer, and straighter longitudinal veins.

Specimens from the Balkans, with shorter thinner leaves than those first described from Mt. Peristeri, were distinguished by Dr. Christ as var. *vermiculata*¹; but such trivial and inconstant differences scarcely deserve a varietal name.

This species is closely allied to *P. excelsa*, but differs remarkably in the narrow pyramidal habit seen both in cultivation and in Bulgaria, where, as Velenovsky states, natural woods look exactly like plantations of Weymouth pine. It has shorter stiffer leaves, more or less appressed to the branchlets, and not spreading or bent as in *P. excelsa*. The green glabrous branchlets distinguish *P. Peuke* from all other species of the *Strobos* and *Cembra* sections.

DISTRIBUTION

This pine has a limited distribution, being confined to three small areas, in Bulgaria, Macedonia, and Montenegro. The largest of these is on the confines of Bulgaria and Macedonia, where the tree is known as *Mura*, and occurs on the Rilo Mountains, on the Mussala Mountain in the Rhodope range, and in the Perim range in Macedonia. Here it forms woods of considerable extent, which extend low down into the valleys, where it is mixed with *Pinus sylvestris*, and ascend up to the alpine zone, where it is associated with *Pinus montana*, var. *mughus*. According to Velenovsky,² trees 100 years old are growing on the Rilo and Mussala Mountains, which are 100 ft. in height and 5 to 7 ft. in girth. There are specimens in the Kew herbarium, which were collected on the Rilo Mountains in June 1899 by Elwes.

The second area of distribution is confined to Mt. Peristeri, above Monastir (lat. 41°, long. 21°), where the species was first discovered in 1839 by Grisebach. The small forest on this mountain, situated on granite soil between 2400 and 5800 ft. altitude, consisted of pines growing rather scattered amongst a dense undergrowth of juniper, and of no great size, scarcely exceeding 40 ft. in height at the lower levels, and becoming mere bushes, 4 ft. in height, at the higher elevations. Orphanides rediscovered the tree on Mt. Peristeri in 1863, and records it as growing between 3000 and 6000 ft. altitude. Halacsy³ is of opinion that its occurrence on the mountains of northern Thessaly is probable, but as yet uncertain.

The third locality is in Montenegro, close to the Albanian frontier, where the tree is known as *Molika*, and occupies a narrow strip of territory, about 22 miles in length, extending from west to east through the mountains, in which the river Lim takes its origin. It is recorded from the high ridge between the valleys of the Perućica and Vermoša rivers in the Kom Mountains, and on the Zeletin, Zjekirica, and Šekular Mountains. According to Beck, the tree is not found on the north Albanian Alps, as these are composed of limestone, on which it never grows in the wild state. In Montenegro it is not much affected by the great differences in climate throughout its extensive range of elevation, 2600 to 6300 ft., in which three species of juniper are found, each confined to a distinct zone of altitude. It assumes a bushy

¹ *Ex* Beissner, *Nadelholzkunde*, 286 (1891).

² *Flora Bulgarica*, 518 (1891), and *ibid.*, *Suppl.* i. 333 (1898).

³ *Consp. Flora Græca*, iii. 451 (1904).

habit both at the lower levels and on the highest parts of the mountains, and never forms pure woods, growing scattered amidst other trees, and only attaining 30 to 45 ft. in height.

CULTIVATION

This species was introduced by Orphanides, who gathered ripe seeds on Mt. Peristeri in 1863, which were distributed by Messrs. Haage and Schmidt¹ of Erfurt.

Through the kind offices of Pierce O'Mahony, Esq., I received a large quantity of seed from King Ferdinand of Bulgaria in April 1908. This has been widely distributed to different friends throughout England, Ireland, and Scotland. Most of it was tardy in germination, and the seed came up irregularly, some not germinating until 1909.²

The finest tree known to us in England is one at Bicton, which, when measured by Elwes in 1906, was 42 ft. high by 3 ft. 8 in. in girth, and was bearing cones. There is also a good one at Grayswood, 36 ft. by 3½ ft., planted in 1881; and one at The Heath, Leighton Buzzard, 37 ft. by 2 ft. 10 in., both measured by Mr. A. B. Jackson in 1908.

A group of healthy trees are growing in Kew gardens, near the Isleworth Ferry gate, which were raised from seed of the original importation sown in 1864. These trees have a thriving appearance, and the largest one measured, in 1909, 42½ ft. by 3 ft. 10 in.

At Westonbirt there are several trees 30 to 35 ft. in height and a foot in diameter, growing beside a tree of *P. monticola*, about 50 ft. high and 15 in. in diameter, which was planted at the same time.

There are two trees at Galloway House, Wigtownshire, the larger of which measured, in 1908, 48 ft. by 4 ft. 9 in.; and a smaller tree is growing at Ochtertyre, Perthshire.

According to Mayr, *P. Peuke* is as fast in growth and as hardy in Germany as the Weymouth pine. It has withstood without injury the severe temperature of -22° Fahr. at Grafrath, near Munich, and for so far has not been attacked by *Agaricus melleus*. It may possibly also be immune to the pine blister (*Peridermium Strobi*), which is so destructive to the Weymouth pine in many places on the continent. For these reasons Mayr is inclined to recommend the immediate planting in Germany of *P. Peuke* in place of the Weymouth pine.

Elwes saw in the nursery of Regel and Kesselring at St. Petersburg in 1908 young trees of *P. Peuke* which on damp and sandy soil had attained 12 ft. high in twelve years, and had resisted 30 degrees centigrade of frost without injury. It seems, therefore, likely to become a valuable forest tree in central Europe.

In New England this species³ is quite hardy in the Arnold Arboretum, where, however, Sargent says that it is a slow-growing tree of no especial ornamental value.

¹ A letter of Haage and Schmidt to Lindley concerning the first seed of this pine, and dated 11th January 1864, is preserved in the Cambridge Herbarium.

² Mr. Storie reports from Highclere that about 300 plants came up in April 1909.

³ *Garden and Forest*, x. 461 (1897).

PINUS AYACAHUITE, MEXICAN WHITE PINE

Pinus Ayacahuite,¹ Ehrenberg, ex Schlechtendal, in *Linnaea*, xii. 492 (1838); Loudon, *Encycl. Trees*, 1023 (1842); Masters, in *Gard. Chron.* xviii. 492, f. 83 (1882), in Lawson, *Pinetum Brit.* i. 9, t. 2 (1884), and in *Journ. Linn. Soc. (Bot.)* xxxv. 579 (1904); Kent, Veitch's *Man. Conif.* 311 (1900); Clinton-Baker, *Illust. Conif.* i. 8 (1909); Shaw, *Pines of Mexico*, 9, t. iv. (1909).

A tree attaining in Mexico 100 ft. or more in height and 12 ft. in girth, and in cultivation resembling *P. excelsa* in habit. Bark rough and scaly on old trees. Buds reddish brown, resinous, ovoid, acuminate, about ½ in. long; scales with long acuminate tips, usually free and directed upwards. Young branchlets covered with a short brown pubescence, occasionally confined to the parts below the insertions of the leaves; older branchlets glabrescent, and bright brown or greyish in colour.

Leaves in fives, spreading, usually persistent for three years, very slender or filiform, 4 to 8 in. long, serrulate, sharp-pointed, straight, scarcely twisted; outer surface green, with two or three short stomatic lines near the top; inner flat surfaces, each with three or four continuous white stomatic lines; resin-canals marginal; basal sheath ¾ in. long, early deciduous.

Cones sub-terminal, pendent, solitary, or in pairs, on stalks about ½ in. long, ovoid-cylindrical, often curved, gradually narrowing towards the obtuse apex, 8 to 18 in. long, 2½ to 6 in. wide towards the base, pale brown and resinous when mature. Scales about 2 or 3 in. long, and 1 to 1½ in. wide; apophysis rhomboidal or triangular, reflexed, ending in a swollen, rounded, inflexed or reflexed resinous tip. Seed ovoid, compressed, ⅜ in. long, brownish, mottled with dark streaks or spots; wing oblong, narrow, oblique, about ¾ in. long, pale brown, with longitudinal darker streaks.

This species so closely resembles *P. excelsa* in habit and foliage that possibly some of the trees passing under the latter name in cultivation may belong to it, but it is readily distinguished by the more slender leaves and the pubescent branchlets, which have in cultivated trees a reddish brown colour. It is quite distinct in cones and seeds.

VARIETIES

This pine varies extremely in the size and shape of the cones, seeds, and seed-wings, and according to Shaw, comprises three distinct geographical races, which are however connected by numerous intermediate forms:—

1. Typical form, described above. Seed with a long narrow wing. Prevalent in Guatemala and the southern states of Mexico.

2. Var. *Veitchii*, Shaw, *Pines of Mexico*, 10, t. v. (1909).

Pinus Veitchii, Roehl,² *Cat. Gr. Conif. Mex.* 32 (1857).

Pinus Bonapartei, Roehl, in *Gard. Chron.* 1858, p. 358; Clinton-Baker, *Illust. Conif.* i. 12 (1909).

Pinus Loudoniana, Gordon, *Pinetum*, 230 (1858).

¹ Roehl's *P. durangensis* is probably typical *P. Ayacahuite*.

² *P. Don Pedri*, *P. hamata*, and *P. Popocatepetli*, names given to certain cones by Roehl, belong to this variety.

Cones larger, as a rule, than in the type. Seed larger, $\frac{1}{2}$ in. long, ovoid, compressed, dark brown or blackish; wing short and broad, about $\frac{1}{2}$ in. long and wide, dark brown in colour. Prevalent in the central states of Mexico.¹

3. Var. *brachyptera*, Shaw, *Pines of Mexico*, 11, t. vi. (1909).

Pinus strobiformis, Engelm., in Wislizenus, *Tour N. Mexico*, 102 (1848).

Differs from the type, according to Shaw, in the larger seeds, with extremely short wings. Occurs in the states of Durango and Chihuahua, in northern Mexico.

DISTRIBUTION

This pine, according to Shaw, is a native of cool temperate altitudes in Central America, and extends from Guatemala throughout Mexico to the borders of the United States.

The typical form of the species was discovered² by Ehrenberg in 1836 in Mexico, who found trees 100 feet high at Omitlan, near Hacienda de Guerrero, and appears to be common in Oaxaca, particularly on the higher points of the Cumbre Mountains and on Mount Pelado. Hartweg found it in Guatemala, where he observed dead trees on the volcano Xetul, near Quezaltenango, at 10,000 ft. elevation.

Var. *Veitchii* was discovered³ by Roehl on the Sierra Madre range at 8600 ft. and at Tenango, and also on the eastern side of Mt. Popocatepetl at 11,000 to 12,000 ft., where it grows abundantly on the borders of deep ravines, never descending into the depths of the gorges, or ascending much above them. Here the winters are dry, the temperature descending to 10° to 14° Fahr., but the summers are long and warm. It is known to the Mexicans as *Ayacahuite colorado*, or red pine, on account of the excellence of its timber.

Var. *brachyptera* was discovered on the mountains of Cosihuiriac in the province of Chihuahua, at about 8000 ft. elevation, where, according to Engelm., it is a large tree, 100 to 130 ft. in height, with short leaves $2\frac{1}{2}$ to 3 inches long, and very resinous cones about 10 in. in length. This northern form does not appear to have been introduced into cultivation. (A. H.)

CULTIVATION

The typical form of the species was introduced into the Chiswick garden of the Horticultural Society by Hartweg in 1840, and seeds were again sent to this country by Roehl in 1857. It is comparatively rare in cultivation, and appears to succeed best in the south-west and west of England, Palmer's frost tables⁴ showing that it was killed in 1860 at Thorpe Perrow in Yorkshire, and at Highnam Court in Gloucestershire.

At Westonbirt a tree, which produces cones freely, from the seed of which numerous seedlings have been raised at Kew and Glasnevin, measured in 1909, 62 ft.

¹ Engelm., in *Trans. St. Louis Acad. Sci.* iv. 178 (1886), considered this variety to be a distinct species (*P. Bonaparteana*), with stout leaves, showing on section seven resin-canals; while *P. Ayacahuite* has more slender leaves with only two resin-canals. The number of resin-canals, however, is variable, two to eight being found by Shaw in wild specimens; and this character alone cannot be relied on for the discrimination of the type and var. *Veitchii*.

² Cf. Loudon, *Gard. Mag.* xv. 129 (1839).

³ Cf. *Gard. Chron.* xxi. 769 (1884).

⁴ Masters, in Lawson, *Pinetum Brit.* loc. cit.

by 6 ft. 8 in. It is pyramidal in habit, with slightly ascending branches. I have raised seedlings from this tree which appeared to me to be hardy, as they endured very severe frosts in early autumn and late spring. Planted, however, on rather heavy soil in a low situation, they succumbed to a frost certainly below zero in the winter of 1908-1909. The tree seems to endure lime in the soil without injury, and may be planted in a dry sunny position in most parts of England.

Another large tree is growing at Beauport, Sussex, and was 55 ft. high and 8 ft. in girth in 1904. At a distance this tree is indistinguishable from *P. excelsa*, having the wide-spreading branches and upturned branchlets which are usual in that species. It bears cones freely, but had increased little in size when seen in 1909.

There is a fine specimen at Bicton, which Mr. H. Clinton-Baker measured in 1908 as 65 ft. by 7 ft. 8 in. At Batsford Park, Gloucestershire, the seat of Lord Redesdale, there are two trees, the larger measuring 42 ft. by 3 ft. The other, more dense in habit and with less spreading branches, is scarcely so tall, and is 2 ft. 10 in. in girth. In Shroner wood, near Winchester, at 450 feet elevation, there is a narrow pyramidal tree, 51 ft. by 3 ft. 8 in., which was bearing ripe cones in February 1910. Mr. E. L. Hillier, who has sent us specimens, stated that this tree was planted in 1889, and is making very rapid growth.

Another in Messrs. Paul and Son's nursery at High Beech, Essex, which was planted probably in 1850-55, is only 30 ft. by 2 ft. 8 in. It survived the severe winter of 1860, which killed a deodar standing beside it; but subsequent hard winters have much damaged the stem on the north side. It bore cones¹ 9 in. long in 1882, and in subsequent years up to 1903, but the seeds proved unfertile when sown.

At Grayswood, Haslemere, trees of this species, growing on light sandy soil, succumbed to the attack of a fungus which affects Weymouth pine in that neighbourhood.

Var. *Veitchii* was introduced in 1857 by Roehl, who gave it many specific names. It is extremely rare in cultivation in England, where, however, it thrives in the mild humid climate of the west and south-west. The largest tree² known to us is growing at Heligan, near St. Austell, Cornwall, in the grounds of John Tremayne, Esq., who informed us in 1906 that it was then 60 ft. in height and 8 ft. 6 in. in girth. It measured in 1909, 66 ft. by 9 ft. 8 in. at 3 ft. above the ground, dividing above into several main stems. Another tree,³ cones of which are preserved in the museum at Kew, is growing at Ballamoar, in the Isle of Man. According to Dr. Tellet, of Ramsey, who sent a specimen branch, it was about 40 ft. high and 4 ft. 8 in. in girth in 1906. At Eastnor Castle a thriving specimen, about 35 feet high, produced cones with apparently fertile seeds in 1908; and the gardener, Mr. Mullins, believes that it was planted about twenty-five years ago. (H. J. E.)

¹ Figured in *Gard. Chron.* xviii. 492, fig. 83 (1882).

² Described and figured as *P. Ayacahuite* in *Gard. Chron.* xx. 748, figs. 131, 132 (1896), when it was said to be 49 ft. high and 7 ft. in girth.

³ Cf. *Gard. Chron.* vi. 599 (1889), and *Garden*, xxxii. 47 (1887). Dr. Tellet's letter was kindly forwarded to me by the owner, Mrs. Farrant. The soil is sandy—glacial drift containing clay. The tree is supposed to have been planted between 1857 and 1860.

PINUS LAMBERTIANA, SUGAR PINE

Pinus Lambertiana, Douglas, in *Trans. Linn. Soc.* xv. 500 (1827); Loudon, *Arb. et Frut. Brit.* iv. 2288 (1838); Lawson, *Pinet. Brit.* i. 47, t. 7 (1884); Masters, in *Gard. Chron.* i. 772, f. 144 (1887), and in *Journ. Linn. Soc. (Bot.)* xxxv. 578 (1904); Sargent, *Silva N. Amer.* xi. 27, tt. 542, 543 (1897), and *Trees N. Amer.* 5 (1905); Kent, Veitch's *Man. Coniferae*, 336 (1900); Clinton-Baker, *Illust. Conif.* i. 29 (1909); Shaw, *Pines of Mexico*, 12 (1909).

A tree, attaining in America¹ about 250 ft. in height, and 40 ft. in girth. Bark of young stems and branches smooth, thin, dark green; becoming on old trunks 2 or 3 in. thick and deeply divided into long irregular scaly ridges. Buds cylindrical, rounded at the apex or short-pointed, $\frac{1}{4}$ in. long, brownish, resinous, with closely, partly glandular appressed scales. Young branchlets smooth, covered with a minute brown, partly glandular pubescence.

Leaves in fives, deciduous in the second and third year, $3\frac{1}{2}$ to 4 in. long, rigid, sharp-pointed, twisted, making a complete turn, serrulate, with two or three stomatic lines on each of the three surfaces; resin-canals marginal; basal sheath $\frac{3}{4}$ in. long, early deciduous.

Cones sub-terminal, cylindrical, 11 to 21 in. long, 3 to 4 in. in diameter when closed; scales woody, 2 to $2\frac{1}{2}$ in. long, $1\frac{1}{2}$ to $1\frac{3}{4}$ in. wide, thickened towards the middle line, thin in margin, flat or slightly convex from side to side; apophysis smooth, orange-brown, slightly reflexed at the apex, which is marked with a small thickened resinous umbo. Seed $\frac{1}{2}$ in. or more in length, ovoid, compressed, dark-brown or nearly black; wing 1 to 2 in. long, $\frac{1}{2}$ in. broad, dark-brown, oblique and broadest below the middle. Cotyledons twelve to fifteen.

This species is very variable in the size of the cones, and of the seeds, which often have very long wings.² It is readily distinguished from all the other pines of the *Strobus* section by the rigid leaves, which are sharp-pointed and twisted, the twist making a complete turn.

DISTRIBUTION

The sugar pine is the largest species of the genus, and derives its name from the sugar³ which exudes from wounds that have been made in the heartwood. It is found in Oregon, from the valley of the Santiam river southward along the Cascade and Coast ranges, at elevations of 3000 to 4000 ft.; and extends in California through the Siskiyou and Coast mountains to Napa county,⁴ and along the western side of

¹ Dr. W. P. Gibbons, in *Erythea*, i. 161 (1893), says that he has seen a sugar pine 12 ft. in diameter, the height of which was 300 ft.; and another 8 ft. thick, the measurement of which when felled was something over 300 ft.

² Sargent, *Trees N. Amer.* 5 (1905), says that the seeds are $1\frac{1}{2}$ to 5 in. long, but this is evidently a misprint for $1\frac{1}{4}$ to 2 in.

³ This sugar exudation is often found on the surface of the heartwood where a forest fire has scarred the tree. It is white in colour and delicious to the taste, but can only be eaten in small quantity as it is laxative, and bears are said never to touch it. Cf. Muir, in *Harper's Magazine*, xxii. 717.

⁴ Jepson, *Flora W. Mid. California*, 20 (1901), says that it forms considerable forests in the high Coast ranges north of Clear Lake, where there are magnificent specimens, 150 to 175 ft. high and 22 ft. in girth. The record in Sonoma County, given in *Erythea*, iv. 152, needs confirmation. Jepson reports it in the Santa Lucia mountains.

the Sierra Nevada at least 200 miles farther south, where it attains its maximum size at 3000 to 7000 ft. high. It also grows in the southern part of the state in the San Bernardino and Cuyamaca mountains; and was discovered by Brandegee¹ on Mount San Pedro Martir in Lower California. It is seldom found growing pure, occurring usually in open woods in company with *P. ponderosa*, and is most common on mountain slopes and on the sides of ravines and cañons. Douglas fir, *Libocedrus*, *Sequoia gigantea*, and *Abies Lowiana* are also often associated with the sugar pine.

This pine is remarkable in its appearance in the forests on account of the long outward and downward sweep of the branches, the first of which often arise at 100 ft. above the ground. Sir Joseph Hooker, who gives a picture of a tree growing near the hotel at Calaveras, not far from the Wellingtonia grove, says² that the drooping attitude of the leaves towards the under side of the branches near their tips is very characteristic. The largest tree recorded seems to have been one near the Umpqua river in Oregon found by Douglas,³ which was 245 ft. in length, as it lay on the ground, girthing at 3 ft. from the ground 57 ft. 9 in. and at 134 ft. up no less than 17 ft. 5 in. Mr. F. R. S. Balfour photographed a fine tree, 27 ft. in girth at 5 ft. from the ground, which was growing near the bend on the M'Cloud river in Shasta County, California. (Plate 271.) Like all travellers, he was much impressed by the size and number of the cones which hung from the ends of the tapering branches. He says that the tree matures at 300 to 400 years old, though trees have been felled with as many as 700 rings. (A. H.)

CULTIVATION

This noble pine was discovered⁴ by Douglas in 1825 on the headwaters of the Multnomah river in Oregon; and was introduced by him in 1827, when plants were raised in the garden of the Horticultural Society at Chiswick, most of which, however, according to Loudon, died before they had attained 5 ft. in height. Lobb⁵ collected a further supply of seed in 1851.

Though rather slow in growth, this pine appears to be hardy, and is represented by single specimens in a few collections, more especially in the south of England.

A tree at Dropmore raised from seed given to Lady Grenville by the Duke of Buccleuch in 1843, bore cones for the first time⁶ in 1872; and occasionally in subsequent years, thrice in the last eight years. Mr. Page measured it in 1908 as 85 ft. by 10 ft., and says that occasionally the cones are as much as 18 in. in length. There are two younger trees at Dropmore which have not as yet borne cones.

A fine tree at Arley Castle, also raised from the seed sent by Douglas, measured⁶ 91 ft. by 10 ft. 8 in. in 1903; and so far as Mr. Woodward can ascertain has never borne cones. There is a well-shaped tree at Eastnor Castle (Plate 272), which occasionally bears cones, 83 ft. by 10 ft. in 1909.

¹ Cf. *Zoe*, iv. 201 (1893).

² In *Gard. Chron.* xxiii. 11, fig. 1 (1885).

³ *Comp. Bot. Mag.* ii. 92, 130 (1836).

⁴ *Hortus Veitchii*, 39 (1906). According to Loudon, *Gard. Mag.* xvii. 429 (1841), Dr. M'Laughlin sent home a parcel of cones in 1841 from Fort Vancouver, on the Columbia river; but it is unknown whether any trees were raised from these.

⁵ *Gard. Chron.* 1872, p. 1166.

⁶ *Hortus Arleyensis*, 14 (1907).

A splendid tree at Danesbury, near Welwyn, Herts, measured 90 ft. by 10 ft. 4 in. in 1907, and produced cones for the first time in 1897. There are several other good specimens in the same county; two trees at Brickendon Grange, the larger of which was 49 ft. by 4 ft. 10 in. in 1906, when it bore cones; another at Bayfordbury which measured 64 ft. by 7 ft. 3 in. in 1905, and has borne cones of late years.

At Nuneham Park, Oxford, a fine tree measured 75 ft. high and 10 ft. 9 in. in girth in 1906. Mr. H. Clinton-Baker in 1907 saw a tree at Flitwick Manor, Bedford, 72 ft. by 7 ft. 6 in., which was bearing numerous young cones.

Sir Hugh Beevor reports a tree at Fulmodestone, Norfolk, said to have been planted about 1851, which was 60 ft. by 6 ft. 5 in. in 1903. A tree¹ at Barton, Suffolk, measured 65 ft. by 10 ft. in 1905.

The best specimen in Kew Gardens measured 63 ft. by 4 ft. 7 in. in 1903.

A fine tree, measuring 74 ft. by 7½ ft. in 1908 when it produced cones, grows in the grounds of Bowood Park, Wilts, the seat of the Marquess of Lansdowne. It is said to have been planted about the year 1838.

The following were the only trees of the species mentioned in the reports² sent to the Conifer Conference in 1891:—Revesby Abbey, Lincolnshire, forty-three years old, 50 ft. high, 6 ft. 8 in. in girth; Poltalloch, Argyllshire, 45 ft. high, 9 ft. in girth, said to be growing vigorously.

Murray reported³ in 1860 that a fine tree, now no longer living, in the Keillour Pinetum, had produced cones for several years past. This is remarkable, if true, as this species, rare in Scotland, appears to bear fruit only in the south of England.

In Ireland it is not common, the best I know of being a tree at Woodstock, which in 1909 was 62 ft. by 6 ft.

A tree in the Wellesley Pinetum,⁴ Massachusetts, U.S.A., was 27 ft. high in 1905; but Sargent says that although hardy as far north as Boston, it is not worth growing in New England except as a curiosity. (H. J. E.)

PINUS MONTICOLA, WESTERN WHITE PINE

Pinus monticola, Don, in Lambert, *Genus Pinus*, ii. t. 81 (1832), and iii. t. 87 (1837); Loudon, *Arb. et Frut. Brit.* iv. 2291 (1838); Sargent, *Silva N. Amer.* xi. 23, tt. 540, 541 (1897), and *Trees N. Amer.* 5 (1905); Kent, Veitch's *Man. Coniferae*, 349 (1900); Masters, *Journ. Linn. Soc. (Bot.)* xxxv. 580 (1904); Clinton-Baker, *Illust. Conif.* i. 36 (1909).

Pinus Strobus, Linnæus, var. *monticola*, Nuttall, *Sylva*, iii. 118 (1849).

Pinus porphyrocarpa, Murray, in Lawson, *Pinetum Brit.* i. 83, ff. 1-8 (1884).

Pinus Grozelieri, Carrière in *Rev. Hort.* 1869, p. 126, f. 31.

A tree, usually attaining in America 100 ft. in height and 15 ft. in girth, rarely as high as 150 ft., with a trunk 25 ft. in girth. Bark of young stems and branches thin, smooth, and light grey, becoming on old trees 1½ in. in thickness and divided

¹ There is no record of this tree in Bunbury, *Arboretum Notes*.

² *Journ. Roy. Hort. Soc.* xiv. 492, 503 (1892). A tree at Keir, Perthshire, incorrectly reported (*ibid.* 531) to be *P. Lambertiana*, turns out to be *P. Strobus*.

³ In *Trans. Bot. Soc. Edin.* vi. 370 (1860).

⁴ Sargent, *Pin. Wellesley*, 10 (1905).

by fissures into small square scaly plates. Buds, as in *P. Strobus*, but larger. Branchlets, covered with short, brown, partly glandular¹ pubescence, retained in part in the second year.

Leaves, in fives, slightly spreading, dense upon the branchlets, persistent for three or four years, about 4 in. long, often only 2 to 3 in. long in native specimens, rigid, broader and thicker than in *P. Strobus*, serrulate, narrowed but blunt at the apex, with several stomatic lines on the inner surfaces, and two to three broken lines of stomata on the outer surface near the tip; resin-canals marginal; basal sheath about ¾ in. long, early deciduous.

Cones spreading, on short stout incurved stalks, cylindrical; very variable in length in wild specimens, averaging 5 to 8 in., occasionally 12 and rarely 18 in.; in cultivated specimens usually about 5 in. Scales thin, oblong-cuneate, averaging 1½ in. long and ¾ in. broad; apophysis rounded and thin in upper margin, slightly convex from side to side, and tipped with a small dark-coloured resinous umbo. Seed narrowed at the end, ½ in. long, reddish brown, mottled with black; wing about 1 in. long, narrow, pointed, dark brown. Cotyledons 6 to 9.

The cones are usually green in colour before ripening, but a tree at Glenalmond in Scotland produced purple cones and has been named var. *porphyrocarpa*, (A. H.) Masters.²

DISTRIBUTION

This tree represents *P. Strobus* in the Pacific coast region of North America, where it occurs in the north in Vancouver Island, in the Columbia river valley, and on the Selkirk range in British Columbia; and extends southwards to Idaho, where it attains its maximum size in the Bitter Root Mountains, and to the western slopes of the Rocky Mountains in northern Montana; and is found throughout the coast ranges of Washington and Oregon, and on the Cascade and Sierra Nevada ranges as far as the Kern river valley in California. It descends³ to sea-level in Vancouver Island, ascends in the Selkirks to 2500 ft., and reaches 10,000 ft. altitude in the Californian Sierras, where trees with enormous stems and short twisted branches withstand for centuries the fiercest mountain gales.⁴

It does not often grow as pure forest, but wherever I have seen it, is mixed with other conifers, and most abundant in regions where there is a heavy rainfall, though usually not a large tree in comparison with others in the same region, and commonly about 100 ft. high. Sargent gives 150 as its extreme height, and Sheldon says 100 to 200 ft. I measured at 1650 ft. elevation near Camp 6 of the Victoria Lumber Company at Chemainus in Vancouver Island, a tree which was at least 200 ft. high by 13½ ft. in girth, with a stem clear of branches to 80 or 90 ft. It is not abundant

¹ Some of the hairs are tipped with a globose gland.

² In *Journ. R. Hort. Soc.* xiv. 235 (1892). This is *P. porphyrocarpa*, Murray, in Lawson, *Pin. Brit.* i. 83 (1884).

³ Throughout the greater part of its range, it occurs at considerable altitudes, and though in south-western Vancouver Island it grows sparingly through the coast forest, it is more abundant at 500 ft. where the fogs are less and the summer days are warmer. Close to the sea, trees are usually somewhat stunted. Cf. Butters, in *Postelsia, Year Book of the Minnesota Seaside Station*, 1906, p. 160.

⁴ *Garden and Forest*, x. 460 (1897). In this journal, v. 1, figs. 1 and 2 (1892), there are two excellent illustrations of trees of great age, growing in an exposed situation in the Yosemite valley.

here, and though occasionally cut up in the sawmills, does not form an important item in the timber resources of British Columbia.

According to Macoun and Anderson¹ the wood is used for the same purposes as eastern white pine. It is useful for window-sashes, doors, powder barrels, and similar work, but being a white and very light wood it is unfit for outside work and decays rapidly in contact with the ground.

In north-western Montana, this species does not ascend above 4000 ft. and never crosses the continental divide. It is of rather rare occurrence in the Flathead region where scattered trees grow in the mixed forest, which is mainly composed of western larch and Douglas fir. It thrives best on moist soil, but on swampy ground has shallow roots and is often blown down. Seedlings² germinate in the open, where the soil is not too dry; but they bear a certain amount of shade, though they are never seen under the dense cover of *Thuja plicata* or *Tsuga Albertiana*.

CULTIVATION

Though discovered by David Douglas in 1831 and introduced by him soon afterwards, the tree did not become common in England until Lobb and others sent seeds in quantity between 1851 and 1855. It seems to be perfectly hardy as regards cold everywhere, but does not succeed as well in England generally as in Scotland, and even there it seems very subject to the attacks of a rust which was identified by Mr. W. G. Smith as *Peridermium pini*,³ and which is described by Mr. J. Laurie, gardener at Murthly Castle, as spreading over all the trees there, but not attacking *P. Strobus* which grows close by. From what I have seen elsewhere this or a similar rust has destroyed other trees in different parts of the country. It seems to succeed best in the wetter parts of Scotland, and to dislike lime, as the seedlings I have raised will not grow at Colesborne. It cannot be recommended on our present knowledge as a forest tree in this country.

Among the finest I have measured in England are those at Adhurst St. Mary near Petersfield, the seat of Miss Bonham Carter, where in 1908 I measured a tree growing on the lower greensand which was 78 ft. by 5½ ft. At Barton, in 1904, a tree with three leaders was 79 ft. by 8 ft. It was planted in 1848⁴ and bore cones in 1864. At Beauport, two trees, 81 ft. by 7 ft. and 68 ft. by 7½ ft., were healthy and covered with cones in 1905. At Enville Hall, Staffordshire, Henry saw a beautiful glaucous tree which in 1904 was 77 ft. by 6 ft. At Kew, a tree on the lawn north-west of the Water Lily house, planted in 1843, measured in 1903, 63 ft. by 5 ft. 1 in.⁵ At Highnam, Major Gambier Parry in 1906 measured a tree 64 ft.

¹ *Brit. Columbia, Bureau Inform., Bull. No. 15*, p. 239 (1903).

² Cf. Whitford, in *Bot. Gaz.* xxxix. 201 (1905). Henry in 1906 saw numerous seedlings near Nyack on the Great Northern railway. The tree is of no economic importance in Montana, and is estimated by Ayres to yield about one per cent of the total timber in the Lewis and Clarke Forest Reserve. Elrod gives 10 ft. as the maximum girth.

³ *Gard. Chron.* xxiii. 244 (1898). Smith says that the rust is *Peridermium pini* and not *P. Strobi*. The two fungi are distinct. Cf. Smith, *ibid.* 202. According to Ulmer, in *Naturw. Zeitsch. forst. Landwirtschaft*, 1908, pt. 12, of all the five-leaved pines in the forest garden at Tharandt in Saxony, only *P. monticola*, of which there are several trees eighteen years old, is attacked by *Peridermium Strobi*. Experiments in that place have shown that the only species of *Ribes* infected by the spores is *R. sanguineum*.

⁴ Bunbury, *Arboretum Notes*, 133 (1889).

⁵ *Kew Hand-List Conifera*, xiv, xxii (1903).

by 6 ft. 8 in. At High Leigh, Hoddesdon, Mr. Clinton-Baker in 1908 measured a tree 66 ft. by 4 ft. 10 in.

In Scotland the largest known to us is a tree at Murthly (Plate 273), which, when I saw it in 1906, was 85 ft. by 6½ ft. and covered at the top with cones. The next is at Scone, in Perthshire, the seat of the Earl of Mansfield. This, when measured in 1891 for the Conifer Conference, was 71½ ft. high, by 5 ft. 11 in. in girth at about forty years of age; and when measured by Henry in 1904 had increased to 82 ft. by 7 ft. 9 in., and was quite healthy. Another at Keillour, which is probably one of Douglas's original introduction, as it was planted in 1834, was in 1904 80 ft. by 6 ft. 9 in.; and there are many others in Scotland which are from 60 ft. to 70 ft. high. One at Monreith, Wigtownshire, planted in 1876, measured in 1908 56 ft. by 4 ft. 11 in., whilst *P. Cembra*, planted with it at the same time, is only 16 ft. high. Another at Poltalloch, raised from the seed of a tree at Lamb Abbey, measured 50 ft. by 5¼ ft. in 1906, and has itself produced fertile seed.

In Ireland it also grows well. At Hamwood, Co. Meath, the seat of C. R. Hamilton, Esq., there is a splendid tree planted in 1847 which Henry measured in 1904 and found to be 76 ft. by 7 ft. At Fota, another measured 69 ft. by 6 ft. 8 in. in 1907. (H. J. E.)

PINUS STROBUS, WEYMOUTH PINE, WHITE PINE

Pinus Strobus, Linnæus, *Sp. Pl.* 1001 (1753); Loudon, *Arb. et Frut. Brit.* iv. 2280 (1838); Sargent, *Silva N. Amer.* xi. 17, tt. 538, 539 (1897), and *Trees N. Amer.* 4 (1905); Kent, *Veitch's Man. Conifera*, 377 (1900); Masters, in *Journ. Linn. Soc. (Bot.)*, xxxv. 579 (1904); Clinton-Baker, *Illust. Conif.* i. 52 (1909).

Pinus tenuifolia, Salisbury, *Prod.* 399 (1796).

Pinus alba canadensis, Provancher, *Fl. Canadienne*, ii. 554 (1862).

A tree, attaining in America at the present time 150 to 175 ft. in height and 10 to 15 ft. in girth, but stated to have been much larger formerly. Bark on young stems, thin, smooth, and greenish; on old trunks 1 to 3 in. in thickness, and divided by shallow fissures into broad connected scaly ridges. Buds ovoid, sharp-pointed, ¼ in. long, brown, resinous, with some of the scales free at the tips. Young branchlets with short tufts of pubescence below the insertions of the leaf-clusters on the slightly raised pulvini, being glabrous elsewhere.¹

Leaves in fives, persistent two or three years, spreading, 3 to 4 in. long, very slender, straight, serrulate, whitened with stomatic lines on the two inner surfaces; resin-canals marginal; basal sheath ⅝ in. long, early deciduous.

Cones sub-terminal, pendulous on stalks (usually less than 1 in. long), cylindrical, often curved, pointed at the apex, 4 to 6 in. long, 1 in. in diameter. Scales 1 to 1¼ in. long, ½ to ⅝ in. wide, usually very convex from side to side; apophysis smooth, rounded, and thin in upper margin, slightly thickened in the centre, terminating in a

¹ Occasionally the pubescence is diffused over the whole surface of the branchlet, but remains densest on the pulvini.

small resinous flat umbo. Seed ovoid, $\frac{1}{4}$ in. long, reddish brown, mottled with black; wing narrow, 1 in. long. Cotyledons 7 to 14.

VARIETIES

Several forms with variously coloured foliage or of peculiar habit have arisen in European nurseries.¹

1. Var. *nana*, Knight, *Syn. Conif.* 34 (1850). A compact round-headed shrub rarely exceeding 6 ft. in height, with short slender branches, and crowded branchlets; leaves short, $\frac{3}{4}$ to $1\frac{1}{2}$ in. in length. A specimen of this variety planted at Bayfordbury in 1849 is about 15 ft. high. Sargent says that this is perhaps one of the most distinct and beautiful of all the dwarf conifers in cultivation; and those which Elwes saw at Underley Hall, Westmoreland, the seat of Lord H. Cavendish-Bentinck, confirmed this opinion.

2. Var. *nivea*, Booth, *ex Knight, loc. cit.* Leaves short, and silvery white beneath.

3. Var. *aurea*. Leaves yellowish when young.

4. Var. *variegata*. Leaves variegated with yellow.

5. Var. *zebrina*. Leaves striped with yellow.

6. Var. *monophylla*, Tubeuf, *Forst. naturw. Zeitschr.* vii. 34 (1897). A variety with the needles more or less cohering throughout their length, and forming a single needle.

7. Beissner also mentions fastigiate and prostrate varieties, which do not seem to be in cultivation in England.

DISTRIBUTION

P. Strobus is the largest of all the conifers indigenous in North America eastward of the Rocky Mountains; and its original area of distribution comprises a vast territory in Canada and the northern United States, roughly bounded on the north by the parallel of 50° from south-eastern Manitoba to Newfoundland, and on the south by the parallel of 42° from Iowa to Connecticut; while it spreads southwards in the Alleghany mountain region from Pennsylvania and New Jersey, through Maryland, West Virginia, Virginia, Kentucky, North and South Carolina, Tennessee, to the northern parts of Alabama and Georgia, becoming rarer and confined to high altitudes towards the south. It grows up to about 3500 ft. on the Blue Ridge, but does not there attain anything like the size it does farther north, 60 to 70 ft. high being about the size of the trees which Elwes saw in North Carolina.

Although still met with throughout this vast region, the original forest has in many parts been cut away, and in some districts, as in New England and eastern Canada, the species only remains in small areas. The great forests, where the pine occurs in commercial quantity, are now confined to Michigan, Minnesota, and Wisconsin in the United States, and to the Ottawa valley, and to the districts bordering Lake Huron and Lake Michigan in Canada.

¹ Sargent, in *Garden and Forest*, x. 460 (1897), mentions two varieties of American origin growing in the Arnold Arboretum; one, dwarf with pendulous, nearly prostrate branches; the other, with short, slender, nearly erect branches, in whorls of three, growing a dense, low, round-topped head.

The white pine is less gregarious than many other pines, and originally formed an important component of the mixed deciduous forest of New England, New York, and Pennsylvania, attaining its best development along water-courses, and reaching its greatest size when growing in mixture with beech, maples, and birches, often towering in such woods high above the general level of the other trees. It is often, however, in the same regions associated with hemlock; and in eastern Canada is frequent in company with hemlock, spruce, and *Thuja occidentalis*.

The pine forests, which cover large tracts of sandy soil in the Lake States, are composed of varying mixtures of *P. Strobus*, *P. resinosa*, and *P. Banksiana*.¹ On poor dry sand the two latter species outgrow and supplant the former, while on moist deep sand *P. Strobus* is the more vigorous. Its growth is much aided by the presence of organic matter and loam in the sand, and on soil of this kind, pure woods of white pine, sometimes several square miles in extent, occur. With an increase of loam in the soil, deciduous trees make their appearance, and the forest becomes a varied mixture of these trees and *P. Strobus*. On heavy clay soil, the white pine tends to disappear, and a forest of only hardwoods results.

On sandy soil in the eastern states, *P. rigida* is the companion of the white pine, and in the southern states, *P. echinata*.

This tree prefers a climate with considerable moisture in the air, as is shown by its abundance in the region of the Great Lakes and towards the sea-board. It withstands windy and cold exposures, but suffers from strong sea-breezes. It excels all pines in its capacity for bearing shade in the early stage of its growth, and reproduces itself naturally under oak, but not under beech or maples. It is long in cleaning its stem, even where the young growth, as is often the case, forms dense thickets. (A. H.)

Though it is improbable that any such trees now exist, Sargent quotes various old writers to show that in former times trees rivalling the giant pines of California were found in New England. A tree, 7 ft. 8 in. in diameter at the butt, on the Merrimac river; and another, 6 ft. in diameter and 260 ft. high, in Lincoln,² N.H., are mentioned as instances. But trees of 150 ft. high, 24 in. in diameter, are now quite uncommon, and the largest actually measured in Pennsylvania by Pinchot was 155 ft. high, $3\frac{1}{2}$ ft. in diameter at $4\frac{1}{2}$ ft. from the ground, and 357 years old.

Emerson tells us³ that fifty years ago several trees at Blanford, which grew

¹ In the Cass Lake Forest Reserve, in Minnesota, which I visited in 1906, these three pines occur; and *P. Strobus* invariably occupied the better soil where the sand contained a percentage of blackish mould.

² With regard to the gigantic heights given by early writers I am very sceptical, and Prof. W. A. Buckhout, of the Pennsylvania State College, to whom I wrote for information, shares my doubts. The most authoritative statement is by Fox, in *U.S. Forestry Bull.* No. 34, p. 8 (1902), who says: "there is a record of a white pine cut in Meredith, Delaware County, New York, that measured 247 ft. in length as it lay on the ground." He adds: "Many New York lumbermen still living recall giant white pines 7 ft. or more across the stump, and over 220 ft. in height." Fox does not state where the record exists or its authority; and Springer, in *Forest Life and Forest Trees*, 40 (New York, 1851), says: "In Dr. Dwight's *Travels*, there is an account of a tree in Lancaster, New Hampshire, which measured 264 ft. in length. I have worked in the forests among the timber several years, have cut many hundreds of trees and seen many thousands, but have never found one larger than the one I felled on a little stream which emptied into Jackson Lake in the eastern part of Maine. Its trunk was 6 ft. in diameter at 4 ft. from the ground. It was about 9 rods in length or 144 ft., about 65 ft. of which were free of limbs, and retained its diameter remarkably well." The tree mentioned in *Garden and Forest*, 1894, p. 188, which grew in Wisconsin, and was said to be 200 ft. high and 45 in. in diameter, is also exaggerated, I believe, as regards its height.—(A. H.)

³ *Woody Plants Massachusetts*, i. 74 (1875).

on rather dry land, measured after they were felled over 223 ft., and speaks of a mast cut on the Penobscot river in 1841, which, after being hewn to an octagonal shape, measured 90 ft. long, 36 in. in diameter at the butt, and 28 in. at the top.

The tree lives to a very great age, remaining sound up to 350 or 400 years, and it is said in New England that no one has lived long enough to see the stump of a white pine decay. Fences made from the stumps after they have been torn up by the roots, show after 100 years few signs of decay.

The white pine grows naturally on all kinds of soil, and varies very much in its habit according to the soil and surroundings, but flourishes best in a deep, moist sandy loam, and in land which, being covered with a thick growth of moss, never dries in summer.

The trees now commonly seen by the traveller in New England, which have been left when the original forest was felled, or which have sprung up from seed on abandoned farms, or as second growth in forest which has been logged, give no idea of what the tree is in a virgin forest. These are now only found in remote localities from which the logs cannot be profitably extracted; and the ingenuity of the lumberman is so great, and the present value of large clean logs so high, that it is not easy to find any which have not been cleared of their finest timber.

The reproductive power of the tree is very good, whenever fire is kept out of the forest, and large areas of land which have been abandoned by the descendants of the original settlers as unprofitable to cultivate, are now becoming¹ re-covered with white pine, from which second growth in New Hampshire and Vermont alone, Sargent tells us that no less than 100,000,000 ft. of lumber were manufactured in the year 1880.

A remarkable instance of the rapid growth and branching habit of the white pine on land which has been burnt over is described by Mary Robbins in *Garden and Forest*, viii. p. 333. These trees are in a large cemetery at St. Stephen, New Brunswick, on land which was devastated by fire in 1821. The largest of them in 1895 were 75 ft. high and 11 ft. or more in girth, with high horizontal or perpendicular branches coming off close to the ground, some of which are as much as 7 ft. in circumference and spread 40 to 60 ft. from the trunk.

HISTORY AND CULTIVATION

The white pine was first described by Plukenet² in 1696, and according to Aiton³ was first cultivated⁴ at Badminton in Gloucestershire by the Duchess of Beaufort in 1705. Its common English name was given it because Lord Weymouth planted it⁵ largely in the beginning of the 18th century at Longleat, Wilts;

¹ In *U.S. Forest Service, Circular 67* (1907), a leaflet on the planting of this species, it is said that in many situations, if the land is protected from fire, white pine will extend itself rapidly by natural seeding; and planting is recommended only when natural regeneration is impracticable.

² Plukenet, *Amalth. Bot.* 171 (1705).

³ *Hort. Kew.* iii. 369 (1789).

⁴ It was introduced earlier into France, as a plant was growing in the Royal Nurseries at Fontainebleau in 1553. Cf. Belon, *De Arboribus Coniferis*, published in that year, and quoted by Bolle, in *Gartenflora*, 1890, p. 434.

⁵ The date of first planting at Longleat is uncertain, and possibly preceded that at Badminton. In *London Catalogue of Trees by Society of Gardeners*, 57 (1730), it is said that "Lord Weymouth's pine was raised from seed in Badminton Gardens several years since, and has been growing many years in the gardens of Lord Weymouth, where it hath produced ripe seed for several years."

and Miller says that at Mersham le Hatch, near Ashford, Kent, then the property of Sir Wyndham Knatchbull, and still held by his descendant of the same name, it produced, as early as 1726, good seed from which many of the trees in England were raised. I have been unable to find any trees either at Badminton or at Longleat which can be certainly looked on as the original trees;¹ but there are many places in England where trees dating from at least the middle of the 18th century still survive, and some of these, as will be shown later, are of great size.

The tree is apparently at home on all good deep sandy soils, and when not too dry, grows vigorously for 100 years or more in all the southern half of England; ripening seed in most seasons and often reproducing itself naturally; but in Scotland it does not seem to thrive so well, probably on account of insufficient heat in summer. I do not, however, think that it is likely in any part of Great Britain to prove a profitable forest tree in comparison with Scots or Corsican pine, as the value of its timber depends on climatic and soil conditions rarely found in this country.

The Weymouth pine has been extensively planted in Germany, there being, for example, 3,000,000 trees in the state forests of Bavaria. In central Europe, it is remarkably hardy, as it is not injured by the severe winter climate, never suffers from spring or autumn frosts, and is not easily broken by heavy snow. It is considered, on account of the abundant fall of its soft needles, which speedily decay, to be a better soil-improver than any European pine. Slow in growth during the first five years, it attains about the same height as the Scots pine in the twentieth year, and exceeds the latter species considerably in height and diameter growth after this period. Dr. L. Wappes,² a Bavarian forester, states that it seeds early and heavily, is readily reproduced naturally,³ withstands crowding and shading, and produces even on poor soils a large amount of timber. On very inferior soil in the Palatinate, pure plantations, 104 years old, yielded per acre, 13,000 cubic ft. of timber, exclusive of branches and stumps. In spite of such results, much exceeded on loamy sands at other stations in Prussia and Thuringia, it is doubtful if this tree will be planted extensively in the future. It is much subject to the attacks of fungi, many plantations being ruined by *Agaricus melleus* and *Peridermium Strobi*, while deer bite the shoots and gnaw the bark, injuring many trees in the German forests.

The timber produced in central Europe appears to be as good as that of America, and Wappes states that though little valued at first, it is now readily saleable, the price in 1899 being double that of 1882. Mayr⁴ gives an instructive comparison of the wood of two trees, one 87 years old, grown in Bavaria; the other, 138 years old, grown in Wisconsin. The specific gravity of both was identical; and the Bavarian

¹ Forbes, in *Pin. Woburn.* 83 (1839), says: "The original tree, first brought to England by Viscount Weymouth, is now standing, though perfectly decayed, in a timber grove at Longleat." According to *Museum Rusticanum*, iv. 381 (1765), gold and silver medals were offered by the Society for the Encouragement of Arts, in 1765 and succeeding years, for plantations of Weymouth Pine. According to Dillwyn, *Hortus Collinsonianus*, 40 (1843), Bartram sent a small tree to Collinson in 1737, which was growing at Mill Hill in 1756, when it was 40 ft. high.

² The articles on the cultivation of this pine in Germany, which Dr. Wappes published in Lorey's *Allgemeine Forst- und Jagdzeitung* for 1899, are abstracted by Spalding, in *U.S. Forestry Bulletin*, No. 22, *The White Pine*, p. 68 (1899).

³ Unwin, *Future Forest Trees*, 90, fig. 1 (1905), gives a good picture of natural reproduction of the Weymouth pine in the Rhine Palatinate.

⁴ *Fremdländ. Wald- und Parkbäume*, 378 (1906). Mayr's article on "White Pine in Europe," published in *Garden and Forest*, 1888, p. 10, should also be consulted.

tree excelled in having a less proportion of sapwood. These two trees contained nearly the same percentage of resin; and Mayr's researches have shown that the wood of the Weymouth pine contains more resin than that of Scots pine, larch, spruce, or silver fir. He considers that its qualities of lightness and softness, for which it is esteemed in America, render it useful for many purposes, for which it is better fitted than any European species.

In Belgium the finest specimens of the Weymouth pine are a group of seven trees standing close together in good soil beside a pond on the farm of St. Michel, in the western Ardennes, not far from St. Hubert. These are growing at an altitude of 1000 ft., and the largest measured in 1909, when they were seen and photographed by Henry, 110 ft. high and 8 ft. 8 in. in girth. They have produced seed freely from an early period, and there are many seedlings of different ages in the vicinity, some, believed to have been of this source, being as far away as two miles to the westward. The dry easterly winds open the cones, and distribute the seeds to a great distance. To the eastward of the tree the seedlings, though numerous, only extend about 200 yards. The older trees are not attacked by the "rouge" (*Peridermium Strobi*¹), but many of the younger trees are affected. This pine succeeds well at considerable elevations in the Ardennes, and would be a desirable acquisition were it not for its liability to disease.

This tree grows well as far north as Christiania, where I have seen in the grounds of Baron Wedel Jarlsberg at Bogstad a healthy specimen about 90 ft. high, with a clean trunk of about 12 ft. in girth. According to Schübeler, it has been planted at many places on the coast as far north as Trondhjem, and in Sweden as far as 64° N.

On the Isola Bella, in Lago Maggiore, I saw in 1906 a fine tree, 98 ft. by 10½ ft. and covered with cones, which is said to have been brought from Paris in 1815.

REMARKABLE TREES

By far the largest tree of which we have an exact record, grew in a sheltered valley at Ironmill Wood not far from Tortworth, Gloucestershire, and, as I learn from the Earl of Ducie, was measured² in 1864 by Sir Joseph Hooker and Professor Balfour, who made it about 114 ft. high by 10½ ft. in girth. It was blown down in 1875 when it was believed to be about 105 years old, and measured 122 ft. high and 46 ft. to the first branch, containing no less than 324 cubic feet of good timber, which was cut up and used on the estate.

The next largest is a tree at Stowe, probably at least 150 years old, which in 1905 when I measured it, was 104 ft. high by 13 ft. 2 in. in girth at 3 ft., where the stem divides into several massive ascending limbs.

At Pains Hill, Surrey, there is a remarkable old tree with very spreading branches, not mentioned by Loudon, which in 1904 was about 90 ft. high by 12 ft. 8 in. in girth.

¹ This fungus was first noticed in England, in 1892, at King's Lynn. Cf. Plowright, in *Gard. Chron.* xii. 133, figs. 22, 23 (1892); xiii. 425 (1893); xxvi. 72, 94 (1899). Dr. Somerville, in *Quart. Journ. Forestry*, iii. 232 (1909), gives an account of its ravages in late years.

² In *Gard. Chron.* 1853, p. 725, this pine was reported to have been planted in 1772; and it measured in 1853, 114 ft. by 9 ft. 10 in.

At The Grove, Herts, there are two large rough and branching old trees, one of which Henry in 1904 found to be 96 ft. by 12 ft. 2 in. Another at Cassiobury Park measured 102 ft. by 8½ ft. in the same year.

In the Belvedere plantation, Windsor, there are a number of fine Weymouth and Scots pines planted about 1760, according to Menzies, though Mr. Simmonds, who showed them to me, thought that they may be older. The best of the former measure about 100 ft. by 9 ft., are clean for half their length, and are little if anything less in size than the Scots pine presumably of the same age.

At Hollycombe, Sussex, the seat of J. C. Hawkshaw, Esq., there are some of the cleanest and best grown trees of their age in England growing among larch near the entrance to the lodge. The best I measured was over 100 ft. high by 8½ ft. in girth, and contained 120 to 150 ft. of timber. Mr. Hawkshaw informs me that these trees are about 100 years old.

At Woburn Abbey this tree has been planted to some extent on sandy soil, which suits Scots pine very well, but which is apparently too dry for *P. Strobus*. On the Green Drive there are some large old trees left, of which the best measured in 1908 about 90 ft. by 7½ ft., but the majority have died or been felled; and the self-sown seedlings which are numerous in the plantation are mostly suffering from the attacks of a species of Chermes.¹

At Arley Castle there is a tree 95 ft. by 11 ft. 4 in. in 1905, which is perhaps not over 80 years old. At Ombersleigh Court, the seat of Lord Sandys, a tree, with large branches forking low down, in 1906 was 90 ft. by 16½ ft. near the ground.

At Nuneham Park, Oxford, a tree with a clean stem, was 95 ft. by 7 ft. 9 in. in 1908. At Burwood House, near Cobham, Surrey, Mr. R. Woodward in 1903 measured a tree 92 ft. by 8 ft. 3 in. A tree in a field near Coombe Bank, Sevenoaks, was 80 ft. by 9 ft. 8 in. in 1904.

At Black Park, near Slough, the property of Sir R. Harvey, Bart., in a dense wood of Scots pine near the upper end of the lake, there is a very fine Weymouth pine growing on moist sandy soil, which, when I measured it in 1908, was about 110 ft. high by 9 ft. in girth; the stem forking at 58 ft. from the ground contains about 200 ft. of timber.

At Gwydyr Castle, N. Wales, the property of Earl Carrington, there are several large clean trees growing in a wood, with stems clean to a considerable height, which I saw in 1906 and found to be from 100 to 110 ft. high and 9 to 10 ft. in girth.

The largest in Scotland of which I have certain knowledge is one of nine trees on the banks of the Almond, at Logiealmond, the property of the Earl of Mansfield. Mr. A. Kinnear has recently measured these, and informs me that the largest is 94 ft. high and 7 ft. 9 in. in girth, with a cubic content of 119 ft. over bark. The remaining eight are from 60 to 80 ft. high, growing on a steep bank of light, dry soil, facing west.

¹ Gillanders, *Forest Entomology*, 331, 336, fig. 307 (1908), says that *Chermes corticalis*, Kalt., is common in the south of England, and is said to do great injury to the trees. The stems attacked resemble in appearance those of beech trees, affected by *Cryptococcus Fagi*; but the two insects have no connection whatever, although on one occasion the absurd proposal was made to cut down Weymouth pines to prevent the extension of the beech disease on a certain property. This aphid is also harmful to the Weymouth pine in Germany.

Sir Herbert Maxwell reports¹ a very large tree at Dunkeld, 13 ft. 3 in. in girth. At Keir, Perthshire, there is a tree 59 ft. by 6 ft. 11 in., which was reported² at the Conifer Conference in 1891 to be 40 years old, and 46 ft. by 6 ft.

In Ireland, there are two fine old trees, both about 80 ft. by 7½ ft., at Woodstock; and a tree at Muckross, Kerry, was in 1908 about 65 ft. high, and 8 ft. in girth. Another at Coolattin, Wicklow, was 73 ft. by 7 ft. 7 in. in 1906; but the forester here reported that larger trees were to be found on this property, where this species thrives, and produces valuable timber.

TIMBER

The wood of the white pine is, in Sargent's words,³ "light, soft, not strong, close, straight-grained, very resinous, easily worked, light brown, often tinged with red, with thin, nearly white sapwood, weighing only 24 pounds to the cubic foot when quite dry."

For a century or more it has played a conspicuous part in the material development of the United States and Canada. "Great fleets of ships and long railroads have been built to transport the lumber sawn from its mighty trunks, men have grown rich by destroying it, building cities to supply the needs of their traffic, and seeing them languish as the forests disappear." Fifty years ago the supply seemed inexhaustible, and for a long period the price of white pine lumber governed that of most other woods, whilst it formed a basis of comparison for the quality of other kinds of trees.

Now the best sources of supply are so much depleted that though, in Michaux's time, three-quarters of the houses, except in the great cities, were built mainly of white pine, it has become so scarce and risen so much in price that Canadian forests are largely purchased by American lumbermen to supply their own needs, and the export to Europe has very much diminished.

Much of what still comes is moreover cut from smaller and younger trees, often of second growth, and is inferior in quality to that which gave its reputation, and which was preferred to all others on account of the facility with which it worked up for all domestic purposes.⁴

Laslett, as timber inspector to the British navy at a time when ships were still built of wood, gives numerous details⁵ of the experiments which were made on its strength, elasticity, and durability, and states that it was used for masts, yards, bowsprits, and in the form of deals, but says it was not strong enough for light spars subject to great and sudden strains, for which it was inferior in strength and durability to Oregon fir.

Mr. Weale of Liverpool writes to me as follows:—"It is the most generally useful of all the pines, and is largely exported to Europe. As a building timber it is

² Erroneously named *P. Lambertiana*, in *Journ. Roy. Hort. Soc.* xiv. 531 (1892).

³ *Silva*, xi. 19 (1897).

⁴ *Popular Science Monthly*, xxviii. 682.

⁵ *Timber and Timber Trees*, 356-66 (1894).

durable for such purposes as windows and doors, but deteriorates if exposed to alternate heat and damp. It is in favour for the inside linings of furniture, but for this purpose is rapidly giving place to the American whitewood, *Liriodendron tulipifera*, the latter having a lower price to recommend it. For pattern-making, the yellow pine¹ is preferred to all other woods, being soft, easily worked, straight-grained, and of a mellow texture. Its value has been steadily advancing for some years, the fine trees producing the best timber becoming scarce in the more accessible districts, and a great and growing demand from the United States, being the chief reasons. The first quality wood in 1905 was 20 per cent greater in price than ten years previous. It is generally imported into Europe in the form of sawn deals, and the disposal in England is practically in the hands of two firms." (H. J. E.)

PINUS PARVIFLORA, JAPANESE WHITE PINE

Pinus parviflora, Siebold et Zuccarini, *Fl. Jap.* ii. 27, t. 115 (1844); Syme, in *Gard. Chron.* x. 624, f. 103 (1878); Engelmann, *Revision Genus Pinus*, 178 (1880); Masters, in *Journ. Linn. Soc. (Bot.)* xviii. 504 (1881), and xxxv. 578 (1904); Mayr, *Abiet. jap. Reiches*, 76, t. v. f. 19 (1890), and *Fremdländ. Park- u. Waldbäume*, 386 (1906); Kent, *Veitch's Man. Conifera*, 353 (1900); Clinton-Baker, *Illust. Conif.* i. 40 (1909).

A tree attaining in Japan in favourable situations 100 ft. in height, but usually smaller. Bark smooth and greyish for many years, ultimately becoming on old trunks darker in colour and fissuring into small scales. Buds ovoid, less than ¼ in. long, not acuminate at the apex, light brown, slightly resinous, with some of the scales free at the tips. Young branchlets smooth, greyish, with a scattered minute pubescence.

Leaves in fives, persistent for three years, spreading, about 2 in. long, curved, usually blunt at the apex, serrulate, with the inner flat surfaces marked by three or four white stomatic lines; resin-canals two, marginal; basal sheath ½ in. long, early deciduous.

Cones sub-terminal, sessile, spreading, in clusters of three or four, ovoid-conic, 2 to 2½ in. long; scales spreading widely when open, woody, about ¾ to 1 in. long and ½ to ¾ in. wide, convex from side to side, thin in margin; apophysis thickened, incurved in the centre of the rounded broad upper margin, with a minute dark-coloured or resinous umbo. Seed obovoid, ⅜ in. long, ⅓ in. wide, compressed, brown; wing short and broad, scarcely exceeding ¼ in. long, usually left in part on the scale when the seed falls. Cotyledons 8 to 10. Seedlings very slow in growth for several years.

Var. *pentaphylla*.

Pinus pentaphylla, Mayr, *Abiet. jap. Reiches*, 78, t. vi. f. 20 (1890), and *Fremdländ. Park- u. Waldbäume*, 377 (1906); Kent, *Veitch's Man. Conifera*, 356 (1900); Masters, in *Journ. Linn. Soc. (Bot.)* xxxv. 577 (1904).

In the northern part of Hondo, Yezo, and the Kurile Isles the tree bears more

¹ The timber when imported is known as *yellow pine*, a name used in America for other species, and liable to be confused with yellow deal, a London trade name for the timber of Scots pine from the Baltic.

pendulous larger cones,¹ up to $3\frac{1}{2}$ in. in length, and seeds with a longer wing, up to $\frac{1}{2}$ in. in length. Mayr considers this variety to be a distinct species; but there is great variation in the size of the cones and in the length of the seed-wing; and we have found no constant characters by which the wild and cultivated specimens that we have examined could be clearly separated into two distinct groups. There is no difference in the foliage or the branchlets.²

This species³ is a native of Japan and the Kurile Islands; the typical form, according to Mayr, being restricted to southern Hondo, Shikoku, and Kiusiu, where it either grows scattered in the beech and chestnut forests, or forms large woods in company with Tsuga. In Kiso he found single trees in woods mainly composed of *Cupressus obtusa*. Sargent⁴ says it is a common inhabitant of mountain forests above 5000 ft. elevation, usually occurring singly or in small groves, occasionally reaching a height of 60 or 70 ft., and overtopping the deciduous trees by its handsome head of long, graceful, somewhat pendulous branches. Mayr, however, says that it attains 100 ft. in favourable situations.

The large-coned variety is the prevalent, if not the only form found north of lat. 35° , where it is met with in the great central chain of Hondo, being very common in Kotzuke. Mayr states that it is always found in the broad-leaved forest, never ascending into the fir region, and becoming in deep valleys a tree of the first magnitude, but in elevated regions scarcely higher than 50 or 60 ft. Faurie⁵ collected it on the precipitous mountains of Aomori, and Sargent⁴ states that it is a rare inhabitant of the mountain forests of southern Yezo.

This species is known in Japan both as *himeko-matsu* and *goyo-matsu*, the former name being restricted in books to the type, and the latter being assigned to var. *pentaphylla*; yet, as is acknowledged by Mayr, in the mountains of the interior the colloquial usage varies, showing that there is little or no difference between the two forms, which only vary in the size of their cones. This pine is cultivated in pots everywhere in Japan, being dwarfed and distorted in many ways. The timber is little used.

(A. H.)

I saw this tree in the forest above Agematsu in Kisogawa, at an elevation of about 3000 ft.; and, as I noted at the time, it looked so peculiar in habit and bark, that until I got the leaves and cones I could not believe that it was a pine. The illustration which I give of this tree (Plate 274) was taken for me by Mr. Masuhara of Tokio, and would, I think, be generally taken for a cypress. It was growing alone in a grassy valley, and though not of very large size seemed to be an old tree. In this part of Japan it is scattered here and there among deciduous trees and is not gregarious.

¹ Cones collected in Yezo by Maries in 1879 and by J. H. Veitch in 1892 are preserved in the Kew Museum, and though larger than those from other localities, differ in no essential character.

² Mayr says that in *P. pentaphylla* the branchlets are glabrous, but in the Yezo specimens which we have seen they are distinctly pubescent. In the northern tree, according to Mayr, the bark separates into larger scales.

³ This species is represented in Formosa by a closely allied species, *P. formosana*, Hayata, in *Journ. Coll. Sc. Tokyo*, xxv. 217 (1908), referred to in *Gard. Chron.* xliii. 194 (1908) as *P. morrisonicola*, Hayata. The Formosan tree has longer leaves (3 to 4 in.) and larger cones, with strongly reflexed scales.

⁴ In *Garden and Forest*, viii. 306 (1895) and x. 461 (1897).

⁵ Cf. Masters in *Bull. Herb. Boissier*, vi. 270 (1898).

CULTIVATION

*P. parviflora*¹ was introduced into cultivation in England by John Gould Veitch in 1861. In England, as is the case in Japan, it bears cones at an early age, which render it rather unsightly as an ornamental tree. The seeds ripen early in the season, and are eaten by finches with great avidity. Seedlings have been raised from home-grown seed. The largest tree that I have seen is one at Wilton House which in 1906 was 36 ft. by $3\frac{1}{2}$ ft. At Eggesford, in Devonshire, it forms a large spreading bush. At Blackmoor, at Westonbirt, and many other places I have seen very similar specimens, of from 20 to 30 ft. high, on lawns, and except as a purely ornamental tree it has no value whatever.

At Grafrath, near Munich, the tree is rather fast in growth, and perfectly hardy; but it suffers much from attacks of *Agaricus melleus*.

In New England,² *Pinus parviflora* grows rapidly, and resists the most severe cold. There are specimens 20 to 25 ft. in height, which produce cones in profusion.

(H. J. E.)

PINUS CEMBRA, ALPINE PINE

Pinus Cembra, Linnæus, *Sp. Pl.* 1000 (1753); Loudon, *Arb. et Frut. Brit.* iv. 2274 (1838); Murray, in Lawson, *Pinet. Brit.* i. 17, t. 3 (1884); Willkomm, *Forstliche Flora*, 169 (1887); Mathieu, *Flore Forestière*, 622 (1897); Kent, Veitch's *Man. Coniferae*, 317 (1900); Masters, in *Journ. Lin. Soc. (Bot.)* xxxv. 583 (1904); Kirchner, Loew u. Schröter, *Lebensgeschichte Blütenpfl. Mitteleuropas*, i. 241 (1905); Clinton-Baker, *Illust. Conif.* i. 14 (1909).
Pinus sibirica, Mayr, in *Allgem. Forst- u. Jagdzeitung*, 1900, ex *Fremdländ. Wald- u. Parkbäume*, 388 (1906).

A tree attaining about 130 ft. high in Siberia and 70 ft. in central Europe. Bark of young trees greenish grey, smooth or warty, with resin blisters; on old stems reddish grey, and dividing into thin scaly plates. Buds ovoid, resinous, about $\frac{1}{2}$ in. long, acuminate at the apex, the long subulate free points of the scales being usually appressed together and not spreading as in *P. koraiensis*. Young branchlets with prominent pulvini, and densely covered with an orange-brown shaggy tomentum. Older branchlets roughened by scars and dark in colour.

Leaves³ in fives, persistent three to five years, densely crowded, more or less spreading or appressed and nearly parallel to the branchlets, $2\frac{1}{2}$ to $3\frac{1}{2}$ in. long, slender, curved, acute or acuminate at the apex; margin with fine and not very close serrulations, which are not continued to the extreme tip; dark green, with inconspicuous whitish stomatic lines on the two inner surfaces; resin-canals three, median.

Staminate flowers sessile, about $\frac{1}{2}$ in. long, yellow; connective violet, serrulate. Young cones, violet, nearly $\frac{1}{2}$ in. long, erect, solitary, or in whorls of two to six.

¹ Cf. *Gard. Chron.* 1861, p. 265. The cones collected by J. Gould Veitch in 1860, figured by Murray in *Proc. Hort. Soc.* ii. 272, fig. 13 (1862), as well as those collected by Maries in 1879 and by J. H. Veitch in 1892, came from Yezo, and are those ascribed to var. *pentaphylla*. From the seeds of these cones some of the trees in cultivation in this country are derived, yet these invariably bear short cones, like those of the typical form described by Siebold. Similarly, in the Arnold Arboretum, a small tree of *P. pentaphylla*, raised from Yezo seed, has borne short cones.—(A. H.)

² *Garden and Forest*, viii. 306 (1895) and x. 461 (1897).

³ The leaves emit, especially in summer, a very agreeable peculiar odour. Cf. *Gard. Chron.* xx. 301, 309 (1883).

Cones subterminal, short-stalked, never opening, spreading, ovoid, obtuse at the apex, 2 to 3 in. long, $1\frac{1}{2}$ to 2 in. wide, greenish with a violet tinge before ripening, brown when mature. Scales numerous, scarcely woody, brittle, about 1 in. long and $\frac{3}{4}$ in. broad; apophysis, bent at nearly a right angle to the concealed part of the scale, with semicircular, sharp, and bevelled margin, and minutely tomentose outer surface; umbo terminal, thickened, triangular or rounded.

Seed obovoid, about $\frac{1}{2}$ in. long, dull brown, convex on the lower, flattened on the upper surface, with rounded and scarcely sharp angled sides, wingless,¹ edible. These are distributed by nutcrackers, squirrels, and dormice, who break the scales of the cone, which never open, and carry away the seeds to their larders or holes; and as some are often dropped by the way, seedlings are observed in the Alps and elsewhere at a considerable distance from the parent tree.

VARIETIES²

1. Var. *sibirica*, Loudon (*Pinus sibirica*, Mayr³). The tree occurring in Siberia is scarcely to be distinguished by any definite morphological characters from the typical form of central Europe (var. *helvetica*, Loudon), though Willkomm and others state that it has longer cones and larger seeds. The physiological differences are, however, considerable, as the Siberian tree attains a much greater height, forming a narrow pyramidal tree, like *P. Strobus* in habit; and is faster in growth in the young stage, with longer shoots, and more branchlets developed in each whorl. These differences are preserved in trees growing in severe climates, like Scandinavia and Germany; but in this country the Siberian variety is very slow in growth, and does not appear to be long-lived.

2. Several varieties of horticultural origin have been described, as var. *aurea*, *Kew Handlist of Conifera*, 127 (1903), and a dwarf form and a single-leaved form, mentioned by Carrière in *Conif.* 389 (1867).

DISTRIBUTION

This species occurs in two distinct regions, one embracing a vast area in Russia and Siberia, and the other confined to narrow limits in the Alps and Carpathians. In Europe it is widely spread in isolated tracts throughout nearly the whole of the Alps, scarcely ever descending⁴ below 5000 ft., and reaching timber line in different places at 6200 to 8000 ft. elevation. In France it is called *arole* or *auvier*, and is confined to the northern part of the Maritime Alps, the high peaks of Dauphiné, the Graian Alps, and Mont Blanc. In the Maurienne, close to Modane, it is well seen in the wild forest of Villarodin Bourget, where it begins at about

¹ Kirchner, *op. cit.* 270, fig. 136, describes and figures the vestiges of the rudimentary wing, which remains attached to the scale.

² Var. *pumila* is now considered to be a distinct species, *P. pumila*, Regel. (See p. 1045.)

³ Mayr relies on trifling differences in the colour of the leaves, and in the shape and colour of the buds, characters which I have not been able to verify. The two trees, one of Swiss, and the other of Siberian origin, in the Christiania Botanic Garden, though strikingly different in habit, show no differences in leaves, buds, or branchlets.

⁴ The lowest altitude, according to Dr. Rikli, is 4000 ft., near Raron, in the upper Rhone valley.

5000 ft., where *Pinus sylvestris* and *Abies pectinata* cease to grow, and is common mixed with larch and spruce at about 6000 ft., assuming in this dense part of the forest a narrow pyramidal form. Higher up, at about 7000 ft., it grows nearly pure in groups, scattered amidst rhododendrons, where seedlings are numerous, and is of a much more branching and picturesque habit, while far above on the rocky crests up to 8000 ft. isolated and broken trees are visible on the sky line. The largest specimens, which are at about 7000 ft., are of great girth, one tree which I saw in 1904 measuring 5 ft. in diameter, and dividing at 8 ft. from the ground into two stems. It is about 60 ft. high. Taller trees, up to 70 or even 80 ft., but of lesser girth, occur at the lower levels. Still larger specimens are said to exist in the forest of Arvieux in the same district.

In Switzerland¹ the tree is usually called *Zürbel*, *Zirbe*, or *Arve*; but is named *Schember* in the Engadine, which corresponds to the Italian name *zembra* or *zimbro*. The most extensive woods occur in the great central chain, as in the Pennine Alps and in the Engadine, though the tree is nearly extinct in Tessin; whilst smaller woods and scattered trees are met with in the limestone Alps from Vaud and Freiburg to Chürfürsten in St. Gall. From here the distribution extends through the Bavarian Alps to Salzkammergut, whilst it is continued through the Tyrol in the main chain to Gamstein, on the Styrian frontier, its most northern and eastern station in the Alps. In the southern Alps the tree grows here and there from Mt. Adamello in the Tyrol to Bleiberg in Carinthia and the Steiner Alps in Carniola. Throughout the Alps *P. Cembra* is seen on all formations—granite, slate, limestone, dolomite, etc.—but it thrives best and forms the largest woods on moist soils containing a considerable amount of clay, and remains stunted on dry limestone.

(A. H.)

In the Swiss Alps it is becoming in most places a scarce tree,² as the wood is in great request for carving, and the seeds are mostly eaten by mice and birds. But in the high Alps on the south side of the Valais many fine old trees may yet be seen.

A very beautiful one is shown in Plate 275, which is reproduced from a negative lent me by M. Coaz, Chief Inspector of the Swiss Government Forests, and forms plate xvi. of *Les Arbres de la Suisse*. It grows at Muotta da Celerina, near Pontresina, on a formation of mica schist and syenite rocks, at an elevation of 2120 metres, and measures 15 to 16 metres high, with a girth of 4.20 metres. It is divided into three principal stems, with many great branches, which extend to a diameter of $16\frac{1}{2}$ metres, and is surrounded by numerous seedlings, which often grow from seeds dropped by the nutcracker (*Nucifraga caryocatactes*).

By far the best illustrations that I have seen of this tree in its native Alps are a series of twelve plates (27 B to 36 B) in *Vegetationsbilder* 11 (1905), by Dr. L. Klein. Of these the most remarkable is a tree broken off at a few feet up, where it measures $4\frac{1}{4}$ metres in girth, with eight ascending candelabra-like branches. This grows at

¹ A very complete account of this pine in Switzerland has lately been published by Dr. M. Rikli, *Die Arve in der Schweiz*, pp. xi + 455, with 21 maps and 60 illustrations (Georg et Cie, Basel, 1909). A review of this important work is given in *Nature*, lxxxii. 399, figs. 1, 2 (1910).

² This species, according to Kirchner, *op. cit.* 250, was formerly much more widely spread in the Alps and Carpathians than it is at the present time.

2300 metres behind the Findelen Hotel, on the Riffel Alp. Another decayed tree grows near it, measuring, close to the ground, no less than 7.67 metres (about 25 ft.) in girth, which Dr. Klein computes, from a careful counting of the rings in other trees, to be from 1000 to 1100 years old, and considers to be the oldest recorded tree of the species in Switzerland.¹

In the Carpathians² the woods of *P. Cembra* are smaller in extent and less frequent than in the Alps, occurring from the Tatra mountains in the north to Baiku in Banat, and ranging from 4200 to 7500 ft. altitude.

In north-eastern Russia *P. Cembra* occurs in the plains of Vologda, Viatka, and Perm, to the eastward of a line drawn from the source of the river Vaga to the middle reach of the Petchora in lat. 65°, and often forms extensive forests of tall trees, without a branch to 70 or 80 ft., which are seldom, however, cut for their timber. In the Ural mountains its range is from lat. 64° to lat. 55°.

In Siberia this species occupies a wide territory, its northern limit crossing the Obi at lat. 66°, the Yenisei at 68°, the Lena at 60°, and the Aldan at 55°, and it does not appear to extend farther east than long. 130°, being replaced by *P. pumila* in north-eastern Siberia and Kamtschatka, and by *P. koraiensis* in Amurland, Manchuria, and Korea. The southern limit, beginning in the Ural at lat. 55°, crosses the plain to reach the Alatau, Altai, and Sayan mountains, and, passing south of Lake Baikal, ends in north-eastern Mongolia.³

In the Ural Mountains this tree is abundant, though I did not see it myself so far south as the line of the Siberian railway. It occurs in the neighbourhood of Ekaterinburg, where Pallas first described it.⁴ He called it the Siberian cedar or pine of Liban, probably confusing it with the true *Cedrus Libani*. He says that it grows so slowly that in a tree only 5 in. 4 lines in diameter he counted sixty-two rings, whilst a larch of fifty-nine years old was only 5 in. 9 lines in diameter. He further states that in the Ural it only produces much seed when two wet seasons occur in succession, and that in marshy places it grows to a much greater size than on the mountains.

Ledebour⁵ says that in the south-western Altai this tree ascends from about 4500 ft. to the timber line, which is here about 6500 ft., but this is not the case in the more eastern district of the Altai which I visited, and where, probably on account of the much drier soil, I saw few or no *Pinus Cembra* in the Katuna and Tchuja mountains. But on my return journey it formed a considerable part of the forest on the steep mountains forming the southern shore of the north end of Lake Teletskoi, mixed with *Abies sibirica*, and was frequented by flocks of nutcrackers, which were feeding on its seeds. These seeds are a favourite article of food in Siberia, as well as in the Ural, and were sold in the market at Barnaoul in September.

¹ Cf. Correvon in *Gard. Chron.* xvii. 80, fig. 12 (1882), who figures an old tree in the Tyrol, about 7 ft. in diameter.

² Cf. Pax, *Pflanzenverh. Karpathen*, i. 126 (1898), and ii. 247 (1908). Heuffel saw, just below the alpine pasture of Baiku, the only grove of *P. Cembra* in the whole territory of the Banat Alps. According to Golesco, in *Bull. Soc. Dend. France*, 1907, p. 178, it occurs as a scattered tree in the *P. montana* belt of the mountains of the Muscel district in Roumania.

³ Radde, *Reisen im Süden von Ost-Sibirien*, 117 (1861), gives the limit of elevation in the East Sayan as 7095 ft. On the mountains of N.W. Mongolia at Sochondo it only attains 6500 ft.

⁴ Pallas, *Voyages*, ii. 252 (1789).

⁵ *Reise Altai Gebirge*, i. 345-9 (1829). Ledebour, *op. cit.* 144, mentions a tree in the south-west Altai at 5700 ft. altitude, which measured 13 ft. 8 in. in girth at a foot from the ground.

CULTIVATION

According to Hempel¹ the ripe seeds of the Cembra pine fall with the cones in the early spring, and as a rule lie a year before germinating; but a small proportion of the seeds that I have sown have germinated in England in the first season, and some will remain two or even three years before coming up.

The seedling has nine to twelve, usually ten cotyledons, and makes but a short shoot in the first year. As mice and birds will probably devour the seeds unless protected, it is best to sow them in boxes filled with rich light sandy soil, and covered with fine wire netting. The seedlings should remain two or three years in the boxes, and will require three to five years or more in the nursery before they are large enough to plant out.² They are not often injured by spring frosts, but appear to dislike lime in the soil, and the seedlings which I raised from seed brought from Siberia all died at Colesborne, though one which I planted on sand in Norfolk grew much better.

Though a native of climates where the summer is extremely short, and growing naturally on dry rocky situations, the tree seems to want good and fairly deep soil to develop into a fine tree in England, and is usually a very slow grower,³ though when established it will make growths of 9 to 15 in. annually until it reaches 40 to 50 ft. in height. It does not seem so difficult to transplant as some pines.

REMARKABLE TREES

This tree is said by Loudon to have been introduced by Archibald Duke of Argyll in 1746; and one of the original seedlings mentioned as being at Whitton in 1838 still survives; and though somewhat crowded by other trees which have prevented it from branching in a natural manner, it is still fairly healthy and the tallest known to us in England, being 80 ft. by 5 ft. when measured by Henry in 1903.

At Walcot in Shropshire, the seat of the Earl of Powis, a large number of this species were planted, according to Lambert, about 1820, having been raised from Swiss seed some years previously; but when I visited this place in 1906 I could not find many survivors, though five or six handsome specimens remain in the grounds, the largest of which were 59 ft. by 8 ft. 11 in., 59 ft. by 8 ft. 10 in., and 65 ft. by 7 ft. 5 in. respectively.

At Oakly Park near Ludlow there is a very well-shaped tree, probably of the same age as those at Walcot, on a steep bank below the house, which, though difficult to measure accurately, is about 70 ft. by 8 ft. 4 in. The trunk of this is much cleaner than usual, and contains about 80 ft. of timber.

¹ Hempel u. Wilhelm, *Bäume und Sträucher des Waldes*, i. 175 (1889).

² In his garden at Stratton Strawless, Mr. W. J. Birkbeek showed me in 1907 some seedlings which he had raised from seeds gathered by him at Tolga Monastery in Russia, which were only about 3 in. high four years after sowing.

³ Correvon, in *Gard. Chron.* xvii. 80 (1882), states that seeds sown at Vevey, at 300 ft. elevation above Lake Geneva, and at a high altitude in the mountains, produced seedlings markedly different in their rate of growth. Those at the high elevation attained 8 ft. high, while those at Vevey were scarcely 3 ft. high at the same age.

At Barton, Bury St. Edmunds, there is a tree planted in 1825, which is 57 ft. by 5 ft. 1 in. At Linton Park, Kent, a tree which was the largest reported to the Conifer Conference in 1891, when it measured 68 ft., when I saw it in 1903 was only 70 ft. by 4 ft. 6 in., and did not look at all healthy.

At Woburn there is a very healthy specimen, branched to the ground, which in 1903 measured 53 ft. by 8 ft. 6 in. At Dropmore a tree said by Loudon to have been about 40 ft. high is now about 60 ft. At Osberton Hall, Notts, there is an old tree 50 ft. by 6 ft. 2 in.

At Essendon Place, Herts, Mr. Clinton-Baker in 1907 measured a specimen 60 ft. by 5 ft. 4 in. At Bayfordbury a tree planted in 1840, is now 41 ft. by 5½ ft.

In Scotland this tree does not seem to have been much planted at an early date, and I have heard of no trees of great age; but it seems to have been a great favourite with the late Queen Victoria and the Prince Consort, and a great number of thriving specimens are growing at Balmoral, where the soil and climate seem to suit it remarkably well, and where it ripens good seed. There is an avenue 12 yards wide from the stables to the back door of the castle, which Mr. Michie believes to be fifty years old, and the trees, planted 6 yards apart, averaged in 1904, 38 to 40 ft. high by 3 to 4 ft. in girth. A much larger tree grows on the north side of the castle, and a number of the trees planted by royal and distinguished visitors in memory of their visits are of this species. This seems to show what I have not noticed in England, that a cold climate and dry sandy soil are, as might be expected, favourable to the health of this tree.

At Abercairney, in Perthshire, Henry measured a tree 55 ft. high by 5 ft. 7 in. in girth; and Hunter records one at Cultoquhey near Crieff, planted out from a pot in 1826, which in 1883 was 40 ft. by 6¼ ft.

In Ireland the damper climate does not seem to suit it, as we have not seen any trees of considerable size.

A tree planted in the Park of Bogstad near Christiania, which Schübeler thought to be about 100 years old, and which he says was in 1885, 60 ft. high, was, when I measured it in 1903, about 85 ft. high with a trunk 10 ft. in girth, and divided at about 30 ft. into four stems. It is the largest cultivated tree that I have seen anywhere, and shows that it might prove a valuable forest tree in Norway.

There is in the Botanical Garden at Christiania a tree believed to be of the Siberian variety which looks healthier, and is growing faster, than the European form. When I saw it in 1903 it was growing at the rate of about a foot per annum, and according to Schübeler is now about forty-one years old. This variety was growing healthily but slowly at the forest nursery at Storgaard in the upper part of Saltdalen, latitude 67°.

TIMBER

The wood of this tree is almost unknown in England except in the form of carvings and toys, for which it is preferred in its native country to that of any other conifer, on account of its softness, density, and the absence of hard rings. It is, however, difficult to procure in large sizes without knots; and among a large

quantity of this timber which I saw at Innsbruck, I could not find a log that would cut into clean boards over a foot wide.

It is used in the Tyrol for wainscoting and domestic furniture on account of its durability and fragrance, which is said to endure for a very long period.

Seeböhm,¹ who found this tree growing on the Yenesei as far north as latitude 67½°, says that the timber has a much higher market value than that of *P. sylvestris*, and is the best timber found in Siberia. It is dark in colour, but not so dark as larch, and is reputed never to rot, shrink, warp, or crack. It is soft and easy to work, fine in grain, and almost free from knots. (H. J. E.)

PINUS KORAIENSIS, KOREAN PINE

Pinus koraiensis, Siebold et Zuccarini, *Fl. Jap.* ii. 28, t. 116 (excl. figs. 1-4) (1844); Masters, in *Journ. Linn. Soc. (Bot.)* xviii. 504 (1881), and xxxv. 582 (1904); Mayr, *Abiet. jap. Reiches*, 73, t. v. f. 18 and t. vi. f. 18 (1890), and *Fremdländ. Wald- und Parkbäume*, 386 (1906); Shirasawa, *Icon. Ess. Forest. Japon.*, text 12, t. ii. ff. 17-33 (1900); Kent, *Veitch's Man. Coniferae*, 334 (1900); Komarov, *Fl. Manshurica*, i. 183 (1901); Clinton-Baker, *Illust. Conif.* i. 28 (1909). *Pinus mandshurica*² Ruprecht, in *Bull. Phys. Math.* xv. 382, and *Mél. Biol.* ii. 567 (1857); Maximowicz, *Prim. Fl. Amur.* 263, 393 (1859), and *Mél. Biol.* xi. 349 (1881).

A tree, attaining in Manchuria 150 ft. and in Japan 100 ft. in height, with a trunk 9 ft. in girth, but usually considerably smaller. Bark reddish grey, not unlike that of a spruce, with scales about 4 in. long and 2 in. broad, the freshly peeled places being reddish brown in colour. Buds, ½ to ¾ in. long, cylindrical-ovoid, resinous, bristly at the apex, owing to the long subulate free points of the scales. Young branchlets covered with a reddish brown tomentum, and similar to those of *P. Cembra*, but with the pulvini less prominent; older branchlets brownish or grey, and much smoother than in that species.

Leaves similar to those of *P. Cembra* in number, size, persistence, arrangement, and structure; differing in the blunter apex,³ which is closely and sharply serrulate to the extreme tip, the apex in *P. Cembra* being long-acuminate, more remotely and less sharply serrulate, and often entire at the extreme tip as viewed with a lens. The leaves of *P. koraiensis* are whiter on the inner surfaces than in *P. Cembra*, the stomatic lines being more numerous and more conspicuous, and occasionally show a few broken lines of stomata on the outer surface near the apex.

Staminate flowers in clusters, ¼ in. long, pinkish. Female flowers upright, reddish, about an inch long, on stout stalks about ½ in. long.

Cones subterminal, but often becoming lateral by the growth of a summer shoot, on short stalks, ovoid-cylindrical, 5 to 6 in. long, and about 3 in. in diameter at the base, opening when ripe. Scales, 1½ to 2 in. long, 1 in. broad, woody;

¹ *Siberia in Asia*, 234 (1882).

² This is identical with *P. koraiensis*, as pointed out by Maximowicz, *Mél. Biol.* xi. 349 (1881); and this opinion is shared by Komarov.

³ In the apical centimetre of the leaf the serrations average seventeen in *P. koraiensis* and only four in *P. Cembra*.

apophysis shining brown, broadly triangular, reflexed in its upper third, tipped by a resinous thickened umbo. Seed $\frac{1}{8}$ in. long, $\frac{1}{2}$ in. wide, obovoid, sharply angled on the two sides and on the upper margin, wingless, brownish, edible.

This species closely resembles *P. Cembra*, though the cones are very distinct; but differs in the bristly buds, more silvery foliage, smoother branchlets, and faster growth in this country; and examination with a lens will show the different character of the apex of the leaf in the two species.

Var. *variegata*.¹—A form introduced from Japan, in which the leaves when young are yellowish white in colour, and said to be liable to injury if planted in a place exposed to full sunshine. Though mentioned in the *Kew Handlist*, we have seen no specimens of this variety.

DISTRIBUTION

Pinus koraiensis is widely distributed in eastern Asia,² occurring in Amurland, Manchuria, Korea, and Japan. It is not a native of China, being represented in that country by *P. Armandi*, with which it has been much confused by several authors.³

Its northern limit in Amurland is, according to Maximowicz, about $51\frac{1}{2}^{\circ}$ lat. in the interior in the Bureja range, and about 49° on the coast. In Manchuria, according to Komarov, it grows throughout the mountain forests, extending westward to the valleys of the Chun-dsien⁴ and Sungari rivers, and southwards to the middle valley of the Yalu river; often growing in extensive forests mixed with *Picea ajanensis*, *Abies holophylla*, and many species of deciduous trees, between 500 and 5000 ft. altitude. It attains a great size, up to 150 ft. in height, and the wood is highly valued by the Chinese settlers in Manchuria, and is exported for making coffins and for building purposes. Timber which we believe to be of this tree, resembling that of *P. Cembra*, has lately been imported from Nikolaievsk to London, and is considered likely to serve as a good substitute for the wood of *P. Strobus*, if it can be procured in quantity of a good size. In Korea the pine attains its southern limit in the district of Kang-ge, and was seen by Mr. J. H. Veitch in 1892 wild in various localities, notably in the Diamond mountains, where it is very abundant.⁵ The seeds, which are much used by the Koreans, have been sent to Kew by Consul Carles. They are known to the Chinese in the north as *Hai-sung-tze*.

This tree was long believed by the Japanese⁶ to be an exotic in Japan, brought from Korea by the soldiers who invaded that country. It is now known to be a native of the great forests of central Japan, where it usually grows mixed with deciduous trees, and occasionally ascends into the higher region of firs and spruces. Mayr saw large trees wild in Kiso and in the virgin forests of the mountains of Kotzuke. It is largely planted in Japan as an ornamental tree, the finest specimens

¹ *Gard. Chron.* i. 710 (1887).

² This species has been erroneously supposed to grow in Kamtschatka and the Karagin Island, where the only pine known is *P. pumila*, Regel. Cf. Maximowicz, *Mit. Biol.* xi. 349 (1881).

³ *P. koraiensis* is erroneously stated to be a native of China in Veitch's *Man. Conifera*, 335, in *Gard. Chron.* xxxiii. 34 (1903), *Journ. Bot.* 1903, p. 269, etc. Beissner's record of it from Shensi is also incorrect. Cf. synonymy given under *P. Armandi*.

⁴ An affluent of the Yalu.

⁵ Kent, Veitch's *Man. Conifera*, 335 (1900).

⁶ It is known in Japan as *Chosen-matsu*, i.e. Korean pine.

being reputed to be those in a temple grove at Chusenji near Nikko, which measure about 100 ft. in height and 10 ft. in girth, with clean stems of 30 to 40 ft.

CULTIVATION

This tree was introduced in 1861 from a Japanese nursery by J. Gould Veitch.¹ It appears to be perfectly hardy, but rather slow in growth. The best specimens known to us are growing in Ireland—one at Fota, which was, in 1903, 32 ft. high, with a girth of 2 ft. 2 in.; and another at Kilmacurragh, 40 ft. by 2 ft., in 1907, when it bore cones. A tree at Bicton, 34 ft. high by 2 ft. in girth in 1908, has produced cones, with fertile seed, from which a seedling was raised three years ago. A good specimen at Highnam, about 25 ft. high, was bearing cones in March 1910. Another at Grayswood, planted in 1882, is 24 ft. by 1 ft. 4 in.; and one at Tregrehan is 20 ft. by 1 ft. We know of none in Scotland.²

At Segrez in France there is a fine specimen, which in 1904 was 40 ft. high and 4 ft. in girth. It has peculiar epicormic branches on the trunk, and bears cones and good seeds, from which plants have been raised. At Ansorge's nursery, Flottbeck, near Hamburg, there is a tree 25 ft. high, which has produced fertile seed.

It is perfectly hardy in New England,³ and on account of its dense foliage is very ornamental. It produces freely cones and good seeds. The finest specimen, which is growing in Mr. Hunnewell's pinetum at Wellesley, Massachusetts, was 38 ft. high in 1905, and was bearing cones when I saw it in 1906. (A. H.)

PINUS ARMANDI

Pinus Armandi, Franchet, *Plantae Davidianae*, i. 285, pl. 12 (1884), and in *Journ. de Bot.* xiii. 254 (1899); Beissner, in *Mit. deut. dend. Ges.* 1896, p. 68, *Nuov. Giorn. Bot. Ital.* iv. 184, t. 5, f. 2 (1897), and *Bull. Soc. Bot. Ital.* 1899, p. 310; Masters in *Journ. Linn. Soc. (Bot.)* xxvi. 549 (1902), xxxv. 582 (1904), in *Gard. Chron.* xxxiii. 66, figs. 30, 31 (1903), and in *Journ. Bot.* 1903, p. 269; Clinton-Baker, *Illust. Conif.* i. 6 (1909).

Pinus Armandi, Franchet, var. *Mastersiana*, Hayata, in *Tokyo Journ. Coll. Science*, xxv. 216, fig. 8 (1908).

Pinus quinquefolia, David, *Voyage en Chine*, i. 192 (1875), and in *Nouv. Archiv. Muséum*, vii. 95 (1884).

Pinus scipioniformis,⁴ Masters, in *Bull. Herb. Boissier*, vi. 270 (1898).

Pinus koraiensis, Masters, in *Gard. Chron.* xxxiii. 34, figs. 18, 19 (1903), in *Journ. Bot.* xli. 269 (1903), and in *Journ. Linn. Soc. (Bot.)* xxxv. 582 (1904) (in part); Beissner, in *Bull. Soc. Bot. Ital.* 1899, p. 310; Diels, *Flora von Central-China*, 215 (1901). (Not Siebold et Zuccarini.)

Pinus Mastersiana, Hayata, in *Gard. Chron.* xliii. 194 (1908).

A tree, attaining 60 ft. in height, with smooth and greenish bark. Buds cylindrical, obtuse, either non-resinous and bristly with free long-pointed scales, or

¹ *Gard. Chron.* 1861, p. 1114; *Hortus Veitchii*, 90 (1906).

² The tree at Ochertyre, reported in *Journ. Roy. Hort. Soc.* xiv. 534 (1892) as being 13 ft. in height in 1891, cannot now be found, and may have been wrongly named.

³ *Garden and Forest*, 1897, p. 296.

⁴ This species is based on a specimen of *P. Armandi*, with young cones, collected by myself. The aberrant position of the resin-canals in some of the leaves, noticed by Masters, is not unusual. Cf. Franchet, *Journ. de Bot.* loc. cit.

resinous with appressed scales. Young branchlets smooth, olive green, glabrous or with minute scattered hairs, becoming dark grey in the second year. Leaves in fives, spreading, and often bent as in *P. excelsa*, 4 to 6 in. long, green on the convex surface, conspicuously white with stomatic lines on the two flat surfaces, serrulate; resin-canals usually median; basal sheath and scale-leaves early deciduous.

Staminate flowers cylindrical, $\frac{3}{4}$ in. long, yellow, with spatulate scarious scales at the base.

Cones sub-terminal, on stalks about an inch long, pendulous or spreading, cylindrical, but tapering to an obtuse apex, 4 to 7 in. long, 2 to 3 in. in diameter. Scales rigid, woody, about $1\frac{1}{4}$ in. long and 1 in. broad; concealed part broadly triangular, reddish brown; apophysis triangular, yellow, tipped with a minute brown mucro; apex of the scale rounded and not reflexed, or shortly cuspidate and slightly reflexed. Seed edible, wingless, $\frac{1}{2}$ in. to $\frac{5}{8}$ in. long, mottled black on the convex surface, dark brown on the flatter surface, girt all round with a very narrow sharp ridge.¹

This species² is variable in the size of the cones, and in the shape of the scales, which are, however, never so much reflexed at the apex as in *P. koraiensis*. The foliage resembles that of *P. excelsa*; but the resin-canals are marginal in the latter species. The grey-coloured branchlets, which are either glabrescent, or show under the lens a very scattered minute pubescence, are characteristic of *P. Armandi*; and are very different from the glaucous glabrous branchlets of *P. excelsa*, or the reddish brown tomentose branchlets of *P. koraiensis*.

This species is widely spread throughout the mountains of western China, at elevations of 4000 to 6000 ft., from lat. 34° in Shensi to lat. 23° in Yunnan. It usually grows on wooded cliffs or on rocky situations, scarcely ever forming pure woods, and seldom attaining more than 50 ft. in height and 6 ft. in girth. The wood is used for building and for the coarser kinds of furniture; and the edible seeds are sometimes sold in the markets. It is called *kuo-sung* (fruit-pine) in Yunnan, and *ts'ung* or *niu-sung* (cow-pine) in Hupeh. It is one of the remarkable discoveries made by Père David in his third journey through China in 1873, when he first saw it in the Tsin-ling range, south of the Yellow River in Shensi, where it has since been collected by Père Giraldi. It was subsequently found by Père Delavay and myself in Yunnan and Hupeh, and by Père Farges, von Rosthorn,³ and Wilson in Szechwan.

This species has lately been discovered by several Japanese botanists in Formosa, where it grows on Mount Morrison at altitudes ranging from 8000 to 10,600 ft. The Formosan tree bears cones with scales slightly reflexed at the tip, as is commonly the case in Yunnan specimens, and on that account has been distinguished as a variety⁴ by Hayata.

Père Farges sent seeds of this species in 1895 to M. Maurice L. de Vilmorin,

¹ This rim-like margin is absent in the seeds of *P. koraiensis*.

² Some of Père Giraldi's specimens, which I saw in the museum of Florence, have been considered by Beissner to be *P. koraiensis*, on account of their short leaves; but in the branchlets, cones, and seeds they are indistinguishable from *P. Armandi*.

³ Diels, *Flora von Central-China*, 216 (1901).

⁴ Var. *Mastersiana*, Hayata, in *Tokyo Journ. Coll. Science*, xxv. 216, fig. 8 (1908); *Pinus Mastersiana*, Hayata, in *Gard. Chron.* xliii. 194 (1908).

who informs me that the largest specimen raised from this introduction is growing at Harcourt (Eure), and is now about 8 ft. high, and producing annual shoots about a foot in length. There are smaller trees at Les Barres and Verrières. There are also specimens of the same origin at the Arnold Arboretum, and some of these sent by Professor Sargent in 1902 to Kew are only about $2\frac{1}{2}$ ft. in height. A tree from the same source planted at Colesborne in 1905 has gradually pined away, possibly on account of the limy soil.

The finest specimens of this species in cultivation are seven trees at Kew, which were raised from seed sent by me from Mengtse in Yunnan in 1897. They are 10 to 15 ft. high; and three of them bore fully developed cones in 1909. Wilson¹ sent seeds from Hupeh to the Coombe Wood Nursery in 1900, and the seedlings raised are about $2\frac{1}{2}$ ft. high and very flourishing. *P. Armandi* promises to be a valuable ornamental tree. (A. H.)

PINUS PUMILA

Pinus pumila, Regel, in *Cat. Sem. Hort. Petersb.* 23 (1858), and in *Bull. Soc. Nat. Mosc.* xxxii. 1, p. 211 (1859); Mayr, *Abiet. jap. Reiches*, 80, 103, t. vi. fig. 21 (1890); Komarov, *Fl. Mansh.* 189, 190, 214 (1901); Clinton-Baker, *Illust. Conif.* i. 46 (1909).

Pinus pygmaea, Fischer, ex Endlicher, *Syn. Conif.* 142 (1847).

Pinus Cembra, Linnæus, var. *pumila*, Pallas, *Flora Rossica*, i. 3 (1784); Kent, Veitch's *Man. Conif.* 318 (1900).

Pinus Cembra, Linnæus, var. *pygmaea*, Loudon, *Arb. et Frut. Brit.* iv. 2276 (1838); Fischer, in Middendorf, *Reise, Flora Ochot.* 88 (1856).

Pinus mandshurica, Murray, in Lawson, *Pin. Brit.* i. 61 (1884). (Not Ruprecht.)

A shrub, usually prostrate, and rarely if ever exceeding 10 ft. in height. Buds resinous, about $\frac{1}{4}$ in. long, cylindrical-conic, ending in a sharp-pointed apex; scales reddish brown, closely appressed. Branchlets covered with a dense brown tomentum. Leaves closely crowded on the branchlets and directed forwards, parallel with them, in fives, those in each cluster appressed together, incurved, $1\frac{1}{2}$ to 2, rarely 3 in. long, white with stomatic lines on the two inner surfaces, entire or faintly serrulate² in margin; resin-canals marginal; basal sheath entirely deciduous.

Cones never opening, sub-sessile, about $1\frac{1}{2}$ in. long and 1 in. in diameter, ovoid, often curved, reddish or orange brown when ripe; scales few, about $\frac{1}{10}$ in. broad, concave interiorly with a partition between the cavities for the seeds, upper edge sharp and bevelled; umbo terminal, darker in colour than the rest of the apophysis, ending in a minute, thickened, triangular, reflexed tip. Seed about $\frac{1}{4}$ in. long, pear-shaped, convex on the lower, and flattened on the upper surface, brownish, wingless, edible.

¹ Cf. *Hortus Veitchii*, 343 (1906). Seeds of this species, erroneously ascribed to *P. koraiensis*, were sent by Wilson in 1899 from Ynanchiang in Yunnan, but do not appear to have germinated. Kent, in Veitch's *Man. Conifera*, 335 (1900), also erroneously considers the Yunnan tree to be *P. koraiensis*.

² Specimens from Japan show both entire and serrulate leaves. Those from other regions have apparently always entire leaves. The cones are identical.

This pine, which always remains a shrub, is distinct from *P. Cembra*, in the small size and different shape of the cones and seeds, and in the position of the resin-canals in the leaves, which are shorter, and entire or serrulate in margin.

It is widely spread¹ in eastern Asia, occurring in Kamtschatka, Siberia to the eastward of Yakutsk, Amurland, northern Russian Manchuria, Saghalien, Kurile Isles,² and Japan. It is a native of very cold regions, growing as a dense scrub on wind-swept plateaux or on mountains close to the snow-line. In Kamtschatka³ and the Kurile Isles to the north of Urup, it thrives where no other pine is known, at elevations little above sea-level. In Iturup it grows between 1000 and 3000 ft. elevation, and in Yezo at over 3000 ft. In central Hondo it is confined to mountain peaks over 7000 feet elevation, and is often seen in the vicinity of sulphur springs, the poisonous exhalations of which it bears without injury.

It is known to the Japanese as *Hai-matzu*, and to the Ainus as *Todonup* or *Henekkeri*; and its seeds⁴ are much esteemed by the natives of the Kurile Isles as an article of diet.

This species appears to have been early introduced into St. Petersburg from eastern Siberia; and Loudon mentions a plant at Dropmore which was only 6 in. high in 1837, though twenty years old, and had increased to 8½ in. in height in 1866 when it was examined by Murray. The latter procured seeds for sowing in this year from Regel, but we have not found any specimens now living in England.

Specimens with cones and seeds have lately been sent home by Capt. L. Clinton-Baker, R.N., who procured them from Nyoho San, near Nikko, at 8000 ft. elevation; and two plants⁵ from this locality have been planted at Bayfordbury.

(A. H.)

PINUS FLEXILIS

Pinus flexilis, James, in *Long's Exped.* ii. 34 (1823); Murray, in *Gard. Chron.* iii. 106, and iv. 356 (in part), f. 75 (1875); Sargent, *Silva N. Amer.* xi. 35, tt. 546, 547 (1897), and *Trees N. Amer.* 7 (1905); Kent, *Veitch's Man. Coniferae*, 330 (1900); Masters, in *Journ. Linn. Soc. (Bot.)* xxxv. 589 (1904); Clinton-Baker, *Illust. Conif.* i. 21 (1909); Shaw, *Pines of Mexico*, 12 (1909).

A tree, usually 40 to 50, occasionally 80 ft. high, with a short trunk 6 to 15 ft. in girth. Bark of young stems and branches thin, smooth, grey or silvery white; becoming on old trunks 1 or 2 in. thick, dark brown, and deeply fissured into broad, scaly ridges. Branches very tough and flexible. Buds ovoid, short-pointed, ⅜ in. long, resinous, with the scales appressed or free at their subulate tips. Young branchlets glabrous or covered by a minute dense brown pubescence.

¹ It is said by Masters, in *Journ. Linn. Soc. (Bot.)* xviii. 505 (1881), to have been found on the bay of Kotzebue in Alaska, but we have been unable to confirm this report.

² Miyabe, *Flora of the Kurile Isles*, 261 (1890).

³ This species was early mentioned by Abbé Chappe d'Auteroche, who, in *Voyage en Sibérie*, i. 360 (1768), says that little cedars, creeping on the ground and never growing upright, are found on the mountains and moss-covered plains of Kamtschatka. The inhabitants gather large quantities of the seed for food, and make a drink, something like *kwass*, by boiling and fermenting the young shoots, considered to be a cure for scurvy.

⁴ Batchelor and Miyabe, *Ainu Economic Plants*, 230 (1893).

⁵ One of these plants is figured in *Gard. Chron.* xlv. 93, fig. 41 (1909).

Leaves in fives, persistent for five or six years, densely crowded on the branchlets, directed forwards, 2 to 3 in. long, stout, rigid, curved, scarcely twisted, entire¹ in margin, sharp-pointed, marked on the three surfaces with three or four stomatic lines; resin-canals marginal; basal sheath ½ in. long, early deciduous.

Cones sub-terminal, erect when young, spreading in the second year, sub-sessile, 3 to 5, rarely 10 in. long,² ovoid-cylindrical; scales³ opening and spreading horizontally when mature, about 1 in. long and ¾ in. wide, obovate, with the upper margin reflexed; apophysis thickened, brown, tipped with a triangular umbo. Seed ovoid, compressed, ⅓ to ½ in. long, brownish, angled on the lateral and upper margins; wing rudimentary, about ⅓ in. long, lacerated when the seed falls.

This species is distinguished from all the cultivated five-leaved pines with a completely deciduous leaf-sheath, except *P. pumila*, by the leaves being entire in margin. The latter species, which in its continental form has also non-serrulate leaves, is readily distinguishable from *P. flexilis* by the shaggy reddish brown tomentum on its young branchlets.

VARIETY

Shaw considers the following to be a variety of this species:—

Var. reflexa, Engelmann, in Rothrock, *Rep. Geol. Surveys*, vi. 258 (1878).

Pinus reflexa, Engelmann, in *Bot. Gazette*, vii. 4 (1882); Mayr, *Fremdländ. Wald- u. Park-bäume*, 388 (1906).

Pinus strobiformis, Sudworth, *U.S. Forestry Bull.* No. 14, p. 17 (1897) (not Engelmann⁴); Sargent, *Silva N. Amer.* xi. 33, tt. 544, 545 (1897), and *Trees N. Amer.* 6 (1905).

This differs from the type in the much reflexed, usually thin cone-scales. The leaves, either entire or serrulate in margin, are with or without stomatic lines on the back. It was found in northern Chihuahua in Mexico by Pringle in 1887, and seems to be intermediate between *P. flexilis* and *P. Ayacahuite*, though all the cones seen by Shaw resembled those of *P. flexilis* in size and general appearance. According to Sargent, this pine attains 80 to 100 ft. in height, and is scattered singly, or in small groups, on rocky ridges of the Santa Catalina, Chiracahua, and Santa Rita mountains of southern Arizona, and on the Sierra Madre of Chihuahua in Mexico. It has not been introduced.

DISTRIBUTION AND CULTIVATION

This species is widely distributed on the eastern slope of the Rocky Mountains⁵ from Alberta to Texas, and occurs also in the mountains of northern Arizona, Utah,

¹ In rare cases the leaves are slightly serrulate, and have been distinguished as *var. serrulata*, Engelmann, in Rothrock, *Wheeler's Report*, vi. 258 (1878).

² Cones of abnormal length, in addition to those of the ordinary size, are produced on trees growing in the San Francisco mountains of northern Arizona; and have been distinguished as *var. macrocarpa*, Engelmann, in Rothrock, *Wheeler's Report*, vi. 258 (1878).

³ Shaw, *loc. cit.*, says: Scales straight or reflexed, and variable in thickness.

⁴ *P. strobiformis*, Engelmann, is a variety of *P. Ayacahuite*.

⁵ In the Rocky Mountains of Canada *P. flexilis* is found only on the margins of the rivers issuing from the mountains. Cf. Macoun, in *Trans. R. Soc. Canada*, xii. 4, p. 13 (1894).

Nevada, and south-eastern California, where it reaches the western side of the Sierra Nevada at the head of King's River. It occupies the sub-alpine zone, usually growing singly or in small groups, but forming open forests on the eastern foot hills of the Rocky Mountains in Montana and on the ranges of central Nevada. At low elevations it is associated with *P. contorta*, var. *Murrayana*, and at higher altitudes in the southern part of its area is often scattered with *P. aristata*. In Colorado, according to Engelmann, it has a tapering trunk, branching almost from the base, and attaining, at 200 or 300 years old, a diameter of one foot. It is largest in size in Arizona and in northern New Mexico, where Fendler saw it 60 to 80 ft. in height.¹ In the Sandia Mountains² in this state it ascends to 12,000 ft.; but in the north is restricted to elevations of 4000 to 6000 ft. It also occurs in a limited area in northern Mexico, where it was collected in Coahuila by Nelson. Sargent figures³ a fine tree, growing in the Yellowstone Park, at 7000 ft. elevation, which was 5 ft. in diameter.

P. flexilis was discovered in 1820 by Dr. Edwin James, near the base of Pike's Peak in Colorado. Plants³ were raised in the Harvard Botanic Garden from seeds collected in Colorado by Dr. Parry in 1861, but after thirty-five years' growth were not more than 5 ft. high with tufts of stunted foliage on the ends of naked branches. There are three trees in Kew Gardens, probably of the same origin, growing near the Isleworth gate, one of which produced cones⁴ for the first time in 1896, when it was 25 ft. high and 2 ft. in girth. This tree produces fruit every year, and is now 32 ft. by 2 ft. 10 in. At Highnam, a specimen, about 20 ft. high, has borne cones. There are also two trees at Terling Place, Essex, the origin of which is unknown. Both were bearing cones in 1907, the larger measuring 32 ft. by 2 ft. 4 in. They have smooth green bark and ascending branches. There are four trees about 15 ft. high at Westonbirt which are not thriving. Elwes saw a small tree at Murthly in 1906.

(A. H.)

PINUS ALBICAULIS, WHITE-BARK PINE

Pinus albicaulis, Engelmann, in *Trans. St. Louis Acad.* ii. 209 (1863); J. D. Hooker, in *Gard. Chron.* xxiv. 9, f. 2 (1885); Sargent, *Silva N. Amer.* xi. 39, t. 548 (1897), and *Trees N. Amer.* 8 (1905); Kent, Veitch's *Man. Coniferae*, 310 (1900); Masters, in *Journ. Linn. Soc. (Bot.)* xxxv. 588 (1904).

Pinus flexilis, Balfour, *Bot. Exped. Oregon*, 1, t. 2, f. 1 (1853) (not James).

Pinus flexilis, James, var. *albicaulis*, Engelmann, in Brewer and Watson, *Bot. California*, ii. 124 (1880).

Pinus Shasta, Carrière, *Conif.* 390 (1867).

A tree, attaining 80 ft. in height and 12 ft. in girth, usually smaller, and becoming at very high elevations a low shrub.⁵ Bark of young trees white or pale grey, smooth; on old trees remaining thin and scaling in small polygonal plates. Young

¹ *Trans. St. Louis Acad. Science*, ii. 208, 209 (1863).

² *Garden and Forest*, x. 162, fig. 19 (1897).

³ *Ibid.* 461.

⁴ *Garden*, li. 73 (1897).

⁵ On high cold sites, as in northern Montana, where I saw this pine in 1906, it dwindles in size till at absolute timber line it is prone on the ground in the depressions of the rock, with matted branches and a stem less than a foot in height.

branchlets reddish brown, with a scattered minute stiff pubescence. Leaves similar to those of *P. flexilis*, persisting five to eight years.

Cones sub-terminal, sessile, spreading, never opening, ovoid, 1½ to 3 in. long, dark purple when growing, light brown when mature; scales much thickened, very brittle at their base, ¾ in. long, ⅝ in. broad, many undeveloped and unfertile; apophysis triangular, ending in a sharp-pointed umbo. Seed, ⅓ to ½ in. long, ovoid, more or less compressed, pointed at the apex, pubescent; wing rudimentary or absent.

In the absence of cones, this species is best distinguished from *P. flexilis* by the minute scattered stiff hairs on the reddish brown branchlets. The young branchlets of *P. flexilis* are either quite glabrous or covered with a soft fine tomentum.

This species is more alpine in distribution than *P. flexilis*, forming the timber line on many mountain ranges from lat. 53° in Alberta and British Columbia,¹ southward along the Rocky Mountains to the Yellowstone plateau, and through Washington and Oregon in the Cascade and Blue mountains, and in California, along the Sierra Nevada to the San Bernardino mountains. It reaches an elevation of 5000 ft. in the north, and 12,000 ft. in the south. This species² endures great seasonal ranges of temperature from -60° to 100° Fahr.; severe winds and a very short growing season being characteristic of its habitat. It is probably the least exacting of all conifers as regards both soil and moisture—the annual precipitation, a large proportion of it in the form of snow, sometimes being as little as 15 in.

In north-western Montana this species³ does not cross the continental divide, and grows at elevations between 6000 and 8000 ft., usually in scattered groves, either pure or mixed with *Picea Engelmanni* and *Abies lasiocarpa*. It is often seen on high exposed ridges, and strongly resembles *P. Cembra* in general appearance, being often irregularly branched and with a flattened crown of foliage. The largest tree (Plate 276) measured by me on Mount Nicholas, and photographed by Prof. Elrod, was 84 ft. high and 9 ft. 2 in. in girth.

Sir Joseph Hooker describes and figures⁴ this tree on Mount Shasta, where the trunk becomes scored and polished by the sand blasts. Elwes saw it here in 1904 at about 7000 to 8000 feet elevation.

The most remarkable feature of this pine, in which it resembles *P. Cembra*, is that the cones never open, the seeds being distributed by squirrels, who readily break off the scales, which are very brittle towards the base.

P. albicaulis was discovered⁵ on the mountains rising above the valley of the lower Fraser river, near Fort Hope, in 1851 by John Jeffrey, who sent seeds from Mount Shasta, California, in 1852, to Scotland, from which a few plants were raised, but none of these appear to have survived. The only specimens we know in cultivation are seedlings at Kew about 6 in. high.

The timber when accessible is used by miners for props, fuel, and sleepers.

(A. H.)

¹ Dawson, in *Canad. Naturalist*, ix. 328 (1881) says: "In the coast or Cascade ranges as far north as the Iltsayouco river (lat. 53°)."

² Cf. *U.S. Syltical Leaflet 37, White Bark Pine* (1908).

³ It occurs also in the Helena National Forest in Montana.

PINUS BUNGEANA

Pinus Bungeana, Zuccarini, *ex* Endlicher, *Syn. Conif.* 166 (1847); Murray, *Pines and Firs of Japan*, 18 (1863); Hance, in *Journ. Linn. Soc. (Bot.)* xiii. 87 (1873); Maximowicz, *Mél. Biol.* xi. 348 (1881); Masters, in *Gard. Chron.* xviii. 8, figs. 1, 2 (1882), in *Journ. Linn. Soc. (Bot.)* xxvi. 549 (1902), and xxxv. 590, pl. 23, fig. 10 (1904); Lavallée, *Arbor. Segrezianum*, 111, t. 32 (1885); Kent, Veitch's *Man. Coniferae*, 316 (1900); Mayr, *Fremdländ. Wald- u. Parkbäume*; 372 (1906); N. E. Brown, in *Bot. Mag.* t. 8240 (1909); Clinton-Baker, *Illust. Conif.* i. 11 (1909).

Pinus excorticata, Lindley and Gordon, in *Journ. Hort. Soc.* v. 217 (1850).

Pinus Napoleoni, Simon, in *Bull. Soc. d'Acclim.* 1863, p. 281.

A tree, attaining in China 80 to 100 ft. in height, and 12 ft. in girth. Bark on young trees dark brown, smooth, and scaling off in thin flakes, exposing the whitish inner cortex; in old trees white¹ externally, as if washed with lime and marked by inconspicuous scattered brown lenticels; on the inner surface it is fawn-coloured and covered with minute resinous depressions. Buds spindle-shaped, brown, about $\frac{3}{8}$ in. long, slightly resinous; external scales few, lanceolate, acuminate, free at the tips. Young branchlets glabrous, greenish, with slightly raised pulvini, which disappear in the second year, leaving the surface smooth and greyish green.

Leaves in threes, with the basal sheaths entirely deciduous early in the first year, remotely placed on the branchlets, persisting three or four years, about 3 in. long, rigid, curved, serrulate, sharp-pointed, marked with stomatic lines on the three surfaces; fibro-vascular bundle undivided; resin-canals four, marginal.

Staminate flowers in a loose spike, about 4 in. long; each flower $\frac{1}{4}$ in. long, girt at the base by ovate-triangular acute bracts.

Cones, solitary or in pairs, sub-terminal, though often becoming apparently lateral by the growth of a summer shoot, on stout short stalks; globose-ovoid, 2 to 2 $\frac{1}{2}$ in. long; scales small at the base of the cone and unfertile, well-developed in the centre and about $\frac{7}{8}$ in. long and $\frac{1}{2}$ in. broad; apophysis brown, rhomboidal, with a transverse ridge near the upper margin; the narrow umbo terminating in a short triangular spreading or reflexed prickle. Seeds, one or two on each scale, brownish, pear-shaped, $\frac{3}{8}$ in. long, $\frac{1}{4}$ in. wide and thick, the testa produced into a narrow rim on each side and a short lacerated wing above, deciduous when the seed falls, incapable of flight, out of the cone.

This remarkable pine occurs wild in the mountains of northern China, where Mayr observed it growing on stony slopes; and it has recently been found by Wilson² south-west of Ichang in Hupeh, on precipitous mountains at an altitude of 2000 to 4000 ft. He saw many hundreds of trees scattered for miles, evidently the remains of a considerable forest. Many of these trees were curved at the butt, a few being branched near the ground. It was also collected in northern Shensi, by Père Giraldi,³ who reports it to be a rare tree 30 to 40 ft. high. It

¹ Mayr states that the bark is dazzling whitish-blue on the sunny side of the tree and greenish-white on the shady side. The name "lace-bark pine" occasionally given to the species is inappropriate.

² *Gard. Chron.* xli. 422 (1907).

³ Note in Botanical Museum at Florence.

was formerly only known as a tree cultivated around temples, as at Peking, Shanghai, and other localities in central and northern China. It is known to the Chinese as *pai-sung*, "white pine," or *pai-kuo-sung*, "pine with a white bark." *Chiu-lung-sung*,¹ the pine of the nine dragons, cited as the Chinese appellation by Endlicher, is the name given to a single tree of this species, standing in the celebrated temple of Tieh-tai-sze, near Peking; and was so named by the Emperor Chien Lung, who admired its nine tall stems. As usually seen in cultivation in China, the tree has a short trunk, sometimes 12 ft. in girth, dividing at a few feet from the ground into several upright stems, which, in the oldest examples, attain a height of 80 to 100 ft. Fortune² gives a good picture illustrating this peculiar habit. Wilson says that the wood is brittle, and only used for fuel. The seeds do not appear to be eaten by the Chinese.

P. Bungeana was discovered at Peking by Dr. A. Bunge in 1831, and Zuccarini's description was based upon his specimens. Fortune introduced this pine into cultivation in England in 1846; and young plants reared from seed sent by him were growing in 1857 in Glendinning's nursery, Turnham Green.³ Murray reported in 1863 that specimens about 5 ft. high had withstood without injury the severe winter of 1860. Simon⁴ sent young plants to Paris from Peking in 1862.

No trees in cultivation in Europe are as yet old enough to show the beautiful white bark which renders this pine so remarkable at Peking. As a small tree, however, it is fast in growth, ornamental and distinct in habit owing to its vivid green foliage, and is worthy of a place in all collections. The largest specimen known to us is growing at Pampisford, Cambridge, and is about 30 ft. high, dividing into four slender stems near the ground; but it has been retarded in growth by the crowding of other trees. At Kew, where there are several very healthy specimens, which have produced cones for several years, the tree either assumes an erect pyramidal habit or is rounded and bushy in appearance. The largest tree is 25 ft. high and 23 in. in girth at three feet from the ground. Small trees bearing cones also exist at Flitwick, Highnam, and Tregrehan.

At Messrs. Simon-Louis' nursery⁵ near Metz, it grows well on calcareous soil and ripened seed when only 12 ft. high. Mayr says that it is perfectly hardy at Grafrath, near Munich, where the winters are very severe.

It is very hardy in eastern Massachusetts, where, though it still retains a bushy habit, cones are produced in abundance. The largest specimen in the United States is growing in Mr. Josiah Hoopes' pinetum at West Chester, Pennsylvania.⁶

PINUS GERARDIANA, GERARD'S PINE

Pinus Gerardiana, Wallich, *ex* Lambert, *Genus Pinus*, ii. 145, t. 79 (1832); Loudon,¹ *Arb. et Frut. Brit.* iv. 2254 (1838); Royle, *Illustr. Him. Plants*, 353, t. 85, f. 2 (1839); Forbes, *Pinetum Woburnense*, 53, t. 19 (1839); Cleghorn, in *Journ. Agric. Hort. Soc. India*, xiv. 266, t. 4 (1867); Hooker, *Fl. Brit. India*, v. 652 (1888); Kent, Veitch's *Man. Coniferae*, 331 (1900); Gamble, *Indian Timbers*, 709 (1902); Masters, in *Journ. Linn. Soc. (Bot.)* xxxv. 590 (1904); Brandis, *Indian Trees*, 690 (1906); Clinton-Baker, *Illustr. Conif.* i. 22 (1909).
Pinus Gerardi, Forbes, *Hort. Woburn.* 210 (1833).

A tree, attaining 80 ft. in height and 12 ft. in girth. Bark thin, grey, with scattered brown lenticels, exfoliating in irregular scales, which leave shallow brownish depressions, dotted over with minute holes.

Buds about $\frac{3}{8}$ in. long, conic, acuminate; scales appressed and resinous. Young branchlets glabrous, olive green, with prominent pulvini, which are less marked in following years. Leaves in threes, more crowded on the branchlets, duller in colour, and less rigid than those of *P. Bungeana*, straight or slightly curved, 3 to 4 in. long, serrulate, sharp-pointed, marked with stomatic lines on the three surfaces; fibro-vascular bundle undivided, resin-canals marginal; basal sheaths loose, $\frac{1}{2}$ in. long in the first year and completely deciduous in the second year.

Cones, on short scaly peduncles, subterminal, broadly ovoid, variable in size, 4 to 9 in. long, and 3 to 5 in. in diameter; scales $1\frac{1}{2}$ in. long, 1 in. broad, very thick and woody; apophysis triangular, reflexed downwards at nearly a right angle, and ending in a swollen umbo, which is often tipped with a recurved spine. Seed cylindrical, $\frac{5}{8}$ to 1 in. long, edible; rudiment of the wing present as a narrow deciduous border, remaining on the scale when the seed falls.

Gerard's pine is a native of the western Himalayas, extending eastward to the Niti Pass in Garhwal, and occurring also in the mountains of Baluchistan, northern Afghanistan, Kafiristan, and in the Hariab district. It grows in the inner arid valleys, beyond the reach of the south-west monsoon, never forming dense forests, but occurring in isolated groups on dry steep rocky slopes, especially on granite and slate formations; and ranges between 6000 and 11,000 ft. elevation. Thomson² describes it as a compact small tree, with twisted ascending branches and a mottled grey bark, smooth on account of the shedding of the outer layers. Aitchison³ speaks of it as a very handsome tree, branching more like an oak than a pine, and readily distinguished at a distance by its ashy grey bark, which on close examination consists of patches of all tints from light green to red and brown, due to the peculiar way in which it exfoliates.

According to Gamble, its growth is moderate, about 13 rings per inch of radius. The wood is tough, and used for the hook supporting the passenger's seat on the native rope bridges; but the tree is hardly ever felled as it is very valuable on

¹ Loudon cites as synonyms, *P. Neoza*, Govan, and *P. Chilghoza*, Elphinstone, MS. names without description; and it is doubtful whether they were applied to this species or to *P. longifolia*.

² *W. Himalaya and Tibet*, 74.

³ *Journ. Linn. Soc. (Bot.)* xviii. 98 (1881).

account of its edible seeds. These are known as *neoza* or *chilghoza*, and are an article of food in Kunawar and other parts of the Himalayas, being largely imported into the plains of India from the hills of the Punjab and Afghanistan. They are oily, with a slight flavour of turpentine, and are eaten roasted at dessert by Europeans. The bark is made into baskets and water buckets.

The forests of this pine in the Shinghar and Sherghali hills, in north-eastern Baluchistan, and on the adjoining Suliman range and the Maidan plateau, in the North-west Frontier Province of India, have been fully described¹ by Mr. E. P. Stebbing. In his account, which is accompanied by excellent illustrations of fine isolated trees and of scattered woods on the arid slopes of the mountains, Mr. Stebbing says that the species is here seen at its best, trees with fine straight stems 70 to 85 ft. high and 9 to 12 ft. in girth occurring at 7500 to 8500 ft. elevation. The tree grows on what is apparently solid limestone rock, with the scantiest possible supply of water. The tribesmen collect the cones into heaps, and extract the seeds by setting fire to the mass, which causes the cone-scales to gape asunder. Occasionally the tree is tapped for resin.

It was first introduced² into England by Lord Auckland, who sent seeds in 1839 to the Horticultural Society, from which plants were raised in the Chiswick Garden.

The tree has never thriven in this country, and is the rarest of all pines in cultivation, the only specimen, exclusive of nursery plants, that we know of in England being a tree, about 15 ft. high, in the Cambridge Botanic Garden, which is probably over thirty years old. In Ireland there is also a single specimen, growing in Lord Ardilaun's grounds at St. Anne's, near Dublin. It measured, in 1903, 25 ft. high and 1 ft. 9 in. in girth, and is pyramidal in habit, with mostly ascending branches. According to Mr. Campbell, the gardener at St. Anne's, it was about 5 ft. high in 1870. Seedlings planted out in 1908 endured the severe winter at Colesborne, with a slight protection of branches, and are now growing slowly.

This species has lived out of doors at Grafrath,³ near Munich, for nineteen years, but has made little growth in height. Elwes saw a tree in the Botanic Garden at Montpellier, which was about 20 ft. high in January 1910. It had produced cones⁴ in the preceding year.

PINUS BALFOURIANA, FOXTAIL PINE

Pinus Balfouriana, Balfour, *Oregon Exped. Report*, 1, t. 3, f. 1 (1853); Murray, in *Gard. Chron.* v. 332, f. 58 (1876); Sargent, *Silva N. Amer.*, xi. 59, t. 553 (1897), and *Trees N. Amer.* 8 (1905); Kent, Veitch's *Man. Coniferae*, 313 (1900); Masters, in *Journ. Linn. Soc. (Bot.)* xxxv. 589 (1904).

A tree, usually 30 to 40 ft. high and 6 ft. in girth, rarely attaining 90 ft. in height and 15 ft. in girth. Bark of young trees thin, smooth, and whitish; becoming on old trunks $\frac{3}{4}$ in. thick, dark red brown, and deeply divided into broad flat scaly ridges. Young branchlets stout, yellowish brown, covered with a minute pubescence. Buds ovoid, acuminate at the apex, about $\frac{1}{4}$ in. long, with closely appressed brownish scales.

Leaves in fives, densely crowded on the branches, persisting ten or twelve years, nearly appressed together in the clusters, incurved, about $1\frac{1}{2}$ in. long, rigid, sharp-pointed, entire in margin, green and shining on the back, whitened with numerous stomatic lines on the inner surfaces; resin-canals marginal; basal sheath speedily splitting into five segments that become reflexed and form a rosette around the base of the leaf-cluster.

Cones sub-terminal, spreading, sessile, cylindrical-conic, $3\frac{1}{2}$ to 5 in. long; scales narrow, elongated; apophysis convex, rhomboidal, transversely keeled, with a minute incurved prickle. Seed pale mottled with violet, $\frac{1}{3}$ in. long; wing narrow and oblique at the apex, about 1 in. long.

This species is confined to California, where it is found on Scott Mountain in Siskiyou County, on the mountains at the head of the Sacramento river, on Mount Yolo Bally, in the northern coast range, and in the southern Sierra Nevada, where it attains its largest size. It occurs at elevations of 5000 to 12,000 ft., often forming the timber line,¹ and growing usually on bare rocky slopes and the summits of ridges, in loose granitic soil. At high elevations it occurs in small pure scattered groves or in mixture with *P. albicaulis*, while at lower levels it is associated with *P. monticola*, *P. contorta*, var. *Murrayana*, and other conifers.

The illustration (Plate 277) is from a photograph by Mr. F. R. S. Balfour in the Sierra Nevada mountains, between King's River and Kaweah River, at an elevation of 9000 to 10,000 ft.

This species was discovered in 1852 on Scott Mountain by Jeffrey, who sent a few seeds to the Oregon Association of Edinburgh. It is rare in cultivation, though specimens of small size are to be seen in the botanic gardens of Kew, Edinburgh, and Glasnevin. At Messrs. Little and Ballantyne's nursery, Carlisle, there is a tree about 20 ft. high, which was planted about thirty years ago. It has never produced a single cone; but large numbers of grafts have been propagated from it. At Welbeck, Elwes saw a small tree about 15 ft. high. (A. H.)

¹ Cf. Pinchot, *U.S. Forest Service, Sylvical Leaflet* 26 (1908).

PINUS ARISTATA, BRISTLE-CONE PINE

Pinus aristata, Engelmann, in *Trans. St. Louis Acad.* ii. 205, pl. 5, 6 (1863); Murray, in *Gard. Chron.* iv. 549, fig. 117 (1875); Sargent, *Silva N. Amer.* xi. 63, t. 554 (1897), and *Trees N. Amer.* 9 (1905); Masters, in *Journ. Linn. Soc. (Bot.)* xxxv. 590 (1904); Clinton-Baker, *Illust. Conif.* i. 5 (1909).

Pinus Balfouriana, Balfour, var. *aristata*, Engelmann, in Brewer and Watson, *Bot. California*, ii. 125 (1880); Webster, in *Gard. Chron.* xx. 719, fig. 126 (1896); Kent, Veitch's *Man. Coniferae*, 314 (1900).

A tree, occasionally attaining 40 to 50 ft. in height, with a short trunk 6 to 9 ft. in girth. Bark, buds, branchlets, and foliage, as in *P. Balfouriana*, though in cultivated specimens the young branchlets of *P. aristata* differ in being covered with a dense reddish brown pubescence; whilst both on wild¹ and cultivated trees of *P. aristata* the leaves are remarkable in being dotted over their outer surface with resinous exudations.

Cones subterminal, spreading, sessile, about 3 in. long, ovoid-conic; scales thin, oblong-cuneate, $\frac{3}{4}$ to 1 in. long; apophysis rhomboidal, transversely keeled, with a slender incurved brittle prickle, nearly $\frac{1}{4}$ in. long. Seed light brown, mottled with black, $\frac{1}{4}$ in. long; wing $\frac{1}{3}$ to $\frac{1}{2}$ in. long.

This alpine species is widely distributed from the eastern range of the Rocky Mountains in Colorado westward through the mountains of southern Utah, and central and southern Nevada, southwards in the San Francisco peaks of northern Arizona, and in the mountains of south-eastern California. It grows on rocky or gravelly slopes, forming the timber line in these mountainous regions at 9000 to 12,000 ft. elevation, and producing a soft light wood, which is occasionally used for fuel and in the mines.

This species was discovered² in 1861 by Dr. Parry on Pike's Peak in Colorado, and plants raised from seed sent by him to Boston had only attained 18 in. in height at the end of thirty-five years.³ Seeds were sent⁴ in 1863 from Colorado to England, and small trees may be seen in botanic gardens, the specimen at Glasnevin, which has produced cones of late years, being about 15 ft. high. The best specimen we have seen in England is one at Hardwick, near Bury St. Edmunds, which is about 25 ft. high by 2 ft. in girth. It was planted by Sir Joseph Hooker, and bore cones in 1905 when Elwes measured it. There is also one at Aldenham about 20 ft. high which bore cones in 1908. There are also specimens at Ponfield, Herts, and at Ochtertyre,⁵ in Perthshire. (A. H.)

¹ Cf. Engelmann, in *Trans. St. Louis Acad.* ii. 206 (1863).

² Murray, in *Gard. Chron.* iv. 549 (1875), says that it was first seen by Captain Gunnison in 1853, near Pike's Peak.

³ *Garden and Forest*, x. 470 (1897).

⁴ *Gard. Chron.* iv. 549 (1875). Gordon, in *Pinetum*, 292 (1875), says that it was first introduced by Mr. Cripps of Tunbridge Wells.

⁵ See Masters, in *Gard. Chron.* xxvi. 371 and 382 (1899).

PINUS MONOPHYLLA, ONE-LEAF NUT PINE

Pinus monophylla, Torrey, in Fremont, *Report*, 319, t. 4 (1844); Masters, in *Gard. Chron.* xx. 48, f. 8 (1883), *Ann. Bot.* ii. 126 (1888), and *Journ. Linn. Soc. (Bot.)* xxvii. 269, f. 10 (1891), xxxv. 584 (1904); J. D. Hooker, in *Gard. Chron.* xxvi. 136, f. 24 (1886); Sargent, *Silva N. Amer.* xi. 51, t. 551 (1897), and *Trees N. Amer.* 12 (1905); Clinton-Baker, *Illust. Conif.* i. 33 (1909).

Pinus Fremontiana, Endlicher, *Syn. Conif.* 183 (1847); Gordon, in *Journ. Hort. Soc.* iv. 293, fig. (1849).

Pinus cembroides, Zuccarini, var. *monophylla*, Voss, in *Deut. Gartenrat*, Beilage 123 (1904); Shaw, *Pines of Mexico*, 5 (1909).

A tree usually 25 to 30 ft., occasionally¹ 40 to 50 ft. high, with a short trunk rarely more than 5 ft. in girth. Bark reddish, divided by deep irregular fissures into narrow connected scaly ridges. Young branchlets slender, grey, with scattered minute pubescence. Buds cylindrical, obtuse, $\frac{1}{4}$ in. long; scales few, closely imbricated, greyish tinged with brown, ovate, apiculate, entire in margin.

Leaves solitary, remotely placed on the branchlets, persistent for four or five years or longer, incurved and directed forwards, rigid, terete, about $1\frac{1}{2}$ in. long, $\frac{1}{16}$ in. in diameter, marked with about twenty stomatic lines, and ending in a sharp cartilaginous point; resin-canals, 3 to 14, marginal. Basal sheath $\frac{1}{4}$ in. long, its upper part deciduous in the first year, while the lower part persists in the following years as an irregular rosette of reflexed segments. According to Dr. Masters, the solitary leaf is due to the arrested development in the bud of one leaf of a two-leaved cluster. Occasionally the second leaf is fully developed, and two-leaved clusters result. In cultivation adventitious shoots bearing flattish primordial leaves are occasionally produced on the lower branches.

Cones sub-terminal, short-stalked, $1\frac{1}{2}$ to 2 in. long; scales few, with a thick pyramidal non-prickly apophysis and a central umbo. Seed edible, about $\frac{5}{8}$ in. long and $\frac{1}{4}$ in. wide, brownish, oblong, full and rounded at the base, acute at the apex, with a thin brittle shell, and a narrow wing, about $\frac{1}{3}$ in. wide, remaining attached to the scale. Cotyledons 7 to 10. The primary flattened leaves, about an inch in length, persist on the seedling till it is about five years old; after which they become shorter, buds forming in their axils and producing the adult leaves.

This species is readily distinguished by its glaucous terete solitary² leaves, with reflexed basal sheaths, and its peculiar buds. When two-leaved clusters appear the leaves are semi-terete and entire in margin.³

This pine is widely distributed, extending from the western base of the Wasatch mountains in Utah, westward through the mountain ranges of Nevada, to the Sierra Nevada in central California, and southwards to Arizona, and the coast ranges of

¹ According to Pinchot, *U.S. Forest Service, Syltical Leaflet* 16 (1908), a few trees have been seen in the Tehachapi mountains, 4 ft. in diameter and nearly 100 ft. in height.

² Solitary leaves occasionally occur as a sport in other pines, as in *P. sylvestris*, var. *monophylla*, but such cases present no difficulty, as the buds, leaves, and basal sheaths are entirely different.

³ Cf. Engelmann, in Rothrock, *Report Geol. Surveys*, vi. *Botany*, 259 (1878).

southern California and of northern Lower California. It grows in a very dry climate, the rainfall varying from 16 in. in the northern part of its area to 5 in. in the southern part, while the temperature is extreme, ranging from a minimum of -2° Fahr. in the Sierra Nevada to a maximum of 122° Fahr. in the Mojave desert. It occurs in arid situations on foothills, gravelly slopes, and rocky elevations, at elevations of 3800 to 6800 ft. in Utah and Nevada, and 4000 to 9500 ft. in the San Bernardino mountains, where the tree is abundant. It usually grows in mixture with other species, but frequently forms pure open woods over large areas. In Arizona it is associated with *Pinus edulis*, *Juniperus monosperma*, *J. pachyphloea*, and *Cupressus arizonica*. In Utah its chief companion is *Juniperus utahensis*, while in southern California it occurs sparingly in the chaparral formations, together with *J. californica*, oaks, and tree yuccas. Occasionally it grows with *Abies concolor* or with *Pinus Jeffreyi*.

P. monophylla was considered by Newberry¹ to be a depauperate or desert form of *P. edulis*, which has a more easterly distribution. Sir Joseph Hooker, however, was convinced that the two species are distinct, and that two-leaved forms of *P. monophylla* are not identical with *P. edulis*. The latter has dull leaden grey foliage, whereas that of *P. monophylla* is glaucous with a silvery sheen. *P. monophylla* is the stronger plant of the two, and cannot be regarded as depauperate.

This peculiar pine was discovered by Fremont in 1844, and was introduced into Europe by Hartweg² in 1848. It is extremely slow in growth, a specimen $5\frac{1}{2}$ in. in diameter from Utah, which was examined by Sargent, showing 113 annual rings. It is occasionally seen in botanic gardens, there being a healthy specimen about 5 ft. high at Cambridge. Hooker, writing in 1886, mentions a tree at Kew, no longer living, which was only 6 ft. high, though it was twenty years old, yet he considered it to be faster in growth than *P. edulis*. The best specimen we know of in England is a tree at Dunburgh House, Beccles, which is about 14 ft. high, and bore a single cone in 1908. Another at Paul's Nursery, Cheshunt, was 13 ft. high in 1909. Seedlings received from Kew have proved hardy at Colesborne, though they grow very slowly. Elwes saw a specimen, about 20 ft. high, in the Botanic Garden at Montpellier, which bore young and old cones with good seed in 1910.

The seeds are the staple food of the Indians in Nevada, and are highly esteemed by white people, who eat them roasted. The timber is used for firewood, and is also largely employed in the mines. (A. H.)

¹ *Bull. Torrey Bot. Club*, xiii. 183 (1886). M. E. Jones, in *Zoe*, iii. 307 (1893), states that the leaves of *P. monophylla* are much more robust and vigorous than those of *P. edulis*.

² *Journ. Hort. Soc.* iii. 226 (1848).

PINUS EDULIS

- Pinus edulis*, Engelm., in Wislizenus, *Tour Mexico, Bot. App.* 88 (1848), and in Rothrock, *Geol. Surveys, vi. Botany*, 260 (1878); Sargent, *Silva N. Amer.* xi. 55, t. 552 (1897), and *Trees N. Amer.* 11 (1905); Masters, in *Gard. Chron.* xii. 563, fig. 86 (1892), and in *Journ. Linn. Soc. (Bot.)* xxxv. 587, fig. 2 (1904); Clinton-Baker, *Illust. Conif.* i. 19 (1909).
- Pinus monophylla*, Torrey, var. *edulis*, M. E. Jones, in *Zoe*, ii. 251 (1891).
- Pinus cembroides*, Zuccarini, var. *edulis*, Voss, in *Deut. Gartenrat, Beilage* 123 (1904); Shaw, *Pines of Mexico*, 6 (1909).

A tree, usually small in size, rarely attaining 40 ft. in height and 8 ft. in girth, with a short, often divided trunk. Bark $\frac{1}{2}$ to $\frac{3}{4}$ in. thick, irregularly divided into scaly ridges. Young branchlets stouter than in *P. cembroides*, grey, glabrous. Buds ovoid, acute, $\frac{1}{5}$ in. long, with brownish, densely imbricated, apiculate scales.

Leaves in pairs, with occasional three-leaved clusters, persistent three to five years, not so crowded on the branchlets as those of *P. cembroides*, appressed together in each cluster, $\frac{3}{4}$ to $1\frac{1}{2}$ in. long, rigid, stout, curved, sharp-pointed, entire in margin, with numerous stomatic lines on both surfaces; resin-canals marginal; basal sheath as in *P. cembroides*.

Cones similar to those of *P. cembroides*, but usually smaller, with the pyramidal apophysis of each scale more elevated than in that species, and the slightly deflexed umbo armed with a minute prickle, often obscured by resin. Seed smaller and lighter in colour than in *P. cembroides*; shell thin and brittle; wing rudimentary, about $\frac{1}{8}$ in. in length.

This species is widely distributed along the eastern foothills of the Rocky Mountains, from Colorado through New Mexico to western Texas, and extends westward through south-western Wyoming to Utah, northern and central Arizona, and southward over the mountains of northern Mexico. Associated with junipers (*J. monosperma* and *J. pachyphloea*), it forms extensive open forests between 5000 and 7700 ft. elevation, rarely ascending as a stunted shrub to 9000 ft. F. J. Phillips¹ states that in southern Colorado, Arizona, and New Mexico it is a tree of great economic and silvicultural importance. It succeeds in arid localities, where the average annual precipitation is less than 13 in. Its wood is much used for fuel; and to a lesser extent for fencing, railway sleepers, and mining timber. The seeds are an important article of food among Indians and Mexicans, and are sold in the markets of Colorado and New Mexico.

This species was described by Engelm. from specimens collected in 1846 by Dr. Wislizenus in New Mexico; and was introduced into cultivation² at Kew many years ago, but is now only represented there by one or two small plants. We have not seen it elsewhere.

(A. H.)

¹ In *Bot. Gaz.* xlviii. 216-223 (1909).² Cf. J. D. Hooker, in *Gard. Chron.* xxvi. 136 (1886).

PINUS CEMBROIDES

- Pinus cembroides*, Zuccarini, in *Abhand. Akad. München*, i. 392 (1832); Sargent, *Silva N. Amer.* xi. 47, t. 550 (1897), and *Trees N. Amer.* 10 (1905); Kent, Veitch's *Man. Coniferae*, 321 (1900); Masters, in *Journ. Linn. Soc. (Bot.)* xxxv. 586 (1904); Clinton-Baker, *Illust. Conif.* i. 15 (1909); Shaw, *Pines of Mexico*, 5 (1909).
- Pinus Llaveana*, Schlechtendal, in *Linnaea*, xii. 488 (1838).
- Pinus osteosperma*, Engelm., in Wislizenus, *Tour Mexico, Bot. App.* 89 (1848).

A tree, usually 20 ft. high with a short trunk rarely more than a foot in diameter, occasionally attaining in sheltered cañons 50 or 60 ft. in height. Bark about $\frac{1}{2}$ in. thick, slightly fissured, and separating on the surface into thin reddish brown scales. Young branchlets slender, glaucous, minutely pubescent or glabrous. Buds spindle-shaped, acute at the apex, brownish, about $\frac{1}{4}$ in. long, with densely imbricated scales, free at their subulate points.

Leaves in threes, with occasional two-leaved clusters, densely crowded on the branchlets, persistent for three or four years, nearly appressed together in each cluster, $1\frac{1}{2}$ to 2 in. long, curved, sharp-pointed, entire in margin, conspicuously whitened with stomatic bands on the inner surface, green with two or three stomatic lines on the outer surface; resin-canals marginal; basal sheath $\frac{3}{10}$ in. long, the basal segments speedily becoming reflexed and forming a rosette around the bases of the leaf cluster.

Cones subterminal, nearly sessile, almost globose, $1\frac{1}{2}$ to 2 in. in diameter; scales few and only well-developed and fertile in the middle of the cone, about an inch long; apophysis pyramidal, with a sharp transverse keel, and a depressed brown oval unarmed dorsal umbo. Seed, rather more than $\frac{1}{2}$ in. long; ovoid, irregularly conical or obscurely three-angled; blackish on the lower surface, dark brown on the upper surface; wing rudimentary, about $\frac{1}{3}$ in. in length, remaining attached to the scale when the seed falls.

This species is widely distributed through northern Mexico, where it often forms scattered open forests of considerable extent on the lower slopes of the mountain ranges, though it occasionally ascends to 10,000 ft. The seeds are sold in the markets of Mexican cities, forming an important article of food, and are eaten roasted or are ground into flour. This pine also occurs in the mountains of central and southern Arizona, usually above elevations of 6500 ft., and was found by Brandegee, forming a forest, on the top of the Sierra de Laguna in Lower California.

This species¹ was introduced into England in 1830, when the Horticultural Society obtained a plant from Mr. Otto of Berlin; and seeds were subsequently sent from Mexico by Hartweg in 1839. The largest specimen is at Highnam, and measured, in 1908, 33 ft. by 2 ft. 8 in. Another at Glasnevin, which is about 25 ft. high, divides into two stems at 8 ft. from the ground, and bears cones freely. There are smaller trees at Kew and Menabilly.

(A. H.)

¹ Loudon, in *Arb. et Frut. Brit.* iv. 2267 (1838), gives an incorrect figure of the cone of *P. Llaveana*, a synonym of the species; but in his *Trees and Shrubs*, 993 (1842), cones of *P. cembroides*, both from Otto of Berlin and from Hartweg, are correctly figured; and the tree in the Horticultural Society's Garden, which was $4\frac{1}{2}$ ft. high in 1837, appears to have been undoubtedly this species. Cf. also Loudon, *Gard. Mag.* xv. 128 (1839).

PINUS PARRYANA

Pinus Parryana, Engelmann, in *Amer. Journ. Science*, xxxiv. 332, note (1862) (not Gordon), and in Brewer and Watson, *Bot. California*, 124 (1880); Masters, in *Journ. Linn. Soc. (Bot.)* xxxv. 586, fig. 1 (1904); Sargent, in *Bot. Gaz.* xlv. 227 (1907); Clinton-Baker, *Illust. Conif.* i. 39 (1909).

Pinus quadrifolia, Parry, ex Parlatore in DC., *Prod.* xvi. 2, p. 402 (1868); Sudworth, *U.S. Forestry Bull.* No. 14, p. 17 (1897); Sargent, *Silva N. Amer.* xi. 43, t. 549 (1897), and *Trees N. Amer.* 10 (1905).

Pinus cembroides, Zuccarini, var. *Parryana*, Voss, in *Deut. Gartenrat*, Beilage 123 (1904); Shaw, *Pines of Mexico*, 6 (1909).

A tree, usually 20 to 30, occasionally 40 ft. in height, and rarely exceeding 5 ft. in girth. Bark, buds, and branchlets similar to *P. monophylla*.

Leaves in fours, with occasional five-leaved clusters, remotely placed on the branchlets, appressed together in the clusters, persistent three or four years, $1\frac{1}{4}$ to $1\frac{1}{2}$ in. long, incurved, rigid, sharp-pointed, entire in margin, with white stomatic bands on the inner surfaces; resin-canals marginal; basal sheath as in *P. monophylla*.

Cones and seeds similar to those of *P. monophylla*.

This species, which is scarcely distinguishable, except in the leaves, from *P. monophylla*, is restricted in its distribution to the Santa Rosa¹ and Toro mountains in the San Jacinto range of southern California, and to Lower California, where it grows as far south as the foothills of the San Pedro Martir mountain.² It was discovered in 1850 by Dr. Parry, 60 miles south-east of San Diego, California, at 2000 ft. altitude.

The four-leaved *piñon* requires a moister climate³ than *P. monophylla*, thriving where the annual rainfall is 15 to 25 in. and growing at elevations between 2500 and 8000 ft. It usually occurs in open forests, mixed with other species, as *P. monophylla*, oaks, and juniper.

It appears to be exceedingly rare in cultivation, the only specimen which I have seen being a small tree at Grignon in France. Dr. Masters appears to have seen young plants, as he states that the species is remarkable for the abundance and long duration of the primary needles, which are of a beautiful bluish colour.

(A. H.)

¹ It was found, according to S. B. Parish, in *Erythea*, vii. 89 (1899), by H. M. Hill on the desert slope of Santa Rosa mountain, where it exists in considerable quantity at about 5000 ft. altitude. It does not exist on the San Jacinto peak. H. M. Hill, in *Univ. Calif. Publications, Bot.* i. 20 (1902), reports it to be growing sparingly in the neighbourhood of Mount Toro.

² Cf. Brandegee, in *Zoe*, iv. 210 (1893).

³ Cf. Pinchot, *U.S. Forest Service, Sylvical Leaflet* 17 (1908).

PINUS MONTEZUMÆ, MONTEZUMA PINE

Pinus Montezumæ,¹ Lambert, *Gen. Pin.* i. 39, t. 22 (1832); Loudon, *Arb. et Frut. Brit.* iv. 2272 (1838); Kent, Veitch's *Man. Conif.* 345 (1900); Masters, in *Journ. Linn. Soc. (Bot.)* xxxv. 600 (1904); Clinton-Baker, *Illustrations of Conifers*, i. 35 (1909); Shaw, *Pines of Mexico*, 21, t. xiv. (1909).

Pinus Devoniana, Lindley, in *Bot. Reg.* xxv. Misc. 62 (1839).

Pinus Russelliana,² Lindley, in *Bot. Reg.* xxv. Misc. 63 (1839).

Pinus macrophylla, Lindley, in *Bot. Reg.* xxv. Misc. 63 (1839).

Pinus filifolia,² Lindley, in *Bot. Reg.* xxvi. Misc. 61 (1840).

Pinus Grenvillea, Gordon, in *Journ. Hort. Soc.* ii. 77 (1847); Masters, in *Gard. Chron.* xv. 112, fig. 22 (1881).

Pinus Gordoniana, Hartweg, in *Journ. Hort. Soc.* ii. 79 (1847).

Pinus Winchesteriana, Gordon, in *Journ. Hort. Soc.* ii. 158 (1847).

Pinus occidentalis, Humboldt, Bonpland, and Kunth, *Nov. Gen. et Sp.* ii. 4 (1817) (not Swartz).

A tree, attaining in Mexico 70 ft. in height. Bark brownish red, irregularly divided into scaly plates. Young branchlets stout, glabrous, reddish brown; their decurrent pulvini prominent, keeled, and persistent, with the epidermis peeling off in the second or third year, leaving a greyish-coloured surface. Buds ovoid, pointed, about an inch long, reddish brown, scarcely resinous; scales ending in long acuminate points, with their bases interlaced by whitish marginal fimbriæ. The brown linear-lanceolate scale-leaves with white fimbriæ, persist during the first year.

Leaves in fives, persistent three years, 4 to 18 in. long, crowded on the branchlets, spreading, serrulate, with stomatic lines on the three surfaces, ending in a cartilaginous point; resin-canals median; basal sheath $1\frac{1}{4}$ to 2 in. long, persistent. Flower buds, with the staminate catkins concealed, and not apparent as swellings externally.

Cones, in the first year, subterminal, single or in clusters of 2 to 5, stalked, pale or deep brown, blue, or dull black; scales armed with usually reflexed prickles. Mature cones $2\frac{1}{2}$ to 10 in. long, sessile or stalked, spreading or deflexed, nearly cylindrical or ovoid-conic and tapering, often curved, opening when ripe, and falling soon afterwards, when their stalks and a few basal scales often remain on the branch; scales variable in size; apophyses flat, pyramidal, tumid, or slightly protuberant and reflexed, dull yellowish, reddish brown, dark brown, or nearly black, prickles usually obsolete. Seed oval, brownish mottled with black, $\frac{1}{4}$ in. long; wing narrow, an inch or more in length.

This species is very variable, both in the length of the leaves and in the size of the cones; and is met with, according to Shaw, at all altitudes³ in Mexico, except in the lowlands of the coast, and below 3000 ft. in the interior, where the climate is

¹ Roehl's Catalogue of 82 new Mexican species, published in 1857, does not contain, according to Shaw, a single new species. They represent six or seven pines, all of which had been previously described. Roehl's list is given by Masters, in *Journ. Linn. Soc. (Bot.)* xxxv. 648, and will not be further noticed by us.

² The type specimens of the cones of these two species are preserved in the Botanical Museum, Cambridge. *P. filifolia* is labelled Guatemala.

³ Gadow, in *Journ. Linn. Soc. (Bot.)* xxxviii. 432 (1909), makes the timber line in southern Mexico 13,500 to 14,000 ft., where there are only a few scattered trees of *P. Montezumæ*.

tropical. At 9000 ft. and below, this pine mingles with the oaks in the more fertile and moister soil; while above, and more especially on the summit ridges, it sometimes forms dense forests. Large trees 3 to 4 ft. in diameter occur above Oaxaca.¹ *P. Montezumæ* was discovered near the city of Mexico in 1803 by Humboldt and Bonpland, who mistook it for the West Indian *P. occidentalis*; and it was first recognised and described by Lambert in 1832.

VARIETIES

The following account of the principal forms of this species in the wild state is taken from Shaw, who has made a special study of the Mexican pines:—

1. The typical form is sub-tropical, inhabiting the slopes and table-lands between 3000 and 6000 ft. It is characterised by long leaves, with basal sheaths exceeding an inch in length; by large non-resinous buds; and by cones 6 to 10 in. long, brown in colour, the apophyses of the scales being elevated, with usually prominent brownish umbos.

2. Var. *Lindleyi*, Loudon, *Encyc. Trees*, 1004, fig. 1882 (1842); Shaw, *Pines of Mexico*, 22, t. xv. (1909).

Pinus Lindleyana, Gordon, *Pinetum*, 229 (1858).

Leaves often very slender, and drooping like those of *P. pseudostrabus*, 6 to 10 in. long; cones 4 to 6 in. long; apophyses small and numerous, flat or slightly pyramidal, often rectangular and very like var. *Hartwegii*, but pale brown and not black in colour.

This variety occurs at altitudes with a temperate climate.

3. Var. *rudis*, Shaw, *Pines of Mexico*, 22, t. xvi. figs. 1-5, 8 (1909).

Pinus Montezumæ, Gordon, in *Journ. Hort. Soc.* i. 234 (1846); Masters, in *Gard. Chron.* viii. 466, figs. 91-94 (1890), xv. 273, figs. 29-32 (1894), and xxv. 146, fig. 53 (1899).

Pinus rudis, Endlicher, *Syn. Conif.* 151 (1847).

Pinus Ehrenbergii, Endlicher, *Syn. Conif.* 151 (1847).

Pinus Hartwegii, Parlatore, in DC., *Prod.* xvi. pt. 2, p. 399 (1868) (in part).

Leaves 4 to 6 in. long. Cones in the first year blue or bluish-black; when mature, 2½ to 4 in. long, dull, sometimes shining brown.

This variety, which usually has leaves in fives, though there are occasionally six or seven in a cluster, grows at altitudes with a warm temperate climate, and is connected by intermediate forms with var. *Lindleyi*.

4. Var. *Hartwegii*, Engelmann, in *Trans. St. Louis Acad. Sc.* iv. 177, 181 (1880); Shaw, *Pines of Mexico*, 23, t. xvii. figs. 6, 7 (1909).

Pinus Hartwegii, Lindley, in *Bot. Reg.* xxv. Misc. 62 (1839); Loudon, *Encycl. Trees*, 1000, fig. 1875 (1842); Kent, Veitch's *Man. Conif.* 348 (1900); Masters, in *Journ. Linn. Soc. (Bot.)* xxxv. 600 (1904); Clinton-Baker, *Illust. Conif.* i. 24 (1909).

Pinus Donnell-Smithii, Masters, in *Bot. Gaz.* xvi. 199 (1891), and in *Journ. Linn. Soc. (Bot.)* xxxv. 600 (1904); Smith, in *Bot. Gaz.* xix. 13, t. 2 (1894).

Leaves 3 to 6 in. long, often in threes and fours, as well as in fives. Cones

¹ Cf. *Garden and Forest*, ix. 102 (1896).

similar to those of var. *rudis*, but very dark brown, or almost black in colour when mature.

This variety occurs in colder regions and at higher altitudes than any other Mexican pine, forming the timber line and descending to some distance below it. Mr. Godman wrote to Dr. Masters that this pine forms a complete belt around the Volcan de Fuego, commencing at about 10,000 ft., and on the Volcan d'Agua ascends to the summit. The mixed forest of Cheirostemon and other trees ceases abruptly at about 10,000 ft., and one steps suddenly out of it into the more open pine belt, where the only undergrowth is a coarse grass.

CULTIVATION

Both the typical form and the varieties were introduced by Hartweg in 1839, when numerous plants were raised in the garden of the London Horticultural Society.

As seen in cultivation, this species is readily distinguishable into two principal forms; one, probably identical with the type, as defined by Shaw, and characterised by long leaves, averaging 9 in. in length, with basal sheaths 1¼ to 2 in. long, and large, scarcely resinous buds. In the only specimen which we have seen in fruit, a tree cultivated at Bicton¹ as *P. Russelliana*, the cones produced are 5 in. long, and 2¼ in. in diameter, with large shining pale brown elevated apophyses, terminating in a dark coloured projecting umbo. It was 60 ft. by 6 ft. 9 in. when measured by Elwes in 1906. The gardener in May 1909 reported that this tree was nearly dead, though it was still bearing a few old cones.

The typical form is well represented at Pencarrow, where two trees planted in 1849 measured in 1907, 50 ft. by 9 ft., and 49 ft. by 5 ft. These differ strikingly in habit, but show no differences in botanical characters. Elwes saw a fine spreading tree at Endsleigh in August 1906 which measured about 50 ft. by 9½ ft. in girth. There are good specimens at Tregothnan, Heligan, and other places in Cornwall.

At Eastnor Castle, a small spreading tree, 26 ft. high, seems healthy.

At Grayswood, Haslemere, a tree planted in 1881 had attained 25 ft. by 2 ft. 10 in. in 1906, and did not suffer in the winter of 1895.

In Ireland this succeeds well, as at Woodstock, Kilkenny, where a tree was 48 ft. by 6 ft. in 1904; and at Old Connaught House, near Bray, where a tree planted in 1869 was 34 ft. by 2 ft. 9 in. in 1904.

The other form, which is probably var. *Hartwegii*, produces cones freely, which are ovoid-conic and tapering to an acute apex, 3 to 3½ in. long, with numerous small scales, with flat apophyses, and slightly raised dark brown umbos. The leaves, often in fours as well as in fives, are 5 to 6 in. long, with basal sheaths not exceeding an inch in length. The buds are slender, ½ to ¾ in. long, with usually resinous appressed scales.

Var. *Hartwegii* is much the hardiest form; and we have found specimens, even in the eastern counties, as at Pampisford, near Cambridge, where a tree in a sheltered position is 28 ft. by 1 ft. 10 in. At Bayfordbury, Herts, a tree planted in 1845 died

¹ The Hon. Mark Rolle wrote to the Director at Kew that this tree produced cones for the first time in 1899.

in 1854; another specimen planted in 1875 is now 20 ft. high and 2 ft. 3 in. in girth. At Flitwick Manor, Bedford, a tree measured in 1908, 34 ft. by 2 ft. 7 in. Much finer trees, most of them producing cones, exist farther west, as at Westonbirt, where a tree planted in 1869 measured in 1909, 45 ft. high, and looked very vigorous. At Bicton there are two good specimens, 74 ft. by 5 ft. 3 in. and 46 ft. by 4 ft. 4 in. At Eastnor Castle, a fine tree was 55 ft. by 4 ft. 8 in. in 1909. At Bury Hill, Dorking, a tree, which R. Barclay, Esq., informs us was planted in 1847, is 36 ft. high and 3 ft. 8 in. in girth at 4 ft. from the ground. At Strete Raleigh, Exeter, H. M. Imbert Terry, Esq., reports a tree 52 ft. by 5 ft. 11 in., from which he raised about fifty seedlings in the spring of 1909. It was planted about 1855. At Pencarrow a tree measured 44 ft. by 3 ft. in 1906. At Escot, Devonshire, the seat of Sir John Kennaway, Elwes measured a tree 65 ft. by 7 ft. in 1909, with a clean bole about 35 ft. long, which is the finest of its kind that he has seen. We have also received specimens of this variety from Wadebridge and Luscombe Castle, Dawlish.

A third form, represented by a tree at Menabilly,¹ and another at Fota, has longer leaves and longer cones than in var. *Hartwegii*, though the latter are similar in every respect except in size, and may be referred in all probability to var. *rudis*. The tree at Fota (Plate 278) is a fine one, and measured 50 ft. by 7 ft. 3 in. in 1908, the branches covering an area 52 paces around. Lord Barrymore informs us that it was planted in 1878. (A. H.)

PINUS PSEUDOSTROBUS

Pinus pseudostrobus, Lindley, in *Bot. Reg. xxv. Misc. 63* (1839); Loudon, *Encycl. Trees*, 1008, figs. 1887, 1888 (1842); Masters, in *Journ. Linn. Soc. (Bot.) xxxv. 605* (1904); Shaw, *Pines of Mexico*, 19, t. xii. (1909).
Pinus orizabæ, Gordon, in *Journ. Hort. Soc. i. 237* (1846).

A tree attaining 100 ft. in height and 6 ft. in diameter. Bark of branches and young trees smooth; in old trees very rough at the base. Branchlets slender, glabrous, very glaucous; the decurrent bases of the leaves persistent, conspicuous at first, but ultimately becoming merged in the smooth bark of the older branchlets, on which they are visible as transverse lines. Buds and leaves, the latter 6 to 12 in. long, similar to those of *P. Montezumæ*, but usually more slender.

Cones sub-terminal, described by Shaw as ovate or oblong, 3 to 5½ in. long, nearly symmetrical or oblique, opening when ripe and falling soon afterwards, the peduncle and a few basal scales usually remaining persistent on the branch; apophysis variable, flat or protuberant.

1. Var. *apulcensis*, Shaw, *Pines of Mexico*, 19, t. xii. (1909).

Pinus apulcensis, Lindley, in *Bot. Reg. xxv. Misc. 63* (1839); Loudon, *Encycl. Trees*, 1014, figs. 1899, 1900 (1842).

Differs in the prolongation of the apophyses of the scales of the cone. It grows

¹ Figured in *Gard. Chron.*, *loc. cit.* It bore cones in 1899, when it was 20 ft. high, but Mr. Rashleigh said that no perfect seed was produced.

in Mexico in company with the type, and is connected with it by intermediate forms.

2. Var. *tenuifolia*, Shaw, *Pines of Mexico*, 20, t. xiii. (1909).

Pinus tenuifolia, Bentham, *Pl. Hartw. 92* (1842).

Cones ovate or long-ovate; basal scales and peduncles persistent on the branch. Hypoderm of the leaves extending from the epiderm to the endoderm, forming partitions across the green tissue.¹ Abundant at altitudes with a sub-tropical climate in the western and south-western states of Mexico, and extending southward to north-western Nicaragua.

According to Shaw, *P. pseudostrobus* occurs in Mexico at altitudes between 6000 and 10,000 ft., where the climate is temperate, with warm days and cool nights. This zone includes the tableland and the slope immediately above it.

This species, and var. *apulcensis*, were discovered in 1839 by Hartweg, who sent home in the same year cones and seeds, from which, according to Loudon, numerous plants were raised. Nearly all these have died, as the tree is evidently only suitable for cultivation in districts where the climate is mild, like Cornwall and southern Ireland. The only specimens which we have found, are two trees in Cornwall. One at Pencarrow, was obtained from Knight and Perry in 1849; and measured, in 1906, 47 ft. high, and 5 ft. 8 in. in girth. Mr. Bartlett kindly sent us photographs of this tree, and of several trees of *P. Montezumæ*, and the difference in the bark of the two species is remarkable. That of *P. pseudostrobus* is smooth, and only slightly furrowed; whereas in *P. Montezumæ*, the bark is very rough and scaly. Another, growing at Tregothnan, was measured by Mr. A. B. Jackson as 50 ft. by 6 ft. in 1909. Neither tree has produced cones. (A. H.)

PINUS TORREYANA

Pinus Torreyana, Parry, *ex Torrey*, in Emory, *Bot. Mex. Bound. 210*, tt. 58, 59 (1858); Sargent, *Silva N. Amer. xi. 71*, tt. 557, 558 (1897), and *Trees N. Amer. 34* (1905); Kent, *Veitch's Man. Conif. 348* (1900); Masters, in *Journ. Linn. Soc. (Bot.) xxxv. 602* (1904); Clinton-Baker, *Illust. Conif. i. 56* (1909).

Pinus lophosperma, Lindley, in *Gard. Chron. 1860*, p. 46.

A tree, attaining 60 ft. in height and 8 ft. in girth, but usually considerably smaller. Bark an inch in thickness, deeply divided irregularly into broad flat scaly ridges. Young branchlets glabrous, glaucous; become dull grey in the second year. Buds cylindrical-conic, ½ in. long; scales pale brown, interlaced by their marginal white fimbriæ, and with appressed points.

Leaves² in fives, persistent two years, dark green, 7 to 13 in. long, 1½ in.

¹ A very fine tree near the hotel at Bussaco, Portugal, which Elwes measured in April 1909, 90 ft. in height and 9 ft. in girth, is probably this variety; but in the absence of cones, the identification is uncertain.

² On young plants the leaves are frequently in clusters of three and four.

wide, rigid, marked on three sides by stomatic lines, serrulate, ending in a sharp cartilaginous point; resin-canals median; basal sheath an inch long.

Cones sub-terminal, spreading or deflexed, on long stalks, broadly ovoid, 4 to 6 in. long; scales thick, 2 in. long, $1\frac{1}{4}$ in. wide, shining brown; apophysis rhomboidal, transversely ridged, with an elevated pyramidal four-sided acute umbo, with or without a minute prickle. Seed oval, $\frac{3}{4}$ to 1 in. long, dull brown and mottled below, pale brown above; surrounded by a dark brown wing, thickened at the upper margin of the seed, and extending beyond its apex about $\frac{1}{2}$ in.

Masters describes the seedlings, raised at Kew, as robust, with a long tapering radicle, stout cylindrical stem, and twelve linear cotyledons, succeeded by primary leaves, elliptic in section.

This species is more circumscribed in its distribution than any other pine. It occurs in two localities, the main body growing in a narrow belt, about eight miles long, on the Californian coast, near the mouth of the Soledad river, north of San Diego, nowhere penetrating inland more than a mile and a half. This grove was discovered by Dr. Parry in 1850, whose attention was directed to this pine by J. L. Le Conte, the distinguished entomologist, who was then collecting at San Diego. A single grove, of about one hundred trees, with numerous seedlings, discovered by Brandegee in 1888, also grows on the eastern end of Santa Rosa island,¹ on a bluff 500 ft. above the level of the sea. These trees average 30 ft. high.

Miss Sessions of San Diego, who sends us an account of this pine, which was fast disappearing, states that of late steps have been taken, which will ensure its preservation. It grows on the sea-coast, buffeted, twisted, and often prostrated by the ocean winds, and averages 30 to 40 ft. in height. At Del Mar, 22 miles north of San Diego, the South Coast Land Company has bought a large tract, including all the sandstone cliffs and cañons leading down to the sea, where the Torrey pines grow in this neighbourhood. The Company has built an hotel, and is protecting all the old pines, and preserving the natural seedlings, and planting in addition. The Torrey Pine Park, which is public property, is on a high and exposed point, south-west of Del Mar; and here all the trees are carefully guarded.

William Lobb sent specimens, with cones and seed, to Low's nursery at Clapton in 1860, which were described by Lindley² as *P. lophosperma*. Plants were reported³ to be growing in the Edinburgh Botanic Garden in 1868. It has, however, proved tender there and at Kew, and seems unsuited for cultivation except in warm districts like Cornwall and southern Ireland. The only specimen now living, that we are acquainted with, was planted at Bayfordbury in 1908. Mayr, however, states⁴ that he raised seedlings in Japan, which bore a temperature of -12° Cent. without injury. There are three fairly large trees of this species in the Public Gardens, Christchurch, New Zealand, which bear a few cones.⁵

PINUS COULTERI, COULTER'S PINE.

Pinus Coulteri, Don, in *Trans. Linn. Soc.* xvii. 440 (1836); Loudon, *Arb. et Frut. Brit.* iv. 2250 (1838); Lawson, *Pinet. Brit.* i. 23 (1884); Masters, in *Gard. Chron.* xxxiii. 415, figs. 73, 74 (1885), iv. 764, fig. 109 (1888), and in *Journ. Linn. Soc. (Bot.)* xxxv. 597 (1904); Sargent, *Silva N. Amer.* xi. 99, tt. 571, 572 (1897), and *Trees N. Amer.* 24 (1905); Kent, *Veitch's Man. Conifera*, 325 (1900); Clinton-Baker, *Illust. Conif.* i. 17 (1909).
Pinus macrocarpa, Lindley, in *Bot. Reg.* xxvi. app. 61 (1840).

A tree, attaining in America 80 ft. in height and 12 ft. in girth. Bark about 2 in. thick, dark brown, deeply divided into broad rounded connected scaly ridges. Young branchlets stout, glabrous, glaucous, with very prominent pulvini. Buds ovoid, acuminate or cuspidate, very large, 1 to $1\frac{1}{2}$ in. long, and $\frac{3}{4}$ in. thick; scales appressed, coated with resin, light brown, with white fimbriæ on their margins.

Leaves in threes, spreading, persistent for three or four years, 8 to 12 in. long, $\frac{1}{16}$ to $\frac{1}{12}$ in. wide, rigid, curved, twisted, serrulate, marked with numerous stomatic lines on the three surfaces, ending in a long sharp cartilaginous point; resin-canals median; basal sheath $1\frac{1}{2}$ in. long.

Cones¹ lateral, on short stout stalks, pendulous, ovoid, 10 to 14 in. long, and 4 to 5 in. in diameter, yellowish brown; scales thick, $2\frac{1}{2}$ in. long, $1\frac{1}{2}$ in. broad; apophyses obliquely pyramidal, terminating in flattened elongated umbos, straight or curved, and armed with flattened incurved resinous spines. Seeds, on deep depressions on the scales, oval, compressed, $\frac{1}{2}$ in. long, dark brown or blackish, encircled by the wings which, very narrow and rim-like on the sides, expand above, and are oblique, brown, and about an inch in length. Cotyledons, 10 to 14.

The cones open in autumn in California, remaining, after the seeds escape, on the branches for several years. Occasionally the cones are shorter and thicker than usual, with short spurs, and then resemble those of *P. Sabiniana*; but they may always be distinguished by the long-winged seeds, which leave long depressions on the inner surface of the scales.

This species is scattered singly or in small groves through coniferous forests on the dry slopes and ridges of the coast ranges of California, from Mount Diablo and the Santa Lucia mountains southwards to the Cuyamaca mountains, at elevations between 3000 and 6000 ft. It is most abundant on the San Bernardino and San Jacinto² ranges, at 5000 ft. altitude. It is usually known as the big-cone pine, from the size of the cones, which often weigh three or four pounds. The seeds were formerly gathered in large quantities and eaten by the Indians. *P. Coulteri* differs

¹ According to Lawson, *Pinet. Brit.* i. 24 (1884), a tree, eighteen years old, in the Jardin des Plantes, Paris, produced two cones in 1852.

² H. M. Hall, in *Univ. Calif. Publications, Botany*, i. 20, 53 (1902), says it is commonly met with on the south and west sides of the San Jacinto mountain, where it forms small groves and narrow strips along the lower edge of the belt of *P. ponderosa*. It is also found scattered among the other pines up to 6500 to 7500 ft. on south slopes, but does not occur on the sides of the mountain facing the Colorado desert. The seeds have a strong oily taste, and are not gathered by the Saboba and Santa Rosa Indians, those of *P. monophylla* and *P. Parryana* being much preferred.

much in habit¹ from *P. Sabiniana*, always having a straight undivided stem, with wide spreading branches, forming a broad pyramid of foliage.

This species was discovered by Coulter² in the Santa Lucia mountains in 1832; and in the same year Douglas sent home specimens with seeds, from which plants were raised in the garden of the Horticultural Society. Young plants were raised³ at Kew in 1840 from the seed of a cone, the origin of which is not stated. A further consignment of seed was sent home by William Lobb⁴ in 1851.

P. Coulteri is rare in cultivation, and the finest specimens appear to be in Herts, where a tree at St. Cross, Hoddesdon, planted by Miss Warner in 1857 (Plate 279), bore twenty large cones in December 1908, and measured, according to Mr. Clinton-Baker, 80 ft. in height and 9½ ft. in girth, but Elwes, who measured it carefully in February 1909, only made it 74 ft. by 9 ft. 4 in. Its branches, one of which is 36 ft. long, sweep the ground. At The Frythe, Welwyn, a tree, 56 ft. by 8 ft., bore cones in 1906, and had a few old cones persistent on the stem. At Youngsbury, Ware, a tree, planted in 1866, measured 51 ft. by 6 ft. 5 in. in 1907. At Ponfield, a tree, 40 ft. by 3 ft. 10 in. in 1906, also had a cone persistent on the stem at 25 ft. from the ground. At Bayfordbury, a tree planted in 1841 is 56 ft. by 8 ft. 8 in., and in 1909 for the first time bore a single cone. A larger tree here, planted in 1838, was cut down in 1906, when it measured 72 ft. by 8 ft. 11 in. A plank from it is preserved in the forestry museum, Cambridge. At Garston Manor, Watford, the seat of Mr. Watney, Sir Hugh Beevor has measured a tree⁵ 75 ft. by 9 ft. 10 in. in girth, dividing into two stems at 15 ft. from the ground, which bore cones in 1909.

At Knaphill Nursery, near Woking, Elwes measured in 1907 a tree, 71 ft. by 8 ft. 10 in., which has since died. A fine healthy tree, with a few cones near the top, growing at Enville Hall, Stourbridge, measured, in 1905, 71 ft. by 9 ft. 7 in. At Orton Hall, Peterborough, there is a fine specimen 70 ft. by 7 ft. 9 in. in 1909, which has only produced a few cones at rare intervals.

The largest tree in Kew Gardens is situated near the Succulent House, and measured 55 ft. by 8 ft. in 1909. There is a healthy tree at Toddington Grange, Gloucestershire, the seat of H. Andrews, Esq., which bore cones in 1909 and measures 62 ft. by 6½ ft. At Tortworth, there was a tree, growing on a slope with a westerly exposure, on the lower shaly beds of carboniferous limestone, cones⁶ of which were sent to Dr. Masters in 1896. It died and was cut down in 1902.

We have not seen or heard of any tree in Scotland; but at Powerscourt, Ireland, a tree measured 57 ft. by 7 ft. 1 in. in 1903. (A. H.)

¹ Mayr, in *Wald. Nordamer.* 332 (1890), states that it attains in favourable conditions a height of 150 ft.; but this great height is not confirmed by Sargent or Jepson.

² An account of Coulter's expeditions in Mexico and California is given by Coville in *Bot. Gazette*, xx. 519 (1895).

³ Loudon, *Encycl. Trees*, 985 (1842).

⁴ *Hortus Veitchii*, 343 (1906).

⁵ Cones weighing 3 lb. from this tree were shown at a meeting of the Scientific Committee of the Royal Horticultural Society on 10th October 1905.

⁶ Two cones, dried after keeping seven years, weigh 1½ lb. each. Masters mentions a tree at Kenfield near Canterbury, which produced cones in 1886. The gardener informs us that it is no longer living.

PINUS SABINIANA, DIGGER PINE

Pinus Sabiniana, Douglas, in *Trans. Linn. Soc.* xvi. 747 (1833); Loudon, *Arb. et. Frut. Brit.* iv. 2246 (1838); Lawson, *Pin. Brit.* i. 85, t. 11. (1884); Masters, in *Gard. Chron.* iv. 44, fig. 4 (1888), and v. 44, fig. 6 (1889), and in *Journ. Linn. Soc. (Bot.)* xxxv. 597 (1904); Sargent, *Silva N. Amer.* xi. 95, tt. 569, 570 (1897), and *Trees N. Amer.* 23 (1905); Kent, *Veitch's Man. Conif.* 375 (1900); Clinton-Baker, *Illust. Conif.* i. 50 (1909).

A tree, usually 20 to 50 ft. high, occasionally attaining 80 ft. in height and 12 ft. in girth. Bark about 2 in. thick, dark brown, irregularly divided into thick connected scaly ridges. Young branchlets slender, glabrous, glaucous, with prominent pulvini. Buds narrowly cylindrical, acute at the apex, about 1 in. long; scales closely appressed, more or less coated with resin, pale brown, with long white fimbriae on the margins.

Leaves in threes, persistent for three years, spreading or drooping, 7 to 12 in. long, ½ in. wide, twisted, greyish green, with numerous stomatic lines on the three surfaces, serrulate, ending in a cartilaginous point; resin-canals median; basal sheath 1 in. long.

Cones lateral, on stout stalks, pendulous, ovoid, dark brown, 6 to 10 in. long, 4 to 5 in. in diameter; scales thick, about 2 in. long and 1 in. broad, with an obliquely raised pyramidal apophysis, prolonged into a hooked process, usually ending in a sharp incurved spine. Seeds in deep hollows on the scale, oblong, dark brown or blackish, ¾ in. long, ½ in. wide, with a thick shell, encircled by the wing, which is reduced to a very narrow sharp rim below, expanding above into a brown thickened membrane, about ½ in. long. The seeds are eaten and distributed by the Douglas squirrel, and, having a sweet resinous flavour, were formerly used as food by the Indians of California. Cotyledons about 15 to 18.

This species is readily distinguished from *P. Coulteri* by the greyish green foliage and slender glaucous branchlets. Both have very massive cones, with spurred scales, armed with spines, and very large seeds, differing, however, in the length of the wing. The cones of *P. Sabiniana* are shorter and broader, and in this country open more freely than those of *P. Coulteri*. According to Jepson,¹ the trees in Mitchell Cañon, Mount Diablo, which he refers to *P. Coulteri*, resemble very closely those of *P. Sabiniana* in cones and foliage, and are intermediate between the two species.

This pine, which often divides into three or four stems 14 to 20 ft. above the ground, forming a round-topped tree, remarkable for the sparseness of its foliage, is scattered singly or in small groups over the dry and hot foot-hills of the inner Coast Range, of the Sacramento Valley, and of the Sierra Nevada, throughout almost the whole length of California, attaining its largest size east of the Sierra Nevada near the centre of the state, where it is often the most conspicuous feature of the vegetation.

Muir, in an article in *Harper's Magazine*,² notes that in the Sierra Nevada it grows only in the torrid foot-hills, often amongst thickets of scrubby oaks, *Ceanothus*,

¹ *Flora W. Mid. California*, 22 (1901).

² Reproduced in *Gard. Chron.* iv. 44 (1888).

and Manzanita, and ranges from 500 to 4000 ft. elevation. No other tree that he knows, is so thin and pervious to light, even the largest giving no shade.

In California *P. Sabiniana* is occasionally tapped, and exudes a nearly colourless liquid with a strong aromatic smell, resembling that of oil of orange, which is sold in San Francisco under the names abietene, erasine, aurantine, or theoline, as a substitute for benzine in removing grease spots from clothes. Wenzell described¹ in 1871 as abietene the hydrocarbon obtained by distilling the crude product; and Thorpe² afterwards showed that this was pure heptane, of which he obtained as much as 7 litres from 7½ litres of the liquid exudation of the tree.

This species was discovered by Douglas in 1826, but he did not send seeds till 1832, when plants were raised in the Horticultural Society's garden. It is very rare in cultivation, and is not quite hardy, as Palmer mentions a tree, 46 ft. high, at Rolleston Hall, Staffordshire, which was killed in the severe winter of 1860. A tree planted at Bayfordbury in 1837 was also killed in the same year.

There is a fine tree at Madresfield Court, close to the church, which when measured by Elwes in 1908 was 60 ft. high by 6 ft. 9 in. in girth. It has borne ripe cones, and there were young ones near the top in 1908. At Ledbury, in Lord Biddulph's grounds, a tree (Plate 280) 65 ft. high by 9½ ft. in girth bore cones in 1909. A tree at Tortworth, planted by Lord Ducie in 1856, is now about 63 ft. high and 7 ft. in girth below the fork. It is, however, sickly in appearance. A tree at Eastnor Castle, 62 ft. by 6½ ft., bore fruit in 1908.

At Orton Longueville, a tree with a large lateral branch at 20 ft. up, measured 58 ft. by 7 ft. 8 in. in 1909. At Hunstanton Hall, Norfolk, the seat of Hamon le Strange, Esq., there are fourteen trees growing in the park, variable in height, some with single stems, others branching into two or three stems. The largest is 52 ft. by 7 ft.; and only one tree is bearing fruit, a single old cone.

There are two trees in Kew Gardens, the larger³ of which, in 1909, was 55 ft. high and 6 ft. 4 in. in girth. A tree at Flitwick Manor, Bedford, was reported in 1908, by Mr. H. Clinton-Baker, to be 50 ft. high and 4 ft. 4 in. in girth. Miss Woolward sends us a branch from a tree, 40 ft. high and 4 ft. in girth, growing in a field belonging to Mr. Kennet-Were, Cotlands, Sidmouth. Kent reports trees at Pampisford, Cambridge, and at Highnam Court, Gloucestershire, which appear to be no longer in existence.

PINUS PONDEROSA, YELLOW PINE

Pinus ponderosa, Lawson, *Agric. Manual*, 354 (1836); Loudon, *Arb. et Frut. Brit.* iv. 2243 (1838); Forbes, *Pinet. Woburn.* 44, t. 15 (1839); Sargent, in *Garden and Forest*, viii. 392 (1895), *Silva N. Amer.* xi. 77, tt. 560, 561 (1897), and *Trees N. Amer.* 15 (1905); Masters, in *Gard. Chron.* viii. 557, figs. 110, 111, 114, 115 (1890), and in *Journ. Linn. Soc. (Bot.)* xxxv. 593 (1904); Kent, Veitch's *Man. Conif.* 363 (1900); Shaw, *Pines of Mexico*, 24, pl. 17 (1909); Clinton-Baker, *Illust. Conif.* i. 45 (1909).

Pinus Benthamiana, Hartweg, in *Journ. Hort. Soc.* ii. 189 (1847), and iv. 212, with fig. (1849).

Pinus brachyptera, Engelm., in Wislizenus, *Tour in N. Mexico*, 89 (1848).

Pinus Beardsleyi, Murray, in *Edin. New Phil. Journ.* i. 286 (1855).

Pinus Craigana, Murray, in *Edin. New Phil. Journ.* i. 286 (1855).

Pinus Engelmanni, Torrey, in *Pacific Rly. Rep.* iv. 141 (1856).

Pinus Parryana, Gordon, *Pinetum*, 277 (1875).

A tree, attaining in America 150 to 230 ft. in height, and 15 to 25 ft. in girth. Bark for eighty to a hundred years broken into rounded ridges, covered with small appressed brownish scales; on older trees 2 to 4 in. thick, deeply divided into large plates, separating on the surface into thick reddish scales. Young branchlets stout, glabrous, shining, reddish, becoming nearly black in the second or third year. Buds cylindrical-conic, acute, ¾ in. long; scales reddish brown, closely appressed, resinous.

Leaves in threes, persistent three years, spreading, densely crowded on the branchlets, 6 to 10 in. long, ¼ to ½ in. broad, rigid, curved, marked with stomatic lines on the three sides, serrulate, ending in a sharp cartilaginous point; resin-canals median; basal sheath ⅞ in. long. The lanceolate-acuminate fimbriated scale-leaves persist long on the branchlets.

Cones sub-terminal, solitary or clustered, sessile or sub-sessile, spreading or slightly deflexed, ovoid, 3 to 5 in. long, light reddish brown; scales oblong, about 1¼ in. long, ½ in. wide, thin towards the base and thickened at the apex; apophysis rhomboidal, with a sharp transverse ridge and elevated umbo, armed with a slender prickle. Seed oval, about ¼ in. long, with a dark, mottled shell; wing about 1 in. in length. The cones shed their seeds¹ at the end of the second year, and usually fall soon after, generally leaving some of the lower scales attached to the peduncle on the branch; and hence this species and its varieties are called "broken-cone pines" by Lemmon.

This species spread over an immense area, consists of a number of geographical races which have been distinguished as distinct species by various authors. As these gradually pass into one another, and do not occupy isolated areas, they are best treated as varieties.

1. The typical form described above occurs mainly on the Pacific slope, where it grows to a large size, and is mainly distinguishable from var. *Jeffreyi* by its glabrous, shining, non-glaucous branchlets, which emit when cut an odour of turpentine, and its resinous buds with appressed scales. The cones are ovoid-conic,

¹ R. Douglas states that seeds of this species germinate as well in the fifth year as in the first. Cf. *Gard. Chron.* iv. 185 (1888).

4 to 5 in. long, narrow in proportion to their length. The leaves are variable in size, and average 6 or 7 in. long.

2. Var. *scopulorum*, Engelmann, in Brewer and Watson, *Bot. Calif.* ii. 126 (1880).

Pinus ponderosa, Engelmann, in *Amer. Journ. Sci. Arts*, xxxiv. 332 (1862) (not Lawson); Hooker, in *Gard. Chron.* ix. 796, fig. 138 (1878).

Pinus scopulorum, Lemmon, in *Garden and Forest*, x. 183 (1897); Mayr, *Fremdländ. Wald- u. Parkbäume*, 370 (1906).

Usually 50 to 75, occasionally 150 ft. in length, and 4 ft. in diameter. Bark dark and furrowed, or bright red broken into large plates. Leaves in clusters of both twos and threes, 3 to 6 in. long. Cones, in clusters of two, ovoid-conic, smaller than in the type, about 3 in. long. This variety occurs in the Rocky Mountains and eastward, in eastern Montana, Nebraska, Dakota,¹ Colorado, western Texas, northern New Mexico, and Arizona.

3. Var. *Jeffreyi*, Vasey, *U.S. Rep. Dept. Agric.* 179 (1875); Sargent, *Silva N. Amer.* xi. 79, tt. 562, 563 (1897), and *Trees N. Amer.* 16 (1905); Kent, *Veitch's Man. Coniferæ*, 364 (1900); Shaw, *Pines of Mexico*, 24 (1900).

Pinus Jeffreyi, Balfour, *Bot. Exped. Oregon*, 2, fig. (1853); Lawson, *Pin. Brit.* i. 45, t. 6 (1884); Masters, in *Gard. Chron.* v. 360, fig. 65 (1889); Clinton-Baker, *Illust. Conif.* i. 27 (1909); Hemsley, in *Bot. Mag.* t. 8257 (1909).

Pinus deflexa, Torrey, in Emory, *Rep. Mex. Bound.* 209 (1858); Murray, in *Gard. Chron.* iv. 295, fig. 65 (1875).

Attaining 150 to 200 ft. in height, and 20 ft. in girth. Bark bright red, divided into large irregular scaly plates. Young branchlets glaucous, exhaling, when cut, an aromatic odour like that of lemon. Buds reddish brown, non-resinous, and with the points of the scales free. Cones ellipsoid, very large, 5 to 12 in. long, short-stalked, with either stout or slender recurved prickles. Seeds often $\frac{1}{2}$ in. long, with long wings. This variety occurs in the Sierra Nevada, San Bernardino, San Jacinto, and Cuyamaca mountains in California, and on the San Pedro Martir mountain in Lower California.

4. Var. *Mayriana*, Sargent, *Silva N. Amer.* xi. 81 (1897).

Pinus latifolia, Sargent, in *Garden and Forest*, ii. 496, fig. 135 (1889); Brandegee, in *Garden and Forest*, v. 111 (1892); Koehne, *Deut. Dendr.* 36 (1893).

Pinus Engelmanni, Lemmon, in *Erythraea*, i. 134 (1893) (not Torrey or Carrière).

Pinus Mayriana, Sudworth, *U.S. Forestry Bull.* No. 14, p. 21 (1897); Mayr, *Fremdländ. Wald- u. Parkbäume*, 367 (1906).

Leaves very long and stout, 14 to 15 in. long, $\frac{1}{16}$ in. broad. Cones very oblique; scales with projecting knobbed umbos, armed with sharp prickles.

This variety,² said to be a tree about 80 ft. high, was discovered on the southern slope of the Santa Rita mountains in Arizona by Mayr in 1887.

¹ Cf. Graves, *Black Hills Forest Reserve*, published in *U.S. Geol. Survey*, 1897-98, pt. v. *Forest Reserves* (1899).

² Toumey, in *Garden and Forest*, viii. 22, fig. 4 (1895), figures this tree, or a similar form, on Mount Chiricahui, in south-eastern Arizona, and believes that all the varieties of *P. ponderosa* occur there, gradually passing into one another. Lemmon, in *Erythraea*, ii. 103, fig. 3 (1894), describes and figures the Chiricahui pine as *P. apachea*.

5. Var. *arizonica*, Shaw, *Pines of Mexico*, 24 (1909).

Pinus arizonica, Engelmann, in Rothrock, *Rep. Geol. Surveys*, vi. 260 (1878); Sargent, *Silva N. Amer.* xi. 75, t. 559 (1897), and *Trees N. Amer.* 14 (1905).

A tree 80 to 100 ft. high, with black and deeply furrowed bark. Young branchlets glaucous. Leaves usually in fives, but occasionally also in threes, according to Shaw. Cones ovoid, small, 2 to $2\frac{1}{2}$ in. long.

This occurs on the sides of cañons of the mountain ranges of southern Arizona at 6000 to 8000 ft. elevation, sometimes forming nearly pure forests. It is more abundant and attains its largest size on the sierras of northern Mexico, in Sonora, Chihuahua, and Nuevo Leon.

6. Var. *macrophylla*, Shaw, *Pines of Mexico*, 24 (1909).

Pinus macrophylla, Engelmann, in Wislizenus, *Tour N. Mexico*, 103 (1848), and in *Trans. St. Louis Acad.* iv. 181 (1880).

Pinus Engelmanni, Carrière, in *Rev. Hort.* 227 (1854).

A tree 70 to 80 ft. high. Leaves 12 to 16 in. long, stout, in threes, fours, and fives. Cones large (according to Engelmann, $4\frac{1}{2}$ in. long); scales with apophysis prolonged into a reflexed protuberance, armed with either a stout or slender prickle.

Discovered by Wislizenus on the mountains of Cosiquirachi, where it is said to be abundant. According to Shaw, it occurs in Sonora and Chihuahua in northern Mexico. (A. H.)

DISTRIBUTION AND HISTORY

This splendid tree is the most important species of pine in western North America, being the most widely distributed, the largest except *P. Lambertiana*, and the most variable. It occurs over a vast region, extending eastwards to Montana, the Black Hills of Dakota, Nebraska, Colorado, and western Texas, and westwards to the shores of the Pacific, attaining its most northerly limit in the dry interior of British Columbia,¹ in the north Thompson valley, and around Shushwap lake, in lat. $51\frac{1}{2}^{\circ}$, descending the Fraser river to thirty miles above Yale. It reaches southwards to Lower California, Arizona, New Mexico, and northern Mexico. It is essentially a tree of dry regions and sunny aspects, yet able to endure a great degree of cold in winter. It is the first pine which the traveller sees on going west across the prairies in western Nebraska,² and forms the greater part of the forests, now rapidly disappearing, which cover the Black Hills of Dakota, where it attains a maximum height of 100 ft. and a diameter of 19 in.

In Montana it becomes a larger tree, attaining a height of 150 ft. on the dry slopes of the mountains near Helena, where it ascends to 6000 ft., in company with the Douglas fir and Western larch. In the Flathead valley it grows in scattered groups on the margin of the prairie in the plain of Kalispell, and gradually advances

¹ Macoun, *Cat. Canad. Plants*, i. 466. Palmer, in *Brit. Columbia Bull.* No. 21, p. 10 (1905), gives its habitat as the dry plateau between the Coast and Gold Ranges, where it is largely used for lumber. The seeds were formerly eaten by the natives.

² Bessey, in *Bot. Gazette*, xxii. 245 (1896), gives its distribution in Nebraska, as along the northern border in the valley of the Niobrara river, in the south-western corner, along the river Platte, where I saw it in 1904, and in patches in the centre of the state in cañons of the Loup.

into the dense mixed coniferous forest of the surrounding mountains. Plate 281, from a negative taken by Prof. Elrod, represents a yellow pine near Flathead Lake. Near Whitefish, Henry measured an average tree, 148 ft. in height and 11½ ft. in girth, which showed when felled 3½ in. thick of bark, 3 in. of sapwood, and 360 annual rings. In the Blackfoot valley, near Missoula, I measured a tree 140 ft. high by 15 ft. in girth.

In Colorado the mountain form¹ forms very extensive pure forests on the plateau between 7000 and 8200 ft., ascending occasionally to 9000 ft., and descending to 4500 ft. Here the tree rarely exceeds 80 ft. in height and 3 ft. in diameter. It extends southwards along both sides of the Rockies to western Texas, northern New Mexico, and Arizona, exhibiting in the latter state several peculiar forms, which have been distinguished, on account of their very long needles and peculiar cones, as distinct species (*P. Mayriana*, *P. apachea*). It also spreads into the northern states of Mexico² in varieties with leaves varying in number, distinguished as *P. macrophylla* and *P. arizonica*, the latter being also a native of Arizona.

In wet regions, like the coast of British Columbia and Vancouver Island, the tree is unknown; but it grows in Washington, close to Puget Sound, on dry gravelly prairies. In eastern Washington it forms an open pure forest on the lower timber line, bordering on the arid region, and ranges from 400 to 6200 ft. According to Piper,³ it has a marked preference for granitic soil, though it grows on basaltic clay in the Blue Mountains. It here attains its maximum development at 2000 ft., reaching a height of 200 ft. and a diameter of 6 ft. It is common along the eastern slopes and foothills of the Cascade range, and becomes a conspicuous tree in southern Oregon, where the climate is drier, forming considerable forests at Grant's Pass and in the Siskiyou mountains.

In California it occurs in the coast ranges,⁴ as in Sonoma and Napa counties, and there is a fine forest of this species on the Howell mountain plateau; but no trees are known in the inner coast ranges bounding Solano and Yolo counties. It is not recorded from the San Francisco Bay ranges, except from the Mt. Hamilton ridges. It is abundant in the Sierra Nevada, at or above 5000 ft.; and, according to Muir,⁵ ranges on the western slope from 2000 ft. to timber line, and, crossing the range by the lowest passes, descends to the eastern base, and pushes far out into the hot volcanic plains. The largest tree measured by Muir grew in the Merced valley, and was 220 ft. high and 8 ft. in diameter.

Var. *Jeffreyi* occurs in California,⁶ from Scott's Mountain in Siskiyou county, and along the eastern slopes of the Sierra Nevada, forming large forests at the headwaters of the Pitt and McCloud rivers, and often grows on the most exposed and driest ridges, wandering out among the volcanoes of the Great Basin. Sudworth records it from Douglas county in southern Oregon; and it is the chief pine on the lower slopes of Mount Shasta, which it ascends to about 5500 ft., the largest that I

¹ A tree growing in Monument Park, Colorado, is figured by Sir J. Hooker in *Gard. Chron.* ix. 796, fig. 138 (1878).

² Shaw, *op. cit.* 2, states that *P. ponderosa* extends in Mexico southwards to lat. 23° or 24°.

³ *Contrib. U.S. Nat. Herb.* xi. 50, 92, tt. xiv. xv. (1906).

⁴ Jepson, *Flora W. Mid. California*, 21 (1901).

⁵ In *Harper's Magazine*, xxii. 719.

⁶ Sir J. Hooker, in *Gard. Chron.* xxii. 814, fig. 141 (1884), gives a sketch of a tree growing in the Silver Mountains in the Sierra Nevada range, on the eastern slope, and says he met with no specimens nearly so large as 200 ft., the height given by Sargent.

measured here being 120 ft. high by 13½ ft. in girth. It extends southwards to the San Bernardino and the San Jacinto ranges, up to 8000 ft. elevation, in the Cuyamaca mountains, and finds its most southerly point¹ on the San Pedro Martir mountain,² in Lower California.

P. ponderosa was first mentioned by Lewis and Clarke, who saw it in 1804 on the Upper Missouri, on their memorable journey across the Rocky Mountains. It was not made known to science, however, until David Douglas found it³ on the Spokane river, in Washington, in 1826, and in the *Companion to the Botanical Magazine*, ii. 111, published in 1836, mentioned it as a new pine under the name of *P. ponderosa*. This name was taken up in 1836 by Lawson,⁴ to whom Sargent attributes its description, which was taken from a tree in the Caledonian Horticultural Society's Garden, raised from the seeds sent by Douglas in 1827 to the London Horticultural Society.

The variety *Jeffreyi* was discovered by Jeffrey in October 1852 in the Shasta valley, in northern California, and introduced in the following year.⁵

CULTIVATION

So far as I have seen, this tree succeeds best and attains the greatest size on dry, well drained, but deep soil in the south of England, while it often becomes unhealthy and dies in damp situations; and, though perfectly hardy⁶ in Scotland, is not so large or so thriving there as in the south. It ripens seeds freely in good seasons, from which many plants have been raised at Tortworth and other places. The seedlings are best raised in a box and planted out when a year or two old; when once established they grow fast, and do not seem to suffer from early or late frosts.

There are several trees of *P. ponderosa* in England, which are about 90 ft. in height and some over; but we have seen none to equal the tree at Powis Castle near the Welshpool entrance to the park, which, when I measured it in 1908, was 105 ft. high⁷ and 10 ft. in girth with a clean bole of about 60 ft.

At Bayfordbury a tree planted in 1837, and growing on good loamy soil, was carefully measured with a sextant and different base lines in 1906, when it was 100½ ft. in height, its girth being 9 ft. 4 in. Exactly three years later, in April

¹ The southern form, growing on the mountains east of the San Rafael valley of southern California, and on the mountain of San Pedro Martir, in a dry climate, is figured in *Garden and Forest*, v. 184, fig. 28 (1892), under the name *P. Jeffreyi*, var. *peninsularis*, Lemmon, in *3rd Report Calif. State Forestry Board*, p. 200 (1891).

² Brandegee, in *Zoe*, iv. 201 (1893), describes this mountain as a plateau 7000 to 8000 ft. elevation, with ridges 2000 to 3000 ft. higher. It is cold in winter, ice lasting until May, and the rainfall is considerable. *P. Jeffreyi* is the most common tree on the plateau, a few trees of *P. Lambertiana* occurring on the ridges. *P. Parryana* is common at lower elevations than the plateau.

³ A specimen, collected by Douglas, in the Kew Herbarium, bears a parasitic plant, *Arceuthobium occidentale*, Engelm., figured by Loudon, t. 2137, as *A. oxycedri*, Bieb.

⁴ Lawson, *Agricultural Manual*, 354 (1836).

⁵ These particulars are taken from Jeffrey's advice note, which Prof. I. B. Balfour has allowed us to consult.

⁶ At Thorpe Perrow, Bedale, all the conifers raised from seeds collected by Hartweg were killed in the severe winter of 1860-61, when 46° of frost were registered, except *P. Benthamiana*, the Californian coast variety of *P. ponderosa*, of which two fine trees were surviving in 1888. Cf. *Gard. Chron.* iii. 236 (1888).

⁷ This is the tree mentioned in the notes supplied to the Royal English Arboricultural Society on their visit in 1909 as a Corsican pine, No. 6.

1909, two measurements taken by Mr. H. Clinton-Baker make it 101 ft. by 9 ft. 7 in. It girthed in 1865, 4 ft. 9 in., and in 1900, 9 ft. Sir H. Beevor has measured another at Garston Manor, Watford, 90 ft. by 8 ft. 2 in.

Another at Dropmore is believed to be one of Douglas's original seedlings, planted in 1829, and, as measured by Mr. Page in 1909, was 99 ft. by 8 ft. 9 in.; in 1905 I made it 92 ft. by 8½ ft. At Arley Castle two trees of the same origin, measured by Mr. R. Woodward in 1909, were 104 ft. by 7 ft. 8 in., and 96 ft. by 6 ft. 7 in. At Highnam there is a tree 72 ft. by 9 ft. 4 in. At Escot St. Mary, Miss F. Woolward measured a tree 94 ft. by 7 ft. 8 in. At Brocklesby Park, Mr. Havelock measured, in 1904, a tree 87 ft. by 6 ft. 10 in. On the heavy clay at Orton Longueville the largest is only about 70 ft. by 7½ ft.

In the damper climate of the west it does not seem to grow so fast, the best tree at Killerton being only 72 ft. by 6½ ft. At Eastnor Castle, there are two trees of the typical form, 65 ft. by 7 ft., and 65 ft. by 8 ft. 4 in., and a specimen of var. *Jeffreyi*, 58 ft. by 5 ft., all the measurements being taken by Mr. Mullins in 1909. Var. *Jeffreyi* is 60 ft. by 5 ft. 3 in. at Westonbirt, and 56 ft. by 5 ft. 1 in. at Orton.

In Wales I have not noticed any specially noteworthy trees, the climate at Penrhyn being clearly too wet to suit its requirements.

In Scotland the best we have seen is at Smeaton Hepburn. A tree¹ of var. *Jeffreyi*, planted in 1856, measured in 1902, 72 ft. high and 4 ft. 9 in. in girth. A tree at Scone, Perthshire, measured² in 1891, 50 ft. by 6 ft. 8 in.

Though it grows fairly well in central and eastern Scotland, we have seen no large trees in the west, and Sir H. Maxwell mentions none.

In Ireland also it seems to be unsuccessful; none of the reports of the Conifer Conference in 1891 speak well of it, and we have seen no trees worth recording for their size.

In Germany cones matured³ for the first time in 1894, on a tree at Schaffenberg, near Berlin, which was 25 ft. high and growing with great vigour and apparently hardy. Both *P. ponderosa* and var. *Jeffreyi* have been experimented with in forest plots⁴ in Prussia, and succeeded for a time, but afterwards for some inexplicable reason gradually withered and died. The seedlings are very liable to the leaf-shedding disease, *Lophodermium Pinastri*.

As a timber tree it is not likely to have any importance in Europe, the timber being coarse in comparison with that of the native species. In North America, however, it is one of the most useful for mining and general building purposes.

As a rule, according to Sargent,⁵ *P. ponderosa* and its varieties have not proved satisfactory in the eastern states. The long-leaved Californian forms are not hardy in New England. Var. *scopulorum* is hardy near Boston, where it is impossible, however, to keep it alive more than a few years, as a fungoid disease disfigures and soon destroys it. Var. *Jeffreyi* is more successful, and the best specimens probably

¹ *Hist. Berwickshire Nat. Club*, xviii. 211 (1904).

² *Journ. Roy. Hort. Soc.* xiv. 536 (1892).

³ *Garden and Forest*, vii. 95 (1894), where it is stated that at Berlin *P. Sabiniana* succumbed in the severe winter of 1893; while *P. Coulteri* is hardy, but grows slowly.

⁴ Cf. Schwappach, *Anbauversuche fremdländ. Holzkart.* 57 (1901), and Unwin, *Future Forest Trees*, 57 (1905).

⁵ *Garden and Forest*, x. 470 (1897).

in the eastern states are in Delaware Park, Buffalo, where there are eight trees which, planted in 1871, were in 1897, 25 to 37 ft. high. A fine weeping variety, var. *pendula*, Masters, which was imported from England in 1851, and planted at Woodenethe, Fishkill on Hudson, New York, is figured¹ in *Garden and Forest*, i. 392, fig. 62 (1888); and was, in 1882, 59 ft. high and 5 ft. 7 in. in girth. We have not seen any tree showing this habit either in England or in its native country.

(H. J. E.)

PINUS TUBERCULATA, KNOB-CONE PINE

Pinus tuberculata, Gordon, in *Journ. Hort. Soc.* iv. 218 (1849), and *Pinetum*, 288 (1875), (not D. Don); Lawson, *Pinet. Brit.* i. 93, t. 13 (1884); Masters, in *Gard. Chron.* xxiv. 786, fig. 184 (1885), and *Journ. Linn. Soc. (Bot.)* xxxv. 594 (1904); Kent, Veitch's *Man. Conif.* 386 (1900); Sargent, in *Bot. Gaz.* xlv. 227 (1907); Clinton-Baker, *Illust. Conif.* i. 57 (1909).

Pinus californica, Hartweg, in *Journ. Hort. Soc.* ii. 189 (1847) (not *P. californiana*, Loiseleur).

Pinus attenuata, Lemmon, in *Mining and Scientific Press*, Jan. 16, 1892, ex Sargent, *Silva N. Amer.* xi. 107, t. 575, 576 (1897); Sargent, *Trees N. Amer.* 22 (1905).

A tree, usually 20 to 30 ft. high and 1 ft. in diameter, occasionally attaining 100 ft. in height and 2½ ft. in diameter; often divided about the middle into two ascending stems. Bark ¼ to ½ in. thick, brown, irregularly broken into large loose scales. Young branchlets slender, glabrous, reddish brown, with prominent pulvini separated by linear grooves. Buds cylindrical, pointed, brown, about an inch long, with closely appressed scales.

Leaves in threes, persistent three or four years, spreading, usually 4 to 5 in. long, slender, firm and rigid, serrulate, ending in a sharp cartilaginous point, marked by stomatic lines on the three surfaces; resin-canals median; basal sheath ½ in. long.

Cones lateral, in one, two, or three whorls on the same year's shoot, in clusters of two to four, deflexed, asymmetrical, oblique at the base, short-stalked, pale brown, elongated-conical, 3 to 5 in. long; scales thin, flat; apophyses transversely keeled, on the outer side of the cone, pyramidal, raised into conical knobs, and armed with sharp spines, on the inner side flattened and with minute prickles. Seed oval, black, grooved, ¼ in. long; wing about an inch long.

The cones are developed at an early age, often appearing in whorls on the stem, when it is only 2 or 3 ft. high; and remain both on the stem and branches unopened until the advent of a forest fire or the death of the tree. They are sometimes found embedded in the bark of old trunks.

This species is found in arid sunny situations on the mountains of south-western Oregon, south of the Mackenzie river, in the Siskiyou mountains, and southward along the western slopes of the Cascades and the Sierra Nevada, and in the coast range of California from Santa Cruz to the San Bernardino mountains, where it is abundant at 4000 ft. It is most common in Oregon, usually growing in small groves

¹ This tree is also figured in *Gard. Chron.* x. 236, fig. 42 (1878).

amidst the chaparral, and where I saw it on the boundary between Oregon and California, never attained a greater height than 30 ft. with a maximum diameter of a foot, all the trees being narrowly pyramidal with short branches, and bearing numerous whorls of unopened cones on the main stem. Its range here appears to be between 2500 and 3000 ft. Sargent says it occasionally attains a height of 100 ft., but neither Mr. F. R. S. Balfour nor myself saw any but small trees, those of exceptional size being probably restricted to deep ravines on good soil. The hills on which it grows are very liable to be swept by forest fires, and there is no doubt that it rarely if ever reproduces itself, except on burnt areas,¹ when the scorched cones let out the seeds. It is often attacked by mistletoe. In the same region it is occasionally accompanied by a peculiar variety of *P. contorta* with small cones, a tree of similar size and habit.

P. tuberculata was discovered by Hartweg² in 1847 in the Santa Cruz mountains, about twenty miles north of Monterey, and was introduced by him into the garden of the Horticultural Society, London, in the same year. This species grows slowly in England, and is of rare occurrence in collections; the best specimen we have seen is a tree 50 ft. high at Bury Hill, Dorking, which divides into several stems at 1 ft. from the ground, where it girths 10 ft. 5 in. There is an ill-shaped and decaying tree at Bayfordbury, 36 ft. high, dividing at 3 ft. from the ground into two stems, 3 ft. and 3½ ft. respectively in girth. A branch of the tree 4 ft. in length bore forty-one cones. A tree at The Heath, Leighton Buzzard, measured by A. B. Jackson in 1908, was about 35 ft. high. Smaller specimens occur at Kew, Blackmoor in Hants, and Ochertyre.

In New Zealand,³ this species is a rapid grower, second only to *P. radiata*. At Canterbury, three varieties have arisen, all of which come true from seed and are very constant in character. (A. H.)

¹ A graphic account of this pine and its relation to forest fires, by Muir in *Harper's Magazine*, xxii. 715, is reproduced in *Gard. Chron.* xxiv. 786 (1885). Jepson, in *Flora W. Mid. California*, 23 (1901), says that a burnt forest of the knob-cone pine is promptly re-sown with its own seed.

² Hartweg described it in *Journ. Hort. Soc.* ii. 189 (1847), but erroneously supposed it to be identical with *P. californiana*, Loiseleur.

³ Adams, *Genus Pinus*, 6, paper read at the Philosophical Institute, Canterbury, New Zealand, 7th August 1907.

PINUS RADIATA, MONTEREY PINE

Pinus radiata,¹ Don, in *Trans. Linn. Soc.* xvii. 442 (1836); Sargent, *Silva N. Amer.* xi. 103, tt. 573, 574 (1897), and *Trees N. Amer.* 21 (1905); Kent, Veitch's *Man. Coniferae*, 370 (1900); Masters, in *Journ. Linn. Soc. (Bot)* xxxv. 595 (1904).

Pinus tuberculata, Don, *loc. cit.* (not Gordon).

Pinus insignis, Douglas, *ex Loudon, Arb. et Frut. Brit.* iv. 2265 (1838); Forbes, *Pin. Woburn.* 51, t. 18 (1839); Lawson, *Pin. Brit.* i. 37 (1884); Baines, in *Gard. Chron.* ix. 108, figs. 22, 23 (1878); Masters, in *Gard. Chron.* ix. 337, fig. 77 (1891); Clinton-Baker, *Illust. Conif.* i. 26 (1909).

Pinus Sinclairii, Hooker et Arnott, *Bot. Beechey's Voyage*,² 392, t. 93 (1841).

Pinus Montereyensis, Rauch, *ex Gordon, Pinetum*, 197 (1858).

A tree, attaining at Monterey about 100 ft. in height and 20 ft. in girth. Bark about 2 in. thick, dark brown, deeply divided into broad flat scaly ridges. Young branchlets glabrous, reddish brown, with prominent pulvini. Buds ½ to ¾ in. long, cylindrical, pointed, brown; scales closely appressed and coated with resin.

Leaves in threes, persistent three years, densely crowded on the branchlets, bright green, 4 to 5 in. long, about 1/8 in. broad, slender and flexible, serrulate, ending in a short cartilaginous tip, marked with stomatic lines on the three sides; resin-canals median; basal sheath ½ in. long.

Cones lateral, on stout short stalks, solitary or in clusters of two or three, deflexed or spreading, about 3 to 5 in. long, ovoid with a pointed apex, shining brown, very asymmetrical, with the scales much thickened from the middle to the base on the outer side, their apophyses elevated into protuberances, directed downwards; elsewhere with the apophyses flatter, rhomboidal, marked with a transverse linear ridge and a dark brown umbo, armed with a minute prickle. Seed oval, about ¼ in. long, blackish and tuberculate; wing light brown, with darker longitudinal stripes, about an inch long.

In this species the shoots, when vigorous, are multinodal, and often show a ring of buds in the middle of the branchlet, as well as one subtending the terminal bud. At Monterey,³ the shoots regularly produce two whorls of cones; and many trees show three, four, or even five whorls, but in this case many of the cones remain unfertilised and shrivel up at the beginning of the second year. In cultivated trees in this country and in dense stands at Monterey the cones are persistent, remaining unopened on the branches for several years, or in some cases even retaining the cones on the main stem or on the largest and oldest branches. In exposed trees at Monterey, the cones usually open, immediately after ripening, with the onset of the warm weather that occurs in autumn.

The seedlings have five to seven cotyledons, and are variable in habit, some

¹ This is the oldest certain name, and the one exclusively used by American botanists and foresters. *P. adunca*, Poir., in Lamarck, *Encycl. Suppl.* iv. 418 (1816), may be this species, but the description is very imperfect.

² The drawing and description represent a large coned form of *P. radiata*. The cone in the Kew Museum labelled "*P. Sinclairii* (?)" is *P. Montezumae*; but it is not the cone described by Hooker and Arnott; and Engelmann in Brewer and Watson, *Bot. Calif.* ii. 128 (1880), is incorrect in assuming *P. Sinclairii* to be a factitious species.

³ J. B. Hickman, in *Erythea*, iv. 194 (1896).

young plants giving off lateral shoots immediately above the cotyledons, while others have a long unbranched stem.¹ The primordial needles are very long, narrow, and finely serrate; and are succeeded by the ternate leaves when the stem attains 6 or 8 in. in height.

VARIETIES

Both in wild and cultivated trees there is great variation in the size of the cones; and the length of the leaves is not constant. *P. radiata* was formerly supposed to differ from *P. insignis* in having larger cones; but intermediate forms are numerous.²

Var. *binata*, Engelm., in Brewer and Watson, *Bot. California*, ii. 128 (1880).—Leaves usually in twos. Specimens³ at Kew bear much smaller cones than in the type, symmetrical at the base and with scales not swollen on the outer side. This variety was discovered in 1875 by Dr. Palmer on Guadalupe island, off the coast of Lower California, and was found in 1888 by Brandegee⁴ on Santa Cruz and Santa Rosa isles, off Santa Barbara in California. Dr. Franceschi says⁵ that this pine is found on the northern and north-western part of Guadalupe, which in times past must have been covered with a dense forest. It grows in company with a palm, *Erythea edulis*, and with *Quercus tomentella*, at considerable elevations. The trees⁶ are vigorous and handsome, averaging 70 ft. in height and 7½ ft. in girth. Near the sea they are cut like a hedge owing to the force of the wind.

Var. *aurea*. A form with bright golden foliage has appeared in New Zealand, and is being propagated there for sale.⁷

DISTRIBUTION

This species has a very restricted distribution, occurring only in a narrow belt a few miles wide on the coast of California from Pescadero to San Simeon Bay; on the islands of Santa Rosa and Santa Cruz off Santa Barbara, and on Guadalupe island, off the coast of Lower California, the insular form belonging as described above, to var. *binata*.

It is most abundant and of its largest size on Point Pinos,⁸ south of the Bay of Monterey. At Pacific Grove,⁹ where the forest of this pine is extremely important,

¹ Cf. *Gard. Chron.* ix. 337 (1891).

² Large cones, var. *macrocarpa*, Gordon, *Pinetum*, 206 (1858), are said by Hartweg, in *Journ. Hort. Soc.* iii. 226 (1848), to be characteristic of the pines forming a wood at San Antonio, some distance from the sea. Lemmon, however, in *West American Cone-Bearers*, 6 (1895), says that trees with large cones occur near the sea, those with small cones being seen on the outskirts of the forest, farthest from the ocean.

³ Collected in Guadalupe by Dr. Palmer in 1875, by Dr. Franceschi in 1892, and by A. W. Antony in 1896.

⁴ Cf. *Proc. Calif. Acad.* i. pt. ii. 217 (1889).

⁵ In *Zoe*, iv. 130 (1893).

⁶ According to Palmer, in Watson, *Proc. Amer. Acad.* xi. 119 (1876).

⁷ Cf. T. W. Adams, *Genus Pinus*, 4, a paper read at the Philosophical Institute of Canterbury, New Zealand, on 7th August 1907. Mr. Adams saved seed from a cone without any knobs on its outer side, and all the trees raised are now bearing cones of the ordinary type. A number of varieties have arisen in New Zealand, remarkable for the variation in the size of the cones and in the colour of the foliage.

⁸ Here it mixes slightly with *P. muricata*.

⁹ Cf. G. J. Pierce, in *Bot. Gazette*, xxxvii. 448 (1904), who describes the attacks of a fly, *Diplosis pini-radiata*, Snow, which produces a basal hypertrophy of the needles of this pine. It is also much attacked by a kind of mistletoe, *Arceuthobium occidentale*, Engelm.; and an interesting account of the dissemination of the seeds of this parasite on the pine is given by Pierce in *Ann. Bot.* xix. 99-113 (1905).

being the main protection of the town of that name against the sand, which now piled up in large dunes would otherwise be blown inland over the town. Paths and roads have been cut through the forest, and a few years ago a serious fire swept over part of it, so that the pine is now having a hard struggle for existence.

Prof. Jepson informs me that this pine grows on the Monterey peninsula from the sand dunes of the seashore inland over the adjoining hilly ridges, which nowhere exceed 400 ft. elevation. The average rainfall¹ for the twenty-three years, 1878 to 1900, was 15·37 in. annually, occurring on forty to sixty days in the winter from October to April. The months of June, July, and August are perfectly dry. The number of cloudy days in the year varies from 120 to 150. The thermometer never rises above 89° F., and rarely descends below freezing-point, and then only for short periods in the night,—though 24° F. was registered in 1905, and 27° F. in 1906.

This species was discovered² by Douglas during his stay at Monterey in 1831 and 1832; and from seeds sent home by him in 1833 plants were raised in the garden of the Horticultural Society and in the Duke of Devonshire's grounds at Chiswick, which were 3 to 5 ft. in height in 1838. Coulter also sent cones at about the same time, from Monterey, which were described by Don as *P. radiata* in 1836. Subsequently, in 1850 and 1851, consignments of seed were sent to Messrs. Veitch by William Lobb.³

(A. H.)

CULTIVATION

Near the sea in almost all parts of Great Britain, but especially in the south-west of England, in Wales, and in Ireland, *Pinus radiata* has proved to be a tree of great value for shelter and ornament; and though its timber is too coarse to come into competition with that of Baltic or even home-grown pine, its growth is so extremely rapid that it may prove profitable to grow for mining timber in Cornwall and South Wales.

It produces seed freely at an early age. The seedlings grow more rapidly than those of any other pine which I have raised; and though they are not so easy to transplant as those of the Scots pine, the proportion of losses in transplantation is much less than in the Corsican species. In a mixed plantation made by C. Daubuz, Esq., of Killiow, about two miles from Truro, in 1864, Monterey pines when I saw them in 1902 averaged about 8 ft. in girth, larch 3 ft., chestnut 3 ft., and silver fir about 40 in. The pines were raised from seeds of a home-grown tree under twenty years old; and it seemed to me that in this locality, if planted thick enough and cut at the right size, they might be equal to imported pit-props.

Though the tree is hardy enough to grow in many inland parts of England, it seems to succeed best near the sea; and at Colesborne, though it has endured frosts as low as zero in sheltered places, the growth is slow, the young shoots are

¹ The rainfall, however, has been more considerable lately:—in 1905, 21·63 in.; in 1906, 25·03 in.; and in 1907, 28·98 in.

² Colligon, a gardener who accompanied the La Peyrouse expedition, is supposed to have sent a cone of this species to the museum at Paris in 1787, which was described by Loiseleur in *Novv. Duhamel*, v. 243 (1812) as *P. californiana*. The latter states that a plant raised from the seed of this cone was living in 1812 in the open in the Jardin des Plantes. The seed, however, is described as being large and edible like that of *P. Cembra*, and the foliage as being in twos and threes; and in all probability this plant was *P. Pinna*.

³ *Hortus Veitchii*, 39 (1906).

often killed back by frost, and in low-lying or exposed situations the trees are killed outright in cold seasons.

In the garden of the Rev. A. Boscawen at Ludgvan, near Penzance, the growth of seedlings is extraordinary, and the ability of the tree to bear sea-winds is greater than that of any other pine. As regards soil it must be well drained and light to ensure success.

Mr. Rogers, of Penrose, Cornwall, says¹ that he planted about 1000 trees, many in the most exposed borders of plantations near the sea in Mount's Bay, most of them being seedlings from his older trees. He considers it one of the best of nurses, giving better shelter and growing faster than either the Austrian or maritime pine; but it suffers severely from snow in a cold winter, losing entire limbs and often dying from its effects.² He has used wood of thirty years' growth both for furniture and for wheelbarrows, etc., and finds it easily worked, light in weight, tough and strong, though liable, as might be expected from immature timber, to be worm-eaten. If planted closely, it will produce clean straight timber.

REMARKABLE TREES

The largest specimens reported in 1891 were at Dropmore, then 90 ft. by 11 ft., planted in 1839, and Boconnoc, then 68 ft. by 13 ft.; but these are now far surpassed by many others.

The most remarkable that I have seen is a tree in a sheltered dell called the Wilderness at Cuffnell's, near Lyndhurst, which in 1907 was 116 ft. by 8½ ft., with a clean bole about 40 ft. long. Plate 282 shows how very unlike this is to its usual habit both in California and England.

The next tallest was a tree, no longer living, which, as I am told by Rev. A. Boscawen, was carefully measured at Heligan in Cornwall in 1897 by the Hon. Charles Ellis, who found it to be 108 ft. high. This was a seedling of unknown age, raised from a tree which I saw on the lawn at Heligan in 1905; a very rugged and wide-spreading tree which, though only about 50 ft. high, was 18 ft. in girth. It was blown down in May 1909.

There are many other very large trees, of which I give particulars in tabular form as follows:—

	Height.	Girth.	Year.	By whom measured.
Haldon House, Devonshire . . .	90 ft.	14 ft. 6 in.	1903	H. J. Elwes.
Heanton Satchville, Devonshire . . .	92 ft.	14 ft.	1905	„
Knowle Hotel, Sidmouth, Devonshire	83 ft.	14 ft. 2 in.	1907	Miss F. Woolward.
Lamorran, Cornwall	90 ft.	13 ft. 6 in.	1905	H. J. Elwes. Not over fifty years old; very rough tree.
Coldrennick, Cornwall	83 ft.	14 ft. 5 in.	1905	A. Bartlett.

¹ *Woods and Forests*, 1883, p. 19.

² Loudon, in *Gard. Mag.* xv. 269 (1839), states that plants were killed nearly everywhere in Britain by the severe winter of 1838-39; but one survived at Sunning Hill, in the grounds of Mr. R. Mangles. It was growing on dry elevated ground. A tree at Gunnersbury, 48 ft. high, was reported in *Gard. Chron.* 1868, p. 152, to have been killed by the severe frost of 1867. In the severe winter of 1908-9, when the temperature fell at Kew to 10° F. on 30th December, the leaves on this pine tree were injured, and turned a rusty brown colour. Cf. *Kew Bull.*, 1909, p. 225.

	Height.	Girth.	Year.	By whom measured.
Northerwood, Hants	106 ft.	14 ft. 6 in.	1907	H. J. Elwes. A very fine tree, painted by Mr. Short.
Dropmore, Bucks	77 ft.	15 ft.	1909	C. Page.
Bury Hill, Surrey	98 ft.	14 ft. 6 in.	1908	H. J. Elwes.
Deepdene, Surrey	86 ft.	9 ft. 2 in.	1905	A. Henry.
Goodwood, Sussex (Plate 283)	83 ft.	9 ft.	1906	H. J. Elwes. Very clean stem to 35 ft.; not spreading.
Beauport, Sussex	90 ft.	12 ft. 9 in.	1905	H. J. Elwes. Raised about 1855 from seed of tree by house.
Sandling Park, Kent	85 ft.	15 ft. 10 in. at 2½ ft.	1907	H. J. Elwes. Large branches coming off at 5 ft.
Cobham Hall, Kent	90 ft.	11 ft. 9 in.	1906	A. Henry.
Trebah, Cornwall	95-100 ft.	12 ft. 5 in.	1909	A. B. Jackson.
Essendon Place, Herts ¹	69 ft.	10 ft.	1906	H. Clinton Baker.
Fulmodestone, Norfolk	70 ft.	10 ft. 10 in.	1905	Sir Hugh Beevor.
Eastnor Castle, Herefordshire ²	80 ft.	10½ ft.	1909	J. Mullins.
Bellshill, Northumberland	55 ft.	9 ft.	1906	H. J. Elwes. Healthy in this cold county three to four miles from the sea.
Stackpole Court, Pembrokeshire	90 ft.	9 ft. 9 in.	1906	H. J. Elwes.
Bodorgan, Anglesea	75 ft.	17 ft. at ground	1906	H. J. Elwes. Large branches come off at 5 ft.; 72 paces round.

At Dropmore³ trees from cuttings planted in 1839, treated exactly the same way as seedlings put out in the same year, were in 1882 somewhat smaller in height and in girth. At White Knights, Reading, a tree eighteen years old, from seed, measured in 1904, 52 ft. high by 4 ft. in girth. At Highnam Court, Gloucester, there are two trees, one with short leaves and small cones, which measured in 1906, 54 ft. by 8 ft. 4 in. The other, with much larger cones and larger leaves, was 56 ft. by 4 ft. 7 in. At Bicton a remarkable specimen, 75 ft. high and about 15 ft. in girth near the ground, dividing into many large branches higher up, was measured by me in 1902. A large tree at Longford Castle, planted in 1845 and growing on yellow loam close to the river Avon, in 1893 was 60 ft. high and 15½ ft. in girth at a foot from the ground, dividing above into eleven great branches.⁴ Now it is about 65 ft. high and 75 ft. in diameter, perfectly healthy, and unhurt by frost. There are several fine trees at Osborne.

In Scotland this species was killed⁵ in many places in the severe winter of 1860-1861; and has not thriven subsequently in other places, as it is a failure at Glamis Castle, Forfarshire, and at Murthly, Perthshire. At Hopetoun, Linlithgowshire, the best specimen was killed in 1860, and a survivor was so much injured by the frost of 1879-80 that it was cut down in 1881. Similarly in the north of England, at Lambton Park, Co. Durham, it has been repeatedly tried and failed.

The Monterey pine, however, thrives on the west coast of Scotland; and a tree planted at Monreith, Wigtownshire, in 1884 was 63 ft. high by 5 ft. in girth in 1908.

¹ A tree at Essendon Place, perhaps the same as this, measured, in 1866, 50 ft. high by 2½ ft. in diameter, according to *Gard. Chron.* 1866, p. 950.

² *Gard. Chron.* ix. 108, fig. 23 (1878).

³ Cf. Hutchison, in *Trans. Highland and Agric. Soc. Scotland*, xiv. 59 (1882). Mr. Frost expressed the opinion that cuttings of this pine thrive as well as seedlings.

⁴ *Gard. Chron.* xiv. 725 (1893).

⁵ Cf. Hutchison, *op. cit.* 58.

At Castle Kennedy there are two trees, which girthed in 1904, 9 ft. 4 in. and 8 ft. 6 in., both being 68 ft. in height. At Bargaly, Kirkcudbright, a tree was 75 ft. by 11 ft. 8 in., in 1904. At Keir, Perthshire, there is a healthy tree, although it has never borne cones, which measured in 1905, 73 ft. by 11 ft.

This species thrives amazingly in most parts of Ireland. The finest specimens which we have seen are as follows:—

	Height.	Girth.	Year.	By whom measured.
Woodstock, Kilkenny . . .	110 ft.	12½ ft.	1909	H. J. Elwes.
" " . . .	90 ft.	14½ ft.	1909	H. J. Elwes.
Curraghmore, Waterford ¹ . . .	95 ft.	13 ft. 3 in.	1909	H. J. Elwes.
" " . . .	98 ft.	11 ft. 3 in.	1909	H. J. Elwes.
Fota, Cork . . .	90 ft.	15 ft. 2 in.	1908	H. J. Elwes. An immense tree, 96 paces in circumference.
Muckross, Kerry (Plate 284) . . .	85 ft.	14 ft. 10 in.	1909	H. J. Elwes.
Powerscourt, Wicklow ² . . .	97 ft.	11 ft. 5 in.	1904	A. Henry. Planted 1865.
Kilruddery, Wicklow . . .	82 ft.	16 ft.	1904	A. Henry.
Charleville, Wicklow . . .	86 ft.	11 ft. 9 in.	1904	A. Henry.
Mountshannon, Limerick ³ . . .	89 ft.	15 ft. 2 in.	1905	A. Henry.
Adare, Limerick . . .	87 ft.	6 ft. 10 in.	1905	A. Henry. A narrow, pyramidal tree.
Glenstal, Limerick . . .	91 ft.	15 ft.	1903	A. Henry.
Clonbrock, Galway . . .	90 ft.	12½ ft.	1903	A. Henry. Planted 1857.
Hamwood, Meath . . .	70 ft.	17 ft. at ground	1905	A. Henry. Divided into four stems.

The Monterey pine has been largely planted on the Pacific coast as far north as Washington, and as a rule has been successful. It thrives well near the coast at San Francisco; but requires careful watering in the arboretum of the Stanford University in the Santa Clara valley.

It has been largely planted of late years in South Africa, but is only climatically suited to the winter rainfall districts, and the wholesale planting of the tree in Natal and the Transvaal has produced disappointment.⁴ According to Mr. J. S. Lister, Conservator of Forests, the average annual increment per acre of ten-year-old trees has been no less than 526 ft., as compared with 152 ft. for Blue Gum and 203 ft. for *Pinus Pinaster*. Lately the leaves have been injured by the larva of a moth, *Antheræa cytherea*.

In New Zealand,⁶ no other tree approaches this species in rapidity of growth, and even should it be found that the timber is not of a durable kind, the rate at which it is produced will render it profitable to grow. Mr. T. W. Adams says that his experience of the wood grown in New Zealand satisfies him that it will prove valuable for many purposes.

In Madeira, as I am informed by Dr. Watney, it grows with extraordinary rapidity. A tree at Camacha, sown *in situ* in 1883, measured in 1907, 99 ft. high, and about 8 ft. in girth at the base. (H. J. E.)

¹ Here trees about ten years old and 10 to 23 ft. in height were killed in the severe winter of 1879-80. Cf. Hutchison, *op. cit.* 64.

² Seedlings have been raised from home-grown seed at Powerscourt.

³ This tree was reported, no doubt erroneously, by the gardener, H. Lynch, to have been 98 ft. high in 1878. Cf. *Gard. Chron.* xv. 21 (1894).

⁴ Hutchins, in Flint and Gilchrist, *Science in South Africa*, 396 (1905).

⁵ In *Agric. Journ. Cape of Good Hope*, xxii. 447 (1903), and in *Rep. Conserv. Forests*, 1899, p. 93, *app.* N.

⁶ Adams, *loc. cit.*

PINUS PATULA, MEXICAN PINE

Pinus patula, Schlechtendal et Chamisso, in *Linnaea*, vi. 354 (1831), and xii. 488 (1838); Lambert, *Genus Pinus*, i. 36, t. 19 (1832); Loudon, *Arb. et Frut. Brit.* iv. 2266 (1838); Masters, in *Gard. Chron.* xxiii. 108, tt. 20, 22 (1885), and in *Journ. Linn. Soc. (Bot.)* xxxv. 598 (1904); Kent, Veitch's *Man. Conif.* 355 (1900); Clinton-Baker, *Illust. Conif.* i. 41 (1909); Shaw, *Pines of Mexico*, 29, t. xxii. (1909).

A tree, attaining 80 ft. in height. Bark towards the base fissured longitudinally into large scaly plates; higher up thin, papery, reddish brown, and scaling off similarly to that of *P. sylvestris*. Young branchlets glabrous, glaucous, with slightly raised pulvini, becoming reddish brown in the second year. Buds cylindric-conic, acuminate, ½ in. to ¾ in. long; scales brown, interlaced by their white marginal fimbriæ, with apices free and directed upwards or spreading.

Leaves in threes, persistent two to four years, very filiform and slender, 6 to 9 in. long, ⅓ in. or less in width, flexible, bent, pendulous, serrulate, ending in a cartilaginous point, marked with stomatic lines on the three sides; resin-canals median; basal sheath about an inch long.

Cones lateral, in clusters of two to five, on stout short scaly stalks, deflexed, ovoid-conic, slightly curved, oblique at the base, about 3 to 4 in. long, pale brown, shining; scales oblong, thin, ⅞ in. long, ½ in. wide; apophysis rhomboidal, with upper margin rounded, and a slightly elevated linear ridge; umbo dark grey, depressed, with a minute or obsolete prickle. Seed triangular, grey mottled with black, ⅓ in. long; wing ½ in. to ¾ in. long.

Cones are borne freely on cultivated trees in Cornwall and the south of Ireland, and apparently contain good seed, though we have not heard of any seedlings being raised. These cones remain closed on the old branches for seven or eight years, as they also do on native trees in Mexico.

This species is easily recognisable by its bark, peeling off in the upper part of the stem like *P. densiflora* and *P. sylvestris*, its very slender filiform long needles, multinodal glaucous reddish branchlets, and buds with scales free at the points.

This species, according to Shaw, attains 40 to 50 ft. in height, and grows, in company with *P. Teocote*, at warm temperate altitudes in the central and eastern states of Mexico. Near Jalapa it occurs at 7000 to 8000 ft., mixed with *P. Montezumæ* and various species of oak. Hartweg found it in the mountains around Real del Monte at 9700 ft. Stahl, in Karsten and Schenk, *Vegetationsbilder*, ii. pl. 13 (1905), figures a wood of this species under the Vigas, about 7000 ft. above sea-level, on the road from Perote to Jalapa.

This species was discovered by Schiede and Deppe in 1828, and was probably introduced by them, as Lambert, according to Loudon, had a plant 6 ft. high at Boyton in 1837. Hartweg collected seeds in 1838 from which plants were raised in the garden of the Horticultural Society. (A. H.)

This species succeeds in the mild climate of the south-west of England as in

Cornwall, and of the south of Ireland, where there are many fine specimens. One at Carclew (Plate 285) measured, in 1908, 61 ft. in height and 6 ft. 3 in. in girth. At Luscombe Castle, Dawlish, a tree 55 ft. by 6 ft. 3 in. was bearing cones abundantly when I saw it in 1908. At Tregrehan, a tree,¹ 42 ft. by 8 ft. in 1898, was 60 yards round the branches. At Bicton, Mr. A. B. Jackson measured in 1908 a tree 48 ft. high, dividing at 2 ft. from the ground into two stems, 5 ft. 11 in., and 7 ft. 5 in. in girth. At Pencarrow, Lamorran, and Menabilly, I have seen other specimens of less dimensions. At Fota, near Queenstown, a branchy tree, with a short bole of 8 ft. dividing into wide-spreading limbs, measured in 1908, 63 ft. high by 11 ft. in girth. Many of the branches had been broken by previous gales. This tree was planted in 1847.

(H. J. E.)

PINUS TEOCOTE

Pinus Teocote,² Schlechtendal et Chamisso, in *Linnæa*, v. 76 (1830); Lambert, *Genus Pinus*, i. 37, t. 20 (1832); Loudon, *Arb. et Frut. Brit.* iv. 2266 (1838), and *Encycl. Trees*, 991 (1842); Kent, Veitch's *Man. Conif.* 356 (1900); Masters, in *Journ. Linn. Soc. (Bot.)* xxxv. 598 (1904); Shaw, *Pines of Mexico*, 16, t. ix. (1909).

A tree, attaining 90 ft. high in Mexico, with bark fissured into scaly plates. Young branchlets glabrous, glaucous, pale brown; the epidermis of the decurrent pulvini peeling off in the second and third year. Buds cylindric-conic, obtuse, about $\frac{3}{4}$ in. long, resinous; scales with tips free, interlaced at their bases by white marginal fimbriæ.

Leaves in threes, persistent three years, 4 to 8 in. long, $\frac{1}{20}$ in. broad, spreading, rigid, sharp-pointed, serrulate, with stomatic lines on the three surfaces; resin-canals median; basal sheath about an inch long.

Cones sub-terminal, rarely lateral, single or in pairs, spreading or reflexed, short-stalked, opening when ripe, and falling soon afterwards, ovoid-cylindrical, about $2\frac{1}{4}$ in. long, dull brown or slightly shining; scales numerous, $\frac{3}{4}$ in. long, $\frac{1}{3}$ in. broad; apophysis thickened at the margin, slightly raised, transversely ridged; umbo usually depressed and ashy-grey, with a minute, straight, often obsolete prickle. Seed small, with a narrow wing.

Var. *macrocarpa*, Shaw, *Pines of Mexico*, 17, t. x. (1909).

Pinus leiophylla, Bentham, *Pl. Hartw.* 58 (1842) (in part).

Leaves in threes, fours, or fives. Cones considerably larger than in the type, and illustrated by Lambert's plate. Recorded from a few localities in Mexico, Chiapas, and Tlaxcala.

P. Teocote, according to Shaw, grows at temperate altitudes in the southern, central, western, and north-western Sierras of Mexico, associated with *P. leiophylla*,

¹ This tree is figured in *Gard. Chron.* xxiii. 108, fig. 22 (1885). Fig. 20 represents a cone from a Carclew tree. Three trees are mentioned as existing at Carclew in 1885, measuring 30 ft. by 6 ft., 40 ft. by 6½ ft., and 30 ft. by 5 ft., the girths being taken at three feet from the ground. One of these has since been destroyed by lightning. The dimensions of other trees in 1885 were:—Lamorran, 24½ ft. by 3 ft. 10 in.; Pencarrow, 43 ft. by 7 ft. 3 in.; and Bicton, 36 ft. in height.

² According to Shaw, the word "ocote," from which the tree derives its name, signifies in Mexico, pitch pines and their products. Small bundles of firewood offered for sale in the markets of the cities are also called "ocote."

Schiede and Deppe. It grows on the high lands, particularly on the sloping sides of the mountains of Orizaba and Real del Monte. It is also plentiful in Oaxaca,¹ at 9000 ft. elevation, on dry, hard, and poor soil, composed of reddish clay, where it is a slender tree, of moderate size, with hard and resinous reddish wood.

According to Loudon, a single plant was in cultivation at Boyton in 1826. Subsequently, in 1839, cones were sent by Hartweg to the Horticultural Society of London, who distributed the seed, from which many plants were raised. Most of these succumbed in severe winters; and only a few trees are now living in this country. There are two at Bicton, one² of which, measured by Mr. H. Clinton-Baker in 1898, is 60 ft. by 5 ft. 9 in.; the other is 57 ft. by 6 ft. 10 in. At Luscombe Castle, another is about 50 ft. high by 5 ft. 4 in. in girth. A small tree also exists at Fota, which I saw in 1907.

(A. H.)

PINUS RIGIDA, NORTHERN PITCH PINE

Pinus rigida, Miller, *Dict.* ed. 8, No. 10 (1768); Loudon, *Arb. et Frut. Brit.* iv. 2239 (1838); Sargent, *Silva N. Amer.* xi. 115, t. 579 (1897), and *Trees N. Amer.* 20 (1905); Kent, Veitch's *Man. Conifera*, 373 (1900); Masters, in *Journ. Linn. Soc. (Bot.)* xxxv. 599 (1904); Mayr, *Fremdländ. Wald- u. Parkbäume*, 361 (1906); Clinton-Baker, *Illust. Conif.* i. 49 (1909); Bean, in *Gard. Chron.* xlv. 178, fig. 75 (1909).

Pinus Taeda, Linnæus, var. *rigida*, Aiton, *Hort. Kew.* iii. 368 (1789).

Pinus Taeda, Linnæus, var. *A.*, Poiret, in Lamarck, *Dict.* v. 340 (1803).

A tree, attaining in America 80 ft. in height and 9 ft. in girth. Bark on young stems thin and broken into reddish brown scales, on old trunks an inch thick and deeply and irregularly fissured into broad flat scaly ridges. Young branchlets glabrous, reddish brown, with prominent keeled pulvini. Buds cylindrical or conical, sharp-pointed, $\frac{1}{2}$ to $\frac{3}{4}$ in. long; scales interlaced and matted together by their white fimbriated edges, their long acuminate brown apices free and spreading.

Leaves in threes, persistent two years, spreading, $3\frac{1}{2}$ to $4\frac{1}{2}$ in. long, rigid, slightly curved and twisted, serrulate, ending in a callous point, marked on the three faces by numerous stomatic lines; resin-canals median; basal sheath $\frac{3}{8}$ to $\frac{1}{2}$ in. long.

Cones lateral, usually clustered, sub-sessile, spreading, variable in size, averaging $2\frac{1}{2}$ in. in length, ovoid, light brown, symmetrical at the base; scales thin, flat, $\frac{7}{8}$ in. long, $\frac{3}{8}$ in. wide; apophysis shining, rhomboidal, with a raised sharp transverse keel, and an elevated dark-coloured umbo, terminating in a recurved slender prickle. Seed triangular, with a blackish roughened shell, and a pale brown wing, broadest below the middle; seed with wing about $\frac{3}{4}$ in. long. Cotyledons five. The cones often persist on the branches, and even on the stem, for many years, many opening when ripe and letting out the seed, others remaining closed for an indefinite period. Cones are freely produced on very young trees.

This species is remarkable amongst pines for the frequent occurrence on untouched old stems of adventitious buds, which usually produce branchlets, the shortest of these resembling tufts of leaves arising from the bark, the largest

¹ Cf. *Garden and Forest*, ix. 102 (1896).

² This tree was labelled *P. oocarpa*. The other was named correctly *P. Teocote*.

attaining a few inches in length and branching. Carrière¹ records an instance where clusters of staminate flowers, without any foliage, issued from the trunk of a tree of this species.

In New Jersey,² after the destruction of the trees by fires or by felling, sprouts arise from the stumps, which grow to a considerable size, 6 to 8 in. in diameter; and suckers also spring from the roots, giving rise to a dense bush-like growth. At Grafrath,³ near Munich, only 4 per cent of a number of trees, broken by snow, gave stool-shoots, most of which were short-lived. Similarly, at Les Barres, numerous stool-shoots were produced from the stumps of felled trees, but M. Pardé⁴ believes that these will never make trees. This faculty of regeneration by coppice shoots, so rare amongst conifers, appears in this case to be of no economic value.

DISTRIBUTION

This species is the one always known in eastern North America as the pitch pine, though having nothing in common with the pitch pine of commerce (*P. palustris*). It is widely distributed, crossing the northern boundary of the United States, as far north as the valley of the St. John River in southern New Brunswick, the north shore of Lake Ontario, and the valley of the lower Ottawa river; extending southward in the Atlantic States from Franklin County, Maine, where it is a mere shrub, to northern Georgia, and crossing the Alleghany Mountains to their western foot-hills in eastern Ohio, Pennsylvania, West Virginia, Kentucky, and Tennessee. It is common in the New England states, often forming extensive forests, and grows mainly on sandy plains and dry gravelly slopes, though occasionally it is seen in swamps. In New Hampshire, where I saw this species, the greater part of the land on which it occurs has been repeatedly burnt over;⁵ and it appears to be adapted for regeneration after forest fires, as, like *P. Banksiana*, it produces cones freely and at an early age; and a considerable percentage of the cones hold the seed for several years. Near Hinsdale, it grows in pure open woods on poor sand, the trees scarcely ever exceeding 60 ft. in height and 4 ft. in girth; but in slightly better soil, where the sand contained the mould of decayed leaves, *P. Strobus* grows with it in mixture, and will eventually suppress it, owing to the taller growth of the Weymouth pine.

Sargent⁶ gives an account of a pure forest of the species in Ocean County, New Jersey, which occupies land that had been farmed fifty years previously. An illustration shows a forest of crowded small slender trees about 50 ft. in height. According to Prof. Cooke,⁷ it is one of the most profitable trees to plant in this

¹ *Conif.* 448 (1867).

³ Mayr, *Fremdländ. Wald- u. Parkbäume*, 363, fig. 116 (1906), the figure showing a burnt tree with numerous adventitious shoots on the stem.

⁴ *Principaux Végét. Ligneux Exotiques*, 37. Mr. T. W. Adams, in a paper read 7th August 1907, at the Philosophical Institute, Canterbury, New Zealand, says:—"Trees nearly a foot in diameter, which I cut down in thinning a plantation, sent out leaves along the trunk, while lying on the ground, as some broad-leaved trees do."

⁵ Cf. Chittenden, *U.S. Forestry Bulletin*, No. 55, p. 55 (1905).

⁶ *Garden and Forest*, i. 166 (1888).

⁷ *Ibid.* 59.

state, where, after thirty years, it yields a net profit averaging \$15 per acre. Owing to the facility with which it can be raised by sowing¹ on the poorest soil, it has lately been planted in barren tracts on the coast of Massachusetts and New Jersey, for the production of firewood, though old houses timbered and floored a hundred years ago with this wood, grown on better soil, are still in a good state of preservation. Grown singly, it assumes a ragged appearance, as is well shown in a picture of a wind-swept specimen given in *Garden and Forest*, iv. 397, fig. 65 (1891).

(A. H.)

CULTIVATION

According to Aiton, it was in cultivation at Woburn before 1759; but though it grows better and lives longer than any of the eastern American pines, except *P. Strobus*, it has never become common, and has no qualities which make it desirable to cultivate in this country, except in botanic gardens and collections of conifers. It is hardy, and often ripens seed in the south of England; and as it grows well on the seashore and does not object to salt in the soil, it might be planted on barren sandy shores, though it might not be so suitable for this purpose as *P. radiata* or *P. austriaca*. It has been tried as a forest tree in Germany, where it was at first believed to be the species which produced the pitch pine of commerce, but has not shown any promise of success.² In France, according to M. M. de Vilmorin,³ it is only fit for firewood and of no economic importance, though it might be tried on sandy soils in localities too cold for *P. Pinaster*.

I saw trees at Baleine, near Moulins, and at Geneste and Catros, near Bordeaux, of considerable age, but of no great size, which seems to prove that a warmer climate does not favour its development.

In the Hertogenwald, in Belgium, about fifty trees⁴ of this species, planted in mixture with the common pine at 1500 ft. elevation, on poor soil, at fifty-five years old, average 48 ft. high, and, though healthy and bearing cones, show no advantage in this situation over *P. sylvestris*.

Forbes states that there were several trees of this species believed by him to have been planted in 1743 in the evergreens at Woburn in 1839, one of which measured 75 ft. high and 11 ft. in girth; but I could hear of none now living.

The largest tree, which we have seen or heard of, is growing at Dropmore, and in 1909 was 84 ft. high by 7 ft. 8 in. in girth. It was probably planted in 1847. There are three good trees at Arley Castle, two of which, represented in Plate 286, measured in 1904, 69 ft. and 66 ft. in height, both being 7 ft. 2 in. in girth. The third is 66 ft. high by 5 ft. 11 in. in girth. A tree in Mr. Kaufmann's grounds, The Wilderness, White Knights, measured in 1904, 48 ft. by 8 ft. 1 in., and has thrown out from the stem numerous small adventitious branchlets. Mr. A. B. Jackson measured in 1909 a tree at Bury Hill, Dorking, 56 ft. by 4 ft. Another at Essendon Place, Herts, measured 45 ft. by 6½ ft. in 1908. There are also smaller

¹ It is sown broadcast or in shallow drills. No other conifer grows so rapidly in New England on dry sterile gravels. Cf. Sargent, in *Garden and Forest*, x. 470 (1897).

² Cf. Mayr, *op. cit.*; Schwappach, *Anbauversuche fremdländ. Holzarten*, 58 (1901); and Unwin, *Future Forest Trees*, 49, 86 (1905).

³ *Garden and Forest*, x. 113 (1897).

⁴ Seen by Henry in 1908.

specimens in Kew Gardens, where most of the trees of the species show similar adventitious branchlets; at Nuneham Park, Beauport, Bayfordbury, and Tortworth. A tree at Bargally, in Kirkcudbright, measured 42 ft. by 4 ft. 1 in. in 1904. Trees at Coollattin, Wicklow, about 30 ft. high, are very thriving.

TIMBER

The wood¹ of this pine is little valued in its own country except for firewood, being light, soft, and brittle; and so far as I know is never exported. It contains large quantities of resin; and a century ago was of some economic importance in the production of tar and turpentine, though when the pitch pine of the south became more generally known, it was superseded by the abundant supplies yielded by that tree. (H. J. E.)

PINUS SEROTINA, POND PINE

Pinus serotina, Michaux, *Fl. Bor. Amer.* ii. 205 (1803); Sargent, *Silva N. Amer.* xi. 119, t. 580 (1897), and *Trees N. Amer.* 20 (1905); Masters, in *Journ. Linn. Soc. (Bot.)* xxxv. 599 (1904); Clinton-Baker, *Illust. Conif.* i. 51 (1909).
Pinus rigida, Miller, var. *serotina*, Loudon, *Arb. et Frut. Brit.* iv. 2242 (1838); Engelmann, in *Trans. St. Louis Acad. Science*, iv. 183 (1880); Kent, Veitch's *Man. Conif.* 374 (1900).

This species, which is probably only a southern geographical variety of *P. rigida*, is distinguished from the latter by its more resinous buds, and by its longer leaves, usually 6 to 7, rarely 8 to 10 in. long. The cones are variable in shape, either sub-globose or shortly ovoid, or elongated conical, 2 to 3 in. in length, similar in position and colour to *P. rigida*, but with the more slender prickles usually deciduous. The cones, moreover, as a rule, remain closed on the tree for several years before opening and letting out their seeds. Adventitious branches are produced on old trunks.²

The pond pine grows in low wet flats or in sandy or peaty swamps, near the Atlantic coast from Albemarle Sound southward to the head of St. John's river in Florida, and occurs also, according to Roth,³ on the west side of the peninsula of Florida, and along the Gulf of Mexico westward to near Pensacola. In its manner of growth it resembles *P. Tæda*, and produces similar timber, and is occasionally⁴ tapped for turpentine. It is generally found, either mixed with *P. Tæda* or with *P. Caribæa*, occasionally associating in North Carolina with broad-leaved trees, and is rarely seen in considerable quantity. It often takes possession of abandoned fields.

This species was introduced in 1713, according to Loudon,⁵ who mentions trees about 30 ft. high, at Dropmore, Syon, Pains Hill, and Kenwood. It is probably

¹ Hough, *Trees N. States and Canada*, 9 (1907), says the wood is of medium weight and hardness, with coarse conspicuous grain, resinous and of a brownish red colour with abundant lighter sapwood. It is used for coarse lumber, flooring, sills, etc.; and to some extent for fuel and charcoal.

² Cf. *Garden and Forest*, x. 209 (1897). Engelmann, *loc. cit.*, states that felled trees or posts set in the ground sometimes produce sprouts bearing primary leaves.

³ In *U.S. Forestry Bulletin* No. 13, p. 169 (1897).

⁴ According to Sargent, in *Trees N. Amer.* 21 (1905), but it is not mentioned by Mohr, and must be done on a very small scale.

⁵ *Ency. Trees and Shrubs*, 979 (1842).

short-lived in our climate, where it bears shorter foliage than in America; and the only trees we have been able to identify, are one at Bickton,¹ which was 53 ft. by 4 ft. 8 in. in 1908; and another at Bayfordbury, in an unhealthy state, measuring 41 ft. in height, and 5 ft. 7 in. in girth. This was planted in 1842. (A. H.)

PINUS PALUSTRIS, LONG-LEAF PINE, PITCH PINE

Pinus palustris, Miller, *Dict.* ed. viii. No. 14 (1768); Sargent, *Silva N. Amer.* xi. 151, t. 589, 590, (1897), and *Trees N. Amer.* 17 (1905); Kent, Veitch's *Man. Conifera*, 352 (1900); Masters in *Journ. Linn. Soc. (Bot.)* xxxv. 604 (1904); Clinton-Baker, *Illust. Conif.* i. 38 (1909).
Pinus lutea, Walter, *Fl. Carol.* 237 (1788).
Pinus longifolia, Salisbury, *Prod.* 398 (1796).
Pinus australis, Michaux, *Hist. Arb. Amer.* i. 64, t. 6 (1810); Loudon, *Arb. et Frut. Brit.* iv. 2255 (1838).

A tree, attaining in America 120 ft. in height and 9 ft. in girth. Bark thin, dark, scaly. Young branchlets thick, orange-brown, much roughened by the numerous prominent pulvini. Buds non-resinous, cylindrical, pointed, 1½ in. to 2 in. long; scales lanceolate-acuminate, silvery white, interlaced by their white marginal fimbriae and with their apices free and reflexed. These persist as a dense sheath of reflexed bud-scales at the apex of the branchlet of the second year.

Leaves in threes, deciduous at the end of the second year, about 8 in. long on old trees, 9 to 18 in. long on young vigorous trees, densely crowded on the branchlets, slender, flexible, serrulate, ending in a cartilaginous point, with stomatic lines on all three sides; resin-canals median; basal sheath ¾ in. to 1 in. long.

Cones sub-terminal, spreading or pendulous, on short stout scaly stalks, cylindrical-conic, slightly curved, 5 to 8 in. long; scales thin, flat, 2 in. long, ¾ in. wide; apophysis rhomboidal, slightly elevated, crenate in upper margin, with a transverse sharp ridge, and projecting umbo, armed with a small reflexed prickle. Seed triangular-oval, rather less than ½ in. long, inner surface whitish and three-ridged, outer surface dark-spotted; wing narrow, 1½ in. long. The seeds are shed during dry weather in autumn; and occasionally, when wet sultry weather sets in late, begin to sprout in the cones. The cones usually fall, after dehiscence of the seeds, in the latter part of the winter of the second year, leaving as a rule the lowest rows of scales attached to the branch.

(A. H.)

This² is perhaps of all the pines of North America the one which formerly existed in greatest abundance, throughout a wide belt of country from Virginia through the Carolinas, Georgia, Alabama and Florida, where it extends south to Tampa bay, west to the valley of the Trinity river in Texas, and up the Mississippi valley to the northern borders of Louisiana. It is mainly confined to low-lying tertiary sands and gravels; but Mohr³ found it in Talladega county, Alabama, up to

¹ This tree has long been labelled erroneously "*P. resinosa*."

² A complete account of this pine is given by Mohr in *U.S. Forestry Bulletin*, No. 13, pp. 29-75 (1897). Cf. also G. F. Schwarz, *The Longleaf Pine in Virgin Forest*, pp. 135, 23 illustrations (1907).

³ Mohr, *op. cit.* p. 73.

2000 ft. above the sea. It averages about 100 ft. in height, and occasionally reaches 120 ft., girthing 6 ft. to 8 ft.; and grows usually in pure forests, but near the limits of its area is mixed with other trees.

No tree has suffered so much at the hand of man as the pitch pine. When I first passed through the southern States in 1888 it formed an almost unbroken forest for hundreds of miles along the railway, but is now diminishing so rapidly, that to use Sargent's words, "it seems hopelessly doomed to lose its commercial importance at no distant day."

The literature of this species is very voluminous, and has been largely quoted by Sargent and Loudon; but as it seems impossible to cultivate in this country, we need not say much about it, except that it has been repeatedly tried since 1730 and has usually failed to grow¹ for more than a few years. However, a tree of about 12 ft. high exists in a stunted state at Kew; and another similar in size and unhealthy was seen by Mr. H. Clinton-Baker in 1908 at Menabilly, Cornwall. A seedling raised at Steventon and planted in the Tubney arboretum near Oxford, survived about 25° of frost in the winter of 1908-9.

In France *P. palustris*² has been grown successfully in one place at least, as we learn from an article³ by M. Maurice de Vilmorin, who gives an excellent photograph of two trees at Geneste, near Bordeaux, which were sown in 1831, and are the only survivors of seventeen. In 1897 the largest was 18 metres high by 1.70 metre in girth, the other 16 metres by 1.50 metre. Near them was a Loblolly pine, whose volume was said to be twice as great, though no dimensions were mentioned. They grow on the edge of the dunes near the sea, and M. de Vilmorin states that as producers of timber they cannot in that region compare with *P. Pinaster*, which is mature at forty years old. I visited Geneste, the property of Mlle. Ivoy, in April 1909, and measured these trees carefully. The two largest are 68 ft. by 6 ft. 3 in., and 59 ft. by 5 ft. They seem perfectly healthy, but bear no cones. As the temperature in occasional severe winters, as in 1893, descends at Bordeaux to -16° Cent., it seems as though the want of sufficient heat in summer is the reason why this tree will not grow in England. I believe that on the coast of Portugal it would succeed well.

On the banks of Lago Maggiore, however, in the garden of Rovelli Frères, there is a pitch pine with a clean trunk measuring about 60 ft. by 5½ ft.; and at Intra, in the grounds of the Villa Barbot, I measured a still finer tree, about 75 ft. by 7 ft.

Though the import of the timber of this species to Europe has only assumed great importance in the last twenty years, it is now shipped in larger quantity than any other American timber. Marshall Ward⁴ identified the pitch pine of commerce with *P. rigida*, which it certainly is not; but Laslett himself was evidently writing of the true pitch pine, which he said came chiefly from the ports of Savannah, Darien, and Pensacola, where *P. rigida* is not found. He says it was much used for masts in shipbuilding, and in architecture wherever long, straight, and large

¹ Webster in *Hardy Coniferous Trees*, 95 (1896), says a few specimens have done well at Penrhyn and Woburn. There are no trees of this species at either place, the tree named *P. australis* at Penrhyn being *P. ponderosa*.

² According to *Ann. Hort. Paris*, xix. 212, quoted by Loudon, *Gard. Mag.* xv. 236 (1839), the species may be grafted on *P. Laricio*, and is then rendered much hardier.

³ *Garden and Forest*, x. 112 (1897).

⁴ Laslett, *Timber and Timber Trees*, 367 (1894).

scantlings were needed; and gives details of experiments on its strength and elasticity made for the Admiralty.

Sargent describes the timber as exceedingly hard, very strong, tough-grained, and durable, of light red or orange colour, with nearly white sap-wood. In the United States it is preferred to any other wood for the construction of railway cars, and is now in great demand for railway sleepers, which are replacing those made of oak and chestnut in the northern states.

In consequence of the large consumption in America, and of the great quantity of trees destroyed for resin and by fire, the price has lately risen very much in the English market, being in February 1906 as much as 1s. 6d. to 2s. per cubic foot; and for very long squared balks a higher price is obtained.

Mr. Weale writes as follows:—"The heaviest of the American pines; principally exported from Pensacola and Mobile. It contains resin in quantity, which makes it very durable, and permits its employment in exposed situations. Is moderately hard and straight-grained, and being easily obtainable in long lengths, is in demand for bridge and pier work, and as a building timber. The wood is frequently figured, and used for panelling. For school fittings and furniture, church pews and seatings, it is eminently suitable. In America it is in request for railway sleepers and mining timber, but the low prices at which the Baltic goods are imported prevents its use for the latter purposes in this country."

A handsomely marked variety of this wood, known as curly pitch pine, is found on the outside of some logs, which, when polished, has a nice effect in panels, and being cheap and easy to match, is oftener used in England than the more beautiful, though softer, curly redwood, a variety of the wood of *Sequoia sempervirens*.

Pinchot¹ states that in the Government statistics, under the heading "Yellow Pine," are grouped all the reports of pine production in the south and west, except those of white pine (*P. Strobus*) and Norway pine (*P. resinosa*). Several species, such as *P. palustris*, *P. Tæda*, *P. caribæa*, *P. echinata*, and *P. rigida*, enter into this total. Most of the lumber cut in Texas, Louisiana, Mississippi, Alabama, Georgia, and Florida is *P. palustris*; while practically all that of Arkansas and Missouri is *P. echinata*. Most of the pine cut in Virginia and North and South Carolina is *P. Tæda*.

The resin² or crude turpentine obtained by tapping *P. palustris*, and to a lesser extent *P. caribæa*,³ furnishes the raw material for the production of resin and spirits of turpentine. At present these two species furnish the great bulk of the supply for the whole world. France and Austria, the only other countries where resin is produced on a considerable scale, account for perhaps one-tenth of the total produce. In 1907 the total export of resin from the eastern states was 2½ million barrels, valued at \$11,000,000; while that of spirits of turpentine amounted to 16 million

¹ *U.S. Forestry Bull.* 77, p. 18 (1906).

² This industry is known in America as turpentine orcharding, and is well described by Ashe in *N. Carolina Geol. Survey Bull.* No. 5 (1894); by Mohr, *op. cit.* 67 (1897); and by Bastin and Trimble, *N. Amer. Conifera*, 48 (1897).

³ *P. serotina* is occasionally tapped in the coast region of North Carolina. *P. Tæda* is never tapped. See our remarks under these species.

gallons, valued at \$10,000,000. Judging from the statistics,¹ the annual production is stationary, but the price has increased enormously since 1903. *P. rigida* was tapped for resin in the colonial days in the northern States.

Pine-wool,² used in the manufacture of carpets and mats, is prepared from the leaves of this species. (H. J. E.)

PINUS TÆDA, LOBLOLLY PINE

Pinus Tæda, Linnæus, *Sp. Pl.* 1000 (1753); Lambert, *Genus Pinus*, i. 14, t. 15 (1832); Loudon, *Arb. et Frut. Brit.* iv. 2237 (1838); Forbes, *Pin. Woburnense*, 43, t. 14 (1839); Sargent, *Silva N. Amer.* xi. 111, tt. 577, 578 (1897), and *Trees N. Amer.* 19 (1905); Mohr and Roth, *U.S. Forestry Bulletin* No. 13, p. 113, tt. 17-20 (1897); Kent, *Veitch's Man. Conif.* 382 (1900); Masters, in *Journ. Linn. Soc. (Bot.)* xxxv. 598 (1904); Clinton-Baker, *Illust. Conif.* i. 54 (1909).

A tree, 80 to 100 ft. high, with a straight trunk, usually 6 ft., occasionally 15 ft. in girth. Bark about an inch thick, reddish brown, divided by shallow fissures into broad flat scaly ridges. Young branches glabrous, glaucous, becoming yellowish brown, roughened by the raised and imbricated pulvini. Buds conic, about $\frac{1}{2}$ in. long; scales brown, matted together by their white marginal fimbriæ, and with their apices free and reflexed.

Leaves in threes, persistent for three years, densely crowded, spreading, 6 to 9 in. long, $\frac{1}{16}$ in. wide, rigid, slightly twisted, serrulate, ending in a sharp cartilaginous point, pale green, with numerous stomatic lines on the three sides; resin-canals median; basal sheath nearly an inch in length. The reflexed bud-scales remain as a persistent sheath at the apex of the shoots of the second and third years.

Cones lateral,³ solitary or clustered, sub-sessile, spreading, cylindrical-conic, usually 3 in. long, occasionally 4 or 5 in., light brown; scales thin, about an inch long and $\frac{1}{2}$ in. wide; apophysis rhomboidal, raised, with a transverse elevated ridge, and a triangular umbo, ending in a short, usually reflexed prickle. Seed rhomboid, $\frac{1}{4}$ in. long, with two or three distinct ridges, dark brown mottled with black, surrounded to the base by the narrow border of the delicate wing, which is pale brown, shining, and about an inch long. Cones are produced abundantly every year, opening in autumn and winter of the second year, and falling off in the succeeding season through the decay of their short stalks. The seedlings have usually six cotyledons, and grow fast, producing adult ternate leaves in their first season, when they attain 6 to 8 in. in height. They average in the forest at the end of the fourth year 3 ft. in height.

The Loblolly pine extends along the coast from Cape May in New Jersey, and the Delaware and Maryland peninsula, southwards to Cape Malabar and Tampa Bay in Florida, and westward to near New Orleans, extending inland as far northward as

¹ Pinchot, *U.S. Forest Circular* No. 153 (1908).

² Cf. J. R. Jackson, in *Gard. Chron.* xlv. 366 (1908), who states that pine-wool is also prepared in Breslau, Silesia, from the leaves of the Austrian pine (*P. Laricio*, var. *austriaca*). The latter is used for stuffing cushions, and is made, mixed with ordinary wool, into a kind of flannel. Specimens of both kinds may be seen in the Kew museum.

³ They are subterminal in badly-developed trees.

the parallel of 35°, occupying large tracts in the Carolinas, Georgia, Alabama, and Mississippi, extending into southern Tennessee. West of the Mississippi river it occurs as far north as the south-eastern border of Indian Territory and southern Arkansas, where it frequently grows in extensive nearly pure forests on the rolling uplands, and occurs in Louisiana and eastern Texas as far west as the valley of the Colorado river.

On the Atlantic slope, near its northern limit, it grows most frequently on the flat lands of the tidewater districts, usually crowded with other pines, oaks, and hickories; and in Virginia and North Carolina springs up rapidly on lands exhausted by agriculture, the primeval forests having nearly all disappeared. In the swamps bordering the Albemarle and Pimlico sounds, gigantic trees of this species, known as the Rosemary pine, sometimes attained¹ a height of 170 ft.

In Berkeley county, South Carolina, the forest land² consists of four distinct regions. On the fresh and moist uplands, where the soil is a light sandy loam, *P. Tæda* occurs both in pure stands or in mixture with *P. palustris* and broad-leaved trees. *P. palustris* is confined mainly to the higher situations and the drier and lighter soils, either pure or mixed with *P. Tæda* and hardwoods. In the alluvial land, either along rivers or bordering swamps, where the soil is best, the forest is mixed, consisting of maple, ash, hickory, oaks, with *P. Tæda* and *P. serotina*. In the swamps, where there is standing water all the year round, there is the same admixture of species, with the addition of *Taxodium distichum*. (A. H.)

This pine is of considerable economic importance in the southern and south-western states, where it forms considerable forests; and though there are no reliable statistics, it appears to be one of the main trees cut for lumber at the present time in Virginia and the Carolinas.³ A considerable proportion of the long and heavy sticks of hewn timber reaching the Mobile market from Alabama for export as "pitch pine" are Loblolly pine.⁴ Half the lumber cut in Arkansas and shipped as "yellow pine" to northern markets is Loblolly pine, the other half being *P. echinata*. The timber is very variable in quality under different conditions of growth. Sargent says that very large and fine masts were formerly made of this tree, and used in the United States as well as shipped to Europe; but were not distinguished by Laslett from those made of *P. Strobus*.

In England this tree has been grown for nearly two centuries, having been introduced⁵ by Bishop Compton before 1713, but though it has attained a considerable size in some instances, it cannot be said to thrive in this country, requiring a much greater degree of heat than our climate affords.

Loudon figures a tree 75 ft. high, growing at Syon in 1838, and mentions others at Kew, Dropmore, Whitton, and Pains Hill, the latter being then 60 to 70 ft. high, and, as he said, the handsomest tree in Europe. All these are now dead,

¹ Cf. Curtis, *Trees and Shrubs, N. Carolina*, 23 (1860).

² Cf. Chapman, in *U.S. Forestry Bulletin* 56, pp. 8-10 (1905).

³ Pinchot, in *U.S. Forestry Bulletin* 77, p. 18 (1906), says:—Most of the pine cut in Virginia and North and South Carolina is *P. Tæda*, which is widely known in commerce in the United States as North Carolina pine.

⁴ Mohr says the best qualities are equal to true pitch pine, and are used by house carpenters. Large amounts of inferior stuff are shipped as firewood from the coasts of Virginia and North Carolina.

⁵ Aiton, *Hort. Kew.* iii. 368 (1789).

and the only tree¹ which we have found is one growing at Bicton which Mr. H. Clinton-Baker measured in 1908, as 50 ft. in height, and 6 ft. 9 in. in girth at 3 ft. from the ground. This tree bears cones;² but the seed does not seem to be fertile. The leaves are $4\frac{1}{2}$ to 5 in. in length, much shorter than is usual in American trees of this species.

At Geneste, near Bordeaux, I saw several large trees of this pine in 1909 growing near the pitch pines, which they much exceeded in size. The largest was 92 ft. by $9\frac{1}{2}$ ft., and bore abundant cones, which produce fertile seed, and natural reproduction is here common. Another was 95 ft. by 9 ft., a third about 85 ft. by $9\frac{1}{2}$ ft. Mademoiselle Ivoy informed me that the resin of this tree was much more aromatic than that of the native *P. Pinaster*.

Mr. Weale sends us the following note:—"Loblolly pine is not imported into this country in steady quantities and is often sold as Carolina pine. When pitch pine is imported in the form of sawn boards, this wood is frequently observed amongst them. It is not comparable with pitch pine in strength and durability, and cannot hope to find a market upon any other considerations than those of price."

Though the wood of this species contains but little less resin than that of *P. palustris*, and the composition and the distribution of the resin in the log are the same in both species, yet for some unexplained reason the resin of the Loblolly pine does not flow freely, and hardens so rapidly on exposure that it cannot be worked. The statements frequently made³ as regards the use of this tree for resin are erroneous and can only be explained by a confusion of names, and it is most likely that the Cuban pine (*P. caribæa*) was referred to.⁴

(H. J. E.)

PINUS CANARIENSIS, CANARY PINE

Pinus canariensis, Ch. Smith, in Buch, *Phys. Besch. Canar. Ins.* 159 (1825); De Candolle, *Pl. Rar. Jard. Genève*, i. tt. 1, 2 (1829); Loudon, *Arb. et Frut. Brit.* iv. 2261 (1838); Webb et Berthelot, *Phyt. Canar.* iii. 280, Atlas, t. 6 (1845-50); Christ, in Engler, *Bot. Jahrb.* vi. 486 (1885); Masters, in *Gard. Chron.* iii. 723, f. 94 (1888), and in *Journ. Linn. Soc. (Bot.)* xxxv. 593 (1904); Clinton-Baker, *Illust. Conif.* i. 13 (1909).

A tree, attaining 80 ft. in height and 10 ft. or more in girth. Bark thick, reddish, slightly fissured, and separating on the surface into irregular scales. Young branchlets glabrous, yellow, with prominent keeled pulvini. Buds ovoid, acute, $\frac{3}{4}$ in. long, $\frac{1}{2}$ in. broad; scales reddish brown, matted together at the base by their marginal white fimbriæ, spreading, with their tips free and reflexed. The apices of the branchlets of the second and third years are each marked with a conspicuous sheath of the persistent reflexed bud-scales.

Leaves in threes, persistent two years, densely crowded on the branchlets, spreading, 7 to 12 in. (averaging 9 in.) long, $\frac{1}{20}$ in. wide, flexible, serrulate, ending in a fine cartilaginous point, with two to four stomatic lines on each of the three sides; marginal canals median; basal sheath $\frac{3}{4}$ in. long.

¹ The tree at Tortworth Court, mentioned as *P. Teda* by Kent in Veitch's *Manual*, p. 383, is *P. rigida*.

² Figured by Clinton-Baker, *Illust. Conif.* i. 54 (1909).

³ As in Bastin and Trimble, *North American Conifera*, 44 (1897).

⁴ Cf. Mohr, *op. cit.* 121.

Cones subterminal, solitary or clustered, deflexed or pendent, on short stout scaly stalks, cylindrical-conic, with a flattened apex, very variable in length, averaging 5 in. long; shining yellowish brown, and closely resembling those of *P. Pinaster* in appearance; scales thick, about $1\frac{3}{4}$ in. long, and $\frac{3}{4}$ inch wide; apophysis rhomboid, slightly elevated, with a transverse sharp ridge, and a dark brown prominent non-prickly umbo. Seed $\frac{1}{2}$ in. long, pointed at both ends, with a pale brown wing $1\frac{1}{4}$ in. long.

The seedlings have six to eight cotyledons, and grow rapidly, attaining 10 in. in their first year. In *Gard. Chron.* xv. 333 (1881), it is stated that Hochstetter had succeeded in fixing the juvenile form of this species and of *P. Pinea* by cuttings, producing beautiful bushes with solitary needles.

This species is endemic in the Canary Islands. It does not occur on some of the dry eastern islands, as Lanzarote and Fuerteventura; and only a single tree exists on Gomera, and a small wood on Ferro. According to Christ, it is called *tea* by the Spaniards, and was formerly widely spread, and descended lower on the mountains, than at present. Large woods still exist in Teneriffe, Palma, and Grand Canary, beginning at 3700 ft. altitude and ascending to where the snow lies in winter, solitary trees being met with on Teneriffe as high as 6600 ft. It grows on dry slopes, exposed to the sun and wind, and appears to prefer basalt, where the soil contains no lime. Its upper elevation is limited not so much by the cold, as by the poverty of the soil, which at high elevations consists of pumice stone, on which no tree growth can exist. Christ saw many beautiful woods, with an undergrowth of *Cistus*, and numerous seedlings growing under the shade of the parent trees. Many of the trunks¹ show the same character as *P. rigida*, as they produce epicormic branches covered with solitary primary leaves.

The trees are conical in shape, often branched to the ground, and somewhat weeping in habit, with pendulous leaves. Most of the famous trees of this species, one of which was mentioned by Loudon as 30 ft. in girth near the ground, were destroyed even in Webb's time; and the largest tree seen by Christ, the *Pino del Paso*, in Teneriffe, is only 10 ft. in girth; but he mentions old trees on Palma twice as thick.

The timber is reported to be remarkably heavy and durable. In the museum at Kew, there is preserved part of the beam of a wine-press, made of the heart-wood, which is quite sound, although the press was over 200 years old and had stood all the time in the open air.

This species is rare in cultivation in England, except as a green-house plant. Loudon states that specimens in the open were killed at Dublin. There is, however, a small tree, at Heligan, Cornwall, which in 1906 was fifteen years old and about 25 ft. high; and another at Carclew about 6 ft. high, which was slightly damaged by frost in 1908-1909.

It succeeds well on the Riviera, even on calcareous soil; and there are fine specimens at La Mortola and Grimaldi.² Elwes measured one at the Villa Thurêt, Antibes, 92 ft. by $5\frac{1}{2}$ ft., which bore fertile cones in January 1910. (A. H.)

¹ Cooley, in *Bot. Gazette*, xxxviii. 441, fig. 1 (1904), describes a tree in the Botanic Garden at Naples, the stem of which is clothed to the ground with shoots like those of *P. rigida*.

² Cf. *Gard. Chron.* iv. 39 (1888).

PINUS ECHINATA, SHORT-LEAF PINE

- Pinus echinata*, Miller, *Dict.* Ed. 8, No. 12 (1768); Sargent, *Silva N. Amer.* xi. 143, t. 587 (1897), and *Trees N. Amer.* 29 (1905); Mohr, *U.S. Forestry Bulletin* No. 13, *Timber Pines of Southern U.S.* 91, plates 13-16 (1897); Masters, in *Journ. Linn. Soc. (Bot.)* xxxv. 624 (1904).
Pinus virginiana, Miller, var. *echinata*, Du Roi, *Obs. Bot.* 44 (1771).
Pinus squarrosa, Walter, *Fl. Carol.* 237 (1788).
Pinus Teda, Linnæus, var. *variabilis*, Aiton, *Hort. Kew.* iii. 368 (1789).
Pinus Teda, Linnæus, var. *echinata*, Castiglioni, *Viag. negli Stati Uniti*, ii. 312 (1790).
Pinus mitis, Michaux, *Fl. Bor. Amer.* ii. 204 (1803); Loudon, *Arb. et Frut. Brit.* iv. 2195 (1838); Kent, Veitch's *Man. Coniferae*, 342 (1900); Mayr, *Fremdländ. Wald- u. Parkbäume*, 358 (1906); Clinton-Baker, *Illust. Conif.* i. 32 (1909).
Pinus variabilis, Lambert, *Genus Pinus*, i. 22, t. 15 (1803).

A tree, attaining in America 120 ft. in height and 12 ft. in girth. Bark about an inch thick, broken into large irregular scaly plates. Young branchlets slender, brittle, glabrous, glaucous; in the third year the bark of the branchlets exfoliates in large flakes. Buds, $\frac{1}{4}$ in. long, cylindrical, sharp-pointed, brownish, shining, with resinous and appressed scales.

Leaves, both in pairs and in threes, deciduous in the second and third years, spreading, about 3 in. long, slender, flexible, curved, slightly twisted, serrulate, sharp-pointed, with stomatic lines on all three surfaces; resin-canals median; basal sheath $\frac{3}{8}$ in. long.

Cones lateral, either sessile and spreading, or short-stalked and pendulous, in pairs or clusters of three or four, ovoid, $1\frac{1}{2}$ to 2 in. long, dull brown; scales about $\frac{3}{4}$ in. long, obovate, cuneate, rounded at the apex, thin and flexible; apophysis slightly thickened, with a transverse ridge and a central umbo, armed with a short, often deciduous, prickle. Seed triangular, brownish-black, $\frac{3}{16}$ in. long; wing $\frac{1}{2}$ in. long, pale, streaked with brown lines; cotyledons 4 to 7.

This species is readily distinguishable by the leaves, both two and three in a cluster, and by the peculiar scaling of the bark on the branchlets in the third year.

A complete account of this pine, with a map of its distribution, is given by Mohr, who states that it is a tree of the plains and foothills, in the south rarely ascending to 2500 ft., and in the north never higher than 1000 ft. East of the Mississippi it is now found scattered amongst the broad-leaved trees; but in the beginning of the nineteenth century it formed a considerable part of the coniferous forest, growing on light sandy soil in the Atlantic states from New York to Virginia. (A. H.)

This tree has much the same distribution as *P. Teda*, occurring from Staten Island, New York, and east Pennsylvania, through the Atlantic states to northern Florida, crossing the Alleghany Mountains to Kentucky and Tennessee, and extending west to north-eastern Texas, north-western Louisiana, Arkansas, southern Missouri and south-west Illinois. It is more abundant inland than on the coast region of the Gulf states, where the pitch pine replaces it; and is most abundant and in the greatest perfection west of the Mississippi river, where it forms large forests and is the most important source of the timber known in the United States as yellow

pine, which is used more largely for ordinary building purposes in the south-western states than any other wood; and as this tree has the power of spreading itself rapidly over abandoned fields, which it soon covers with healthy forest, it is not likely to become scarce. According to Mohr, average trees in Arkansas and Texas range from 95 to 120 ft. high, and 17 to 25 in. in diameter, at ages of 100 to 200 years.

According to Sargent this timber¹ is very variable in quality, but only second to true pitch pine in its class, and being less resinous, softer and more easily worked, is often preferred for cabinet-making, interior finish, doors, window-sashes, etc. It is also largely used for flooring, weather-boarding, railway cars and sleepers.

Though it does not yet seem to be well known in Europe, yet as pitch pine becomes scarcer and dearer, it will no doubt be substituted for it, or for white pine (*P. Strobus*), which is already known in the English market as yellow pine.

This pine is remarkable for its capacity of producing vigorous sprouts² from the stumps, when the tree is felled or injured by fire. These coppice shoots, ten to thirty in number from each stump, remain bushy, attaining no great height, and are of no value for the regeneration of the tree.

P. echinata was introduced into England about 1739, as Miller had it in cultivation in that year; but has proved as unsuitable for this climate as most of the other pines of the Atlantic coast, and is probably short-lived, as it is very rare in collections.³ A tree at Dropmore, which in 1908 measured 50 ft. high and 3 ft. 4 in. in girth, is probably the specimen mentioned by Loudon as being cultivated there under the name *P. variabilis*, which it still bears. Mr. Page says that it occasionally bears a few cones, but that he has not succeeded in raising plants from the seed. Another specimen at Bayfordbury is 34 ft. by 3 ft.; and one in Kew Gardens, which bore a few cones in 1908, measured 32 ft. by 2 ft. 4 in. in 1909.

(H. J. E.)

PINUS HALEPENSIS, ALEPPO PINE

- Pinus halepensis*, Miller, *Dict.* Ed. 8, No. 8 (1768); Loudon, *Arb. et Frut. Brit.* iv. 2231 (1838); Boissier, *Flora Orientalis*, v. 695 (1884); Masters, *Gard. Chron.* xxii. 552, f. 97 (1884), iii. 627, f. 84 (1888), and *Journ. Linn. Soc. (Bot.)* xxxv. 606 (1904); Willkomm, *Forstliche Flora*, 237 (1887); Mathieu, *Flore Forestière*, 607 (1897); Kent, Veitch's *Man. Coniferae*, 332 (1900); Clinton-Baker, *Illust. Conif.* i. 23 (1909).
Pinus alepensis, Poirer, in Lamarck, *Dict.* v. 338 (1804).
Pinus hierosolymitana,⁴ Duhamel, *Traité des Arbres*, ii. 126 (1755).
Pinus maritima, Lambert, *Gen. Pinus*, i. t. 6 (1832) (not Miller).

A tree attaining 80 ft. in height and 12 to 15 ft. in girth, though often, on poor soils, considerably smaller. Bark at first smooth, silvery grey, and shining, becoming

¹ The wood of this pine is indistinguishable from that of *P. Teda*. Cf. Fernow and Roth, in *U.S. Forestry Bulletin* No. 13, pp. 13, 14 (1897).

² Cf. *Garden and Forest*, x. 192, 209 (1907), and Roth, in *U.S. Forestry Bulletin* No. 13, p. 111 (1897), who observed hundreds of acres along the railways in Texas and Arkansas, covered with bushy clusters of vigorous sprouts from the pine stumps. In *Bot. Gaz.* xxviii. 69 (1899), *P. echinata* is said to produce root-suckers, but this seems to be erroneous.

³ A tree at Bicton, of which we have specimens with stunted foliage, doubtfully referable to this species, died recently.

⁴ This name is uncertain, and cannot be adopted; moreover, it would be inconvenient to set aside *halepensis*, which has been in use for over a century. Cf. Graebner, in *Mitt. deut. dend. Ges.*, 1908, p. 68.

on old trunks reddish brown, fissured, and scaly. Young branchlets glabrous, glaucous grey, flexible, with slightly raised pulvini. Buds conical, slender, less than $\frac{1}{2}$ in. long, brownish white; scales interlaced by white fimbriated margins, with the tips free and often reflexed. Base of the shoot girt with a sheath of reflexed bud-scales.

Leaves in pairs, persisting two years, $2\frac{1}{2}$ to 4 in. long, slightly spreading, slender (about $\frac{1}{3}$ in. wide), curved, twisted in the upper third, serrulate, short-pointed, with stomatic lines on both surfaces; resin-canals marginal; basal sheath $\frac{1}{3}$ in. long, persistent.

Cones, solitary or two or three together, lateral, spreading or deflexed, on thick scaly stalks (about $\frac{1}{2}$ in. long), ovoid-conic, 2 to 3 in. long; scales shining, yellowish brown, oblong, flat, about an inch long and $\frac{5}{8}$ in. wide; apophysis rhomboidal, flat, or slightly raised towards the centre, with a transverse linear ridge; umbo greyish, depressed, often with a slight ridge, unarmed. Seed, nearly $\frac{1}{4}$ in. long, light brown on the lower and blackish on the upper surface; wing pale brown with a dark border, nearly an inch in length. The cones are variable in direction, though often directed backwards, and are irregular in the time of opening, some remaining closed till May in the third year, others not letting out the seeds till the fifth or sixth year.

VARIETY

Var. *Brutia*.

Pinus Brutia, Tenore, *Flora Napolitana*, i. Prod. p. lxxii (1811), iv. 136 (1830), and v. 266, f. 200 (1835); Loudon, *Arb. et Frut. Brit.* iv. 2234 (1838); Boissier, *Flora Orientalis*, v. 695 (1884); Masters, in *Journ. Linn. Soc. (Bot.)* xxxv. 608 (1904).

Pinus resinosa, Loiseleur, in *Nouveau Duhamel*, v. 237 (1812) (not Solander).

Pinus Pithyusa,¹ Steven, *Bull. Soc. Nat. Mosc.* i. 49 (1838).

Pinus persica, Strangways, in Loudon, *Gard. Mag.* xv. 130 (1839).

Pinus Loiseleuriana, Carrière, *Conif.* 382 (1855).

Pinus Paroliniana, Webb, ex Carrière, *Conif.* 391 (1855).

Pinus pyrenaica,² Carrière, *Conif.* 391 (1855); Masters, in *Gard. Chron.* iv. 267, f. 32 (1888); Kent, Veitch's *Man. Coniferae*, 368 (1900); Mayr,³ *Fremdländ. Wald- u. Parkbäume*, 360 (1906).

Pinus Parolinii, Visiani, *Mem. Ist. Venet.* vi. 243 (1856).

Pinus Eldarica, Medwejew, in *Act. Hort. Tiflis*, vi. 2, p. 21 (1902), and *Bäume u. Sträucher Kaukasus*, i. 20 (1907); Masters, in *Gard. Chron.* xxxiv. 251 (1903).

This is a geographical variety of *P. halepensis*, distinguished by its longer, darker green, and more rigid leaves, 4 to 6 in. in length. The cones,⁴ which occasionally arise in whorls of three to six, are never deflexed, but always spreading or pointing forwards, and are in rare cases sub-sessile. The staminate flowers are also larger

¹ Referred to *P. Brutia* by Lipsky, in *Act. Hort. Petrop.* xiv. 309 (1898). According to Loudon, *Gard. Mag.* xv. 130 (1839), the cone is like that of *P. halepensis* in the strong woody peduncle.

² Probably not *P. pyrenaica*, Lapeyrouse, *Hist. Abrégée Pl. Pyrén.* Suppl. 146 (1818), occurring in the Pyrenees, and identified by Calas with the Pyrenean variety of *P. Laricio*. Cf. our vol. ii. 407, note 2. The large forests of *P. pyrenaica* in Spain, described by Captain Cook, are *P. Laricio*. Cf. Willkomm, *Pflanzenverb. iberischen Halbinsel*, 109 (1896).

³ Mayr places *P. halepensis* and var. *Brutia* in different sections, though the character on which he relies for this distinction, the position of the cones, is identical in both.

⁴ All the specimens of *P. Brutia* in Parlatore's herbarium at Florence are from cultivated trees, and differ only from *P. halepensis* in their longer leaves and larger cones. So far as I could judge from these, and from a Calabrian specimen, the differences between this variety and typical *P. halepensis* simply depend on the greater vigour of the former, due to better soil and climate.

than in the type. The differences observable, due to the influence of soil and climate, are similar to those seen in the Austrian and Corsican varieties of *P. Laricio*.

DISTRIBUTION

The Aleppo pine is a Mediterranean species, occurring in almost all the countries bordering on its shores, from Spain to Asia Minor, and from France and Dalmatia to Morocco and Algeria.

In France this species occurs in Provence, in the region of the olive, from the foot of the Alps westward to Sommières, Gard, never extending far from the sea-coast, and not extending above 2700 ft. altitude. It grows mainly on limestone, occupying dry rocky slopes, where scarcely any other tree will grow, but is also common on the porphyry of the Estérel, and is met with on gneiss near Cannes.¹ On Mount Ventoux it ascends to 1300 ft., but at this elevation and distance from the sea is liable to suffer from frost. Large forests occur, as that of Mérindol on Mount Luberon, which covers 4000 acres, and is composed of a mixture of Aleppo pine and *Quercus Ilex*.

Here the trees are usually small in size and stunted in growth, with crooked stems, as the soil is arid and shallow limestone; but in a ravine, where there was some moisture and a growth of ferns, I measured a tree 80 ft. in height, with a straight stem, free of branches to 50 ft., and 8 ft. in girth. In Spain² this species is a native of all the provinces bordering on the Mediterranean, and extends inland as far as Huesca, Saragossa, Teruel, Cuenca, and Guadalajara, growing in the lower regions of the mountains up to 3300 ft., and somewhat rare on the coast itself, though there is a remarkable wood, covering the greater part of the Dehesa de Valencia, a sandy spit of land, about 8 miles long, separated from the sea by the Albufera lagoon. There are small woods on limestone east of Gaucin, north of Gibraltar, where I measured a tree at 900 ft. elevation, 65 ft. in height, and 10 ft. 8 in. in girth.

It is common in the Balearic Isles, where it ascends in Majorca as a tree to 3200 ft., becoming a mere bush at 3900 ft. On Iviza there is a forest 16,000 acres in extent, consisting of *P. halepensis*, partly pure and partly mixed with deciduous trees.

In Italy it is not found north of the Apennines, but it is fairly common on the west and east coasts. It grows,³ though in much less abundance than in the Riviera, on serpentine rocks between Savona and Genoa, and occurs in the mountains of Umbria between Spoleto and Terni, ascending on Somma to about 2000 ft. About the falls of the Velino, and in the defile through which the Nar flows below Narni, it is pretty frequent, growing on limestone amidst the woods of *Quercus Ilex*. On the eastern side of the Adriatic⁴ it succeeds as a planted tree in Dalmatia, but is only wild south of latitude 43°, occurring in small quantity about Ragusa and in the Meleda and Curzola islands. It has also been observed by Baldacci in Albania.

It is common in Greece, except in southern Peloponnesus, and also occurs in Crete and most of the islands, often forming extensive forests near the sea-coast, and

¹ Bunbury, *Bot. Fragments*, 8 (1883).

² Willkomm, *Pflanzenverb. iberischen Halbinsel*, 95, 190 (1896).

³ Cf. Bunbury, *Bot. Fragments*, 8 (1883). Sprenger, in *Mitt. deut. dendr. Ges.*, 1905, p. 182, says there are fine trees on the heights of Posilippo, near Naples, and notes the great quantity of its cones, even when the trees are very young. The pollen is so abundant that people who suffer from hay fever avoid it.

⁴ Cf. Beck, *Veget. illyrischen Länder*, 135 (1901).

occasionally ascending to 3000 ft. Prof. Samios of Athens informs us that a tree at Chalcis, which Elwes saw many years ago, is 130 ft. in height, and 10½ ft. in girth. In Cyprus¹ this is a finer tree than *P. Laricio*, often attaining in the forest 10 ft. in girth, but on dry ground on the hot coast it assumes a bushy form. Mr. A. K. Bovill, Principal Forest Officer in Cyprus, informs us that he has photographed a tree 15 ft. in girth. According to Madon,² it flourishes on all soils up to 5000 ft., mixing above 4500 ft. with *P. Laricio*.

This species also occurs in west and south Asia Minor, covering the sand dunes of the Cilician coast westwards from Mersina; and on the coast of Syria and the lower ranges of the Lebanon is a handsome tree, judging from a photograph (Plate 287) sent us by Dr. Day of Beyrout.

In Algeria *P. halepensis*, pure or mixed with *Quercus Ilex*, forms the greater part of the forests, where the rainfall is less than 12 in. annually, and extends from the sea-coast to about 5000 ft. altitude. It grows mainly on limestone, but is occasionally seen on clay, sandstone, and conglomerate. It is remarkable for its reproductive power, as seedlings are very numerous, and regeneration is certain to ensue after the destruction of the forests by axe or fire. In the dry regions of Algeria, where forest fires are common, it is apparently adapted for natural regeneration on burnt areas, as cones with fertile seed are always present on the trees. Young trees bear cones when only 5 or 6 ft. high, while older trees retain many of the cones closed for six or eight years; and these, when scorched by fire, burst and scatter the seed to a distance of 10 or 20 yards.³ This is well seen in a forest near Affreville, where *P. halepensis* is the predominant species, mixed with a small proportion of *Callitris quadrivalvis* and *Quercus coccifera*. Here the trees are of no great size, but I measured one in the open 70 ft. high and 14 ft. 11 in. in girth.

In Morocco it apparently does not occur near the coast, but is reported by Ball⁴ to grow in the mountains to the south at 4000 to 5500 ft. altitude. It is met with in Egypt, near Alexandria, but is probably planted there.⁵

Var. *Brutia* has a more restricted and a more easterly distribution than the type. It is met with in Calabria in Italy, where it was discovered by Tenore in the Aspromonte mountains between 2400 and 3600 ft. altitude. According to Sprenger,⁶ it grows here on limestone, ascending to 5000 ft., and attaining about 80 ft. in height and 250 years in age. He says that the wood is white and free from resin. According to Halacsy,⁷ it is absent from the mainland of Greece, but occurs at high elevations in Crete. It grows on the shores of the Sea of Marmora, where it is known as *kara jcham* or black pine.⁸ It seems to be the mountain form in Asia Minor, occurring in Pamphylia, Cilicia, and on the Taurus and Lebanon, the tree near the coast being typical *P. halepensis*. Specimens collected in 1874 by Elwes in Lycia, and noted as growing on

¹ Cf. Hartmann, in *Mitt. deut. dend. Ges.*, 1905, p. 169.

² *Forests of Cyprus*, in *Cyprus, Parliament. Paper No. 366*, of 1881.

³ Cf. Lefebvre, *Les Forêts de l'Algérie*, 421 seq. (1900). The part which the persistent closed cones play in the regeneration has not been understood by local observers, who assert that the cones on very young trees produce unfertile seed. This requires further investigation.

⁴ In *Journ. Linn. Soc. (Bot.)* xvi. 669 (1878).

⁵ In *Mitt. deut. dend. Ges.*, 1904, p. 191.

⁶ Specimens procured for Mr. H. Clinton-Baker by Mr. Stuart Hogg.

⁷ Boissier, *Flora Orientalis*, v. 695 (1884).

⁸ *Consp. Fl. Graecae*, iii. 453 (1904).

limestone, are var. *Brutia*. This variety¹ also grows sparingly on the north-east coast of the Black Sea near Pizunda,² and a small forest, about 4 miles in length, of trees not exceeding 40 ft. in height, occurs in the centre of Transcaucasia, at the foot of the great Caucasus, on the west edge of the Eldar Steppe, between 1400 and 2000 ft. elevation.³

This variety is cultivated in Afghanistan, where it was collected by Aitchison, and in Persia where, Dr. Stapf informs us, it is a tall tree, resembling *P. sylvestris* in habit, and very hardy, as it bears without injury severe winters and a heavy snow-fall. Two plants raised at Vienna from seed brought home by Dr. Stapf from Shiraz were at first indistinguishable from seedlings of typical *P. halepensis*, but as they grew older bore the longer foliage of var. *Brutia*. (A. H.)

CULTIVATION

Though this tree was introduced by Bishop Compton in 1683, and has been often planted since, it is not hardy enough to endure severe winters;⁴ and the trees mentioned by Loudon⁵ at White Knights, Berks, and Croome, Worcester, which in 1838 were 57 and 40 ft. high, are no longer living. The only trees⁶ of considerable size which we have seen are one at Margam, Glamorganshire (Plate 288), which in 1907, when I saw it, was a healthy tree, measuring 72 ft. by 10 ft., and bearing many cones, which are conspicuous from their green colour, and another in the Botanic Garden, Bath, which was 46 ft. by 4 ft. 6 in. in 1909, and is a healthy tree with smoother and greyer bark than *P. Pinaster*. There are small trees at Kew and Bicton.

Seedlings which I raised from Spanish seed in 1907 were, with three exceptions, killed by the frost of January 1909, though protected by boughs laid over them, and it seems useless to attempt to grow this tree except in very dry, warm, and sheltered situations near the sea in the south of England.

According to Loudon,⁷ var. *Brutia* was introduced in 1836, when it was raised from seed by the Earl of Mountnorris. Strangways, in 1839, obtained seeds from Persia, plants from which were raised in the garden of the Horticultural Society, and were known as *P. persica*. No trees of this variety are now in cultivation in this country, so far as we know, except a small specimen at Kew.

In February 1910 I saw the tree in the Botanic Garden at Naples, on which Tenore founded his description of *P. Brutia*. It is very vigorous, with a wide-spreading crown of foliage, and measured 82 ft. by 10 ft. A branch sent to Cambridge by the director, M. Cavara, bears seven young cones in a whorl, and two mature cones in a second whorl, which scarcely differ from those of *P. halepensis*.

¹ Lipsky, in *Act. Hort. Petrop.* xiv. 309 (1898), denies the occurrence of *P. halepensis* in Russian territory bordering on the Black Sea, all the specimens being *P. Brutia*.

² Radde, *Pflanzenverbreit. Kaukasus*, 147 (1899).

³ This is supposed to be a distinct species, *P. eldarica* of Medwejew, who refers the tree on the Black Sea to *P. pithyusa*, Strangways. Cf. *Derezya Kavkasa*, 12, 14 (1905), and *Moniteur Jardin Bot. Tiflis*, ii. 26 (1906).

⁴ Mouillefert, *Essences Forestières*, 386 (1903), says that it is killed by 14 or 15 degrees of frost, and that it grows rapidly in youth, and is very intolerant of shade.

⁵ Lambert says that he saw a flourishing tree of this species bearing cones abundantly at 17 years after planting in the garden of Stoke Park, Wilts, on sandy soil; but Lady Lushington informs me that when she first lived, in 1881, at this place, now called Stokke, there was no such tree there.

⁶ The tree at Penrhyn, a cone of which was figured in *Gard. Chron.* xxii. 552, fig. 97 (1884), no longer exists. Webster in *Woods and Forests*, 19th November 1884, says it was 45 ft. high and 4 ft. in girth.

⁷ *Trees and Shrubs*, 968 (1842), and *Gard. Mag.*, 1839, p. 267.

The leaves are longer than is usually the case in var. *Brutia*, measuring about 7 in. in length, which is probably due to the rich volcanic soil in which the tree is growing. Henry sees no reason for supposing that the tree is a hybrid, though from its vigour M. Cavara thinks that it differs from the wild trees in Calabria, which are ascribed to var. *Brutia*.

There is a fine tree, under the name *P. pyrenaica*, in the grounds of the Villa Thurêt, Antibes, which was 70 ft. by 6 ft. 2 in. when I saw it in 1910, and bore cones larger than those of typical *P. halepensis*.

The timber¹ is considered in France inferior to that of *P. Pinaster*, and is characterised by large resin-canals, which often cause infiltrations of resin in the wood, rendering it hard, heavy, and difficult to saw. It is little used, except for making packing-cases, though sometimes it is suitable for telegraph poles and sleepers. Tapping for resin, formerly practised in Provence, is now little in vogue; but in 1906, an experiment was made in the forest of Slisser, in western Algeria, when about a million trees were tapped. The resin produces a turpentine of good quality. The bark contains a considerable amount of tannin, and in Provence is occasionally ground into powder, which is used for dyeing fishing nets, and for mixing with the tanning material obtained from the bark of *Quercus coccifera*.

(H. J. E.)

PINUS MURICATA, BISHOP'S PINE

Pinus muricata, Don, in *Trans. Linn. Soc.* xvii. 441 (1836); Lambert, *Genus Pinus*, iii. t. 84 (1837); Loudon, *Arb. et Frut. Brit.* iv. 2269 (1838); Masters, in *Gard. Chron.* xxi. 49, tt. 7-9 (1884), and *Journ. Linn. Soc. (Bot.)* xxxv. 620 (1904); Sargent, *Silva N. Amer.* xi. 139, tt. 585, 586 (1897), and *Trees N. Amer.* 32 (1905); Kent, Veitch's *Man. Conif.* 350 (1900); Clinton-Baker, *Illust. Conif.* i. 37 (1909); Bean, in *Gard. Chron.* xlv. 260, figs. 112, 113 (1909).
Pinus Edgariana, Hartweg, in *Journ. Hort. Soc.* iii. 217, 226 (1848).

A tree, usually 40 to 50, occasionally 90 ft. high, and 6 to 10 ft. in girth. Bark reddish brown, fissuring into long narrow rounded scaly ridges, becoming very thick,² 4 to 6 in., towards the base of old trunks. Young branchlets glabrous, stout, reddish brown, with projecting pulvini, separated by linear grooves. Buds conic or cylindrical, pointed, $\frac{3}{4}$ to 1 in. long, encrusted with white resin. Scale-leaves persistent at the base of the leaf-clusters.

Leaves³ in pairs, persistent for three or four years, spreading, crowded on the branchlets, 4 to 6 in. long, yellowish green, rigid, slightly curved and twisted, serrulate, marked with numerous stomatic lines on both surfaces, ending in a short callous tip; resin-canals median; basal sheath $\frac{1}{2}$ in. long.

Cones, both sub-terminal and lateral, in clusters of 3 to 7, deflexed, sessile, asymmetrical, oblique at the base, ovoid, about 3 in. long, shining brown, very prickly: scales transversely keeled; on the inner side of the cone with flattened apophyses and slender prickles; on the outer side of the cone with elevated

¹ Mr. Hutchins, however, informs me that in Cyprus it is of better quality, and is used for all purposes for which deal is used here.

² In *Garden and Forest*, x. 232, fig. 30 (1897), a figure of the tree is given, showing the remarkable thickness of the bark.

³ The leaves have a strong peculiar odour.

pyramidal apophyses, armed with stout sharp spines, in the basal scales directed downwards, in the apical scales recurved and pointing upwards. Seed triangular, $\frac{1}{4}$ in. long, roughened, grooved, and blackish; wing nearly 1 in. long.

The cones often remain closed for many years, persisting on the stem and branches of the tree, without becoming embedded in the bark. As in the case of other pines, with late-opening cones, this is a provision for the germination of the seeds, which retain their vitality for a long period, until forest fires cause the scales to gape asunder.

This species, in the absence of cones, is readily distinguished amongst the two-leaved pines with persistent sheaths, by its long yellowish green leaves, and its long buds whitened in a peculiar manner by resin. On a vigorous branch two whorls of buds, branchlets, and cones are usually produced.

This species is one of the four coast trees¹ of California, only growing near the sea within the range of the sea-fogs, and occasionally rising to 2000 ft. altitude. It occurs in Mendocino County, where it attains its largest size, southwards, usually in widely separated localities, to Tornaes Point, north of San Francisco Bay; and from Monterey to San Luis Obispo County. It is also met with in Lower California, on Cedros island, and on the coast between Ensenado and San Quintin.

This pine, like *P. contorta*, which replaces it northward, grows on ocean bluffs, and sometimes is common over considerable tracts of poor sandy soil. In Sonoma County,² it reaches its most vigorous development in peat-bogs, the trees attaining a height of 80 to 150 ft. It is remarkable in its native habitat for its flattened crown of foliage. Jepson mentions a very fine forest of this species on Point Reyes, within a few miles of Olema. (A. H.)

P. muricata was first discovered in 1832 by Dr. Coulter at San Luis Obispo, and is sometimes known as Bishop's pine, from its occurrence in this locality, named after Bishop St. Louis. It was introduced into England in 1846 by Hartweg, who found it near Monterey, and who named it *P. Edgariana*, after Mr. T. Edgar, Secretary of the Horticultural Society.

It is perfectly hardy in most parts of England, and though seldom planted is perhaps suitable as a shelter tree on the sea-coast, though it is much surpassed in growth in such situations by *P. radiata*. Mr. Bean says that it thrives very well in Scilly and in the Channel Isles in very exposed situations.

Probably the finest specimen of this species in England is a tree, growing at Claremont, which has a tall straight stem, and measured in 1907, 71 ft. high by 7 ft. in girth. In Kew Gardens there is a tree of no great height, but of considerable age, remarkable for the old cones, which are borne unopened on the stem; and another,³ near the Pagoda, prostrate and bushy in habit, is very peculiar in its appearance. In the wilderness at White Knights, a fine healthy tree, 57 ft. by 7 ft., was measured by Henry in 1904. At Pitt House, Chudleigh, there is a large spreading tree, about 50 ft. high, with many stems, and covered with old persistent cones, of

¹ The others are *Pinus radiata*, *P. contorta*, and *Cupressus macrocarpa*.

² Jepson in *Flora W. Mid. California*, 23 (1901). Engelmann, in Brewer and Watson, *Botany of California*, ii. 128 (1880), says it is also found of large size growing in peat-bogs in Mendocino County.

³ Figured in *Gard. Chron.* xlv. 260, fig. 111 (1909). Mr. Bean attributes its prostrate habit to the attacks of a boring beetle in early life, which killed many buds and prevented the formation of leading shoots.

which I counted about sixty whorls, the oldest of which were nearly buried in the bark. At Eastnor Castle, a tree was about 40 ft. by 6 ft. in 1907, with large bunches of cones, no less than thirty-seven of which were counted in one cluster.

At The Heath, Leighton Buzzard, a large but ill-shaped tree measured 55 ft. by 7 ft. 2 in. in 1908. At Flitwick Manor, Bedford, Mr. H. Clinton-Baker measured in 1908, a tree 64 ft. by 8 ft. 8 in. At Essendon Place, Herts, there is a fine wide-spreading tree,¹ 49 ft. by 7 ft. 3 in. in 1906. At Garston Manor, Watford, Sir Hugh Beevor found one which measured 64 ft. by 6 ft. 3 in. in 1909. At Brickendon Grange, in the same county, there is a tree, about 25 ft. high, from the seed of which, obtained by heating in an oven an old cone from a main branch, Mr. J. Trotter raised seedlings in 1907. At Bayfordbury, a tree planted in 1850 measures 45 ft. by 4 ft. 7 in.; and numerous seedlings were raised in 1906 from the seed in its old cones.

A healthy wide-spreading tree at Enville Hall, Stourbridge, measured 56 ft. by 8 ft. 9 in. in 1904. At Highnam, Gloucestershire, there is a tree with a divided stem about 60 ft. high. At Hafodunos, North Wales, a wide-spreading tree, densely clothed to the ground, was 56 ft. by 7 ft. 3 in. in 1905.

In Scotland, Sir Herbert Maxwell reports a tree of this species at Stonefield, Argyllshire; and Mr. Austin Mackenzie measured a tree at Carradale, in the same county, 43 ft. by 4 ft. 9 in. in 1906. At Castle Kennedy, a spreading tree, bearing numerous cones, was 35 ft. by 5 ft. 7 in. in 1904.

In Ireland,² the finest specimens, five in number, are growing in Lauragh churchyard, near Derreen, one of which in 1907 measured 66 ft. by 6 ft. There is also a tree about 50 ft. high in the grounds of Derreen. At Coolattin, Co. Wicklow, a tree, very vigorous in growth and coning freely, was 42 ft. by 4 ft. 8 in. in 1906. At Castlemacgarrett, Co. Mayo, another measured 49 ft. by 5 ft. 9 in. in 1904.

(H. J. E.)

PINUS PUNGENS

Pinus pungens, Lambert, in König and Sims, *Ann. Botany*, ii. 198 (1806); Michaux f., *Hist. Arb. Amer.* i. 61, t. 5 (1810); Loudon, *Arb. et Frut. Brit.* iv. 2197 (1838); Sargent, *Silva N. Amer.* xi. 135, t. 584 (1897), and *Trees N. Amer.* 33 (1905); Kent, Veitch's *Man. Conifera*, 367 (1900); Masters, in *Journ. Linn. Soc. (Bot.)* xxxv. 623 (1904); Clinton-Baker, *Illust. Conif.* i. 47 (1909).

A tree, attaining 60 ft. in height and 9 ft. in girth; but usually smaller with a short thick trunk, frequently clothed to the ground, and forming a flat-topped or rounded head of foliage. Bark 1 in. thick, broken into irregular reddish brown scaly plates. Young branchlets glabrous, shining brown, with projecting pulvini, separated by linear grooves. Buds cylindrical, pointed, about $\frac{3}{4}$ in. long, resinous.

Leaves in pairs, deciduous in the second and third years, crowded on the branchlets, spreading, dark green, stout, rigid, curved, twisted, 2 to $2\frac{1}{2}$ in. long, serrulate, ending in a sharp cartilaginous point, marked with numerous stomatic lines on both surfaces; resin-canals median; basal sheath $\frac{1}{4}$ in. long.

¹ According to an account of the pinetum at Essendon in *Gard. Chron.*, 1866, p. 950, this tree was, in 1866, 35 ft. high, and bore cones twenty years old on the branches.

² In *Gard. Chron.*, 1869, p. 193, a tree, 20 ft. high, was reported as growing at Somerville, near Navan, Co. Meath, which had branches with seven to nine whorls of cones.

Cones lateral, usually in clusters of three or four, rarely seven or eight; sessile, spreading or deflexed, oblique at the base by the greater development of the scales on the upper side, light brown and shining, ovoid-conical, about $2\frac{1}{2}$ in. long; scales thin and tough, about 1 in. long and $\frac{1}{2}$ in. broad; apophysis pyramidate divided by a sharp transverse ridge into a narrow upper and a broad lower part, umbo produced into a long sharp-curved spine. Seed nearly triangular, $\frac{1}{5}$ in. long, light brown; wing $\frac{3}{4}$ to 1 in. long; cotyledons 7 or 8.

This pine is readily distinguished from the other species with short leaves in pairs, by the stout sharp-pointed rigid leaves, and the shining reddish brown branchlets, which, when vigorous, develop buds, branchlets, or young cones about their middle point.

This species occurs in the Alleghany mountains, from Pennsylvania to North Carolina and eastern Tennessee, ascending to 3000 ft., and growing mainly on dry gravelly table-lands and slopes. To the northward it is local in its distribution, and generally scattered among other trees, as *Pinus echinata*, *P. rigida*, and *P. virginiana*, oaks and hickories; but in the southern Alleghanies it forms nearly pure forests of considerable extent. It is also found¹ in three isolated stations, distant from its mountain home: in Virginia, between Fredericksburg and Washington city; in Lancaster County, Pennsylvania; and near Rosemount, in New Jersey. It is hardy and thrives well when planted in the middle and eastern states, as far north as New England; but according to Sargent, has little to recommend it but its large abundant cones, which often, after opening, remain persistent on the branches for many years. The wood² is light, soft, brittle, and coarse-grained, and is little used except for fuel and charcoal.

This pine was introduced³ into England in 1804, by Sir W. Strickland,⁴ but has never become common. The only trees which we have found, besides one or two specimens of no great size in Kew Gardens, are two at Bayfordbury, planted in 1851, and now about 30 ft. high and a foot in diameter, which bear cones profusely; a tree at Bicton, 42 ft. by 3 ft. 7 in.; and another at Grayswood, Haslemere, 35 ft. by 2 ft. 7 in. There is also one about 30 ft. high at Menablyly. (A. H.)

PINUS VIRGINIANA, JERSEY PINE, SCRUB PINE

Pinus virginiana, Miller, *Dict.* Ed. 8, No. 9 (1768); Sargent, *Silva N. America*, xi. 123, t. 581 (1897), and *Trees N. America*, 30 (1905); Masters, in *Journ. Linn. Soc. (Bot.)* xxxv. 623 (1904). *Pinus inops*, Solander, in Aiton, *Hort. Kew.* iii. 367 (1789); Loudon, *Arb. et Frut. Brit.* iv. 2192 (1838); Kent, Veitch's *Man. Conifera*, 333 (1900); Clinton-Baker, *Illust. Conif.* i. 25 (1909). *Pinus Royleana*,⁵ Jamieson, ex Lindley in *Journ. Hort. Soc.* ix. 52 *cum icone* (1855).

A tree, attaining 40 ft. in height, with a short trunk rarely more than 5 ft. in girth. Bark $\frac{1}{4}$ to $\frac{1}{2}$ in. thick, broken by shallow fissures into scaly

¹ Cf. T. C. Porter, in *Garden and Forest*, 1893, p. 204.

² Hough, *Trees U. States and Canada*, 19 (1907).

³ Aiton, *Hort. Kew.* v. 314 (1813).

⁴ The late Sir C. Strickland informed us that he remembered the tree at Boynton, 10 or 12 ft. high, and bearing prickly cones, which never produced good seed, and died many years ago.

⁵ The specimen described under this name, was a tree 30 ft. high, cultivated in the Residency Garden at Kathmandoo, India. According to Gordon, quoted by Lindley, in *Gard. Chron.*, 1855, p. 612, this is *P. inops* (*P. virginiana*), with which the figure of the cone and leaves agrees. Seeds were sent to the Horticultural Society from India, and only a few germinated.

plates. Young branchlets slender, tough, flexible, glabrous, glaucous, violet in colour. Buds about $\frac{3}{8}$ in. long, cylindrical, pointed, coated with resin.

Leaves in pairs, deciduous¹ in the third and fourth year, slightly spreading, $1\frac{1}{2}$ to 3 in. long, curved, slightly twisted, serrulate, sharp-pointed, marked by numerous stomatic lines on both surfaces; resin-canals median; basal sheath $\frac{3}{16}$ in. long.

Cones lateral, spreading, solitary or in pairs, shortly stalked, ripening and opening the scales in the autumn of the second year, ovoid-conic, 2 to $2\frac{1}{2}$ in. long, reddish brown, prickly; scales, $\frac{3}{4}$ in. long, $\frac{3}{8}$ to $\frac{1}{2}$ in. broad, thin, nearly flat, oblong-cuneate; apophysis rhomboidal, elevated, crenate in the upper margin, with a sharp transverse ridge, and a convex umbo, tipped by a slender spreading prickle. Seed nearly oval, pale brown, $\frac{1}{4}$ in. long; wing $\frac{1}{3}$ in. long; cotyledons 4 to 6.

This species is readily distinguishable from the other species with short leaves in pairs, by the glaucous violet branchlets, which, when vigorous, develop about their middle either buds or young cones.

*P. virginiana*² occurs from New York and Long Island, southward, generally near the sea-coast to the Savannah river in Georgia, usually growing on sandy soil, never in great abundance, and often spreading over lands gone out of cultivation, branching in habit and of small size. It extends inland to north-eastern Alabama, central Tennessee, Kentucky, and southern Indiana, in the latter state sometimes attaining³ on low hills as much as 100 ft. in height and 10 ft. in girth. It is of little economic value in any part of its range, the wood⁴ being brittle and soft with abundant sapwood, and mostly used for firewood. It is often planted as a shade tree.

This species was introduced into England before 1739, when Philip Miller had it in cultivation at Chelsea; but, having neither useful nor ornamental qualities to recommend it, it has remained very scarce in cultivation. The trees mentioned by Loudon as existing in 1838 at Pains Hill, Dropmore, White Knights,⁵ and Syon, have died or disappeared; indicating that this species is usually short-lived in England.

The largest specimen known to us is at Bayfordbury. Planted in 1842, it is now 47 ft. high, with a short butt, dividing at 2 ft. from the ground into four stems, the largest of which is 4 ft. in girth, with wide-spreading branches and sparse foliage. It bears cones freely. A tree probably planted in 1845 in the Queen's Cottage grounds at Kew is about 20 ft. high with a trunk 1 ft. in diameter, and dividing at 3 ft. up into two wide-spreading limbs. There are smaller specimens at Kew on the mound near the Lily House.

(A. H.)

¹ Galloway, in *Bot. Gaz.* xxii. 437 (1896), states that in young trees the needles fall in the second year, whereas on old trees, growing on good soil, they persist for three to five years.

² *Pinus clausa*, Sargent, *Forest Trees*, 199 (1884), a closely allied species, growing on the coasts of Florida and Alabama, differs mainly in the ashy grey, usually clustered and reflexed cones, which remain closed on the tree for several years, before opening their scales to let out the seeds. This species is not introduced, and probably would not be hardy in our climate.

³ Galloway, who, in *Bot. Gaz.* xxii. 433 (1896), gives an account of the ravages on this pine of a fungus, *Coleosporium Pini*, says that it attains 100 ft. high and $2\frac{1}{2}$ ft. in diameter, and is the most common species around Washington, D.C., many of the abandoned fields being covered with trees 10 to 15 ft. in height.

⁴ Hough, *Trees of U. States and Canada*, 17 (1907).

⁵ A tree at White Knights, supposed to be this species, is *P. montana*; and a tree long labelled *P. inops* at Kew, and referred to by John Smith, in *Records of Kew Gardens*, 286 (1880), has been recognised for several years to be *P. montana*. The species cultivated on the sand-dunes of east Prussia and Denmark, sometimes known as *P. inops*, is also *P. montana*. Cf. Mayr, *Fremdländ. Wald- u. Parkbäume*, 357 (1906).

PINUS BANKSIANA, JACK PINE¹

Pinus Banksiana,² Lambert, *Genus Pinus*, i. t. 3 (1803); Loudon, *Arb. et Frut. Brit.* iv. 2190 (1838); Kent, Veitch's *Man. Conifere*, 315 (1900); Mayr, *Fremdländ. Wald- u. Parkbäume*, 353 (1906); Sargent, in *Bot. Gazette*, xlv. 226 (1906); Clinton-Baker, *Illust. Conif.* i. 9 (1909).

Pinus sylvestris, Linnæus, var. *divaricata*, Aiton, *Hort. Kew.* iii. 366 (1789).

Pinus divaricata, Dumont de Courset, *Bot. Cult.* iii. 760 (1802); Sargent, *Silva N. America*, xi. 147 t. 588 (1897), and *Trees N. America*, 27 (1905); Masters, in *Journ. Linn. Soc. (Bot.)* xxxv. 620 (1904).

Pinus rupestris, Michaux f., *Hist. Arb. Amer. Sept.* i. 49, t. 2 (1810).

Pinus Hudsoni, Poirer, in Lamarck, *Encycl.*, v. 339 (1804).

Pinus Hudsonica, Parlatore, in DC. *Prod.* xvi. 2, p. 380 (1868).

A tree, attaining in America in favourable situations, 90 ft. in height³ and 6 ft. in girth; but usually smaller, and sometimes becoming a mere shrub. Bark thin, dark brown, irregularly divided into narrow connected scaly ridges. Young branchlets slender, flexible, glabrous, greenish, turning purplish brown in the first winter and following year. Buds ovoid, pointed, covered with resin, about $\frac{1}{2}$ in. long.

Leaves in pairs, the clusters not very dense on the branchlets, persistent for two or three years, spreading, 1 to $1\frac{1}{4}$ in. long, more or less curved, slightly twisted, serrulate, ending in a short cartilaginous point, with about ten stomatic lines on each surface; resin-canals median; basal sheath $\frac{1}{8}$ to $\frac{1}{6}$ in. long, lacerated.

Cones lateral, solitary or clustered, shortly stalked, directed towards the apex of the branchlet, much incurved, oblique at the base with the scales on the outer side most developed, ovoid-conic, $1\frac{1}{2}$ to 2 in. long, yellow and shining when ripe, often remaining unopened for several years; scales thin and stiff, about $\frac{3}{4}$ in. long and $\frac{1}{4}$ to $\frac{3}{8}$ in. broad; apophysis raised, pyramidal; umbo depressed or projecting, the minute incurved prickles of the first year usually becoming obsolete. Seeds only developed on the large scales of the outer side of the cone, triangular, blackish, $\frac{1}{8}$ in. long; wing $\frac{1}{3}$ in. long, broadest at the middle, full and rounded at the apex.

This species is readily distinguished by the short needles, and the occurrence of a whorl of buds, branchlets, or cones in the middle of each year's shoot when this is well-developed. The cones are peculiar in colour, shape, and direction.

This species has the most northerly range of all the pines of eastern North America, extending in Canada over a vast territory, bounded on the north by a line drawn in a north-westerly direction from northern Nova Scotia, lat. 45° , to near the southern end of Great Bear Lake, lat. 65° , not touching Hudson Bay or James

¹ The tree is commonly known by this name in Michigan, Minnesota, and Canada. Scrub pine, Grey pine, and Black pine are also used in New England and Canada. From Quebec to Hudson Bay it is called Cypress. Banksian pine is often used in books on forestry.

² This is the correct name, according to the rules for botanical nomenclature adopted by the Vienna Congress. Cf. Graebner, in *Mitt. deut. dend. Ges.*, 1908, p. 68, who points out that the name *divaricata* was not accompanied by a sufficient description. Sargent now accepts *P. Banksiana* as the correct name.

³ This is the maximum size given in *U.S. Forest Service Circ.* 57 (1907). According to Mayr, *op. cit.* 356, Macoun gives 115 ft. (35 metres) as the height which the tree sometimes attains in Canada. I have seen no exact measurements quoted, higher than those taken by me in Minnesota.

Bay; and reaching on the west the valley of the Mackenzie river and the Rocky Mountains. This pine extends southwards in the United States to Maine,¹ northern New Hampshire, Vermont, and northern New York, where it is rare and local and stunted; becoming common and of large size in Michigan, Wisconsin, and central Minnesota, and reaching its most southerly point in the northern parts of Indiana and Illinois.

In Canada, it attains its maximum size and is most abundant west of Lake Winnipeg and north of the Saskatchewan river, where it spreads over great areas of poor sandy soil, and is common and large in size in the regions north of Lake Superior.²

Mr. J. C. Langelier,³ in his description of the immense forests of the province of Quebec, north of lat. 48°, where this tree is only second in importance to black and white spruce as a source of supply of sawn timber, says:—"Botanists describe Banksian pine as a stunted, short, and branchy tree. This description certainly applies not to the Banksian pine of the Lake St. John and Saguenay district, where these trees grow to a considerable height, and attain a diameter which renders them fit for saw-logs. On the Rivière au Rat in 1898, a jobber cut a tree of this kind, which gave 91 ft. of usable timber, viz. five saw-logs and two ties. This tree measured 15 in. across the stump and over 7 in. at the top. At the Escoumains Mills, they sawed for many years Banksian pine logs, turning out good boards which were exported to the United States. Banksian pine ties are from year to year coming to the front, and are transported by railway from Roberval to Quebec, a distance of 190 miles. When there will be no more cedar (*Thuja occidentalis*) to supply the enormous quantities of ties required yearly by railroads, one of its most valuable substitutes will unquestionably be found in the Banksian pine, which the northern region is in a position to supply for a very long period."

In the province of Quebec, south of lat. 48°, Banksian pine grows nearly everywhere on the poor rocky and gravelly lands, chiefly in the dry plains which have been formerly laid waste by fire. It is not so tall or so good as in the northern region, but nearly always is large enough to make railway ties. In this part of Quebec province, *P. Strobos* and *P. resinosa* are more important as sources of supply of sawn timber.⁴ This pine never approaches the sea-coast, but it occupies outlying stations in the centre of Nova Scotia and of New Brunswick.⁴

In Michigan, northern Wisconsin, and central Minnesota, immense tracts of poor sandy soil are covered by Banksian pine, either pure or in mixture with red pine (*P. resinosa*). In Michigan⁵ these tracts are known as Jack pine plains or barrens;

¹ Around Lake Umbagog, in Maine, it attains a height of 60 ft.; but is usually in New England a low tree, 15 to 30 ft. high. Cf. Dame and Brooks, *Trees of New England*, 8 (1902).

² Bell saw large groves on Albany river, south-west of James Bay, with trees 70 ft. high and 2 ft. in diameter at the butt. Cf. *Gard. Chron.* xx. 503 (1883).

³ *Canadian Forestry Association, 6th Annual Report*, 1905, pp. 64, 67, 69.

⁴ *Bot. Gazette*, xxiv. 299 (1897).

⁵ Cf. E. J. Hill, in *Garden and Forest*, iv. 278 (1891). In Michigan the trees are usually not more than 30 or 40 ft. high, with short scraggy trunks, and are occasionally mere shrubs. Britton, however, measured trees near Marquette on Lake Superior, 70 ft. high. Cf. *Bull. Torrey Bot. Club*, 1883, p. 82. An account of this tree on the dunes bordering Lake Michigan is given by Cowles, in *Bot. Gaz.* xxvii. 371 (1899).

and the soil, containing little or no vegetable mould, is often nothing but a shifting mass of sand. In Wisconsin, according to Roth,¹ it is always a small tree, generally less than 10 in. in diameter and below 60 ft. in height. In Minnesota, where I saw it on the Cass Lake forest reservation, it is much finer, many groves averaging over 80 ft. in height and 1 ft. in diameter, the largest tree which I actually measured being 87 ft. high and 3 ft. 3 in. in girth. These groves of pure Banksian pine, which in other localities are often many square miles in extent, consist of tall slender trees, all of the same age and very uniform in size and appearance, with a stem clear of branches to 30 or 40 ft., and a narrow crown of foliage, standing very close together on the ground, which is bare of undergrowth. Plate 289 is taken from a photograph for which I am indebted to the U.S. Forestry Bureau.

The Banksian pine not only withstands extreme cold, but even thrives in a severe climate, as is witnessed by its luxuriant development in the northern and western parts of Canada and in Minnesota. It has been successfully cultivated in the Dakotas and Nebraska² for shelter belts, where a better tree will not thrive; and according to Saunders³ has succeeded when transplanted quite young, on the experimental farms at Brandon, Manitoba, and at Indian Head in the North-west Territories.

Barty and Jack say:⁴—"Timber made from it in former times when it was fairly abundant was considered to be of good size if it averaged three-quarters of a ton to a tree. The wood is hard, full of pitch, and free from sap, but apt to be full of streaks. It is much used for ties and railway sleepers, being one of the best woods for this purpose. Certain sections of country on the south-western Miramichi, the forests on which were destroyed by the great fire of 1825, have since become so thickly covered by forests of Banks's pine that it is almost impossible to force one's way through the trees."

It is specially adapted for seeding burnt areas, which have resulted from time immemorial by lightning striking dead trees. It produces cones at an early age, often when only four or five years old; and on adult trees many of the cones⁵ remain for years unopened on the older branches and even on the stem, the seeds retaining their fertility for an indefinite period. These cones open their scales when scorched by fire, and disseminate large quantities of seed, usually in spring and summer, the season of the forest fires, when the seed of other species is not mature. The seedlings⁶ are very rapid in growth, often attaining 1½ ft. in height when only three years old; and once an area is covered with the seedlings of this pine, no other

¹ *Forestry Conditions of Wisconsin*, 21 (1898), published as Bull. 1 of *Wisconsin Geolog. and Nat. Hist. Survey*.

² Cf. *U.S. Forest Service Circ.* 57 (1907), a planting leaflet, which gives hints concerning the cultivation of this species.

³ *Ottawa Exper. Farm Bull.* No. 47, p. 46 (1904).

⁴ *Trans. Scot. Arb. Soc.* xi. p. 11.

⁵ Dr. Bell, in *Canad. Forest. Assoc. 6th Ann. Report*, 1905, p. 59, states that the cones must be scorched before the seeds will escape. Many cones, however, open, like other pines, when two years old. Specimens which I collected, show that the opening of the cones is very irregular; and no explanation is forthcoming as to why some cones open and others do not. Unwin, *Future Forest Trees*, p. 83 (1905), supposes that the cones after opening, close again in damp weather. This is incorrect, as the old unopened cones contain the normal number of seeds, some of which would have escaped if the cones had opened.

⁶ Schwappach, in *Anbauversuche mit fremdländischen Holzarten*, 54 (1901), gives as instances of the very rapid growth of seedlings, the average size of two-year-old plants, 8 in.; five years old, 5 ft.; nine years old, 10 ft. It is incorrectly stated that it makes two or three shoots in a year; the two or three whorls of branches produced are all formed in the winter bud, and appear on the first and only shoot of the season.

species can obtain a footing. This explains the occurrence of dense woods of this species, uniform in age, over large areas. After a time the growth slackens, and at 60 to 80 years ceases, so that other species, attaining a greater age and height, eventually succeed in replacing this species.

(A. H.)

CULTIVATION

The date of introduction of this tree into Great Britain is unknown, though Aiton says that it was in cultivation before 1783.

Lambert described it in 1803 from a tree growing at Pains Hill which had probably been planted by the Hon. Charles Hamilton, who founded that place before 1735,¹ and which he describes as a remarkably fine tree, though he gives no measurements. He also mentioned trees then growing at Kew and at Croome in Worcestershire. All these² had disappeared when Loudon wrote, and he says that a tree at Dropmore, which in 1837 was 27 ft. high and 1½ in. in diameter, was then the finest known to him. There was also one at White Knights 30 ft. high. Neither of these is still alive, and we have found only a few trees now living in England besides those at Kew. One growing at Arley Castle, which is the only survivor of five or six planted there probably about 70 years ago, measured in 1909, according to Mr. Woodward, 45 ft. by 3 ft. 3 in. Another at Nuneham Park, Oxford, covered with cones, and apparently having attained its maximum height, was 44 ft. by 4 ft. 7 in. in 1907. Another at Pencarrow measured by Mr. A. Bartlett in 1906 was 35 ft. by 3½ ft.; and there is a poor stunted tree bearing cones at Menabilly. A specimen at G. Paul's Cheshunt Nursery, is about 30 ft. high by 3 ft. 4 in. in girth. Mr. Paul says it was probably planted in 1845-1850, and remembers it in 1860 nearly as tall as it is now.

All these facts show that this species is likely, from an economic point of view, to be worthless in this country, as might be expected, considering that the tree inhabits a climate unlike that of any part of Britain. Nevertheless, several writers have strongly recommended this tree for planting in England on the strength of a very short experience on the barren sands of northern Germany,³ where the tree, growing very rapidly from seed, has been widely puffed by enterprising nurserymen, and where it may possibly be useful for shelter in places where nothing better will grow. I was seriously advised by an expert in forestry to plant it on a large scale, and might have done so if I had not previously known the tree in its own country.

Dr. Mayr of Munich, whom I consulted before utterly condemning the tree, and who is second to none in his knowledge of the trees of the northern hemisphere, agrees with me that, if planted at all, it is only fit for the worst class of sandy soil; but as young plants can now be procured at a cheap rate in Germany, there will

¹ Loudon, *op. cit.* i. 70.

² Loudon, in *Gard. Mag.* xviii. 585 (1842), mentions a *P. Banksiana*, 14 ft. high, at Dalhousie Castle, where many American trees had been introduced by the Earl of Dalhousie when he was Governor of Canada.

³ In Bavaria, according to Mayr, over 500,000 have been planted in the State forests, and one firm in Germany sold 6,000,000 plants in 1905. The tree has also been planted extensively at Römershof, near Riga, and experiments are now being made with it on the sand dunes of Jutland.

be no harm in trying a few as an experiment on dry poor soils on the mountains of eastern Scotland. Mayr's account, in his recent work, of the favourable results obtained by the cultivation of this tree in Germany should be studied by those who wish to try it; but he recommends it only as a sheltering and improving crop for the worst kinds of sand and gravel soil in places which suffer severely from spring frost, and where nothing better will grow. He does not expect it to produce valuable timber. Its growth is remarkably fast when young, and it produces good seed when only fifteen years old.

Of these recent introductions, Dr. Mayr showed me, in May 1905, a tree growing at Grafrath, near Munich, from seed brought from Wisconsin in 1885. It was 20 ft. high, and bore fertile cones.

(H. J. E.)

PINUS PINASTER, MARITIME PINE

- Pinus Pinaster*,¹ Solander, in Aiton, *Hort. Kew.* iii. 367 (1789); Loudon, *Arb. et Frut. Brit.* iv. 2213 (1838); Lawson, *Pinet. Brit.* i. 71 (1884); Willkomm, *Forstliche Flora*, 233 (1887); Mathieu, *Flore Forestière*, 610 (1897); Kent, Veitch's *Man. Coniferæ*, 358 (1900); Kirchner, *Lebensgesch. Blütenpfl. Mitteleuropas*, 238 (1905); Clinton-Baker, *Illust. Conif.* i. 43 (1909).
Pinus maritima, Lamarck, *Flore Franç.* ii. 201 (1778); Poirer, in Lamarck, *Encycl.* v. 337 (1804); Masters, in *Journ. Linn. Soc. (Bot.)* xxxv. 621 (1904).
Pinus syrtica, Thore, *Prom. Gascogne*, 161 (1810).
Pinus Lemoniana, Bentham, in *Trans. Hort. Soc.* i. 512 (1835).
Pinus Hamiltoni, Tenore, *Cat. Hort. Neap.* 90 (1845).

A tree attaining 120 ft. in height and 14 ft. in girth. Bark soon becoming scaly and furrowed; on old trees deeply fissured and broken up into scaly plates, dark-brown externally, and reddish internally. Young branchlets brown, glabrous, with raised keeled pulvini; older branchlets, from which the leaves have fallen, roughened by the pulvini, bearing at their apices the reflexed bases of the scale-leaves; the bases of the shoots surrounded by a sheath of reflexed bud-scales. Buds ¾ to 1 in. or more, stout, spindle-shaped, pointed; scales brown, interlaced by their white fimbriated margins, and with free and reflexed points.

Leaves in pairs,² persistent usually for three years, slightly spreading, 5 to 6 in. long, stout, rigid, curved, ending in a callous point, serrulate, with numerous stomatic lines on both surfaces; resin-canals marginal; basal sheath an inch long, persistent.

Staminate flowers in a dense spike. Young cones ¾ in. long, brownish red, with non-prickly scales, on a scaly peduncle, about ½ in. long. Mature cones,³ sub-terminal, in a whorl⁴ of 2 to 8, shortly stalked, spreading or much deflexed, ovoid-

¹ This is the oldest certain name, and the one almost universally adopted. *P. maritima*, Miller, *Gard. Dict.* Ed. 8, No. 7 (1768), is insufficiently described, and has been referred to both *P. Pinaster* and *P. Laricio*. Cf. Graebner, in *Mitt. d. dend. Ges.*, 1908, p. 68.

² They sometimes occur in clusters of threes on young trees.

³ The cones in France usually open and let out the seed in the spring of the third year; but in Corsica and Spain I observed many trees, with cones unopened and five to twelve years old. Here also trees begin to bear cones very early, which remain unopened in numerous whorls on the main stem, resembling exactly the trees of *P. tuberculata* in the Siskiyou mountains. One tree, 10 ft. high, had seven whorls of cones, the upper five of which, two to six years old, were unopened. Another tree twenty-two years old bore cones in twelve whorls on the stem, all unopened. This is undoubtedly an adaptation for regeneration on burnt areas, due to the frequent fires in these dry regions.

⁴ Mr. H. Clinton-Baker obtained in 1908 from a tree at Boldre Grange, Lympington, a branch with sixty-one small cones in a cluster.

conic, 3 to 7 in. long, $1\frac{1}{2}$ to $2\frac{1}{2}$ in. in diameter near the oblique base, shining reddish yellow; scales oblong, about $1\frac{1}{2}$ in. long and $\frac{3}{4}$ in. broad, flat; apophysis rhomboidal, convex and slightly raised in the centre, or pyramidal and much elevated, with a linear transverse ridge, and a dull grey elevated sharp-pointed or blunt umbo. Seed $\frac{1}{3}$ in. or more, shining black above and dull mottled grey below, with a detachable brown wing, 1 to $1\frac{1}{2}$ in. in length.

The seedling has seven or eight cotyledons, entire in margin and dull green in colour; and the stem is clothed during the first two years with solitary sharply serrate primary needles, the adult geminate foliage only appearing in the third year. Seedlings thrive only in full sunlight, and grow fast, attaining often a foot in height in the first year, and 10 to 12 ft. at the end of the tenth year. This pine¹ has a strong tap-root, but speedily develops in addition lateral roots which either spread horizontally or descend into the soil.

VARIETIES

This species varies, in the wild state, in the length of the leaves and in the size of the cones,² the scales of which show considerable differences in the amount of prominence of the apophyses. The following varieties have been distinguished.

1. Var. *Aberdoniae*, Loudon, *Gard. Mag.* xv. 128 (1839). Leaves pale green. Cones shorter and more ovoid than in the type. Introduced in 1825 from Nice by the Earl of Aberdeen, who raised plants, one of which was presented to Lord Granville, and was reported by Loudon to have been 17 ft. high at Dropmore in 1837. Reported trees of this variety, labelled *P. Escarena*,³ are now growing at Dropmore, and only differ from the type in having a thinner and less fissured bark.

2. Var. *Hamiltoni*, Gordon, *Pinetum*, 178 (1858) (*Pinus Hamiltoni*,⁴ Tenore, *Cat. Ort. Bot. Nap.* 90 (1845)), is supposed⁵ to be identical with the preceding variety; but a tree at Kew, named var. *Hamiltoni*, only differs from the type in having more slender branchlets. It has not borne cones.

3. Var. *minor*, Loiseleur, in *Nouv. Duhamel*, v. 242, t. 72 (1812), found on barren sands near Le Mans, France, was said to bear small cones, and to be hardier than the type.

4. Var. *Lemoniana*, Loudon. *P. Lemoniana*, Bentham, in *Trans. Hort. Soc.* i. 512 (1835). Cone solitary and erect at the end of the branchlet, the terminal bud not

¹ After felling, the stools occasionally grow, like those of the silver fir, and for the same reason, because their roots are connected with those of adjacent living trees. The annual rings of wood continue to be formed on the stump after the trunk has been felled, as illustrated by a specimen from Gordon Castle; and this new formation in the amputated stump owes its origin to inoculation of the roots. A remarkable example of the fusion of the roots of two trees of *P. Pinaster*, discovered in a Portuguese forest, and now preserved in the Museum at Coimbra, is illustrated in *Gard. Chron.* xxii. 300, fig. 58 (1884).

² Cones of this species, differing in the arrangement of the scales, are described and figured by Dickson, in *Trans. Roy. Soc. Edin.* xxvi. 505, Pl. 19-22 (1871). At Woburn the cones of old trees growing close together vary considerably in the prominence of the apophyses, and in the size of the seeds; but seedlings raised from the two kinds of seed are indistinguishable in appearance at present.

³ *P. Escarena*, Risso, *Hist. Nat. Europ. Mérid.* ii. 340 (1826), is a doubtful plant; and according to the Duke of Bedford, ex Loudon, *Gard. Mag.* xv. 127 (1839), is a variety of *P. sylvestris*. The seeds brought home by the Earl of Aberdeen from trees near Nice were erroneously supposed by him to be Risso's species, which was named *P. Escarena* in honour of the Count d'Escarène, who discovered it wild in the mountains near Nice. Gordon, in *Gard. Chron.*, 1841, p. 564, gives an inaccurate account of this, which he calls *P. ascarena*, from a village named Ascaren in Italy.

⁴ A tree labelled *P. Hamiltoni* still exists in the Botanic Garden at Naples, of which Prof. Cavara has kindly sent us a branch with cones, which are indistinguishable from those of typical *P. Pinaster*.

⁵ By Gordon, and by Koch (*Dendrologie*, ii. 2, p. 292 (1873)).

developing.¹ This variety was first observed by Sir C. Lemon; and in Loudon's time there were numerous examples at Carclew, the largest being about 30 ft. high in 1837. It was reported to come true from seed. When Elwes visited Carclew in 1905 there was only one survivor to be found, a poor scrubby tree in a hedgerow, and covered with ivy, a specimen from which shows the peculiarity in the position of the cone.

5. Hybrids² between this species and *P. halepensis*, twenty to forty years old, obtained by sowing seed of trees of the former species at Mirabeau, Vaucluse, show a grey bark like that of *P. halepensis*, and leaves 4 in. long, thinner than those of *P. Pinaster*.

DISTRIBUTION

The maritime pine is a native of the Mediterranean region, extending as far eastward as Greece, and reaching the shores of the Atlantic in France and Portugal. *P. Pinaster* and *P. halepensis* have a somewhat similar distribution, but they occur on different soils, the former usually occupying siliceous sands, and the latter occurring on limestone. The maritime pine is usually confined to the coast regions and islands, seldom extending far inland.

It forms extensive woods in western Portugal; and in Spain, occurs in Galicia, Estremadura, and the eastern parts of Granada. North of Gibraltar it grows in mixture with *A. Pinsapo* on the Sierra de Bermeja, elsewhere forming scattered pure woods of no great extent, the largest trees which I saw being about 10 ft. in girth.

In France it is a native of Gascony, where small woods, called *pignadas*, undoubtedly occur in the wild state; but its natural area has been much increased by plantations, the artificial forest of this species in the Landes between Bordeaux and Bayonne being perhaps the most extensive ever created by the hand of man. The total extent of the *Pignada Landaise* amounted in 1892 to 1,715,000 acres, of which 1,600,000 acres belong to communes and private owners, the remainder comprising the dunes on the coast, which cost the government immense sums in various works. The total expenses of planting, road-making, etc., of the 1,600,000 acres is estimated to have been £2,100,000. The value of this forest was £8,200,000 in 1877, which had increased, according to Mr. Huffer,³ to £18,000,000 in 1904, the annual revenue obtained by the sale of timber, turpentine, and resin being £560,000, or 7s. per acre. Recent improvements in transport, such as the construction of light railways, have raised the annual returns considerably. The greater part of this immense area has been planted subsequently to 1855, as in that year the total area under *P. Pinaster* was only 50,000 acres.

This species is also found⁴ in the Mediterranean region of France, in the

¹ Masters, in *Journ. Roy. Hort. Soc.* xiv. 237 (1892), says that he twice met with a similar condition in *P. sylvestris*.

² *Pinus halepensis-Pinaster*, Saporta, in *Comptes Rend. Acad. Sc. Paris*, cix. 656 (1889). Cf. Ascherson and Graebner, *Syn. mitteleurop. Flora*, i. 232 (1896).

³ *Économie Forestière*, i. 177 (1904).

⁴ Fliche and Grandeau, in *Ann. Chimie et Physique*, 383 (1873), found that in Champagne it only thrives on sand, loam, or clay containing less than 0.35 per cent of carbonate of lime, and became stunted and died on chalk soils. Yet it is frequent near Nice on limestone, according to Bunbury, *Bot. Fragments*, 7 (1883); and Mr. Tansley has lately found it on the Riviera flourishing in mixture with *P. halepensis*, in soil which effervesced freely when acid was applied close to the roots.

mountains of the Maures and Estérel, and in the Albères, but here it rarely occurs pure, and is a smaller tree than in the Landes. It has also been planted in France far to the north of its natural habitat, up to latitude 49° in Brittany. Nearly 200,000 acres were planted with this species in Sologne in the centre of France, but most of the trees here were killed by the severe winter of 1879, and *P. sylvestris* has been planted in its place.

In Corsica it occurs from the sea-coast up to 2700 ft. on northern aspects, and to 4000 ft. on southern slopes, mixing in its upper level with *P. Laricio*, and often becoming a fine tree, the largest which I measured in the mountains near Calvi, at 3000 ft. altitude, being 100 ft. high and 10 ft. 10 in. in girth, with a stem clear of branches to 50 ft.

(A. H.)

In Portugal this is perhaps the most abundant tree in all the coast region; and on poor sandy soil unfit for agriculture, covers immense areas, mixed to a small extent with oaks on the better land, but generally pure, and reproducing itself freely everywhere. The trees are seldom allowed to grow very large, the tallest that I saw on deep sand near the Oporto coast being about 100 ft. high and 5 or 6 ft. in girth. But in the Royal forest near Leiria a tree, in 1843, measured 39 metres by 4.48 metres; and in the same forest in the Canton d'Alvenha two trees then existed, of which the first was 40 metres by 3 metres, with a clean bole 27 metres long; the second 38 metres by 4.20 metres. In the forest of Busaco on granite soil there are a few trees scattered among the oaks, of which the largest that I measured was 80 ft. by 9 ft. 4 in. The bark was here not so red and shining as on old trees in England, but quite easy to distinguish from the greyer bark of *P. Pinea*. *P. Pinaster* is known in Portugal as *Pino bravo* or wild pine, whilst *P. Pinea* is called *Pino manzo* or cultivated pine. It grows wild up to about 2500 ft., and was being sown on the hills above Caldas do Gerez, in the Gerez mountains north-east of Oporto, up to about 3000 ft. on dry slopes, where the soil was not good enough for oak.

In Italy this species appears to be limited to the west of the Apennines, on the sandy plains and in the lower hills, from Savona and Genoa¹ to Mount Argentaro. On the eastern side of the Adriatic it occurs on the islands of Lussin, Brazza, Lesina, and Curzola, where it is a tree of moderate height, resembling the Austrian pine in habit. It occurs also in Greece. In Algeria² it is only known on the hills overlooking the coast, between Bougie and Cape Bougarone, where it covers an area of about 4000 acres.

In Cape Colony, where it has been introduced, it grows like a weed along the southern coast, where there are winter rains, and is now largely planted for railway sleepers and firewood by the Forestry Department.³ At Port Phillip, in Victoria, Australia, it averages 40 ft. high in 20 years.⁴ It is also largely planted in the Madeiras and Canaries.

¹ According to Bunbury, *loc. cit.*, it grows on serpentine in the hills between Savona and Genoa, and between Sestri and Spezia.

² Lefebvre, *Les Forêts de l'Algérie*, 432 (1900).

³ Hutchins, in Flint and Gilchrist, *Science in S. Africa*, 393 (1905).

⁴ Von Mueller, *Select Extratropical Plants*, 360 (1891).

CULTIVATION

The maritime pine was introduced by Gerard more than three centuries ago, and though it has at various times been very largely planted in some parts of England, it has never taken the place of a forest tree, and has no qualities which will justify its being considered as such, except in a few places.

It seems, however, so much at home¹ on the warm sands of south-east Dorsetshire, where it reproduces itself freely by seed, that it might perhaps take the place of Scots pine for pit props in places where sea carriage is available. On the road from Christchurch to Heron Court it attains a very large size. The best I measured was about 85 ft. by 9½ ft. on almost pure sand among rhododendrons and tall bracken. I could not learn, however, that the timber was valued here, and was unable to find out the age of the trees.

Though the tree is a native of the Mediterranean region, it seems able to endure great extremes of wet and cold in this country, as I have seen it growing well in the damp climate of Wigtownshire and on the sandhills of Norfolk.

We have measured a great many adult trees in various parts of England, among which a tree (Plate 290) near the house at Foxley Hall, near Hereford, is one of the finest, measuring, in 1907, 95 ft. by 11 ft. 8 in. with a bole clean to 50 or 60 ft. This was remarkable, because the soil and climate at Foxley seem to be more suitable to oaks than to maritime pines, though the situation is well drained and sheltered.

In the grounds of the Earl of Mount Edgcumbe at Mount Edgcumbe, Cornwall, Mr. A. B. Jackson measured an immense old tree, which in 1909 was 18 ft. in girth.

In the kitchen garden at Penrhyn Castle, there is a remarkable tree 80 ft. high and forked close to the ground, forming two huge trunks 11½ ft. and 8 ft. 10 in. in girth, between which a large aviary is fixed.

Other large trees are as follows:—

	Height.	Girth.	Year.	By whom measured.
Arno's Grove, Middlesex	90 ft.	8 ft. 10 in.	1906	A. Henry.
Buxsted Park	96 ft.	12 ft. 5 in.	1908	H. J. Elwes.
Burwood House, Surrey	75 ft.	8 ft. 10 in.	1909	Col. H. Thynne.
" " " "	78 ft.	7 ft. 10 in.	"	" "
Ashburnham Park, Sussex	80 ft.	10 ft. (about)	"	H. A. James.
Holwood, Kent	85 ft.	8 ft. 7 in.	1890	A. D. Webster.
Stackpole Court, Pembroke	80 ft.	7 ft. 6 in.	1906	H. J. Elwes.
Dropmore, Bucks ²	75 ft.	10 ft. 9 in.	1910	C. Page.
High Canons, Herts	69 ft.	7 ft.	1908	H. Clinton-Baker.
Hatfield Park, Herts	65 ft.	11 ft. 5 in.	1905	A. Henry.

At Westwick, Norfolk, according to Loudon, who quotes the *Trans. Soc. Arts*, xxviii. 37 (1811), J. B. Petre, Esq., planted in 1809, on upwards of 500 acres, over 200,000 trees raised from his own seed from trees planted about 1702. I am informed by Mr. M. P. Price that in March 1909 he measured roughly some of the largest surviving trees, and found them to be from 75 to 80 ft. high by 9 to 10 ft. in girth,

¹ Cf. Clement Reid, *Origin British Flora*, 12 (1899). Boswell Syme, *Eng. Bot.* viii. 270 (1868), erroneously states that it is a native of the south of Ireland.

² A tree labelled *P. Escarena*, planted in 1841, measured 66 ft. by 8 ft. 3 in. in 1909.

the boles having very thick bark, and tapering considerably. The tallest tree was found by Henry in 1910 to be 93 ft. by 5 ft. Most of the trees were blown down in the gale of March 24, 1895, the survivors being now scattered among Scots pines which were planted with them. There is no natural reproduction, as the squirrels eat every seed as soon as it is ripe. The present owner, Major B. J. Petre, states that the timber is inferior to that of Scots pine, rarely selling for more than 4d. per foot, while the latter is readily saleable at 6d.

On the sandhills at Holkham this pine has been planted to some extent, and reproduces itself from seed, but does not grow so well as *P. Laricio*.

In Scotland, the finest tree we know is one¹ growing in a wood at Monreith, Wigtownshire, which measured 82 ft. by 9½ ft. in 1905. At Smeaton-Hepburn, East Lothian, there are three trees in a wood, about 70 ft. high by 6 ft. in girth.

In Ireland the best tree which we have seen is at Curraghmore, Waterford, and measured 91 ft. by 7 ft. 10 in. in 1907. At Castlemartyr, Cork, there is a good tree, 70 ft. by 9 ft. At Powerscourt, Wicklow, a tree 67 ft. by 9 ft. 11 in. was bearing cones profusely in 1906. Capt. John Campbell reports that in an exposed position on peat bog, near Moycullen, Galway, this species is thriving; and it appears to have been the only tree that survived in the disastrous experiment of planting on peat bog at Knockboy. At Shelton Abbey, Co. Wicklow, there are four trees, growing in a sheltered situation on a gravelly bank, the dimensions of which, as given by Mr. Shivas in 1910, are 60 ft. by 10 ft., 80 ft. by 8 ft. 9 in., 50 ft. by 9 ft. 8 in., and 60 ft. by 7 ft. 9 in. At Tullymore, Co. Down, there is a fine old tree in the same valley where the Silver firs (Plate 211) grow. Being crowded among other trees, I could not measure its height, which I estimated at 75 ft.; the bole, 10½ ft. in girth, was clean to 40 or 50 ft. up.

TIMBER

The timber of this tree is one of the most important articles of export from the south-west of France. Of late years great quantities of pit props have also been exported from Portugal to South Wales, and as their local value is very small, and the cost of transport to the shipping ports low, this source of supply cannot be overlooked in considering the probable future value of pit props in our southern counties.

An account of the uses of this tree, quoted from a French author, was given by Loudon in 1838, which is worth reading, though perhaps rather out of date. Resin seems then to have been the most valuable product of the tree, but lamp-black was also an important item, and the methods of extracting both are fully described. Now, however, a great quantity of the trees after having been tapped until their resin is exhausted, are shipped in the form of pit props to the South Wales coal ports at a very low rate of freight, in the coal ships, which would otherwise return empty from Bordeaux; and are delivered on the wharf in suitable lengths, in such quantities, and at such a low price, now 20s. to 21s. per ton, that they govern the price of home-grown mining timber. It has been pointed out by Mr. R. Anderson of Cirencester in a

¹ Figured in *Woods and Forests*, 1884, p. 737.

paper on the conversion of home-grown timber,¹ that British timber is further handicapped by the railway companies' practice of giving lower rates for carriage of pit props to the collieries from these landing ports, than they do for English timber over the same lines of railway from inland stations. He calculates that this preferential rate may mean a disadvantage of £12 : 10s. per acre as compared with foreign timber. Mr. Anderson tells me that in consequence, as he believes, of these disadvantages, he has seen no home-grown pit props or English timber in the Derbyshire collieries; and on more than one occasion when I have tried to sell timber to coal owners in that district, I have found that Norwegian timber from the north-east ports was delivered at a price which, after paying haulage and railway charges over about the same distance, would make it impossible for me to grow such wood profitably.

(H. J. E.)

PINUS PINEA, STONE PINE

Pinus Pinea, Linnæus, *Sp. Pl.* 1000 (1753); Loudon, *Arb. et Frut. Brit.* iv. 2224 (1838); Schouw, in *Ann. Sci. Nat.* iii. 236 (1845), and *Journ. Hort. Soc.* iii. 120, 130 (1848); Willkomm et Lange, *Prod. Fl. Hispanica*, i. 20 (1861); Laguna, *Fl. Forestal Española*, 49 (1883); Boissier, *Fl. Orientalis*, v. 694 (1884); Fliche, *Assoc. Franç. Avance. Sciences, Nancy* (1886); Willkomm, *Forstliche Flora*, 240 (1887); Mathieu, *Flore Forestière*, 620 (1897); Kent, Veitch's *Man. Conifera*, 360 (1900); Masters, in *Journ. Linn. Soc. (Bot.)* xxxv. 613 (1904); Clinton-Baker, *Illust. Conif.* i. 44 (1909).

Pinus fastuosa, Salisbury, *Prod.* 398 (1796).

Pinus maderiensis,² Tenore, *Ind. Sem. Hort. Neap.* in *Ann. Nat. Sci.* 379 (1854).

A tree, attaining 100 ft. or more in height, with a trunk rarely 20 ft. in girth, and a broad rounded head of ascending branches and very dense foliage. Bark at first smooth and brown, ultimately deeply furrowed and scaly. Young branchlets glabrous, yellowish green, with raised keeled imbricated pulvini, terminating in lanceolate fringed reflexed scale-leaves, which persist during the first year. Buds ¼ to ⅓ in. long, ovoid, pointed; scales brown, matted together by the long white fimbriæ on their margins, free and reflexed at their apices.

Leaves in pairs,³ persistent two years, densely crowded on the branchlets, spreading, 4 to 5 in. long, curved, serrulate, sharp-pointed, marked with about twelve stomatic lines on the outer and six on the inner surface; resin-canals marginal, numerous; basal sheath whitish, ¼ in. long.

Cones sub-terminal, solitary or two or three together, on stout stalks, which are clothed with scale-leaves and ½ in. to ¾ in. long; erect, ovoid or nearly globular, 4 to 6 in. long, and 4 in. broad, symmetrical, shining and light brown; scales 1½ in. or more in length, ¾ in. wide, hollowed at the base for the seeds; apophysis much thickened, pyramidal, four to five angled, and marked with four or five radial linear ridges; umbo rhomboidal, ⅓ in. wide, dark coloured, showing in its centre an inner umbo, which is often tipped with a triangular reflexed process. Seeds⁴ numerous,

¹ *Journ. Roy. Agr. Soc. England*, lxiv. 50 (1903).

² Cf. *Gard. Chron.*, 1855, p. 334.

³ On well-developed vigorous branches, a few of the leaves are sometimes in clusters of threes.

⁴ Seeds kept in the cones apparently retain their germinating power indefinitely, an instance being recorded in *Gard. Chron.*, 1856, p. 39, where seedlings were raised from cones said to be forty years old.

nearly 100 in a cone, one or two on each scale, $\frac{5}{8}$ in. to $\frac{3}{4}$ in. long, dark purplish brown, convex on the inner and flattened on the outer surface, with a thick shell and an edible kernel; wing $\frac{1}{8}$ in. to $\frac{1}{4}$ in. long, surrounding the apex and part of the sides of the seed, remaining on the scale when the cone opens.

The cones of this species are remarkable in taking three years to ripen, the seeds usually falling out in the spring of the fourth year; and each scale shows distinctly the growth of three seasons, the inner and outer umbo indicating the growth of the first and second year, while the rest of the apophysis is formed in the third year.

The seedling¹ has ten to thirteen cotyledons, nearly 2 in. long, triangular in section, sharp-pointed and stomatiferous on the upper two sides. The primary leaves, solitary, $\frac{1}{2}$ to 1 in. long, linear, flattened, serrate, and stomatiferous on both surfaces, are produced for several years, in mixture, after the first season, with the adult geminate leaves. Seedlings are very vigorous in growth, often attaining a foot in length in six months, and develop lateral branches and a long tap-root.

In this species,² adult trees frequently produce branches, which bear solitary glaucous flat linear leaves, similar to the primary leaves on the seedling plant. Hochstetter³ has succeeded in fixing the juvenile form by cuttings, producing beautiful shrubs with solitary needles.

The Comte de Paris sent in 1894, from his estate near Seville in Spain, to the Museum at Kew,⁴ a cone, from the apex of which a stout leafy shoot had sprung, a foot in length and with three branches. It died after it had exhausted all the nourishment from the cone, which had been severed from the tree when the shoot was about 6 in. in length.

The stone pine shows little or no tendency to vary; but there is a form in cultivation in Italy, var. *fragilis*, with a very thin shell to the seed.

DISTRIBUTION

The stone pine is a native of the Mediterranean region, and undoubtedly occurs wild,⁵ as well as planted, in the Iberian peninsula, south-eastern France, Corsica, Italy, Greece, and Asia Minor, extending a little distance into Russian territory on the south-east of the Black Sea. It has been recorded as a native of the Canaries and Algeria, but there is no doubt that it has been introduced into these regions. It has been extensively planted for centuries, and it is difficult to ascertain whether existing woods are natural or artificial in many localities; while on the other hand, owing to the advance of agriculture, it has probably disappeared in historic times from many places.

It is more widely distributed in Spain and Portugal than elsewhere, its northern limit, according to Willkomm,⁶ being a line following the Douro from its mouth to its source, continued through southern Aragon to the coast of Catalonia. Remark-

¹ Excellent figures representing different stages in the germination are given by Sachs, *Text-book Bot.* 508 (1882).

² Cf. Masters, in *Gard. Chron.* xx. 48, fig. 9 (1883), and *Journ. Linn. Soc. (Bot.)* xxvii. 259, fig. 8 (1891).

³ *Gard. Chron.* xv. 333 (1881).

⁴ Thiselton-Dyer, in *Ann. Bot.* xvii. 779, t. 40 (1903), and *Kew Bulletin*, 1894, p. 226.

⁵ Nymán, *Sylog. Fl. Europ.* 347 (1854-5), doubts the spontaneity of this tree in Europe; but this opinion is contrary to that of most botanists.

⁶ *Pflanzenverbr. iber. Halbinsel*, 96 (1896).

able woods occur at Albufeira in Algarve, and on the shores of the Bay of Cadiz. It ascends in the mountains of the coast region of Granada to 3000 ft., an elevation unattained elsewhere, as it is usually a native of the plains and low hills near the sea.

(A. H.)

In Portugal the stone pine is not nearly so common a tree as the maritime pine, and is usually seen on dry hill-sides and exposed places, where its umbrella-shaped crown makes it a very conspicuous tree. The finest that I saw was a very remarkable tree near Covilha in the province of Beira Baixa, growing at an elevation of about 2000 ft. Padre J. de Silva Tavares lent me a splendid negative of this tree, reproduced on Plate 291, and informed me that its height was 31.25 metres, the girth of the trunk, which is 14½ metres high, being 5.36 metres at the base. He said that an old man, who remembered the French invasion, stated that it was then about the same size as at present, so the tree must be a very long-lived one. On the Pena Verde, near Cintra, I measured another fine old tree of very gnarled and rugged habit, owing to its exposed situation. It was about 75 ft. high, with a trunk of about 30 ft. by 12 ft., the bark divided into very broad reddish plates, which do not become smooth and shining like those of *P. Pinaster*. Both of these are exceeded in size by a tree said to have been cut down at Curto,¹ which measured 40 metres by 6.40 metres. A section of this tree, 4.77 metres in girth, showed 300 annual rings.

(H. J. E.)

In France isolated trees are met with in the forests of Aleppo and maritime pines in the extreme south of Provence and Languedoc; and nearly pure woods, which are undoubtedly wild, occur on several points of the Mediterranean, from Aigues Mortes to Cannes. The largest of these, 750 acres in extent, lies between Aigues Mortes and Les Saintes. Another wood at La Plage, near Hyères, is 160 acres in area. Others occur at Vidauban, Saint Raphael, and between Cannes and Napoule. The most northerly station in France is the remarkable forest of Bigourdin near Fonscolombe, which consists of a mixture of *P. Pinea* and *P. halepensis*, and is undoubtedly natural. Here the mean annual temperature is 58°, the same as at Ravenna, the northern limit of the tree on the Adriatic. The most remarkable specimen is the *Pin de Bertaud*,² growing in the department of Var, two miles from Saint-Tropez, on the main road to Toulon. It is 53 ft. high, well shaped, and with a perfectly sound trunk 20 ft. in girth, the spread of foliage being 85 ft. in diameter. In France the stone pine is cultivated as far north as Angers, which has a western mild climate.

In Corsica there is a wood of this species, about 25 acres in area, near Porte Vecchio.

In Italy *P. Pinea* is wild at intervals on the west coast, from Genoa, where it occurs on the low hills, to Ostia, mainly growing on sandy plains in mixture with *P. Pinaster*. The natural forest of San Rossore, between Leghorn and Pisa, in which *P. Pinea* predominates amidst *P. Pinaster* and broad-leaved trees, like *Quercus pedunculata* and *Q. Ilex*, with an undergrowth of *Erica scoparia* and grasses, occurs on soil containing very little lime, less than $\frac{1}{2}$ per cent. The pines

¹ Gebhart, in *Rev. des Eaux et Forêts*.

² *Journ. Soc. Nat. Hort. France*, 1888, p. 367, fig. 1.

attain a height of about 70 ft. There is also a wood of this species at Castel Fusano near Rome. The most celebrated forest¹ of *P. Pinca* in Italy, the *Pinete di Ravenna*, in which Dante, according to tradition, composed the *Divina Commedia* whilst he walked amidst its glades, is situated east of Ravenna, forming a band 2 miles distant from the Adriatic coast, about 16 miles in length and a mile in width; and in 1866 covered about 10,500 acres, according to Balestreri,² who visited it in that year, when the pines were about 60 ft. in height and 8 ft. in girth. There are three distinct sections,—the *Pineto di S. Vitale*, about 5000 acres, and the *Pineto di Classe*, about 2500 acres, which belong to the city of Ravenna; while the third, the *Pineto di Cervia*, about 3000 acres, is owned by the commune of Cervia. This forest was greatly damaged³ by the long and severe winter of 1879, when the thermometer fell to -10° or -12° C., all the young pines, less than twenty-five to thirty years old, being killed outright. The older trees, with their foliage brown and withered in the spring of 1880, were believed to be dead; and orders were given to fell them and sell the timber. A large area was at once completely cut down. Later in the season, the trees were observed to be still living, and the destruction was stopped. About 2700 acres remained untouched, and the old trees here are now thriving. About 5000 acres of the area which had been felled, was subsequently sown with seed; and the young pines are now flourishing and about 15 to 25 ft. in height. For the preceding information we are indebted to M. Bandi, the forester in charge, whom I saw in 1909, when I visited the *Pineto di Classe*, which lies about 5 miles south-east of Ravenna. The soil is sandy, but is said to contain a notable quantity of lime, nearly five per cent. The forest is an open one, mainly composed of pines with a few scattered oaks (*Q. pedunculata*), and an undergrowth of *Cratægus Pyracantha*, *Rosa sempervirens*, clematis, juniper, and bracken. Towards the margin, where the soil improves, the pines become fewer, and are replaced by oak and *Fraxinus oxycarpa*. The largest pines which I saw measured 70 to 80 ft. in height and 5 to 7 ft. in girth.

In Italy the tree is cultivated for its edible seeds from the foot of the Alps to Sicily, and is planted from sea-level up to 1000 ft. in the north and 2000 ft. elevation in the south. The timber, which was formerly used for shipbuilding, is no longer employed.

According to Beck v. Mannagetta⁴ it is scarcely wild on the eastern shore of the Adriatic, and is even rarely planted, and only for ornament. Boué's observation that it occurs in Herzegovina near the sea has not been confirmed; and Poscharsky's statement that it forms woods at Ragusa is erroneous.

In Greece it is recorded⁵ at many stations on sandy soil in the plains and on the low hills, in Attica, Peloponnesus, and in the islands of the Cyclades, Crete, Cephalonia, Zante and Corfu. It is common⁶ in the islands in the Sea of Marmora, and the seeds are called *fistik* by the Turks.⁷

¹ It was described by Ginanni, in a large book published at Rome in 1774, entitled *Istoria Civile et Naturale delle Pinete Ravennati*.

² *Pinete di Ravenna*. (Florence, 1866.)

³ In *Gard. Chron.* xv. 736 (1881), and *Woods and Forests*, i. 146 (1884), there are accounts of this calamity.

⁴ *Veget. illyrischen Länd.* 185 (1901).

⁵ Halacsy, *Consp. Fl. Græca*, iii. 451 (1904).

⁶ Walsh, in *Trans. Hort. Soc.* vi. 47 (1826).

⁷ In Cyprus it is sometimes planted, but Mr. Hutchins thinks that it is not indigenous.

Boissier records it in the littoral region of Anatolia and Syria; and it reaches its most easterly point as a wild tree on the left bank of the Tschoroch river, near Artun, south of Batoum, where it forms an open wood in mixture with *Arbutus Andrachne*.¹

It does not appear to be wild in northern Africa, and forms no part of the flora of Egypt, though two cones were found in a tomb of the 12th dynasty (2200-2400 B.C.), which are now preserved in the museum at Boulac.

A cone has been found in a turf-bog in Alsace, lying beside the skull of a bison, but this is supposed to have been brought there by early traders. A fossil species, resembling *P. Pinca*, was discovered by Saporta in a miocene deposit at Ardèche.

(A. H.)

CULTIVATION

The tree is now widely cultivated in warm countries; and, according to Bunbury,² there were in his day extensive groves of it on the lower slope of Table Mountain and on the sandy flats to the east of Cape Town,³ where it flourished as well as in Italy.

It was early introduced into England, being mentioned in Turner's *Names of Herbes*, published in 1548. It grows very slowly, and is somewhat tender, though trees may be seen in all the southern counties. According to Bunbury,² the trees at Hardwicke, in Suffolk, were all killed by the severe winter of 1860, those at Barton being injured and not doing well afterwards. In the woods at Addington Park all the trees of this species, which were forty to fifty years old, were dead or dying in 1890. Trees, however, at Kew and Richmond seem to have been unaffected by the severe frosts of exceptional years, and bear fruit in abundance.

The seeds⁴ may be liberated by knocking the cone with a mallet, or by placing it in water hot enough to soften the resin which keeps the scales together. The scales will also come asunder if the cones are placed in a warm oven. Seeds should be soaked in water before sowing, and the seedlings should be kept in a cool frame for at least two years.

REMARKABLE TREES

If I had not seen the remarkable plantation of this pine at Matchams, near Ringwood, I should have supposed that it was incapable of developing its normal character in any part of England, but here it seems so much at home that the conditions under which it grows are of interest. Hamilton Leigh, Esq., owner of this place, informs me that the trees were raised from seed sent by Lord Nelson from the Mediterranean about one hundred years ago, to the then owner of the estate. They grow close to the road and railway, at the foot of a great sandhill on the open barren heath, two or three miles south-west of Ringwood, in sand which is apparently never dried up in summer, owing to the percolation from the hill above;

¹ Radde, *Pflanzenverb. Kaukasuslând.* 126 (1899).

² *Arboretum Notes*, 125 (1889).

³ According to Hutchins, *Science in South Africa*, 395 (1905), there are some noble specimens still on the old farms; but about thirty years ago this species was attacked by a fungus (*Peronospora sp.*), and the tree is now likely to become extinct in Cape Colony.

⁴ *Gard. Chron.* xxxvii. 240 (1905).

the trees being well sheltered from the south-west and drawn up by maritime pines which grow around them. They have the umbrella-shaped head of the true Roman pine, and are from 50 to 60 ft. high by 4 to 5 ft. in girth. They produce cones abundantly, which are attractive to squirrels, which eat the seed before it falls. By their bark, their cones, and their habit they are easily distinguished from the maritime pines.

Another place where the stone pine may be seen of some size, though in a climate evidently too moist to suit it, is at Killerton, where, on the top of the hill above the house, there are several old trees about 50 ft. by 7 to 8 ft., but they have an unsightly appearance owing to numerous half-dead branches. At the foot of this hill, on Taverner's farm there is another tree of the same kind, which is healthier.

At Saltram,¹ Devonshire, there are several trees, the largest of which is 60 ft. high and 8½ ft. in girth. The late Lord Morley sent me a photograph of this tree, which, however, is by no means typical in habit. At Mount Edgcumbe, Plymouth, there is another tree 54 ft. high, and 9½ ft. in girth at 3 ft. from the ground, with a spread of foliage 46 ft. in diameter. This tree has not borne cones, though two smaller trees at the same place produce fruit freely.

At Heron Court, in Dorsetshire, the seat of the Earl of Malmesbury, there are several stone pines, the largest of which is no less than 13 ft. in girth at 2½ ft., where it divides into large branches, but does not exceed 40 to 45 ft. high. There are two groups in the park of smaller size, all of which seemed to bear ripe seed in 1906.

At Melbury, Dorsetshire, there is a well-shaped tree about 50 ft. by 7 ft., showing bark rather like that of *P. Pinaster*, with broad flat plates, but duller and not so shining, and marked at intervals of about a foot, with irregular transverse rings, which seemed to show its annual growth.

At Kew the old tree near the Director's office measured,² in 1903, 31 ft. high and 7 ft. 7 in. in girth, with a spread of foliage 46 ft. in diameter.

A large tree³ in the Red Lodge Nursery, Southampton, was blown down in 1903. It measured 61 ft. in height, and 8 ft. 7 in. in girth at 3 ft. from the ground, and was said to have been seventy-five years old.

At Eastnor Castle there is a group of stone pines which are curiously distorted by irregular concentric swellings round their trunks. They are only about 30 to 35 ft. high; but one, which forks very low, is no less than 8 ft. 10 in. in girth at 1½ ft. from the ground.

Sir Hugh Beavor reports a good tree at Chorley Wood Cedars, 50 ft. high by 9 ft. 11 in. in girth. At Burwood House, Surrey, Mr. R. Woodward reports a tree 50 ft. high and 8½ ft. in girth.

At Stackpole Court, Pembrokeshire, there is a tree about 30 ft. by 6½ ft. bearing cones which seem fertile, though here the climate seems too damp for this tree. There are two trees near the Orangery at Margam, about 40 ft. by 7½ ft., from which seedlings have been raised. At Penrhyn, North Wales, a tall slender tree was, in 1905, 53 ft. high by 4 ft. 10 in. in girth.

¹ *Gard. Chron.* xxxiv. 413 (1903).

² Cf. *Kew Handlist of Conifera*, xxiii. (1903). This tree is figured in *Gard. Chron.* iv. 602, fig. 85 (1888).

³ *Gard. Chron.* xxxiv. 285, figs. 121, 122 (1903).

A remarkable instance of the hardiness of this tree in Scotland was given by Captain Norman, R.N., at a meeting of the Berwickshire Naturalists' Club, in September 1905. He states that a group of six trees of this species are growing at the foot of a railway embankment close to the post road at Dunglass, East Lothian. They were identified at Kew, and bear cones annually, the largest being about 30 ft. high. These trees are said to have been planted by an Edinburgh firm soon after the railway was made in 1846. But though there are many parts of Scotland where the climate would seem to be much more suitable for this pine, we have seen none worth mentioning.

In Ireland, there is a fair-sized tree in the Trinity College Botanic Garden, Dublin; and at Hamwood, Co. Meath, a tree, planted in 1844, had attained, in 1904, 50 ft. in height and 6½ ft. in girth.

Mouillefert¹ says that the wood of *P. Pinea* is like that of *P. Pinaster*, but is less resinous, and the sapwood is abundant at a considerable age. At the Cape of Good Hope he thought that the lignification was quicker and more complete than in Europe. As to the comparative value of the wood of this pine and *P. Pinaster*, opinions differ in Portugal, but most people consider the stone pine the best.

(H. J. E.)

PINUS DENSIFLORA, JAPANESE RED PINE

Pinus densiflora, Siebold et Zuccarini, *Fl. Jap.* ii. 22, t. 112 (1844); Masters, in *Journ. Linn. Soc. (Bot.)* xviii. 503 (1881), and xxxv. 619 (1904); Mayr, *Abiet. jap. Reiches*, 72 (1890), and *Fremdländ. Wald- u. Parkbäume*, 343 (1906); Shirasawa, *Icon. For. Japon.* text 10, t. 1, ff. 1-14 (1899); Kent, Veitch's *Man. Conifera*, 326 (1900); Clinton-Baker, *Illust. Conif.* i. 18 (1909).

A tree attaining in Japan 120 ft. in height and 12 ft. in girth. Bark of branches and young trees, and of the upper half of the stem of old trees, reddish, and peeling off in thin scales, resembling that of *P. sylvestris*; towards the base of old trees rugged and dividing into small plates. Young branchlets glabrous, glaucous, with raised pulvini, separated by linear grooves. Buds cylindrical, sharp-pointed, dark-brown, ½ in. long, slightly resinous; scales free at their apices, but not reflexed.

Leaves in pairs, persistent about three years, spreading, 3 to 4 in. long, soft in texture, twisted, dull green, with eight to ten stomatic lines on each surface, ending in a short callous tip, serrulate; resin-canals marginal; basal sheath ⅜ in. long, often ending above in two long narrow filaments.

Cones subterminal, spreading, two or three together, sub-sessile, ovoid-conic, 2 to 2½ in. long, dull grey in colour; scales about 1 in. long and ⅔ in. wide, oblong, thin, with the concealed part pale brown above and reddish below, flat or slightly convex from side to side; apophysis rhomboidal, slightly raised, transversely ridged, upper margin irregularly sinuate, dull grey, with an elliptical dark brown umbo tipped with a minute mucro. Seed ¼ in. long, bright brown; wing narrow, pale brown, ½ to ⅔ in. long.

¹ *Essences Forestières*, 395 (1903).

This species,¹ which closely resembles *P. sylvestris* in the bark and buds, is readily distinguishable by the dull green longer leaves and the glaucous branchlets.

Numerous varieties of *P. densiflora* are in cultivation in Japan, no less than twenty-two being enumerated by Mayr. Some are dwarf, pendulous, globose, or otherwise peculiar in habit; whilst others have variously coloured foliage, golden, striped, variegated, etc. These are apparently unknown² in England. The hybrids between *P. densiflora* and *P. Thunbergii* are mentioned under the latter species.

P. densiflora appears to be confined to Japan, as the herbarium specimens from Korea and the Shantung hills³ in China, supposed to belong to this species, are different in appearance, though undoubtedly closely allied. The representative of this species in central China is *P. Henryi*,⁴ Masters, not yet introduced into cultivation.

(A. H.)

This species, which is known by the Japanese as *aka-matsu*, red pine, or *me-matsu*, female pine, is the commonest conifer in Japan; but in most cases is planted, as it has been cultivated from ancient times, usually on poor dry soil, where other trees will not thrive. It is considered to be a native of the hilly mountainous district, generally between 500 and 3000 ft. elevation, scarcely ever ascending into the higher region, which is occupied by the silver firs and spruces, and being absent⁵ from the sea-coast, where it is replaced by *P. Thunbergii*. According to Mayr it is rare in the subtropical forests at low elevations in the southern islands; but occurs as far north as south-western Yezo. In the wild state, I found the tree scattered here and there through the mixed forests, up to about 2000 ft., generally on dry ridges or sandy stony river banks. In the forest near Koyasan, it was larger than elsewhere, up to 12 ft. in girth; and one tree standing alone in a dense forest of *Cupressus obtusa* and *Sciadopitys* had a clear trunk of 60 ft. high or more, and measured about 100 ft. by 11 ft. 9 in. The best planted trees which I saw, were near the foot of the low pass between Shimonosuwa and Shiojiri in Shinshu, in private grounds by the roadside. These were over 100 ft. high and 8 or 9 ft. in girth, clean to 70 ft., and though not so straight in the stem as *P. sylvestris*, were very fine trees. More often, however, this pine has a crooked unsightly stem, and does not grow to any great size, being usually crowded, and cut when young; and it is only rarely that it has a chance of showing its full development, and becomes a

¹ It is often known in cultivation, both in Europe and in the United States, as *P. Massoniana*, a species of southern China, not in cultivation.

² The varieties mentioned in *Kew Handlist Coniferae*, 111 (1903), are not in cultivation in Kew Gardens.

³ Mayr brought home from Korea living plants, which he considered to be this species. The Shantung tree, which grows on the hills near Chefoo, is imperfectly known, and has been mentioned by Masters in *Journ. Linn. Soc. (Bot.)* xxvi. 551 (1902), as *Pinus Massoniana*, Lambert, var. *planiceps*, Murray, MS. in Mus. Brit. It bears cones different in colour from those of *P. densiflora*; and is certainly quite distinct from *P. Massoniana*, a long-leaved species, inhabiting the plains of central China and the low hills of southern China. The Korean pine is *P. funebris*, Komarov, referred to on p. 1144, note 2.

⁴ *Pinus Henryi*, Masters, in *Journ. Linn. Soc. (Bot.)* xxvi. 550 (1902) and xxxv. 618 (1904). This species, discovered by me in 1888, is a small tree, rarely exceeding 40 ft. in height, forming open woods, at 4000 to 6000 ft., in the mountains of Hupeh, Szechwan, and Shensi. The cones are subterminal, shortly-stalked, ovoid, 1½ in. long, shining reddish brown; scales oblong, ⅝ in. long, ⅜ in. wide; apophysis rhomboidal, slightly raised, with four radial ridges, and a depressed umbo, tipped by a minute prickle. Seeds light brown, with short, broad, dark brown wings. The foliage resembles that of *P. densiflora*.

⁵ Mayr says that it is occasionally planted near the coast, and is sometimes found on the second range of hills near the coast, *P. Thunbergii* occupying the strand and the first range. The largest trees, up to 120 ft. in height, which he saw, were in the warm valleys of the central mountains of Hondo.

fine tree; and then, with its reddish yellow bark on the upper half of the stem, and spreading crown, it reminds one much of *P. sylvestris*.

CULTIVATION

This species was introduced¹ by Siebold in 1854, into the Botanic Garden at Leyden; but was not generally distributed until 1861, when seeds were sent home from Japan by J. Gould Veitch. It is, however, very rare in cultivation,² except in botanic gardens, as at Kew, where it is a handsome tree, ripening its cones perfectly, and displaying the characteristic bark. We have also seen specimens, of no great size, at Brocklesby, Lincolnshire; Bagshot, Surrey; High Canons, Herts; and Murthly, Perthshire.

At Grafrath, near Munich, it has proved perfectly hardy during the last twenty-five years; but is easily injured by snow. Young plants are liable to the attacks of the leaf-shedding disease.

According to Sargent,³ it is hardy in New England, where it produces fertile cones in abundance, and is already beginning to assume its mature picturesque habit. So far as can be judged from an experience of twenty-five years, it appears to be the most promising of the two-leaved pines introduced into the eastern states from foreign countries.

The wood is usually coarse and knotty, but being the cheapest building timber in Japan, is largely used there. Mayr says it is very similar to that of *P. sylvestris*, and, as in that species, the amount of heartwood depends on the situation and age.

(H. J. E.)

PINUS MONTANA, MOUNTAIN PINE

Pinus montana, Miller, *Gard. Dict.* Ed. 8, No. 5 (1768); Willkomm, *Forstliche Flora*, 209 (1887); Mathieu, *Flore Forestière*, 593 (1897); Kent, Veitch's *Man. Coniferae*, 343 (1900); Masters, in *Journ. Linn. Soc. (Bot.)* xxxv. 611 (1904); Schröter, *Pflanzenleben der Alpen*, 74 (1904); Kirchner and Schröter, *Lebensgesch. Blütenpfl. Mitteleuropas*, 202 (1906); Clinton-Baker, *Illust. Conif.* i. 34 (1909).

Pinus mugus,⁴ Scopoli, *Fl. Carniol.* ii. 247 (1772).

Pinus pumilio, Haenke, *Beob. Reis. Riesengeb.* 68 (1791); Loudon, *Arb. et Frut. Brit.* iv. 2186 (1838).

Pinus uncinata, Ramond, in De Candolle, *Flor. Franç.* iii. 726 (1805); Cook, *Sketches in Spain*, ii. 230 (1834).

Pinus humilis, Link, in *Abhand. Berl. Akad.* 171 (1827); Kerner, *Nat. Hist. Pl. Eng.* Trans. i. 548, fig. 135 (1898).

Pinus obliqua, Sauter, in Reichenbach, *Flora Germ. Exc.* 159 (1831).

Pinus uliginosa, Neumann, *Schles. Ges.* 95 (1837).

Variable in habit, a tree or prostrate shrub, with greyish black scaly bark. Young branchlets brown, glabrous, with raised keeled pulvini. Buds ovoid or cylindrical, short-pointed, ¼ to ½ in. long, covered with resin.

¹ A plant, 18 in. high, in cultivation at Woburn in 1839, is named *Pinus japonica*, Forbes, in *Pin. Woburnense*, 33 (1840); but it is impossible to say from the description whether it was *P. densiflora* or *P. Thunbergii*.

² A thousand plants, imported from Japan, were planted in 1907 at Ampton Park, Suffolk; and about a hundred were living in 1910.

³ *Garden and Forest*, x. 471 (1897).

⁴ This name occurs in Scopoli as *mugus*, but *mughus* is adopted by all later writers. It is derived from the Italian name of the tree, *mugo*, used in south Tyrol.

Leaves in pairs,¹ persisting five to ten years, $1\frac{1}{2}$ to $2\frac{1}{2}$ in. long, rigid, curved, dark green,² ending in a short blunt cartilaginous point, serrulate, with stomatic lines on both surfaces; resin-canals marginal; basal sheath $\frac{1}{2}$ to $\frac{6}{10}$ in. long.

Cones subterminal, solitary or two or three together, sessile or sub-sessile, 1 to 2 in. long, conical, ovoid or sub-globose; scales with shining dark brown apophyses, the ashy grey or light brown umbo being surrounded by a darker coloured ring. The variations in the size and shape of the cones and of the apophyses will be dealt with under the varieties. Seed similar to that of *P. sylvestris*, but slightly larger in the body and shorter in the wing. Seedling with two to eight, usually four to six cotyledons, about $\frac{1}{8}$ in. long, entire in margin; primary needles shorter than the cotyledons, serrate, clothing the first year's shoot, and gradually replaced in the second year by the adult geminate leaves. The seedlings grow very slowly, attaining about an average height of an inch in the first year, and 2 to 3 ft. high in the tenth year. No well-developed tap-root is formed.

VARIETIES

This species consists of numerous geographical races, which are difficult to define, as the variations in habit are not exactly coincident with the variations in the characters of the cones. In certain cases peculiarities in habit appear to be fixed and hereditary, whilst in other cases these are due to soil, climate, and exposure, and are not transmitted by seed. The cones are not constant in the various races; in rare cases they vary even on the same tree, and are often different in trees from the same locality. There is great difference of opinion amongst foresters and botanists as to the varieties, the number described being very great, but for practical purposes the following arrangement is convenient:—

1. Var. *uncinata*, Willkomm, *Forstliche Flora*, 171 (1875); Masters, in *Gard. Chron.* xxii. 208, fig. 42 (1884).

Usually a tall tree, with a single undivided stem, 60 to 80 ft. in height. Cones asymmetrical, very oblique at the base, ovoid-conical, 2 to $2\frac{1}{2}$ in. long, directed downwards or pendulous, with the scales on the outer side strongly developed, their much raised and pyramidal apophyses ending in hook-like processes, which are directed towards the base of the cone. This variety, which has been called by Sir John Stirling Maxwell³ the upright mountain pine, is the only form met with in Spain, in the eastern and central Pyrenees, and in the French Alps, and is of rare occurrence in Switzerland. It forms extensive woods in sub-alpine regions up to timber line.

With this variety must also be classed a shorter tree, 30 to 50 ft. high, which is met with in pure woods on some of the high-lying peat mosses in the Vosges, Jura, Switzerland, lower Austria, and Bohemia. Isolated trees of this form are also occasionally seen amongst the dwarf *P. montana* in the Alps of Switzerland and

¹ Occasionally the needles are in threes, as in var. *mughus* in the Raxalp. Cf. Kronfield, in *Verhand. zool. bot. Ges. Wien*, xxxviii. 96 (1888).

² Koehne, *Deut. Dendrologie*, 39 (1893), states that in all forms of *P. montana*, the epidermal cells are twice as thick as in all other species, and have only linear cavities.

³ In *Trans. Roy. Scot. Arb. Soc.* xxi. 10 (1908).

in the Tyrol; but it is not known to occur in the dwarf pine belt of the Silesian and Carpathian ranges. Dwarf pines with cones of this type are sometimes seen in exposed and barren spots in the western Alps, but these are supposed to be stunted by the nature of the situation where they grow.

2. Var. *rotundata*, Willkomm, *Forstliche Flora*, 174 (1875).

Cones asymmetrical and oblique, as in the preceding variety, conical or ovoid, $1\frac{1}{2}$ to 2 in. long, spreading or bent downwards, sessile, with the lower and occasionally the middle scales on the outer side ending in a short four-sided blunt pyramid, directed slightly downwards. Usually a tree, scarcely exceeding 30 ft. in height, with several stems arising close to the ground, due to the rapid development of the lateral branches which turn upwards, and becoming erect, grow as fast as the leader. This, which Sir John Stirling Maxwell calls the intermediate form¹ of the mountain pine, is found on sunny precipices, rocky slopes, and high peat-mosses, and is common in the whole of the Alps, except in France. The dwarf mountain pine in the Swiss Alps often bears cones of this type.

3. Var. *pumilio*, Willkomm, *Forstliche Flora*, 175 (1875).

A shrub, rarely over 6 ft. in height, prostrate in habit, with the branches tending to lie flat on the ground, only turning up at the ends. No definite leader is formed. Cones symmetrical, usually sub-sessile, ovoid or globose, smaller than in the preceding varieties, 1 to $1\frac{1}{2}$ in. in diameter, spreading, tinged with violet before ripening; scales uniform in size; apophysis unequally divided with the umbo placed near the lower edge. This, one of the forms of the dwarf mountain pine, which comes true from seed, occurs in the Jura, Switzerland, Black Forest, Fichtel mountains, Bohemian and Bavarian forests, Riesen and Iser mountains, extending southward to Bosnia, Herzegovina, and Montenegro.

4. Var. *mughus*, Willkomm, *Forstliche Flora*, 177 (1875).

Similar to the last in habit, and in size, shape, and direction of the cones, and only distinguishable by the apophysis of the scale being very flattened with the umbo in the centre. This form is common in the eastern Alps and in the Balkan States, and is very rare in Switzerland.

Several hybrids between this species and *P. sylvestris* have been described, which are arranged by Ascherson and Graebner² as follows:—

(a) *P. sylvestris*, var. *engadinensis* × *P. montana*, var. *uncinata*. Found in the Upper Engadine, near Samaden, at 6000 ft. altitude.

(b) *P. sylvestris* × *P. montana*, var. *rotundata*. Found in peat-mosses on the boundary between Lower Austria and Bohemia and in southern Bohemia.

(c) *P. sylvestris* × *P. montana*, var. *pumilio*. Found in the southern Bohemian forest and in the Tyrol.

¹ This form was introduced into Denmark in 1798 from Eisenach, in Thuringia, and has kept true from seed. Occasionally one of the stems takes the lead and suppresses the others, but in such cases the stem is always bent near the ground.

² *Syn. mitteleurop. Flora*, i. 229 (1896-98). These authors (*op. cit.* 232) state that a tree in the Botanic Garden at Vienna, supposed by Wettstein to be a hybrid between *P. Laricio*, var. *austriaca*, and *P. montana*, has been shown by Beck to be a pure Austrian pine.

DISTRIBUTION

This species is widely spread in the mountainous regions of central and southern Europe,¹ extending from Spain in the west to Bukovina in the east, and from the Vosges and Lausitz (Saxony) in the north to the Abruzzi mountains in Italy and Perim Dagh in Macedonia, its most southerly stations.² The distribution of the mountain pine and of its varieties appears to depend mainly on the encroachment and competition of other species of conifers. In the west and south-west, where the spruce, its greatest rival, is rare or absent, it descends to comparatively low levels, and is a fine tree forming extensive forests; whereas in the central, eastern, and south-eastern parts of its range it has to contend with the spruce or larch, and occasionally with *P. Cembra*, and driven to high altitudes, it has become a mere shrub. In many parts it also forms woods on peat-mosses at moderate elevations in the mountains, where it grows better than either *P. sylvestris* or the spruce.

In Spain it occurs from the Sierra de Cuença through Aragon and Catalonia to the central³ and eastern Pyrenees, forming vast forests, which were first described by Capt. Cook (Widdrington).⁴ In the Pyrenees the spruce is a rare tree, found sparsely mixed with silver fir, and the larch is totally absent. In consequence the mountain pine reigns alone in this range at high elevations, occurring between 5000 and 8000 ft., and attaining its maximum development, trees 100 ft. in height and 9 ft. in girth having been measured by the French forest officers. Sir J. Stirling-Maxwell,⁵ who visited this region in winter, says that the finest forests were then inaccessible, but he obtained excellent photographs of woods of this species at lower levels, where trees about seventy years old averaged 55 ft. in height and 3 ft. in girth. He notes the straight cylindrical stems of the Pyrenean variety, with grey coloured bark, and a narrow crown of foliage, and compares the tree in all its stages of growth to the Corsican pine. On account of its narrow pyramidal habit and tough elastic wood it scarcely suffers from heavy snowfall, and is in marked contrast in this respect to *P. sylvestris*, which grows from lower levels up to where the mountain pine begins. Up to forty years old it is relatively fast in growth, being a slender and regular tree, but after this age there is a marked diminution in height growth, accompanied by increase in thickness of the stem and by a rounder crown. Still at seventy years it preserves its narrow pyramidal habit, the stout cylindrical stem carrying branches which are remarkably short and light. Its root system is shallower than that of *P. sylvestris*, which can only keep pace with it in growth in the Pyrenees on the better soils. The mountain pine is the least exacting of trees, whether as regards soil, aspect, or climate.

¹ C. Reid, in *Journ. Linn. Soc. (Bot.)* xxxviii. 220 (1908), doubts the occurrence of this species in British pre-glacial deposits, where it had been identified by Heer and Saporta.

² Judging from the description, *P. Kochiana*, Klotsch, and *P. armena*, Koch, both in *Linnaea*, xxii. 297 (1849) are incorrectly referred to *P. montana* by Medwejew in *Bäume u. Sträucher Kaukasus*, i. 14 (1907). This peculiar pine occurring in the Caucasus around Ardahan, near Kars, and in Daghestan, has hooked cone-scales, and is *P. sylvestris*, var. *hamata*. Steven, in *Bull. Soc. Nat. Mosc.* xi. 52 (1838).

³ The forests in the central part of the Pyrenees (departments of Ariège and Haute-Garonne) are nearly all destroyed; those in the eastern part (Pyrénées Orientales and Hautes-Pyrénées) are still of considerable extent.—Mathieu, *op. cit.* 596.

⁴ Cf. Loudon, *op. cit.* 2188.

⁵ In *Trans. Roy. Scot. Arb. Soc.* xxi. 10-15, figs. 1-9 (1908).

In France the tall upright variety also occurs on Mt. Ventoux and throughout the Alps of Provence, Dauphiné, and Savoy, where it grows at high elevations from 4800 to 8000 ft., on dry, poor, and rocky soils. At Briançon it does not attain so large a size as in the Pyrenees, and, according to Sir J. Stirling-Maxwell, at forty years scarcely attains 40 ft. in height, averaging 20½ in. in girth, while Scots pine alongside it is about the same height, but 27 in. in girth. The finest trees of this variety in the French Alps occur in the wild forest of Villarodin-Bourget, near Modane, which I visited in 1903. Here it forms a dense wood on the sides of a dry ravine between 5000 and 7000 ft. elevation, mixing at the lower level with *P. sylvestris*, the trees being about 60 to 70 ft. in height and 1 to 1½ ft. in diameter, and remarkable for their narrow pyramidal habit and their number on the ground, casting a dense shade. Higher up on the side of the ravine there are many isolated trees, very old, and of great size, up to 80 ft. in height and 9 ft. in girth. The stems of some of the smaller trees are marked with ring-like swellings, one above another, and full of resin, which are caused by the larva of a beetle. Seedlings are common here, and Elwes, who visited this locality in 1907, brought home some alive, which are now growing at Colesborne.

In the Jura, near Pontarlier, on peat-mosses, the shorter upright form, characteristic of this situation, occurs in small open woods. Here the trees rarely exceed 40 ft. in height, and are much more widely branched than those at Modane.

The upright form is also found sparingly in several localities in the Swiss Alps, Swabia, Oberpfalz, Silesia, Bohemia, and the Erz mountains. An extensive forest, with an area of 6000 acres, occurs on dolomite in the Lower Engadine, near Zernetz, at 5800 to 7000 ft. elevation, extending through the Ofen Pass to the Münster valley. Here the trees, many of which are of the intermediate form, gradually mix at the lower edge of the forest, with spruce, larch, and *P. sylvestris*. This forest is illustrated in *Les Arbres de la Suisse*, pl. xvii., which shows trees like those of Modane, but smaller, the largest depicted being 47 ft. high and 3 ft. 4 in. in girth. Another is recorded as 50 ft. by 5 ft. 3 in.

The intermediate form is common, mixed with the upright form, in all the localities of the latter, except in the Pyrenees and French Alps, and is usually met with on sunny precipices, rocky slopes, and high-lying peat-mosses.

The dwarf form (vars. *pumilio* and *mughus*) is widely spread throughout the Swiss, Italian, Austrian, and Bavarian Alps, ranging in the latter from 2000 to 4800 ft. elevation; and it extends through the Black, Bohemian, and Bavarian forests; in the Fichtel, Reise, Glatzer, and Iser mountains, occurring in the latter from 2000 to 2700 ft. altitude; in the Carpathians between 4200 and 6500 ft.; in the Bihar mountains of Hungary; in the mountainous regions of Carinthia, Carniola, Dalmatia, Bosnia, Herzegovina, Roumania,¹ Bulgaria, reaching its southernmost point in Perim Dagh in Macedonia. In Italy it is only known, outside of the Alps, on Mount Amaro in the Majella group of the central Apennines, where

¹ Golesco, in *Bull. Soc. Dend. France*, 1907, p. 176, gives a good description of the dwarf pine in the mountains of the Muscel district in Roumania, which comprise the highest summits of the Transylvanian ranges.

it¹ occurs between 6000 and 8700 ft., the latter being the highest elevation known for the species.

The dwarf mountain pine,² known as the *Legföhre*, is one of the most characteristic shrubs of the Alps and Carpathians, in some places covering large areas with a dense, almost impenetrable thicket, composed of decumbent stems, whose branches are so interlaced that though one may pass through it with difficulty in a lateral direction, and slide downwards over it on a steep hill-side, yet to ascend it is practically impossible. These thickets are well described by Kerner,³ who says that the stems, even when of great thickness, assume a horizontal position, with their growing ends always directed on mountain slopes towards the valley. The branches are remarkably elastic, and in winter are pressed downwards upon the soil by the heavy snow-fall; and in summer rise up again, often plastered with earth and small stones, and take a curved ascending position.

P. montana is remarkable for its different behaviour in regard to the chemical elements in the soil in different parts of its area. In the French Alps the extensive woods of this species cease to grow when the Jurassic chalk comes to the surface. Near the Aiguilles the tree is absent from slate formations, but immediately appears wherever the soil is composed of lime or chalk. At Grächen in Nicolai valley it grows on slate, and at Davos on serpentine. In the Engadine it occurs mainly on dolomite, but is not entirely absent from the gneiss formation. In the Carpathians it is indifferent to the nature of the soil. Christ says that in the Swiss Alps generally it is decidedly a lover of lime, often growing on rubbly limestone rocks, and alternating markedly with *Alnus viridis*, which clothes the declivities of the primitive non-calcareous rocks.⁴

In the Pyrenees the tree is found to be especially valuable for windy plateaux. It thrives in soils too poor for any other trees to grow, and succeeds better⁵ on peat than *P. sylvestris*. It is extremely hardy, easy to raise from seed, and presents no difficulty in transplanting. It is used now throughout the French Alps for planting at high altitudes and in all difficult situations. It is comparatively free from the attacks of fungi and insects.

(A. H.)

CULTIVATION

This species was first cultivated in England in 1779, at Orford Hall, near Warrington, Lancashire, where the shrub of var. *pumilio* originally introduced was still living, though in a shattered condition, in Loudon's time.

¹ Described as *P. majellensis*, Schouw, in *Ann. Sc. Nat.* iii. 233 (1845). Referred to *P. Laricio* by Parlato; but as Masters points out, in *Journ. Linn. Soc. (Bot.)* xxxv. 613 (1904), the resin-canals are marginal, and not median as in *P. Laricio*.

² At Innsbruck, according to Beissner, in *Mitt. d. dendr. Ges.*, 1905, p. 69, the tall, intermediate, and dwarf pines are distinguished by different names, Spirke, Latsche, and Zunder or Knieholz; but these names are not current everywhere with the same signification.

³ *Nat. Hist. Plants*, Eng. trans., i. 548, fig. 135 (1898).

⁴ Cf. Schimper, *Plant Geography*, 100, 104 (1903).

⁵ In the high peat-moors of the Hertogenwald, in Belgium, at 2000 ft. altitude, a few plants of the intermediate variety were doing better on deep peat than any other tree when I saw these plantations in 1909.

The Pyrenean form was apparently introduced by Captain Cook, as young plants were raised in the garden of the Horticultural Society from seed procured by him. Apparently this variety has been entirely neglected since, and we are scarcely in a position to judge concerning its capabilities as a forest tree in mountainous districts and on peat-mosses in this country; but recently some experimental planting has been done by Sir John Stirling Maxwell¹ at Corrou, Inverness-shire, with seeds obtained from the government seed-establishment at Mont Louis, in the Pyrénées Orientales. The finest examples of this form that we have seen is a tree at Essendon Place, Hertford, which measured, in 1907, 51 ft. in height, with a stem clear of branches to 30 ft., and 5 ft. 5 in. in girth. A good specimen in the Cambridge Botanic Garden measures 41 ft. by 3 ft. 5 in. At Sir H. Farquhar's seat, Gilmanscroft, Ayr, there is a tree of this variety. At Glasnevin a slender tree measures 35 ft. high by 2½ ft. in girth.

When Henry was at Annecy in 1904 the late Mr. Guinier, Inspecteur des Forêts, showed him a plantation of *P. montana*, twelve years old, raised from Pyrenean seed. He considered that this race is quite distinct and much finer than the race in the French Alps. Its growth is only slightly less vigorous than that of *P. sylvestris*, over which it has certain advantages, as it is the sole species in France available for planting peat-mosses, and, moreover, thrives on arid soils, where *P. sylvestris* grows very slowly. It has a dense cover, but always lets a little sun fall on the ground, even in the thick forests of the Pyrenees. The two races, that of the French Alps and that of the Pyrenees, planted in the Forêt du Crêt du Maure, near Annecy, retain their characteristic differences.

The intermediate form seems to be the one most general in cultivation, not only in this country, but also in Denmark, where it has been extensively used for planting the dunes and barren tracts in Jutland. It was introduced into Denmark from Eisenach in Thuringia in 1786, and has come true from seed. It attains on poor soil about 20 ft. in thirty or forty years, and then ceases to grow; and can scarcely be looked upon as of any economic value, though the improvement of the soil may prepare the way for other species. In Denmark² it is usually planted on the dunes pure at first, and afterwards the common spruce is introduced, which is a more valuable species, but one impossible to start by itself on poor soil covered with heather. Müller, who is the greatest authority on this species of pine, introduced the upright variety³ of the French Alps in 1886; but it is said to be more liable to the attacks of fungi. It is remarkable in this, as in many other cases of introduction of a species, that the seed from the best form (from the Pyrenees) should not have been selected.

In England the best specimen we have seen of the intermediate variety is a tree at The Wilderness, White Knights, near Reading, which consists of six stems, arising from a very short butt 6 ft. in girth, and rising to 60 ft. in height. There

¹ *Trans. Roy. Scot. Arb. Soc.* xx. 7 (1907). The seed of the Pyrenean variety, which can be obtained through the British Embassy at Paris, has been regularly supplied to the Norwegian Government for the last three years.

² Cf. *Quarterly Journ. Forestry*, iii. 74 (1909), where a full account of the heath plantations in Denmark is given by Mr. A. C. Forbes.

³ Known as the *Pin de Briançonnais*, or in seed catalogues as *P. montana gallica*.

are also four trees at Bayfordbury, which are about 40 ft. high, each with three to five stems from near the base, where they curve and turn upwards. Another at Arley was 32 ft. by 3 ft. 2 in. in 1904.

My father some fifty years ago planted some thousands of this tree at Colesborne in ignorance of their habit, and though they will live on the poorest and thinnest oolite, yet not one of the survivors would repay the trouble of cutting down, except for burning in closed stoves or for charcoal; for which it is said to be very well adapted. Here and there a tree drawn up among others has grown to be 20 to 30 ft. high, but the majority form straggling bushes, which produce cones abundantly, but have no beauty; and I cannot honestly recommend any one to plant this species at present.

Of the shrubby form, var. *pumilio*, the most remarkable specimen is probably one at Burwood House, Surrey, of which Col. Thynne has taken a photograph. It measures about 11 ft. high, and is 156 ft. in circumference around the prostrate ends of the branches. At Belton Park, Grantham, a large shrub of this kind is about 15 ft. high, and spreads on all sides for about 30 ft. There is a large spreading bush, about 30 ft. high and 45 paces round, at Spetchley Park, near Worcester, the seat of R. V. Berkley, Esq.

(H. J. E.)

PINUS CONTORTA

Pinus contorta, Loudon, *Arb. et Frut. Brit.* iv. 2292 (1838); Sargent, *Silva N. Amer.* xi. 89, t. 567 (1897), and *Trees N. Amer.* 26 (1905); Kent, Veitch's *Man. Coniferae*, 323 (1900); Masters, in *Journ. Linn. Soc. (Bot.)* xxxv. 630 (1904); Clinton-Baker, *Illust. Conif.* i. 16 (1909); Shaw, *Pines of Mexico*, 29 (1909).

Pinus inops, Bongard, in *Mem. Phys. Math.* pt. ii. *Acad. Sc. St. Petersb.* ii. 163 (1831) (not Solander).

Pinus Boursieri, Carrière, in *Rev. Hort.* 1854, p. 225.

Pinus Mackintoshiana, Lawson, *Cat.* (1855).

Pinus Bolanderi, Parlatore, in *DC. Prod.* xvi. 2, p. 379 (1868).

This species is very variable in habit and size, constituting a series of geographical races, which require further study in the field. It may be described as follows:—A tree or shrub, with either thin or thick bark. Young branches glabrous, with slightly raised keeled pulvini. Buds cylindrical, acute at the apex, about $\frac{1}{2}$ in. long, encrusted with white resin. Leaves in pairs, persistent three to eight years, curved, twisted, 1 to 3 in. long, serrulate, ending in a callous point, with numerous stomatic lines on both surfaces; resin-canals median; basal sheath $\frac{1}{4}$ in. long.

Cones sub-terminal, on short stout scaly stalks, in pairs or clustered, opening when ripe or remaining closed¹ for many years, ovoid or conical, $\frac{3}{4}$ to $2\frac{1}{2}$ in. long,

¹ Sargent, in *Bot. Gazette*, v. 54 (1880), says that he sowed in 1879, seed from closed cones collected by Engelmann in Colorado in 1874. Seeds of cones thirteen and ten years old did not germinate, but the seeds of some cones of nine, eight, and seven years old did germinate. This shows according to Engelmann, *Bot. Gazette*, v. 62 (1880), that the object of the tree keeping the cones closed, is to preserve the vitality of the seeds for a number of years beyond their maturity.

unequal and oblique at the base, spreading or deflexed. Scales thin, variable in size, up to $\frac{3}{4}$ in. long and $\frac{3}{8}$ in. wide; those on the outer side near the base with elevated pyramidal apophyses; the others with a rhomboidal transversely ridged apophysis and an elevated umbo, which is armed with a minute recurved, often deciduous prickle. Seed $\frac{1}{8}$ to $\frac{1}{6}$ in., triangular, blackish, furrowed; wing variable in length; cotyledons,¹ three to five, usually four.

This species is only liable to be confused with *P. montana*, from which it is readily distinguishable by the short basal sheaths of the leaves and the median resin-canals. Two main varieties, considered by many botanists and foresters to be distinct species, are recognizable:—

1. SHORE PINE, typical *P. contorta*.—Usually a small tree, 10 to 30 ft. high, though attaining 60 to 70 ft. when sheltered and on good soil. Bark $\frac{3}{4}$ to 1 in. thick, deeply divided into oblong scaly plates. Leaves dark green, 1 to $1\frac{1}{2}$ in. long, slender, $\frac{1}{4}$ to $\frac{1}{8}$ in. wide. Cones ovoid, very variable in size, $\frac{3}{4}$ to $1\frac{1}{2}$ in. long, some opening their scales when ripe, others remaining closed on the tree for many years.

Typical *P. contorta* occurs on the Pacific Coast from Alaska² to Mendocino County,³ in California, usually inhabiting sand-dunes or barrens or growing on ocean bluffs. In western Vancouver island it is a low twisted shrub when growing along the edges of the forest next the ocean; but on peat-mosses⁴ in the forest it is a small irregular flat-topped slow-growing tree. It begins to flower and fruit when only a few feet high; and the ripe cones remain unopened on the older branches and on the stem of the tree. On the high mountains opposite Vancouver I saw this tree growing in the forest in small glades on rocky poor soil, at 500 to 750 ft. altitude, not far from the sea; and it did not exceed 20 ft. in height, producing small ovoid cones, $\frac{3}{4}$ in. in diameter, most of which opened as soon as ripe.

On the seashore close to Crescent city in northern California, this species occurs on the ocean bluffs and on the barren gravelly flat to about a mile inland, and is very variable in size, in exposed situations dwindling to a picturesque shrub, but where sheltered attaining a considerable size, one tree which I measured being 65 ft. high and 7 ft. in girth. This tree had dark grey thin unfurrowed bark, covered with small scales, and resembling exactly that of var. *Murrayana*. A slightly smaller tree, beside it, which I took in the same photograph, had the thick coarsely fissured bark of typical *P. contorta*. Most of the cones were persistent.

2. LODGE-POLE PINE.

Var. *Murrayana*, Engelmann, in Brewer and Watson, *Bot. California*, ii. 126

¹ The seedling is described by Hill and de Fraine, in *Ann. Bot.* xx. 472 (1906) and xxiii. 203 (1909).

² Gorman, in *Pittonia*, iii. 69 (1896), says it is confined to lake borders and margins of sphagnum marshes in Alaska, where it is comparatively rare and little used, except for fuel. The inner bark is eaten by the natives. He adds that he saw one specimen on Square Island 100 ft. in height and 18 in. in diameter.

³ Jepson, in *Flora W. Mid. California*, 23 (1901), says it is frequent on the Mendocino coast, northward of Pt. Arena, as a low tree, 5 to 20 ft. in height.

⁴ Cf. Butters, in *Postelsia*, 157, plate xii. (1906), where a picture is given of this tree growing in a sphagnum swamp.

(1880); Sargent, *Silva N. Amer.* xi. 90, t. 568 (1897), and *Trees N. Amer.* 27 (1905); Kent, Veitch's *Man. Coniferæ*, 324 (1900).

Pinus Tamrac, A. Murray, in *Gard. Chron.*, 1869, p. 191.

Pinus tenuis, Lemmon, in *Erythea*, vi. 77 (1898).

A tall tree, varying from 70 to 200 ft. in height; bark rarely more than $\frac{1}{4}$ in. thick, covered with small loosely appressed scales. Leaves $1\frac{1}{2}$ to 3 in. long, $\frac{1}{16}$ to $\frac{1}{8}$ in. broad, yellowish green. Cones very variable: in specimens which I gathered in the Siskiyou mountains, Oregon, from small trees occupying burnt areas, an inch in length, very oblique, deflexed, and remaining closed for an indefinite period; in specimens collected in Montana, slightly larger, but many opening when ripe; in the Sierra Nevada, usually larger, up to 2 in. in length, and apparently always opening when ripe, and falling from the tree in the following season. Probably three distinct forms of this variety can be distinguished:—

1. Rocky Mountain form, occurring from Alaska to Montana. A slender tree, rarely over a foot in diameter, and 100 ft. in height in its best development. Cones late in opening. The form in Colorado, distinguished as *P. Murrayana*, var. *Sargentii*, Mayr, in *Waldungen Nord-Amer.* 350 (1890), seems to be similar to the tree in Montana, and like it has long leaves (3 in. in length).

2. Sierra Nevada form. A large stout tree, attaining 150 ft. in height and 9 ft. in girth. Cones usually opening when ripe.

3. Intermediate forms between var. *Murrayana* and typical *P. contorta* occur as small trees, 40 ft. or less in height, in the Cascades and the Siskiyou mountains; and have slender foliage and closed cones.

The lodge-pole pine has an exceedingly wide distribution in western North America, extending from the hills in the valley of the Yukon river, Alaska, through the interior plateau of British Columbia, where it occurs at 2000 to 4000 ft. It crosses the Rocky Mountains in the valley of the Peace river, lat. 56° , its eastern boundary in Alberta being the meridian of 114° longitude, west of Edmonton and Calgary. A small isolated forest² of this pine occurs at 3000 ft. altitude, south-east of Medicine Hat, in the Cypress Hills, which take their name from this tree, as both it and *P. Banksiana* were called *cyprès* by the early French voyageurs.

In the United States, it forms extensive forests on both sides of the Rocky

¹ The type specimen of *P. Murrayana* is preserved in the herbarium of the Royal Botanic Garden at Edinburgh, and is labelled in Jeffrey's handwriting as follows:—"Pinus sp. No. 740. Found in the Siskiyou mountains in lat. $43^{\circ} 30'$, elevation 7500 ft., growing on moist, deep, loamy soil, Oct. 21st. This, all the cones I could procure. Tree 40 ft. high, of a conical form." Lat. $43^{\circ} 30'$, far to the northward of the Siskiyou mountains, is evidently a mistake for lat. $41^{\circ} 30'$, as we know from Jeffrey's type specimen of *P. Jeffreyi*, which was collected three days later (Oct. 24, 1852) in lat. $41^{\circ} 30'$ in the Shasta valley. Another specimen at Edinburgh, of which there is a duplicate at Kew, is labelled:—"740. Pinus sp. Same as No. 740 of 1852 collection. Summit of Sierra Nevada mountains near Walker's Pass, Sept. 20, 1853." This specimen did not reach Edinburgh until after the publication of the species by Balfour.

² Macoun, in *Proc. Roy. Soc. Canada*, xii. 4, pp. 13, 15 (1894).

Mountains in Montana; and extends southward, in the Yellowstone Park, at 7000 to 8000 ft., through the mountains of Wyoming and Colorado, to New Mexico and Arizona. Westwards it is common on the ranges of eastern Washington, Idaho, and Oregon, extending through the Siskiyou mountains into California, where it attains its largest size in alpine forests on the Sierra Nevada, at 8000 to 9500 ft.; and in the southern part of the state, forms the timber line on the highest peaks of the San Bernardino and San Jacinto mountains. It is also found¹ on the San Pedro Martir mountain in Lower California.

In Montana, where I saw it in the Lewis and Clark Reserve, it is essentially the tree which occupies burnt areas, its seedlings appearing in profusion in the mixed Douglas and larch forests, when these are destroyed by fire. In consequence, it is usually seen in dense even stands of tall slender trees, which attain about 100 ft. in height and a foot in diameter at 150 years old. Klers Koch,² forester in the Gallatin Reserve, reports on its facility of reproduction, as it bears cones early in life, even at 10 to 15 years old when crowded, and says that fire after fire may sweep over a district, and after each fire a new growth of pine springs up, denser than the preceding one. In a sample plot 10 ft. square, taken in a burnt area, 95 pine seedlings had sprung up. In 1885, a fire completely swept the whole length, 20 miles, of the Gallatin cañon, and there is at present a dense growth of young pines covering the mountain sides. He says that the root system is superficial, and the tree is easily blown down by the wind, as I witnessed myself near Flathead lake, when the tall slender trees came down in a sudden storm like ninepins. The tree appears to grow on most soils, though Koch has noticed that it avoids limestone, and it occurs at a great range of altitude, being met with, according to Leiberg,² in the Bitter-root Reserve in Idaho, at 2000 to 9000 ft. In Gallatin county, above 7000 ft. it mixes with spruce and *Abies lasiocarpa*, being replaced at 8500 ft. by *P. albicaulis*.

In Idaho, though it usually occurs as dense stands on fire-swept areas, it also grows in considerable quantity in swampy tracts, north-east of Grace Peak, and attains a much greater size, up to 200 ft. in height, with trunks 16 in. in diameter, and clear of branches to 140 ft. and showing 275 years' growth. Low branching trees, resembling *P. contorta* in habit, are met with in northern Idaho at elevations below 3000 ft. The tree demands light in order to grow well, but bears a considerable amount of shade, though in that case making little growth, a tree 43 years old that had been suppressed, measuring only $6\frac{1}{2}$ ft. high and $1\frac{1}{2}$ in. in diameter. In Colorado, it appears to be a smaller tree than farther north, averaging 75 ft. in height and 8 to 14 in. in diameter.

Mr. F. R. S. Balfour has kindly supplied us with the following account of the fine form of var. *Murrayana*, which grows in the Sierra Nevada of California:—

"On the main ridge between the valleys of the Kaweah and King's rivers, there are large quantities of fine tall trees 100 to 125 ft. high, and earning for *contorta* the more dignified name of *Murrayana*. I camped for two nights in a grove of these trees where there were many 12 ft. in circumference and over 100 ft.

¹ Shaw, *Pines of Mexico*, 29 (1909).

² From notes supplied by the U.S. Forestry Department, Washington.

high. The whole character of the tree differs utterly from the little lodge-pole pine usually growing elsewhere. These had bark of a warm pinky brown in small flat flakes pressing closely to the stem. They were for the most part over 200 years old, and indeed I counted over 300 rings in one tree not 2 ft. in diameter. The altitude was about 8500 to 9500 ft., and therefore covered with deep snow for about eight months in the year. Many dead trees stood among the living ones, white and bleached, but showing uniformly that the fibre of the timber grows with a twist. This twist in the wood saves it from the lumbermen. In their opinion it would be a first-rate timber of great hardness and lasting quality, were it not for this peculiarity. The older trees have fine open crowns with perfectly straight stems, and no large branches. Where the bark has been bruised off from any cause, the sap-wood shows bright saffron yellow till healed over. I never saw this variety of *Pinus contorta* lower down than 8500 ft., and it grew immediately above the *Abies magnifica* belt."

HISTORY AND CULTIVATION

P. contorta was discovered in 1825 by Douglas, near Cape Disappointment in Washington, at the mouth of the Columbia river; but it does not appear to have been introduced until 1855, when it appeared in Lawson's Catalogue under the name *P. Macintoshiana*.¹

Var. *Murrayana* was discovered in 1852 by Jeffrey, who sent specimens and seed, which reached Edinburgh in the following year. A further supply, which he collected on 20th September 1853, on the summit of the Sierra Nevada in California, near Walker's Pass, arrived in 1854.

The characters, which separate *P. contorta* and its variety *Murrayana* in the wild state, are not entirely preserved under cultivation. Trees labelled *P. contorta* in Kew Gardens, show vigorous branchlets with broad leaves; and owing to the occurrence of spring shoots, the cones are often pseudo-lateral in position. These trees have furrowed bark, as in their native home, and are widely branched, with peculiarly curved branchlets.² Trees of var. *Murrayana* in cultivation show a narrow pyramidal habit, with fine scaly bark; but their leaves are scarcely as broad as in wild specimens. Coming from the interior of the continent, they are not so vigorous in growth as the typical form from the Pacific coast. At the nursery of the Arboretum at Tervueren in Belgium, there are batches of seedlings of both forms, those of typical *contorta* having vigorous shoots with short needles, those of var. *Murrayana* with shorter shoots and longer bright green needles.

(A. H.)

The finest specimens of var. *Murrayana* which we have seen, are growing in the pinetum at Westonbirt, where there are two trees narrowly pyramidal in habit

¹ Cf. Masters, in *Journ. Linn. Soc. (Bot.)* xxxv. 647 (1904). Fowler, in *Gard. Chron.*, 1872, p. 1070, states that it was often grown then under this name; but he is in error in stating that *P. contorta* was introduced by Douglas, as there is no record of this in Loudon, who first described the species.

² This is well shown in *Gard. Chron.* xix. 45, fig. 5 (1883), where a branch of typical *contorta* from Barron's nursery at Borrowash is figured. Engelmann, in *Gard. Chron.* xix. 351, erroneously supposes, on account of the broad needles, that the figure represents var. *Murrayana*.

and with scaly bark, 59 ft. by 4 ft. 7 in., and 50 ft. by 3 ft. 3 in. Both were bearing cones in 1909. In addition, there are about twenty trees, smaller in size, about 30 ft. high and twenty-five years old. At Westonbirt this species becomes yellow in foliage, and does not thrive on limestone. It is said to be a bad rooter, and easily blown down by the wind. At Merton Hall, Norfolk, there is a tree 47 ft. by 4 ft. 5 in. (Plate 292).

At Bayfordbury, a tree with a straight stem and scaly bark, measured in 1905, 49 ft. high by 4 ft. 9 in. in girth. There are two specimens at Pampisford, Cambridge, drawn up in a wood, which measure about 40 ft. in height and 2 ft. in girth. At Highclere, where there are six trees, one growing in a plantation measures 50 ft. by 3 ft. 5 in., and one in the open is 40 ft. by 5 ft. There are also smaller trees at Nuneham Park, Oxford, and at Ochertyre, Perthshire. The best we know in Scotland is at Castle Menzies, which I found in 1908 to be 51 ft. by 5 ft. 10 in. A tree of typical *contorta*, planted in 1886 at Grayswood, Haslemere, as *P. Bolanderi*, measured, in 1906, 28 ft. by 3 ft. 1 in.

Mayr considers var. *Murrayana* to be close to *P. Banksiana*, both from a botanical and a biological point of view, and recommends it for planting in cold situations on high-lying moors. When planted closely, it cleans its stem readily, and at Grafrath, near Munich, where it has been planted in a cold peaty soil, it has endured a minimum temperature of -22° Fahr. But at Nürnberg, where 65,000 young trees were planted in a moist situation, they are reported to be tender to frost. At Grafrath this species grows even faster than *P. Banksiana*.

The lodge-pole pine, introduced¹ from Colorado into the Arnold Aboretum about 1877, has proved hardy in New England and produced cones; but it suffers from fungi and gives no promise of permanent success.

TIMBER²

The wood of the lodge-pole pine is coarse in grain, full of knots; and warps and cracks badly. It is soft, white, light, and not very strong, with little sapwood. It has been little used hitherto, except for mining purposes, the Amalgamated Copper Company having purchased, for example, fifty million feet (board measure) in 1906 from the Hellgate Reserve in Montana. It is coming into use, however, of late, for railway sleepers, for which it is suitable when creosoted, and the Burlington and Missouri Railway Company has begun to make extensive experiments in the preservation of this timber. It is in considerable use for fencing, but cannot be used for posts or telegraph poles, as it rots quickly when placed in contact with the ground.

(H. J. E.)

¹ Sargent in *Garden and Forest*, x. 471 (1897).

² Notes taken by forest officers, in the U.S. Bureau of Forestry, Washington, are here summarised.

PINUS RESINOSA, RED PINE

Pinus resinosa, Solander, in Aiton, *Hort. Kew.* iii. 367 (1789); Loudon, *Arb. et Frut. Brit.* iv. 2210 (1838); Sargent, *Silva N. Amer.* xi. 67, tt. 555, 556 (1897), and *Trees N. Amer.* 25 (1905); Kent, *Veitch's Man. Coniferae*, 372 (1900); Masters, in *Journ. Linn. Soc. (Bot.)* xxxv. 614 (1904); Mayr, *Waldungen Nord-Amer.* 211-214 (1890), and *Fremdländ. Wald- u. Parkbäume*, 346 (1906); Clinton-Baker, *Illust. Conif.* i. 48 (1909).

Pinus sylvestris, Linnæus, var. *norvegica*, Castiglioni, *Viag. Negli Stati Uniti*, ii. 313 (1790).

Pinus rubra, Michaux f., *Hist. Arb. Amer.* i. 45, t. 1 (1810) (not Miller).

A tree, usually attaining in America a height of 70 to 90 ft., and a girth of 6 to 9 ft.; occasionally, under most favourable conditions, reaching 150 ft. high and 15 ft. in girth. Bark about an inch thick, divided by shallow fissures into broad flat scaly ridges. Young branchlets orange-brown, glabrous, with raised rounded imbricated pulvini, which persist as rough protuberances on the older branchlets, from which the leaves have fallen. Buds elongated, conical, pale-brown, $\frac{1}{2}$ to $\frac{3}{4}$ in. long, coated partly with white resin, with a few of the appressed scales free at their acuminate tips.

Leaves in pairs, deciduous in the fourth year, densely crowded on the branchlets, forming cup-like tufts at their apices, more or less spreading below, 5 to 6 in. long, dark green, shining, soft and flexible, sharp-pointed, serrulate, obscurely stomatic on the inner and outer surfaces; resin-canals marginal; basal sheath $\frac{7}{8}$ in. long.

Cones¹ sub-terminal, solitary or in pairs, sub-sessile, spreading, ovoid-conic, about 2 in. long, light brown, shining; scales $\frac{7}{8}$ in. long, $\frac{1}{2}$ in. wide; apophysis thickened, rhomboidal, with a transverse ridge, and a central depression, in which lies the rounded shining dark brown unarmed umbo. Seed ovoid, compressed, mottled brown, about $\frac{1}{5}$ in. long; wing pale brown, $\frac{3}{4}$ in. long; cotyledons six or seven.

This species is only liable to be confused with *P. Laricio*, which it resembles in the branchlets and general appearance of the foliage; but is readily distinguished by the long basal sheaths of the leaves, the resin-canals of the latter being marginal and not median as in *P. Laricio*.

DISTRIBUTION

The red pine is the representative of *P. sylvestris* in Canada, and the northern border of the United States, where it is often called "Norway Pine," its northern limit extending from Lake St. John in Quebec, lat. 48°, westwards through central Ottawa to the southern end of Lake Winnipeg. In Quebec it forms thick groves on sandy and gravelly hills, and the forests still uncut contain an immense quantity of lumber of this species.² On dry ridges near Toronto, Elwes saw trees over 90 ft. high, with clean stems to 50 or 60 ft.

¹ The cones in falling, as I have observed in Minnesota and on cultivated trees at Bayfordbury, leave some of the basal scales and the short stalk on the branchlet.

² J. C. Langelier, in *Canadian Forestry Association, Sixth Ann. Report*, 69 (1905), estimates the timber of this pine still standing in Quebec, at 7500 million feet board measure.

The tree extends southwards through Nova Scotia, New Brunswick, Maine,¹ New Hampshire, and Vermont, becoming very rare and local in Massachusetts, and reaching its most southern limit in the mountains of Chester County, Pennsylvania. In New Hampshire² it occurs mainly in the low sandy country in the Saco river basin, where it either grows pure or in mixture with *P. Strobus*. In the Pisgah forest, near Hinsdale, in this state, I saw in 1906 a few trees growing on rocky ridges, one of which measured 94 ft. by $7\frac{1}{2}$ ft.

It extends westwards, through north-eastern Ohio, north of Cleveland; and in central Michigan, northern Wisconsin, and north-eastern Minnesota, attains its greatest abundance and largest size. In northern Wisconsin,³ it grows mixed with *P. Strobus* on loamy sands; and either pure or mixed with *P. Banksiana*, occupies the poorer lands, which are known as pine barrens. It is occasionally met with on clay soils on the slopes along Lake Superior. It grows rapidly when young, about as fast as *P. Strobus* up to the age of 100 years; but afterwards increases very slowly in diameter. In the Cass Lake Forest Reserve in Minnesota, it occurs in similar situations, and is the timber chiefly valued for beams, that of *P. Strobus* being almost entirely used for indoor finish. *P. resinosa*, in pure stands in this state, has very straight stems, free of branches to a great height. Tables that I obtained in Washington show that in Itasca County, Minnesota, and in Bayfield County, Wisconsin, trees occur 120 ft. in height and 30 in. in diameter; and at 200 years old, they average 26 in. in diameter.

This species is very intolerant of shade at all ages; and in America,⁴ where it is occasionally planted, is either used pure, or in mixture with *P. Strobus*. Measurements made of plantations near Lake Winnepesaukee in New Hampshire, show that at twenty-seven years old the red pine averages 35 ft. high, and is taller than white pine of the same age.

(A. H.)

Bailey and Jack in a paper "In the Woods of New Brunswick,"⁵ say of this pine that lumbermen recognise two varieties, which they call "Sapling" and "Old Red Pine." The former has an inferior timber, which, however, was largely used in Maine for hogshead heading. The latter, nearly extinct in 1887, sometimes attained a height of 90 ft., and a diameter of 3 ft., clean to 40 or 50 ft. up. The wood is strong and durable, resembling that of pitch pine, but with less resin, and was formerly largely employed for the decking of vessels and for beams, having a fine compact grain with few knots. It grew best on dry and sandy soil, in the granite boulder country fifty miles north of St. Andrews, and also on the Tobique river, where in some places the trees were so thick that there was hardly room to turn a sled between the stumps.

In *Canadian Forestry Journal*, 1905, p. 172, two illustrations are given of a remarkable instance of a tree of this species, from which a ring of bark 1 ft. wide was removed all round the tree nine years previously. The tree was still alive,

¹ It is common in Maine, generally on dry ridges, but in Greenbush and Passadumkeag grows abundantly on peat bog with black spruce. Dame and Brooks, *Trees of New England*, 10 (1902).

² Chittenden, *Forest Conditions of New Hampshire*, U.S. Forestry Bulletin No. 55, p. 54 (1905).

³ Roth, in *Wisconsin Geol. Survey Bull.* No. 1, *Forestry Conditions of Northern Wisconsin*, 20, 67 (1898).

⁴ U.S. Forest Service Circ. 60 (1907).

⁵ *Trans. Scot. Arb. Soc.* xi. 11 (1887).

and had made an increase in girth of 6 in. above the place where it was girdled. Mr. A. Knechtel, at that time forester to the New York Forest, Fish, and Game Commission, found this tree close to the road from Paul Smith's to M'Colloms' in the Adirondack mountains, and gave the dimensions as follows:—Height, 30 ft.; diameter of girdled part, 5 ft. 3 in.; ditto, just below the girdle, 6 ft. 4 in.; ditto, just above, 8 ft. 3 in. Mr. Knechtel writes me on May 10, 1909, that the tree was still alive when he last saw it in October 1908, and explains the fact as follows:—"The plant food ascends the tree through its interior; the elaborated material descends between wood and bark. Since there is no bark at the girdle, it does not cross it. Hence the tree grows above the girdle and not below it."

CULTIVATION

It was introduced¹ by Hugh, Duke of Northumberland, as long ago as 1756; but it seems unable to live long or to attain timber size in any part of this country. Lambert says that in 1804 he found it in a flourishing state at Pains Hill, at Caen Wood (in a small island), and at Syon, where the first trees were planted, yet from their size he concluded that it would not produce valuable timber. At White Knights a number of trees were planted by the Marquess of Blandford about the end of the eighteenth century, raised by Loddiges from seeds received from America, and some of them existed in Loudon's time. But at these places none are now living; and the only trees we have seen are two specimens at Bayfordbury, planted in 1851, one of which is 54 ft. high and 5 ft. 3 in. in girth, and the other 50 ft. by 3 ft. 10 in.; two trees at Dropmore, 68 ft. by 4 ft. 5 in., and 62 ft. by 4 ft. 3 in. in 1909; and one or two small trees at Kew. In my nursery at Colesborne small imported trees closely resemble the Austrian pine, but are far less vigorous in growth, and have been gradually dying ever since I had them.

TIMBER

The timber of this tree was at one time imported to a considerable extent, and according to Laslett was then known as red pine, and when straight and clean enough for masts was considered superior to the Riga and Dantzic pines for that purpose.

Macoun says that it is neither so tall nor so large as the white pine (*P. Strobus*), and that though the wood is much harder, stronger, more elastic and resinous, is often not separated in commerce from the wood² of that species. It is valuable for piles, masts, and spars, and though formerly worth more than white pine, is not nearly so abundant in Canada.

Mr. Weale writes as follows:—"Canadian red pine (*Pinus resinosa*) is produced in Canada generally, but not largely imported into this country owing to the competition of the Baltic *Pinus sylvestris*. It is harder and not so easily worked as yellow pine (*Pinus Strobus*), and not so hard as pitch pine (*Pinus palustris*). For

¹ Aiton, *Hort. Kew.* iii. 367 (1789).

² Dr. H. T. Bovey, in *Trans. Roy. Soc. Canada*, xii. 3, p. 11 (1894), gives the results of tests on the comparative strength of red pine, white pine, and Douglas fir.

work that needs much application of the tool the yellow pine is therefore preferred. On the other hand, where long lengths, hardness, and durability are required, consumers employ the pitch pine. The Canadian red pine in consequence does not find the ready market in Great Britain it deserves."

Mayr gives a comparison between the wood of a tree of this species felled in Dakota and a tree of *P. sylvestris* felled in Bavaria; the latter had heavier wood with less sapwood, but contained a less percentage of resin. (H. J. E.)

PINUS THUNBERGII, JAPANESE BLACK PINE

Pinus Thunbergii, Parlatore, in DC., *Prod.* xvi. 2, p. 388 (1868); Masters, in *Journ. Linn. Soc. (Bot.)* xviii. 504 (1881), xxvi. 552 (1902), and xxxv. 629 (1904), and in *Gard. Chron.* xxiii. 344, fig. 63 (1885); Mayr, *Abiet. jap. Reiches*, 69, t. v. f. 16, and t. vii. f. 1 (1890), and *Fremdländ. Wald- u. Parkbäume*, 350 (1906); Shirasawa, *Icon. Forest. Japon.* text 11, t. i. ff. 15-29 (1899); Kent, Veitch's *Man. Coniferae*, 383 (1900); Clinton-Baker, *Illust. Conif.* i. 55 (1909).
Pinus Massoniana, Siebold et Zuccarini, *Fl. Jap.* ii. 24, t. 113 (1844) (not Lambert).

A tree, attaining in Japan 130 ft. in height and 20 ft. in girth. Bark greyish brown, deeply fissured. Young branchlets glabrous, brown, with slightly raised pulvini, bearing at their apices long lanceolate-acuminate fimbriated scale-leaves, persisting during the first year, and leaving, when they fall, transverse projecting ridges, roughening the older branchlets. Buds ovoid, cuspidate, $\frac{1}{2}$ to $\frac{3}{4}$ in. long, greyish white; scales appressed and matted together by their fimbriated edges, and ending in long subulate points.

Leaves in pairs, persistent for three years, densely crowded on the branchlets, more or less spreading, 3 to 4 in. long, rigid, twisted half a turn, so that the apices of the two leaves in each cluster face each other by their outer surfaces, serrulate, ending in a spine-like cartilaginous point, marked with numerous stomatic lines on both surfaces; resin-canals median; basal sheath $\frac{1}{2}$ in. long, ending above in two long filaments.

Cones sub-terminal, spreading, clustered, on short stalks, ovoid-conic, about $2\frac{1}{2}$ in. long; scales oblong-cuneate, thin, concave laterally, with the concealed part dark reddish brown on the outer and pale brown on the inner surface; apophysis thickened, rhomboidal, shining brown, upper edge irregular, depressed in the centre, with numerous radial lines, transverse ridge slightly marked, umbo reddish brown or white with resin, armed with a minute, often rudimentary prickle. Seed greyish or brown, mottled with black, $\frac{1}{5}$ to $\frac{1}{4}$ in. long; wing narrow, pale brown, about $\frac{3}{4}$ in. long.

This species, which is the representative of *P. Laricio* in Japan, is readily distinguished by its remarkable white buds and rigid needles. The long filaments of the basal sheaths are peculiar to this species and *P. densiflora*.

Mayr describes ten varieties which are cultivated in Japanese gardens. In var. *monophylla* the two leaves in the cluster coalesce. Forms of peculiar habit are known, globose or pendulous, or with twisted stems. Var. *aurea*, in which the

leaves assume a golden yellow colour during winter, and var. *variegata*, in which the leaves are marked with one or two transverse yellow bands about the middle, were introduced¹ into Kew Gardens in 1897.

According to Mayr, this species forms hybrids with *P. densiflora*.

(A. H.)

DISTRIBUTION

This species is restricted to Japan,² where, according to Shirasawa and Mayr, it is only known in the wild state on the eastern sea-coast, from Kiusiu and Shikoku to the northern part of Hondo. On account of the dark grey bark, uniform in colour to the top of the tree, it is usually called *kuro-matsu* or black pine by the Japanese. Commonly forming a stout trunk, with irregular wide-spreading strong branches, it is also termed *o-matsu*, or male pine, in contradistinction to *P. densiflora*, which, from its more slender stem and more graceful appearance, is named female pine. Varied and picturesque in appearance, the black pine is frequently depicted by Japanese artists.

It is one of the trees which has been planted from a very early period in gardens and about temples. The most celebrated tree of the species grows on the shore of Lake Biwa at Karasaki, which is easily reached in two hours from Kioto, and is well worth a visit. It is certainly a remarkable tree, though nothing like so large as stated in Murray's *Handbook to Japan* (1903).³ The correct measurement, as taken by myself, is as follows:—Girth at ground, 20 ft.; at 5 ft., where a very large limb is already thrown off, 29 ft. The largest limbs are about 12 ft. each in girth, and the main trunk above them about 20 ft. high. The highest branch that I could find on the tree is not over 50 ft. from the ground, but the spread is astonishing. As nearly as I could follow the extremities of the branches, they cover an area 180 paces round, and though the tree is decayed in places and is said to be a thousand years old, it is full of foliage and had many cones which bear fertile seeds.

Another famous tree at the Naniwaga tea-house in Osaka, seen by Siebold, had the branches artificially extended, and formed a circuit of 135 paces.

This pine is also largely planted for timber in Japan, and is of great service near the sea-coast for fixing the dunes and for shelter belts. It will grow in the poorest soil, but then remains dwarf and of no value unless planted wide apart. On good

¹ *Gard. Chron.* xxi. 250 (1897). These varieties cannot now be found.

² A pine, widely spread in the mountains of northern Korea, and of the Manchurian provinces, S. Ussuri, Kirin, and Mukden, has long been confused with *P. Thunbergii*, and has only lately been accurately described as a distinct species—*Pinus funebris*, Komarov, *Flora Manshurica*, i. 177 (1901). The leaves of this species differ in having marginal resin-canals; and the buds are reddish, ovoid, short-pointed, with appressed scales. The cones, similar in size to those of *P. Thunbergii*, differ in the greyish apophyses of the scales, each of which has an elevated umbo, ending in an inflexed short point. The seeds are shining dark brown, with short broad wings. This pine resembles in stature *P. sylvestris*, but has ashy grey coloured bark. It is often planted in Korea and Manchuria, and in the vicinity of Peking, around temples and tombs; but has not yet been introduced into this country. It is erroneously referred to *P. Thunbergii* by Masters in *Journ. Linn. Soc. (Bot.)* xxvi. 553 (1902).

The specimens from Yunnan and eastern Szechwan referred to *P. Thunbergii* by Franchet, in *Journ. de Bot.* xiii. 253 (1899), are certainly not this species.—(A. H.)

³ A photograph of this remarkable specimen, sent by Sir Thomas Hanbury, who considered it to be *P. densiflora*, is reproduced in *Gard. Chron.* xv. 366, fig. 44 (1894). Another remarkable pine, either *P. Thunbergii* or *P. densiflora*, is figured in *Gard. Chron.* xv. 140, fig. 15 (1894). This stands in the Kinkakuji monastery in Kioto, and is trained to represent a junk with a mast and sail. Cf. Kent, Veitch's *Man. Conifera*, 385, fig. (1900).

soils it attains enormous dimensions, Mayr recording a tree 140 ft. in height and 11 ft. in girth. The timber is difficult to work, and inferior in quality to that of *P. densiflora*, but is superior for firewood and yields resin.

CULTIVATION

P. Thunbergii was introduced into Holland by Siebold in 1855, and into England by J. Gould Veitch in 1861. It is often seen in private collections and botanic gardens, as at Kew, Glasnevin, and Bayfordbury; but nowhere has attained considerable dimensions, the finest specimen being one at Dropmore, planted in 1861, which was 52 ft. high by 6 ft. in girth in 1909. There are two trees at Eastnor Castle, the larger of which is 48 ft. by 5 ft., and the smaller 42 ft. by 3 ft. 5 in. Another at Grayswood, near Haslemere, planted in 1881, is a wide-spreading tree, 39 ft. in height and 4 ft. 3 in. girth in 1906. It gives little promise of being a useful tree for planters, though it might be tried near the sea-coast. Lord de Saumarez wrote in 1897 to Kew that he had found this species invaluable for planting in Guernsey on the most exposed points close to the sea, where all other pines, including *P. Pinaster*, had failed. In 1909, trees planted twenty years had attained 25 ft. in height. At Grafrath, near Munich, it is slow in growth and much injured by snow, a tree twenty-five years old being only 13 ft. high. In New England it is perfectly hardy.

(H. J. E.)

CUPRESSUS

- Cupressus*,¹ Linnæus, *Gen. Pl.* 294 (1737); Stark, in *Trans. Roy. Soc. Edin.* xxvii. 651 (1876);
Bentham et Hooker, *Gen. Pl.* iii. 427 (1880); Masters, in *Journ. Linn. Soc. (Bot.)* xxx. 18
(1893), and xxxi. 312-363 (1896).
Chamaecyparis, Spach, *Hist. Vég.* xi. 329 (1842).
Retinispora,² Siebold et Zuccarini, *Fl. Jap.* ii. 36 (1844).
Thuya, section *Chamaecyparis*, Bentham et Hooker, *Gen. Pl.* iii. 427 (1880).

EVERGREEN trees, or rarely shrubs, belonging to the division Cupressineæ of the order Coniferae. Bark³ usually divided into ridges, and separating on the surface into loose or appressed scales. Branches, ascending or spreading, much ramified, and terminating in so-called "branchlet systems" or "herbaceous shoots," which are green in colour, two- or three-pinnately divided, and covered with scale-like leaves; most of the branchlet systems⁴ are deciduous in the third or fourth year, a few developing by their main axes into permanent branches. Ultimate branchlets slender, quadrangular or flattened. Leaves on adult trees, minute, more or less coalesced with the axes, ovate, with spreading or appressed tips, in four rows, in opposite decussate pairs, around the branchlets; either (a) all uniform in size and shape, or (b) of two kinds, a flattened pair on the front and back of the branchlet, and a lateral conduplicate pair. On vigorous leading shoots and on seedling plants the leaves are needle-shaped or linear-lanceolate, spreading, and uniform in four ranks. In certain horticultural varieties, formerly considered to be species of a distinct genus, *Retinispora*, the foliage either resembles that of seedling plants or is intermediate in character between the primordial and the adult foliage.

Flowers monœcious, terminal, solitary, the two sexes on separate branches. Staminate flowers cylindrical, composed of numerous decussate stamens, with short filaments, enlarged into ovate connectives bearing two to six pendulous globose anther-cells. Pistillate flowers, composed of decussate peltate scales, in which no distinction between the "ovuliferous scale" and the "cover-scale" or "bract" is apparent, continuous in series with the leaves at the end of the branchlet, and

¹ We are indebted to Mr. Cecil Hanbury for a fine set of specimens, sent by Mr. Berger from La Mortola on the Italian Riviera, and to Mr. Flahault for a set of all the species cultivated at Montpellier.

² This name was first applied to the Japanese species, which have conspicuous resin-vesicles on their seeds. (*C. Lawsoniana*, discovered afterwards, has the same character.) It is derived from *ρητινῆ*, resin, and *σπορά*, seed. Subsequently it was wrongly spelled *Retinispora*, and was made to comprise the juvenile forms of *Cupressus* and *Thuya*.

³ The bark of *C. Lawsoniana*, q.v., differs remarkably on old trees from that of all the other species.

⁴ A "branchlet system" arises from a bud, and forms in the first year an axis and secondary lateral branchlets; in the second year tertiary branchlets are developed. The branchlet system usually falls off in October of the third year, but in certain species the fall is in the second or in the fourth year; in the latter case the tertiary branchlets develop another set of branchlets.

bearing either (a) in one row, two to five, or (b) in several rows, numerous erect urceolate ovules. Fruit, a globose cone, composed of four to fourteen woody peltate scales, abruptly dilated at the apex, and bearing in the centre of the outer surface a mucro, boss, or knob. Seeds erect on the base of the scale, acutely angled, compressed or rounded, with two thin lateral wings.

The genus consists of about fifteen species,¹ widely distributed throughout the warm temperate region of the northern hemisphere; and is divided into two sections, which are by many authors considered to be two distinct genera. The only constant difference between the sections appears to lie in the margin of the leaves. The different periods of ripening of the cones, the number of seeds on each scale, and the flattened or tetragonal branchlets, are too variable to form any real base of distinction. Penhallow² points out that while the microscopic structure of the wood of *Cupressus* and *Thuya* is distinct, there is no difference in the wood of *Cupressus* and *Chamaecyparis*; and considers that the latter must disappear as a genus.

About fourteen species are in cultivation, which are distinguishable as follows:—

I. EU-CUPRESSUS.

Leaves, fringed with a narrow thin translucent serrated border,³ either uniform in four ranks, or dimorphic with conduplicate lateral pairs and flattened facial pairs. Branchlet systems either flattened with their pinnæ in one plane, or arising at varying angles with their pinnæ in several planes. Cones large,⁴ usually $\frac{1}{2}$ in. or more in diameter, ripening in the second year. Seeds,⁴ usually six to twenty on each scale, in several rows. Cotyledons two to five.

A. Branchlet-systems flattened with the pinnæ in one plane.

* Leaves appressed.

1. *Cupressus torulosa*, Don. Western Himalayas. See p. 1158.

Branchlets equal-sided. Leaves obtuse, uniform in four ranks. Cones, $\frac{1}{2}$ in., globose or ellipsoid, on short usually curved stalks; scales eight or ten, external surface depressed, with a minute process. Seeds six to eight on each scale.

2. *Cupressus funebris*, Endlicher. China. See p. 1162.

Branchlets compressed. Leaves dimorphic, non-glandular, with a mucronate scarcely spreading apex. Cones,⁴ $\frac{1}{3}$ in., globose, on long slender stalks; scales eight, external surface not depressed, with a minute process. Seeds three to five on each scale.

- 2A. *Cupressus lusitanica*, Miller, var. *Benthami*, Carrière. Mexico. See p. 1177.

Branchlets compressed. Leaves dimorphic, usually with a depressed circular gland, apices mucronate and spreading. Cones and seeds as in *C. lusitanica*.

¹ *Dacrydium Franklinoi*, Hooker, the Huon pine, a native of Tasmania, which is occasionally cultivated in the west of Scotland and in Cornwall, is frequently mistaken for a cypress. On close examination the leaves, which are dotted over with white stomata, will be seen to be spirally arranged, and not in opposite decussate pairs, as in *Cupressus*.

² In *Trans. Roy. Soc. Canada*, ii. § 4, p. 43 (1896).

³ This narrow serrated border can only be seen with a lens of considerable magnifying power.

⁴ *C. funebris* is exceptional in its small cones with few seeds on each scale, and is a link between the two sections.

** *Leaves spreading.*

3. *Cupressus cashmeriana*, Royle. Himalayas. See p. 1161.

Branchlets compressed. Leaves glaucous-blue, widely spreading above their decurrent base, subulate, with a mucronate apex. Cones, $\frac{1}{2}$ in., ellipsoidal; scales ten, outer surface depressed, with a minute reflexed process. Seeds ten on each scale.

- B. *Branchlet-systems arising at varying angles, with their pinnæ not in one plane.*

* *Leaves with a conspicuous circular pit, exuding resin.*

4. *Cupressus Macnabiana*, Murray. California. See p. 1174.

Branchlets compressed. Leaves dimorphic, thick, obtuse. Cones globose, $\frac{1}{2}$ to $\frac{3}{4}$ in., reddish brown, often glaucous; scales six, with prominent processes, those on the upper scales thickened, conical, and incurved. Seeds ten to twelve on each scale.

5. *Cupressus arizonica*, Greene. Arizona, Northern Mexico. See p. 1183.

Branchlets equal-sided, glaucous in native specimens. Leaves uniform, acute or acuminate. Cones, $\frac{1}{2}$ to $\frac{3}{4}$ in., glaucous at least in the first year; scales six to eight, with the external surface not depressed, and a prominent process. Seeds eight to ten on each scale.

** *Leaves not conspicuously glandular.*

† *Branchlets equal-sided. Leaves uniform in four ranks, closely appressed.*

6. *Cupressus sempervirens*, Linnæus. Mediterranean region. See p. 1151.

Leaves $\frac{1}{2}$ in. long, obtuse. Cones sub-globose or ovoid, 1 to $1\frac{1}{4}$ in., pale brown or greyish; scales eight to fourteen, either with a central pit overhung by a minute process, or pyramidal ending in a mucronate process. Seeds twenty on each scale.

7. *Cupressus macrocarpa*, Hartweg. Monterey (California) and Guadalupe Island. See p. 1165.

Leaves $\frac{1}{8}$ in. long, obtuse, swollen towards the tip. Cones ellipsoid, 1 to $1\frac{1}{4}$ in. long, shining reddish brown; scales eight to fourteen, with a central depression overhung by a thin-edged ridge-like arcuate process. Seeds twenty on each scale.

8. *Cupressus Goveniana*, Gordon. California. See p. 1171.

Leaves $\frac{1}{2}$ to $\frac{1}{6}$ in. long, swollen near the apex, which is acute and often mucronate. Cones globose, $\frac{1}{2}$ to $\frac{3}{4}$ in., shining dark brown; scales six to ten, projecting in the centre, which bears a prominent process. Seeds ten to twelve on each scale.

‡ *Branchlets compressed. Leaves nearly uniform in four ranks, free at the tips.*

9. *Cupressus lusitanica*, Miller. Mexico, long cultivated in Portugal. See p. 1176.

Leaves $\frac{1}{6}$ in. long, acuminate, often mucronate. Cones remarkably glaucous, at least in the first year, globose, $\frac{1}{2}$ in., on straight stalks; scales eight, with a prominent process. Seeds eight to ten on each scale.

II. CHAMÆCYPARIS.

Leaves entire in margin; always dimorphic, lateral pair conduplicate, facial pair flattened. Branchlet systems usually flattened, with their pinnæ in one plane. Cones small, not more than $\frac{1}{3}$ in. in diameter, usually ripening¹ in one year. Seeds one to five on each scale, in one row. Cotyledons invariably two.

A. *Lateral leaves much larger than the dorsi-ventral leaves, longer than them on the main axes.*

10. *Cupressus obtusa*, Koch. Japan, Formosa. See p. 1185.

Leaves obtuse, non-glandular. Under surface of the foliage marked with x-shaped clearly-defined white markings. Cones $\frac{1}{3}$ in., orange-brown; scales eight or ten. Seeds one to five on each scale, with large conspicuous resin-vesicles.

11. *Cupressus Lawsoniana*, Murray. South-western Oregon, north-western California. See p. 1200.

Leaves acute, usually glandular. Under surface of the foliage green or with ill-defined white markings. Cones $\frac{1}{3}$ in., glaucous; scales eight. Seeds two to five on each scale, with large conspicuous resin-vesicles.

B. *Lateral leaves not much larger than the dorsi-ventral leaves, equal in length with them on the main axes.*

12. *Cupressus pisifera*, Koch. Japan. See p. 1190.

Leaves acuminate, with spreading often mucronate tips, obscurely glandular. Lower surface of the foliage with white markings in hollows of the leaves. Cones $\frac{1}{4}$ in., dark brown; scales ten, wrinkled and deeply depressed in the centre. Seeds one to two on each scale, with large conspicuous resin-vesicles.

13. *Cupressus nootkatensis*, Don. Alaska, British Columbia, Washington, Northern Oregon. See p. 1194.

Leaves acute, mucronate, green, without any white markings. Cones ripening in the second year, $\frac{1}{3}$ in., plum-coloured; scales four or six, with prominent pointed processes. Seeds two on each scale, without resin-vesicles.

14. *Cupressus thyoides*, Linnæus. Near the sea from southern Maine to northern Florida, and westward to Mississippi. See p. 1210.

Leaves acute, green, without white markings, with a conspicuous raised gland on the back. Cones $\frac{1}{4}$ in., glaucous; scales six. Seeds one to two on each scale, without resin-vesicles.

The following species are not yet introduced, and are imperfectly known.

CUPRESSUS FORMOSENSIS, Henry.

Chamæcyparis formosensis, Matsumura, in *Tokyo Bot. Mag.* xv. 137 (1901); Matsumura and Hayata, *Enum. Pl. Formos.* 402 (1906); Beissner, in *Mitt. deut. dendr. Ges.* 1907, p. 115; Hayata, in *Journ. Coll. Sc. Tokyo*, xxv. 208 (1908).

¹ *C. nootkatensis* is an exception. Cf. p. 1196, note 4.

This species, which occurs on Mount Morrison in Formosa, at 7000 to 10,000 feet altitude, appears to be allied to *C. Lawsoniana*, and is reported to attain an enormous size, Beissner having received from A. Unger of Yokohama a photograph of a tree said to be 72 feet in girth.¹ There are herbarium specimens at Berlin, which I have not seen. It is described as having acute green leaves not marked with white lines as in *C. pisifera*; and the cones are intermediate in size between those of that species and those of *C. obtusa*. No seeds of this remarkable species have as yet reached Europe.

CUPRESSUS HODGINSII, Dunn, in *Journ. Linn. Soc. (Bot.)* xxxviii. 367 (1908).

Described² from specimens collected near Foochow, China, consisting of detached foliage and cones. The former resembles the foliage of young trees of *Libocedrus macrolepis* in cultivation at Kew. The cones are very peculiar, resembling those of a cypress, but containing seeds with two very unequal wings, and indicate a new and interesting species, doubtfully referable to *Cupressus*.

CUPRESSUS THURIFERA, Humboldt, Bonpland, and Kunth, *Nov. Sp. et Gen.* ii. 3 (1817); Masters, in *Journ. Linn. Soc. (Bot.)* xxxi. 349, figs. 25-27 (1896); Kent, Veitch's *Man. Conif.* 230 (1900).

Chamaecyparis thurifera, Endlicher, *Syn. Conif.* 62 (1847).

A rare species, recorded for three or four localities in Mexico, and doubtfully referable to *Cupressus*. There are cones in the Kew herbarium collected by Botteri³ at Orizaba which were attributed to this species by Dr. Masters. These cones are globose, composed of six non-peltate scales, decussately arranged, and fitting close together by their margins; each scale bears the scars of attachment of one to three wingless seeds. Kent described this species from specimens, said to have been sent from La Mortola, but which cannot now be found in Messrs. Veitch's museum at Chelsea; and Mr. A. Berger writes⁴ that no tree of this kind now exists at La Mortola. It is doubtful if this species was ever introduced, as Carrière⁵ states that the plant formerly grown under this name was a *Biota*; and seeds of supposed *C. thurifera*, distributed in 1909, by the Dendrological Society of France, differed in no respect from those of *C. lusitanica*. (A. H.)

¹ While these pages were finally going through the press, Mr. H. Clinton-Baker has shown me a photograph, taken by Mr. A. R. Firth, Consul at Tamsui, of an enormous tree of this species, growing on Mt. Ari, which measures 125 ft. in height, with a stem free of branches for 45 ft. and 67 ft. in girth. Capt. L. Clinton-Baker, R.N., has just brought home excellent specimens in fruit, and two living plants, which will be planted at Bayfordbury.

² While these pages were finally going through the press, Mr. H. Clinton-Baker has received from Capt. Hodgins, excellent specimens in fruit. There are now four living plants at Bayfordbury, two sent in 1909, and two brought home in April 1910, by Capt. L. Clinton-Baker, R.N.

³ Lindley, in *Gard. Chron.* 1856, p. 772, states that Botteri sent cones of a cultivated plant, from which very glaucous seedlings like a *Thuja* were raised in the Chiswick Garden.

⁴ Mr. Berger states that two plants formerly cultivated under this name at La Mortola turned out to be *Cupressus sempervirens* and *C. lusitanica*, var. *Benthani*.

⁵ *Conif.* 135 (1867).

CUPRESSUS SEMPERVIRENS, MEDITERRANEAN CYPRESS

Cupressus sempervirens, Linnæus, *Sp. Pl.* 1002 (1753); Pallas, *Fl. Ross.* I. pt. ii. p. 11, t. 53 (1784); Loudon, *Arb. et Frut. Brit.* iv. 2464 (1838); Boissier, *Fl. Orient.* v. 705 (1881); Hooker, *Fl. Brit. Ind.* v. 645 (1888); Masters, in *Journ. Linn. Soc. (Bot.)* xxxi. 325 (1896); Kent, Veitch's *Man. Coniferae*, 228 (1900); Gamble, *Indian Timbers*, 697 (1902); Kirchner, *Lebengesch. Blütenpfl. Mitteleurop.* i. 280 (1906).
Cupressus horizontalis, Miller, *Dict. No. 2* (1768), sphalmate "horizontalibus."
Cupressus lugubris, Salisbury, *Prod.* 397 (1796).
Cupressus fastigiata, De Candolle, *Flor. Franç.* vi. 336 (1815).
Cupressus patula, Spadoni, *Xilog.* i. 193 (1826).
Cupressus Tournefortii, Audibert, *Cat.* (1834).

A tree, attaining in the Mediterranean region an immense age and size. Bark very thin, even on old trees, smooth or slightly fissured longitudinally, greyish brown, with a light brown cortex. Branchlet systems, alternate, not distichous, spreading irregularly at varying angles, tri-pinnate, with the pinnæ not disposed in one plane. Ultimate branchlets tetragonal, equal-sided, $\frac{1}{8}$ in. in diameter. Leaves, in four equal ranks, $\frac{1}{2}$ in. long, rhomboid, obtuse, closely appressed, often marked with a longitudinal furrow.

Staminate flowers, yellow, $\frac{1}{8}$ in. long; stamens about ten pairs, with sub-orbicular dentate connectives, each of which bears four or more anther-cells. Female flowers globose, $\frac{1}{4}$ in. in diameter; scales decussate, three to seven pairs, thick and fleshy with a thin edge, and bearing at the base about twenty urn-shaped ovules.

Cones ripening in the winter of the first year or in the following spring, opening in the succeeding autumn by the separation of the scales at their edges, when the seed falls out; on short stout curved stalks, sub-globose or ovoid, 1 to $1\frac{1}{4}$ in. in length, shining, pale brown or greyish; scales eight to fourteen, very variable in form, either flattened with a central pit overhung by a minute rounded thin process, or pyramidal with a mucronate process. Seeds eight to twenty on each scale, $\frac{1}{8}$ in. long, oblong, rounded or angled, without resin-vesicles; wing very narrow.

The seedling¹ has two opposite cotyledons, $\frac{2}{5}$ in. long, linear, flattened, shining green below, and dull bluish green above with stomata. The primary leaves, $\frac{1}{3}$ in. long, green and spreading, have stomata on their upper surface; the first pair opposite and alternating with the cotyledons, and followed by a series of whorls of four, ultimately being replaced by decussate pairs of adult scale-like leaves.

VARIETIES

The Mediterranean cypress has been known to exist from the most ancient times in two forms.

¹ Cf. Kirchner, *op. cit.* 281, 282.

1. Var. *horizontalis*, Gordon, *Pinetum*, 68 (1858).

Cupressus horizontalis, Miller, *Dict. No. 2* (1768).

Branches spreading, the tree assuming the habit of a cedar. This is the common form in the wild state.

2. Var. *stricta*, Aiton, *Hort. Kew.* iii. 372 (1789).

Var. *pyramidalis*, Nyman, *Consp.* 675 (1881).

Var. *fastigiata*, Hansen, in *Journ. Roy. Hort. Soc.* xiv. 287 (1892).

Cupressus pyramidalis, Targioni-Tozzetti, *Oss. Bot.* iii.-v. 53 (1808).

Cupressus fastigiata, De Candolle, *Fl. Franç.* v. 336 (1815).

Cupressus conoidea, Spadoni, *Xilog.* i. 189 (1826).

Branches erect, nearly parallel to the stem, forming a tree of narrowly pyramidal outline. This is the form most commonly met with in cultivation.

It is doubtful if the varieties, which depend upon the form of the fruit, though distinguished by Parlatore, can be maintained, as he admits that he observed on the same tree cones of different shapes, ovate-oblong, oblong, and globose, with both umbonate and umbilicate scales. The following may be mentioned, although it is extremely doubtful if it can be distinguished in cultivation.

3. Var. *indica*, Parlatore, in De Candolle, *Prod.* xvi. pt. ii. p. 469 (1868).

Cupressus Whiteyana, Carrière, *Conif.* 128 (1855).

Cupressus Doniana, Royleana, and *australis*, Koch, *Dendrologie*, II. pt. ii. p. 146 (1873)

Habit of var. *stricta*, with globose cones and mucronate umbonate scales. This variety as well as the spreading form is cultivated in northern India.

4. Variegated and dwarf varieties, which we have not seen, are mentioned by Carrière.

5. Var. *thujæfolia*, Knight and Perry, *Syn. Conif.* 19 (1850).

A sub-variety of the upright cypress, in which the branchlet systems are regularly arranged in one plane.

DISTRIBUTION

This species is indigenous in the mountains of northern Persia, in Syria, Cilicia, Greece, and the islands of Rhodes, Crete, and Cyprus. Pliny believed that it was introduced from Crete into Italy. Humboldt considered the native home of the cypress to be in the mountains of Buseh, west of Herat, but so far as our present knowledge goes it is now a rare and always a planted tree in Afghanistan. Hehn's¹ supposition that it was in ancient times imported from Persia into the Lebanon and Cyprus is without any foundation.²

Dr. Stapf informs me that this tree is truly wild in the Elburz mountains in northern Persia, where he saw it on rocky slopes opposite Mendjil and Rudbar. Buhse collected it on the sides of the Safed Rud valley.

¹ *Wanderings of Plants and Animals*, 212.

² Mouillefert, *Essences Forestières*, 402 (1903), identifies with this species some pieces of wood found at Carthage, which had been used for coffins by the Carthaginians about 500 B.C. At present the tree only exists in Algeria near houses and in gardens.

In Greece,¹ it is now found wild on Mount Parnassus and forms woods between Messene and Kalamata in Peloponnesus.

In Cyprus,² the spreading form of the cypress, var. *horizontalis*, grows in a wild state throughout the northern range of mountains, which consist mainly of limestone, thriving luxuriantly up to the highest point, 3300 ft. above sea-level. There are no large trees now in the forests of this range, the best being about 35 ft. high and 5 ft. in girth, since in former times, whenever a tree was large enough to make a rafter it was cut by the villagers, and much damage was also done by forest fires. In the southern range, which is mainly composed of volcanic rocks, there are only a few isolated specimens, which ascend to 3500 ft. elevation. The fastigiata variety is commonly planted in gardens in the plains; and the finest specimens are one at the Ayia Nicola church in the Famagusta district, 70 ft. high and 9½ ft. in girth; another of the same height and 12 ft. in girth at the Chrysostomos monastery, Kyrenia district; while a third at the Ayia Katerina mosque, in the Nicosia district, is 78 ft. by 7 ft. 3 in. Attempts to raise cypress from seed on Troodos at 5500 ft. elevation failed, as the plants were killed by the cold.

According to Pliny,³ it grew in the White Mountains of Crete, being in great abundance on the very summits, from which the snow never departs. Evelyn⁴ states that a vast forest of this species in Crete was destroyed by a fire which raged from 1400 to 1407. Mr. A. Trevor Battye found the horizontal form wild in Crete at elevations of about 3000 ft., attaining about 50 ft. high, by 6 ft. in girth. A photograph taken by him in the entrance to the gorge from the plain of Omalu, shows a group of these trees.

According to Boissier⁵ it occurs on the Lebanon between 3500 and 5000 ft., and appears to have been collected in the wild state in northern Syria near Beila, and in the mountains of Cilicia. Post⁶ states that the upright variety is everywhere cultivated in the cemeteries in Syria under the name of *Saru*.

The cypress has been carried by man both eastward and westward of its original home, and is occasionally even planted in China.⁷ It is much cultivated in northern India, the fastigiata variety being the most common and attaining occasionally a height of 100 ft. with a girth of 9 ft.

The cypress is naturalised in many places, as on the eastern shore of the Adriatic,⁸ where, however, it does not thrive at elevations exceeding 1000 ft., and in the Caucasus.⁹ In Italy it is perfectly naturalised in Tuscany, where in a mixed wood of oak and ash, between Castelfiorentino and Montagone, Sprenger¹⁰ noticed thousands of trees of all ages from seedlings to a hundred years old.

The cypress is cultivated on the continent in a few places north of the Alps, as on the island of Mainau¹¹ in Lake Constance, and at Metz; but in France it

¹¹ A fine tree on this island is figured by Beissner in *Gart. Zeitung*, November 1891.

is commonly planted in Provence and Languedoc about as far north as Valence, and in the south-west; but is not hardy near Paris. Carrière¹ states that the southern slope, on part of which Montpellier is built, appears to have been formerly occupied by an extensive wood of cypress. The remains of the wooden beams are known as *mélèze*, which is the name still used for the cypress by many of the inhabitants of Montpellier. One of these ancient trees still survived in Carrière's time, and was supposed to be 800 years old. It measured 13 ft. in girth at 3 ft. from the ground, and 4 ft. in girth at 71 ft. up, where it had been broken off by lightning. This remarkable tree belonged to the spreading type, and was situated on a property named Mas-Limasson. (A. H.)

In January 1910 Professor Flahault showed me at the Colline de la Vallette, about two miles north of Montpellier, on a dry limestone hill, a remarkable wood which was planted in 1810 by Pyrame de Candolle, with cypress. The original trees are supposed to have been cut; and M. Flahault thought that the existing ones are seedlings from them. The difference in habit between the two forms is very marked, and is well shown in the photograph reproduced on Plate 293 A. The best trees of the pyramidal form are about 50 ft. by 4 ft., the average about 35 to 40 ft. Of the horizontal form the best are about 35 ft., the average 20 to 30 ft. There are many small seedlings coming up in the more sheltered parts of this wood, though it is regularly grazed by sheep, and one of these seedlings, though only 3 ft. high, bore fruit. The trees growing with the cypresses are *Pinus halepensis*, which seem to be self sown. In the botanic garden at Montpellier there is a fine specimen of the horizontal form measuring 88 ft. by 8½ ft.

There are large and beautiful trees in the Generalife Gardens at Granada, which are called *cipreses de la reina*. These are supposed² to have been planted by the Moors, and are about 500 years old.

The most celebrated cypress in Europe is one at Somma in Lombardy, which is said to have been planted in the year of the Nativity of our Lord. Loudon³ was informed by the Abbé Belèze that a chronicle exists at Milan, proving it to have existed in 42 B.C. But after having visited the tree I cannot believe that this legend is true, as the tree has no appearance of great age, and I should rather suppose that it is a descendant of some old tree which formerly existed here. Somma is a village about four miles north of Galarate on the railroad from Milan to the Alps, and the tree grows in the corner of a walled garden close to the road, which is said to have been diverted by Napoleon to avoid cutting it down. Manetti, who measured the tree for Loudon, said that⁴ it was 121 ft. high and 23 ft. in girth near the ground. I measured it carefully, and found it to be 85 ft. by 17 ft. 3 in. at five feet from the ground. It forks on one side at about 12 ft., and on the other at 15 ft., and then divides into six or seven large trunks. It seemed to be sound, but I could not see into the fork. It is of the *horizontalis* type, and was covered with full-grown but unripe fruit in October 1906.⁵

¹ *Conif.* ii. 149 (1867).

² Willkomm, *Forstl. Flora*, 247 (1887).

³ *Arb. et Frut. Brit.* iv. 2470, fig. 2325. The figure is copied from a drawing sent to London by Manetti.

⁴ Evidently an error, as the Abbé Belèze measured the tree in 1832, and found it to be 70 ft. high and 20 ft. in girth; it had for many years lost its leading shoot. Cf. Loudon, *op. cit.* i. 169 (1838), and *Ann. Soc. d'Hortic.* xii. 76.

⁵ The story in Loudon, p. 2471, about this tree being wounded by Francis I. is erroneous, as Loudon points out in pp. 2589, 2605. The tree struck by this king, in his despair after the loss of the battle of Pavia, was a Lombardy poplar. More details about the age and history of this tree will be found in *Notes and Queries*, for Nov. 17, and Dec. 29, 1894.

Sprenger¹ says that this tree grows larger in Tuscany than in the south of Italy, and that he had seen trees on the Lago Maggiore known to be 620 years old, which were over 10 metres in girth near the ground, but I found no such trees myself.

The cypresses in the court of the Diocletian Museum at Rome are said to have been planted by Michael Angelo; and when measured by M. Simond in 1817 the largest was about 13 ft. in girth. Mr. Victor Ames tells me that these are the most picturesque of the fastigate type that he has seen in Italy. The largest he knows of the *horizontalis* type near Florence are at Marignolle, the tallest at Pozzo Imperiale. Outside the Porta Romana there are some good specimens, which on account of their pendulous growth look like ancient spruce trees. There is a good cypress at Villa d'Este in Tivoli.² A tall very slender cypress at La Mortola measured 33 metres by 1½ metres in 1910.

In the garden of Mr. R. Whittaker near Palermo, I saw a tree in 1910 which measured about 85 ft. by 5 ft., 50 years after planting. Its lateral branches were horizontal, and more regular than usual. On the Isola Bella in Lake Maggiore, I measured a very handsome fastigate tree planted in 1859, which in 1910 was 65 ft. high.

There are very large cypresses at Scutari, where, as generally in Turkey,³ it is planted abundantly in cemeteries, but I can obtain no exact measurements of the size it attains here.

The largest cypress recorded in Greece was one near Mistra, six miles west of the ruins of Sparta, which Lord Aberdeen⁴ found to be 36 ft. in girth at 4 ft. from the ground in 1803. When he saw it again in 1839 it had scarcely gained in girth, and was estimated to be about 150 ft. in height. This immense tree was destroyed⁵ by fire lit by gipsies in 1881. Another large cypress at Patras, which Long⁶ measured in 1820 as 22 ft. 2 in. in girth at 4 ft. from the ground, was destroyed⁷ in the wars of the Greek Revolution. This tree was 18 French ft. in girth in 1676, according to Spon. Prof. Samios of Athens informs us in a letter that the largest specimen he knows of in Greece at the present time is at Oetylos, and measures 50 metres high by 2 metres in girth.

CULTIVATION

It is uncertain when the cypress was first introduced into England. The first mention that we know of it is by Turner, who was physician at Syon in 1548, and says⁸ that it was growing plenteously there. Gerard,⁹ in 1597, says that there are trees of it at "Syon, a place neare London, sometime a house of nunnes. It groweth also at Greenwich, and at other places, and likewise at Hampstead, in the garden of Mr. Wade."

¹ *Mitt. deut. dendr. Ges.* 1904, p. 195.

² In *Gard. Chron.* xiii. 752, fig. 130 (1880), an illustration is given of the cypress trees in the Buena Vista Garden at Verona. Cf. also Karsten and Schenck, *Vegetationsbilder*, iii. tt. 23, 24 (1906), for illustrations of this tree at Gardone on Lake Garda.

³ In *Gard. Chron.* iii. 48, fig. 11 (1875), the cypresses growing in the garden of the Seraglio at Constantinople are figured.

⁴ In Loudon, *Gard. Mag.* xv. 697 (1839), with a figure of the tree, reproduced from a drawing of it made on the spot by Lord Aberdeen.

⁵ Willkomm, *Forstliche Flora*, 246 (1887), who gives its height as 170 ft. and its girth as 36 ft.

⁶ In Loudon, *Gard. Mag.* xiv. 530 (1838).

⁷ Lord Aberdeen, *loc. cit.*

⁸ *Names of Herbes*, 32 (1548).

⁹ *Herball*, 1185 (1597).

Evelyn¹ says: "Within a few years past, reputed so tender, and so nice a plant, that it was cultivated with the greatest care, and to be found only among the curious, whereas now we see it in every garden, rising to as goodly a bulk and stature, as most which you shall see even in Italy itself; for such I remember to have seen once in his late Majesty's gardens at Theobald's before that Princely seat was demolished."

Evelyn and Boutcher both give instructions for raising the cypress from seed in the open ground, but the latter adds that as it is no uncommon thing for a hard winter to destroy whole beds of them, it is better to sow some seeds in pots.

I have always adopted the latter practice, and have raised many from seeds gathered in Rome, not planting out the seedlings till they are two years old, when they should be about a foot high. In good soil, if not exposed to severe frost, they then make rapid growth,² and will be fit to plant out at four years old, though they may be kept in the nursery longer, and successfully transplanted when 5 or 6 ft. high. The seeds will keep good for a very long period; and I have seen at Blackmoor, some trees which were raised from seed collected in the cemetery at Scutari by the present Lord Selborne in 1884. These seeds were sent by him to his father, who kept them in a drawer till 1895, when they were sown, and the young trees in April 1905 were from 10 to 15 ft. high. Though fruit is produced in most parts of England the seed does not always ripen, and I should prefer Italian or French grown seed. The tree should always be planted in well-drained soil, and in the warmest and best-sheltered position that can be found, as it does not thrive and is liable to be killed in severe winters in low-lying or damp situations. A great many trees of considerable size were killed during the severe winters of 1860-61 and 1879-80-81; almost all those in the north and in Scotland, of which Mr. Palmer obtained particulars, having succumbed during the latter period, whilst many old ones in warmer parts of England were injured.

REMARKABLE TREES

Among the finest cypresses that I have seen in England is one on the lawn at Heron Court (Plate 293), which in 1906 I found to be 60 ft. high by 5 ft. in girth.

At Enville Hall, Staffordshire, Henry measured one which in 1904 was 62 ft. by 9 ft.

In the garden at Langley Hall, Norwich, a tree raised from seed gathered in the Garden of Gethsemane in 1870 by Sir R. Beauchamp was 32 ft. high in 1905.

At Dropmore a tree is 42 ft. high by 5 ft. 9 in. at 3 ft. from the ground.

At Killerton some trees planted near the church about 1841 are from 50 to 60 ft. in height by 4 to 5 ft. in girth.

In the Palace gardens at Wells there is a very broad-topped tree in full vigour about 48 ft. high.

There is a remarkable old tree at Crowcombe Court, Somerset, of which one

¹ *Sylva*, 115 (1670).

² Kirchner, *op. cit.* 282, says that the growth on the Riviera of seedlings in the open is rather slow, averaging 12 to 16 in. high at six years old.

half fell down some years ago. The other half, which leans a good deal, is about 50 ft. high, with a clean bole 8 ft. in girth.

At Shedfield House, near Botley, Hants, the residence of Lady Phillimore, Sir Hugh Beevor measured a tree 57 ft. by 6 ft. in 1906. Prof. Phillimore, who has kindly sent a specimen branch and a photograph, says that this tree is believed to be 120 to 200 years old, and to have been planted about the same time as a plane standing near it, which measures 15 ft. in girth at the base.

At Barton, Bury St. Edmunds, there is a tree of the horizontal variety which was 46 ft. by 3 ft. 8 in. in 1904.

On the lawn at White Knights Park, Reading, Mr. A. B. Jackson measured in 1909 a tree 65 ft. high and 6 ft. 11 in. in girth.

In Wales, at Penrhyn Castle, there is a group of very fine trees, supposed to be only about fifty years planted, and of which the tallest tree in the centre in 1906 was 65 ft. high by only 2 ft. 10 in. in girth; another was 55 ft. by 4½ ft.; a third was 55 ft. by 3 ft. 2 in.

In Scotland I have seen no old trees, and but few young ones. A tree at Monreith raised by Sir H. Maxwell from seed gathered at Florence in 1878 was about 25 ft. high in 1906.

At Keir,¹ Perthshire, there are about forty trees of this species trained against the house, the largest of which is 29 ft. high and 21 in. in girth. A lithograph of the house made in 1858 shows that they were then about 10 ft. high.

In Ireland,² a tree at Kilruddery, near Bray, was 38 ft. by 5 ft. 5 in. in 1904; and another at Powerscourt was 36 ft. by 3 ft. 7 in. in 1909.

TIMBER

The timber³ is light brown in colour, hard, and close-grained, with very numerous fine medullary rays, and annual rings usually distinctly marked by a firm line. According to Mathieu,⁴ the wood is easy to work, and gives off a penetrating agreeable odour. It is very durable, lasts indefinitely under water, and longer than oak when used for vine-props. In France and Italy it is considered excellent for furniture; and the doors of St. Peter's at Rome, which lasted from the time of Constantine to that of Pope Eugene IV., nearly 1000 years, were said to be made of cypress.⁵ According to Madon⁶ it yields in Cyprus wood of the first quality for building.

It has been frequently stated that the Egyptians used this wood for mummy cases,⁷ but all the specimens in the Kew Museum have proved to be the wood of *Ficus Sycomorus*.

The large chests which are supposed to have been used for importing silk from

¹ The account of these trees in *Journ. Roy. Hort. Soc.* xiv. 531 (1892), is not accurate. We are indebted to the owner, Archibald Stirling, Esq., for the particulars given above.

² In *Gard. Chron.* 1868, p. 1289, a tree in the Bridgetown garden, Castlemartyr, was reported to be 60 ft. high and 13 ft. in girth in 1868; but neither Henry nor I saw this tree on our visits to Castlemartyr.

³ Gamble, *Indian Timbers*, 697 (1902).

⁴ *Flore Forestière*, 523 (1897).

⁵ Loudon, *Gard. Mag.* xv. 271 (1839). Cf. also *Gard. Chron.* 1843, p. 87.

⁶ *Cyprus Parly. Paper*, No. 366 of 1881, Encl. No. 2. Madon considers it to have been the shittim wood of Scripture, out of which the ark of the covenant was constructed; but Canon Tristram, *Fauna and Flora of Palestine*, 293 (1884), identifies shittim wood with *Acacia seyal*, Delile.

⁷ *Kew Bull.* 1909, pp. 74-6.

the Levant in early times, and which are usually ornamented with carving, and sometimes bear Greek lettering, are believed to be made of this wood. Shakespeare, in *The Taming of the Shrew*, II. i. 353, says:

In ivory coffers I have stuffed my crowns;
In cypress chests my arras counterpoints,
Costly apparel, tents, and canopies.

(H. J. E.)

CUPRESSUS TORULOSA, HIMALAYAN CYPRESS

Cupressus torulosa, Don, *Prodr. Fl. Nepal.* 55 (1825); Lambert, *Genus Pinus*, ii. 18 (1824); Loudon, *Arb. et Frut. Brit.* iv. 2478 (1838); Lawson, *Pinet. Brit.* ii. 201, t. 35 (1867); Hooker, *Fl. Brit. Ind.* v. 645 (1888); Masters, in *Journ. Linn. Soc. (Bot.)* xxxi. 335 (1896); Kent, Veitch's *Man. Conif.* 233 (1900); Gamble, *Indian Timbers*, 696 (1902); Collett, *Fl. Simlensis*, 483 (1902); Brandis, *Indian Trees*, 693 (1906).

Cupressus Tournefortii, Tenore, in *Mem. Soc. Ital. Sc. Modena*, xv. pt. 2, p. 194 (1855) (not Audibert).

Cupressus pendula, Hopf, in Regel, *Gartenflora*, iii. 279 (1854) (not Thunberg).

Cupressus majestica, Knight and Perry, *Syn. Conif.* 20 (1850).

Cupressus Corneyana, Knight and Perry, *Syn. Conif.* 20 (1850).

A tree, attaining in the Himalayas 150 ft. in height and 37 ft. in girth. Bark, $\frac{1}{2}$ in. thick, brown, peeling off in long, narrow fibrous strips. Branches horizontal or ascending, with pendulous tips, forming a broad pyramidal crown. Branchlet systems alternate, distichous, two- or three-pinnate, with the pinnæ disposed more or less in one plane. Ultimate branchlets often curved, tetragonal, equal-sided, $\frac{1}{2}$ in. in diameter. Leaves¹ uniform in four ranks, closely appressed, $\frac{1}{8}$ in. long, ovate, obtuse at the apex, convex on the back, and often with an obscure longitudinal glandular depression. Older branchlets reddish brown, not glaucous, terete, with the leaves completely deciduous in the fifth year.

Staminate flowers $\frac{1}{2}$ in. long, when open, with three to four anthers on each of the twelve to sixteen stamens. Cones, when young, green variously tinged with plum colour, ripening in October and November of the second year, often persistent after the fall of the seeds for one or two years longer; when mature, on short recurved stalks, globose or ellipsoidal, $\frac{1}{2}$ in. in diameter, dark reddish brown; scales, eight to ten, with the outer surface depressed in the centre and giving off a small triangular, rounded or acute, often recurved process. Seeds, six to eight on each scale, pale brown, $\frac{1}{8}$ in. long, flattened on one surface, convex and scarcely ridged on the other, with inconspicuous resin vesicles; wing rather broad, with a narrow translucent border. Cotyledons, three to five.²

¹ Hood, in *Gard. Chron.* 1847, p. 766, states that the foliage gives off a peculiar scent, noticeable on a windy day to leeward of the tree.

² Described by Hill and De Fraine, in *Ann. Bot.* xxii. 699 (1908).

We have not been able to distinguish, in England, var. *majestica*,¹ Carrière, *Conif.* 118 (1855); but the following variety is noteworthy:—

Var. *Corneyana*, Carrière, *Conif.* 151 (1867).

Cupressus Corneyana, Knight and Perry, *Syn. Conif.* 20 (1850).

Cupressus funebris, Koch,² *Dendrologie*, ii. pt. 2, p. 160 (1873) (not Endlicher).

Branches and branchlets pendulous. Branchlet systems irregularly arising at varying angles, and not so distichous as in the type, forming a more diffuse and not flattened mass of foliage. This variety was first put into commerce by Knight and Perry, who stated that: "It is not certain whence it has been introduced, but it is supposed to be a native of either Japan or the north of China," and acting on this belief they named it after Mr. Corney, a merchant in China, who occasionally sent seeds to their nursery at Chelsea; but they never affirmed that it was raised from Chinese or Japanese seed. Doubtless it originated in the Chelsea nursery, as it differs in no respect, except in habit, from the type; and *C. torulosa* is unknown in China and Japan.

DISTRIBUTION

This beautiful tree is a native of the outer ranges of the western Himalayas, from Chamba to Nepal, between 5500 and 9000 ft. elevation. It is rather local in its distribution, and usually grows on limestone. Brandis³ mentions several localities—small patches on the Ravi, parts of Kulu, limestone rocks of the Shali and Tika hills, near Simla;⁴ limestone hills of Lokandi and Moila, and below the Karamba peak in Jaunsar; on the Chinar peak below Naini Tal, where it is found exceptionally on clay slate, but near limestone. It also grows in the Bamsu valley in Tehri-Garhwal, attaining a considerable size. Webber⁵ says that it only grows on sunny slopes over 7000 ft. altitude in isolated localities, and mentions trees on the Chinar peak 150 ft. high with stems clean to near the top, the greatest girth that he measured being 37 ft. Gamble speaks of a tree at the Deota temple in the Tons valley, which is 154 ft. high and 22 ft. in girth.

This species reproduces well from seed, and seedlings are often found in the crevices of vertical precipices, as at Moila, producing trees which grow first outward and then straight up the rock. It succeeds, when planted, at low elevations, even in the plains of India, as at Calcutta, Dehra Dun, Saharanpur, and Chikalda in Berar. Young plants are often attacked by a fungus,⁶ *Gymnosporangium Cunninghamianum*, which occurs as a yellow gelatinous mass. (A. H.)

CULTIVATION

The first description of this tree was based by David Don, in 1825, on specimens collected by Buchanan-Hamilton, in Nepal, in 1802-3; and seeds were first

¹ *Cupressus majestica*, and also *Cupressus flagelliformis*, Knight and Perry, *Syn. Conif.* 20 (1850). A specimen of *C. majestica* cultivated at Montpellier is identical with typical *C. torulosa*.

² Both Gordon, *Pinet. Suppl.* 24 (1862), and Koch, *loc. cit.*, erroneously considered this variety to be the weeping cypress of China.

³ *Forest Flora N.W. India*, 533 (1874).

⁴ Collett, *Fl. Simlensis*, 483 (1902), says that it occurs at Simla, where it is known to the natives as deodar, on the road to the pumping station, and beyond the tunnel. On the north side of Mount Shali it grows at 8000 to 9000 ft.

⁵ *Forests of Upper India*, 42 (1902).

⁶ The alternate generation of this fungus occurs on the leaves of *Fyrus Fashia*. Cf. *Indian Forester*, xxv. 435.

sent to Europe by Dr. Wallich in 1824.¹ Though it has been planted at many places since that date, it has never become common in cultivation, and evidently requires, in order to succeed, a warmer climate than most parts of England afford.

Lawson quotes Palmer's tables to the effect that, in the winter of 1860-61, out of 52 specimens in England, 34 were killed, 9 much injured, 2 slightly injured, and only 7 unhurt. In Scotland and Ireland the results were very similar. Rarely, except in the south of England or near the sea, and in Ireland, where severe frosts have less effect, are trees of any size to be found.²

REMARKABLE TREES

The largest that we know of at present is in the grounds at Killerton, where there is a fine tree of about 65 ft. by 5 ft. 4 in., which when seen in 1905 was very thriving.

There is a fine avenue of *C. torulosa* at Cuffnells, near Lyndhurst, Hants (Plate 294), which, I am informed by Mr. Hargreaves, were raised from seed brought from India by Mr. C. Harland in 1860. This avenue consists of nine trees on each side of a walk, which are very regular in habit, and measure about 45 ft. by 4½ ft. They bore fruit in October 1907.

Mr. A. B. Jackson measured several trees in a plantation at Tregothnan, about 40 to 45 ft. by 3 ft., in 1909; and two trees at Pencarrow, which are 48 ft. by 4 ft. 8 in. and 35 ft. by 4 ft. 1 in. At Heanton-Satchville, North Devon, I measured, in 1905, a tree, about 45 ft. high and 3 ft. 5 in. in girth, dividing into three stems at 10 ft. from the ground, and forming a dense pyramid of foliage. At Haldon House, Exeter, a tree, which I saw in April 1908, measured 46 ft. At Melbury there is a tall fine tree of var. *Corneyana*, bearing fruit near the summit, which was 65 ft. by 4 ft. 11 in. in 1908.

At Eastnor Castle there is a tree 39 ft. high by 3 ft. 1 in. in girth, measured by Mr. Mullins in 1909. At Hewell Grange, Redditch, there are four trees of this species, the largest of which, measured by me in 1909, was 56 ft. high by 3 ft. 11 in. in girth. It is almost fastigiata in habit. These trees are growing at 530 ft. elevation, on sloping ground, exposed to the south-west. At Woburn there is a tree about 30 ft. in height; and Mr. J. M. Rogers has sent specimens from a tree at Riverhill, near Sevenoaks, about 40 ft. high.

In Ireland, the best specimen which we have seen is at Fota, and measured 56 ft. by 7 ft. in 1908. Another at Powerscourt is 27 ft. by 3 ft. 4 in.

In the nursery of Rovelli Frères, at Pallanza, I measured in 1906 a very

¹ Wallich sent seeds again in 1836; and Loudon, in *Gard. Mag.* xvi. 586 (1840), mentions a large stock of plants at Cullis's nursery at Leamington in 1840. Considerable quantities of seed of this cypress, as well as of the deodar, were imported in 1853 from the Himalayas by the Commissioners of Woods.

² According to *Gard. Chron.* 1868, pp. 152, 465, plants of *C. torulosa* were killed at Dropmore and Gunnersbury Park in the severe winter of 1867-68. According to *Kew Bulletin*, 1896, p. 8, the severe frost of 26th January to 22nd February 1895, when the thermometer fell at Kew on two occasions to 1° and 2° Fahr., proved fatal to *C. torulosa* and *C. lusitanica*, while *C. sempervirens* and *C. macrocarpa* were badly injured.

handsome tree, with stouter branchlets than usual, 80 ft. by 9 ft., which was bearing cones, and may be the variety described as var. *majestica*.

TIMBER

According to Gamble, the timber is even more durable¹ than that of the deodar, and is used for building temples and for sleepers, though not procured in sufficient quantity to have much commercial importance. The wood is also burned as incense in Hindu temples. It weighs from 34 to 44 lbs. per cubic foot. It is moderately hard and close-grained, with white sapwood, and light brown and very fragrant heartwood, which shows darker streaks. The annual rings are distinctly marked by a narrow dark-coloured belt, with resin-cells in lines near them, which are very numerous in old trees.

(H. J. E.)

CUPRESSUS CASHMERICANA

Cupressus cashmeriana, Royle,² ex Carrière, *Conif.* i. 161 (1867).

Cupressus funebris, Endlicher, var. *glauca*, Masters, *Kew Handlist Conif.* 37 (1896).

Cupressus torulosa, Don, var. *kashmiriana*, Kent, Veitch's *Man. Conif.* 234 (1900).

Juniperi sp.,³ Griffith, *Itin. Notes*, 100, No. 27 (1848).

A tree, the dimensions of which in the wild state are not known, but described by Griffith as small, extremely elegant, and with smooth bark. In cultivation narrowly pyramidal, with ascending branches, and very pendulous branchlets, the bark being divided into long narrow scaly ridges.

Branchlet systems long and pendulous, alternate, distichous, two- to three-pinnate, with the pinnæ disposed more or less in one plane. Ultimate branchlets compressed, tetragonal, ⅓ in. wide (not inclusive of the spreading leaves). Leaves glaucous blue, the lateral pair conduplicate, ridged on the back, the facial pair flattened with a longitudinal furrow, all four ranks about ⅓ in. long, decurrent in their basal half, with lanceolate acuminate spreading apices, tipped with a fine cartilaginous point. Older branchlets reddish brown, bare of leaves in the third or fourth year.

Cones, when young, greenish yellow, with a glaucous bloom confined to the prominent spreading umbos; ripening in the second year, when they become dark brown, almost blackish, ellipsoidal, nearly ½ in. in diameter when closed; scales ten,

¹ Experiments were made at Dehra Dun, with sleepers of various timbers, put down in 1881 and taken up in 1892, and the cypress wood was found to have resisted best of all. Cf. *Ind. Forest.* xix. 207.

² We are unaware of the reason why this species is ascribed to Royle, as no mention of it can be found in his published writings.

³ Griffith's description is as follows:—"Arbor parva elegantissima cortici levi. Ramulis pendulis foliis senioribus ferrugineo-brunneis, junioribus glaucis. Dewangiri near the faqueer's house." This locality is in Bhutan, and specimens labelled No. 27 are preserved at Kew and Cambridge. Mr. J. Claude White in *Sikkim and Bhutan* (London, 1909), speaks of an immense weeping cypress which he saw at Chalimaphe, and which measured 50 ft. in girth. He also speaks of fine forests of cypress at 8000 to 9000 ft. in Bhutan. I supposed that these might be the same as Griffith's tree; but am informed by Mr. W. C. Smith, curator of the Herbarium at Calcutta, that he can find no specimens of cypress in Mr. White's collection, and suspects that the tree in question may be a juniper.—(H. J. E.)

with a central depression and an acute triangular reflexed process. Seeds about ten on each scale, reddish or pale brown, $\frac{1}{8}$ to $\frac{1}{6}$ in., with narrow wings and scattered resin-vesicles.

This species, judging from the cones, which resemble those of *C. torulosa*, is possibly a form of that species with juvenile acicular foliage. A solitary example was seen in cultivation in Bhutan by Griffith. Hooker, who apparently did not distinguish this species from *C. funebris*, collected two specimens from cultivated trees in Sikkim. Carrière states that it was introduced into Europe from Tibet about 1862.

The only specimen which we know of in this country is the beautiful tree in the Temperate House at Kew, which is now about 30 ft. high, having recently been topped, as its summit had reached the roof.¹ It bears fruit abundantly, but no seed has been sown, and we do not know whether seedlings, if produced, would preserve the character of the parent tree. Messrs. Veitch tell us that it has not proved sufficiently hardy to be kept out of doors at Coombe Wood, and they have no plants at present. There is, however, a small tree doing well in the open air at Rostrevor House, near Newry.

(A. H.)

In Italy the finest specimen is growing in front of the villa on the Isola Madre in Lake Maggiore.² This is one of the most beautiful conifers that I have seen anywhere, and measured in November 1906, 60 ft. high by 6 ft. in girth, and covered an area 35 paces in circumference. It bore fruit near the top of the tree. Seedlings of this lovely species can be had from the nursery of Rovelli Frères at Pallanza.

(H. J. E.)

CUPRESSUS FUNEBRIS, CHINESE WEEPING CYPRESS

Cupressus funebris, Endlicher, *Syn. Conif.* 58 (1847); Planchon, in *Flore des Serres*, vi. 90 (1850); Lindley, in Paxton, *Fl. Gard.* i. 47 (1850); Hooker, *Fl. Brit. Ind.* v. 646 (1888); Masters in *Journ. Linn. Soc. (Bot.)* xxxi. 337 (1896), and xxvi. 540 (1902); Franchet, in *Journ. de Bot.* xiii. 263 (1899); Kent, Veitch's *Man. Conif.* 203 (1900); Diels, *Flora von Central-China*, 219 (1901); Brandis, *Indian Trees*, 694 (1906).

Cupressus pendula, Staunton,³ *Embassy to China of Earl Macartney*, ii. 525, pl. 41 (1798) (not Thunberg⁴); Lambert, *Genus Pinus*, ii. 124, t. 66 (1832); Loudon, *Arb. et Frut. Brit.* iv. 2479 (1838); Griffith, *Itin. Notes*, 131, 143 (1848).

Cupressus amœna, Koch, in *Monatssch. Garten- u. Pflanzkunde*, i. 110 (1873), and *Dendrologie*, ii. pt. 2, p. 164 (1873).

A tree, attaining in China 70 ft. in height and 2 ft. in diameter. Bark brown, smooth. Branches ascending and horizontal, ending in long pendulous reddish

¹ This tree was presented to Kew in 1894 by Mrs. Forster, Homewood, Chislehurst, who informs us that she had received it from the Rev. F. Murray, formerly Rector of Chislehurst. Its origin is unknown.

² Cf. Beissner in *Mitt. deut. dend. Ges.* 1906, p. 98.

³ Staunton's specimen, on which Lambert founded his description of this species, is preserved in the British Museum. It is identical with specimens collected by Fortune and by myself in China, and was collected near Lake Sihoo in Chekiang. The plate represents a view of the lake with a very pendulous cypress in the foreground, much more weeping in habit than any trees we have seen.

⁴ *Cupressus pendula*, Thunberg, *Fl. Jap.* 265 (1784), is *Thuja orientalis*, L., var. *pendula*, Masters.

brown terete slender branchlets. Branchlet systems alternate, distichous, bipinnate, with the pinnæ more or less in one plane. Ultimate branchlets compressed, $\frac{1}{20}$ in. wide, $\frac{1}{80}$ in. thick. Leaves of two kinds; lateral pairs conduplicate; facial pairs flattened, ovate, keeled or with a median furrow; all appressed, but with the mucronate apex free and slightly spreading, greyish green, not marked by whitish lines or streaks, about $\frac{1}{2}$ in. long.

Staminate flowers yellow, $\frac{1}{10}$ in. long; stamens about 8. Cones globose, $\frac{1}{3}$ to $\frac{1}{2}$ in. in diameter, on long slender often curved stalks, ripening in the second year and falling soon afterwards, dark brown covered with a plum-coloured bloom; scales eight, scarcely depressed in the centre from which arises a minute ovate usually appressed process. Seeds three to five on each scale, $\frac{1}{8}$ in., shining reddish brown, with scattered resin-vesicles and narrow wings. Cotyledons two.

This species is a native of central China, occurring in mountainous districts, at elevations usually below 3000 ft., in the provinces of Szechwan, Hupeh, Anhui, and Chekiang. It was discovered by Sir George Staunton, who was Secretary to Lord Macartney's embassy to China in 1793, in the Vale of Tombs,¹ near Lake Sihoo, in the Hangchow prefecture of Chekiang, where it was planted in quantity around the graves. Fortune² in 1848 found it common in the green tea district of Huichou in Anhui, growing in clumps on the sides of the hills, generally near villages or amongst graves. He afterwards saw it in great abundance in the mountains southwest of Ningpo, and at Nanche and Yenchou in the Chekiang province. Fortune also noticed it in cultivation at Shanghai.

It is common in the neighbourhood of Ichang, close to the Yangtze, in the centre of China, where I found it in 1884. Here it grows in valleys, often forming pure woods of considerable extent, which are the home of the Reeves' pheasant in this district.

According to Wilson,³ it is common from Ichang westward both in the immediate vicinity of the great river, and in the mountains north and south of it up to 3000 ft. altitude. He noticed it particularly in the Yangtze gorges between the Hsinlung rapid and Wanhsien. Here the temperature sometimes falls in winter below freezing point, and there are occasional heavy falls of snow, but the climate is excessively hot in summer, and wherever this cypress grows wild the orange can be cultivated to perfection. In Szechwan it was collected by Père Farges⁴ at 4000 ft. elevation in the Chengkou district, and by von Rosthorn in the Nanchwan district. Wilson describes its great utility for boat-building at Wanhsien. With the exception of a few cross-beams of oak, the river boats are built entirely of the timber of *C. funebris*. The wood is close-grained, and is much used in central and western China for house-building and general carpentry.

¹ This locality is erroneously stated by Lindley in *Gard. Chron.* 1849, p. 243, and by Kent, to be in northern China, where the tree is unknown, as the climate in winter is much too severe. The distribution as given by Masters in *Journ. Linn. Soc. (Bot.)* xxxviii. 202 (1908), also erroneously includes northern China and is much too extensive.

² Fortune, in *Gard. Chron.* 1850, p. 228, gives an account of his discovery of this tree. Cf. also his *Tea Countries*, 16, 61, 64, 107, 314, and fig. on p. 63 (1852), and *Residence among the Chinese*, 145, 177 (1857).

³ In *Gard. Chron.* xxxviii. 94 (1905).

⁴ Franchet, in *Journ. de Bot.* xiii. 263 (1899).

The tree, which has been known to the Chinese as *poh* or *peh* from the earliest times, was planted¹ by the founder of the Yin dynasty about the altars of the spirits of the land. In the *Ch'un Ts'iu Wei* (100 B.C.), the cypress was directed to be planted around the tumuli, where feudal princes were buried, the pine being reserved for the tombs of the emperors; while Koelreuteria and Sophora were planted around the graves of officials of various degrees, only the willow being allowed in the case of the common people.

This species is cultivated in the eastern Himalayas, in Nepal, Sikkim, and Bhutan,² at 4000 to 8000 ft., chiefly near temples and monasteries, and no doubt it was early introduced from western China by the Buddhist monks. Sir J. Hooker³ measured a tree in a temple at Doobdi, probably the oldest specimen in Sikkim, at 6470 ft. elevation, apparently 90 ft. high, and with a girth of 16½ ft. at 5 ft. from the ground. This tree was not pyramidal, as all the young trees were, but had spreading branches, those at the top being dead and broken.

According to Gamble⁴ it is a fine species, easy to grow, and in the Dhobijhora plantation near Kurseong, trees planted in 1866 had attained in 1899 a girth of over 4 ft. There are several specimens about Darjeeling, and a remarkably fine tree at the Tasingthong Monastery in British Bhutan.

The wood is moderately hard, close and even in the grain, light yellow, with the annual rays only visible in young trees, but with concentric bands of lighter and darker tissue. The medullary rays are very fine, close, and numerous. There are occasional resin-ducts and resin-cells.

Lambert thought that this species was introduced from south China by W. Kerr in 1804; but Loudon says "supposed to have been introduced in 1808, but respecting which we know nothing with certainty," and was in doubt as to whether a pendulous cypress at Chiswick, and another growing in the Kew Arboretum in 1838, were this species.⁵ Fortune⁶ sent cones to Standish in 1848, from which plants were raised at Bagshot. A further supply of seed was also forwarded from Huichou by Fortune in 1853. All the seedlings planted out at Kew⁷ were soon killed; and this species is not hardy,⁸ except in the south-west of England and in Ireland.

(A. H.)

This tree is rarely seen except in the south and west,⁸ and is too delicate to

¹ Bretschneider, *Bot. Sinicum*, ii. 336, 381 (1892). The name *poh* is also given to *Thuja orientalis*, *Juniperus chinensis*, and *Libocedrus macrolepis*.

² Griffith, *Itin. Notes*, 131, 143, found this tree in Bhutan at 6400 ft. often attaining 80 ft. in height. Anderson, in Eden, *Political Missions to Bootan*, Botany, 135 (1865), says it is cultivated much more frequently in Bhutan than in Sikkim, and at lower elevations, down to 2000 ft., while in Sikkim it is never found lower than 5000 ft.

³ *Himalayan Journals*, i. 316, 317, 336, fig. on 337 (1854).

⁴ *Indian Timbers*, 697 (1902).

⁵ J. Smith, *Records of Kew Gardens*, 290 (1880), says that a plant at Kew, 9 ft. high in 1864, and known as the "weeping cypress of China," was perfectly hardy, and had been introduced prior to Fortune's time. This is no longer living, and doubtless was a pendulous variety of *Thuja orientalis*.

⁶ Cf. Lindley, in *Gard. Chron.* 1849, p. 243, where it is erroneously stated that Fortune obtained the cones from a place 200 miles north of Shanghai. We have to understand here south-west of Shanghai, as Fortune collected this seed at Huichou, in Anhui. The most northerly point ever reached by Fortune was Soochow, lat. 31° 19'.

⁷ It is frequently seen in conservatories as a handsome pot plant, with slightly glaucous, juvenile acicular foliage. Some of the branchlets, however, usually display adult leaves of the normal form, and occasionally bear cones. This juvenile form is readily propagated by cuttings, and is often considered to be a juniper.

⁸ A tree in the park at Bath stood uninjured for twenty years, and was 20 ft. high in 1880 (*Gard. Chron.* xiv. 503 (1880)). It has succumbed since. At Linton, Kent, a tree was reported to be 16 ft. high in the same year.

stand out of doors in the colder parts of Britain. There are specimens in the temperate house at Kew.

At Haldon House, Exeter, there is a fine tree, 50 ft. by 6 ft. in 1908.

At Tortworth there is a healthy tree, about 35 ft. high in 1909, the origin of which, according to Lord Ducie, is unknown.

Trees about 30 ft. to 35 ft. high have also been observed at Killerton,¹ near Exeter; at Lamellan, Heligan, and Penjerrick in Cornwall; and at Osborne, Isle of Wight.

In Ireland, a tree at Powerscourt was found by Henry to be 30 ft. by 2 ft. 7 in. in 1906. There are also trees at Kilmacurragh and at Castlemartyr, which I saw in July 1908.

(H. J. E.)

CUPRESSUS MACROCARPA, MONTEREY CYPRESS

Cupressus macrocarpa, Hartweg, in *Journ. Hort. Soc.* ii. 187 (1847); Gordon, in *Journ. Hort. Soc.* iv. 296 (1849); Lawson, *Pinet. Brit.* ii. 195, t. 32 (1884); Engelmann, in Brewer and Watson, *Bot. Califor.* ii. 113 (1880); J. D. Hooker, in *Gard. Chron.* xxiii. 176, fig. 34 (1885); Sargent, in *Garden and Forest*, vii. 241 (1894), *Silva N. Amer.* x. 103, t. 525 (1896), and *Trees N. Amer.* 77 (1905); Masters, in *Journ. Linn. Soc. (Bot.)* xxxi. 342 (1896); Kent, Veitch's *Man. Conif.* 215 (1900); Mayr, *Fremdl. Wald- u. Parkbäume*, 286 (1906); Jepson, *Flora Calif.* 60 (1909).

Cupressus Lambertiana, Carrière, *Conif.* 124 (1855), and in *Rev. Hort.* 1855, p. 232.

Cupressus Hartwegii, Carrière, in *Rev. Hort.* 1855, p. 232, and *Conif.* 168 (1867).

Cupressus guadalupensis, S. Watson, in *Proc. Am. Acad.* xiv. 300 (1879).

Cupressus torulosa, Lindley, in Paxton, *Flower Garden*, i. 167, fig. 105 (1850), and in *Flore des Serres*, vii. 192 (1851) (not Don).

Cupressus Reinwardtii, Beissner, *Nadelholzkunde*, 103 (1891).

A tree, attaining at Monterey 70 ft. in height and 20 ft. in girth. Bark, about an inch thick, irregularly divided into broad flat connected ridges, separating on the surface into narrow elongated thick persistent scales, dark reddish brown on young stems, almost white on old and exposed trunks.

Branchlet systems alternate, spreading at various angles upwards and outwards, bi-pinnate, with the pinnæ not in one plane. Ultimate branchlets tetragonal, equal-sided, ½ in. in diameter. Leaves² uniform in four rows, appressed, 1½ in. long, ovate, obtuse at the apex, convex from side to side and swollen towards the tip, occasionally with a linear longitudinal furrow.

Staminate flowers yellow, ½ in. long; stamens, six to eight, each with an ovate connective bearing four or five dark-coloured anther cells. Pistillate flowers brownish, with reflexed thin-edged scales. Cones in the first year with prominent pyramidal scales, tipped with a mucro; ripening at the end of the second year, and persistent for many years afterwards on the branchlets; when mature, on stout, reddish brown scaly stalks, ellipsoidal, 1 in. to 1½ in. long, ¾ in. broad, shining reddish brown; scales usually ten, occasionally eight, twelve, or fourteen, with a central depression, overhung by an arcuate ridge-like thin-edged process. Seeds,

¹ Cultivated as *C. sinensis*.

² The foliage when rubbed emits an agreeable odour, resembling that of lemon.

about twenty on each scale, $\frac{1}{8}$ in. long, ridged, convex or angled on the two surfaces, which are marked with minute vesicles; wings broad, with a narrow, translucent border. Cotyledons,¹ three or four.

VARIETIES

In the wild state at Monterey, this species shows no variation, except the marked difference in habit due to age, young trees being narrowly pyramidal, while old trees assume a broad and flattened crown, resembling Lebanon cedars in their general appearance.

1. Var. *guadalupensis*, Masters, in *Journ. Linn. Soc. (Bot.)* xxxi. 343 (1896).

Cupressus guadalupensis, Watson, in *Proc. Amer. Acad.* xiv. 300 (1879), and Engelm. in Brewer and Watson, *Bot. Calif.* ii. 114 (1880).

This variety, growing on Guadalupe Island, differs slightly in the glaucous leaves and globose cones. Specimens of this variety growing at Montpellier show more slender branchlets and smaller leaves than typical *C. macrocarpa*. The foliage has a bluish tint. A young plant in the Temperate House at Kew is similar, but green in colour.

Under cultivation, the Monterey tree tends to assume two distinct habits, which are, however, connected by intermediate forms. Both have been found as seedlings in beds raised from the seeds of a single tree:—

2. Var. *fastigiata*,² Masters, *loc. cit.* Branches fastigate; tree narrowly pyramidal in form.

3. Var. *Lambertiana*,³ Masters, *loc. cit.* Branches spreading, the tree resembling when old a Lebanon cedar.

The following varieties⁴ have also arisen in the seed-bed:—

4. Var. *Crippsii*, Gordon, *Pinetum*, 93 (1875). A plumose or juvenile form, with short rigid branches, and leaves not appressed, but more or less spreading and sharp-pointed. This variety was raised in Cripps' nursery at Tunbridge Wells from an imported seed.

5. Var. *lutea*, Kent, Veitch's *Man. Coniferæ*, 215 (1900). Young shoots light yellow, turning green in the second year. Earl Annesley, *Beautiful Trees*, 57 (1903), figures this variety 21 ft. high, planted eight or nine years previously; and states that it is fastigate in habit, strikes easily from cuttings, and preserves its colour.

6. Var. *variegata*.⁵ Young branchlets irregularly blotched with white.

7. Var. *farallonensis*, Masters, in *Journ. Linn. Soc. (Bot.)* xxxi. 344 (1896). A peculiar form reported to exist on the Farallones Islands, near San Francisco.

¹ Described by Hill and De Fraine, in *Ann. Bot.* xxii. 702 (1908).

² Carrière states that the fastigate form is much less hardy than the other. This must have been an accidental peculiarity in a few trees noted by him.

³ This form is said to be obtained artificially by topping off the leading shoots of ordinary seedlings. The tops, if treated as cuttings and struck, assume also the flat-headed form. Such trees, obtained from cuttings, are said to be superior, when this species is used for a hedge or wind-break. Cf. *Gard. Chron.* xxvii. 44 (1900).

⁴ In *Gard. Chron.* 1872, p. 609, Messrs. Garraway, of Bristol, are said to have raised from seed a dwarf variety, 4 in. high at nine years old.

⁵ Lemaire, *Illust. Hort.* t. 587 (1869), and *Gard. Chron.* 1869, p. 1036.

Mr. Jepson writes to me that these islands are barren rocks without any woody vegetation. The specimens ascribed to this variety appear to be a form with glaucous foliage, which arose as a sport in the California University garden, and is unknown in cultivation in England.

DISTRIBUTION

This tree has a very restricted range¹ in the wild state, as it only occurs near Monterey in California, and on the island of Guadalupe, off the coast of Lower California. At Monterey, the main grove occupies an area along the sea-coast about two miles long and 200 yards wide, from Cypress Point to the shores of Carmel Bay. A smaller grove occurs on Point Lobos, the southern boundary of the bay. In this narrow area, which extends from the sea-cliffs inland to where the cypress begins to mingle with *Pinus radiata*, the trees are of different ages and appearance. When young and crowded, they have tall stems and narrow pyramidal crowns; older trees tend to stand wide apart and have flattened crowns, with far-spreading and gnarled stout branches. Plate 295 shows how different is the appearance of mature trees at Monterey from the young specimens which we see in this country.

Many of the trees at Monterey² are exposed to constant strong winds from the sea, which often prevent the development of branches on the windward side of the trunk, and cause many of the stems to lie almost prostrate on the ground. Near Monterey this cypress, in conjunction with *Pinus radiata*, is planted on the sand-dunes down to the margin of the breakers, so that the trees are often bathed in salt water, thrown up by large waves at high tide. Frost is almost unknown at Monterey,³ yet *C. macrocarpa* is cultivated on the Pacific coast, as far north as Oregon and Washington, where the winters are cold; and Mayr states that it thrives at Tokyo, where the thermometer often falls to 14° Fahr.

On the island of Guadalupe, this cypress is almost confined to the high central plateau, where it covers an area of two or three square miles. It is said by Dr. Franceschi⁴ to be very variable both in habit and in the size, shape, and colour of the cones.

(A. H.)

CULTIVATION

This species⁵ was cultivated in the Horticultural Society's Garden at Chiswick in 1838, from seeds of unknown origin presented by Lambert. Two or three years

¹ Cf. Sargent, in *Garden and Forest*, vii. 241, fig. 41 (1894), where the trees at Cypress Point are described and figured. Two photographs of the Monterey grove are also reproduced in *Gard. Chron.* xxii. 52, figs. 17, 18 (1897). Cf. also *The Garden*, xxx. 189, cum fig. (1886).

² Hickman, in *Erythea*, iv. 195 (1896), describes a miniature forest of this species at Monterey, consisting of trees scarcely a foot in height, yet bearing clusters of ripe fruit. In all probability these trees are *C. Goveniana*.

³ The climate at Monterey is described in our article on *Pinus radiata*, p. 1081.

⁴ *Zoe*, iv. 138 (1893).

⁵ Cf. Gordon, in *Journ. Hort. Soc.* iv. 296 (1849), and A. Murray, in *Garden*, i. 330 (1872). The date is wrongly given as 1831 by Kent, in Veitch's *Manual*.

afterwards plants were noticed in Low's nursery at Clapton, which had been raised from seed received from Fischer, Director of the St. Petersburg Botanic Garden, as a new species of cypress from California. Hartweg found the tree near Monterey in 1846, and sent home a further supply of seed.

Though the natural habitat of this tree is in a region where frost rarely occurs, yet its constitution is so robust that it thrives on dry soil in many inland districts where the thermometer descends to zero, and in the warmer and moister counties of the south and west has already attained as great a height as any recorded in its native country; but it cannot be called hardy¹ everywhere, as it is on heavy or wet soil liable to be severely cut by frost in winter and spring, especially in low-lying situations.

Its power of resisting strong gales from the sea, and its partiality for a maritime climate, make it a valuable tree for planting where shelter belts are required on the coast; and its rapid growth when young, coupled with its bushy habit, are additional points in its favour for this purpose.

Lawson's *Pinetum Britannicum* gives many particulars of its comparative hardiness in various parts of the country, and quotes statistics from Palmer's tables showing that in the severe winter of 1860-61 it was killed in 57 places, injured in 24, and unhurt in 27. Of the latter all those in the north are near the sea, but even as far north as the Orkney Islands it was said by Mr. Macdonald,² gardener at Balfour Castle, to be the most valuable of all the conifers, enduring the storms and saline winds without any signs of injury.

It seems indifferent to the nature of the soil in a well-drained situation, and grows well on limestone, sand, and peat.

It produces seed freely in this country, and is easy to raise from seed, growing faster when young than any other cypress, and attaining 6 to 10 in. in the first year's growth. It transplants without much risk in the spring or early autumn, and can be raised so cheaply and rapidly that there is every inducement to plant it more freely than has hitherto been done as an ornamental tree. But its timber seems to be so coarse and knotty as compared with that of other cypresses, that it is not likely to be of any economic value.

In habit it varies very much, and it is possible that by selection of seed from trees showing an upright and fastigate habit, varieties may be fixed in cultivation, which do not produce branches so freely as those commonly seen.

This cypress is one of the most valuable species for making hedges, good examples of which may be seen at Torquay.³ It bears clipping well, grows very fast, much faster than yew, and is of a lively green colour. It is said to be rarely attacked by rabbits,⁴ but I cannot say this from personal experience.

¹ According to *Gard. Chron.* 1868, p. 152, a tree planted at Gunnersbury Park in 1854, and which had attained 61 ft. in height, was destroyed by the severe frost of the winter 1867-68. In *Gard. Chron.* 1870, p. 249, it is stated that nearly all the specimens in the Thames valley were killed in 1860. This species was badly injured at Kew by the severe frost of February 1895. Cf. *Kew Bulletin*, 1896, p. 8.

² *Journ. Roy. Hort. Soc.* xiv. 526 (1892).

³ Cf. *Gard. Chron.* xxvi. 342 (1899). A hedge of this species, 10 ft. high and 400 yds. long, at Lofthouse, Torquay, which was planted in 1892, is illustrated in *The Garden*, lxvii. 358 (1905).

⁴ A. Gooden, in *Gard. Chron.* xxvi. 466 (1904), reports that four bullocks were killed at Burton Park, Petworth, it was supposed, through eating *C. macrocarpa*, but this is unconfirmed.

REMARKABLE TREES

Perhaps the largest tree¹ that I know of in England grows on an open hillside at Lamorran, on Lord Falmouth's property in Cornwall, and this in 1905 I found to be 86 ft. by 12½ ft. At the same place in a wilderness, which was once the garden of the late Hon. Rev. T. Boscawen, there are several trees almost if not quite as tall, with boles 8 to 9 ft. in girth, clear of branches up to about 20 ft.

At Enys, the seat of J. D. Enys, Esq., in the same county, there is a tree 80 ft. by 11 ft. 5 in., which he considered the finest in Cornwall; and at Carclew there is another 84 ft. by 11½ ft., which, however, has increased but little since 1891, when it was reported under the name of *C. Lambertiana* as 82 ft. high, and then the largest in England.² At Luscombe Castle there is a fine tree which Mr. Seaborne measured as 91 ft. by 14 ft. 2 in. in 1909. At Penrose, near Helston, a tree planted thirty-five years previously measured³ in 1894 80 ft. in height and 19 ft. in girth at 4 ft. from the ground, dividing above into six stems.

At Beauport, Sir A. Lamb showed me in 1905 a number of fine trees varying extremely in habit, of which Plate 296 shows one growing near his Araucaria grove, which spreads very widely and branches near the ground. At 3 ft. it is no less than 17 ft. in girth and about 64 ft. high. Another in an open part of the park is about 65 ft. by 14 ft., and of such an extremely dense bushy habit that a litter of fox cubs were bred in it at some distance from the ground. A third tree below the stables has a narrow fastigate habit, quite different from the others, and measures about 70 ft. by 9½ ft.

At Coolhurst near Horsham there is a fine timber-like tree about 70 ft. high by only 5 ft. in girth. Sir H. Maxwell has sent us a photograph of a tree at Wakehurst Place, Haywards Heath, which measured in 1907 70 ft. high and 9 ft. 8 in. in girth at 3 ft. from the ground.

At Brickendon Grange, Herts, which is 365 ft. above sea-level, with considerable cold in winter, yet little spring frost, there are numerous trees in an avenue averaging 65 ft. high and 5 ft. 2 in. in girth. Mr. Trotter, who presented a plank to the museum at Cambridge, considers the timber excellent, being very durable and strong, suitable for making wheelbarrows, carts, and rafters and beams in buildings; used for rails and posts in a fence, it has remained perfectly sound for fifteen years.

At Youngsbury, Ware, Herts, a tree planted in 1866 was 67 ft. by 8½ ft. in 1907. At Cobham, Kent, a tree measured in 1906 71 ft. by 9 ft. At Wexham Place, Stoke Poges, Bucks, there is a remarkable narrowly pyramidal tree, closely resembling the fastigate Mediterranean cypress in habit, which Mr. R. Woodward found to be 71 ft. in height and 5 ft. in girth.

At the Butlands, Burghley Park, Stamford, there is a fine specimen growing in

¹ Mr. H. Clinton-Baker made this tree 88 ft. by 13 ft. in 1909.

² *Journ. Roy. Hort. Soc.* xiv. 488 (1892).

³ *Gard. Chron.* xvi. 658 (1894).

a plantation, 75 ft. in height and 12 ft. 7 in. in girth at 3 ft. up, dividing above into three stems. At Wimpole, Cambridgeshire, a tree measured 68 ft. by 7 ft. 8 in. in 1909. At Fulmodestone, Norfolk, a tree planted in 1861 measured in 1903, according to Sir Hugh Beevor, 68 ft. by 6½ ft. At Orwell Park, on the coast of Suffolk, *C. macrocarpa* grows well, and is quite hardy, several trees being about 70 ft. high. In Northumberland, at Twizell, there is a good-sized tree of spreading habit.

Of the flat-topped and spreading variety *Lambertiana*, the best I have seen in England, is on the lawn at Cuffnells, near Lyndhurst, which in 1907 measured 75 ft. by 10 ft.; but this is not so typical as trees of much smaller size at Killerton, and at Coldrenick in Cornwall, the latter measuring in 1908 about 55 ft. by 7 ft., whilst a tree of the fastigate type growing close to it was about 70 ft. by 8 ft. In *Pinetum Britannicum* there is a coloured plate of a tree of this type, planted at Osborne in August 1846 by the Prince Consort, which in 1865 was of very regular and perfect shape, and 40 ft. high. Col. Kilkelly informs me that it now measures 78 ft., with a girth of 16 ft. at 3 ft. from the ground. It is perhaps the finest tree of its type in England. (Plate 298.)

In Wales this tree is quite at home all round the coast, the largest I have seen being a fine and spreading tree at Bodorgan, in Anglesea, which in 1906 was about 80 ft. by 11 ft. 4 in. At Stackpole Court there is a tree 72 ft. by 8½ ft.; but I have not noticed large trees anywhere in the interior of Wales, or in the English counties on the borders of Wales, where most conifers grow so well.

In Scotland it seems to thrive best in the south-west. The most remarkable tree I have seen is in the park at Poltalloch, which has the habit of a spreading Lebanon cedar, with small but very persistent cones. It measured in 1906 about 50 ft. by 11 ft. 9 in. Mr. Austin Mackenzie reports a considerable number of specimens at Carradale, Argyllshire, mostly flat-topped and like a Lebanon cedar in habit. The largest in 1906 was 50 ft. high and 9½ ft. in girth.

In Bute, on the Marquis of Bute's property, Mr. Kay reported in 1892 a splendid vigorous tree 57 ft. by 5 ft. 8 in., but I did not see it when I visited this place in 1906.

At Castle Kennedy large numbers were planted, and Mr. Fowler's account of this species in Lawson's *Pinetum Britannicum*, vol. ii. p. 197, is worth reading; but though it grows vigorously and has ripened seeds for many years, the soil is apparently too poor, or the exposure too great here to allow the tree to attain large dimensions, as I saw none worth measuring in 1906.

It is absent from all the Perthshire lists sent to the Conifer Conference, except that from Keir, where a tree was reported as 47 ft. by 4 ft. in 1891; and I saw a tree at Murthly which was nearly killed by the severe winter of 1895-96 when the thermometer went below zero. Though it survived some severe winters at Durriss and Gordon Castle, we have seen no tree of any size in other parts of Scotland.

In Ireland the Monterey cypress is at home in most parts, and there are numerous natural seedlings at Derreen in Kerry.

At Castlemartyr, Co. Cork, a tree measured in 1907 70 ft. by 9 ft. The finest tree, however, appears to be growing in a garden between Wicklow and Rathnew,

which Mr. A. C. Forbes found in 1908 to be 85 ft. in height and 14 ft. 3 in. in girth. At Hamwood, Co. Meath, there is also a splendid specimen, with a tall upright clean stem, which was planted in 1844, and measured in 1903 85 ft. by 10½ ft. There are fine specimens at Castlewellan,¹ Powerscourt, and Fota.

At Tykillen, Co. Wexford, the seat of Captain J. Walker, there is a large spreading tree (Plate 297) about 60 ft. by 11 ft., the branches covering an area 74 paces round; and at Adare, Co. Limerick, the seat of the Earl of Dunraven, there is another very densely branched and spreading tree of about the same dimensions. Mr. Bowles, the gardener here, told me that its seedlings did not preserve the habit of the parent tree, a circumstance which had been previously referred to in *Pinetum Britannicum*, ii. 196. (H. J. E.)

CUPRESSUS GOVENIANA, GOWEN'S CYPRESS

Cupressus Goveniana,² Gordon, in *Journ. Hort. Soc.* iv. 295, cum fig. (1849); Engelmann, in Brewer and Watson, *Bot. Califor.* ii. 114 (1880); Masters, in *Journ. Linn. Soc. (Bot.)* xxxi. 346 (1896); Sargent, *Silva N. Amer.* x. 107, t. 527 (1896), and *Trees N. Amer.* 79 (1905); Kent, Veitch's *Man. Conif.* 204 (1900).

Cupressus californica, Carrière, *Conif.* 127 (1855).

Cupressus attenuata, Gordon, *Pinetum*, 57 (1858).

Cupressus Sargentii, Jepson, *Flora Calif.* 61 (1909).

A tree attaining in California a maximum of 50 ft. in height and 2 ft. in diameter, usually considerably smaller, and often a small shrub. Bark about an inch thick, dark reddish brown, irregularly divided into narrow ridges, covered with thin persistent oblong scales. Small branches reddish brown, terete, and giving off alternate branchlet systems, which are tri-pinnate, short, with the pinnæ at varying angles and not in one plane; ultimate branchlets tetragonal, equal-sided, ¼ in. in diameter. Leaves in four equal ranks, ¼ to ⅓ in. long, ovate, appressed, acute and often mucronate at the apex, convex on the back, which is occasionally marked with a longitudinal depression.

Staminate flowers, ⅓ in. long, yellow. Cones ripening in the second season, and persistent for several years, on long stout stalks, globose, ½ to ¾ in. in diameter, dark purplish brown, shining; scales usually eight, occasionally six or ten, smooth, projecting and not depressed in the centre, which bears a prominent triangular, mucronate or rounded process. Seeds, ten to twelve on each scale, variable in size and colour, either (a) large, ⅓ to ⅔ in., brown, shining, marked with resin-vesicles on both sides, and with very narrow wings; or (b) small, ⅓ to ⅔ in., blackish.

Both in wild and cultivated specimens two forms of this species are readily distinguished: (a) the typical form described above, characterised by coarse

¹ Figured in *Flora and Sylva*, ii. 215 (1904), and in Earl Annesley, *Beautiful Trees*, 42 (1903).

² *Cupressus cornuta*, Carrière, in *Rev. Hort.* 1866, p. 250, fig. 32, with very irregular fruit, the upper scales of which bear long thick conical processes, described from a plant cultivated in the garden of M. Denis at Hyères, was considered by Carrière, *Conif.* 171 (1867), to be an abnormal variety of *C. goveniana*. We have not seen this plant.

branchlets and short branchlet systems, which give a rigid habit to the tree; and (b) the following variety:—

1. Var. *attenuata*, Carrière, *Conif.* 172 (1867).

Cupressus attenuata,¹ Gordon, *Pinetum*, 57 (1858).

Characterised by looser branching, with longer branchlet systems, and very slender ultimate branchlets, about $\frac{3}{16}$ in. in diameter. Leaves $\frac{1}{25}$ in., swollen towards the apex, which is tipped with a minute mucro. Two kinds of seed are produced, as in the typical form. This variety is said by Gordon to have been introduced by French collectors; but as seen in cultivation, it appears to be a seminal variety, and is commoner than the type.

2. Var. *pendula*.

Cupressus californica, Carrière, *Conif.* 127 (1855).

A shrub, pendulous in habit, with long and slender drooping branchlet systems, some of the branchlets being covered with spreading sharp-pointed leaves. This appears to be a transition form between the seedling and adult stages. A plant of this variety, cultivated under the name *C. californica*, Carrière, is growing in M. Allard's arboretum at Angers; and another specimen occurs at Kilmacurragh in Co. Wicklow.

The following is considered by Sargent to be a distinct species, but, so far as we can judge, the variation in the seed is sporadic, and depends upon unknown conditions, which should be studied in the field.

3. Var. *pygmaea*, Lemmon, *W. Amer. Cone-bearers*, 77 (1905).

Cupressus pygmaea, Sargent, in *Bot. Gaz.* xxxi. 239 (1901), *Silva N. Amer.* xiv. 95, t. 740 (1902), and *Trees N. Amer.* 79 (1905); Eastwood, *Trees of California*, 18 (1905).

Cupressus Goveniana, Jepson, *Flora Calif.* 60 (1909) (not Gordon).

A name given to trees bearing cones with small blackish seeds. This variety is prevalent near Monterey; and occupies a narrow belt in Mendocino County, California, beginning three-quarters of a mile from the ocean, and extending inland for about four miles from Ten Mile Run in the north to Navarro in the south. It is said to remain shrubby as a rule, producing fruit when only one or two feet high,² and grows commonly on poor soil, consisting of yellow clay covered with sand or peat; but it is admitted by Miss Eastwood to attain on good soil 30 or 40 ft. in height at fifty years old.

The typical form of *C. Goveniana* is rare and local,—apparently uncommon in the coast region of California, though it was found by Hartweg³ at Monterey,—and usually grows on dry mountain slopes, ascending in the cañons of the mountain ranges of the central part of the state to nearly 3000 ft. Jepson,⁴ who says it is a

¹ Erroneously identified with *C. Lawsoniana* by Masters in *Journ. Linn. Soc. (Bot.)* xxxi. 353 (1896).

² Cf. p. 1167, note 2.

³ Hartweg's specimen, No. 1971, in the Kew Herbarium, collected at Monterey, has large brown seeds, and is the type on which Gordon, who states that the seeds are brown, founded his description. Jepson, in *Flora California*, 60, 61 (1909) erroneously considers the form with small black seeds to be typical *C. Goveniana*; and on this account invents a new name, *C. Sargentii*, for the true *C. Goveniana* with large brown seeds. Both forms occur at Monterey, as Hartweg's specimen, No. 1979, preserved at the Cambridge Herbarium, was collected there and bears cones with small black seeds.

⁴ *Flora W. Mid. Calif.* 25 (1901).

shrub or small tree, 6 to 15 ft. high, gives as localities the Mayacamas Range, Mt. Tamalpais in Marin County, Cedar Mountain in Alameda County, and one or two stations in the Santa Cruz and Santa Lucia Mountains. According to Mayr,¹ it becomes a mere shrub on hot rocky precipices, but attains 50 ft. high on the banks of streams.

(A. H.)

This species was discovered² in 1846, growing near Monterey in company with *Pinus muricata*, by Hartweg, who sent home seeds to the Horticultural Society, from which plants were raised in the Chiswick Garden. It was named in compliment to J. R. Gowen, secretary of this Society at the time. It appears to be short-lived in this country, and has never become a popular or common tree; and is not now often to be found in nurseries.

The finest specimens we have seen are both on the property of J. B. Fortescue, Esq., one at Boconnoc in Cornwall, which measures 43 ft. high by 6 ft. 8 in. in girth, nearly as large as it grows in California; the other, at Dropmore (Plate 299), is 36 ft. by 5 ft. 6 in. Both of these are healthy and produce cones freely. At Luscombe Castle there is a good tree about 50 ft. by 4 ft. 4 in.

At Pencarrow, Cornwall, Mr. A. B. Jackson in 1909 measured a tree 38 ft. high and 9½ ft. in girth. Another at Heligan is 37 ft. by 3 ft. 4 in.

At Barton, near Bury St. Edmunds, Henry measured a tree in 1905 38 ft. by 2 ft. 6 in., which, according to Bunbury,³ was planted in 1862. It is now decaying. A healthy tree at Melbury, Dorchester, is 47 ft. by 4 ft.

A tree at Tortworth is 40 ft. high and 5 ft. 1 in. in girth. The Earl of Ducie informs us that the date of planting is uncertain, but it was recorded as 12½ ft. high in 1855. It seems to be failing, but may live a few years longer. Several plants have been raised from its seed. It withstood without injury the severe frosts of 1860 and 1895.

At Eastnor Castle a tree measured in 1909 37½ ft. high, girthing at 2 ft. from the ground 3 ft. 2 in. A tree in the Victoria Park, Bath, measured in 1909 46 ft. by 4 ft. 8 in. Mr. A. B. Jackson reports three healthy trees at Ponfield, Herts. A tree at Coldhayes, near East Liss, Hants, was measured by Mr. Gamble as 36 ft. by 6 ft. 2 in. at the base.

In Ireland, the best specimen is at Castlemartyr, which Henry found to be 48 ft. by 4 ft. 11 in. in 1907. Another at Fota measured, in 1903, 40 ft. by 4 ft. 4 in. A large bushy tree with many stems from the ground at Woodstock, Kilkenny, was about 40 ft. high in 1909. Webster⁴ mentions one at Churchill, Armagh, nearly 40 ft. high, growing on moist loam in an exposed situation.⁵

(H. J. E.)

¹ *Waldungen Nordamerika*, 272 (1890).

² Cf. Gordon, in *Journ. Hort. Soc.* iv. 295 (1849).

³ *Arboretum Notes*, 156. The tree at Barton is var. *pygmaea*.

⁴ In *Gard. Chron.* xx. 624 (1896). Cf. also Webster, *Hardy Conif. Trees*, 38 (1896).

⁵ While these pages were going finally through the press, I received specimens from Mr. Jepson, which shew that the trees of this species growing in Marin County and on Mt. Tamalpais bear larger cones than the type, with large reddish brown glaucous seeds. This form may be called var. *Sargentii*. Mr. Jepson's specimens shew various intermediate forms, one at least of which (from Monterey) is very probably a hybrid with *C. macrocarpa*.—(A. H.)

CUPRESSUS MACNABIANA, MACNAB'S CYPRESS

Cupressus Macnabiana, Murray, in *Edin. New Phil. Journ.* i. 293, t. 11 (1855); Lindley, in *Gard. Chron.* 420 (1855); Carrière, in *Rev. Hort.* 1870, p. 155; T. Moore, in *Florist and Pomologist*, 88, cum fig. (1874); Engelmann, in Brewer and Watson, *Bot. Califor.* ii. 114 (1880); Masters, in *Gard. Chron.* ix. 403, fig. 90 (1891), and in *Journ. Linn. Soc. (Bot.)* xxxi. 347 (1896); Sargent, *Silva N. Amer.* x. 109, t. 528 (1896), and *Trees N. Amer.* 80 (1905); Kent, Veitch's *Man. Conif.* 213 (1900); Jepson, *Flora W. Mid. California*, 25 (1901), and *Flora Calif.* 61 (1909); Eastwood, *Trees of California*, 18 (1905).
Cupressus nivalis, Lindley, in *Gard. Chron.* 1855, p. 421.
Cupressus glandulosa, Hooker, ex Gordon, *Pinetum*, 64 (1858).

Usually a shrub with several stems, 5 to 10 ft. in height, rarely a small wide-branching tree, attaining 40 ft. in height and 4 ft. in girth. Bark thin, reddish brown, separating on the surface into long thin persistent scales. Branches of the fourth and succeeding years smooth and purplish brown. Branchlet systems arising irregularly and spreading at varying angles, tri-pinnate, with the pinnæ not disposed in one plane. Ultimate branchlets short, tetragonal, compressed, $\frac{1}{20}$ to $\frac{1}{24}$ in. wide, and $\frac{1}{40}$ in. thick. Leaves $\frac{1}{20}$ in. long, appressed, ovate, thick, obtuse; lateral ranks conduplicate; facial ranks convex from side to side and somewhat flattened; all usually marked on the back with a circular glandular pit, often exuding resin. In native specimens, the foliage on the back and front is often covered with white streaks, and is said to be very fragrant.¹

Cones, ripening in the second year, erect on short stout stalks, globose, $\frac{1}{2}$ to $\frac{3}{4}$ in. in diameter, reddish brown, more or less covered with a glaucous bloom; scales usually six, rarely eight, with prominent processes, those on the lower scales thin and recurved, those on the upper scales thickened, conical, more or less incurved. Seeds numerous, ten to twelve on each scale, dark brown, $\frac{1}{8}$ in. long, with resin-vesicles; wings very narrow.

C. Bakerii, Jepson, *Fl. Calif.* 61 (1909), of which I have seen no specimens, appears to be a variety with small and very glaucous cones, the umbos of which are short, conical, and not incurved. It is said to be a small tree growing on lava beds in south-eastern Siskiyou and south-western Modoc counties.

C. Macnabiana is a native of California and is common in the hill country of eastern Napa County, from Samuel's Springs to Pope Valley, and extends northwards through Lake County to Red Mountain on the east side of Ukiah Valley in Mendocino County. It also occurs in Trinity County between Shasta and Whiskeytown. Carl Purdy² gives an interesting account of this species on Red Mountain, on the eastern slope of which it forms a pure forest about half a mile square, composed of old gnarled twisted trees, 12 to 20 ft. high, and covered with

¹ Miss Eastwood says that the fresh foliage has a delightful fragrance, somewhat like that of sandalwood with a flavour of pine-apple. Carrière, in *Rev. Hort.* 1870, p. 155, compares the odour to that of *pomme de Reimelle*, and says that branches cut and put in water purify the air of a room.

² In *Garden and Forest*, ix. 233 (1896), reproduced in *Gard. Chron.* xx. 65 (1896).

moss; while on the western side there is a dense thicket of cypress bushes, 6 to 8 ft. high in exposed situations and 15 ft. high in the gullies. Seedlings were observed in areas swept by fire; and a few seeds carried down the stream to the gravelly flats in the valley had produced a grove of handsome pyramidal specimens. Miss Eastwood¹ says that this cypress is more partial to the banks of streams than to dry slopes, and is often associated with *C. Goveniana*, though no hybrids have been observed. She mentions trees 30 to 40 ft. high between Hopland and Highland Springs, very unsymmetrical and loosely branching in habit. M'Lean found it on the road from Callistoga to the Etna mines, and Dr. Parry collected it at Chico, in Butte County.

This species was discovered by Jeffrey² in the Sierra Nevada in 1853, and was found soon afterwards in 1854 by W. Murray.³ Lobb sent seeds in the latter year to Messrs. Veitch, who raised young plants,⁴ remarkable, according to Lindley, for their glaucous green foliage and deep rich brown branchlets. They appear⁵ to have borne without injury the severe winter of 1860. This cypress appears to be short-lived,⁶ and having been neglected for many years, has almost gone out of cultivation, the best specimen we know being one at Highnam, 30 ft. high, forking near the ground, with the main stem 2 ft. 8 in. in girth at 18 in. from the base. This was bearing young and old cones and staminate flowers in February, 1910. A slender tree⁷ in Kew Gardens, with wide spreading branches is about 20 ft. high; and another⁸ at Brickendon Grange, Herts, 25 ft. high, and bearing fruit in 1909, is said to have been planted in 1860. There is also a small tree 15 ft. high at Bicton. Another about 8 ft. high, at Nymans, Handcross, was badly injured by frost last winter.

Elwes collected a specimen bearing fruit at Angers, France, in September, 1907. (A. H.)

¹ In *Zoe*, v. 11 (1900).

² Jeffrey's account of his specimen, taken from the advice note of his packet of plants sent in 1853, is: "Juniperus, No. 1481, Sierra Nevada mountains, growing in barren sandy places. Tree 15 ft. high, 1 ft. diameter, Oct. 1st, 1853."

³ In *Gard. Chron.* 1855, p. 420, the locality where Murray found the plant is said to be, "In California, about lat. 41°, at 5000 ft. elevation."

⁴ Lindley had described these young plants as *C. nivalis*, but was anticipated in his publication of this name by A. Murray's *C. Macnabiana*.

⁵ *Gard. Chron.* 1860, pp. 336, 362.

⁶ Those in the Botanic Gardens at Glasnevin and Edinburgh died many years ago. In the Kew herbarium there is a specimen dated 1878, from a tree 10 ft. high, growing at the upper end of the lake at Tortworth Court; but it is no longer living.

⁷ Obtained from Smith of Worcester in 1881.

⁸ Growing at the margin of a plantation. There were formerly two much finer specimens here, growing on the lawn, which were removed some years ago.

CUPRESSUS LUSITANICA, MEXICAN CYPRESS

- Cupressus sinensis*,² Lee, ex Gordon, *Pinetum*, 63 (1858).
- Cupressus mexicana*,³ Koch, *Dendrologie*, ii. pt. 2, 159 (1873).

A tree, attaining in Mexico 100 ft. in height and 12 ft. in girth. Bark reddish brown, fissuring longitudinally into long thin brown strips. Branches widely spreading with pendulous branchlets. Branchlet systems alternate, not distichous, spreading at varying angles, bi-pinnate, with the pinnæ not disposed in one plane. Ultimate branchlets tetragonal, slightly compressed, $\frac{1}{16}$ in. wide, $\frac{1}{20}$ in. thick. Leaves nearly uniform in four ranks, $\frac{1}{16}$ in. long, appressed, but slightly free at the tips, ovate-acuminate, often mucronate, convex from side to side, occasionally marked with a depressed circular pit.

Staminate flowers yellowish, $\frac{1}{4}$ in. long; stamens about 20. Cones in the first year covered with a glaucous bloom, with the points of the scales spreading and reflexed; in the second year ripening and letting out the seeds, and remaining on the branches for about a year afterwards, globose, about $\frac{1}{2}$ in. in diameter, on straight long stalks, dark reddish brown, but covered with a glaucous bloom, whitish and thick in trees growing in Mexico, France, and Portugal, faint or absent in England and Ireland; scales eight, each with a central, usually prominent, triangular and reflexed process. Seeds eight to ten on each scale, $\frac{1}{8}$ in. long, brown, with conspicuous resin-vesicles; wing narrow with a translucent border.

¹ The plant described by Forbes in 1839 as *C. Coulteri* was raised from seeds taken from a cone, said to have been fifteen years old, in Coulter's herbarium. Loudon, *Encycl. Trees*, 1077 (1842) states that this plant was raised at Glasnevin in 1837; but as Coulter did not arrive in Mexico till 1834 there must be some error in the age ascribed to the seeds. A specimen in the Kew herbarium, dated 1878, from the tree at Glasnevin is *C. lusitanica*, and this tree is probably one of the rare Mexican cypresses which was destroyed by a storm in 1878, as Mr. F. W. Moore informs me. Further storms in 1883 and 1893 swept away the remaining Mexican trees at Glasnevin. Masters, in *Journ. Linn. Soc. (Bot.)* xxxi. 348 (1896) is in error in identifying the specimen of *C. Coulteri*, preserved at Kew, with *C. Macnabiana*.

² Specimens cultivated under this name at Tokai, near Cape Town, are *C. lusitanica*.

³ A tree cultivated under this name at Glasnevin, which was destroyed in 1878, is *C. lusitanica*, according to a branch preserved in the Kew herbarium.

VARIETIES

A careful examination of all the native material in the Kew herbarium and in Lindley's collection at Cambridge, together with a study of the numerous examples in cultivation in England, Ireland, France, Italy, and Portugal, show that there is only one species of *Cupressus* in Mexico, comprising two main forms, distinguishable by their habit of growth, and resembling in this respect *C. sempervirens* and *C. macrocarpa*. Pringle writes to me as follows: "After a score of years of vain endeavour to distinguish several species of *Cupressus* on the mountains of Mexico, it is gratifying to learn that you think it possible that there exists only one variable species there. The Mexican cypress, so far as I have seen, varies no more in all its characters than any one of the admitted species of Mexican pines. Consider its distribution through sixteen degrees of latitude and from 4000 to 10,000 ft. altitude, and its growth in widely different soils, from the richest humus to the poorest volcanic soil, infinitely varying conditions which tell effectively on the character of the species."

1. The typical form, which has been described above, and which is identical in every particular with the "cedar of Goa," long cultivated in Spain and Portugal, is distinguished by its wide-spreading branches and pendulous branchlets, the ultimate ramifications of which arise at varying angles and are not disposed in one plane. The other form, usually cultivated as *C. Knightiana*, is distinguished as follows:—

2. Var. *Benthami*, Carrière, *Conif.* 155 (1867).

Cupressus Benthami, Endlicher, *Syn. Conif.* 59 (1847); Hemsley, in *Biol. Cent. Amer.* iii. 183 (1883); Masters, in *Journ. Linn. Soc. (Bot.)* xxxi. 338 (1896); Kent, *Veitch's Man. Conif.* 201 (1900).

Cupressus thurifera, Schlechtendal, in *Linnaea*, xii. 493 (1838) (not Humboldt, Bonpland, and Kunth); Bentham, *Plant. Hartweg.* 57 (1840).

Cupressus Knightiana, Knight and Perry, *Syn. Conif.* 20 (1850); Carrière, *Conif.* i. 158 (1867).

Cupressus Udeana, Carrière, *Conif.* 129 (1855) (not Gordon).

Cupressus elegans,¹ Low, ex Koch, *Dendrologie*, ii. pt. 2, p. 156 (1873).

This variety usually forms a narrow pyramidal tree, with very regular branches. Branchlet systems and their pinnæ disposed in one plane. Ultimate branchlets more flattened and compressed than in the type, $\frac{1}{8}$ in. wide, $\frac{1}{32}$ in. thick. Leaves, lateral pair narrow, conduplicate, with acuminate free mucronate tips; facial pair flattened, ovate-acuminate; all usually marked with a central circular glandular depression. Bark, cones, and seeds, as in the type.

This variety occurs in the wild state in Mexico, and is represented in the Kew herbarium by specimens collected by Hartweg at Banco, by Bourgeau at Orizaba, and by Parry and Palmer at 6000 to 8000 ft. near San Luis Potosi, and is doubtless sporadic throughout the whole range of the species.

3. Var. *Skinneri*.

Cupressus Skinneri,² Carrière, *Conif.* 128 (1855).

Cupressus excelsa, Scott, ex Carrière, *Conif.* 128 (1855).

¹ This is referred to as a garden name for *C. Knightiana*, in Carrière, *Conif.* 127 (1855).

² Skinner was one of the partners in the firm of Klee, Skinner, and Co., in Guatemala, and was much interested in natural history. Cf. Koch, *Dendrologie*, ii. pt. 2, 157 (1873).

This cypress which occurs in Guatemala, where it was collected¹ by Donnell-Smith at 5000 ft. altitude, does not differ from var. *Benthani* in botanical characters, but is perhaps more tender in cultivation. The late Lord Annesley raised some plants from seeds imported from Guatemala, one of which succumbed at Castlewellan to the frost of April 1908. Another plant given to Canon Ellacombe in 1897, is, however, thriving at Bitton and has attained 14 ft. in height.

4. Var. *glauca*. Specimens with very bluish glaucous foliage from Monserrat in Portugal may provisionally be distinguished by this varietal name. The leaves show usually the dorsal resin-gland, which is characteristic of *C. arizonica*, and afford evidence that the latter species is only a geographical form of *C. lusitanica*.

DISTRIBUTION

This species is widely distributed in Mexico,² and extends into the high mountains of Guatemala. According to Pringle it is found at altitudes between 4000 and 10,000 ft., usually growing in the neighbourhood of mountain streams, and on moist slopes. It rarely forms a forest to the exclusion of other species, and even when crowded generally branches from near the ground. Pringle speaks, however, of a small wood straggling along brooks for a mile or more on the mountains overlooking the valley of Mexico on the south, the trees showing great variation in foliage and mode of branching. This species attains its largest size, 2 to 4 ft. in diameter, in damp volcanic soil on the plains at the base of the mountains, as near the city of Mexico. It is also generally planted in the towns of the southern tablelands. (A. H.)

The only place where I remember to have seen this beautiful tree in Mexico was in a grove of planted trees in the so-called "Sacro monte" at Amecameca, a village on the lower slopes of the great volcano of Popocatepetl, at an elevation of nearly 8000 ft. Here it was a picturesque tree with buttressed trunks 5 or 6 feet in diameter, and clothed with pendulous branches, which in many places were covered with *Tillandsia* and other epiphytes. Many of the trees were dying at the tops and seemed of great age. A good illustration of these trees is given under the name *C. Benthani* by Karsten and Schenck.³ The vegetation and climate of this region is subtropical, and, though very dry at the season when I was there, has a long rainy season, and, as far as I could learn, little frost or snow.

HISTORY

So far as I know, no account has been written in English of the forest of Bussaco, in Portugal, which is celebrated as the home of the tree called *Cupressus lusitanica*, Miller, by botanists, and popularly known as the cypress or cedar of Goa. An attempt to decide the origin of this tree was made by the late Dr.

¹ Heyde and Lux also gathered specimens of *C. lusitanica* in the Santa Rosa department of Guatemala at 4000 feet altitude in 1892.

² Hartweg collected both the typical form and var. *Benthani* in Mexico in 1839.

³ *Vegetationsbilder*, ii. t. 16 (1905).

Masters in the *Journal of the Royal Horticultural Society*, xvii. 1-11 (1894); but I cannot accept his conclusion that *C. sempervirens*, *C. torulosa*, and *C. lusitanica* may have all arisen from a common stock, and at a relatively not very remote period. All the trees that I have seen of *C. sempervirens* in England, Portugal, and other countries are of a very different habit, at all stages and under all conditions of growth. The same applies to *C. torulosa*.

Dr. Goeze's statement in his letter to Dr. Masters that the old monks' chronicles gave the Azores¹ as the native country of the tree is not supported by any historical or botanical evidence. I prefer to believe that it is of Mexican origin, as a careful comparison of numerous Portuguese and Irish specimens with native specimens of *Cupressus Lindleyi* from Mexico shows that Carrière and Koch² were correct in identifying *C. lusitanica* with that species. The tree may as easily have been introduced by Spanish friars³ from Mexico as by Portuguese monks from Goa,⁴ though we cannot now discover by whom and when; and as the real origin seems lost in antiquity, and the tree has for at least three centuries been naturalised in Portugal, the name of *C. lusitanica*⁵ is not inappropriate.

I visited Portugal in April 1909, mainly with the object of studying on the spot the cypress and the oaks of Portugal, which are extremely variable and interesting. Professor Henriques, of Coimbra, was good enough to accompany me to Bussaco, which is reached by a short railway journey from Coimbra to Luzo; whence a drive of two miles brings one through the village to the entrance of the Royal domain, which was formerly the property of a Trappist monastery; on the site of which a large and beautiful hotel has been erected. The forest is surrounded by a wall about three miles long, and appears to be a virgin forest in which have been planted at various times, but mainly forty to fifty years ago by Rodrigo de Moraes Soares, an immense variety of exotic trees. The old monks appear to have planted the cypresses at first round the monastery, and later at many points

¹ In the Azores large logs of a coniferous timber are frequently found deeply buried under volcanic debris. A block of this wood, presented to the Kew Museum by Dr. Goeze, and supposed by Dr. Masters to be *Cupressus sempervirens* or *C. lusitanica*, has recently been examined at the Jodrell laboratory by Mr. Boodle, and proves to be that of a juniper, and is probably *Juniperus brevifolia*, Parlatores, a tree still common on the Azores. There are not any grounds for supposing that *C. lusitanica* ever inhabited the Azores. Cf. *Gard. Chron.* 1867, p. 929; Kent, Veitch's *Man. Conif.* 180 (1900); and Trelease, *Missouri Bot. Gard. Rep.* viii. 169 (1897).—(A. H.)

² Koch, *Dendrologie*, ii. pt. 2, p. 155 (1873), who describes the Mexican native species under the name *C. Coulteri*, Forbes, and *C. lusitanica* under the name *C. pendula*, L'Héritier, states that the former is probably the wild form of the latter, and adds that it is often impossible to distinguish one from the other.—(A. H.)

³ *C. lusitanica* is common in cultivation in southern Spain, and there is a specimen at Kew labelled Los Martyres Monastery, Granada City. According to Willkomm and Lange, *Prod. Fl. Hispan.* i. 21 (1861), Guira found it apparently wild in Torre de Guil, at the base of the Sierra de Carrascoy, in Murcia.—(A. H.)

⁴ The tree is unknown at Goa, and there is not a single specimen from any part of India in the Kew herbarium. Dalzell and Gibson, *Bombay Flora, Suppl.* 83 (1861), say: "Now common in gardens, native and European, does not succeed below the Ghauts, and above only where the soil is deep and rich. The healthiest appears to be those planted in front of Sir Jamsetjee's bungalow in Poona, but they are young and have their trials to go through." Gammie wrote from Poona, 17th July 1903: "Said never to fruit in the Bombay Presidency. This is the result of repeated inquiries on my part. It is by no means common in Poona now, as many plants were killed in the drought of 1899-1900." Brandis, *Forest Flora*, 534, and Hooker, *Fl. Brit. India*, v. 645, are apparently in error in stating that the tree is extensively cultivated in the western Ghats. No one, in any case, has ever seen old trees in India.

Hutchins, in *Gard. Chron.* xxxvi. 275 (1904) and xxxvii. 219 (1905), reports that he cultivated *C. lusitanica*, *C. sinensis*, and *C. torulosa*, so-called, at Tokai, near Cape Town, and concluded that the two former were cultivated varieties of *C. torulosa*. Hutchins kindly sent us copious specimens of the three forms, which he had in cultivation, and they are all *C. lusitanica*. He had not obtained true plants of *C. torulosa*.—(A. H.)

⁵ *C. lusitanica* is the oldest name of the species, and is adopted by us on that account.—(A. H.)

along the roads and paths which lead to the nine entrances to the forest, but always singly or in lines, apparently for ornament alone. The oldest of these trees are still, with one or two exceptions, quite sound, and although difficult to measure on account of their being crowded by other trees, I was able to make the following measurements:—

1. A tree near the hotel, just below the road leading to the Coimbra gate, about 110 ft. by 11 ft. 2 in., with a clean bole about 40 ft. high.
2. A tree which M. Lacerda, the director of the domain, considers the largest of all, is 85 to 90 ft. high, with a bole of 30 ft., 15 ft. 10 in. in girth, and situated just below the small chapel of San José.
3. A little above this is a tree, perhaps 100 ft. high or possibly more, with a straight clean bole 66 ft. by 12 ft. 8 in.
4. Above the avenue of Mosteiro a very tall fine tree, possibly taller than No. 1, but I could not measure it.
5. A little way down towards the water-staircase a very large hollow tree, the only one which seems to be decayed, measured 15 ft. 10 in. in girth.

There is much variation in the form and habit of this cypress according to the situation; it seems capable of growing in fairly dense shade, and when crowded by other trees cleans its trunk well. Some fine young trees, said to be about fifty years old, in the deep moist hollow called the Valle dos Abietos, measured about 90 ft. high by 4 to 5 ft. in girth, and were clean to half their height. I have no doubt that these, in the course of another fifty years or so, will attain a greater height than any of the old ones, and may eventually equal, if not surpass, the splendid young silver firs which are growing in the same valley; whose seedlings come up as thickly and evenly as I have ever seen them do in their native country. The cypress, though it sows itself freely, requires more light when young, and reproduces best where a shallow bed of leaf-mould is partially exposed to the sun. In such places I found plenty of seedlings which seemed to have an excellent root system, and I was able to transplant some of them to the garden of Baron Soutelinho (Mr. A. Tait), of Oporto, and to send some small ones home by post.

Owing to the kindness of Senhor Lacerda I have received a fine plank and section of the wood, cut from a tree which shows 160 annual rings on a radius of 18 in.; it appears to be very similar to the wood of *Cupressus sempervirens*. This account¹ has been read by Prof. Henriques, who informs me that the mountain of Bussaco is on the inferior Silurian formation. With regard to the date of its introduction, he says that it must certainly have existed before 1634, when it was mentioned in a poem called *Soledades de Bussaco*. When the mountain was acquired by the Trappists from the monks of Vacarica in 1626, there was already a great variety of trees, forming a dense forest. The chapel of San José, near which the largest tree grows, was founded in 1644, and the *Chronicles of the Carmelite* (cap. xx. p. 110), published in 1721, speaking of this chapel, says that near it is found the first cypress, progenitor of all the others in the forest. In 1689 Tourne-

¹ M. Jacques L. de Vilmorin, in *Bull. Soc. Deud. France*, 1907, p. 49, gives an interesting account of the forest of Bussaco, which he visited in 1906.

fort, in the original manuscript of his *Voyage en Portugal*, which is now in Prof. Henriques' possession, describes the species as follows: *Cupressus lusitanica*, patula, fructu minori.

I saw this cypress growing at many other places in Portugal, but nowhere very large, except in the beautiful garden of Monserrat, formerly the property of Mr. Beckford, but purchased in 1855 by Sir Francis Cook, whose son, the present Sir Frederick Cook (Viscount Monserrate in Portugal), keeps up this unique place with the greatest care. The oldest cypresses here seem to have been planted something like a century ago, and are extremely varied in habit, as well as in the size, shape, and colour of their fruit. The tallest, in a low sheltered valley north of the house, was blown down a year ago, and measured 3 ft. 5 in. in diameter on the stump. It is said to have been taller than two trees still standing in the same place, one of which is from 105 to 110 ft. high by 10 ft. 5 in. in girth, the other being about 90 ft. by 12½ ft. In the Mexican garden there is an old tree about 70 ft. high, with a flat umbrella-shaped top and a trunk clean to about 50 ft.; several others on the slope just below the house are extremely unlike this in habit, having spreading branches down to the ground profusely covered with old cones, some of which were persistent on branches twenty to thirty years old. Some of these trees were very glaucous in colour, and had longer fruit with larger protuberances. The fruit was much more abundant on these comparatively young and spreading trees than on the tall old ones, and seed was escaping from the cones in the middle of April. Some trees were so covered with male flowers as to give them a yellow appearance, and these bore comparatively few cones.

INTRODUCTION

This tree was in cultivation¹ in 1682 in the Chelsea and Fulham gardens and at Badminton, and was probably introduced from Portugal a short time previously. Miller, writing² in 1768, says that it was then rare in English gardens, and mentions large trees that had been killed by the frost of 1740 and 1762. It was probably re-introduced during the Peninsular War, when many officers must have seen this species at Bussaco; and Loudon³ states as a fact that Lord Ferrard brought seeds to Ireland in 1809, which produced many plants. Plants were raised⁴ at Glasnevin in 1837 from seeds obtained from Coulter's Mexican specimens; and in all probability Hartweg sent seeds from Mexico in 1840 to 1843.

Var. *Benthami* was introduced, according to Loudon,⁵ under the name *C. thurifera*, in 1838, when there was a plant a few inches high in the Horticultural Society's garden at Chiswick. In 1843, a plant⁶ 7 ft. high was growing in Lucombe, Pince, and Co.'s nursery at Exeter. Uhde,⁷ who was Prussian Consul at Matamoras, in Mexico, also sent seeds soon afterwards to Berlin, the plants from which were known as *C. Uhdeana*. This variety was sent out under the name *C. Knightiana*

¹ Cf. Masters, in *Journ. Roy. Hort. Soc.* xvii. 5 (1894). It is mentioned by Ray, *Hist. Plant.* ii. 1414, 1798, 1916 (1688).

by Knight and Perry, who stated¹ their ignorance of its origin in 1850; but in all probability their plants were raised from seed sent by Hartweg.

REMARKABLE TREES

In England² we know of no trees which can be certainly distinguished as of Portuguese origin.

There is a fine one at Hemsted Park, Cranbrook, which measured 50 ft. by 10 ft. in 1905, and seems to be a very old tree (Plate 300). At Westonbirt there are two good trees, about 50 ft. high, somewhat differing in habit, one with rather wide-spreading branches, which was bearing cones in 1909; the other, a narrow pyramidal tree, was without fruit in that year. At Luscombe Castle, Dawlish, a tree, which I saw in 1908, was about 50 ft. by 5 ft. There are several trees in Cornwall, which Mr. A. B. Jackson measured in 1909; at Heligan, a good specimen, 40 ft. by 6 ft. 8 in.; and at Glendurgan, two trees, the larger, 40 ft. by 4 ft. 11 in. There are smaller ones at Liphook, and at Grayswood, Haslemere. This species is not hardy at Barton,³ Suffolk, where all the specimens were killed in the winter of 1860-61.

In Ireland this species thrives at several places. The finest,⁴ perhaps, is at Woodstock, and in 1909 measured about 57 ft. by 10½ ft., dividing low down into six large stems, and bearing many new and old cones. The forester informed me that 23° of frost had been registered here.

Loudon records a tree at Oriel Temple, Co. Louth, now the seat of Lord Masserene, which was 32 ft. high in 1834, and had been raised, as stated above, from seed brought from Portugal by Lord Ferrard in 1809. I visited this place in July 1908, and found no less than three large trees, which may be of the same age. The first is a stunted tree, with a wide-spreading crown 19 yards in diameter, and a short trunk only 4 ft. high and 7 ft. 7 in. in girth. It was covered with new fruit, while those of the preceding year remained, and contained plenty of ripe seed. The second is a much finer tree (Plate 301), about 40 ft. high, with spreading branches and a straight trunk 8 ft. 1 in. in girth and about 20 ft. high. The third is forked near the ground, where it is 7 ft. 9 in. in girth, and it is about 40 ft. high, with wide-spreading branches.

A tree at Kilmacurragh, which is probably of the same age and origin, is 48 ft. by 8 ft., with a bole of 10 ft. high. From it a cutting was struck many years ago (as I was informed by Mr. Moore, of Glasnevin) which has now grown into a fine tree, and had abundance of new and old fruit containing ripe seeds.

There is a tree⁵ at Rostrevor House probably of the same origin as those at Oriel Temple. At Fota there is a fine specimen, cultivated under the name

¹ *Syn. Conif.* 19 (1850).

² We have seen no trees in Scotland. The specimen at Rosdhu, Dumbartonshire, reported in *Journ. Roy. Hort. Soc.* xiv. 507 (1892), was incorrectly named, and is *C. Lawsoniana*. Cf. Masters, in *Journ. Roy. Hort. Soc.* xvii. 1, note (1894).

³ Bunbury, *Arboretum Notes*, 155.

⁴ This tree measured at 2 ft. from the ground 3 ft. 9 in. in 1825, 4 ft. 8 in. in 1834, 6 ft. 8 in. in 1854, and 6 ft. 8½ in. in 1860.

⁵ A much larger tree than the one now standing at Rostrevor was blown down in 1903.

C. Macnabiana, which was 55 ft. by 6 ft. 3 in. in 1907. There is also a fine tree in the old deer park, Castlemartyr, about 60 ft. high, which Henry saw in 1907. At Birr Castle, King's County, the Earl of Rosse informs us that there is an old tree, 8 ft. in girth at 2 ft. from the ground, and dividing above this into many stems.

In England we have distinguished as belonging to var. *Benthami* a tree at Lamorran, Cornwall, which Mr. A. B. Jackson measured as 49 ft. high in 1909.

At Culver, Exeter, a tree, raised from seed brought by Mr. Byrom from the south of France in 1879, measured, in 1909, 35 ft. high, and 7 ft. in girth close to the ground.

In a sheltered dell at Bicton, there is a tree—No. 286 in the Bicton MS. catalogue—of var. *Benthami*, which, though the main stem is broken off some distance from the ground, measured, in 1906, 56 ft. in height, and 12½ ft. in girth at the base. There are two tall trees, close to it, of which No. 290 is typical *C. lusitanica*, and No. 274 is *C. torulosa*. No. 283 in the same dell, a tall narrow tree, labelled *C. religiosa*, and 55 ft. by 7 ft. in 1909, is *C. lusitanica*, var. *Benthami*. There was formerly a tree of var. *Benthami* growing near the Rhododendron dell at Kew, which was cut down about twelve years ago. A specimen preserved in the Arboretum herbarium shows that it produced fruit freely.

In Ireland the largest tree of this variety grows on Fota Island (Plate 302), and measured no less than 75 ft. high by 7 ft. 4 in. in girth in 1908. Lord Barrymore informs us that his beautiful specimens of *Abies religiosa* and *Pinus patula* were sent by J. Knight in 1844, and planted in 1847. He suspects that this tree, long known under the name *C. Lindleyana*,¹ was of the same origin. There is another of similar habit at Woodstock which in 1909 was 57 ft. by 6 ft. 3 in.

In the nursery of Rovelli Frères at Pallanza, there is a fine specimen of typical *C. lusitanica*, 50 ft. by 6 ft. 8 in. in 1909, which is erroneously labelled *Cupressus sp.*, *Hills of India*.² Var. *Benthami* is represented by several large trees, which are named incorrectly *C. elegans* and *C. Hügelii*. (H. J. E.)

CUPRESSUS ARIZONICA

Cupressus arizonica, Greene, in *Bull. Torrey Bot. Club*, ix. 64 (1882); Rusby, in *Bull. Torrey Bot. Club*, ix. 79 (1882); Masters, in *Gard. Chron.* x. 364 (1891); Sargent, *Silva N. Amer.* x. 105, t. 526 (1896), and *Trees N. Amer.* 78 (1905); De Wildeman, *Icon. Hort. Thén.* iv. 111, t. 145 (1903); Purpus, in *Mitt. deut. dend. Ges.* 1904, p. 50, t. iv.; Eastwood, *Trees of California*, 17 (1905).

Cupressus guadalupensis, Sargent, *Tenth Census Report, U.S. Forest Trees N. Amer.* 180 (1884) (not Watson).

Cupressus Benthami, Endlicher, var. *arizonica*, Masters, *Kew Hand-list Coniferae*, 37 (1896), and in *Journ. Linn. Soc. (Bot.)* xxxi. 340 (1896).

A tree attaining in Arizona a height of 70 ft. and a girth of 12 ft. Bark reddish brown, separating on the surface into long shreds, which are about 1 in. or

¹ This name goes to show that Knight and Perry raised from Mexican seed both the type *C. lusitanica* (*C. Lindleyi*) and the variety *C. Benthami* (*C. Knightiana*).

² This is erroneously referred to it in *Mitt. deut. dend. Ges.* 1906, p. 98, as a juvenile form of *C. torulosa*. The small plants at Pallanza, labelled "*Cupressus* from Kumaon," are very glaucous, and may be a form of *C. lusitanica*; but are too young to be accurately determined. I have raised plants, which have hitherto proved hardy at Colesborne.

2 in. wide, and often persist for many years. Branchlets of the third year purplish brown, terete, smooth, and often covered with a glaucous bloom. Branchlet systems irregularly disposed at varying angles, bi-pinnate, with the pinnæ not in one plane. Ultimate branchlets tetragonal, equal-sided, $\frac{1}{20}$ in. in diameter. Leaves light green or conspicuously glaucous, uniform in four ranks, appressed, marked with a glandular pit on the back exuding resin, ovate-acuminate and $\frac{1}{12}$ in. long on young trees, ovate-acute and $\frac{1}{20}$ in. long on old trees.

Cones, on short stout straight stalks, globose, $\frac{1}{2}$ in. to $\frac{3}{4}$ in. in diameter, covered with a thick whitish bloom, ripening in the second year; scales usually six, occasionally eight, with spreading or incurved prominent processes. Seeds, eight to ten on each scale, $\frac{1}{8}$ in. long, marked with a few inconspicuous resin-vesicles; wings narrow.

This species is probably a northern form¹ of *C. lusitanica*, but is distinguishable by the peculiar pits on the leaves, which exude a whitish resin. The foliage, closely appressed to the stout quadrangular branchlets, often glaucous in colour, and covered with a protecting layer of resin, is adapted, through diminution of evaporation, for arid sunny regions. *C. arizonica* is a native of the mountains of central, eastern, and southern Arizona, and also occurs in the provinces of Sonora and Chihuahua in northern Mexico. It was discovered in 1880 by Greene near Clifton in eastern Arizona, and shortly afterwards was seen by Rusby in the San Francisco mountains of the same state, where it is abundant in the cañons and on northern slopes, forming almost pure forests of considerable extent² at 5000 to 6000 ft. altitude. Like most species of cypress it is variable in habit, tall and narrow, or short with wide-spreading branches, and showing all tints of foliage from light green to silvery white. Purpus, who gives a picture of the tree³ in the Mogollones mountains, says that it grows there on rocky places on the cliffs on the sandstone formation.

C. arizonica, introduced⁴ into England in 1882 from the Arnold Arboretum, U.S.A., has proved considerably hardier than its near relative *C. lusitanica*, and promises to be a most valuable ornamental tree. At Cambridge it is one of the few cypresses that thrive out of doors, and is fast in growth. The finest specimen we know is growing in Messrs. Hillier's nursery at Shroner, Winchester, and is now about 25 ft. high; it bears occasionally a few cones, and is said to have been planted in 1889. Another at Nymans, Handcross, was planted in 1899 when about 3 ft. high, and is now 20 ft. high by 1 ft. 3 in. in girth, and is bearing cones which show in the mature state none of the thick white glaucous bloom so characteristic of the fruit in Arizona. None of the plants that I have seen in England show any glaucous hue on the branchlets. Another tree, similar in size at the same place, procured in the south of France, with bluish glaucous foliage, has not yet borne cones. A plant at Castlewellan, 9 ft. high, bore fruit in 1909. At Trebah, Cornwall, a tree, obtained from Messrs. Veitch about 1892, is 15 ft. high, but has not as yet produced cones.

¹ Scarcely distinguishable in botanical characters from *C. lusitanica*, var. *glaucæ*.

² In *Garden and Forest*, viii. 22 (1895), mention is made of a large grove, containing many thousands of trees, at the Natural Bridge in central Arizona.

³ In *Mitt. deut. dendr. Ges.* 1904, p. 50.

⁴ *Gard. Chron.* x. 364 (1891).

Seeds were introduced into Germany by Purpus,¹ who says it is the hardiest of all the true cypresses, and that young seedlings grow extraordinarily fast, but are somewhat difficult to transplant. Beissner,² however, states that in many parts of Germany it is tender and has suffered much from frost.

At Angers there is a tree of this species with remarkably glaucous silvery foliage, which bore fruit in 1907. Elwes found this also in E. Rovelli's nursery at Pallanza. He also saw a fine specimen under the name *C. guadalupensis* in the Botanic Garden at Montpellier. It was about 30 ft. high, with handsome glaucous foliage, but bore no fruit. (A. H.)

CUPRESSUS OBTUSA, HINOKI CYPRESS

Cupressus obtusa, Koch, *Dendrologie*, ii. pt. ii. p. 168 (1873); Masters, in *Journ. Linn. Soc. (Bot.)* xxxi. 355 (1896); Kent, *Veitch's Man. Conif.* 220 (1900).

Chamaecyparis obtusa, Siebold et Zuccarini, ex Endlicher, *Syn. Conif.* 63 (1847); Mayr, *Fremdländ. Wald- u. Parkbäume*, 277 (1906).

Chamaecyparis breviramea and *pendula*, Maximowicz, in *Mél. Biol.* vi. 25 (1866).

Retinispora obtusa, Siebold et Zuccarini, *Fl. Jap.* ii. 38, t. 121 (1844).

Thuya obtusa, Masters, in *Journ. Linn. Soc. (Bot.)* xviii. 491 (1881).

A tree, attaining in Japan 120 ft. in height and 12 ft. in girth, larger trees of very rare occurrence being reported by Mayr. Bark reddish brown, scaling off in long thin strips. Branches and branchlet systems similar to those of *C. Lawsoniana*. Ultimate branchlets flattened, compressed, $\frac{1}{15}$ in. wide. Leaves appressed; lateral pair conduplicate, $\frac{1}{12}$ in. long, obtuse at the apex, which often bears a minute mucro; facial pair, much smaller, $\frac{1}{24}$ in. long, flattened, rhomboid, often keeled, non-glandular, with a triangular scarcely acute apex. The foliage is dark green on the upper side of the branchlet, but is marked below with X-shaped white markings, due to a coating of wax on the inner margins of the lateral leaves and on both margins of each ventral leaf. Leaves on the main axes oblong, unequal, the lateral $\frac{1}{4}$ in. long, the facial $\frac{1}{8}$ in. long, with spreading rather obtuse tips.

Staminate flowers yellow. Cones on the ends of short scaly branches, ripening in the autumn of the first year, and falling in the following year, globose, $\frac{1}{3}$ in. in diameter, orange brown when ripe; scales eight, rarely ten, with the outer surface depressed in the centre, from which arises a minute ovate appressed process. Seeds, two to five on each scale, ovate, $\frac{1}{8}$ in. long, brown, with conspicuous large resin-vesicles and narrow wings.³ Seedling with two cotyledons, which are about $\frac{1}{4}$ in. in length.

VARIETIES

This species has long been cultivated in Japan, where it has given rise to numerous peculiar varieties.

¹ Cf. *Mitt. deut. dendr. Ges.* 1906, p. 32.

² *Ibid.* 1908, p. 61.

³ Some seeds from a tree growing at Nikko have three wings, instead of the normal lateral two wings.

1. Var. *breviramea*, Masters, in *Journ. Linn. Soc. (Bot.)* xxxi. 355 (1896).

Var. *filicoides*, Masters, in *Kew Handlist Conif.* 45 (1896).

Chamaecyparis breviramea, Maximowicz, *Mél. Biol.* vi. 25 (1866); Beissner, *Nadelholzkunde*, 97 (1891).

Thuja obtusa, Masters, var. *breviramea*, Masters, in *Journ. Linn. Soc. (Bot.)* xviii. 494 (1881).

Thuja obtusa, Masters, var. *filicoides*, Masters, in *Journ. Linn. Soc. (Bot.)* xviii. 494, fig. 5 (1881).

Retinispora filicoides, Veitch, ex Gordon, *Pinetum*, 363 (1875); Syme, in *Gard. Chron.* v. 235, fig. 40 (1876).

Retinispora Nobleana, Beissner, *Nadelholzkunde*, 94 (1891).

Denser and dwarfer in habit, with sub-opposite oblong branchlet systems, composed of short equal closely-set opposite pinnæ. Ultimate branchlets tetragonal, scarcely compressed. Leaves nearly equal in four ranks, ovate, obtuse, often glandular. The foliage is usually dark green, but is occasionally marked with white streaks beneath. The cones are similar to, but slightly smaller than those of the type.

Maximowicz saw this peculiar form wild on the northern shore of the island of Kiusiu, but states that it is often cultivated in gardens at Tokyo. It was introduced¹ by J. Gould Veitch in 1861. A small tree of this variety is growing well at Tregothnan; and at Haldon, Exeter, it is about 20 ft. high and was bearing yellow staminate flowers in April 1908.

2. Var. *tetragona aurea*, Masters, in *Journ. Linn. Soc. (Bot.)* xxxi. 355 (1896).

Var. *filicoides aurea*, Kent, Veitch's *Man. Conif.* 221 (1900).

Retinispora tetragona aurea, Kent, Veitch's *Man. Conif.* 250 (1881).

Chamaecyparis obtusa, Siebold et Zuccarini, var. *tetragona aurea*, Beissner, *Nadelholzkunde*, 95 (1891).

A dwarf form, with tufted branchlet systems, the pinnæ of which arise at varying angles in different planes. Ultimate branchlets tetragonal, scarcely compressed; leaves nearly uniform, ovate, acute, spreading at the tips. Young shoots golden yellow, becoming dark green in the second year.

This originated in the Elvaston Nursery in 1873, and obtained a first-class certificate at the Royal Horticultural Society in 1876. It is very slow in growth, a plant at Castlewellan being only 5 ft. high after twenty years' growth.²

3. Var. *lycopodioides*, Masters, in *Journ. Linn. Soc. (Bot.)* xxxi. 355 (1896).

Retinispora lycopodioides, Standish, ex Gordon, *Pinet. Suppl.* 92 (1862).

Retinispora monstrosa, Gordon, *loc. cit.*

Thuja obtusa, Masters, var. *lycopodioides* in *Journ. Linn. Soc. (Bot.)* xviii. 493 (1881).

Chamaecyparis obtusa, Siebold et Zuccarini, var. *lycopodioides*, Carrière, *Conif.* 132 (1867).

A dwarf form with rigid branches. Branchlet systems closely set, overlapping, but tending to be in one plane. Ultimate branchlets fasciated, crowded with closely appressed, elongated, obtuse leaves in many ranks. Foliage dark green in colour.

According to Gordon this was sent by Fortune to the Bagshot Nursery in 1861; but it is stated by J. H. Veitch³ to have been introduced in the

¹ *Hortus Veitchii*, 339 (1906).

² Earl Annesley, *Beautiful Trees*, 74 (1903).

³ *Hortus Veitchii*, 339 (1906).

same year by J. Gould Veitch. There are fine shrubs of this variety at Tregothnan, at Coldrenick, and at Chipping Campden in the garden of Mr. Griffiths.

4. Var. *pendula*, Masters, in *Journ. Linn. Soc. (Bot.)* xxxi. 355 (1896).

Chamaecyparis pendula, Maximowicz, *Mél. Biol.* vi. 26 (1866).

A form resembling *Thuja orientalis*, L., var. *pendula*, Masters, in habit, with long pendulous branches, and tetragonal branchlets and obtuse leaves.

This was seen by Maximowicz in gardens around Tokyo; but does not seem to be known in Europe, unless it is identical with an extremely handsome pendulous form,¹ which originated from Japanese seed sown in Prince Lobkowitz's nursery at Eisenberg in Bohemia.

The principal forms, which only differ from the type in the colour of the foliage are:—

5. Var. *aurea*. Young branchlets golden yellow. This is said to have been sent from Japan by Fortune to the Bagshot Nursery. According to the late Earl Annesley, it is dense in habit, holding its rich colour in spring and early summer. Kent considers it to be the most remarkable of all the coloured conifers.² In var. *gracilis aurea*, the branches are pendulous, with yellow branchlets, turning to light green when mature. Var. *Keteleeri*, though said by Parlatores³ to have juvenile foliage, is described by Gordon⁴ as resembling the type in every respect, except that about half the branchlets are yellow; and apparently this was early introduced from Japan. Var. *Crippsii*, at Kew, is a form with pale yellow young branchlets. A shrub cultivated at Osborne as var. *nana aurea*, planted in 1873, is now about 15 ft. high.

6. Var. *albo-spica*. Young shoots cream coloured when they first appear, gradually changing to pale green in summer. Var. *argentea*, introduced from Japan by Fortune, is similar, but silvery white or glaucous.

7. The principal dwarf forms are var. *nana* and var. *compacta*. The latter has lately produced⁵ fertile seeds, but the seedlings are too young as yet to judge of their precise character. Var. *pygmaea* scarcely exceeds a foot in height and spreads horizontally on all sides, and is much used for rockeries.

8. Var. *Troubetzkoyana*, Rovelli, ex Masters, in *Gard. Chron.* vii. 108 (1890).

A dwarf compact form, densely branched, with short, divaricating branchlets, and appressed light green, rather thick, lanceolate, acute but not acuminate leaves, which bear a central gland on the back. This originated at Pallanza, in the garden of Prince Troubetzkoy.

9. Var. *erecta*. A fastigiate variety, like *C. Lawsoniana*, var. *erecta viridis*. Introduced by Waterer and Sons.⁶ (A. H.)

¹ Described as *Chamaecyparis obtusa pendula*, by Beissner, *Nadelholzkunde*, 96 (1891).

² Mayne, in *Gard. Chron.* xli. 217 (1907) reports two specimens 25 ft. high at Bicton.

³ In DC. *Prod.* xvi. 2, p. 466 (1868).

⁴ *Pinetum*, 368 (1875).

⁵ Cf. *Proc. Roy. Hort. Soc.* xxxiv. p. cxxix. (1908).

⁶ It obtained a first-class certificate at the Horticultural Society, according to *Gard. Chron.* 1870, p. 315.

DISTRIBUTION

In Japan this tree is indigenous, so far as I could learn, only in the central and southern parts of the main island, and in Kiusiu and Shikoku; but it is so highly valued for its timber, which is considered the best of all the soft woods of Japan, that it has been largely planted in many places, and is always found in the grounds of Shinto temples, which are usually built of its wood. It is one of the five royal trees which were reserved for imperial and religious uses in ancient times; and is known in Japan as *Hinoki*.

The best natural forests which I saw are in the districts of Kisogawa and near Koyasan, where the tree grows at an elevation of from about 2000 to 5000 ft. on rich volcanic and granitic soil, usually mixed with *C. pisifera* and other conifers and hardwood trees, and sometimes attains very large dimensions. It is not easily distinguished in the forest from *C. pisifera*, but has smoother and paler bark; and the branches have a more ascending and less drooping habit.

Though in the forest the trees do not usually attain more than 80 to 90 ft. high, yet I saw many at Koyasan over 100 ft., and measured one close to the gate of the great temple at Koyasan which was 108 ft. by 12½ ft.; and in the temple court at Nikko there were two fine trees said to be about 300 years old, and nearly as large.

Plate 303 shews an isolated tree which I found at Maichi near Nikko. Plate 304 represents a tree grown in forest for timber.

Mayr says that at its upper limit, where it mingles with *Picea Alcockiana* and *P. hondoensis*, it attains about 80 ft., but that on good soil, mixed with chestnuts and other hardwoods, over which its crown towers in the forest, it attains 140 ft. in height and 7 ft. in girth, with a stem clear of branches to 60 ft. The largest tree recorded by Mayr grew in Mizumine, mixed with Zelkova, maples, and oaks.

In Japan the reproduction by seed is easy; and though the growth is much slower than that of *Cryptomeria*, yet *C. obtusa* is preferred for planting wherever the soil and climate are suitable.

This species has recently been discovered in Formosa, growing on Mount Morrison, with leaves, cones, and seeds somewhat smaller than is usual in Japan.¹

CULTIVATION

This species was introduced into cultivation in Europe by J. Gould Veitch in 1861, and has become popular as an ornamental small tree in English gardens. It is perfectly hardy, but probably requires more heat than our climate affords to bring it to timber size; and being generally propagated by cuttings is usually seen in a shrubby form. It dislikes lime in the soil, and, according to Mr. Coleman, does not thrive on that account at Eastnor. It ripens its seed perfectly in the south of England.

¹ Distinguished as *forma formosana* by Hayata in *Gard. Chron.* xliii. 194 (1908), and in *Journ. Coll. Sc. Tokyo*, xxv. 208 (1908). Mr. Hayata informs us that this tree attains an enormous size in the mountains of Formosa.

The largest trees which we have seen are one at Bicton, 36 ft. by 4 ft. 4 in. in 1906; and another at Dinas Mawddy, 30 ft. by 2 ft. in 1906, growing well on slate here and at Tan-y-bwlch. There are good specimens also at Tortworth, Westonbirt, Campden (Gloucestershire), and at Castle Kennedy in Scotland. In Ireland it grows well, a tree at Woodstock, Kilkenny, 38 ft. high, having a number of layered branches, which are now growing erect round the parent.

This species has been tried at fourteen different forestry stations in Prussia, the plots amounting to 10 acres in extent. Dr. Schwappach¹ says that seedlings grow slowly in the first two years, but attain in five years 20 to 40 in. in height, in ten years 5 to 9 ft., and in fifteen years 11 to 15 ft. Young plants are susceptible both to heat and to frost; and he advises planting out well-rooted transplants at five years old in gaps in woods of broad-leaved trees. This species, like all of the section *Chamaecyparis*, seems very liable in Germany to attacks of the fungus, *Pestalozzia funerea*.

In New England² *C. obtusa* is quite hardy, and in its early years makes a handsome plant, but it soon develops a tendency to grow thin, and well-furnished specimens more than 20 ft. high are not common.

TIMBER

No coniferous timber is now so highly valued in Japan for the finest buildings, as well as for interior work, as that of the *Hinoki*; and Sargent says that the palaces of the Mikado, as well as the temples, are built of it. But the high-priest of the Gemyo-in Temple, where I stayed at Koyasan, said that the wood of *Tsuga* used to be preferred until it became too scarce. To this very courteous gentleman I am indebted for a large slab 3 ft. across, cut from a burr of this tree, which was quite free from flaws, sound to the centre, and showed a very twisted and varied grain; in colour resembling satinwood, from which a highly ornamental table top has been made in England, the legs and framing of which are of Japanese yew.

Hinoki wood is white, straw-colour, or pale pink, very straight-grained, light, strong, and tough, and is distinguished by its remarkably fine-grained and silky lustre, which make it suitable for lacquer. Neat round rice-boxes are made in Kiso from thin pieces of this wood, ⅓ of an inch thick, bent into a circle, and sewed with cherry bark, which are sold for a few sen. For any fine work requiring a perfect surface it seems to me unsurpassed among coniferous woods, resembling most nearly in texture that of *Cupressus nootkatensis*.

The most beautiful ceiling which I saw in Japan, in a new inn at Nakatsugawa, was made from thin boards of this wood, about 18 in. square, cut from the butts of old trees, and showing a most varied wavy figure. These cost on the spot about fifteenpence each, and if they could be imported would be highly valued in Europe. The wood is also used for making chip braid; and an ordinary quality is worth in Tokyo about 80 yen or £8 per 100 cubic feet. The bark is also highly valued for

¹ *Anbauvers. Fremd. Holzarten*, 28 (1901).

² Sargent, *Garden and Forest*, x. 431 (1897), and *Pinetum Wellesley*, 13 (1905), where a tree is said to have attained 31 ft. high in Mr. Hunnewell's pinetum.

roofing temples and palaces. This bark is stripped from living trees, and as I was informed by a forester at Koyasan, this can be done about once in ten years without injuring the tree. It was worth 2s. to 4s. per tree. It is used for roofing in strips of about a foot long by 3 to 6 in. wide, which are laid together in packets of eight or ten strips, and put on the roof to the thickness of about a foot, the eaves and ridge being protected with wood or bamboo work. Such a roof will last for about fifty years even in this damp hot climate. (H. J. E.)

CUPRESSUS PISIFERA, SAWARA CYPRESS

Cupressus pisifera, Koch, *Dendrologie*, ii. pt. ii. p. 170 (1873); Masters, in *Journ. Linn. Soc. (Bot.)* xxxi. 355 (1896); Kent, Veitch's *Man. Conif.* 224 (1900).
Chamaecyparis pisifera, Siebold et Zuccarini, ex Endlicher, *Syn. Conif.* 64 (1847); Mayr, *Fremdl. Wald- u. Parkbäume*, 276 (1906).
Retinispora pisifera, Siebold et Zuccarini, *Fl. Jap.* ii. 39, t. 122 (1844); Syme, in *Gard. Chron.* v. 235 (1876).
Thuya pisifera, Masters, in *Journ. Linn. Soc. (Bot.)* xviii. 489 (1881).

A tree similar to *C. obtusa* in dimensions, bark, branches, and branchlets. Ultimate branchlets flattened, $\frac{1}{16}$ to $\frac{1}{12}$ in. wide. Leaves appressed, but with their mucronate tips free and slightly spreading; lateral pair conduplicate, acute; facial pair slightly smaller, $\frac{1}{16}$ in. long, ovate-acuminate, flattened, often ridged, obscurely glandular. The foliage is shining green above, while below it is marked with conspicuous white patches in hollows, two on the bases of the lateral leaves towards the middle line, and two on the base of each ventral leaf. Leaves on the main axes equal in four ranks, oblong, $\frac{1}{8}$ to $\frac{1}{5}$ in. long, with spreading triangular acuminate points.

Staminate flowers yellowish, with eight or ten pairs of stamens. Cones on the ends of short scaly branchlets, ripening in the autumn of the first year, and falling in the second year, globose, $\frac{1}{4}$ in. in diameter, dark brown; scales usually ten, with the outer surface wrinkled, deeply depressed in the centre, from which arises a very minute process. Seeds, one or two on each scale, brown, ovate, with large prominent resin-vesicles, $\frac{1}{10}$ in. long and $\frac{1}{5}$ in. wide, inclusive of their broad lateral wings, when these are well developed. Seedling with two cotyledons, similar to that of *C. Lawsoniana*.

VARIETIES

This species has been cultivated for centuries in Japan, and has given rise to many varieties.

1. Var. *squarrosa*, Masters, in *Journ. Linn. Soc. (Bot.)* xxxi. 356 (1896).

Retinispora squarrosa, Siebold et Zuccarini, *Fl. Jap.* ii. 40, t. 123 (1844); Kent, Veitch's *Man. Conif.* 249, fig. 59 (1881).

Chamaecyparis squarrosa, Siebold et Zuccarini, ex Endlicher, *Syn. Conif.* 65 (1847).

Cupressus squarrosa, Lawson, ex Gordon, *Pinetum*, 296 (1858).

Thuya pisifera, Masters, var. *squarrosa*, Masters, in *Journ. Linn. Soc. (Bot.)* 490 (1881).

This variety, which retains indefinitely the juvenile form of foliage, occurring on seedlings in their first three or four months, is a low tree or large dense shrub, with

glaucous silvery foliage; ultimate branchlets tetragonal; leaves soft in texture, in opposite decussate pairs or whorls of fours, decurrent on the branchlet, sessile, linear, flattened, $\frac{1}{4}$ in. long, whitened on both surfaces, acuminate. The bluish tint of the foliage is very handsome.

According to Siebold, "it is said to occur wild in Kiusiu," but in all probability it is only known in the cultivated state in Japan, where it is called *Himuro* or *Shimofuri-hiba*. It was introduced into Europe in 1843, and for a long time was considered to be a distinct species; but Syme¹ in 1879 found a tree of this variety giving off a branch with foliage exactly like that of *C. pisifera*; and in 1882 it produced² fruit with Messrs. Veitch, unmistakably the same as the species. Elwes brought from Japan specimens in fruit collected by Watanabe on Nokogiri-yama. The seed produced in England appears to be unfertile.

Syme first showed³ the true nature of these *Retinispora* forms. In 1875 he raised 2000 seedlings of *C. pisifera*, many of which were 2 ft. high in 1879. These seedlings during the first four months resembled *Retinispora squarrosa*, but towards the end of the season the great majority assumed the branchlets and leaves of *R. plumosa*, and in the following year developed the adult foliage of *C. pisifera*. A few of the seedlings, however, did not change from the juvenile stage till they were two years old, and one plant when three years old changed into the plumose stage, and remained so. Probably var. *squarrosa* and var. *plumosa* originally were accidental seedlings; but in most cases now plants of the different stages of *Retinispora* are artificially produced by propagation from cuttings. Hochstetter⁴ states that if lateral branches are used as cuttings, *Retinispora* forms are produced, while terminal shoots give *C. pisifera*. Var. *squarrosa* and var. *plumosa* can also be produced by using offsets from young seedlings of *C. pisifera*.⁴

A sub-variety, known as var. *squarrosa sulphurea*, yellowish in colour, is known; and Mr. Paul has a specimen of this at Cheshunt, which is growing into the form *plumosa*, while still retaining its colour.⁵

This variety⁶ has attained 29 ft. in height at Wellesley, Massachusetts, U.S.A.

2. Var. *plumosa*, Masters, in *Journ. Linn. Soc. (Bot.)* xxxi. 356 (1896).

Retinispora plumosa, Veitch, ex Koch, *Dendrologie*, ii. pt. ii. p. 170 (1873); Syme, in *Gard. Chron.* v. 236, fig. 42 (1876).

Thuya pisifera, Masters, var. *plumosa*, Masters, in *Journ. Linn. Soc. (Bot.)* xviii. 490, fig. 2 (1881).

Chamaecyparis pisifera, Siebold et Zuccarini, var. *plumosa*, Beissner, *Nadelh.* 87 (1891).

A dense shrub or small tree, usually of conical habit; branchlet systems crowded, more or less overlapping, often curved at the distal end, bi-pinnate, with the pinnæ in one plane. Leaves crowded in decussate pairs, decurrent in their basal half, $\frac{1}{8}$ in.

¹ *Journ. Linn. Soc. (Bot.)* xviii. 490 (1881).

² Syme in *Gard. Chron.* xviii. 395 (1882). At the present day it often produces fruit, as at Kilmacuragh and elsewhere. Shepherd sent a specimen covered with cones from Wolverston Park to Dr. Masters. Cf. *Gard. Chron.* iv. 671 (1888).

³ In *Gard. Chron.* xviii. 395 (1882).

⁴ *Gartenflora*, xxix. 362 (1880), translated in *Gard. Chron.* xv. 333 (1881).

⁵ *Proc. Roy. Hort. Soc.* xxxiv. p. cxxviii. (1909).

⁶ Sargent, *Pinetum Wellesley*, 13 (1905), who says that the inability of the Japanese cypresses to flourish in the eastern United States for any length of time has been well shown at Wellesley, where of the several hundred individuals, in nearly all the obtainable varieties, that had been planted at different times, few have survived.

long, subulate, ending in a sharp cartilaginous point, slightly spreading, concave from side to side, and whitened on the inner surface.

This variety is known in Japan as *Shinobu-hiba*, and was introduced from there by J. Gould Veitch in 1861. It produces fruit¹ similar to that of the type, but smaller, as at Osborne, where it is 25 ft. high.

Syme² observed on this variety branches with the foliage of *C. pisifera*; and Beissner mentions a tree at Wilhelmshöhe, Cassel, the lower half of which is bushy and covered with foliage of var. *plumosa*, the upper half having the loose branches and foliage of *C. pisifera*.³

This variety is very hardy, and as a small plant is suitable for window boxes out-of-doors in winter.⁴ During the severe frost of February 1882, the golden Retinisporas at Kew⁵ lost many small branches; while those with green, glaucous, or silvery foliage remained uninjured.

Several coloured sub-varieties are known:—

Var. *plumosa albo-picta*. Tips of many of the branchlets pure white.

Var. *plumosa argentea*. Young branchlets creamy white, becoming green in the following spring.

Var. *plumosa aurea*. Young branchlets golden yellow, gradually changing to green as the season advances.

3. Var. *filifera*, Masters, in *Journ. Linn. Soc. (Bot.)* xxxi. 356 (1896).

Retinispora filifera, Standish, ex Gordon, *Pinetum*, 364 (1875); Syme, in *Gard. Chron.* v. 235, fig. 43 (1876).

Thuya pisifera, Masters, var. *filifera*, Masters, in *Journ. Linn. Soc. (Bot.)* xviii. 491, fig. 3 (1881).

Chamaecyparis pisifera, Siebold et Zuccarini, var. *filifera*, Beissner, *Nadelh.* 90 (1891).

A low tree, with spreading branches, and long pendulous branchlets, undivided for the greater part of their length, and terminating towards the end in bi-pinnate divisions. Leaves in decussate pairs, subulate, sharp-pointed, about $\frac{1}{8}$ in. long, decurrent in their basal half, concave and whitened on their inner surface.

This is known in Japan as *Hiyoku-hiba*, and was apparently introduced by Fortune into the Bagshot Nursery in 1861. There is a good specimen of this at Tortworth, bearing fruit exactly like that of the type. Planted at Osborne in 1873, it is now 15 ft. high and covered with small cones. Both Syme and Beissner mention cases in which branches reverted to the ordinary foliage of *C. pisifera*.

Sargent⁶ says this is one of the most remarkable of pendulous conifers, but in New England it is very capricious, sometimes flourishing with great luxuriance, as in Mr. Hunnewell's pinetum at Wellesley, Massachusetts, but more often perishing from the cold of severe winters.

4. Var. *aurea*. Normal branching and foliage, the latter in the first year bright yellow, changing to green in the following year. This originated in Barron's nursery at Borrowash. (A. H.)

¹ Masters, in *Gard. Chron.* iv. 671 (1888), mentions a tree at Canterbury of this variety, laden with cones of *C. pisifera*.

² In *Gard. Chron.* xviii. 395 (1882).

³ Mr. Bartlett sent from Pencarrow to Dr. Masters a branch of var. *plumosa*, which was produced on a tree of *C. pisifera*, about eighteen years old. Cf. *Gard. Chron.* xxvii. 9 (1900). Elwes saw the same thing at Woodstock.

⁴ *Gard. Chron.* xvi. 410 (1881).

⁵ *Kew Bull.* 1896, p. 8.

⁶ *Garden and Forest*, x. 431 (1897).

DISTRIBUTION

This tree¹ has much the same distribution as *C. obtusa*, and is called *Sawara* in Japan. Where the two are mixed in natural forest it is usually the commoner, as it reproduces more freely from seed, and on account of the lower value of its timber is not so much felled except in places easy of access. Its habit of growth is more pendulous and graceful, and it attains about the same size as its congener. The largest that I measured in the Atera valley was by the roadside, and had its roots partially cut through. It appeared to be about 150 years old, and was 115 ft. by 13 ft.; but Mayr states that he saw, in a chestnut forest, a tree 120 ft. high and 3 ft. in diameter; and among beech and oak, another 130 ft. high and 3 ft. in diameter, whose first branch was at 80 ft. from the ground. The tallest he measured was 134 ft. high, and the thickest 7 ft. in diameter. On a stump recently cut in the forest of Atera I counted about 200 rings in a diameter of 4 ft., but the heart was rotten and the tree must have been 250 years or more old.

I saw no trees of the numerous varieties which are grown as pot plants in a dwarfed condition, but these do not seem to be so popular among the Japanese as among foreigners.

The timber, though fine in grain, is not so much valued, though used for the same purposes as that of *C. obtusa*. When the trees have died standing, it turns to a greyish colour, and a large slab of this wood which I brought home shows a very pretty grain.

CULTIVATION

This species was introduced by J. Gould Veitch in 1861, and like *C. obtusa* has become widely spread in gardens, where it is usually seen as a small shrubby tree. It is perfectly hardy, and ripens seed freely in the warmer parts of England, but shows no signs of attaining timber dimensions in this country. It appears to grow slightly faster than *C. obtusa*, and like it dislikes lime in the soil.

The finest specimens that we have seen are:—at Bicton, 41 ft. by 4 ft. 10 in. in 1906 (Plate 305); at Canford Manor, Dorset, 40 ft. by 4 ft. 3 in. in 1906; at Moncrieffe, 38 ft. by 3 ft. 10 in. Smaller trees have been seen by us at Chatsworth, Killerton, Tortworth, Dropmore, High Canons (Herts), Golden Grove, Tan-y-bwlch, and Castle Kennedy.

This species is well adapted for hedges, as it bears pruning well, and by continual cutting acquires a very dense habit.

In New England² it is a more rapid-growing and perhaps a hardier tree than *C. obtusa*, but with its loose narrow crown of more upright branches is less ornamental than that species. It has attained 32 ft. high at Wellesley, Massachusetts.³

In Prussia⁴ this cypress has been tried in thirteen experimental plots, covering

¹ It is unknown in the wild state out of Japan, and is not yet recorded for Formosa. We have not been able to find the specimen, collected in Yunnan by Anderson, referred to by Kent, Veitch's *Man. Conif.* 227, note (1900).

² Sargent, in *Garden and Forest*, x. 431 (1897).

³ Sargent, *Pinetum Wellesley*, 13 (1905).

⁴ Schwappach, *Anbauvers. fremd. Holzarten*, 30 (1901).

five acres. It grows quicker than *C. obtusa* in youth, attaining in its fifth year a height of 2 to 5 ft., in its tenth year 7 to 10 ft., and in its fifteenth year 13 to 20 ft. It begins to bear fertile seed when about fourteen years old. It appears to be more hardy in Prussia than either *C. obtusa* or *C. Lawsoniana*. (H. J. E.)

CUPRESSUS NOOTKATENSIS, SITKA CYPRESS.

- Cupressus nootkatensis*, Don, in Lambert, *Genus Pinus*, ii. 18 (1824); Loudon, *Arb. et Frut. Brit.* iv. 2480 (1838); Masters, in *Journ. Linn. Soc. (Bot.)* xxxi. 352 (1896); Sargent, *Sitka N. Amer.* x. 115, t. 530 (1896); Kent, *Veitch's Man. Conif.* 217 (1900).

A tree, attaining in America 120 ft. in height and 18 ft. in girth. Bark about $\frac{1}{2}$ in. thick, brownish grey, and separating on the surface into large thin loose scales. Branches of the fifth year smooth, terete, brown; those of the third and fourth year roughened with persistent brownish remote leaves. Branchlet systems distichous, on the upper part of the tree pendulous in vertical planes at right angles to the stem, tri-pinnate, with alternate pinnæ disposed in one plane. Ultimate branchlets flattened, compressed, $\frac{1}{15}$ in. wide. Leaves, $\frac{1}{8}$ to $\frac{1}{12}$ in. long, green, not marked with whitish lines or streaks, appressed; lateral pair conduplicate, acute and minutely mucronate at the spreading apex; facial pair flattened, rhomboidal, with an acute or mucronate apex, and a shining median ridge, often furrowed longitudinally. Leaves on the main axes equal in length, $\frac{1}{4}$ in. long, with acute free tips.

Staminate flowers yellow, $\frac{1}{8}$ in. long, with eight to twelve stamens. Pistillate flowers dark plum colour. Cones, ripening in the second year, and falling soon after the escape of the seed, on the ends of short leaf-clad branchlets, dark brown tinged with a glaucous plum colour, globose, $\frac{1}{3}$ in. in diameter; scales usually four, rarely six, bearing near their centre a prominent triangular sharp-pointed process, occasionally covered with resinous glands. Seeds two on each scale, flattened-pyriform, acute at the apex, reddish brown, without resin-vesicles; with the broad wings nearly $\frac{1}{4}$ in. wide.

Seedling:—Cotyledons two, $\frac{1}{3}$ in. long, sessile, linear, rounded at the apex. Primary leaves usually in whorls of fours, occasionally in pairs or threes, $\frac{1}{3}$ in. long, decurrent at the base, acute or acuminate at the apex, linear, green beneath with indistinct stomatic bands. The stem in the first year attains about an inch in height,

developing about eight whorls of leaves and a tiny lateral branchlet, and ending in a tuft of smaller leaves. The tap-root is slender, flexuose, about $1\frac{1}{2}$ in. long.

VARIETIES

Scarcely any varieties have been noticed in the wild state. Under cultivation it has shown much less tendency to variation than *C. Lawsoniana*. The most notable varieties are:—

1. Var. *pendula*. Branches and branchlets very pendulous. Fine examples occur at Bayfordbury. Dr. Masters¹ figures a pendulous variety in a forest clearing in British Columbia.
2. Var. *lutea*. Young branchlets yellow, changing to a yellowish green when older. It is fast in growth and is similar in habit to the type.² At Powerscourt this variety is pendulous and remarkably beautiful.
3. Var. *glauca*. Leaves glaucous.
4. In var. *argenteo-variegata* some of the young branchlets are creamy white, while in var. *aureo-variegata* some are yellowish. There are good specimens of these at Highnam.
5. Dwarf forms are also known, as var. *compacta*, a shrubby form with crowded branchlets; and var. *gracilis*, with very slender branches.
6. Var. *nidifera*,³ Rovelli, which originated at Pallanza, is said to be feathery-looking, owing to the slender shoots, densely covered with appressed deep green subulate leaves, each with a central gland on the back. (A. H.)

DISTRIBUTION

According to Pinchot,⁴ this species, which is universally known in its native habitat as yellow cedar, grows in the Pacific Coast region from the head of the Santiam river in the Cascade mountains of northern Oregon, northward through Washington, British Columbia, and Alaska to Prince William Sound.

It is most abundant, and reaches its best development, on the coast and adjacent islands of British Columbia and southern Alaska, where it often predominates in the forest. In Washington small stands, covering thirty or forty acres, sometimes yield as high as 150,000 board feet per acre.⁴

It occurs occasionally pure; but is usually scattered through the forests in British Columbia and Alaska, with Sitka spruce, giant Thuya, western hemlock, and swamp hardwoods; and at timber line occurs in a stunted form with Sitka spruce, black hemlock, and lodge-pole pine. Farther south on the coast it is associated with lowland fir and yew; while at higher elevations, in the Cascades, it is mixed with black hemlock, lodge-pole pine, *Abies amabilis* and *A. nobilis*, Douglas fir, western larch, white pine, alpine fir, and Engelmann's spruce. On the coast of Puget Sound this tree is not seen, as in this latitude it hardly extends

² Cf. *Gard. Chron.* vii. 108 (1890).

³ Figured by Earl Annesley, *Beautiful Trees*, 55 (1903).

⁴ *U.S. Forest Service, Sylvical Leaflet*, No. 12 (1908).

to sea-level, though farther north, in Queen Charlotte Sound and Islands, it becomes one of the most common trees. In Vancouver Island¹ I did not see it, as it grows only at a higher elevation and farther north than I reached, and as yet forms no part of the produce of the lumber mills.

In Washington it is found only in small areas, and is not abundant. Plummer says² that it is found between 2600 and 7400 ft., generally associated with mountain fir, pine, and hemlock, preferring shady valleys and basins, and not exceeding 100 ft. high by 3 ft. in diameter. But I found on the road from Longmire Springs to Paradise Valley, on Mt. Rainier, a tree of remarkable size, 108 ft. high and 17 ft. 10 in. in girth; above the point at six ft. where the tree forks just below this, it measured no less than 26 ft. in girth, and seemed quite sound. This appears to be the largest girth recorded for this species. Plate 306 from a photograph taken in this district, and Plate 307 from photographs taken in Washington, give a good idea of the habit of the tree in its native forests.

In Washington it crosses the Cascade mountains to the valleys running east, where Mr. Gorman found it from 2100 ft. on the Stehakin, to 6000 ft. about the headwaters of the Methow and Rattlesnake Creek. He says:³—"Of all the trees of this region the Alaska cedar is the most pronounced lover of moisture, and on this account it is not only confined to the moist valleys, but to those only which head in or about the main divide of the Cascade range. The finest specimens are in the Stehakin and Agnes Creek, where it ranges from 50 to 75 ft. high and 10 to 25 in. diameter. About its upper limits, especially in Horseshoe Basin, the tree was quite alpine in habit and very stunted in growth, but even the most stunted trees, some of which did not exceed 10 ft. in height, were found to be fairly well covered with the typical small barbed cones, which take three years to mature their seed.⁴ The bark of the young tree is somewhat red and shreddy, becoming checked and grey with age, when it bears a strong resemblance to that of *Thuja plicata*; but the mature tree, unlike the latter, continues sound at the core."

HISTORY AND CULTIVATION

The yellow cedar was discovered in 1793 by Archibald Menzies, who accompanied Vancouver, as surgeon and naturalist, in his voyage round the world. His specimens, gathered on the shore of Nootka Sound, were described by Don in 1824. It was first cultivated about 1850 in the St. Petersburg Botanic Garden,

¹ According to Butters, in *Postelsia*, 199 (1906), it is common in the south-eastern part of Vancouver Island, at elevations above 1000 feet. Anderson, in *Canad. Forestry Convention Report*, 1906, p. 71, says the nearest point to Victoria where trees are found is on the Nanaimo River and on Mt. Benson; and adds that it grows in large quantities in the interior of the island, and extends to the snow-line.

² 21st Ann. Rep. Geol. Survey, Mount Rainier Forest Reserve (1900).

³ 19th Ann. Rep. Geol. Survey, Washington Forest Reserve, 339 (1899).

⁴ Pinchot, in *U.S. Sylvical Leaflet*, 12, p. 3 (1908), says: "Flowering takes place in April, and the seeds mature and are scattered in the early autumn of the same season. They are distributed by the wind, and though they will germinate on moss and decaying wood, mineral soil is preferred as a seed-bed." Sargent also states that the fruit ripens in the first season. Both, however, in America and in England, the seeds do not ripen till late in the spring of the second year, and the cones usually do not open until the autumn following.

whence it was sent out under the name of *Thujopsis Tschugatskoi*, Fischer;¹ and, soon after, it became known in France² under the name *Thujopsis borealis*, Carrière. It appears to have been first introduced¹ into England by Pontey, of Plymouth, who received plants from Booth, of Hamburg, which in 1854 were 3 ft. high.

Though not so generally planted, or so common, in gardens as Lawson cypress, it has been during the last fifty years a popular tree among nurserymen under its old name of *Thujopsis borealis*. Though looked on as an ornamental tree only, my experience of it on poor dry soil justifies me in thinking that, if it could be procured at a reasonable cost, it would be one of the most valuable trees for such soils that can be planted; because it is not only absolutely hardy³ under all conditions in every part of the country, but will thrive where no other tree whose timber at all approaches it in value, except perhaps the larch, will grow to any size. Though a slow grower at first, and not likely to attain in this country the dimensions of *Thuja plicata*, it has all the other good qualities of that tree in an even greater degree. The difficulty of raising it from seed, which I and others have experienced, is one that I cannot yet explain, for though I have on several occasions sown carefully both imported seed and freshly gathered seeds saved from my own trees, I have never had more than a very small percentage of germination, the seeds mostly lying dormant for more than a year without losing their apparent freshness.

Mr. J. Rafn, of Copenhagen, whose tests of the germination of tree seeds have been published in the *Trans. Roy. Scot. Arb. Soc.* xvi. 277 (1900), informed me that his experience was similar.

In October 1905, I gathered a quantity of seed from my own trees, which had been produced in 1904, and seemed mature in the spring of 1905, though the cones remained closed till autumn. Part of this seed was sown under glass in boxes, part in a frame, and part in the open ground, as soon as it was dry; but the proportion which germinated in the following year was not 1 per cent. I was much surprised, therefore, when in the spring of 1907 the seed germinated regularly and well, a unique instance, in my experience, with seeds of this character when properly treated. I am however informed by Capt. the Hon. R. Coke, that he raised a considerable number of seedlings of this tree, by gathering the fruit in May, drying it in the sun, and sowing at once. In this case, the seed germinates in the succeeding spring, and so gains a year over autumn sowing.⁴

As it is easily propagated from cuttings, the plants sold in nurseries are usually so produced; and though I have the same preference for seedlings in this case as in others, I am not able to say from experience that cuttings will not make as good trees eventually.

¹ Cf. Lindley, in *Gard. Chron.* 1854, p. 727, and 1856, p. 772, who says that the seeds were supposed to have come from "Tschukotsk, a cape on the west coast of Kamschatka."

² It was exhibited, as *Thujopsis borealis*, by Thibaut and Keteleer, at a horticultural meeting in Paris in 1852, and occurs in the list of plants cultivated in the Jardin des Plantes in 1853. Cf. *Gard. Chron.* 1854, p. 727. It was also called *Pinus Tschugatskoi* by French nurserymen. Cf. *Gard. Chron.* 1856, p. 342.

³ In Palmer's frost-tables, quoted by Lawson, out of seventy-eight places from which he had reports of the effects of the severe winter of 1860-61, not one tree was killed, and only three were slightly injured.

⁴ On 19th October 1909, I sowed a packet of seed freshly gathered at Bayfordbury, and kept the pot in a cold frame. On 10th April 1910, a large proportion of this seed had germinated. Messrs. B. Reid of Aberdeen also inform me that for the first time in their experience, seeds of this species have germinated in the next spring after sowing; so there is evidently some condition that we do not yet understand, which governs the germination of the seeds of this species.

I have rarely seen a sickly, diseased,¹ or frost-bitten tree of this species in England, and though on good soils I would prefer Lawson cypress, I have so much confidence in its ultimate value as a timber tree, that I would on my own soil plant ten thousand, if I could get that number of seedlings at anything like a forest tree price. It seems to grow equally well on limestone, clay, or sand, but I have no experience on peat. I have not observed any case of rabbits eating the bark of this tree.

In its native country the yellow cedar seems to grow best in a mild damp climate, where the rainfall ranges from 30 to 100 in. or more. It seems absolutely indifferent to any sudden changes, and endures the severest frosts, whether in winter, spring, or autumn, without the slightest injury.

Though it grows faster and larger on deep fertile well-drained soils, it seems to suffer less from drought on dry oolite soil than any of the trees which accompany it in its native country. It will grow, perhaps, better than any other western conifer on this soil. Six trees which I planted in 1876 or 1877 are now 35 ft. high by 2 ft. in girth, and very uniform in height and habit; whilst Corsican pines planted close to them at the same time are about 40 ft. It does not seem to respond to good soil so well as most trees; the largest that I know in England having made about the same rate of growth, namely, one foot per annum.

It has a narrow conical crown, a rapidly-tapering stem set with persistent, horizontal or slightly-drooping branches, and flattened pendent sprays of foliage. The branches do not seem to die, however closely the tree may be crowded, until it has attained considerable age. The root-system is comparatively shallow and fibrous, making the tree very easy to transplant in spring or autumn; and the percentage of death after transplantation on my soil is unusually small.

REMARKABLE TREES

The largest that I have measured in England grows not far from the great Douglas fir at Eggesford, and in 1908 measured 61 ft. by 5 ft. 7 in., a tree of perfect shape with a very good trunk. At Killerton there is one of 52 ft. by 5 ft.

At Streatham Hall, near Exeter, there are many good trees growing on each side of the drive, which prove the fitness of this species for planting avenues of moderate width and length. At Tortworth there are two fine trees, one of which (Plate 308) is about 55 ft. by 4½ ft.; another, with a double leader, is about 50 ft. high. At Eastnor Castle there is one which Mr. Mullins reported in 1909 to be 57 ft. by 4½ ft.

At Leonardslee there is a well-shaped tree about 50 ft. high and only 3 ft. 8 in. in girth. At Hewell Grange there is a very thriving specimen 60 ft. high by 4 ft. 4 in. in girth. At Bayfordbury, in a drier soil and climate, there is a tree with such a graceful pendulous habit, and which has the rank disagreeable smell, usually possessed by this species, so faint, that I at first mistook it for *Cupressus funebris*.

¹ In Germany, according to Unwin, *Future Forest Trees*, 96 (1905), it suffers more even than Lawson cypress, from a fungus, *Pestalotia funerea*, which causes the decay of the bark of the young shoots.

At Shadwell Court, near Thetford, Henry measured a tree 58 ft. by 3 ft. 8 in., growing on poor sandy soil which contains lime.

In all parts of Scotland where I have seen it, especially in the west, this species grows well, and should be valuable, not only for ornament, but also for planting in rocky and exposed situations, though so far as we know it has not yet been planted under forest conditions. The largest that I have measured is a very healthy tree in the Dolphin Walk at Murthly, which, in 1906, was 45 ft. by 3 ft.¹ At Poltalloch, in the same year, I measured one of 42 ft. by 3½ ft.

In Ireland we have seen fine trees at many places, the largest perhaps at Woodstock, about 55 ft., the average rate of growth being about one foot per annum, though at Powerscourt it was 40 ft. high twenty-four years after being planted. Everywhere it seems to grow as well as in England, and to be worth planting more extensively.

In France and Germany the climate does not seem to suit it so well as in Great Britain, and we have seen no specimens of remarkable size. But a tree is reported² to be growing in the grounds of the Villa Lindenhof, at Lindau, on the Lake of Constance, which was no less than 30 metres high, though I suspect this to be a misprint, for I have found no other records at all approaching this. Pardé³ states that it has produced natural seedlings at Auteuil (Oise), and that the plantations of it which he saw at Weinheim, in Baden, are superb. In Norway, Schübeler says, it is hardy as far north as Trondhjem, and grows well at Christiania and Stockholm.

TIMBER

Of all the coniferous trees of North America, none has better wood than this, though it is little known even in its own country, on account of the difficulty of getting it in commercial sizes from the comparatively inaccessible places where it grows. Hough says that for cabinet-making it has few if any equals among North American woods, and that it has been exported to China in considerable quantities where it is used as a substitute for satin-wood. Though its lustre does not equal that of satin-wood, yet the section in Hough's book which was cut from a tree growing on Mt. Hood, Oregon, shows a remarkable density and slowness of growth. Hough counted 427 rings in a radius of 9¼ in. only; and I have never seen any coniferous wood so compact, or in which the rings are so hard to distinguish.

Ordinary commercial boards of much inferior quality to this were quoted in 1904 at Victoria, B.C., at 60 dollars per 1000 ft., or more than double the price of the finest Oregon fir or red cedar; and though, owing to this high price, it is little used except in the best houses, yet the work done with it in the house of the Hon. James Dunsmuir, Lieut.-Governor of British Columbia, proved to me that it was a wood which, if it could be procured in this country, would take a high rank among fancy woods for furniture, cabinet-making, and panelling.

¹ In *Journ. Roy. Hort. Soc.* xiv. 533 (1892) a tree was reported here as 50 ft. by 1 ft. 9 inches, but this I could not find, and suspect a misprint. Another at Brahan Castle was said (*op. cit.* 541) to have been then 45 ft. by 6 ft. 8 in., which also seems doubtful.

² *Mitt. deut. dendr. Ges.* 1905, p. 32.

³ *Arb. Nat. des Barres*, 39 (1906).

I do not find that the strong, and to most persons offensive smell, which is present in the leaves and bark of this tree, is noticed in the wood except when freshly planed, and this smell soon disappears after exposure.

A small importation of this wood which I recently purchased in Liverpool, has been tested by my house carpenter, who reports that it takes a finer surface and absorbs less polish than any soft wood he knows.

Mr. J. R. Anderson,¹ Deputy Minister of Agriculture in British Columbia, writes to me as follows, in reply to my inquiry as to this timber:—

“It is a grand wood, and you are quite right in designating it the finest of the N. American coniferous woods. It is a tree of slow growth, and therefore close grained. A specimen I have which was cut on the Nanaimo river, where it grew on good soil not far above sea-level, shows 137 rings for 13 in., that is at the rate of about 10 years to the inch, assuming that the rings represent a year's growth; and at high altitudes it is reasonable to expect a still slower growth. The soil that it affects is not what may be termed poor, but rather of a peaty cold nature, and in this latitude high up on the mountains. Two to four feet is a good size, and I have seen quite extensive groves at the base of Mount Arrowsmith, and elsewhere where the size is much less.”

Mr. Anderson enclosed me a letter from Mr. C. Harrison, who states that yellow cedar claims were, in 1907, for disposal at 3½ dollars per acre, which would carry on an average about 12,000 ft. board measure to the acre, with a quantity of spruce and hemlock in addition. But the obligation to cut all timber within a few years which existed under the Government leases of timber lands in British Columbia, and which was described by one of the best authorities in Canada as insane, offers no inducement to any one to take up timber limits in the province, who has not the intention and the means to realise everything that can be got to market at a profit, and then abandon the land as quickly as possible.

CUPRESSUS LAWSONIANA, LAWSON CYPRESS

Cupressus Lawsoniana, Murray,² in *Edin. New Phil. Journ.* i. 292, t. 10 (1855); Hooker, in *Bot. Mag.* t. 5581 (1866); Murray, in Lawson, *Pinet. Brit.* ii. 191 (1866); Masters, in *Journ. Linn. Soc. (Bot.)* xxxi. 353 (1896); Sargent, *Silva N. Amer.* x. 119, t. 531 (1896); Kent, Veitch's *Man. Conif.* 205 (1900).

Cupressus fragrans, Kellogg, in *Proc. Calif. Acad.* i. 103 (1857).

Cupressus nutkanus, Torrey, in *Bot. U.S. Explor. Exped. Wilkes*, ii. t. 16 (1874).

Chamaecyparis Lawsoniana, Parlatores, in *Ann. Mus. Stor. Nat. Fir.* i. 181 (1864); Sargent, *Trees N. Amer.* 84 (1905).

Chamaecyparis Boursierii, Carrière, *Conif.* 125 (1867) (not Decaisne).³

A tree attaining in Oregon about 200 ft. in height, and 6 to 12 ft. in diameter above the abruptly enlarged base. Bark on old trunks, 3 to 10 in. thick, reddish

¹ In *Canad. Forestry Convention Report for 1906*, p. 71, Anderson says that the strong but rather unpleasant odour is objectionable to insects. The Indians make canoes and carvings of the wood.

² This description is reprinted in *Gard. Chron.* 1855, p. 372.

³ *Chamaecyparis Boursierii*, Decaisne, in *Bull. Soc. Bot. France*, i. 70 (1854), is *Juniperus occidentalis*, Hooker. Cf. *Gard. Chron.* xi. 726 (1879).

brown, with a dark compact inner thin layer, and a spongy outer thick layer, dividing on the surface into rounded ridges covered with small appressed scales; on young stems thin, slightly scaly, with narrow longitudinal fissures.

Branches of the fourth year slightly compressed, brown, with traces of the leaves. Branchlet systems disposed in planes tangential to the trunk of the tree, distichous, tri-pinnate, with the pinnæ in one plane. Ultimate branchlets flattened, compressed, about $\frac{1}{16}$ in. wide. Leaves appressed, usually marked on the under surface with ill-defined streaks of white, partly on the ventral leaf and partly on the lateral leaves; lateral pair conduplicate, $\frac{1}{12}$ to $\frac{1}{16}$ in. long, often minutely mucronate; facial pair rhomboidal, much smaller, $\frac{1}{20}$ in. long, acute, often marked with a glandular furrow or circular pit. Leaves on the main axes, oblong, unequal, the lateral pair $\frac{1}{4}$ in., the facial pair $\frac{1}{8}$ in. long, with acute or acuminate, slightly spreading apices.

Staminate flowers¹ crimson, the connectives usually bearing two anther-cells. Pistillate flowers plum-coloured, with horizontally spreading scales. Cones, ripening in the first autumn, globose, $\frac{1}{3}$ in. in diameter, reddish brown and covered with a glaucous bloom; scales eight, depressed in the centre and with an ovate acute reflexed process. Seeds, two to five on each scale, ovate, acute, $\frac{1}{8}$ in. long, brown, with conspicuous large resin-vesicles, and narrow wings.

The seedling² has two cotyledons, about $\frac{1}{3}$ in. long, broader and more rounded at the apex than in *C. nootkatensis*. Primary leaves arranged in whorls, as in that species, acuminate at the apex, $\frac{1}{5}$ in. long, conspicuously white beneath. The young plant attains 1 to 2 in. in height in the first year, frequently giving off two or three lateral branches, and has a very long slender flexuose tap root.

VARIETIES

Hardly any tree has shown under cultivation so much variation as the Lawson cypress, no less than forty-eight varieties being mentioned in the *Kew Handlist of Coniferae*.³ The more important⁴ may be arranged as follows:—

1. *Columnar or fastigiata in habit.*

1. *Var. erecta viridis* (var. *stricta*). Narrow, erect, pyramidal, with a close dense mass of branches, all set with their foliage-bearing ramifications in planes radially disposed to the main stem. Foliage bright green. This originated⁵ in Waterer's nursery at Knap Hill as a seedling, which was raised from seed imported from California in 1855. It was propagated and sold for some time as var. *erecta*, but in

¹ Masters describes in *Journ. Linn. Soc. (Bot.)* xxvii. 312, fig. 19 (1890), an androgynous flower, the lower scales bearing anthers and the upper scales bearing ovules.

² Trees often produce seed abundantly when only 6 to 12 ft. high; and plants were raised from seed of very small trees in England as early as 1863 by W. Tillery. Cf. *Gard. Chron.*, 1864, p. 1013. Barron, in *Gard. Chron.*, 1861, p. 718, gives an instance of plants only 2 ft. high bearing cones.

³ Beissner, in the second edition of his *Handbuch* (1909), describes 77 named forms, many of which seem to be hardly worth notice.

⁴ *Var. fragrans*, kept up in the *Kew Handlist*, differs in no respect from the type, and appears from Gordon, *Pinetum*, 88 (1875), to have been sent out by Standish, and possibly may have been raised from seeds sent by Beardsley. See *infra*, p. 1206, note 1.

⁵ Cf. *Gard. Chron.*, 1870, pp. 249, 279, fig. 49; and 1874, ii. 329.

1870, when the original plant was 9 ft. high, it obtained a first-class certificate at a meeting of the Royal Horticultural Society, and was renamed *erecta viridis*. It is quite unique as regards beauty, and never needs pruning or cutting; but snow or even heavy rain will bend and break the branches, which never recover, leaving unsightly hollows in its outline. It is most useful as a small decorative plant; but in some places has succeeded as a walk or avenue tree, and at Terling Place, Essex, has attained 30 ft. in height. It is perfectly hardy, even in the south of Norway. This has been largely planted in many places, the tallest that we have seen being at Bowood, where it is 43 ft. high. At Westonbirt and at The Hendre there are fine specimens 35 to 40 ft. high. At Baron's Court, Co. Tyrone, the seat of the Duke of Abercorn, there are several good specimens about 25 ft. high, planted about forty years ago, which, like most of the older trees of this variety, have become bare at the base on the north side.

2. Var. *Allumi* (var. *Fraseri*). Similar to var. *erecta viridis* in habit, but bluish in colour, due to the presence of a glaucous bloom on the leaves. Sir Herbert Maxwell tells us that this variety has come true from seed.

3. Var. *erecta filiformis*.¹ Similar to var. *erecta viridis* in habit, but with very slender branches and branchlets.

4. Var. *ericoides*. Branchlets very slender; leaves bright green, free and spreading at the apex.

5. Var. *Smithii* is columnar in habit, being nearly the same in diameter at the top as it is at the base. The foliage is glaucous.

6. Var. *Wisseli*¹ is also columnar in habit, with erect crowded branches and branchlets. The leaves are said to be juvenile in character, subulate, and spreading, with a glaucous tint; but in an example at Kew they are only slightly more spreading than in the type.

II. *Pendulous in habit.*

7. Var. *gracilis*. This name may be given to varieties with slender pendulous branches, the original form² of which originated in Waterer's nursery at Knap Hill, and received a first-class certificate from the Royal Horticultural Society in 1870. A more pendulous form, var. *gracilis pendula*, originated in Barron's nursery, Borrowash, Derby. In var. *gracilis aurea*³ all the branches are similarly pendulous, but the growths of the current season are golden yellow in spring, changing to bright green in autumn, and to dark green in the succeeding year. A pendulous variety with white foliage, var. *pendula alba*, raised by Paul and Son, obtained⁴ a first-class certificate at a meeting of the Royal Horticultural Society in 1869. At Little and Ballantyne's nursery, Carlisle, there is a peculiar pendulous variety, about 8 ft. high, resembling in form the weeping variety of *Sequoia gigantea*.

¹ Cf. *Gard. Chron.* xxv. 116 (1899).

² *Gard. Chron.*, 1870, p. 249.

³ The original plant was raised in the Hillsborough Nursery, Co. Down, and was purchased by the late Earl Annesley, *Gard. Chron.* xvi. 192 (1894). It was very beautiful in colour when I saw it in July 1907.

⁴ *Gard. Chron.*, 1869, p. 1067.

III. *Spreading in habit.*

8. Var. *intertexta*. A robust plant, with distinct and arching branches, and remote stout divaricate branchlets. Foliage slightly glaucous or bluish green.¹

9. Var. *juniperina*. Branchlets regularly pinnate, the ultimate divisions slender, with the leaves free at their apices, and yellowish green in colour.

10. Var. *patula*. Of pyramidal compact habit, with the branchlets very slender and forming fan-shaped expansions; leaves dark green, shining.

11. Var. *Youngi*, Masters, in *Gard. Chron.* i. 176 (1887). Of elongated pyramidal habit, with ascending, loosely-arranged, more or less concave and twisted branches.

12. Var. *filifera*. Branches spreading or sub-pendulous; the terminal branchlets being very long, with short remote lateral branchlets. There are good examples of this peculiar variety at Grayswood, Haslemere, and at Brickendon Grange, Herts.

IV. *Dwarf in habit.*

13. Var. *nana*. This includes the dwarf varieties, the original form having been obtained² in 1861 by Dauvesse. It is ovoid in shape, with stiff erect flattened branches and branchlets, and seldom exceeds 3 ft. in height. There is, however, a specimen at Westonbirt, said to be forty years old, which is about 7 ft. high. There are two distinct forms, one bluish green, which is the best, and another light green. Coloured dwarf varieties are also known as var. *nana alba*, with yellowish white foliage, and var. *nana glauca*, with very glaucous foliage.

V. *Coloured varieties.*

14. Var. *albo-spica*. Densely pyramidal in habit; terminal branchlets variegated with creamy-white. Forms known as *albo-maculata*, *albo-picta*, and *argenteo-variegata*, are very similar, if not identical, with this variety. The best example that we have seen of this is at Inverary, where it measured about 30 ft. in 1908.

15. Var. *argentea* (var. *glauca*). Foliage very glaucous, varying from almost a silvery white to steel blue. The forms known as "Silver Queen" and "Triomphe de Boskoop"³ are similar, but differ somewhat in their degree of glaucescence. The latter is said to be the bluest conifer known. Other glaucous forms known as var. *Bowleri* and var. *californica* are in cultivation at Kew.

16. Var. *albo-variegata*. A dwarf compact variety, with the foliage profusely spotted and blotched with white. This originated in the Coombe Wood Nursery.

17. Var. *aurea*. Foliage golden yellow in the spring and summer of the first year, greenish yellow in autumn and winter following, becoming green in the second year. This is one of the best and most vigorous golden conifers for formal gardens and lawns, and has been largely planted at Baron's Court, where it forms a number of round compact bushes about 15 ft. high and as much in diameter. It requires exposure to full sunlight to bring it to perfection. It was shown by Waterer⁴

¹ A MS. note of Dr. Masters says that this was the form which first appeared in cultivation at Lawson's nursery.

² *Gard. Chron.*, 1864, p. 579. In the King's Acre Nursery, Hereford, a dwarf bright green variety, known as var. *pygmea*, is only 3 ft. high after twenty-four years' growth.

³ Cf. *Gard. Chron.* xxv. 116 (1899).

⁴ *Gard. Chron.*, 1870, p. 315.

at a meeting of the Royal Horticultural Society in 1870, and obtained a first-class certificate.

18. Var. *lutea*.¹ Paler yellow in colour, but equally fine, and of a more erect habit. About the best that we have seen is a tree now about 25 ft. high at Castlewellan.² Var. *ochroleuca* appears to be another yellowish variety.

DISTRIBUTION

The Lawson cypress in its distribution occupies a much smaller area than *Thuja plicata*, with which it mingles at its northern limit, and which it entirely resembles in its occurrence as a shade-bearer in the mixed coniferous forest of western North America at low altitudes. It grows in south-western Oregon and north-western California, in a climate characterised by moderate temperatures, heavy rainfall, a high degree of humidity, a foggy atmosphere, and a large proportion of cloudy days. On the coast the temperature ranges between 10° and 95° Fahr., and the rainfall between 30 and 100 in., averaging 56 in. Increase in altitude is attended by greater seasonal and daily ranges of temperature, and by an increase in snowfall; but the Lawson cypress, usually growing below 3000 ft. (rarely reaching 5000 ft.), is only luxuriant and plentiful in the region under the influence of the ocean winds.

In Oregon it reaches its northern limit on Coos Bay, and is most abundant in Coos and Curry counties on the western slopes of the foothills of the coast range.³ It extends across the coast range to Camas valley in Douglas County, twenty-six miles south-west of Roseburg, and goes farther inland in Josephine County, extending to Love's Station, sixteen miles west of Grant's Pass, and to Selma and Waldo; while it appears to be scattered throughout the Siskiyou mountains between Oregon and California. In California it extends southward as an unimportant component of the Redwood belt on the coast as far south as Humboldt County,⁴ and attains its most inland point (a hundred miles from the coast) on the southern slopes of Mount Shasta, at the headwaters of the Sacramento river.

This cypress nowhere forms pure woods, but is always scattered through the forest singly or in small groups, though near Port Orford it is very abundant, and in some places forms 25 per cent of the mixed forest of Douglas fir, Sitka spruce, hemlock, and Thuja. At Coquille, the most northerly point where I saw this species, it occurs on the slopes of the low hills, on which there is a luxuriant forest of enormous trees of several species, with a dense underwood of *Acer circinatum* and tall fern (*Aspidium munitum*), forming a scene like that of the Redwood belt in California. Here the Lawson cypress is most prized on

¹ Mentioned as an entirely new plant in *Gard. Chron.*, 1873, p. 6.

² Figured by Earl Annesley, *Beautiful Trees*, 52 (1903).

³ Sargent in *Gard. Chron.* xvi. 8 (1881), estimated that the belt in which this tree occurs most abundantly from north of the mouth of the Coquille river southward, about twenty miles long and twelve miles wide, contained 200,000 million feet, board measure, and speaks of the immense destruction of Port Orford cedar by a forest fire some years previously, which raged for three months in the vicinity of Coos Bay.

⁴ Mr. Henry Melde of Eureka says that trees 75 to 100 ft. high occur along the gulches of the Mad river in Humboldt County (*Erythea*, v. 99 (1897)).

account of its superior timber; but it is surpassed both in size and numbers by the Douglas and Thuja, which attain 250 to 300 ft. in height and 20 to 30 ft. in girth, while the largest cypress that I measured was¹ only 200 ft. by 14 ft. 6 in. A tree which had been felled had a diameter, exclusive of bark, of 44 in., and showed 220 annual rings, with 2½ in. of sapwood, containing thirty-three rings.

I saw a great deal of this species on my way by stage-coach from Grant's Pass, on the railway, through the Siskiyou mountains to the Redwood belt on the coast of California at Crescent City. Here it follows the course of the streams up to 3000 ft., growing in company with Douglas fir and other species in shady ravines, and attaining about 120 ft. in height and 3 ft. in diameter. On the dry hills it is immediately replaced by *Libocedrus decurrens*, though Pinchot says it is occasionally found on dry and sunny exposures in company with *Pinus ponderosa* and *P. Lambertiana*. Both here and at Coquille I saw numerous seedlings, less numerous but very uniform in appearance, in the shade of the parent tree in the forest; while they were excessively common on clearings and on agricultural land on the outskirts of the forest, and showed great variation when they were exposed to sunlight in youth. They grow most freely on mossy banks, rooting between the crevices. In the Redwood belt I saw cypress trees only on the banks of wide streams, where they are much smaller in stature and girth than the immense redwoods behind them. Pinchot says, however, that this species grows well in the north-west of California in swampy situations near the sea, associated with Sitka spruce, *Abies grandis*, and hemlock, but rarely forming a considerable part of the forest.

In Oregon close to the coast it thrives on sandy soil, and grows even on the sand dunes within reach of the spray of the ocean. In this State it has to compete with *Thuja plicata* in the moister deeper soil, as the latter species tends to outgrow and suppress it. In the forest it has a straight cylindrical stem, free of branches for half its height, with a slender drooping leader, which is bent away from the direction of the prevailing wind. It begins to bear seed when six to twelve years old, continuing annually in profusion to an advanced age. This abundance of seed enables it to spring up readily on logged-over and burnt areas. Seedlings in Oregon 5 ft. high showed ten annual rings. It occasionally is seen with a double stem; but, as a rule, it repairs its leader readily, which is, however, rarely injured except high up in the mountains when there is a heavy snowfall. It differs from all the other cypresses in its remarkably thick bark, which in its structure of two layers resembles that of the redwood. (A. H.)

CULTIVATION

William Murray first sent seeds of this tree from the valley of the upper Sacramento river in California to Lawson's nursery at Edinburgh in 1854, but only

¹ Sargent, Pinchot, and Mayr all agree in giving 200 ft. in height and 12 ft. in diameter as the maximum measurements of the Lawson cypress, but I doubt if it ever exceeds 7 ft. in diameter. The Douglas fir, Redwood, and Thuja, wherever they are associated with the Lawson cypress, much surpass it both in height and girth. Sir Victor Brooke, quoted by Lord Annesley in *Beautiful Trees*, 8 (1903), states that he measured a Lawson cypress 66 ft. 11 in. in girth, but he evidently refers to *Thuja plicata*, as there is nothing in his diary to show that he was ever in the region where the Lawson cypress grows.

four plants were raised, of which one growing at this nursery was 11 ft. 2 in. high in 1865, and is figured in *Pinetum Britannicum*, p. 194. In 1855¹ a larger supply of seed was sent by the same collector, and it soon became one of the most popular and generally cultivated trees all over Great Britain, where it is seen in almost every villa garden; but its value as a forest tree has been almost lost sight of. It yields seed² profusely at a very early age, and develops so many varieties of size, habit, and colour that it is hardly possible to believe that they have all had a common origin. The usual manner of propagation adopted by nurserymen is by cuttings, which are easily struck, and reproduce the different named varieties which are most admired; but if it is desired to plant the tree in a situation where it will have room to develop its natural size and habit, it is far better to gather seed from the tallest and most clean-stemmed trees, and select from the seedlings those which follow their parent most closely.

Self-sown seedlings of this tree are found in many places where the soil and shelter are suitable, but of the millions of good seeds which must be shed annually, only a very small proportion succeed in passing through their delicate first stage. It is best to sow the seeds in a box, and keep them shaded and watered in a frame for a year or two. I have seen a self-sown seedling at Penllergare, near Swansea, 30 ft. high, which Sir John Llewellyn thought to be about as many years old.

The seedlings can be raised as cheaply as spruce, and much more so than silver fir. They grow fast and vigorously after the first two years on almost any soil, and are very easy to transplant in autumn or spring, though for cold localities I prefer September. Large plants should not be used in exposed situations, as on account of their dense foliage they are apt to be swayed by the wind.

It is perhaps premature to say that this is a valuable forest tree, for it has not been long enough in Europe to show whether it will grow to a really large size; and has seldom been planted closely enough together, or in situations where it has had a fair chance to show its capacity for forming a fairly clean trunk.

Its hardiness is astonishing, as in the greater part of the native habitat the climate is mild and damp, and severe frosts are unknown; and yet in Murray's³ own words: "So far as is yet known there is not a hardier plant in Britain. Exposed in the winter of 1860-61 to the extremest cold which has visited this country in the memory of the present generation, it remained as green and fresh in the greatest frost and most exposed and unfavourable districts as in the midst of summer. Mr. Palmer's tables give only two slightly injured out of seventy-nine reported on." This was written about 1865, and has been amply confirmed by later experience.⁴

As regards soil it is equally accommodating, for though like all other trees it enjoys a good fertile loam, it will grow on dry sandy and on poor limestone

¹ Beardsley found this tree near Empire City on Coos Bay in 1855, and Kellogg described his specimens as *C. fragrans* in 1857. Plants cultivated under the latter name are identical with *C. Lawsoniana*. Cf. *Gard. Chron.*, 1869, p. 252.

² Unwin, *Future Forest Trees*, 94 (1905), states that a pint of seed weighs $\frac{1}{3}$ lb., and contains nearly 300,000 seeds. Of seed raised in the forest district of Freising near Munich, 70 per cent germinated.

³ In Lawson, *Pinet. Brit.* ii. 193 (1866).

⁴ Masters, in *Journ. Roy. Hort. Soc.* xix. 433 (1896), says that the young growths of Lawson's cypress suffered in the vicinity of London from the abnormal frost of February 1895 as they had never before been observed to do. *Var. erecta viridis* was much more injured than the ordinary spreading forms.

soils, a cold and wet peat being, according to Kent, the only one unfavourable to it.¹

It is not, so far as we know, subject to any fungoid disease in this country.

It endures heavy shade and requires close planting to keep its trunk free from large branches. It has a tendency to fork, especially when grown from cuttings. Judging from what I have seen, the beech will probably be its best nurse, though on damper ground alder might be preferable, and I should expect it to be one of the best evergreens to use for under-planting, or filling up gaps in thin woods. In Earl Bathurst's park at Cirencester a large number were planted on the edge of one of the broad grass drives leading west from the "Ten Rides," and these, surrounded and shaded by beech trees, have grown to be over 60 ft. high in about fifty years or less, and for the most part have trunks which are much less branchy than spruce or silver fir would be in similar conditions. These trees are growing on thin dry oolite soil not more than 6 to 8 in. deep, and as Mr. R. Anderson tells me were planted in 1864. The average height of twelve of them in January 1909 was 55 ft., and the average girth 3 ft. If we estimate their cubic contents at about 10 ft. each, one might reasonably expect to grow on this land 200 to the acre, giving 2000 cubic feet per acre in fifty years. Our Plate 98, of Larches, near the Woodhouse in the same park, shows trees under similar conditions.

For avenues, Lawson cypress seems very suitable, provided that trees of uniform habit and equal growth are selected, and for this purpose they should be frequently transplanted before their final selection, as in the nursery some vigorous trees generally take the lead and keep it, whilst others remain comparatively dwarfish.

As a cheap and ornamental hedge plant it has many advantages. Its shade of green is more agreeable than any other evergreen used for this purpose, and its feathery branchlets are more graceful than the rigid shoots of the holly or yew. According to a writer in *Woods and Forests*, small plants, 18 in. to 4 ft. high, should be used for this purpose, as they can be clipped and headed back until they become dense at the base. They may be planted, 12 to 18 in. apart, according to the size of the plants. Such hedges are best clipped in early September.

In the eastern United States, Lawson cypress thrives from New York southwards; but in New England it merely survives in sheltered situations, and Sargent² says that it cannot be used for general planting.

In Germany³ Lawson cypress has been tried in forest plots at different stations in Prussia, the total area being about thirty acres, and at Grafrath in Bavaria. Judging from an experience of twenty years, the wood grown in Germany is as good as that of Oregon. Heartwood begins to form in the tenth year with the characteristic fragrant odour of the timber in America. Trees, which had succumbed to the worst enemy of this species, *Agaricus melleus*, were successfully used for palings, without removing the bark. Another fungoid disease, *Pestalozzia funerea*,

¹ It grows, however, on deep bog at Churchill, Armagh, where it had been planted with Scots pine and birch, and numerous natural seedlings sprang up which were used for transplanting on other parts of the estate.—(A. H.)

² *Garden and Forest*, x. 430 (1897).

³ Cf. Schwappach, *Anbauversuche fremdl. Holzarten*, 26 (1901); Mayr, *Wald- u. Parkbäume*, 272, fig. 74 (1906); and Unwin, *Future Forest Trees*, 93, fig. 2 (1905).

has proved disastrous to many plantations in Germany. This attacks the young branchlets, and is readily recognised by the appearance of a white resinous drop, by the decay of a band of bark, and by a characteristic swelling in the part of the branchlet beyond, which continues to grow for a time. Mayr says that after a severe frost in April, when the temperature fell to 10° Fahr., Lawson cypress at Grafrath was attacked by *P. funerea*, which, however, killed only the weakly trees, the stronger plants surviving. Mayr recommends close planting, about 3 ft. apart, in mixture with light-loving deciduous trees; and gives a picture of a plot where oaks thirty-five years old had been underplanted successfully twenty years ago with Lawson cypress.

REMARKABLE TREES

There are many specimens of this tree all over Great Britain from 50 to 60 ft. high; but it is difficult to select the finest. The tallest that I have measured in England is one at Eggesford, which in 1908 was 70 ft. by 5 $\frac{3}{4}$ ft. At Killerton two of very different habit stand together on the slope behind the house (fig. 309), and measured in 1906 about 65 ft. by 6 ft.

At Brickendon Grange, Herts, there is a beautiful avenue, 100 yds. long and 8 ft. wide, of this tree, planted 8 ft. apart in the line; and an average specimen measured in 1907, 52 ft. high and 2 $\frac{1}{2}$ ft. in girth. At Ryston Hall, Downham, Norfolk, there is another fine avenue.

At Canford Manor, the seat of Lord Wimborne in Dorsetshire, I measured in 1906 a fine specimen, said to have been planted about forty years ago, which was 53 ft. by 6 ft.; and at Belvoir Castle one of about the same age was 56 $\frac{1}{2}$ ft. by 4 ft. 10 in. in 1908.

At Leaton Knolls near Shrewsbury, the seat of Major Lloyd, there is a very handsome tree 59 ft. by 4 ft. 4 in.; and at Willey Park, the seat of Lord Forester, near Broseley, a slender tree is 59 ft. by 3 ft. 9 in.

In south Wales the tree grows everywhere very vigorously, the tallest I have seen being a slender tree crowded in the pinetum at Singleton Abbey, the seat of Lord Swansea, which, in 1907, was about 75 ft. by 3 $\frac{1}{2}$ ft. At Penrhyn Castle and elsewhere in north Wales there are many fine trees.

In Scotland the tree is as common as in England, every place where conifers have been planted having some fine examples, but at Murthly there are more and bigger ones than I have seen elsewhere. In a flat below the castle, a lawn, measuring 50 yds. by 25 yds., has been surrounded with fine trees nearly 50 ft. high, very uniform in habit, whose branches now touch each other and form a dense enclosure.

At Dupplin Castle, near Perth, there are fine trees, one¹ of which was 55 ft. high in 1891, and is probably now the tallest in Scotland; and at Moncrieffe House there are some nearly as large. At Shanbally, Dumfries, Henry measured in 1904 a tree 60 ft. by 8 ft. 5 in. at 3 ft., dividing above into three stems; and at Benmore, where the tree has been largely planted, it seems to enjoy the very wet climate as much as *Thuja plicata*.

¹ Malcom Dunn, in *Journ. Roy. Hort. Soc.* xiv. 89 (1892), who reports a tree of similar height at Rossie Priory.

In Ireland this species is, if possible, even more vigorous than in Scotland, and certainly grows faster. A tree at Kilmacurragh, Co. Wicklow, was reported¹ in 1906 as being about 80 ft. high, but the tallest that I could find when I was there in 1908, and which I believe to be the same tree, was only 60 ft. by 6 ft. There are three very fine ones in a group in the valley west of Castlewella, of which the late Lord Annesley took a photograph (Plate 310) at my request shortly before his death. Though I was unable to measure them accurately, I believe they are well over 60 ft. high, and a tree in his garden which forms the first illustration in his book, measured 62 ft. high in 1903.

TIMBER

Though this splendid timber has long been known and valued in Oregon and California, where it is second in value only to that of *Cupressus nootkatensis*, it does not appear to be known in European commerce. Sargent describes it as light, hard, strong, and very close-grained, abounding in fragrant resin, very durable in contact with the soil, easily worked and capable of taking a good polish. All these good qualities are well shown by some boards of this wood which I purchased in San Francisco, and which have been used for lining a wardrobe made for me by Messrs. Emanuel of London, who considered it one of the nicest woods for the purpose they had ever seen. The scent is extremely fragrant and persistent, so that linen kept in this wardrobe comes out with an odour more agreeable and delicate than that of camphor wood; but this scent is not present in a sample brought by Henry from Myrtle Creek, Oregon, which I believe to be taken from a tree long dead. This gives it a great advantage over the wood of *C. nootkatensis* for all inside work; and if selected and sawn from the butts of old trees, which show some figure, it would be very handsome wood for decorative purposes.

Mr. L. J. Simpson, manager of the Simpson Lumber Co. at North Bend, Oregon, whose mills are near the forest of this tree in Coos County, writes to me as follows:—"We have cut many logs of white cedar which are 6 to 8 ft. in diameter. Some of them get hollow at heart after attaining a great age, but this is very much less frequent than it is in red cedar or redwood. I enclose you a photograph of a spruce tree 7 $\frac{1}{2}$ ft. in diameter, which has grown on the fallen stem of a smaller white cedar, the roots extending like the claws of a parrot around each side of the tree, and locking together underneath. The spruce tree must be over 200 years old, and the white cedar is to-day as sound as any of the green standing trees near it. You will notice in this photograph that the moss and dead leaves which have accumulated on the fallen log have been scraped away to show the soundness of the wood."

The Simpson Lumber Co. state in their circular that vessels built of this wood on Coos Bay over forty years ago are still as sound as when launched, the essential oil in the wood seeming to act as a preservative; and the smell is stated to be an absolute safeguard against moths when used for chests, presses, or wardrobes.

¹ *Gard. Chron.* xl. 351 (1906).

They also say that the trees are usually sound and free from hollow butts, and produce a large proportion of lumber free from knots.

Mayr¹ states that each species of the cypress family, including *Thuja*, etc., has a wood recognisable by a special odour, that of *C. nootkatensis* being the strongest and most disagreeable. The wood of Lawson cypress, he adds, is so strongly aromatic, that it can easily be smelt on approaching a saw-mill where it is being cut up, and many pieces of the wood are so saturated with an oily resin that they become heavy and reddish in colour. He speaks of the durability of the wood in the highest terms, saying that, when used as piles for building in swampy ground near the sea-coast, it lasts four or five times as long as that of Douglas fir.

The trees in this country are as yet too young and mostly too branchy to show how soon these good qualities will be developed, but I have no doubt that in time it will be one of our most valuable home-grown timbers. (H. J. E.)

CUPRESSUS THYOIDES

Cupressus thyoides, Linnæus, *Sp. Plant.* ii. 1003 (1753); Loudon, *Arb. et Frut. Brit.* iv. 2475 (1838); Masters, in *Journ. Linn. Soc. (Bot.)* xxxi. 352 (1896); Sargent, *Silva N. Amer.* x. 111, t. 529 (1896); Kent, Veitch's *Man. Conif.* 231 (1900).

Chamaecyparis spherioidea, Spach, *Hist. Veg. Phaner.* xi. 331 (1842).

Chamaecyparis thyoides, Britton, Steens, and Poggenburg, in *Prel. Cat. New York*, 71 (1888); Sargent, in *Garden and Forest*, ii. 484 (1889), and *Trees N. Amer.* 82 (1905).

Thuja spheroidalis, Richard, *Mém. Conif.* 45 (1826).

Thuja spherioidea, Sprengel, *Syst.* iii. 889 (1826).

A tree, attaining in New England 50 ft. in height and 2 ft. in diameter, and in the south-eastern United States 80 ft. high and 4 ft. in diameter. Bark, an inch thick, reddish brown, irregularly divided into narrow flat connected scaly ridges, which are often spirally twisted around the stem. Branches of the sixth year very slender, terete, brown, smooth, but retaining traces of the leaves, which roughen with their brown acute spreading tips the branchlets of the third, fourth, and fifth years. Branchlet systems alternate,² somewhat umbellate or radiating, forming short erect wedge-shaped expansions, tri-pinnate, with the pinnæ more or less in one plane and often directed to one side. Ultimate branchlets flattened, $\frac{1}{30}$ in. wide. Leaves, $\frac{1}{16}$ to $\frac{1}{12}$ in. long, glaucous green, and not marked with whitish lines or streaks; lateral pairs conduplicate, with mucronate spreading tips; facial pairs appressed, ovate-triangular, acute, flat or keeled; most of the leaves marked on the back with a conspicuous raised circular resinous gland. Leaves on the main axes, equal in length, glandular, $\frac{1}{8}$ in. long, oblong, with a triangular mucronate spreading tip.

Staminate flowers minute, dark brown, with five or six pairs of stamens. Pistillate flowers with ovate acute spreading dark brown scales, and black ovules.

¹ *Waldungen N.-Amer.* 318 (1890).

² The peculiar branching of this species is described by Masters, in *Journ. Linn. Soc. (Bot.)* xxvii. 288 (1890).

Cones ripening in the autumn of the first year, globose, $\frac{1}{4}$ in. in diameter, on the end of a short scaly branchlet, bluish purple and covered with a glaucous bloom when ripe, ultimately reddish brown; scales six, each with an ovate acute, often reflexed central process. Seeds one or two on each scale, $\frac{1}{10}$ in. long, ovate, brown, without resin-vesicles, and with narrow wings. Cotyledons two.

VARIETIES

This species appears to show little or no variation in the wild state. Under cultivation a number of peculiar forms have arisen:—

1. Var. *leptoclada*, Kent, Veitch's *Man. Conif.* 232 (1900).

Var. *andelyensis*, Carrière, *Conif.* 123 (1867).

Retinispora leptoclada, Gordon, *Pinetum Suppl.* 91 (1862).

Retinispora andelyensis, Carrière, in *Rev. Hort.* 1880, p. 36, figs. 4, 8.

Chamaecyparis leptoclada, Henkel and Hochstetter, *Syn. Nadelh.* 257 (1865).

A shrub with close-set branches, terminating in flattened branchlet systems, bearing partly adult foliage and partly primordial acicular leaves, which soon tend to disappear. This originated in M. Cauchois's nursery at Andelys (Eure) about 1850, and the plants were, in 1861, put on the market by Messrs. Henderson and Co., of the Wellington Nursery, St. John's Wood. This shrub produces fruit freely, and according to Carrière comes true from seed.¹ It is cultivated for sale at Rogers's nursery near Southampton, but is such a slow grower, that it is not much in favour, and seems to be less hardy than the type.

2. Var. *ericoides*, Beissner, *Nadelholzkunde*, 67 (1891).

A small dense pyramidal bush, with spreading subulate primordial leaves, glaucous in colour, but turning bronze or purplish brown in winter. This is supposed to be a juvenile form of *C. thyoides*; but its origin is doubtful, and by different authors it has been called a *Cupressus*, a *Juniperus*, a *Retinispora*, a *Frenela*, and a *Widdringtonia*.²

3. Var. *glauca*, Endlicher, *Syn. Conif.* 62 (1847). Occasionally known as var. *lewensis*. A shrubby form with glaucous foliage.

4. Var. *nana*, Endlicher, *Syn. Conif.* 62 (1847).

A dwarf bluish form, forming a small rounded bush.

5. Var. *Hoveyi*, a slender form with short ultimate branchlets, forming dense terminal tufts.

6. Var. *variegata*, Endlicher, *Syn. Conif.* 62 (1847).

Leaves yellowish. Loudon mentions a variegated form which was received at Chiswick from the Dunganstown Nursery in Ireland about 1831.

DISTRIBUTION

This tree grows mainly in maritime swamps in the Atlantic and Gulf states, which are liable to be overflowed by the sea during several months of the year.

¹ This is confirmed by Mr. Paul. Cf. *Proc. Roy. Hort. Soc.* xxxiv. p. cccix. (1909).

² Cf. Sargent, in *Garden and Forest*, x. 430 (1897). It is probably the same as *Retinispora pseudosquarrosa*, Carrière, *Conif.* 140 (1867), and in *Rev. Hort.*, 1880, p. 96, who says it was obtained at Le Mans in 1840 by M. Bergeot from a seed of *C. thyoides*.

It extends from southern Maine to northern Florida, and westward to Pearl River, Mississippi, forming pure forests in the north, and mingling with deciduous cypress and other moisture-loving species in the south. It is confined in Maine to the southern part of York County, and in New Hampshire to Rockingham County. It is common in south-eastern Massachusetts and in Rhode Island, and is occasionally seen in Connecticut on wet peat mosses.¹ Harper² describes the cedar swamp along Baldwin Creek on Long Island, where there are thousands of trees 30 to 40 ft. high and 3 to 10 in. in diameter. He says it is one of the very few trees in the north that are indigenous both in the glaciated region, and on the coastal plain. In the south, Harper states that it has a very erratic and local distribution, being entirely absent from Georgia, and confined strictly to near the sea-coast. He found it abundant for a few miles in Moore County, North Carolina, between Aberdeen and Keyser, where it grew in non-alluvial swamps between the sand-hills. It also grows in some parts of New Jersey and Maryland, and in the great Dismal Swamp of Virginia. Mayr³ found the average size of trees growing on white sandy soil in Alabama to be 86 ft. in height and 2 ft. in diameter; in New York it attains 19 in. in diameter at 128 years old. Plate 311 is from a photograph taken in North Carolina, for which we are indebted to the U.S. Forestry Bureau. (A. H.)

CULTIVATION

The white cedar was introduced⁴ into England by Peter Collinson in 1736; but it has never flourished except in rare cases, and its cultivation has been entirely neglected for the last fifty or sixty years.

Though Loudon states that in his time there was a magnificent specimen at Pains Hill 50 ft. high and 2 ft. in diameter, and another in the Duke of Devonshire's grounds at Chiswick, we can now find no trace of these.

The only good specimens which we have seen in cultivation are:—At Woburn Abbey, where by a walk leading to the estate office, I found in 1908 the finest tree of the species known in England, growing in rather damp soil, and measuring 46 ft. by 4½ ft. The next best are two at Arley Castle, which measured 44 ft. by 2 ft. 7 in., and 35 ft. by 2 ft. 9 in., in 1907. Another grows in rather heavy land at Strathfieldsaye, and measured in 1907, when it was bearing fruit, 38 ft. by 3 ft. 10 in.

A specimen at Pencarrow was 27 ft. by 3 ft. in 1909. There are others at Bayfordbury and High Canons in Herts, and at Kew. The glaucous form is flourishing at Little and Ballantyne's nursery, Carlisle, where it is reported that this species is perfectly hardy. It ripened seed as far north as Biel in 1825.⁵

We are informed by Mr. F. R. Twemlow that at Peatswood, Market Drayton,

¹ Dame and Brooks, *Trees of New England*, 25 (1902).

² In *Torreya*, iii. 122 (1903), vii. 199 (1907), and in *Rhodora*, vii. 71 (1905).

³ *Waldungen Nord-Amer.* 193 (1890).

⁴ Aiton, *Hort. Kew.* iii. 372 (1789). The following note, written by Peter Collinson, probably refers to this tree:—"Juniper, a new species, raised from Peter Kalm's seeds that he gave me, which he collected in a journey from Philadelphia to Quebec, and so to the Falls of Niagara and back to Pennsylvania. It has fine silver leaves." Cf. Dillwyn, *Hortus Collinsonianus*, 16 (1843).

⁵ *Caled. Hort. Soc.* iii. 412 (1825).

there are three trees of which the best is 31½ ft. high and 4 ft. 4 in. in girth near the ground, where it divides into several stems.

It is probable that if it was planted on the southern coast in suitable places it would be longer-lived, and might be worth trying on account of its ornamental appearance and interest. As Loudon, however, points out, a swamp would probably be too cold in summer in this country; and a deep moist sand is probably the best soil for it.¹

TIMBER

In America the wood of this tree is highly valued for shingles, which were formerly used in New York, Philadelphia, Baltimore, and other towns in the district where it grows, in preference to those made of the wood of the deciduous cypress, because they do not split when nailed on the rafters. They were said to be more durable than white pine shingles, and to last for thirty to thirty-five years. It was also largely used by coopers for casks; and the poles are still highly valued for telegraph and fencing posts.

Defebaugh² quotes from Hough's *Report on Forestry* (1877), and from Cook's *Geology of New Jersey* (1868), very interesting details on the submerged cedar forests, which are found near Dennisville and elsewhere in New Jersey, and which are supposed by geologists to have been caused either by a subsidence of the land or an irruption of the sea. The trees here were larger than any found living in the adjacent country within the memory of man, some having been dug up which were 6 ft. in diameter, while trees 4 ft. through were common.

"The timber which is buried in the swamps undergoes scarcely any change, and trees which have been buried hundreds of years are as sound as ever. It would seem that most of the timber which ever grew in these swamps is still preserved in them. Trunks of trees are found buried at all depths, quite down to the gravel, and so thick that in many places a number of trials will have to be made before a sounding-rod can be thrust down without striking against them. Tree after tree, from 200 to 1000 years old, may be found lying crossed one under the other, some partly decayed, as if they had died and remained standing a long time and then been broken down. Others had been blown down, and some had continued to grow for a long time after falling, as known by the heart being much above the centre, and by the wood on the under side being hard and boxy. The trees lie in all directions, as if fallen at different times, and their united ages, as shown where trees have grown where others have fallen, amounts to some thousands of years. The process of mining this timber is as follows:—With an iron rod the swamp is sounded till it hits what is thought to be a good log. Its length and size is determined by the rod, as near as may be. A hole is dug with a sharp spade

¹ Since writing the above, I have seen *C. thyoides* flourishing in the remarkable plantation near Borleaux, made eighty to ninety years ago at Catros, by a nurseryman of that name. M. Jaille, the present proprietor, showed me, among other rare American trees, a specimen of this measuring 52 ft. by 4½ ft., and others perhaps taller with trunks clean to 8 or 10 ft. high. Several self-sown seedlings were growing in this place on a sandy moist soil, similar to that of the Landes.

² *History of the Lumber Industry of America*, ii. 494 (Chicago, 1907).

down to the log and a chip obtained, which, by its smell, shows whether it was a windfall or a breakdown. If the former, it was probably sound when it fell, and has since remained so. If thought worth working, the matted roots are cut away, the log is sawed off, and when loosened it at once floats in the water, which is always near the level of the swamp. Logs are sometimes worked, though rarely, to a length of 30 ft. These logs come up with as much buoyancy as newly-fallen cedar, not being in the least water-logged, and the bark on the under side is quite fresh. The under side is always lightest, and turns up in rising to the surface. The workmen go over the same ground again and again, and find new logs each time, the lower logs probably rising in the mud when the roots over them are cut loose, and the logs which had laid on them are removed. These logs are found not only in the swamp, but also out in the salt-marsh beyond the living timber, and are worked below present tide-level.”

(H. J. E.)

QUERCUS

Quercus, Linnæus, *Gen. Pl.* 291 (1737), *Sp. Pl.* 994 (1753); Bentham et Hooker, *Gen. Pl.* 407 (1880).

Lithocarpus, Blume, *Bijdr. Fl. Ned. Ind.* 526 (1825).

Synædrys, Lindley, *Introd. Nat. System*, 441 (1836).

Cyclobalanopsis, *Cyclobalanus*, and *Pasania*, Oersted, in *Vidensk. Medd. Kjöbenh.*, 1866, pp. 77-81.

TREES or shrubs, belonging to the order Fagaceæ. Buds usually clustered at the ends of the branchlets, covered with numerous scales, imbricated in five ranks, and marking when they fall the bases of the branchlets with ring-like scars. Leaves either deciduous in autumn or in the following spring, or persistent two to four years; simple, alternate, five-ranked, stalked; lobed, toothed, or entire.

Flowers unisexual or rarely perfect, monœcious, apetalous, in spikes or catkins. Staminate flowers: calyx four- to seven-lobed; stamens four to six, rarely two, ten, or twelve, with slender filaments. Pistillate flowers, each enclosed in an involucre of imbricated scales; calyx six-lobed; ovary with two ovules in each of the three to five cells; styles three to five.

Fruit, a nut (the acorn), ripening in one or two years, with a large pale scar at the base, more or less surrounded by the woody cupule, resulting from the growth of the involucre of the flower. The acorn contains one seed, which is marked at the base, apex, or sides by the aborted ovules; cotyledons thick and fleshy, not raised above the ground on germination.

About 275 species of oak have been described, inhabiting the temperate regions of the northern hemisphere and high altitudes within the tropics, ranging in the New World southwards to Colombia, and in the Old World to the Malay Archipelago.

The genus may be divided into the following sections, one of which, *Pasania*, is now considered by many botanists to be a distinct genus.

* *Staminate flowers in pendulous, slender, clustered spikes. Styles flattened, with the stigmatic surface on the upper side.*

I. LEPIDOBALANUS, Endlicher.

Staminate flowers solitary. Pistillate flowers in few-flowered separate spikes. Cupule of the fruit saucer- or cup-shaped, with imbricated scales, free at their apices.

This section includes, with one exception (*Q. densiflora*), all the oaks of North America, Europe, northern Africa, and western Asia; and a large number

of those in the Himalayas and eastern Asia. Many of these are in cultivation, and may be grouped into the following subsections:—

(a) *Erythrobalanus*, Spach.

Fruit ripening in two years; aborted ovules in the upper part of the acorn; cupule scales all appressed. Trees with bristle-pointed leaves, confined to North America, and comprising the oaks there known as willow, black, and red oaks. The introduced species are—*Q. Phellos*, *Q. cinerea*, *Q. imbricaria*, *Q. nigra*, *Q. marylandica*, *Q. cuneata*, *Q. ilicifolia*, *Q. velutina*, *Q. Kelloggii*, *Q. rubra*, *Q. coccinea*, *Q. palustris*, *Q. Schneckii*, with deciduous foliage; and *Q. agrifolia*,¹ *Q. Wislizeni*, and *Q. crassipes*, with evergreen foliage.

(b) *Cerris*, Spach.

Fruit ripening in two years; aborted ovules at the base of the acorn; cupule scales spreading, often reflexed.

Trees of Europe, northern Africa, and Asia. The species in cultivation are—*Q. Cerris*, *Q. Ægilops*, *Q. castaneifolia*, *Q. Libani*, *Q. macedonica*, *Q. serrata*, *Q. variabilis*, and *Q. dentata*,² with deciduous foliage; *Q. alnifolia* and *Q. coccifera*, with evergreen foliage.

(c) *Leucobalanus*, Engelmann.

Fruit usually ripening in one year; aborted ovules at the base of the acorn; cupule scales appressed.

Trees of North America, Europe, northern Africa, and Asia. All the oaks which are known to produce timber of the first quality belong to this subsection, which may be divided into three groups:—

(a) Leaves evergreen. The species in cultivation are—*Q. Ilex* and *Q. Suber*³ of the Mediterranean region, *Q. incana*³ and *Q. semecarpifolia*³ from the Himalayas, *Q. phillyræoides*³ from Japan, and *Q. chrysolepis* and *Q. glabrescens* from North America.

(β) Leaves deciduous. The white oaks of North America. The species in cultivation are—*Q. alba*, *Q. lyrata*, *Q. macrocarpa*, *Q. lobata*, *Q. bicolor*, *Q. Prinus*, *Q. Muehlenbergii*, *Q. prinoides*, and *Q. obtusata*.

(γ) Leaves deciduous. Natives of the old world. The species in cultivation are—*Q. pedunculata*, *Q. sessiliflora*, *Q. lanuginosa*, *Q. Toza*, *Q. conferta*, *Q. Mirbeckii*, *Q. pontica*, *Q. macranthera*, *Q. lusitanica*, *Q. infectoria*, *Q. glandulifera*, *Q. grosseserrata*.

II. CYCLOBALANOPSIS.

Flowers as in *Lepidobalanus*. Cupule of the fruit cup-shaped, with scales united into concentric zones.

Evergreen trees, inhabiting the Himalayas, China, and Japan; leaves

¹ This species ripens its fruit in one year.

² In this species the fruit ripens in one year.

³ The leaves of *Q. semecarpifolia* are subevergreen. In *Q. Suber*, var. *occidentalis*, *Q. phillyræoides*, *Q. incana*, and *Q. semecarpifolia*, the fruit ripens in the second year.

usually dentate. The introduced species are *Q. glauca*, *Q. Vibrayeana*, and *Q. acuta*.

** *Staminate flowers in erect, simple or panicled spikes. Styles terete, erect, stigmatic at the apex only.*

III. PASANIA.

Staminate flowers solitary or in cymes of two to five. Pistillate flowers, in separate spikes or at the base of the staminate spikes. Fruit ripening in two years; cupule various, (a) completely enclosing the acorn and dehiscent or indehiscent at maturity, (b) cup-shaped, with scales imbricated and free at their apices, or (c) cup-shaped, with scales coalesced into concentric zones.

This section comprises about 100 species, all evergreen trees, with entire or toothed leaves, mostly inhabiting eastern and south-eastern Asia and the Malay Archipelago, one species (*Q. densiflora*) occurring in California. The latter species and two from Japan, *Q. glabra* and *Q. cuspidata*, have been introduced into cultivation.

The following artificial key of the cultivated species of *Quercus* is based upon the characters of the branchlets, leaves, and buds.

I. *Leaves deciduous in autumn, or early in the following year, falling before the new leaves appear.*A. *Leaves entire, with a bristle at the apex.*1. *Quercus Phellos*, Linnæus. United States. See p. 1228.

Branchlets glabrous. Leaves oblong or lanceolate, glabrous beneath, 2½ to 5 in. long, about ½ in. wide; stalk ⅛ to ¼ in.

2. *Quercus cinerea*, Michaux. United States. See p. 1230.

Branchlets tomentose. Leaves lanceolate, white-tomentose beneath, 2 to 3 in. long, ½ to ¾ in. wide; stalk ⅛ to ¼ in.

3. *Quercus imbricaria*, Michaux. United States. See p. 1231.

Branchlets glabrescent. Leaves lanceolate, with a greyish green stellate-pubescent under surface, 4 to 6 in. long, 1 to 2 in. wide; stalk ½ in.

B. *Leaves lobed; lobes and their teeth tipped with long fine bristles.** *Leaves oblong, with short variable lobes.*4. *Quercus heterophylla*, Michaux. A hybrid. See p. 1233.

Branchlets glabrous. Leaves glabrous, except for axil-tufts beneath, 3 to 6 in. long, 1 to 2 in. wide; stalk ½ to 1½ in.

5. *Quercus Leana*, Nuttall. A hybrid. See p. 1232.

Branchlets stellate-pubescent. Leaves with scattered stellate pubescence beneath, 5 to 7 in. long, 2 to 2½ in. wide; stalk ½ to 1 in.

6. *Quercus nigra*, Linnæus. United States. See p. 1235.

Branchlets glabrous. Leaves extremely variable, oblong with three to seven short lobes, obovate, or oval; glabrous beneath, except for axil-tufts; 3 to 4 in. long, 1 to 2 in. wide; stalk short, not exceeding ¼ in. long.

** *Leaves obovate,¹ with three to five lobes.*

7. *Quercus marylandica*, Muenchhausen. United States. See p. 1236.
Branchlets at first stellate-pubescent, later glabrous. Leaves with dense bands of stellate pubescence along the sides of the midrib and nerves, 5 to 7 in. long and wide; stalk not exceeding $\frac{1}{2}$ in.
8. *Quercus ilicifolia*, Wangenheim. United States. See p. 1238.
Branchlets pubescent. Leaves densely white or grey tomentose beneath, 3 in. long, 2 in. wide; petiole $\frac{1}{2}$ in. long.
9. *Quercus cuneata*, Wangenheim. United States. See p. 1237.
Branchlets pubescent. Leaves either (a) cuneate at the base and three-lobed above; or (b) oblong obovate, five- to seven-lobed, cuneate or rounded at the base; densely grey tomentose beneath; 5 to 7 in. long, 3 to 4 in. wide; petiole $\frac{3}{4}$ to 1 in. long.
10. *Quercus Catesbaei*, Michaux. United States. Not now in cultivation in England.
Branchlets glabrescent. Leaves (Plate 333, Fig. 1) divided into three to five long narrow lobes; lower surface glabrous, except for dense pubescence in the axils and on the main nerves; stalk $\frac{1}{4}$ to $\frac{3}{4}$ in. long.

*** *Leaves oval, with seven to nine large lobes, usually toothed.*

(a) *Leaves densely tomentose beneath.*

- 10A. *Quercus cuneata*, Wangenheim. See No. 9, the five- to seven-lobed form.
11. *Quercus pagodaefolia*, Ashe. United States. See p. 1237, note 2.
Not yet introduced. Leaves similar to the five- to seven-lobed form of *Q. cuneata*, but covered beneath with a silvery white tomentum; stalk $1\frac{1}{2}$ to 2 in. long.
- (b) *Leaves, with scattered stellate pubescence over the whole of the lower surface.*
12. *Quercus velutina*, Lamarck. United States. See p. 1239.
Branchlets with scattered stellate pubescence. Leaves shining dark green above; lower surface with rusty pubescent axil-tufts; 5 to 9 in. long, 4 to 5 in. wide; stalk 1 to 3 in. long.
13. *Quercus Kelloggii*, Newberry. California, Oregon. See p. 1241.
Branchlets glabrescent. Leaves without axil-tufts beneath, 3 to 6 in. long, 2 to 4 in. broad; stalk 1 in. long.

(c) *Leaves glabrous beneath, except for tufts of pubescence in the axils.*

Branchlets glabrous.

14. *Quercus rubra*, Linnæus. North America. See p. 1242.
Leaves with axil-tufts inconspicuous or absent, dull green beneath, turning dull red or reddish brown in autumn, 5 to 8 in. long, 4 to 6 in. broad. Buds $\frac{1}{4}$ in. long, reddish, pubescent only at the tip.
15. *Quercus coccinea*, Muenchhausen. North America. See p. 1247.
Leaves with axil-tufts inconspicuous or absent, shining green on both

¹ *Quercus nigra* (See No. 6), in the form with obovate leaves, would be found here.

- surfaces, turning scarlet in autumn, 3 to 6 in. long, $2\frac{1}{2}$ to 4 in. broad. Buds $\frac{1}{8}$ to $\frac{1}{4}$ in. long, whitish pubescent in their upper half.
16. *Quercus palustris*, Muenchhausen. United States. See p. 1250.
Leaves with conspicuous axil-tufts, turning scarlet in autumn, 4 to 6 in. long, 2 to 4 in. wide. Buds $\frac{1}{8}$ in. long, pale brown, glabrous.
17. *Quercus Schneckii*, Britton. United States. See p. 1251.
Not distinguishable with certainty in the absence of fruit from *Q. palustris*.
*** *Leaves ovate, with ten or more sharp triangular teeth or lobes.*
18. *Quercus Ægilops*, Linnæus. Greece, Asia Minor. See p. 1268.
Leaves tomentose beneath, margin and bristles ciliate, 3 to 4 in. long, $1\frac{1}{2}$ to 2 in. broad. Branchlets tomentose. Buds with persistent stipules.
- C. *Leaves serrate, each serration ending in a long projecting bristle or spine.*
19. *Quercus serrata*, Thunberg. Himalayas, China, Japan. See p. 1275.
Branchlets glabrescent. Leaves oblong-lanceolate, with ten to sixteen pairs of lateral nerves, each ending in a serration; green and glabrous beneath, except for slight axil-tufts; 4 to 8 in. long, 1 to 2 in. wide.
20. *Quercus variabilis*, Blume. China, Japan. See p. 1276.
Similar to the last, but with leaves covered beneath with a dense white tomentum.
21. *Quercus Libani*, Olivier. Syria, Asia Minor, Armenia. See p. 1274.
Branchlets pubescent or glabrescent. Leaves lanceolate, with nine to twelve pairs of lateral nerves, each ending in a serration; wrinkled in margin, glabrous beneath except on the midrib and nerves; 3 in. long, $\frac{3}{4}$ in. wide.
22. *Quercus semecarpifolia*, Smith. Himalayas. See p. 1297.
Branchlets stellate-pubescent. Leaves¹ subevergreen, elliptical, with six to ten pairs of lateral nerves, forking before reaching the spinose-serrate margin; 3 in. long, 2 in. broad.
- D. *Leaves lobed or toothed, each tooth or lobe ending in a projecting short mucro.*
* *Axillary buds without persistent stipules.*
23. *Quercus macedonica*, De Candolle. Macedonia, Albania, Montenegro, Herzegovina, and south-eastern Italy. See p. 1273.
Branchlets with scattered pubescence. Leaves lanceolate, 2 in. long, subsessile, broad and auricled at the base, with nine to twelve pairs of nerves each ending in a serration; margin wrinkled.
24. *Quercus glandulifera*, Blume. China, Korea, Japan. See p. 1327.
Branchlets glabrescent. Leaves obovate, 3 to 5 in. long, with eight to eleven pairs of nerves, all but the lowest one or two pairs, ending in a mucronate serration; lower surface appressed pubescent, and usually glaucous.
25. *Quercus Turneri*, Willdenow. A hybrid. See p. 1288.
Branchlets stellate-pubescent. Leaves subevergreen, obovate, 3 to 5 in. long, with five to eight pairs of nerves, all but the lowest one or two pairs,

¹ The leaves on old trees are entire or slightly undulate and without spines.

- ending in a sinuate mucronate tooth;¹ lower surface green, with scattered stellate pubescence.
26. *Quercus pontica*, Koch. Western Caucasus and Lazistan. See p. 1321.
Branchlets glabrous. Leaves elliptic, 6 in. long, 3 in. broad, with fifteen to twenty pairs of nerves, each ending in an incurved mucronate serration; lower surface glaucous, pilose on the midrib and nerves, elsewhere glabrous.
- 26A. *Quercus lusitanica*, Lamarck. See No. 50.
** *Axillary buds surrounded by long filiform stipules.*
27. *Quercus castaneæfolia*, Meyer. Algeria, Caucasus, north Persia. See p. 1271.
Branchlets pubescent. Leaves oblong, 3 to 6 in. long, $1\frac{1}{2}$ to $2\frac{1}{2}$ in. wide, with eight to fourteen pairs of nerves, each ending in a mucronate triangular tooth; lower surface pale green, covered with a minute tomentum.
28. *Quercus Lucombeana*, Sweet. A hybrid. See p. 1259.
Branchlets tomentose. Leaves subevergreen, variable in size and shape, 2 to 5 in. long, with rather irregular mucronate lobes or teeth, densely white or grey tomentose beneath.
- E. *Leaves lobed or toothed, without projecting bristles or points.*
* *Branchlets glabrous or glabrescent.*
(a) *Leaves regularly toothed, or shortly lobed with shallow sinuses.*
† *Leaves obovate.*
29. *Quercus bicolor*, Willdenow. North America. See p. 1307.
Leaves white tomentose beneath and velvety to the touch, with six to eight pairs of rounded, rarely acute teeth; 5 to 6 in. long, 2 to 4 in. wide; petiole $\frac{1}{2}$ in. long.
30. *Quercus prinoides*, Willdenow. United States. See p. 1311.
Leaves white or pale beneath with a minute scattered pubescence; with four to seven pairs of rounded, rarely acute teeth; 4 in. long, 2 in. wide; petiole $\frac{1}{4}$ to $\frac{1}{2}$ in. long.
31. *Quercus Mirbeckii*, Durieu. Portugal, Algeria. See p. 1318.
Leaves glaucous and glabrous beneath, except for brown flocculent tomentum along the midrib; with nine to fourteen pairs of rounded or acute teeth; 4 to 6 in. long, 3 in. wide; petiole $\frac{1}{2}$ to $\frac{3}{4}$ in. long.
32. *Quercus Prinus*, Linnæus. North America. See p. 1309.
Leaves pale beneath with a minute pubescence disappearing in summer; with nine to fourteen pairs of rounded teeth; 6 in. long, 3 in. wide; petiole $\frac{1}{2}$ to 1 in. long.
33. *Quercus Michauxii*, Nuttall. North America. Not now in cultivation.
Leaves (see Plate 336, Fig. 34), lower surface green or whitish, covered with conspicuous stellate tomentum; with twelve to seventeen pairs of small triangular teeth; 6 in. long, 3 in. wide; petiole $\frac{1}{2}$ to $1\frac{1}{2}$ in. long.
34. *Quercus grosseserrata*, Blume. Japan. See p. 1327.

¹ In var. *pseudoturneri* the mucro is often obsolete.

- Leaves, lower surface pilose on the midrib and veins, elsewhere glabrous; with twelve to fifteen pairs of regular triangular teeth; 4 to 6 in. long, 3 to $3\frac{1}{2}$ in. wide; subsessile, petiole not exceeding $\frac{1}{8}$ in.
‡ *Leaves lanceolate.*
35. *Quercus Muehlenbergii*, Engelmann. North America. See p. 1310.
Leaves narrower than in *Q. Prinus*, 6 in. long, 2 in. wide, with eight to fifteen pairs of inflexed, rounded or acute teeth; with a minute pubescence beneath, often disappearing in summer; petiole $\frac{3}{4}$ to $1\frac{1}{2}$ in. long.
(b) *Leaves irregularly toothed, or with conspicuous lobes and deep sinuses.*
† *Leaves quite glabrous beneath.*
36. *Quercus obtusata*, Humboldt and Bonpland. Mexico. See p. 1312.
Leaves subevergreen, falling in March, obovate, 4 to 5 in. long, narrowed and auricled at the base, margin with irregular callous-tipped teeth; petiole $\frac{1}{4}$ to $\frac{3}{8}$ in.
37. *Quercus pedunculata*, Ehrhart. Europe. See Vol. II. p. 282.
Leaves deciduous in autumn, obovate, auricled at the base, with four to six pairs of mostly entire irregular lobes; 3 to 6 in. long; lateral nerves ending both in the lobes and in the sinuses; petiole usually less than $\frac{1}{4}$ in.
†† *Leaves pubescent beneath.*
38. *Quercus sessiliflora*, Salisbury. Europe. See Vol. II. p. 291.
Leaves obovate, cuneate at the base, with four to six pairs of mostly entire irregular lobes; nerves ending in the lobes; 3 to 5 in. long; lower surface green with scattered pubescence, densest on the midrib and nerves; petiole $\frac{1}{2}$ to 1 in. long.
39. *Quercus alba*, Linnæus. North America. See p. 1301.
Leaves obovate, cuneate at the base, with seven to nine irregular, mostly entire lobes; upper lateral lobes smaller than those in the middle; lower surface pale or glaucous, uniformly covered with a very minute pubescence; 5 to 7 in. long; petiole $\frac{1}{2}$ in. long.
40. *Quercus lyrata*, Linnæus. United States. See p. 1303.
Leaves obovate, cuneate at the base, with five to nine irregular triangular lobes, the upper two lateral lobes broad and emarginate and larger than the lower lobes; lower surface pale, with a minute pubescence throughout; 7 to 8 in. long; petiole $\frac{1}{4}$ to $\frac{3}{4}$ in.
** *Branchlets pubescent.*
(a) *Terminal and axillary buds surrounded by persistent stipules.*
41. *Quercus Cerris*, Linnæus. Southern Europe, Asia Minor. See p. 1254.
Leaves oblong or oval, about 5 in. long, with seven or eight pairs of entire or toothed lobes; lower surface green or greyish, covered with a minute stellate pubescence.
42. *Quercus macranthera*, Fischer and Meyer. Caucasus, north Persia. See p. 1322.
Leaves obovate, 4 to 5 in. long, with seven to eleven pairs of short, usually entire lobes; lower surface densely tomentose.

(b) Only the terminal buds surrounded by persistent stipules.

† Leaves large, more than 4 in. long.

43. *Quercus conferta*, Kitaibel. South-eastern Europe. See p. 1316.

Leaves obovate, 5 to 8 in. long, with six to eight pairs of regular, entire or sinuately toothed deep lobes, with sinuses extending half-way to the midrib; under surface green or greyish, covered with a thin minute stellate pubescence. Branchlets with scattered pubescence.

44. *Quercus Toza*, Bosc. France, Spain, and Portugal. See p. 1313.

Leaves obovate, 5 to 8 in. long, with five to six pairs of irregular, entire or sinuately toothed deep lobes; under surface greyish or whitish, covered with a dense soft tomentum. Branchlets densely tomentose.

45. *Quercus macrocarpa*, Michaux. N. America. See p. 1304.

Leaves obovate, 6 to 12 in. long, usually with five to seven lobes, the terminal lobe large and crenately lobulate, lateral lobes small with deep sinuses; under surface pale with a deciduous minute appressed pubescence.

46. *Quercus dentata*, Thunberg. China, Manchuria, Korea, Japan. See p. 1277.

Leaves obovate, 6 to 12 in. long, with six to nine pairs of shallow regular rounded, usually entire lobes; lower surface pale with a scattered minute stellate pubescence.

47. *Quercus stellata*, Wangenheim. North America. Not now in cultivation. See Plate 336, Fig. 32.

Leaves oblong obovate, 4 to 5 in. long, five-lobed, with deep sinuses; upper surface with conspicuous stellate hairs; lower surface densely pubescent.

† Leaves small, not exceeding 4 in. long.

48. *Quercus lobata*, Née. California. See p. 1306.

Leaves obovate, 3 in. long, with seven to eleven irregular lobes, the lateral lobes broad at their apex; both surfaces stellate-pubescent.

49. *Quercus lanuginosa*, Thuillier. S. Europe. See Vol. II. p. 294.

Leaves obovate, 3 to 4 in. long, with four to eight pairs of rounded, usually entire lobes; wrinkled in margin; under surface tomentose.

50. *Quercus lusitanica*, Lamarck. Mediterranean region. See p. 1322.

A very variable species, with leaves 2 to 4 in. long, obovate or oblong; margin wrinkled with regular or irregular teeth, with or without a mucro; lower surface covered with a dense grey tomentum.

51. *Quercus infectoria*, Olivier. Cyprus, Asia Minor, Turkey. See p. 1325.

Mainly distinguished from *Q. lusitanica* by the glabrescent under surface of the leaf.

- 51A. *Quercus Turneri*. See No. 25.

II. Leaves evergreen, persisting more than one year on the branchlets.

A. Leaves entire on margin, or occasionally undulate-crenate towards the apex.

52. *Quercus glabra*, Thunberg. Japan. See p. 1332.

Leaves lanceolate or elliptical, 4 to 5 in. long, acute or cuspidate at the

apex, tapering at the base and prolonged as a narrow wing on each side of the petiole; under surface glabrous. Branchlets glabrous.

53. *Quercus acuta*, Thunberg. Japan. See p. 1330.

Leaves similar to those of *Q. glabra*, but with a long acuminate apex. Young branchlets covered at first with a brown tomentum, which quickly disappears, some, however, remaining near the tip of the branchlets or above the insertion of the leaves.

54. *Quercus cuspidata*, Thunberg. China, Japan, Formosa. See p. 1332.

Leaves elliptical, 2 to 3 in. long, with a long acuminate apex; lower surface glabrous. Branchlets slender, scaly.

55. *Quercus crassipes*, Humboldt and Bonpland. Mexico. See p. 1254.

Leaves oblong, 2 to 3 in. long, with a bristle point at the apex, brown tomentose beneath. Branchlets pubescent.

- 55A. *Quercus Ilex*. See No. 56.

B. Leaves distinctly toothed in margin, and plainly pubescent on the lower surface.

* Leaves white or grey beneath.

(a) Leaves not lanceolate.

56. *Quercus Ilex*, Linnæus. Mediterranean region. See p. 1281.

Leaves very variable, ovate or oval, 1 to 3 in. long; margin entire or spinose-dentate; lower surface covered with a dense greyish or whitish tomentum; lateral nerves, seven to ten pairs; stipules long, linear, persistent around the terminal bud.

57. *Quercus Suber*, Linnæus. Mediterranean region. See p. 1292.

Leaves ovate or oblong, about 2 in. long, usually concave; margin with small mucronate teeth; lower surface covered with a dense greyish tomentum; lateral nerves, five to seven pairs; stipules short, linear-obovate, occasionally persistent, but inconspicuous around the terminal bud.

58. *Quercus alnifolia*, Poech. Cyprus. See p. 1278.

Leaves orbicular or obovate, 1½ to 2 in. long, usually concave; margin with minute mucronate teeth; lower surface covered with a dense yellowish grey tomentum; lateral nerves, five to eight pairs, very prominent.

(b) Leaves lanceolate

59. *Quercus incana*, Roxburgh. Himalayas. See p. 1298.

Leaves elliptic-lanceolate, acuminate at the apex, 3 to 6 in. long; nerves, ten to fifteen pairs, each ending in a mucronate triangular serration; lower surface densely white tomentose.

60. *Quercus glauca*, Thunberg. Himalayas, China, Japan. See p. 1328.

Leaves ovate-lanceolate, acuminate, about 3 in. long; nerves, about ten pairs; mucronate-serrate in the upper half; lower surface white, with scattered appressed silky hairs.

** Leaves green beneath.

61. *Quercus glabrescens*, Benth. Mexico. See p. 1300.

Leaves obovate-oblong, 2 to 2½ in. long, with a few gland-tipped teeth in

the upper half; lateral nerves, seven or eight pairs; lower surface yellowish green with a scattered stellate pubescence.

62. *Quercus chrysolepis*, Liebm. Oregon, California, Lower California. See p. 1299.

Leaves very variable; on young trees, oblong-ovate, 2 in. long, with eleven to twenty-one spine-tipped, small, triangular teeth; lower surface pubescent with scattered yellow appressed hairs and dotted with minute shining glands.

- C. *Leaves distinctly toothed in margin, glabrous or nearly so on the lower surface.*

* *Leaves over 3 in. long.*

63. *Quercus Vibrayeana*, Franchet and Savatier. China, Japan. See p. 1329.

Leaves lanceolate, 3 to 4 in. long, acuminate; lateral nerves, nine to twelve pairs, inconspicuous; margin mucronate-serrate in the upper half; lower surface glaucescent. Branchlets glabrous.

64. *Quercus densiflora*, Hooker and Arnott. Oregon, California. See p. 1331.

Leaves oblong, 3 to 4 in. long, acute at the apex; lateral nerves, about twelve pairs, very prominent; margin serrate; lower surface whitish, glabrous or with rusty pubescence on the midrib at the base. Branchlets stellate-tomentose.

** *Leaves less than 3 in. long.*

65. *Quercus agrifolia*, Née. California. See p. 1252.

Leaves ovate or orbicular, $1\frac{1}{2}$ to 2 in. long, with seven to thirteen spine-tipped teeth; lateral nerves, four to five pairs, prominent; lower surface glabrous, except for conspicuous reddish axil-tufts.

66. *Quercus phillyraeoides*, A. Gray. China, Japan. See p. 1298.

Leaves oval or obovate, $1\frac{1}{2}$ to 2 in. long, with seven to twenty serrations in the upper half or two-thirds; lateral nerves, about eight pairs, very slender, scarcely raised; lower surface glabrous, except for dense pubescence on the midrib at the base, continuous with that on the petiole.

67. *Quercus coccifera*, Linnæus. Mediterranean region. See p. 1279.

Leaves oval or oblong, 1 to $1\frac{1}{2}$ in. long; margin wrinkled, with nine to seventeen spine-tipped teeth; lateral nerves, five to ten pairs, inconspicuous. Buds ovoid, obtuse, $\frac{1}{10}$ in. long.

68. *Quercus Wislizeni*, A. de Candolle. California, Lower California. See p. 1253.

Leaves similar to those of *Q. coccifera*, but darker green in colour. Buds conical, pointed, $\frac{1}{8}$ in. or more in length. (A. H.)

CULTIVATION OF THE AMERICAN OAKS

Though many of the American Oaks have been for at least a century in this country, and have been repeatedly introduced at various times, yet very few have established themselves in popular favour as ornamental trees; and none can be said to have any economic value, which would justify their being

planted as forest trees. The most valuable in America, the white oak, seems unable to live for more than a few years in any part of this country; and none of the group to which it belongs, so far as we know, have ever attained a size which would justify our advising them for general cultivation.

Q. virginiana, Miller, the live oak of North America, which is widely spread in the southern United States and in Mexico, differs only slightly in botanical characters from *Q. Ilex*; but is not hardy in England, although Loudon,¹ who refers to it as *Q. virens*, Aiton, states that there was a tree of it at Kew, 40 to 50 ft. high, in 1838. This tree was no doubt *Q. Ilex*. There is no specimen now at Kew; and Mr. Bean² reports that living plants imported in recent years have died even in mild winters. Bunbury³ says that one planted at Barton, Suffolk, was speedily killed.

Though several of the Californian oaks⁴ have been introduced, and a few are living at Kew, Tortworth, and elsewhere, they do not grow with the same vigour which many of the conifers of the west coast of America have shown, and probably require a much warmer and drier summer climate. *Q. Garryana*, Hooker, *Fl. Bor. Am.* ii. 159 (1839), is a large and picturesque tree, found along the Pacific slope, from British Columbia, Vancouver Island, and Washington, where it is the only species known, through Oregon to the Santa Cruz mountains in California. So far as we know, it has never been tried in England, which is remarkable, considering how easy it would be to procure acorns. It might possibly succeed well in our climate. According to Schneider, *Laubholzkunde*, i. 206 (1904), who mentions a plant in the Darmstadt Botanic Garden, it was recently introduced into Germany by C. A. Purpus.

Of the group, known as the red and black oaks, several have been fairly successful; and though, with the exception of *Q. rubra*, not often planted at the present time, they are well worth more attention than they receive, on account of the beautiful colour of their leaves in autumn.

Most of the American oaks which were grown by Loddiges and other English nurserymen seventy to eighty years ago, were propagated by grafting on the common oak close to the ground; but now that acorns can be procured so much more quickly through the post, it would seem better to raise them from seed. Although the practice of grafting is not to be recommended for many genera of trees, yet we have seen many instances of oaks grafted close to the ground on suitable stocks, which have produced fine and sometimes very large trees. The main points seem to be that the stock shall be a vigorous one, with good fibrous roots which have not been stunted in pots; and that the species selected for the stock should be suited to the scion, and to the soil. *Quercus pedunculata* is a good stock, on strong land, for species allied to it, *Q. sessiliflora* for lighter soil; *Q. Cerris* for the species with mossy cups; *Q. Ilex* for the evergreen oaks of the Mediterranean region; *Q. rubra* for the American

¹ *Arb. et Frut. Brit.* iii. 1918 (1838).

² *The Garden*, lxx. 386 (1904).

³ *Arboretum Notes*, 113 (1889).

⁴ *Q. Gambelli*, Nuttall, a small tree, rarely exceeding 25 ft. in height, is widely spread at high elevations in Colorado, Utah, Nevada, Arizona, Texas, and New Mexico. It does not appear to have been introduced into Europe (cf. Schneider, *Laubholzkunde*, i. 204). The leaves are figured in Plate 333, Fig. 7.

red or black oaks. I have noticed that a better union of stock and scion seems to be produced by saddle- or cleft-grafting, than when the scion is inserted on one side of the stock.

I collected acorns of a good many species about the end of September 1904, in the Arnold Arboretum and other places in North America; and found that by packing them in small tin boxes in slightly damp moss, they arrived here in good condition, though those of the white oak germinated on the voyage. Nearly all of those which I sowed in a cold frame germinated and grew well during the following summer; but when planted out, many of them became sickly and died, apparently from insufficient summer heat to ripen their wood.

Loudon says that at the Leyton Nursery, near Stratford, there were in the autumn of 1836 a great variety of American oaks, selected from the seed beds when two years old and planted in rows. The variety and beauty of these exceeded anything he ever saw, in spring when coming into leaf, in summer when in full foliage, and in autumn when the leaves were dying off of every shade of scarlet, yellow, and purple. They were mostly ten to twelve years from the acorn, and with few exceptions were 20 to 30 ft. high. Many of these were burnt for want of purchasers, but, no doubt some of them survive in old places round London, where there may be some uncommon trees that we have not been able to discover.

Though none of the English nurseries, as far as we know, now pay much attention to the American oaks, yet they may be procured from American nurseries at one or two years old, in autumn, when they travel safely, if well packed; but if older than this the roots are too large to transplant well. The Earl of Ducie has probably planted more species and paid more attention to them than any one in England, and at Tortworth there are young trees of 20 to 30 ft. high of *Q. imbricaria*, *nigra*, *Kelloggii*, and others, which are growing fairly well in a sheltered hollow. The majority seem to prefer a deep fertile soil, rather light than heavy, with little or no lime in it; and though we have little experience as to their tolerance of shade in this country, yet if they were planted in small clearings, in the shelter of a warm sunny wood, they would probably succeed better than when exposed to cold winds in a north or east aspect. The remarkable success of several American oaks at Lyndon near Oakham in an exposed situation, shows what may be done in places where the conditions are not specially favourable.

The ultimate success of exotic trees which ripen their young wood badly in youth, seems to be largely a question of the genial character of the first few summers after planting, for if badly checked in their youth, they recover vigour slowly or never. Care should be taken by judicious pruning when young, to train them into a good shape, for slow-growing oaks resent the pruning of large limbs.

The healthy condition of the oak collection at Kew, which is by far the most complete we know of, seems largely due to the care and skill which has been given to them by a succession of able arboriculturists.

CULTIVATION OF THE MEDITERRANEAN OAKS

Though the species of oaks found in various parts of the Mediterranean region are very numerous, few of them are fit for cultivation in England, as long experience has proved. In the warmest parts of the south and east coast, especially near the sea and on good deep soil in sheltered positions, some of them will attain very large dimensions, as our account of the cork tree and *Q. Ilex* proves; but the severe winters which occur at long intervals even in these favoured places, and the want of hot dry autumnal weather necessary to ripen their late growth, too often cripple them when young, and destroy them when old. At the same time, there are several which may, with care in planting and sheltering them during their early years, be well worth more extended trials than they have had; and now that modern means of communication has brought regions which were formerly remote within easy reach by post, I would advise those planters who like variety, to try such species as *Ægilops*, *Libani*, *alnifolia*, *pontica*, *lusitanica*, *macedonica*, and *Toza*, as well as those which we know to be capable of becoming fine trees like *Mirbeckii*, *conferta*, *castaneæfolia*, and perhaps *macranthera*.

CULTIVATION OF THE ASIATIC OAKS

Though several of the Chinese, Japanese, and Himalayan oaks have proved hardy in the warmer parts of England, and are more or less ornamental on account of their evergreen foliage; yet none, so far as we can judge at present, seem at all likely to attain timber size in this country, or to be worthy of cultivation except in botanic gardens. It is perhaps premature to condemn them until they have been tried for a longer period, but it is evident that they require climatic conditions which are rarely found. The same may be said of the Mexican oaks, many of which grow at high elevations and were introduced long ago, but of which only two or three species seem to have survived.

Acorns should be procured as fresh as possible, and sown at once in deep pots or boxes, which can be kept under glass for two or three years before planting out. If acorns of suitable species are established in the places where the trees are to be planted, to serve as stocks for grafting on, when the scions are large enough, a double chance of success will be had. But in these days too little care and attention is paid to the necessary pruning and training, which almost all kinds of hardwoods require to make them really ornamental trees, and unless this is attended to every two or three years for a considerable time, as at Kew, the side branches often become so strong that the main trunk is weakened, and the shape of the whole tree spoilt. The sooner this is done in reason the better, and as the individuals of most species seem to vary very much in their constitution and vigour, it is never wise to depend on one plant

of a species to get a good tree. If three or more are planted in the space which one will eventually fill, we get to some extent the same power of selection which always operates on seedlings in nature, in the struggle for existence.

As regards soil I have observed that most oaks grow better on red sandstone than on any other soil, and though some of the oriental and Mediterranean oaks naturally grow on limestone, they do not seem to need lime here.

From an economic point of view, I say without hesitation that there is no exotic species capable of competing either on heavy or light soil with our native oaks, and though the timber of the Ilex, the Lucombe, or the cork oak may be very valuable for decorative purposes when large enough, it can rarely be grown to a profit in this country.

In *Journ. Hort. Soc.* ix. 207 (1855) there is a long list of plants describing the effect of the winter of 1853-54, which was more destructive than any since 1838, the temperature registered at Chiswick having been 8° on 28th December, and 4° on 2nd January; near Nottingham, -4°; at Chatsworth, -6°; at Bicton, 15°; and at Dropmore on 3rd January, 4°. In the list of oaks we give the names as printed:—*Quercus*, Mexican, all killed, Chiswick. *Quercus sclerophylla*,¹ killed, Acton Green; injured, Bagshot; killed, Bicton. *Quercus Ilex*, much injured in 1838, Kew; not injured, Chiswick; large tree very much injured, Shifnal; some plants fifty years old dead, Nottingham. *Quercus Gramuntia*,² killed, Rolleston, Oulton; untouched, Chiswick. *Quercus Suber*, injured, Bromley; much injured, Nottingham. *Quercus Brantii*,³ and other Kurdistan oaks, not injured by the winter, but very much injured by the frost on 24th April, Chiswick; injured, Oulton; quite safe, Congleton. *Quercus dealbata*,⁴ uninjured, Bicton. *Quercus australis*,⁵ not injured, Chiswick. *Quercus Cookii*,⁶ leaves injured only, Chiswick. *Quercus glabra*, not affected, Bagshot; not hurt, Exeter or Bicton. *Quercus mongolica*,⁷ uninjured, Shifnal.

(H. J. E.)

QUERCUS PHELLOS, WILLOW OAK

Quercus Phellos, Linnæus, *Sp. Pl.* 994 (excluding vars.) (1753); Loudon, *Arb. et Frut. Brit.* iii. 1894 (1838); Sargent, *Silva N. Amer.* viii. 179, t. 435 (1895), and *Trees N. Amer.* 247 (1905).

A tree, attaining in America 80 ft. in height and 12 ft. in girth. Bark about ½ in. thick, smooth, except on old trunks, which are roughened by longitudinal

¹ A Chinese species, introduced by Fortune in 1846, not now in cultivation, so far as we know.

² A variety of *Q. Ilex*. Cf. p. 1282.

³ *Q. Brantii*, Lindley, in *Bot. Reg.* xxvi., *app.* 74 (1840), and *Gard. Chron.*, 1853, p. 263, was introduced from Kurdistan by Sir A. H. Layard about the year 1853; but, so far as we know, is not now in cultivation. The Earl of Ducie informed me that Lord Somers raised a tree at Eastnor Castle from Sir A. H. Layard's acorns, which had borne fruit before it was blown down.

⁴ *Q. dealbata*, Wallich, *List* 2769, is now identified with *Q. incana*, Roxburgh. Cf. p. 1298.

⁵ A form of *Q. lusitanica*. Cf. p. 1322.

⁶ Identified with *Q. Ilex*, var. *Gramuntia*. Cf. p. 1282.

⁷ Probably incorrectly named. Cf. p. 1328, note 1.

narrow slightly raised scaly ridges. Young branchlets slender, reddish brown, glabrous or glabrescent. Leaves (Plate 339, Fig. 75) deciduous, thin, membranous, lanceolate, 2½ to 5 in. long, about ½ in. wide, gradually narrowing at both ends, glabrous except for slight pubescence along the midrib beneath, entire or slightly undulate in margin, with a single bristle point at the apex; venation pinnate, the primary veins dividing and looping with those adjoining before reaching the margin; petiole ⅓ to ¼ in. long, pubescent. The leaves are revolute in the bud; and on young specimens are dentate or lobed.

Fruit ripening in the second year, sessile or with short stalks, usually solitary; acorn subglobose or hemispherical, pale pubescent, enclosed at the base by a thin saucer-shaped cupule, ½ in. wide, silky pubescent on the inner surface, and covered externally by thin ovate truncate hoary pubescent scales.

This oak is supposed to form hybrids with several species, as *Q. imbricaria*,¹ *Q. marylandica*,² *Q. ilicifolia*,³ *Q. cuneata*,⁴ and *Q. palustris*,⁵ none of which are in cultivation in this country. Under the name *Q. heterophylla* (see p. 1233) a tree is occasionally cultivated, which probably includes hybrids of *Q. Phellos*, with *Q. rubra* and *Q. velutina*.

The willow oak inhabits the banks of marshes and streams, and grows also in deep sandy tracts in the uplands; and, according to Sargent, is distributed from Staten Island, New York, through the Atlantic states, where it is usually confined to the maritime plain, as far southward as north-eastern Florida, extending westward through the Gulf states to the Sabine river, Texas, and ascending the lower Mississippi basin, through Arkansas and south-eastern Missouri to central Tennessee and southern Kentucky.

According to Catesby, this tree was introduced about 1723, when it was growing in the garden of Mr. Fairchild at Hoxton. It appears, from the singularity of its leaves, to have early attracted considerable notice; and Loudon mentions several trees of large size, some of which still survive. (A. H.)

It seems to succeed better in England than most of the American oaks, except *Q. rubra* and *Q. palustris*; and, though a lover of moisture in its own country, grows well in dry situations, as on gravel soil at Kew. So far as we know, however, none of the trees in cultivation have produced acorns.

The largest we have seen is at Whitton, which was mentioned by Loudon as being 70 ft. high by 7½ ft. in girth in 1838. It is now very large, about 100 ft. high by 12 ft. 4 in., but its trunk is attacked by fungus, and though the branches produced healthy foliage in 1905 it is evidently decaying rapidly. At Kew there are two fine healthy

¹ *Q. imbricaria* × *Phellos*, Zabel, *Laubholz-Benennung*, 65 (1903); *Q. Phellos*, var. *subimbricaria*, De Candolle, *Prod.* xvi. 2, p. 63 (1864). Found by Asa Gray in New Jersey. Leaves entire, broader and more obtuse than those of *Q. Phellos*, differing from *Q. imbricaria* in the deciduous pubescence on the under surface. This is included by Sargent under the next hybrid.

² *Q. Phellos* × *marylandica*, Sargent, *Silva N. Amer.* viii. 181, t. 437 (1895); *Q. Rudkiani*, Britton, in *Bull. Torrey Bot. Club*, ix. 13 (1882). Trees, discovered in 1881 near Cliffwood in New Jersey, and subsequently seen in other parts of New Jersey and on Staten Island. Leaves trilobed at the apex; acorns intermediate between *Q. Phellos* and *Q. marylandica*. Dr. MacDougal (*Bot. Gaz.* xliii. 53, fig. 4 (1907)) raised seedlings, all of which bore foliage like that of the parent tree.

³ *Q. Phellos* × *ilicifolia*, Peters, in *Bull. Torrey Bot. Club*, xx. 295 (1893). A tree found at May's Landing, New Jersey.

⁴ Cf. Small, in *Bull. Torrey Bot. Club*, xxii. 74, fig. 232 (1895).

⁵ *Q. Phellos* × *palustris*, Schneider, *Laubholzkunde*, 165 (1904); *Q. schochiana*, Zabel, *loc. cit.*, and *Mitt. deut. dend. Ges.*, 1896, p. 9.

trees, one near the Pagoda which is divided into two main stems, and measured 85 ft. by 7 ft. 9 in. in 1909; the other near the pond is a much more spreading and thicker tree, and now measures about 55 ft. by 11 ft. At Arley Castle there is a healthy tree free from branches to about 30 ft. up and measuring 70 ft. by 5 ft. 9 in. At Cobham Park there is a fine tree of the same type 86 ft. by 8 ft. 10 in. At Croome Court, Worcestershire, there is a tree grafted on the common oak, 65 ft. by 6 ft. 5 in. At Nuneham Park, Oxon, another was in 1906, 60 ft. by 8 ft. 3 in. At Barton, Bury St. Edmunds, a slender tree measured in 1908, 64 ft. by 4 ft. 2 in.; at Ampton Park, Suffolk, another, measured by Henry in 1909, is 40 ft. by 5 ft. 10 in. At Glendurgan, Cornwall, Mr. A. B. Jackson measured a thriving tree, 40 ft. by 4 ft. 2 in. in 1908. In the Knaphill Nursery, near Woking, there are two specimens of moderate size. I have also seen specimens at Milford House, near Godalming, and at West Dean Park.

In Scotland we know of no tree of this species; but in Ireland, at Fota, there is a thriving specimen, 45 ft. by 5 ft. 4 in. in 1907. (H. J. E.)

QUERCUS CINEREA, BLUE JACK

Quercus cinerea, Michaux, *Hist. Chênes Am.* No. 8, t. 14 (1801); Sargent, in *Bot. Gaz.* xlv. 226 (1907).

Quercus Phellos, var. *brevifolia*, Lamarck, *Dict.* i. 722 (1783).

Quercus humilis, Walter, *Fl. Car.* 234 (1788) (not Lamarck).

Quercus Phellos, var. *sericea*, Aiton, *Hort. Kew.* iii. 354 (1789); Loudon, *Arb. et Frut. Brit.* iii. 1895 (1838).

Quercus Phellos, var. *humilis*, Pursh, *Fl. Am. Sept.* ii. 625 (1814).

Quercus brevifolia, Sargent, *Silva N. Amer.* viii. 171, t. 431 (1895), and *Trees N. Amer.* 250 (1905).

A tree, attaining in America 50 ft. in height and 5 ft. in girth, but usually smaller. Bark about an inch thick, dark brown or nearly black, divided into small square scaly plates. Young branchlets slender, coated with white stellate tomentum, most of which disappears in the course of the summer. Buds minute, ovoid, obtuse, chestnut brown, glabrous. Leaves (Plate 339, Fig. 72) deciduous, membranous, 2 to 3 in., occasionally 5 in. long, $\frac{1}{2}$ to $\frac{3}{4}$ in. broad, oblong-lanceolate, rounded or cuneate at the base, acute or rounded and with a bristle at the apex, entire and undulate in margin; upper surface dark green, shining, glabrescent; lower surface coated with thick greyish-white tomentum, disappearing in part in summer; petiole about $\frac{1}{4}$ in. long, tomentose.

Fruit ripening in the second year, sessile or shortly stalked; acorn ovoid, about $\frac{1}{2}$ in. long, hoary pubescent at the apex; cupule variable in shape, saucer or cup-like, pale pubescent within, and covered externally by thin imbricated ovate tomentose scales.

This species,¹ which appears to be a variety of *Q. Phellos*, adapted by its

¹ *Q. pumila*, Walter, which resembles this species, is shrubby in habit, ripens its acorns in one year, and is practically evergreen, carrying its leaves until the new ones appear in the following spring. Cf. Sargent, *Silva N. Amer.* viii. 115, t. 404 (1895).

tomentose leaves and branchlets to drier ground than that species, grows on sandy barren soil and on upland ridges, from North Carolina southward to Cape Malabar and Peace Creek, Florida, and westward to the Brazos river, Texas, usually not penetrating inland more than forty or fifty miles from the coast, though in Texas it has been found as far as Dallas, about lat. 33°.

Q. cinerea is extremely rare in cultivation, the only specimen which we have seen being a healthy tree, about 30 ft. high, growing on the mound in the oak collection in Kew Gardens. (A. H.)

QUERCUS IMBRICARIA, SHINGLE OAK

Quercus imbricaria, Michaux, *Hist. Chênes Am.* No. 9, tt. 15, 16 (1801); Loudon, *Arb. et Frut. Brit.* iii. 1898 (1838); Sargent, *Silva N. Amer.* viii. 175, t. 432 (1895), and *Trees N. Amer.* 251 (1905).

Quercus Phellos, Linnæus, var. *imbricaria*, Spach, *Hist. Veg.* xi. 160 (1842).

A tree, attaining in favourable localities in America 100 ft. in height and 12 ft. in girth, but usually considerably smaller. Bark on young trees thin, smooth, and shining; on old trunks fissuring into broad, flat, scaly ridges. Young branchlets slender, quickly becoming glabrous. Leaves (Plate 339, Fig. 73) deciduous, oblong-lanceolate, 4 to 6 in. long, 1 to 2 in. broad, entire,¹ with slightly undulate margin, rounded or acute at the bristle-pointed apex, cuneate at the base; upper surface dark green, shining; lower surface greyish green, covered with a stellate tomentum; nerves pinnate, dividing and looping before reaching the margin; petiole pubescent, about $\frac{1}{2}$ in. long.

Fruit usually solitary, on stout short stalks, ripening in the second year; acorn nearly globose, obscurely striate, enclosed for one-third its length in a thin shallow turbinate cupule, brown and shining internally, and covered with thin ovate pubescent reddish brown, closely imbricated scales.

This oak is supposed to form hybrids with *Q. marylandica*,² *Q. rubra*,³ *Q. palustris*,⁴ and *Q. velutina*. The hybrid with the last species, the only one known in cultivation in this country, is dealt with under the name *Q. Leana* (see p. 1232).

(A. H.)

This species is a native of fertile soil, growing both on high land and in alluvial flats, and ranges from Pennsylvania westwards through southern Michigan and Wisconsin to northern Missouri and north-eastern Kansas, extending southwards along the Alleghany mountains to northern Georgia, Alabama, middle Tennessee,

¹ The leaves on very vigorous branchlets are sometimes three-lobed at the apex.

² *Q. imbricaria* × *marylandica*, Sargent, *Silva N. Amer.* viii. 176, t. 433 (1895); *Q. nigra*, var. *tridentata*, De Candolle, *Prod.* xvi. 2, p. 64 (1864); *Q. tridentata*, Engelm., in *Trans. St. Louis Acad.* iii. 539 (1877). A single tree, now dead, found by Engelm., near St. Louis.

³ *Q. imbricaria* × *rubra*. Cf. Bush, in *Garden and Forest*, viii. 33 (1895).

⁴ *Q. imbricaria* × *palustris*, Engelm., in *Trans. St. Louis Acad.* iii. 539 (1877). A single tree found near St. Louis. Meehan raised five seedlings from its acorns, which agreed in every respect with the parent tree.

and northern Arkansas. It is comparatively rare in the east, being most abundant in the basin of the lower Ohio and in the State of Missouri, and attains its largest size in southern Indiana and Illinois. Ridgway says that with the possible exception of *Q. alba* it is the most abundant and generally distributed species in Wabash Co., Ill., where it is the most slender of all the oaks; trees 100 ft. high and 50 ft. to the first branch being only 6 to 7 ft. in girth. On poorer soil, however, where it is more abundant, it does not usually much exceed half this size. According to Sargent, it is occasionally planted in the northern states, being hardy as far north as Massachusetts.¹

Although introduced into cultivation by John Fraser in 1786, it was a rare species in Loudon's² time, and no old trees exist, so far as we know, in this country. There are, however, two at Bayfordbury, supposed to have been planted with other American oaks in 1836, one of which measured 52 ft. high and 4 ft. 8 in. in girth in 1909; the other was 40 ft. by 4 ft. 9 in.

At Tortworth there is a healthy tree, about 35 ft. high. There is a well-grown tree in Mr. Young's nursery at Milford, near Godalming, which in 1909 was 60 ft. by 4½ ft., with a bole 20 ft. long. We have also identified trees of this species growing at Westonbirt, Kew, Beauport, Aldenham, and Yattendon Court near Newbury.

(H. J. E.)

QUERCUS LEANA

Quercus Leana, Nuttall, *Sylva*, i. 13, t. 5 bis (1842); Hill, in *Bot. Gaz.* xix. 171 (1894); Sargent, *Trees N. Amer.* 252 (1905).

Quercus imbricaria × *coccinea*, Engelmann, in *Trans. St. Louis Acad.* iii. 539 (1877).

Quercus imbricaria × *velutina*, Sargent, *Silva N. Amer.* viii. 176, t. 434 (1895).

A large tree. Young branchlets stout, reddish, with scattered stellate pubescence. Leaves (Plate 334, Fig. 10) oblong, lanceolate, 5 to 7 in. long, 2 to 2½ in. wide, with three to five pairs of short triangular bristle-pointed lobes, which in some cases are minute or absent; acute and mucronate at the apex, rounded or cuneate at the base; upper surface shining, dark green, with scattered, stellate, mostly deciduous pubescence; lower surface duller and paler, with persistent stellate pubescence, scattered between the veins, but densely crowded in tufts in the axils and in bands along the midrib; venation similar to that of *Q. heterophylla*; petiole, ½ to 1 in. long, with scattered stellate pubescence.

Fruit sub-sessile or on a short stalk, usually solitary; acorn sub-globose, enclosed to near the middle in a turbinate hemispherical cupule resembling that of *Q. velutina*, which is covered with ovate loosely imbricated pubescent scales.

¹ *Q. laurifolia*, Michaux, a more southerly species, is closely allied to *Q. imbricaria*, and is figured in Plate 339, Fig. 74. It is said to have been introduced in 1786; but is apparently not in cultivation at present, and is probably unsuitable for our climate.

² Loudon only mentions one tree, which was growing in the Horticultural Society's garden at Chiswick.

This tree was discovered about 1830 by Mr. T. G. Lea near Cincinnati, Ohio, and has since been found scattered as isolated specimens over a wide area, extending from the district of Columbia and western North Carolina to southern Michigan, central and northern Illinois, and south-eastern Missouri. (A. H.)

The large tree near the Director's Office, Kew Gardens, which has long been labelled *Q. heterophylla*, appears to belong to this hybrid. It was probably planted by Sir W. J. Hooker, though its age and history are unknown. It measured in 1909 60 ft. high and 7½ ft. in girth. A smaller tree in the oak collection at Kew about 25 ft. high, obtained from Smith of Worcester in 1877 under the name *Q. villosa*, is very similar, and is certainly one of the hybrids of *Q. imbricaria*.

A tree was growing in 1903 at Devonhurst, Chiswick, formerly part of the Horticultural Society's garden, which Henry measured as 72 ft. by 6 ft. 8 in. It was cut down shortly afterwards.

At Ham Manor, Sussex, the seat of Sir H. Fletcher, there is a fine tree. When I measured it in June 1907 it was 62 ft. by 7 ft. 2 in., forking at 7 ft., and appeared to be grafted on a stock of the common oak, like the large one at Kew. A smaller tree also exists at Orton Hall.

(H. J. E.)

QUERCUS HETEROPHYLLA, BARTRAM'S OAK

Quercus heterophylla, Michaux f., *Hist. Arb. Am.* ii. 87, t. 16 (1812); Loudon, *Arb. et Frut. Brit.* iii. 1894 (1838); Engelmann, in *Woods and Forests*, 1884, pp. 735, 736; Sargent, *Trees N. Amer.* 248 (1905).

Quercus aquatica, var. *heterophylla*, Aiton, *Hort. Kew.* v. 290 (1813).

Quercus nigra, var., Cooper, in *Smithsonian Rep.*, 1858, p. 255 (1859).

Quercus Phellos × *coccinea*, Engelmann, in *Trans. St. Louis Acad.* iii. 541 (1877).

Quercus Phellos × *velutina*, Sargent, *Silva N. Amer.* viii. 180, *adnot.*, t. 436 (1895).

Quercus Phellos × *rubra*; *Quercus Hollickii*, Schneider, *Laubholzkunde*, 165 (1904).

A tree, occasionally attaining 80 ft. in height. Young branchlets glabrous. Leaves (Plate 334, Fig. 16) deciduous, lanceolate or narrow-elliptic, acute at the apex, cuneate at the base, 3 to 6 in. long, 1 to 2 in. wide; with usually three to five pairs of triangular bristle-pointed lobes, separated by wide sinuate sinuses; glabrous on both surfaces, except for axil-tufts beneath; nerves pinnate, those ending in the apices of the lobes more prominent than the intervening nerves, which divide and loop before reaching the margin; petiole ½ to 1½ in. long, slightly pubescent.¹

The above description is drawn up from a tree in Kew Gardens, about 30 ft. high, which was obtained from the Arnold Arboretum in 1877. Much variation, however, occurs in the shape of the leaves on wild trees, which are often only slightly lobed, and resemble those of *Q. Phellos*; but in all cases, as Engelmann points out,² the elongated petiole will serve to distinguish Bartram's oak from *Q. Phellos* or

¹ The fruit, which I have not seen, is said to be sparingly produced on trees in America, and in some cases is like that of *Q. rubra*, and in other cases similar to that of *Q. velutina*.

² In *Woods and Forests*, 1884, pp. 735, 736.

Q. nigra, two species which have often lobed leaves on young trees and on vigorous barren branchlets of older trees. In these species the petioles are inconspicuous, or merely 1 to 2 lines long. *Q. imbricaria*, which has long petioles, is readily distinguished in all its forms and hybrids by the pubescent leaves.

This oak was first described from a solitary tree¹ growing on the farm of John Bartram, near Philadelphia, on the banks of the Schuylkill, where it was discovered at some time previous to 1750. What appears to be the same tree has since been discovered at a considerable number of stations² from New Jersey to Texas.

Much discussion has arisen as to the relationship of Bartram's oak, and of the individuals that have been found like it; and Engelmann, who had not, however, seen flowers or fruit, considered it to be a distinct species, and not a variety of either *Q. Phellos* or *Q. nigra*, nor a hybrid of any of these oaks. The hybrid origin of *Q. heterophylla* was, however, definitely settled by an experiment of Dr. D. T. MacDougal.³ In October 1905 he collected seventy-five acorns from a tree growing on Staten Island, which had foliage similar to that of Bartram's oak; and fifty-five seedlings were obtained, which exhibited foliage of three kinds. Some of the seedlings had lanceolate entire leaves like those of *Q. Phellos*; others had broad lobed leaves like those of *Q. rubra*, while the remainder were intermediate and resembled the parent tree. In this case the parents may be assumed to be *Q. Phellos* and *Q. rubra*;⁴ but in other cases, though one of the parents is almost certainly *Q. Phellos*, the other, judging from the fruit, may be *Q. coccinea* or *Q. velutina*.

This oak appears to be very rare in cultivation, the only specimen which we have seen in England being the tree at Kew, mentioned above. Loudon says: "Said to have been introduced, but we do not know where it is to be obtained." Older trees, bearing this name, are usually *Q. Leana*. There is, however, a large tree of *Q. heterophylla* at Les Barres,⁵ about 66 ft. by 9 ft., which bears fruit regularly, but in small quantity, and is said to be very hardy. This tree was planted⁶ in 1822. Another tree at Verrières,⁶ probably of the same origin, but with slightly different foliage, measures 73 ft. by 8 ft., and bears a tuft of mistletoe on one of its large branches.

(A. H.)

¹ Otto of Berlin, in Loudon, *Gard. Mag.* xvii. 380 (1841), states that he saw *Q. heterophylla*, a tree 40 ft. high, growing in Bartram's botanic garden at Philadelphia, which was founded in 1717.

² A complete history of the occurrence of these trees is given by Arthur Hollick, in *Bull. Torrey Bot. Club.* xv. 303 (1888).

³ Cf. *Bot. Gaz.* xliii. 49, figs. 2, 3 (1907). Mehan, in *Gard. Chron.*, 1866, p. 365, speaks of two seedlings from the original tree, one a perfect *Q. Phellos*, the other like *Q. heterophylla*.

⁴ *Q. Hollickii*, Schneider, *loc. cit.*, who attempts to divide this form into three sub-varieties.

⁵ Cf. Pardé, *Arb. Nat. des Barres*, 299 (1906).

⁶ *Hortus Vilmoriniannus*, 55 (1906). A specimen branch procured by Elwes shows imperfect acorns.

QUERCUS NIGRA, WATER OAK

Quercus nigra, Linnæus, *Sp. Pl.* 995 (1753); Sargent, *Silva N. Amer.* viii. 165, t. 428 (1895), and *Trees N. Amer.* 246 (1905); Britten,¹ in *Journ. Bot.* xlvii. 349 (1909).

Quercus nigra aquatica, Lamarck, *Encyc.* i. 721 (1783).

Quercus uliginosa, Wangenheim, *Nordam. Holz.* 80, t. 6, f. 18 (1787).

Quercus aquatica, Walter, *Fl. Car.* 234 (1788); Loudon, *Arb. et Frut. Brit.* iii. 1892 (1838).

Quercus hemisphærica, Willdenow, *Sp. Pl.* iv. 443 (1805).

A tree, attaining in America 80 ft. in height and 10 ft. in girth. Bark about $\frac{1}{2}$ in. thick, covered with closely appressed scales. Young branchlets slender, glabrous. Leaves (Plate 334, Fig. 9) deciduous, late in the season, very variable in shape and size; on old trees obovate or oval, cuneate at the base, and enlarged at the broad, rounded, entire or three-lobed apex, about 3 in. long and 2 in. broad at the widest part; on vigorous and sterile branches on young trees longer and narrower, about 4 in. long by 1 in. broad, acute at the apex, cuneate at the base, with three to seven short triangular oblique bristle-pointed lobes; thin, membranous, glabrous, except for axil-tufts beneath; petiole short, $\frac{1}{8}$ to $\frac{1}{4}$ in. long.

Fruit solitary, short-stalked, ripening in the second year; acorn broad and flat at the base, rounded at the pubescent apex, enclosed for one-fourth its length in a thin saucer-shaped cupule,² about $\frac{1}{2}$ in. wide, tomentose within, and covered with ovate acute appressed pubescent scales.

The Water Oak, as its name implies, grows naturally on moist alluvial ground, and on the sandy borders of swamps and streams; and ranges from southern Delaware southward to Cape Malabar and the shores of Tampa Bay, Florida, extending inland to the base of the southern Alleghany Mountains, and westward through the Gulf states to the Colorado river, Texas, and the eastern part of Indian Territory, ascending the Mississippi basin to Arkansas, south-eastern Missouri, central Tennessee and Kentucky. On account of its rapid growth when young, and the facility with which it can be transplanted, it is used extensively as a shade tree in the cities and towns of the southern States.

According to Loudon, it was cultivated in England in Fairchild's nursery as early as 1723. Like many other interesting trees, it has scarcely been planted in this country of late years, though it is worthy of a place in all collections on account of the long persistence of the leaves, which remain fresh and green on the specimens at Kew and Tortworth till January or February, or even later in some seasons. Apparently this species does not produce fruit in England; but we have received a specimen with fully developed acorns from Mille Ivoy, Geneste, near Bordeaux.

(A. H.)

¹ Britten, in the article quoted, explains how the name *Q. nigra*, L., was erroneously transferred at an early date to *Q. marylandica*. The proper usage of the names for these two oaks was restored by Sargent.

² *Q. microcarya*, Small, *Flora S. East. States*, 350 (1903), is a form with smaller acorns, surrounded by a cup-shaped and not saucer-shaped cupule. This was found growing on granite rocks on the Little Stone Mountain in Georgia.

There are several good specimens in Kew Gardens, the largest being a tree near the main entrance, which measured, in 1909, 49 ft. by 4 ft. 5 in. This tree belonged to the old arboretum, and must be older than 1841.

At Beauport, Sussex, a tree, seen by Henry in 1904, measured nearly 50 ft. in height by 3 ft. 11 in. in girth. Another at Lyndon Hall (Plate 312) is 56 ft. by 4½ ft. There is also a smaller tree on the lawn at Tortworth. (H. J. E.)

QUERCUS MARYLANDICA, BLACK JACK

Quercus marylandica, Muenchhausen, *Hausvater*, v. 253 (1770); Sargent, *Silva N. Amer.* viii. 161, t. 426 (1895), and *Trees N. Amer.* 245 (1905); Britten, in *Journ. Bot.* xvii. 351 (1909).

Quercus nigra, var. β , Linnæus, *Sp. Pl.* 996 (1753).

Quercus nigra, Wangenheim, *Beschreib. nordam. Holzart.* 133 (1781); Walter, *Fl. Carol.* 234 (1788); Michaux, *Hist. Chênes Am.* No. 12, tt. 22, 23 (1801); Loudon, *Arb. et Frut. Brit.* iii. 1890 (1838) (not Linnæus).

Quercus nigra latifolia, Lamarck, *Encyc.* i. 721 (1783).

Quercus ferruginea, Michaux f., *Hist. Arb. Am.* ii. 92, t. 18 (1812).

A tree, attaining in America 50 ft. in height and 5 ft. in girth, but usually considerably smaller. Bark about an inch thick, divided into dark brown or nearly black, scaly, square plates. Young branchlets at first covered with a short stellate pubescence, gradually disappearing in the course of the summer; branchlets of the second year glabrous. Buds ovoid, ¼ in. long, covered with rusty brown pubescence. Leaves (Plate 334, Fig. 11) deciduous, averaging 5 to 7 in. in length and breadth, thick and coriaceous, very variable in shape, obovate, with a narrow rounded base, (*a*) with the apex broad, rounded, and indistinctly three-lobed or entire, with or without bristles, or (*b*) with the upper part of the leaf divided into three large oblong lobes, each with one to three bristle-pointed teeth; upper surface dark shining green, with quickly deciduous scattered minute stellate hairs; lower surface often brownish, with numerous stellate hairs in dense tufts in the axils and along the midrib and lateral nerves; petiole stout, ½ in. long, covered with short stellate hairs.

Fruit ripening in the second year, solitary or in pairs, shortly stalked; acorn sub-globose, ¾ in. long, with the shell lined with dense yellowish tomentum, enclosed for ½ to nearly ⅔ its length, in a thick turbinate cupule, covered by loosely imbricated tomentose scales.

This species usually grows on dry sandy barren land, though occasionally it is seen in the south-west on heavy clay soil; and is widely distributed in the United States, from Long Island, New York, southward to Tampa Bay, Florida, and westwards to south-eastern Nebraska, central Kansas, Indian Territory, and the valley of the Nueces river, Texas. Rare or local and poorly developed in the northern part of its range, it is abundant southward, often forming west of the Mississippi, a great part of the forest growth on sterile soils, and attaining its largest size in southern Arkansas and eastern Texas. (A. H.)

This tree, though introduced, according to Loudon, sometime before 1739, is rare in cultivation, and is usually short-lived in our climate. It scarcely attains the dimensions of a forest tree, but is worth a place in collections, on account of the large and curiously shaped leaves, which turn a brownish colour in autumn. It seldom has a healthy appearance, owing to the failure of the wood to ripen in autumn, and should be planted on a dry sandy soil in a warm and sheltered situation.

The largest tree we have seen is one at Lyndon Hall, Rutland, 40 ft. by 4½ ft. in 1908. There are younger trees at Tortworth, Bicton, Aldenham, and Kew. (H. J. E.)

QUERCUS CUNEATA, SPANISH OAK

Quercus cuneata, Wangenheim, *Nordam. Holzart.* 78, t. 5, f. 14 (1787); Sargent, in *Bot. Gaz.* xlv. 226 (1907).

Quercus rubra, var. *hispanica*, Castiglioni, *Viag. Stati Uniti*, ii. 347 (1790).

Quercus falcata, Michaux, *Hist. Chênes Am.* No. 16, t. 28 (1801); Loudon, *Arb. et Frut. Brit.* iii. 1882 (1838).

Quercus triloba, Michaux, *Hist. Chênes Am.* No. 14, t. 26 (1801).

Quercus elongata, Willdenow, in *Neue Schrift. Gesell. Natfr. Berlin*, iii. 400 (1801).

Quercus discolor, Spach, *Hist. Vég.* xi. 163 (1842) (not Aiton).

Quercus nigra digitata, Marshall, *Arb. Am.* 121 (1785).

Quercus digitata, Sudworth, in *Garden and Forest*, v. 98 (1892); Sargent, *Silva N. Amer.* viii. 147, tt. 420, 421 (1895), and *Trees N. Amer.* 242 (1905).

A tree, attaining in America 80 ft. in height and 9 ft. in girth. Bark divided by shallow fissures into broad scaly ridges. Young branchlets covered with a dense short stellate pubescence. Buds ovoid, ⅓ to ¼ in. long, with ciliate scales. Leaves (Plate 334, Fig. 14) deciduous in autumn, about 5 to 7 in. long and 3 to 4 in. wide, variable in shape; either (*a*) cuneate at the base, and divided into three large bristle-pointed lobes above, the terminal lobe longest and oblong, the lateral lobes shorter and ovate, each lobe entire or with one or two teeth; or (*b*) rounded or cuneate at the base, oblong-obovate, pinnately divided into five or seven entire or dentate, ovate, bristle-pointed lobes; upper surface dark green, shining, glabrescent; lower surface densely covered with dull grey minute stellate tomentum; petiole ¾ to 1 in. long, tomentose.

Fruit¹ ripening in the second year, sessile or shortly stalked; acorn sub-globose or ellipsoid, about ½ in. long, enclosed in a saucer-shaped or a deep turbinate cupule, covered with thin obtuse closely appressed scales.

This oak,² which was named Spanish oak by the early settlers from a fancied

¹ The small trees in England have not produced fruit. This species ripens its fruit at Geneste, near Bordeaux.

² *Q. pagodefolia*, Ashe, in *Bot. Gaz.* xxiv. 375 (1897); Sargent, *Silva N. Amer.* xiv. 51, t. 722 (1902), and *Trees N. Amer.* 244 (1905), was formerly considered to be a variety of *Q. cuneata*, from which it differs in the bark and in the shape of the leaves (see Plate 334, Fig. 12), which are always silvery white beneath. Specimens were gathered by Elwes in 1904 at Mt. Carmel, Illinois; but the tree has not yet been introduced. It has much the same distribution as *Q. cuneata*, but is always found in rich land along rivers liable to floods, whereas *Q. cuneata* is confined to the dry uplands. It is very abundant in the river swamps of the Yazoo basin, Mississippi, and of eastern Arkansas.

This is the form mentioned by Ridgway as a rare tree in the bottoms of the White River, where he measured a specimen 14 ft. in girth and estimated at 130 ft. high. It is unlikely to succeed in Great Britain.

resemblance probably to *Q. Cerris*, is an abundant tree on dry sterile hills in the south Atlantic and Gulf states, extending as far westward as the Bragos river, Texas, and ascending the Mississippi basin, through Arkansas, Missouri, Tennessee, and Kentucky to southern Indiana and Illinois. It is rare in the north Atlantic states, where it is only met with near the coast, reaching its most northerly point in southern New Jersey. It is one of the trees which grows, but not in great abundance, in the southern maritime pine belt.

This species was introduced in 1763 by Mr. Murdoch Murchison, and re-introduced in 1800 by Messrs. Fraser. It is extremely rare in cultivation, the only trees which we have seen being two in Kew Gardens, about 25 feet high, which are vigorous and healthy; and a small specimen at Aldenham. (A. H.)

QUERCUS ILICIFOLIA, BEAR OAK

Quercus ilicifolia, Wangenheim, *Nordam. Holzart.* 70, t. 6, f. 17 (1787); Loudon, *Arb. et Frut. Brit.* iii. 1893 (1838); Sargent, in *Bot. Gaz.* xlv. 227 (1907).

Quercus Banisteri, Michaux, *Hist. Chênes Am.* No. 15, t. 27 (1801).

Quercus rubra nana, Marshall, *Arbust. Am.* 123 (1785).

Quercus nana, Sargent, in *Garden and Forest*, viii. 93 (1895), *Silva N. Amer.* viii. 155, t. 424 (1895), and *Trees N. Amer.* 241 (1905).

A shrub or small tree, scarcely exceeding 20 ft. in height. Bark thin and scaly. Young branchlets covered with a minute dense pubescence, glabrous in the second year. Buds minute, ovoid, obtuse, glabrous, $\frac{1}{8}$ in. long. Leaves (Plate 334, Fig. 13) deciduous, about 3 in. long and 2 in. wide, coriaceous, obovate-oblong, cuneate at the base; divided by wide shallow sinuses into five short broad bristle-pointed acute lobes, the terminal lobe usually largest and often with one or two teeth; upper surface dark green, shining, with quickly deciduous minute stellate pubescence; lower surface greyish tomentose; petiole slender, $\frac{1}{2}$ in. long, tomentose.

Fruit ripening in the second year, sessile or stalked; acorn ovoid, about $\frac{1}{2}$ in. wide and long; cupule thick, turbinate, covered with closely appressed, thin, slightly pubescent scales, the minute free tips of the upper rank forming a fringe.

This species grows on dry sandy barren ground and on rocky hill-sides from Maine to eastern Pennsylvania, and along the Alleghany mountains to southern Virginia.

This oak was discovered in Virginia by the missionary John Banister, and was included in his catalogue of Virginian plants published by Ray¹ in 1688. It was introduced in 1800 by Messrs. Fraser, and is a thriving shrub at Tortworth, where it produces acorns freely; and is possibly of some value on that account for planting in game coverts as food for pheasants. There are specimens also at Kew, Westonbirt, and Liphook. At Les Barres in France it grows vigorously, and sows itself, being looked upon as good pheasant covert. (A. H.)

¹ Ray, *Hist. Plant.* ii. pp. 1926-8. It was called *Q. pumila* by Banister.

QUERCUS VELUTINA, BLACK OAK, QUERCITRON OAK

Quercus velutina, Lamarck, *Dict.* i. 721 (1783); Sargent, *Silva N. Amer.* viii. 137, tt. 414, 415 (1895), and *Trees N. Amer.* 237 (1905).

Quercus nigra, Du Roi, *Harbk. Baumz.* ii. 272 (excl. syn.), t. 6, f. 1 (1772) (not Linnæus).

Quercus discolor, Aiton, *Hort. Kew.* iii. 358 (1789).

Quercus tinctoria, Michaux, *Hist. Chênes Am.* No. 13, tt. 24, 25 (1801); Loudon, *Arb. et Frut. Brit.* iii. 1884 (1838); Bentley and Trimen, *Med. Plants*, iv. 251, t. 251 (1880).

Quercus coccinea, Wangenheim, vars. *nigrescens* and *tinctoria*, A. de Candolle, *Prod.* xvi. 2, p. 61 (1864).

A tree, attaining in America 150 ft. in height and 15 ft. in girth, but usually considerably smaller. Bark of young trees smooth, yellowish within; on old trunks divided into broad rounded scaly ridges. Buds ovoid, $\frac{1}{8}$ to $\frac{1}{4}$ in. long, angled, obtuse or pointed, pubescent. Young branchlets, with a scattered minute stellate pubescence, most of which falls off in summer. Leaves (Plate 333, Fig. 5) deciduous in autumn, turning a dull red or dark brown, variable in size and shape, but similar to those of *Q. rubra*, often very large, 9 in. long and 6 in. broad, with five to seven triangular lobes with bristle-pointed teeth; sinuses wide and rounded, variable in depth; upper surface glossy, dark green, with scattered stellate hairs, disappearing in summer; lower surface paler, with stellate hairs scattered between the nerves, and forming dense reddish brown axil-tufts; petiole 1 to 3 in. long, with deciduous or partly persistent stellate pubescence. The inner bark of young branches is bitter when chewed, and gives a yellow tinge to the saliva.

Fruit ripening in the second year, sessile or shortly stalked, solitary or in pairs; acorn¹ ovoid, $\frac{1}{2}$ to $\frac{3}{4}$ in. long, often striated, and sometimes pubescent, enclosed for about half its length in a turbinate cupule, slightly pubescent within, and covered with scales, often lacerate in margin, closely appressed towards the base of the cupule, loosely imbricated above, forming a fringe-like border to its rim.

This species is readily recognised by the bright yellow colour of the inner bark, by the more or less deciduous stellate pubescence on the leaves, petioles, and branchlets, and by the pubescent buds.

Var. *missouriensis*, Sargent, *Trees N. Amer.* 239 (1905), is a more pubescent form, growing in drier situations from western Missouri to north-western Arkansas.

The black oak grows commonly on ridges and on dry gravelly uplands, and is one of the most abundant and widely distributed of North American oaks. It occurs in southern and western Ontario, and throughout the Atlantic States from southern Maine to northern Florida, being one of the commonest oaks on gravelly drift in southern New England and in the middle states; and is generally scattered throughout the maritime pine belt of the south Atlantic

¹ The flesh of the acorn is orange in colour.

coast and of the Gulf states, extending westward to eastern Texas, Indian Territory, eastern Kansas, south-eastern Nebraska, Iowa, and central Minnesota. It forms a large part of the forest growth on the foothills of the southern Alleghany mountains, and is abundant in all parts of the Mississippi basin, attaining its largest size in the valley of the lower Ohio river. (A. H.)

REMARKABLE TREES

This species was introduced, according to Loudon, in 1800; but is much less commonly seen than *Q. rubra*; and though it appears to grow well in southern England, it rarely ripens its acorns.

The finest tree which we know of is growing at Bayfordbury (Plate 313), where it was planted in 1841 under the name *Q. rubra macrophylla*. It was 80 ft. high by 6 ft. 10 in. in girth in 1905.

At Arley Castle there are two fine trees,¹ planted probably about 1820, one of which measured in 1903, 80 ft. by 7 ft. 2 in.; the other, in the following year, was 70 ft. by 6 ft. 6 in.

At Beauport, a tree growing in a rather crowded position, and apparently decaying at the top, is from 60 to 65 ft. in height, and 7 ft. 3 in. in girth. At Lyndon Hall, Rutland, the seat of E. W. P. Conant, Esq., there are two trees, the larger nearly 50 ft. high and 5 ft. 3 in. in girth. At Henham Hall, Suffolk, the seat of the Earl of Stradbroke, there is a tree, measuring in 1909, 53 ft. by 5½ ft. There are also specimens at Syon, Kew, and Tortworth, where it was found labelled *Q. nigra*; and at Liphook, Westonbirt, and Orton Hall.

In the south-west it seems to grow well, as there are healthy trees at Killerton, about 50 ft. by 5 ft. in 1906, and a smaller one at Bicton. At Pixton Park there is a fine tree in the park by the Dulverton Drive, which in 1909 was about 60 ft. by 5 ft. 4 in.

In Scotland, the only tree we know of is one at Castle Kennedy, which Henry found in 1906, bearing the name of *Q. macrocarpa*.

TIMBER AND BARK

Its timber is said by Michaux to be the best of the oaks of this section, but is not distinguished in commerce, and judging from the examples in Hough's work, is very similar in appearance to that of *Q. rubra*. It is largely used for staves and furniture.

The bark is extensively used for tanning, and gives a valuable yellow dye known as *quercitron*, which, according to Loudon, is equal to weld² in the brilliancy of the yellow which it gives, and was at that time largely imported in England. According to Bentley and Trimen, it is used in Europe for dyeing silk and wool.

(H. J. E.)

¹ Cf. R. Woodward, Jun., *Hortus Arleyensis*, 11, 46 (1907).

² Loudon says "woad," evidently a mistake for "weld," *Reseda Luteola*, which yields a yellow dye, much used formerly.

QUERCUS KELLOGGII, CALIFORNIAN BLACK OAK

Quercus Kelloggii, Newberry, in *Pacific R. R. Rep.* vi. 28, f. 6 (1857); Sargent, in *Bot. Gaz.* xlv. 226 (1907).

Quercus tinctoria, Michaux, var. *californica*, Torrey, in *Pacific R. R. Rep.* iv. part i. 138 (1856).

Quercus rubra, Bentham, *Pl. Hartweg.* 337 (1857) (not Linnæus).

Quercus californica, Cooper, in *Smithsonian Report*, 1858, p. 261 (1859); Sargent, *Silva N. Amer.* viii. 141, t. 416 (1895), and *Trees N. Amer.* 239 (1905).

Quercus sonomensis, A. de Candolle, *Prod.* xvi. 2, p. 62 (1864).

A tree, occasionally attaining 100 ft. in height and 12 ft. in girth, frequently smaller, and at high elevations becoming a shrub. Bark of young trees smooth; on old trunks divided into thick irregular oblong scaly plates. Young branchlets quickly becoming glabrous. Buds ovoid, pointed, ¼ in. long, pubescent at the tip; scales pale brown, with dark brown ciliate margins. Leaves (Plate 333, Fig. 2) deciduous in autumn, turning yellow or brown before falling, 3 to 6 in. long, 2 to 4 in. broad, oblong or obovate, with usually seven (rarely five or nine) oblong lobes with bristle-pointed teeth; sinuses usually deep, narrow, and rounded at the base; upper surface shining, glabrous, dark green; lower surface paler, with scattered minute stellate pubescence, and without axil-tufts; petiole about 1 in. long, quickly becoming glabrous.

Fruit, ripening in the second year, solitary or clustered on short stout stalks; acorn ovoid, about an inch long, pubescent; enclosed for about half its length in a deep cupule, covered by thin ovate-lanceolate slightly pubescent scales, which in the lower ranks are closely appressed and swollen on the back, and towards the rim of the cupule are loosely imbricated with thin erose margins.

Q. Morehus, Kellogg, in *Proc. Calif. Acad.* ii. 36 (1863); Sargent, *Silva N. Amer.* viii. 120, t. 407 (1895); a small tree with subevergreen foliage, occurring in a few localities in California, is believed to be a hybrid between *Q. Kelloggii* and the evergreen *Q. Wislizeni*.

Q. Kelloggii is a native of Oregon and California, where it ranges from the basin of the Mackenzie river in western Oregon southwards through the coast ranges and along the western slopes of the Sierra Nevada to the San Bernardino, San Jacinto and Cuyamaca mountains, attaining towards the south 7000 to 8000 ft. altitude. It is mainly found in valleys and on mountain slopes, and is rare in the immediate vicinity of the ocean.

I saw this species in 1906, at about 3000 ft. elevation, on the dry hills of the Siskiyou range, where it is associated with *Q. Garryana*, one of the Californian white oaks. Both species attained about 70 ft. in height with short trunks up to 4 ft. in diameter, dividing into wide-spreading branching limbs. The bark of *Q. Kelloggii* is rather dark in colour, contrasting strongly with the remarkably white bark of the other species. Mr. F. R. S. Balfour, who visited the same district, saw larger trees in the valley of the Illinois river, Oregon, and in the

King's river cañon in California, where their trunks rose tall and straight amongst *Libocedrus decurrens* and *Pinus ponderosa*. In late autumn the foliage turns to fine yellow and crimson colours.

This tree was discovered by Hartweg in 1846 near Sonoma, among the foot-hills of the Californian Sierras; and is named after Dr. Albert Kellogg, the pioneer botanist of California, who was one of the founders of the Californian Academy of Sciences, and Curator of the Herbarium in San Francisco. According to Lemmon,¹ it is generally known as the Kellogg oak.

This species is little known in cultivation; and Schneider doubts if it exists on the continent. It appears to have been first introduced by the Earl of Ducie, who has at Tortworth two fine specimens about 30 ft. high by 2 ft. 3 in. which were raised from acorns obtained from San Francisco in 1878. These are making rapid growth.

There is a smaller specimen at Kew which ripened acorns in 1907.

(A. H.)

QUERCUS RUBRA, RED OAK

Quercus rubra, Linnæus, *Sp. Pl.* 996 (1753); Michaux, *Hist. Chênes Am.* No. 20, tt. 35, 36 (1801); Loudon, *Arb. et Frut. Brit.* iii. 1877 (1838); Sargent, *Silva N. Amer.* viii. 125, tt. 409, 410 (1895), and *Trees N. Amer.* 230 (1905).

A tree, attaining in America 150 ft. in height and 12 ft. in girth. Bark on young trees smooth, thin, grey; becoming on old trunks about an inch in thickness and divided on the surface into small scaly plates. Young branchlets glabrous, dark red, with white lenticels. Buds ovoid, acute, about $\frac{1}{4}$ in. long, reddish brown, often pubescent at the tip; scales glabrous, with ciliate margins. Leaves (Plate 333, Figs. 3 and 8) deciduous, membranous, 5 to 8 in. long, 4 to 6 in. broad, oval or obovate, cuneate or rounded at the base, acute or acuminate at the apex, usually divided about half-way to the midrib, by wide oblique sinuses, into seven to eleven ovate or triangular lobes, broad at the base, and with one to three bristle-pointed teeth at the apex; upper surface dark green, glabrous; lower surface dull or pale green, glabrous, except for slight axil-tufts of pubescence; petiole 1 to 2 in. long, glabrous.

Fruit ripening in the second year, solitary or in pairs, sessile or stalked; acorn ovoid, $\frac{3}{4}$ in. to 1 in. long, broad at the base, rounded at the apex, enclosed only at the base in a thick, shallow, saucer-like cupule, $\frac{3}{4}$ in. to 1 in. in diameter, pubescent within, and covered externally with closely appressed, thin, ovate, minutely pubescent scales.

The red, scarlet, and pin oaks are often confused; but may readily be distinguished by the characters of the buds and leaves, given for each species in the Key, Nos. 14, 15, and 16. See also, under *Q. coccinea*, p. 1248, and *Q. palustris*,

¹ *Oaks of Pacific Slope*, 14 (1902).

p. 1250. Both *Q. rubra* and *Q. palustris* have saucer-like or flat acorn-cupules, those of the former being large and thick; those of the latter species thin and small. The cupules of *Q. coccinea* are deep and turbinate, with a peculiar scaly stalk.

DISTRIBUTION¹

The red oak is one of the largest and most common trees in the eastern parts of Canada and the United States. It is abundant in southern Nova Scotia, New Brunswick, Quebec, and Ontario, and in the northern and central States, attaining its largest size in the region north of the Ohio river. Its western limit is marked by a line drawn from lake Namekagon in Burril County, Wisconsin, through eastern Minnesota, eastern Nebraska, and the Blue river in Kansas. Its southern and south-western limits are not clearly defined, as it is replaced to the southward by *Q. Schneckii*, which has hitherto been generally confounded with it. Its occurrence in Indian Territory, eastern Texas, southern Missouri and Arkansas is doubtful. It is common in the mountainous parts of Kentucky and Tennessee, and reaches its most southerly point, so far as is known, in the Red Mountains near Birmingham, Alabama, where a few isolated stunted specimens have been found. On the Atlantic slope it is common everywhere in New England, except in the mountains, in New York outside the Adirondacks, and throughout New Jersey and Pennsylvania. Farther south it extends along the Alleghanies as far as northern Georgia. Towards the north it is confined to altitudes below 500 ft., in Kansas and Missouri below 1000 ft., while in Virginia it ascends to 3500 ft., and in western North Carolina to 5000 ft.

The red oak thrives best where the rainfall is considerable, 32 to 53 in. annually being registered over its area of distribution. It ceases to grow west of the 90th meridian, where the rainfall falls below 30 in. The climate in which it flourishes is characterised by great extremes of temperature, the thermometer often falling during the long winter to -30° Fahr., and attaining in summer a maximum of 90° to 95° Fahr. It grows well on porous sandy, or on gravelly clay soils, which are well-drained; and is not found on very wet or on very dry ground. It is intolerant of shade, except when quite young. It is not subject to disease or serious insect attacks, and is rarely overthrown by the wind.

In the forest it is usually associated with numerous other species, as other kinds of oak, chestnut, lime, elms, and hickories; and where the canopy is dense and a good layer of humus exists attains a greater height than any other American oak, and in a shorter time, trees 150 ft. high and 5 ft. in diameter being not uncommon in favourable situations; but on drier and poorer soil it does not exceed 100 ft. The stems of forest-grown trees are usually buttressed at the base, and are exceptionally straight and of uniform diameter, and are often free of branches to 40 or 50 ft. The red oak, on account of its abundance over a wide area, and its rapidity of growth, producing timber of commercial value quicker than any other

¹ Compiled in part from notes by Professor C. Mohr, in the Bureau of Forestry, Washington, D.C.

black oak, takes a prominent place among the supplies of hardwood timber east of the Mississippi river, particularly in their northern area.

Isolated trees in the open in Massachusetts do not appear to attain as great a height as they do in England, those mentioned¹ as noteworthy for size being the Charlemont oak, 58 ft. by 14½ ft., the Beaman oak, 70 ft. by 17 ft. 8 in. The Caster oak, the height of which is not stated, growing at Lancaster in this state is 18 ft. 5 in. in girth.

The red oak reproduces freely from coppice shoots, which often attain 6 ft. in their first season. Where natural regeneration cannot be relied on, or where new land is being planted, in America, acorns are sown *in situ*, as the seedling is not easy to transplant, on account of its long tap-root. (A. H.)

CULTIVATION

The red oak has been tried as a forest tree on a considerable scale on the Continent. In Prussia² the area under cultivation at thirty-two different experimental stations was about 100 acres in 1900; and it has shown very rapid growth in youth, averaging 7 to 10 ft. high at five years old, 16 to 25 ft. at ten years old, 25 to 35 ft. at fifteen years, and 40 to 50 ft. at twenty years. It succeeds well on poor land, thriving even on soil considered to be third class for growing the common pine. It is used for underplanting pine woods, and for filling up gaps in broad-leaved plantations.

In Belgium thousands of trees of this species have been planted with the greatest success. Wesmael³ reported in 1890, that trees forty-five years old had attained on an average a height of 60 ft. and a girth of 5 ft. 11 in. He claimed for the tree that the wood was excellent for carriage-building and cabinet-work, and that it grew well on light porous soil, where the common European oak remained dwarfed and stunted. At Tervueren near Brussels M. Bommer showed me in 1909 a plantation of red oaks thirty years old, on fairly good sandy soil, the average height of which was about 50 ft., and the average girth 16 to 24 in. They formed a good cover with straight clean stems, and had recently been underplanted with beech.

Introduced into France as long ago as 1740, and grown by Miller in England in 1739, the red oak is the best known and the most generally successful of the American oaks in England. It ripens its acorns in the south, and self-sown seedlings are occasionally found on the warm light soils which it requires to enable it to become a large tree. It does not, however, seem to be a very long-lived tree, most of the oldest which we have seen already showing signs of decay.

The colour of its foliage in autumn is so beautiful that it should be planted in conspicuous places in all pleasure-grounds and parks, and if sheltered by other trees when young, and on deep well-drained soil, it grows rapidly and soon produces the best effect among other foliage. I have raised seedlings from a tree in Lord Ducie's

¹ In *Garden and Forest*, iv. 586 (1891).

² Schwappach, *Anbauvers. fremdl. Holzart.* 72 (1901).

³ Cf. *Garden and Forest*, iii. 129 (1890).

park, which grow fairly well on my soil, but like all American oaks, require good nursery cultivation when young.

REMARKABLE TREES

The largest that we have seen in England is a tree at Pains Hill on the edge of a belt near the kitchen garden, in light sandy soil. In 1908 this measured about 80 ft. high by 19 ft. in girth, with a short bole, and branches spreading over an area 38 yds. wide. Some self-sown seedlings were coming up near it. At Kew there is a fine old tree¹ near the Pagoda, which in 1909 was about 75 ft. by 13½ ft. with a bole 20 ft. high. This tree a few years ago was decaying, but its vigour has been much increased by cutting out the dead branches, and top-dressing the roots with good soil.² The tallest trees that I have measured are one at Oakly Park, Ludlow, which in 1908 was about 100 ft. by 11½ ft., and one at Brockett Hall, Herts, which in 1905 was 97 ft. by 8½ ft. At Cassiobury in the same county, Henry measured a fine tree in 1904, 90 ft. by 14½ ft. with a clean bole about 20 ft. long. At Whitton there is a tree, probably 150 years old, which in 1903 was 90 ft. by 7 ft. 10 in., with a trunk 40 ft. high.

In the midland counties the best specimens we have seen are at Coombe Abbey, 85 ft. by 11 ft. 9 in. in 1908, and on the lawn at Kedleston, near Derby, a well-shaped tree (Plate 314) measuring in 1909, 90 ft. by 11 ft. with a bole of 30 ft.

In the south-western counties there are good-sized trees at Melbury and at Endsleigh. At Pixton Park, Dulverton, the seat of the Dowager Countess of Carnarvon, there are several fine tall trees in a wood called Puzzlecombe, the best of which was, as nearly as I could estimate, about 100 ft. high, with a clean straight trunk nearly 60 ft. high.

In Wales the finest known to us is at Stackpole Court, which in 1906 was about 90 ft. by 9½ ft. At Margam there is also a good-sized tree of this species. Besides the above we have seen and measured red oaks in a great many other places, many of which are known as scarlet oaks.

In Scotland it has not been planted as generally as in England, but succeeds well in those parts which have a warm summer. The best that I know of are at Brahan Castle, Ross-shire, which was about 80 ft. by 7½ ft. in 1907; and at Murthly, where there are several good trees, 70 to 80 ft. high, in the Birnam Drive. These bore no acorns in 1906, and the forester told me that the leaves were much eaten by the larva of *Tortrix viridana*, which I have noticed also in England.

In Ireland it is comparatively scarce, the largest we have measured about 60 ft. by 7 ft. 8 in. in 1909, being in the Lakeside Drive at Muckross, Killarney. A specimen from a tree at Carton, Maynooth, measuring 50 ft. by 8 ft. 3 in. is preserved in the Kew Herbarium.

¹ This tree bears a single branch, with leaves creamy-white in colour. Efforts to propagate this shoot were not successful.

² A similar instance of the regeneration of the American white oak is shown by Prof. Sargent in two illustrations of a tree in the Arnold Arboretum, one taken before its treatment, the other twelve years afterwards, and the results are certainly very striking.

On the Continent it succeeds even better than in England, and is commonly planted in the parks and pleasure grounds of France, Germany, and Belgium. The largest tree I have seen is at the Château de Longchamps in Belgium, where Baron de Selys Longchamps showed me a splendid tree grafted on the common oak at about 4 ft. from the ground, and measuring no less than 110 ft. by 12 ft. in 1908.

TIMBER

Though the wood of this tree is not highly valued in the United States in comparison with that of the white oak, on account of its want of durability, yet for interior work it seems a good timber, on account of its delicate pinkish colour and handsome silver grain when quartered. Owing to the increased scarcity of white oak it is now largely imported to this country, and often mixed with parcels of boards of other species and sold as American oak. So little is known about its true qualities, that at a recent trial in London, an architect stated in evidence that it was grown in swamps and was subject to dry rot. The former statement is certainly incorrect, and for the latter we can find no foundation; though no doubt badly-seasoned wood of this tree would rot like any other if put into damp buildings. The wood of a tree which was grown at Woolbeding in Sussex, and kindly given me by Archdeacon Elwes, was very easy to rend on account of its straight grain, and had the same pink tinge as the American-grown wood.

We abstract the following from a paper by Prof. Mohr:¹ The heartwood of the red oak is reddish, porous, and of coarse grain. The wide pores in the cross-section mark the annual rings in three or four rows. The medullary rays are conspicuous, but comparatively few. The wood is heavy, strong, and hard, inclined to shrink and check when drying. The structure of the wood not being homogeneous, the wood in drying parts with its moisture unequally, the water being retained in some parts much more than in others. The wood thus retains moisture, and when dried readily reabsorbs moisture; and this explains its liability to decay. In strength the wood is scarcely inferior to white oak, but its want of durability prevents its application for many purposes. Perfectly dried red oak has a specific gravity averaging 0.652, varying from 0.540 to 0.748; and a cubic foot of air-dry wood weighs 40.75 lb. In its mechanical properties, it compares favourably with the more valuable hardwoods. In its resistance to longitudinal compression, it is equal to white oak. In elasticity it surpasses white oak; and in ultimate strength (resistance to transverse pressure) it is slightly superior to white oak. In hardness, *i.e.* resistance to indentation, it falls far below white oak; and this want of hardness renders red oak unfit for cross-ties. Nails exposed to its acid watery juice easily rust, and this sometimes prevents its use in construction.

The wood is very desirable for interior finish and furniture. When sawn on the quarter it has a beautiful grain, and is little less valuable than white oak for cabinet-work.

Red oak timber has been used extensively from the time of the earliest settle-

¹ MS. in the Bureau of Forestry, Washington, D.C.

ments for clap-boards, for the interior finish of houses, and for dry cooperage. Of late years it had been increasingly used for making a cheap class of furniture, as chairs, tables, and other articles. Its very objectionable defect, that of shrinking and checking badly when drying, has been in a large degree overcome by treatment in the dry kiln. Its additional uses are: shipbuilding (to a limited extent), house-building, agricultural implements, baskets, wood alcohol, acetate of lime, and shingles. (H. J. E.)

QUERCUS COCCINEA, SCARLET OAK

Quercus coccinea, Muenchhausen, *Hausv.* v. 254 (excl. *b*) (1770); Loudon, *Arb. et Frut. Brit.* iii. 1879 (1838); Sargent, *Silva N. Amer.* viii. 133, tt. 412, 413 (1895), and *Trees N. Amer.* 236 (1905).

A tree attaining in America 80 ft. in height and 10 ft. in girth. Bark smooth and thin on young trees; on old trunks divided by shallow fissures into scaly ridges. Young branchlets shining, glabrous, with white lenticels. Buds ovoid, acute, $\frac{1}{8}$ to $\frac{1}{4}$ in. long, covered above the middle with whitish pubescence. Leaves (Plate 333, Fig. 6)¹ deciduous late in autumn, turning brilliant scarlet before they fall, 3 to 6 in. long, $2\frac{1}{2}$ to 4 in. broad, obovate or oval, very variable in shape, as a rule more deeply lobed than *Q. rubra*, the sinuses often extending to near the midrib; usually with seven to nine spreading oblong, often falcate lobes, each with two to five bristle-tipped teeth towards the apex; base truncate or cuneate; shining and glabrous on both surfaces, except for occasional inconspicuous axil-tufts beneath; petiole slender, glabrous, $1\frac{1}{2}$ to $2\frac{1}{2}$ in. long.

Fruit ripening in the second year, solitary or in pairs, sessile or short-stalked; acorn $\frac{1}{2}$ to $\frac{3}{4}$ in. long, ovoid, rounded at the base and apex; enclosed for half its length in a deeply turbinate thin cupule, $\frac{1}{2}$ to $\frac{3}{4}$ in. broad at the rim, covered with closely appressed ovate acute slightly pubescent scales. The base of the cupule is formed by a narrow prolongation, resembling a thickened stalk, but differing from a true peduncle in being covered with scales.

Quercus ambigua, Michaux f., *Hist. Arb. Am.* ii. 120, t. 24 (1812); Loudon, *Arb. et Frut. Brit.* iii. 1881 (1838).

Quercus borealis, Michaux f., *N. Amer. Sylva*, i. 98, t. 26 (1819); Britton, *Man. Fl. N. States*, 334 (1901); Small, *Flora South-eastern U.S.* 1322 (1903).

Quercus coccinea, var. *ambigua*, Asa Gray, *Manual*, 454 (1867).

Described by the younger Michaux as a large tree with the leaves of *Q. rubra* and the fruit of *Q. coccinea*. It was first seen by his father on the banks of the St. Lawrence near Quebec, and was found by himself in Maine, New Hampshire,

¹ The figure is drawn from a wild specimen, and represents an extreme form of the leaf. Many wild specimens and most of the trees in cultivation have leaves more like *Q. rubra* in lobing.

Vermont, and Nova Scotia, where it was known as the grey oak. Britton and Small, who consider it to be a distinct species, extend the distribution to New York and Pennsylvania, and as far south as the mountains of North Carolina, and describe the leaves as like those of *Q. rubra*, seven- to thirteen-lobed to the middle or somewhat beyond. Sargent¹ refers to *Q. ambigua* as a form of *Q. rubra*, having fewer lobes to the leaves, and smaller fruits with turbinate cups; but states that these extreme forms are so intermixed and inconstant that it does not seem practicable to consider them even varieties. All this evidence goes to prove that this name covers a series of hybrids² between *Q. coccinea* and *Q. rubra*.

At Arley Castle, trees of typical *Q. rubra*, which freely bear fruit with large flat shallow saucer-like cupules, invariably have leaves turning dull reddish brown and falling off early in autumn. Other trees, with smaller acorn-cups, which though shallow are not quite flat at the base, but prolonged into a short scaly stalk, are deciduous late in the season, and their leaves turn a brilliant scarlet before falling. Such trees correspond to the description given of *Q. ambigua*, and are in all probability hybrids of *Q. rubra* and *Q. coccinea*.

Q. coccinea bears fruit only rarely in England; and we have seen no fruiting specimens of Waterer's *Q. coccinea splendens*, which turns a brilliant crimson in autumn; but this tree is probably true *Q. coccinea*.

In the absence of fruit, *Q. coccinea* is best distinguished by the buds, white-pubescent in their upper half; and by the leaves, shining beneath, more deeply lobed than in *Q. rubra*, falling late in the season, after turning a brilliant scarlet or crimson. Trees with the foliage of *Q. rubra*, dull beneath, but turning scarlet in autumn, and late in falling, may be assigned to *Q. ambigua*.

The scarlet oak is the most ornamental species in North America, on account of its deeply cut foliage, shining green in summer and brilliant scarlet in autumn. The leaves are retained late in the autumn, after most of the other oaks have withered and fallen.³ It attains its northern limit in southern Ontario, and is widely distributed through the northern parts of the United States from south-eastern Nebraska eastward through central Minnesota and Michigan, southern New York, Vermont, and southern New Hampshire to the valley of the Androscoggin river in Maine. It is very abundant on the coast region from Massachusetts to New Jersey, where it is generally found on light dry usually sandy soil; but is less common in the interior, where it grows on dry gravelly uplands, and on the prairies of the west. It extends to northern Illinois and the District of Columbia, and along the Alleghany Mountains to North Carolina. It is occasionally planted in the north-eastern states in towns, but is said to be undesirable for streets, as young trees are disposed to be wide-spreading and unsymmetrical. Its timber is not distinguishable from that of the red oak in commerce, and is identical with it in appearance and quality.

(A. H.)

¹ *Silva N. Amer.* viii. 127, note.

² Baenitz, in *Allg. bot. Zeitschr.*, 1903, p. 85. has, under the name *Q. Benderi*, described similar hybrids growing at Breslau.

³ Cf. Hough, *Trees N. States and Canada*, 147 (1907).

REMARKABLE TREES

The scarlet oak was introduced very early, as a plant is said to have been growing in Bishop Compton's garden in 1691. Loudon states that the largest tree which he had seen and knew with certainty to be this species, was at Syon, 77 ft. high and 2 ft. 9 in. in diameter in 1838. This tree is no longer living. He mentions a considerable number of other trees, of which he had received reports; but we believe that their identification was in many cases erroneous. The scarlet oak does not appear in England to grow so large or attain as great an age as *Q. rubra*; and we have seen only a few trees of considerable size.

The finest is perhaps a tree¹ at Arley Castle, 78 ft. high and 6 ft. 3 in. in girth in 1904. At West Dean Park, Chichester, there are four trees, 63 ft. by 3 ft. 8 in., 59 ft. by 3 ft. 6 in., 60 ft. by 4 ft. 8 in., and 48 ft. by 1 ft. 10 in., two of which bore fruit in 1909. These are considerably smaller than two specimens of *Q. rubra* which were probably planted at the same time, though the date is unknown.

At Stoke Park, Stoke Pogis, Bucks, there is a tree, which was still bearing foliage, scarlet in colour, on 18th November 1909, which Mr. E. H. Wilding reports to be 55 ft. high by 6 ft. 9 in. in girth. At Brocklesby, a tree measured 66 ft. by 3 ft. 9 in. in 1909. At Kew, a tree in the oak collection, about 25 ft. high, bore good fruit in 1907, but died in 1909. At Terling Place, Essex, there is a small tree, turning brilliant scarlet in autumn and about 25 ft. high, which was raised from acorns sent by Asa Gray in 1885. At Syon, there is a thriving young tree, about 30 ft. high, which bore acorns in 1907. This was pronounced by Prof. Sargent to be the best specimen which he had seen in England. At Ponfield, Herts, a small tree 35 ft. by 2 ft. 4 in., planted in 1883, bore fruit in 1909. At Tortworth and Westonbirt there are specimens of this species, none of which appear to have ever borne fruit. At Escot there is a tree rather crowded in a shrubbery, whose leaves, when I saw it on 27th October 1909, had mostly fallen, but which we believe to be of this species. It measures about 70 ft. by 6 ft.

There are probably other trees which we have not seen. But those which I have raised from American acorns, as well as those which I have imported as seedlings, will not grow on my soil; and I believe that it is better to graft scions selected from the best coloured trees on stocks of *Q. rubra*, than to plant this tree on its own roots.

(H. J. E.)

¹ This tree is No. 23 in Mr. Woodward's catalogue, and was probably planted about 1820. It has long borne the name *Q. palustris*. Fruit has not been noticed on this tree.

QUERCUS PALUSTRIS, PIN OAK

Quercus palustris, Muenchhausen, *Hausv.* v. 253 (1770); Loudon, *Arb. et Frut. Brit.* iii. 1887 (1838); Sargent, *Silva N. Amer.* viii. 151, tt. 422, 423 (1895), and *Trees N. Amer.* 232 (1905).
Quercus rubra dissecta, Lamarck, *Dict.* i. 720 (1783).
Quercus rubra ramosissima, Marshall, *Arbust. Am.* 122 (1785).

A tree, attaining in America 120 ft. in height and 15 ft. in girth, but usually considerably smaller. Bark of young trees smooth, shining, light brown tinged with red; on old trunks about an inch thick and covered with small scales. Branches more or less pendulous, with drooping branchlets, which in the first year are slender, glabrous, shining, with white lenticels. Buds ovoid, about $\frac{1}{8}$ in. long, pointed, with glabrous pale brown ciliate scales. Leaves (Plate 334, Fig. 17) deciduous, 4 to 6 in. long, 2 to 4 in. wide, obovate, cuneate at the base, divided about half-way to the midrib by rounded wide sinuses into usually seven, occasionally nine, symmetrical, bristle-pointed, oblong-triangular, entire or two- to three-toothed lobes; the terminal lobe acuminate, the lateral lobes spreading or directed forwards; shining above and below, glabrous except for conspicuous brown axil-tufts on the lower surface; petiole slender, glabrous, $\frac{1}{2}$ to 2 in. long.

Fruit ripening in the second year, short-stalked, solitary or clustered; acorns hemispherical, $\frac{1}{2}$ in. in diameter, enclosed at the base only by a thin saucer-shaped cupule, covered by thin closely appressed ovate minutely pubescent scales.

This species is readily distinguished, apart from the shape of the leaves with their characteristic conspicuous axil-tufts, by the drooping habit of the branches and branchlets.

The pin oak is found on deep rich soil on the borders of swamps and in alluvial land, in company with *Liquidambar*, *Nyssa sylvatica*, *Acer rubrum*, *Populus heterophylla*, and hornbeam, but thrives well when transplanted to drier situations. It is widely distributed in the United States from Massachusetts southwards to Virginia, and westwards through Kentucky, Tennessee, and northern Arkansas to the eastern borders of Indian Territory, Missouri, and Illinois, attaining its largest size on the banks of streams in the basin of the lower Ohio. It is also very common on the coast plain south of the Hudson river, but is rare and of small size in New England.

(A. H.)

CULTIVATION

Though introduced on the Continent prior to 1770, this species does not seem to have been known in England until 1800, when it was introduced¹ by Messrs. Fraser. It is one of the most beautiful American oaks, on account of the varied colour of its leaves both in spring and autumn. As a rule it grows better in England than any American oak except perhaps *Q. rubra*, and seems to prefer a

¹ Aiton, *Hort. Kew.* v. 292 (1813).

deep sandy soil, and a position well sheltered from wind by other trees. As a rule it is easily recognised by the number of small, rather pendulous branches, which it throws out among the larger ones, and by its upright habit. It grows fast on good soil, and Loudon says that in Loddiges' nursery in 1837 he saw some which at seven years from the acorn were 15 ft. high. It rarely ripens fruit in England, but I raised some plants from acorns grown at Kew in 1901, which I believe to be of this species, and which are growing well at Colesborne.

The largest trees that we know of are in Windsor Park, near China Island, one of which in 1910 was 97 ft. by 10 ft. 11 in. (Plate 315). Not far off, there is another tree that has been carefully measured by Mr. Squires, who finds it to be 113 ft. by 10 $\frac{1}{2}$ ft. Another in the Rhododendron Drive was 100 ft. by 7 ft. 8 in. in 1909. At Kew there is a tree at the south end of the Temperate House, which has had its top broken some years ago, and now measures 57 ft. by 10 ft. At Arley Castle there are two trees, of which the finest (No. 189 in Mr. Woodward's catalogue) was 80 ft. by 6 ft. 4 in. in 1905. One at Bayfordbury, planted in 1840, was 71 ft. by 6 ft. 8 in. in the same year.

At Canford Manor there is a very fine tree 80 ft. by 8 ft. in 1906; at Oakly Park, Ludlow, another, 75 ft. by 8 ft. in 1908; at Milford House, Godalming, a well-shaped tree 84 ft. by 7 ft. 9 in. in 1909; and at Deepdene, Surrey, Henry measured a tree, which was perfectly sound, 70 ft. by 9 ft. 10 in. in 1905.

In Scotland and Ireland we know of no trees of any size. (H. J. E.)

QUERCUS SCHNECKII

Quercus Schneckii, Britton, *Manual*, 333 (1901).
Quercus texana, Sargent, *Garden and Forest*, vii. 514, ff. 81, 82 (1894), *Silva N. Amer.* viii. 129, t. 411 (1895), and *Trees N. Amer.* 235 (1905) (not Buckley).¹

A tree, the tallest² of the American oaks, attaining 180 ft. in height, and 8 ft. in diameter above the much enlarged and buttressed base. It is with difficulty distinguishable in the absence of fruit from *Q. palustris*, though the leaves³ (Plate 334, Fig. 15) are broader in proportion to their length than in that species, but have the same conspicuous axil-tufts, while the buds and branchlets are identical.

Fruit, ripening in the second year, stalked; acorn ovoid, about an inch long, pubescent; cupule hemispherical, $\frac{3}{4}$ in. in diameter, covered with closely appressed tomentose scales.

¹ According to Small, *Q. texana*, Buckley, in *Proc. Phil. Acad.*, 1860, p. 444, is a small tree or shrub, occurring in dry and rocky places in Texas, and distinct from *Q. texana*, Sargent, which is now correctly named *Q. Schneckii*, Britton.

² Ridgway says in *Proc. U.S. Nat. Mus.* p. 83, that in the bottoms of southern Illinois, trees straight as an arrow 5 or even 6 ft. in diameter above the spurs, and 50 to more than 70 ft. clear, were formerly not at all rare, but most of them had even then been cut for clapboards or barrel staves. The largest that he had measured was 23 ft. in girth round the top of the stump, with a trunk 76 ft. long and 3 ft. in diameter at the top. At 120 ft. from the ground the limbs were more than a foot in thickness. Assuming the taper of this tree to have been regular, the log would have contained about 1200 cubic ft. by quarter girth measure. Ridgway speaks of these trees as *Q. rubra*; but Sargent considers them to be his *Q. texana*, referred now to *Q. Schneckii*.—(H. J. E.)

³ Figured by us from excellent fruiting specimens, collected by Elwes on Mt. Carmel, Illinois.

This species is widely spread, in wet swampy land, along the borders of streams in the Mississippi basin.

A small tree at Kew, about 12 ft. high, raised from seed sent by Meehan in 1901, under the name *Q. texana*, may be *Q. Schneckii*; but this species, inhabiting a region which is very hot in summer, is not likely to succeed in England.

(A. H.)

QUERCUS AGRIFOLIA, CALIFORNIAN LIVE OAK

Quercus agrifolia, Née, in *Ann. Cienc. Nat.* iii. 271 (1801); Loudon, *Arb. et Frut. Brit.* iii. 1894 (1838); Sargent, *Silva N. Amer.* viii. 111, t. 403 (1895), and *Trees N. Amer.* 256 (1905).

Quercus oxyadenia, Torrey, *Sitgreave's Report*, 172, t. 17 (1853).

Quercus berberidifolia, Liebmann, in *Overs. Dansk. Vidensk. Selsk. Forhandl.* 172 (1854).

Quercus acroglandis, Kellogg, in *Proc. Cal. Acad.* i. 23 (1855).

A large tree, or occasionally a shrub, in California. Bark of young trees thin, smooth; on old trunks 2 to 3 in. thick, and divided into broad scaly ridges. Young branchlets, with a dense stellate pubescence, either quickly deciduous, or retained till the second year. Leaves (Plate 338, Fig. 57) persistent for two years, coriaceous, $1\frac{1}{2}$ to 2 in. long, about $1\frac{1}{2}$ in. broad, ovate or orbicular, acute or rounded at the apex, rounded or slightly cordate at the base; with seven to thirteen spine-tipped teeth, variable in size; lateral nerves very prominent, four or five pairs, reaching the margin; upper surface dark green, shining, glabrescent or with scattered minute pubescence; lower surface glabrous, with conspicuous reddish brown axil-tufts of pubescence; petiole $\frac{1}{4}$ to $\frac{1}{2}$ in. long, stellate-pubescent.

Fruit, ripening in the first year, sessile or sub-sessile, solitary or in pairs; acorn elongated, and gradually narrowing to an acute apex, about an inch long, surrounded at the base by a turbinate cupule, about $\frac{1}{2}$ in. broad, silky pubescent within, and covered with thin glabrous ciliate scales.

This species is readily distinguished from all the other oaks with holly-like foliage, by the conspicuous axil-tufts on the leaves beneath. (A. H.)

In California this is a common oak, extending from Mendocino County southwards to Lower California, less common in the north, very abundant and attaining its greatest dimensions in the valleys south of San Francisco, where it is the largest and most generally distributed oak on the foot-hills between the mountains and the sea. On the coast it often covers the sandy dunes with its semi-prostrate and contorted stems, and in a bushy form ascends the dry slopes in the San Geronio pass to about 2800 ft.

Sargent describes it as a low round-topped tree, sometimes attaining 80 to 90 ft. high, with a thick short trunk from 3 to 6 ft. in diameter, which often divides into great spreading limbs resting on the ground, and covering an area 120 to 150 ft. in diameter.

Excepting for fuel the timber is little used, though in the narrative of Vancouver's voyage it is related that some knees were cut in 1793 from the holly-leaved

oak at Santa Barbara to repair his ship the *Discovery*. The Indians used to consume the acorns for food, preferring them to those of any other oak.

This species was introduced by Hartweg in 1849, when a few miserable living plants, sent home by him, were reported¹ to be growing in the Horticultural Society's Garden at Chiswick. As I can find no further allusion to this species, I suppose that these are the trees which we have found growing in two places in England, and which seem of similar age, namely, at Kew, where it has now attained a height of 30 ft.; and at Killerton, where there are two trees above the house close to the deer-park fence. In 1908 the best of these measured 45 ft. by 7 ft., and forks at 6 ft. from the ground. On April 18, it was budding, and the old leaves were still green. At Tortworth there is a small tree which seems to be younger, and was probably raised in 1878 from American acorns at the same time as *Q. Kelloggii*.

(H. J. E.)

QUERCUS WISLIZENI

Quercus Wislizeni, A. de Candolle, *Prod.* xvi. 2, p. 67 (1864); Sargent, *Silva N. Amer.* viii. 119, t. 406 (1895), and *Trees N. Amer.* 253 (1905).

Quercus parvula, Greene, *Pittonia*, i. 40 (1887).

A tree or shrub, similar to *Q. agrifolia* in habit, size, and bark. Young branchlets with scattered stellate pubescence. Leaves (Plate 338, Fig. 58) deciduous in the second year, variable in shape and size, mostly oblong-lanceolate, averaging $1\frac{1}{2}$ in. long and $\frac{2}{3}$ in. wide, coriaceous, acute at the apex, broad and rounded or truncate at the base, with 9 to 13 spine-tipped teeth in the wrinkled margin, which in rare cases is entire; both surfaces shining, glabrous, with a conspicuous network of fine veinlets; petiole $\frac{1}{8}$ in. long, stellate-pubescent.

Fruit ripening in the second year, sessile or stalked; acorns ovoid, about 1 in. long, acute at the apex, enclosed to a variable height in a turbinate or tubular cupule, slightly pubescent within, and covered by thin lanceolate pubescent scales.

This species, in the absence of fruit, is with difficulty distinguishable from *Q. coccifera*, which has, however, foliage of a lighter tint of green. The buds in *Q. Wislizeni* are long, spindle-shaped, and pointed at the apex; while those of *Q. coccifera* are smaller, ovoid, and obtuse.

Q. Wislizeni, which is closely related to *Q. agrifolia*, is widely spread throughout California, and is also found on the San Pedro Martir mountain in Lower California. It is most abundant and of its largest size in the valleys of the coast range of central California and on the foothills of the Sierra Nevada. It is common in a shrubby form in the cañons of the desert slopes of the mountains in the southern part of the state.

Introduced into Kew by Mr. H. N. Bolander, who sent acorns in 1874, it was only $6\frac{1}{2}$ ft. high in 1897, but of late years is more thriving, and now forms a bushy tree about 15 ft. in height. We have seen no specimens in cultivation elsewhere.

(A. H.)

¹ *Journ. Hort. Soc.* vi. 158 (1851). A figure is given, showing the long narrow pointed acorns.

QUERCUS CRASSIPES

Quercus crassipes, Humboldt and Bonpland, *Pl. Æquin.* ii. 37, t. 83 (1813); Loudon, *Arb. et Frut. Brit.* iii. 1943 (1838); De Candolle, *Prod.* xvi. 2, p. 73 (1864); Hemsley, *Biol. Cent. Amer. Bot.* iii. 170 (1882).

Quercus mexicana, Bentham, *Pl. Hartw.* 56 (1839) (not Humboldt and Bonpland).

A tree of moderate size. Young branchlets slender, covered with a dense minute pubescence. Buds minute, globose. Leaves (Plate 335, Fig. 24) coriaceous, persistent for two years, 2 to 3 in. long, $\frac{1}{2}$ to $\frac{3}{4}$ in. wide; oblong; rounded or acute at the apex, which usually bears a short mucro or bristle; rounded or subcordate at the base; entire or rarely undulate in margin; upper surface dark green, papillose, glabrescent; lower surface grey or brownish tomentose; lateral nerves about 20 pairs, dividing and looping before reaching the margin; petiole $\frac{1}{8}$ to $\frac{1}{4}$ in. long, densely pubescent.

Fruit ripening in the second year, solitary or in pairs, on short stout stalks; acorn ovoid, surrounded about half its length by a turbinate cupule, $\frac{1}{2}$ to $\frac{3}{4}$ in. in diameter, covered with appressed slightly pubescent ovate scales.

This species was discovered by Humboldt near Santa Rosa and Ario in southern Mexico, at 6000 to 8000 ft. elevation, and was said to be a small tree about 20 ft. high, with smoothish grey bark. It was also collected by Hartweg at Tlalpujahuá, and found by Bourgeau in the valley of Mexico.

It was raised¹ in 1839 in the Chiswick Garden of the Horticultural Society from acorns collected by Hartweg near Real del Monte.

The only specimen which we know to be now living in this country, is an unhealthy tree at Carclew, 64 ft. by 5 ft. 4 in. in 1908. A small tree of this species is cultivated in M. Allard's arboretum at Angers, where it is labelled *Q. crassifolia*. A specimen in the Kew Herbarium, collected by Gay at Leroy's nursery, Angers, in 1847, is labelled *Q. confertifolia*. (A. H.)

QUERCUS CERRIS, TURKEY OAK

Quercus Cerris, Linnæus, *Sp. Pl.* 997 (1753); Loudon, *Arb. et Frut. Brit.* iii. 1846 (1838); Willkomm, *Forstliche Flora*, 421 (1887); Mathieu, *Flore Forestière*, 363 (1897).

Quercus crinita, Lamarck, *Encyc.* i. 718 (1783).

Quercus echinata, Salisbury, *Prod.* 393 (1796).

A tree attaining 120 ft. in height and 20 ft. in girth. Bark thick, greyish, divided by vertical and horizontal fissures into oblong rounded ridges. Young branchlets covered with a dense grey tomentum, retained in part in the second year. Buds (Plate 78, Fig. 3) ovoid, with a few pubescent ovate-acuminate scales, and

¹ Cf. Gordon, in Loudon, *Gard. Mag.* xvi. 636 (1840).

surrounded by a whorl of long linear-subulate tomentose stipules. Leaves (Plate 335, Fig. 22) coriaceous, deciduous in autumn, 5 to 6 in. long, 2 to 3 in. broad, oblong to oval, acute at the apex, cuneate or rounded and unequal at the base; variously lobed, with deep or shallow sinuses; lobes, seven or eight pairs, unequal in length, oblong or triangular, entire or with one or two teeth, acute at the apex, which is cartilaginous, without a clearly projecting mucro; upper surface dark green, with numerous minute stellate hairs; lower surface greyish or dark green, covered with a minute stellate pubescence; midrib and nerves reddish with more conspicuous longer pubescence; petiole $\frac{1}{2}$ to $\frac{3}{4}$ in. long, tomentose.

Staminate catkins tomentose, 2 to 3 in. long; calyx tomentose, stamens four. Pistillate flowers, one to four on a short stout tomentose peduncle, only one as a rule developing; stigmas four, reflexed, sessile.

Fruit ripe in the second autumn, one to four on the branchlet of the preceding season, which may or may not have developed a leafy branch of the second year; each solitary on a short stout tomentose stalk; acorn variable in length, averaging one inch, depressed and slightly pubescent at the apex, glabrous elsewhere; cupule hemispherical, $\frac{1}{2}$ to $\frac{3}{4}$ in. in diameter, densely covered with long linear grey tomentose scales, all reflexed and curved or hooked, except those in the upper zone, which are erect and inflexed, forming a loose fringe around the margin of the cupule, closely surrounding the acorn.

VARIETIES AND HYBRIDS

In the wild state there is considerable variation in the shape of the leaf.

1. Var. *austriaca*, Loudon. *Quercus austriaca*, Willdenow, *Sp. Pl.* iv. 454 (1805).

Leaves with regular triangular entire lobes, greyer beneath than in the typical form. This variety is prevalent in south-eastern Europe.

2. Var. *pseudocerris*, Boissier, *Flora Orient.* iv. 1171 (1879).

Leaves deeply divided into linear, entire or three- to five-lobulate segments. This variety occurs occasionally in Greece and Asia Minor.

Several forms have arisen as sports in the seed-bed.

3. Var. *laciniata*, Petzold and Kirchner, *Arb. Musc.* 636 (1864).

Leaves deeply and irregularly lobed, the sinuses extending to near the midrib, some of the leaves only $\frac{1}{2}$ in. wide.

4. Var. *variegata*, Loddiges, ex Loudon.

Leaves variegated with white blotches. This is said¹ to have originated as a sport at Woburn Abbey, where good specimens of it are now growing.

5. Var. *pendula*, Neill, ex Gilpin, *Forest Scenery*, i. 73 (1834).

Branches pendulous. Loudon mentions a remarkable weeping tree at Hackwood Park. This variety² does not seem to be propagated at the present time.

The hybrids are described under *Q. Lucombeana*, p. 1259.

¹ *Gard. Chron.*, 1873, p. 1046.

² It is mentioned as well known in *Gard. Chron.*, 1871, p. 1321.

DISTRIBUTION

The Turkey oak is a native of southern Europe, Asia Minor, and northern Syria. It occurs in central and northern Spain. In Italy it grows in the Apennines mixed with the common oak, occasionally descending into the region of the olive and ascending into that of the beech, reaching its most southerly points in Calabria and Sicily. In France it is a rare and doubtfully wild tree in the Jura, in Vienne, Brittany, Anjou, and in Provence near Grasse; but in the department of Doubs it is very abundant in some of the oak forests, notably that of St. Vit, where it is the dominant tree over an area of 250 acres. It is unknown in the Swiss and French Alps, and in the Tyrol; but is scattered as an isolated and rare tree throughout Croatia, Dalmatia, Istria, Carniola, Styria, and Austria, reaching its northern limit at St. Pölten, west of Vienna, and the Polauer mountain in Moravia.

It becomes much more abundant in Hungary, where it is common in the hilly land and on mountain slopes, extending eastward through Banat to Transylvania. It is perhaps the commonest broad-leaved tree in many parts of the Balkan states, where it either forms pure woods at the higher elevations, or occurs on the lower hills in mixture with *Q. conferta* and *Q. sessiliflora*. In these regions its wood is never exported, and is little used except for firewood. (A. H.)

CULTIVATION

It is uncertain when this tree was first introduced, for though mentioned by Evelyn, it seems doubtful whether he really knew the tree, as he says, "we shall say little of the *Cerris* or *Ægilops*, goodly to look on, but for little else." In Miller's¹ time, however, about 1740, it was in cultivation; and in the latter half of the eighteenth century was largely planted in the south and south-west of England.

Though it is perfectly hardy, and according to Moullefert,² endured at Grignon in the winter of 1879-80 a temperature of -26° Cent., which injured many of the common oaks, it only attains its best dimensions in the warmer parts of England on deep and fertile soils. It endures lime, but prefers a warm sandy soil. It has a long tap root with few fibres, and, as Loudon remarks, is therefore not easy to transplant. When sown in the open the young immature shoots are often injured by frost, and require some protection during the first winter.

This tree grows faster than the common oak on dry sandy soils, and in consequence has been planted in the southern counties more commonly than it deserves to be; for though it is a handsome ornamental tree, yet its timber is so inferior to that of the pedunculate and sessile oaks that it has little market value, as many landowners have found to their loss when the tree is felled. It ripens seed freely in most seasons, and the seedlings, though not so hardy as those of the common oak,

¹ Miller mentions a large tree growing at Ragnal, near Tuxford, Nottinghamshire, which was supposed by Loudon to be a form of the Turkey oak.

² *Essences Forestières*, 93 (1903).

come up freely on sandy soils, and in a few years shoot up rapidly. Loudon says that near London the length of the annual shoot is from 18 in. to 3 or 4 ft., and that at Knedlington in Yorkshire plants of only seven years from seed were 12 ft. high. At Colesborne, however, the growth is very much slower than this, the soil and climate being too poor and cold for this species, which rarely attains any great size in the northern counties. It transplants perhaps better in spring than in autumn, and ripens its wood late, the leaves usually lasting longer than those of the common oak. Its trunk has a tendency to grow straight, and the branches have a peculiarity never seen in common oaks, of thickening close to the trunk. This is shown conspicuously in all the old specimens of the original Lucombe oak, and convince me that its parent was a *Q. Cerris*. It sometimes grows very tall without forming many branches; a young tree standing alone in a grass field at Cuffnells was 80 ft. high, with a girth of only 5 ft.

REMARKABLE TREES

The largest Turkey oaks that we have seen or heard of are at Mamhead Park near Exeter, which seems to have exactly the soil and climate best suited not only for this species, but also for the Ilex and cork oaks. Here there are several trees, of which one is the tallest recorded anywhere, and measures at least 120 ft. high, with a trunk almost free from branches to about 50 ft. and 13 ft. 8 in. in girth in 1908. It grows at an elevation of 500 to 600 ft. in a sheltered ravine facing east above the house, and is well protected by other tall trees (Plate 317). Another tree remarkable for its immense spread, is on the north side of the entrance-drive below the house, and is about 85 ft. high, with a short bole 18 ft. 9 in. in girth, spreading at the ground, where it measures over 40 ft. round (Plate 318). The total circumference of the branches was no less than 140 paces in 1908, being in this respect only surpassed in England by a wonderful Cedar of Lebanon at Langley Park Bucks, the seat of Sir R. Harvey, which I had not seen when Vol. III. was published, and which measures 146 paces round the branches. Besides these grand trees there are two more in the park below the house, one of which is about 115 ft. by 13 ft., with a clean bole 40 ft. long, and the other about 105 ft. by 18 ft. 4 in. Three of these trees are mentioned by Loudon (p. 1861) as having been planted by Lucombe, who is said to have been gardener at Mamhead, and this may have been about 1760, as he raised the original Lucombe oak about 1765; and I could find none of the latter now at Mamhead. Their dimensions are given by Loudon as 100 ft. by 12 ft., 90 ft. by 15 ft., and 80 ft. by 14 ft. 1 in. All of them are still in good health, and show no signs of decay in the branches.

Another very fine tree, though its habit is not at all typical of its kind, is in the deer park at Belton (Plate 316). It measures about 100 ft. high by 18½ ft. in girth, with a short bole of about 12 ft., which in 1905 was attacked by fungus (*Polyporus*), and will, I fear, decay. It is growing on a red sandy loam.

Another is a fine tree at Gatton Park, which measures 108 ft. by 12 ft. 8 in.,

with a bole of about 20 ft. Nearly as tall and even better in its habit, is one at Leeds Castle, Kent, which in 1902 I found to be 105 ft. by 11½ ft., with a clean straight stem over 50 ft. long. At Badminton Park there is a tree about 100 ft. by 10 ft. 4 in. which is known as the "Raglan Oak." At Bayfordbury, a well-shaped tree measures 96 ft. by 11 ft.

At Corsham Court there is a tree with very drooping branches which spread on the grass, and measure 78 paces round. Miss Woolward tells me of a very fine tree at Boughton Malherbe Rectory near Maidstone, which in 1908 was 85 ft. by 17½ ft., and has a spread of 100 ft. At Stratton Park and at Hackwood Park in Hants there are very large Turkey oaks which I have not measured. In the north of England the best I know is a tree in Ray wood at Castle Howard, which has been drawn up by surrounding beeches to a height of 98 ft., with a bole 40 ft. long, girthing 10½ ft.

In Wales by far the largest I have seen is at Dynevor Park, which was carefully measured in 1906 by the Hon. W. Rice, who made it 103 ft. by 14 ft. 7 in., with a spread of 103 ft.

In Scotland the Turkey oak is seldom seen. The largest mentioned by Loudon were at Hopetoun House, 50 ft. by 6 ft. 9 in., and at Brahan Castle, 50 ft. by 6 ft. The last tree may probably be the same as one which I measured in the dell below that beautiful place, and which, in July 1907, was no less than 90 ft. by 10 ft. 4 in., by far the finest of its sort that I have seen in Scotland. At Bruach burn, near Beaufort Castle in the same county, a large Turkey oak is growing in a sheltered situation, which has a short bole 11 ft. 9 in. in girth, and a wide-spreading top.

TIMBER

The timber of this tree has a bad reputation in the trade in England, because it will not stand weather, or alternations of wet and dry, like the common oak; and is therefore useless for outside work. Laslett, who was sent to Asia Minor in 1859 to search for oak suitable for the navy, says that in the valleys near Brussa *Q. Cerris* was found, and that this and the common oak were used by the Turks for naval shipbuilding, but he goes into no details. I have been told by boat-builders in Cornwall that it is excellent for keels; but whatever may have been its value in French shipbuilding formerly, as stated by Bosc and others, it is now, according to Mouillefert, little used in France except for firewood.

Atkinson states¹ that the doors of the principal rooms in the Marquess of Downshire's house at East Hampstead, near Wokingham, were made of the wood of Turkey oaks cut down there about 1828, and that the wood is finer in the grain and takes a better polish than British or foreign wainscot oak, and is more beautiful than any oak he had seen. But the Marquess of Downshire informs me that as the present mansion was built about 1857 it is doubtful whether they still exist.

(H. J. E.)

¹ *Trans. Hort. Soc. Lond.* i. 338 (1835).

QUERCUS LUCOMBEANA, LUCOMBE OAK

Quercus Lucombeana,¹ Sweet, *Hort. Brit.* 370 (1827).*Quercus Cerris*, Linnæus, var. *Lucombeana*, Loudon, *Arb. et Frut. Brit.* iii. 1851 (1838).*Quercus exoniensis*, Loddiges, ex Loudon, *loc. cit.**Quercus hispanica*, var. β, *chêne à feuilles d'Égilops*, Lamarek, *Encyc.* i. 723 (1783).*Quercus agylopiifolia*, Persoon, *Syn.* ii. 570 (1807).*Quercus Pseudosuber*, var. *agylopiifolia*, De Candolle, *Prod.* xvi. 2, p. 44 (1864).

The original Lucombe oak, in habit, vigour of growth, and branchlets, is similar to *Q. Cerris*; but differs in foliage, stipules, and fruit.

Leaves (Plate 335, Fig. 23) smaller than in *Q. Cerris*, never exceeding 5 in. long and 2 in. broad, usually smaller, subevergreen, falling early in the following year, usually in January and February, mostly² oblong ovate, acuminate at the apex, unequal at the base; with about seven pairs of regular triangular entire large teeth, each of which ends in a projecting mucro; lower surface covered with a dense whitish tomentum, different from the green or greyish under surface of *Q. Cerris*. The stipules around the lateral buds are shorter, and fall earlier than in *Q. Cerris*.

Fruit ripening in the second year; cupule turbinate, smaller in diameter than, and not hemispherical as in *Q. Cerris*, with grey tomentose scales shorter and broader than in that species, both reflexed and erect irregularly, not showing the definite arrangement of *Q. Cerris*, in which the upper marginal fringe of erect loose scales is clearly separated from the regularly reflexed scales of the rest of the cupule; acorn not depressed at the apex.

The original Lucombe oak was first described by Holwell in a letter³ dated Exeter, February 24, 1772, which states that "About seven years past," *i.e.* about 1765, "Mr. Lucombe sowed a parcel of acorns saved from a tree of his own growth of the iron or wainscot species; when they came up, he observed one amongst them that kept its leaves throughout the winter. Struck with the phenomenon, he cherished and paid particular attention to it, and propagated by grafting some thousands from it."

Holwell's account is repeated, with some additions, in the *Gentleman's Magazine*, 1773, p. 446, where William Lucombe is described as "an ingenious gardener in the environs of Exeter." There is no doubt that the iron or wainscot oak is a local name in south Devon and Cornwall for *Q. Cerris*, and that Lucombe was at this time owner of the garden, which afterwards developed into the famous nursery at Exeter.⁴ The Lucombe oak is said⁵ to have been common in 1773 about St. Thomas's, a suburb of Exeter, and to have been cultivated with great success by the neighbouring farmers.

Holwell's account is substantiated by Loudon, who was informed by Mr. Pince

¹ Sweet used this name for the first time. Holwell, who is often credited with it, gives no scientific name, and simply speaks of the tree as the Lucombe oak.² All specimens show some irregularly lobed leaves, which also appear in all the descendants of this tree. The leaves are described above from the tree at Carclew.³ Published in *Phil. Trans.* lxii. 128 (1772).⁴ According to the heading of a bill of Lucombe, Pince, and Company, preserved at Kew, the nursery was founded in 1720.⁵ *Gentleman's Magazine*, xliii. 357 (1773).

in 1838 that it was raised about seventy-five years previously (*i.e.* in 1763, a trifling discrepancy in the date) by "Lucombe, who was founder of the Exeter Nursery, from seed gathered by him off a specimen tree of *Q. Cerris* which grew in his nursery, near to one of *Q. Suber*."

The additional fact in Pince's account, which was derived from the younger Lucombe, who perfectly recollected the raising of the Lucombe oak in his father's nursery, is the existence of a cork oak, which must have pollinated one of the flowers of the parent Turkey oak. The botanical characters of *Q. Lucombeana*, which are partly those of *Q. Cerris* and partly those of *Q. Suber*, are thus satisfactorily accounted for; and, as is often the case in first crosses, the original Lucombe oak is remarkable for its vigour of growth.

From Hargham, in Norfolk, Sir Hugh Beevor sends us specimens of a natural seedling, about twenty-four years old, which originated in a similar manner from the acorn of a *Q. Cerris*, situated about 40 yds. to the westward of a *Q. Suber*. This tree, which is taller than a pure *Q. Cerris* of the same age beside it, has not yet borne acorns, but it resembles *Q. Lucombeana* in foliage. The leaves are similar in shape, having acute, triangular, strongly mucronate teeth; but it is only of late that their under surface has begun to develop the dense white tomentum that is so characteristic of the mature Lucombe oak.

The Lucombe oak was always propagated at the Exeter Nursery by grafting it upon *Q. Cerris*. The original tree was cut down when it was about twenty years old; but a grafted tree in the Exeter Nursery, planted in 1802, had attained 50 ft. in height and 8½ ft. in girth in 1837, and is figured¹ by Loudon, who mentions older trees² at Killerton and Carclew, the former eighty years old, and the latter seventy years old in 1834.

SEEDLINGS OF THE LUCOMBE OAK

The original Lucombe oak, and the trees propagated from it by grafts, must be carefully distinguished from its seedlings, the history of which was clearly given to Loudon by Pince. These were raised by the younger Lucombe from acorns gathered from one of the grafted Lucombe oaks in 1792. As usually is the case, when the seed of a first cross is sown, a great number of varieties resulted, of which three were selected and propagated in the Exeter Nursery by grafting on *Q. Cerris*. Two other seedlings were reared at a later period, about 1830. None of these varieties appear to have been as vigorous³ as the parent, and all had very corky bark, and kept their leaves till late in the season. These varieties all agree with the parent in the character of the branchlets and the mucronate points on the teeth or

¹ *Arb. et Frut. Brit.* iii. figs. 1712, 1713. The measurement given under fig. 1712 is erroneous; it is correctly stated on p. 1855, where Loudon quotes a letter from Pince, dated 4th April 1837, describing the tree.

² The ages are given in round numbers, and are not strictly accurate, as none of the trees can be so old as 1763 or 1765, the dates given by Holwell and Pince for the original tree.

³ The comparative rate of growth is shown by the following measurements of the trees in the Exeter Nursery, which were taken in 1837—

	Years old.	Height in feet.	Girth in feet.
Original—grafted Lucombe	35	50	8½
Seedling—var. <i>crispa</i>	45	63	9
„ var. <i>suberosa</i>	45	45	7½
„ var. <i>incisa</i>	45	45	7

lobes of the leaves, but differ in the shape of the leaves and in the characters of the fruit. The five seedlings, raised in the Exeter Nursery, were named by Loudon:—

1. Var. *suberosa*, Loudon. Smaller trees, with very corky bark, raised in 1792. Stipules short and quickly deciduous. Leaves (Plate 339, Fig. 64) smaller than in the original Lucombe oak, 2 to 2½ in. long, 1 in. broad; ovate; broad, rounded, and unequal at the base; acute at the apex, white tomentose beneath, usually with five to seven pairs of rounded or sinuate sharply mucronate teeth; some of the leaves, however, with fewer teeth, and one to three deep sinuses extending half-way to the midrib. Fruit ripening in the second year; cupule turbinate, with short broad grey tomentose scales, reddish at the tips, mostly erect.

2. Var. *heterophylla*, Loudon. Raised about 1830. Leaves oblong-lanceolate, 3 to 4 in. long, 1 to 1½ in. broad, acute at the apex, irregularly and deeply lobed, with the middle part of the leaf occasionally reduced to a narrow fringe on each side of the midrib. Cupules of the fruit turbinate; most of the scales short, ovate, ending in red acuminate tips; a few towards the margin of the cupule, linear-lanceolate, irregularly erect, and reflexed.

3. Var. *crispa*, Loudon, who calls it the new Lucombe oak. This was raised in 1792, and has very corky bark. Leaves subevergreen, falling in March and April, similar to those of *Q. Lucombeana*, but smaller in size and wrinkled in margin, 2 to 3 in. long, oblong-ovate, acute at the apex, unequal at the base, with six to eight pairs of acute triangular mucronate teeth; densely white tomentose beneath. Cupule scales reddish at the tips; those towards the margin long and directed upwards; those below short, some appressed, others reflexed. Acorn scarcely depressed at the apex, which is tipped with a short conical tomentose umbo.

4, 5. Var. *incisa* and var. *dentata*, Loudon, with large leaves, more deeply lobed than those of the preceding forms, are scarcely distinguishable from the original Lucombe oak, except in having more corky bark. Var. *incisa* was raised in 1792, and var. *dentata* about 1830. *Q. Cerris*, var. *cana major*, Loudon, *op. cit.* 1849, the origin of which is unknown, is very similar to these varieties.

In addition to the original Lucombe oak and its selected seedlings there remain a few forms the history of which is unknown, but which have undoubtedly arisen from the same parentage of *Q. Cerris* and *Q. Suber*. It is most convenient to name these as vars. of *Q. Lucombeana*.

6. Var. *fulhamensis*.

Quercus Cerris, var. *fulhamensis*, Loudon, *Arb. et Frut. Brit.* iii. 1850 (1838).

Quercus Cerris, var. *dentata*, Watson, *Dend. Brit.* ii. t. 93 (1825).

Quercus hispanica, a, *chêne de Gibraltar*, Lamarck, *Encyc.* i. 723 (1783).

Quercus Pseudosuber, var. *gibraltaria*, De Candolle, *Prod.* xvi. 2, p. 44 (1864).

Trees with less vigorous branches than *Q. Lucombeana*, forming a rounded head of foliage; bark moderately corky. Branchlets grey tomentose. Stipules around the

¹ Lamarck applied the name *Q. hispanica* not to a Spanish oak, but to three trees cultivated at the Trianon, which were specimens of the Lucombe, Fulham, and Turner's oaks. The first of these was erroneously supposed to grow wild in the neighbourhood of Gibraltar.

axillary buds short and early deciduous. Leaves (Plate 335, Fig. 21) usually deciduous in January and February, ovate, broader in proportion to their length, and smaller than those of *Q. Lucombeana*, about 3 in. long and $1\frac{1}{2}$ in. wide; broad, rounded, and unequal, or occasionally auricled at the base; acute at the apex; with 5 to 8 pairs of sinuate mucronate teeth; white tomentose beneath.

Fruit ripening in the second year; cupule hemispheric, smaller than in *Q. Cerris*, with lanceolate acuminate grey tomentose scales, red at the tips, usually all reflexed, except a few erect and curving inwards at the margin of the cupule, but not forming a regular fringe as in the Turkey oak; acorn not depressed at the summit, which bears a stout short tomentose umbo.

The original Fulham oak grew in Whitley and Osborne's nursery at Fulham, and was,¹ in 1835, 75 ft. high and $11\frac{1}{2}$ ft. in girth. Loudon supposed it to be a seedling; but in 1840 it sent forth a branch from the base, which proved it to have been grafted on *Q. pedunculata*.² It appears to have been always reproduced in the Fulham Nursery by grafting on the common oak. The origin of this tree is unknown; but an oak of apparently the same age, which was 80 ft. high and $4\frac{1}{2}$ ft. in diameter at a foot from the ground in 1835, is said by Pince³ to have been planted by Lucombe at Mamhead. This tree cannot now be identified, if it still exists. We can only conjecture that the Fulham oak, like a large *Q. Lucombeana* which grew beside it in the Fulham Nursery, was procured from Lucombe. Different in foliage and in fruit from the original Lucombe oak, it is possibly one of its earliest seedlings, of which no record was kept.

There are two trees, which we believe to be of this origin, at Kew, growing near the No. 3 Museum; one (Plate 319) measures 69 ft. by $7\frac{1}{2}$ ft.; the other, 63 ft. by 7 ft. 1 in.

7. Var. *fulhamensis latifolia*.

The original Fulham oak produced acorns freely from which many plants were raised, differing greatly in appearance from one another, and from the parent. About 1838, Messrs. Osborne selected a seedling with leaves broader and less dentate than usual, which they propagated under the name *Q. fulhamensis latifolia*. Specimens⁴ corresponding to this description from Westonbirt, Abbotsbury, and Liphook differ from all the other oaks of this series, in having leaves rounded and not acute at the apex, elliptical, about $3\frac{1}{2}$ in. long, and $2\frac{1}{2}$ in. broad, grey tomentose beneath, with 7 or 8 pairs of lateral nerves, each ending in the mucronate apex of a broad shallow sinuate tooth. Fruit not seen.

8. Var. *diversifolia*.

Quercus Ilex, var. *diversifolia*, Nicholson, in *Kew Handlist of Trees*, 189 (1896).

A small tree, with remarkably ascending branches, and thick corky bark.

¹ Loudon, *Gard. Mag.* xi. 128 (1835). Watson, *Dend. Brit.* ii. t. 93 (1825), gives its measurements in 1825 as bole 10 ft., total height 60 ft., diameter 2 ft. 3 ins.

² W. K., in *Gard. Chron.*, 1842, p. 111. There are also specimens at Kew of the original Fulham oak, collected by Nicholson in 1881, which show a branch of *Q. pedunculata*, found growing from the stock.

³ In Loudon, *Gard. Mag.* xi. 128 (1835).

⁴ A small tree outside the garden at Mamhead has foliage very similar, only differing in being somewhat narrower, but with identical nervation and shallow teeth.

Branchlets grey tomentose; stipules early deciduous. Leaves (Plate 339, Fig. 71) about 2 in. long, not exceeding $\frac{3}{4}$ in. in width, very variable in outline, the central part usually reduced to a narrow fringe on each side of the midrib, basal part with one to four mucronate lobes, apical part expanded; rounded or acute at the apex; entire or toothed and mucronate; dark shining green above, white tomentose beneath.

Fruit ripening in the second year; cupule hemispherical, about $\frac{1}{2}$ in. in diameter, with grey tomentose scales, red at the tips, irregular in size, the shorter ovate and appressed, the longer lanceolate-acuminate and slightly spreading, less numerous than the others and irregularly disposed; acorn depressed at the apex, with a conical tomentose umbo.

This peculiar variety, the history¹ of which is unknown, has leaves similar in form, but smaller and more coriaceous than those of var. *heterophylla*, from which it differs strikingly in habit and in fruit. Two trees, about 20 ft. high, in Kew Gardens were procured from Smith of Worcester in 1877.

9. *Quercus Pseudosuber*,² Santi, *Viaggio al Montamiata di Giorgio Santi*, i. 150, t. 3 (Pisa, 1795).

Quercus Fontanesii, Gussone, *Index Sem. Hort. Boccadifalco*,³ 10 (1826).

Under these names a number of wild trees, which so far as we can learn, only occur sporadically in the neighbourhood of their supposed parents, have been described, which are probably hybrid forms between *Q. Suber* and *Q. Cerris*. The original tree, described by Santi, was found near Florence; others were seen by Gussone in Sicily and Calabria. Kotschy mentions isolated trees in Istria, at Pisino-Corridaro, Carpizza, and near Capo d'Istria. It is also recorded from the neighbourhood of Grasse, in Provence. Specimens from Italy in the British Museum resemble in foliage *Q. Lucombeana*, var. *suberosa*. Both *Q. Pseudosuber* and *Q. Fontanesii* were said to have been introduced into cultivation in Loudon's time; but if any survive, we see no means by which they can be distinguished from the seedling forms of *Q. Lucombeana*. (A. H.)

Q. Pseudosuber has been treated by some French botanists as a species, whilst others consider it to be a hybrid between *Q. Suber* and *Q. Cerris*. In order to solve this question I visited the district in which it has been found, near Grasse, in January 1910, and after some inquiry found the only two trees known to M. Richard, the forest officer of Montauroux. One of these grows by the side of a rivulet close to the house of Mr. Nelson, manager of the Mine de Vaux, a coal mine which is being worked by an English company about three miles south of Montauroux, on the road to Frejus. The largest of these is a tree about 55 ft. by 3 ft. 3 in., with an upright habit, differing from all the other oaks which grew near it, namely the cork oak and *Q. lanuginosa* (locally known as *Chêne blanc*). The bark, of which I took a specimen, is corky, but much thinner than that of the cork oak; the leaves are hardly distinguish-

¹ Its corky bark and acorns ripening in the second year exclude it from being a variety of *Q. Ilex*. It is incorrectly identified in *Kew Handlist of Trees*, loc. cit., with var. *incisa*.

² *Q. Pseudosuber*, Desfontaines, is of totally different origin, being the hybrid between *Q. Mirbeckii* and *Q. Suber* which is found in Algeria. See p. 1319.

³ Boccadifalco, where there was formerly a Royal Garden, is near Palermo.

able from those of the Lucombe oak,¹ and are subevergreen, though many of those near the top of both trees had fallen. The other tree, about 50 yds. to the north of the same house, is also by a rivulet, and resembles the first precisely in habit and bark, though the leaves differ slightly.² I could find no trees of *Q. Cerris* anywhere in the neighbourhood, and was inclined to believe that *Q. lanuginosa* and not *Q. Cerris* is the other parent. The tree is known in the Provençal patois of the district as *Drouin*. M. Pardé³ spells this name *Drouis* or *Drouino*.

M. Coufourier, a botanist of Hyères, gave me a specimen from another tree growing in the "Fond des Gavôts" between Montauroux and Grasse, where he said he had seen no *Quercus Cerris*, though it is reported to occur in the district. He afterwards sent me acorns from the same place which confirm the opinion that *Q. Cerris* and not *Q. lanuginosa* is the parent.

During a visit to Italy and Sicily in March 1910, I saw in the herbarium of M. Sommier of Florence, a number of specimens identified with *Q. Pseudosuber* from various places in Tuscany and other parts of Italy. These varied extremely in their foliage. In the Botanic Garden at Florence there is a fine tree about 60 ft. by 6 ft. named *Q. Pseudosuber*.

In Sicily I was directed by Signor Lojacano⁴ to a place called Ficuzza about 25 miles south-east of Palermo where there is a large oak wood in which a few specimens of *Q. Pseudosuber* or *Fontanesi* are found. The forest guard, who knew them under the name of *falso-sughero* (False-cork), guided me to a spot about two miles from the village, where five or six trees were growing scattered in a wood mainly composed of *Q. sessiliflora*, here called *robore*; with some trees of *Q. Ilex (ilice)*, *Q. Suber (sughero)*, and *Q. Cerris (Cerro)*. He considered the two latter to be the parents of the *falso-sughero*, and said that the hybrids produced acorns rarely. The largest tree was very similar in habit to the French trees above mentioned, about 60 ft. by 5 ft., with a hard but slightly corky bark, of which I took a specimen. The leaves were still mostly green on March 3rd, at an elevation of about 1500 ft.

REMARKABLE TREES

All the original Lucombe oaks are extremely uniform in their habit, bark, and foliage; they show no resemblance in their bark to the cork oak; and all are characterised by a peculiar swelling at the base of the limbs, which I have only seen in the Turkey oak, and by an extremely vigorous growth and an upright habit. I formerly

¹ A microscopical examination of the leaves of these trees by Mr. Boodle of the Kew Laboratory shows no evidence of the influence of *Q. lanuginosa*, which has four (sometimes only two) ray-cells in the stellate hairs on the under side of the leaf, whereas in *Q. Pseudosuber* and *Q. Suber* there are seven to twelve ray-cells.

² The specimens from the three trees near Montauroux—two seen by Elwes and one observed by Coufourier—all differ in foliage, showing that all three are probably descendants of the first cross between *Q. Suber* and *Q. Cerris*. The acorn-cupules, sent by Coufourier, are slightly different from any that I have seen on English trees; and have long reflexed marginal scales and short and spreading basal and median scales. The acorns are depressed at the apex, which bears a minute tomentose umbo.—(A.H.)

³ *Arb. Nat. des Barres*, 296 (1906). M. Pardé informs me that the trees here mentioned at Les Barres cannot now be found.

⁴ The oaks of Sicily have been most carefully studied and described by Signor Lojacano, who recognises in his *Flora Sicula*, iv. pp. 364-389 (1904), no less than thirty-three species and hybrids, specimens of which I examined in the herbarium of the Botanic Garden at Palermo. In this garden there is a good-sized tree of *Q. Pseudosuber*, and in the Botanic Garden at Catania another fine tree about 50 ft. by 4 ft. which produces large acorns freely.

supposed the tree from which they were propagated, to have been, as Holwell states,¹ a very vigorous seedling of the Turkey oak which, in the climate of south Devon and Cornwall, where alone this form can be seen at its best, kept its leaves in winter; and I have raised from acorns of the large Turkey oak, growing near the pond at Kew, two seedlings which up to the age of five years have this subevergreen habit. The seedlings of the original Lucombe oaks, of which the two largest specimens grew near the entrance of the old Exeter Nursery and are now both cut down, had a different habit and much more corky bark, and with the exception of a tree near the chapel at Killerton which, however, is not nearly as large, I have seen no others which could compare with them. None of those propagated later ever seem to have attained the size or vigour of the original Lucombe oak, and none of the seedlings which are on their own roots, show any promise of rivalling the original grafted trees in height or girth. There is no doubt that the original Lucombe oaks which I mention as follows, are among the finest ornamental trees in Great Britain, and deserve to be propagated by grafting in the same way as Lucombe did. For none of those we have seen which have been sold by nurserymen in the last century as Lucombe oaks, can be compared in size or vigour with the originals.

In Cornwall the largest I have seen are at Carclew. One of these in a walk leading to the gardens, was believed by Sir Charles Lemon, who formerly owned Carclew, to have been an original Lucombe oak, and from his notebook, which the late Colonel Tremayne showed me, I took the following measurements:—

In 1823	.	.	74½ ft. by 6 ft. 11 in. at 4 ft. from ground.
In 1851	.	.	" 9 " 1 " " "
In 1853	.	.	" 9 " 8 " " "

When I saw it in 1903 it was about 100 ft. high by 13 ft. I have not seen any of its acorns, which, Mr. Simmons, the gardener, told me, are rarely produced. At Carclew, in the park, there are four other trees of similar appearance and grafted in the same way which measure from 90 to 100 ft. by 10 to 12 ft. in girth.

Mr. Napper states that a very fine one stands by the Lodge Gate at Trebarrick, St. Austell; and I am informed by Mr. J. P. Rogers that there are at Penrose, near Helston, some large Lucombe oaks planted about 1773 and grafted on the Turkey oak, which are no doubt original.

In Devonshire the tree by the gardens at Killerton (Plate 321) in 1908 measured about 100 ft. by 12 ft. 11 in. At Powderham in the deer park two trees measured in 1906, 92 ft. by 14 ft. 4 in. and 90 ft. by 13 ft. 4 in. At Ugbrooke Park, Devon, the seat of Lord Clifford of Chudleigh, there are four fine trees in the park near the house, of which the largest in 1908 measured 80 ft. by 16 ft.; another about 80 ft. by 14 ft. At Castle Hill, Devon, a tree on the lawn, which I am told by the Hon. J. W. Fortescue was planted in 1770, in 1905 measured 80 ft. by 15 ft. 8 in. (Plate 320). At Sharpham, near Totnes, just below the house, a rather spreading tree was 90 ft. by 13 ft. 4 in. in 1907. At Kingston Lacy, Dorsetshire, there is a tree 90 ft. by 8 ft.,

¹ Cf. *Gard. Chron.* xxxii. 195, 221 (1902). The original Lucombe oak appears, however, to have been a chance hybrid of *Q. Cerris* with *Q. Suber*, and not a seminal sport of the Turkey oak.

with a clean bole about 40 ft. long. At Sherborne Castle, Dorsetshire, a tree measures about 75 ft. high, and 12 ft. 9 in. in girth at 3 ft. At Corsham Court, Wilts, there are two trees, one 80 ft. by 6 ft. 9 in., which is grafted on the common oak, the other 80 ft. by 7 ft. with a straight clean bole of 40 ft. At Longleat, Wilts, Col. Thynne measured one in 1903, 78 ft. by 11 ft. 10 in. At Bowood, Wilts, I saw a handsome tree in 1906, 92 ft. by 9 ft. At Croome Court a tree 74 ft. by 10½ ft., which on 4th June 1906 still bore some leaves of the previous year, showed no graft mark at the ground, which indicates that it may be a seedling of more recent origin. At White Knights, Berks, in the grounds of the Wilderness, a tree of moderate size is grafted on the common oak. At Kew a very fine tree, which also appears to have been grafted on the common oak, measured, in 1907, 74 ft. by 12 ft. 3 in.

In Wales the only tree that I know is at Stackpole Court. It measured in 1906, 76 ft. by 6 ft. 8 in.

In Scotland I have seen one tree which looks like an original Lucombe oak; it grows in the park at Dunkeld, near the Abbey ruin, and measured in 1904, 62 ft. by 7 ft. 9 in.

In Ireland the only tree I have seen which looks like an original, is one in the grounds of Kilmacurragh, said to have been purchased by Mrs. Acton over a hundred years ago; and when I saw it in 1908 was 78 ft. by 7 ft., with a clean bole of about 40 ft.

Loudon quotes a letter from Pince as follows: "When the original tree had attained 20 years' growth, and was about 3 ft. in circumference, Mr. Lucombe, being then far advanced in years, had it cut down for the purpose of making his coffin out of it. He, however, lived so much longer than he anticipated, that several years before his death, he had another much larger and older tree cut down, sawn into planks, and carefully deposited under his bed in readiness for the above purpose; and inside those planks, over which for many years he had reposed, he was at length put to rest, at the advanced age of 102 years." Of this tree I possess a relic in the shape of a corner piece, which I bought at a sale of the effects of Mrs. Woodman, a granddaughter of Mr. Pince, who told me that it was made with other furniture from the tree above mentioned. The wood is fine and close-grained, showing a good deal of figure, and of a pale yellowish brown. It has not shown the least symptoms of warping or decay, and is untouched by wood-boring beetles.

The seedlings of the original Lucombe oak are quite different in habit, bark, and character, and show their origin very clearly in the corky nature of the bark. The two largest trees of this kind that existed, so far as I know, grew on each side of the entrance of the old Exeter Nursery. One, stated by Napper to be the original var. *crispa*¹ of Loudon, was 12 ft. in girth in 1891. I am informed by Mr. Robert Veitch, of Exeter, that it was cut down some years ago, and I could find no trace of it. The second, when I visited Exeter in 1902, was standing on the west side of the nursery gate, and measured about 60 ft. by

¹ Cf. Loudon, fig. 1718, who gives its dimensions in 1838 as 63 ft. high and 9 ft. in girth. It was raised, as above stated, as a seedling in 1792.

10 ft. with a straight clean bole of 22 ft. This, according to Napper, was the original var. *suberosa* of Loudon. It was cut down the year afterwards, when the nursery was sold for building, and I bought the log, containing about 80 ft. in the butt only, for £2. It turned out some very sound hard wood, which, when sawn on the quarter, showed a very varied and beautiful figure. A board from this tree, showing the bark, is now in the museum at Kew, and a cabinet which I had made from it is extremely handsome.

The only other large tree which I know of similar character, and almost certainly of the same origin, grows near the chapel at Killerton, and measures about 60 ft. by 8 ft., with a bole 15 ft. long; its bark is very corky, and it produces acorns much more abundantly than the larger original Lucombe oak at the same place; its leaves are smaller than those of the latter. I have raised a number of seedlings from this tree which vary a good deal, and are too tender to grow well on my soil, which does not suit either of the parents.

Another very fine tree which I believe to have been of the same origin, though its leaves resemble rather those of the Fulham oak, grows at Redleaf, near Penshurst, Kent, the seat of Mrs. E. Hills. This tree shows in its bark that the cork oak was one of its parents, and has no visible mark of having been grafted. It measures 86 ft. by 9 ft. 10 in., with a clean bole about 20 ft. long, and is a handsome and vigorous tree.

There are numerous seedling forms in cultivation, which vary considerably in their foliage, habit, and in the period which they shed their old leaves. Most of them are of very inferior size to the original tree, and the grafted plants, which are usually sold under the name of Lucombe oaks, are, so far as I have seen, slow growers even in the south-west of England. A good example of this may be seen at Powderham Rectory, the residence of the twelfth Earl of Devon, where an avenue of Lucombe oaks was planted, as he told me, about fifty years ago, which, though they came from Lucombe and Pince's nursery, will never rival their parent trees.

There are a number of trees at Syon, which appear in the old catalogue under various names, and which resemble the Lucombe or Fulham oak in their leaves and subevergreen character, but which are not typical of either in their habit. These are most probably seedlings from the Fulham Nursery, but one of them grafted on the common oak, is probably a graft from the original Fulham oak, and measures 81 ft. by 9 ft. 4 in.

The tree does not come true from acorns, as Mr. Napper says that he was in the habit of gathering them, and that they invariably produced what he knew as bastard oaks, more like the Ilex than anything else; and Lord Ducie, who has raised them, tells me the same thing. I found several pans of seedlings of a so-called Lucombe oak in the St. John's nursery at Worcester in 1902, one of which had made in the first year about 18 in. of growth, but this was not made in one uninterrupted shoot as described in the original, but in two separate periods of growth as usual in the English oak.

(H. J. E.)

QUERCUS ÆGILOPS, VALONIA OAK

Quercus Ægilops, Linnæus, *Sp. Pl.* 996 (1753); Loudon, *Arb. et Frut. Brit.* iii. 1861 (1838).

Quercus ithaburensis, Decaisne, in *Ann. Nat. Sc.* iv. 348 (1835).

Quercus græca, Kotschy, *Eichen*, t. 30 (1862).

Quercus macrolepis, Kotschy, *Eichen*, t. 16 (1862); A. de Candolle, *Prod.* xvi. 2, p. 45 (1864).

Quercus Ungerii, Kotschy, *Eichen*, t. 13 (1862).

Quercus Vallonea, Kotschy, *Eichen*, t. 7 (1862); A. de Candolle, *Prod.* xvi. 2, p. 45 (1864).

A tree, attaining in the Levant, in good moist soil, about 80 ft. in height, but seldom reaching more than 30 to 40 ft. in arid situations. Bark deeply divided into small square scaly plates.

Young branchlets covered with a dense greyish tomentum, persistent in the second year. Buds ovoid-prismatic, about $\frac{1}{4}$ in. long, tapering to an acute or rounded apex, tomentose, usually surrounded by long linear pubescent stipules. Leaves (Plate 335, Fig. 19) deciduous late in autumn or in the following spring, 3 to 4 in. long, and $1\frac{1}{2}$ to 2 in. broad, oval or oblong; base usually broad and rounded, occasionally cuneate, subcordate, or auricled; apex acute; with five or six pairs of lateral nerves, prominent beneath, each ending in a large triangular bristle-pointed tooth or lobule; leaf margin and bristles ciliate; upper surface shining, with scattered short stellate pubescence; lower surface covered with a grey short tomentum, occasionally more or less deciduous between the nerves; petiole, $\frac{1}{4}$ to 1 in. long, tomentose.

Fruit ripening in the second year, sub-sessile, usually solitary; acorn sub-globose and scarcely exserted or cylindrical and projecting, $\frac{3}{4}$ to $1\frac{1}{2}$ in. long, depressed and whitish tomentose at the apex, chestnut brown and glabrescent elsewhere; cupule $\frac{1}{2}$ to 2 in. broad, variable in the shape and consistence of the scales, but broadly distinguishable into two varieties, which are connected by numerous intermediate forms.

1. Var. *macrolepis* (var. *græca*). Cupule hemispheric; scales loosely superposed, thin and ligulate, tomentose, $\frac{1}{4}$ to $\frac{3}{4}$ in. long, spreading or erect, often recurved. This form is prevalent in Greece and the adjoining islands.

2. Var. *Ungerii* (var. *ithaburensis*). Cupule sub-globose; scales fewer, thickened, pyramidal, tomentose, $\frac{1}{4}$ to $\frac{1}{2}$ in. long, spreading or erect, sometimes recurved. This form is prevalent in Asia Minor.

Quercus Pyrami, Kotschy, *Eichen*, t. 3 (1862), which is often considered to be a variety of this species—var. *Pyrami*, Boissier, *Fl. Orientalis*, iv. 1172 (1879)—differs considerably in foliage and is quite distinct for purposes of cultivation. As seen at Kew, where it is a small tree about 20 ft. high, the leaves (Plate 335, Fig. 20) are smaller, about $2\frac{1}{2}$ in. long and $1\frac{1}{2}$ in. broad, often indented below the middle with a deep sinus on one or both sides; lateral nerves six to eight pairs ending in short mucronate teeth. According to Kotschy, *Q. Pyrami* grows in the plain of Cilicia, forming large woods at the mouth of the river Pyramus. (A. H.)

DISTRIBUTION

This species is widely spread throughout Greece and the adjoining islands, either solitary or forming small woods. Mr. F. B. Wood, British Consul at Patras, informs us that in that district it is abundant and attains large dimensions. A tree of which he sends a sketch, is about 60 ft. high, and 13 ft. or more in girth at 3 ft. from the ground, above the spreading roots. The tree flourishes equally well in various soils. The forest in Elis grows in a plain of rich loam, where myrtle, arbutus, and lentisk are found in profusion. In late spring this oak forest with its carpet of bracken, mixed with asphodel, crocus, and countless wild flowers, is very beautiful. In Acarnania and Etolia the trees grow on rocky hill-sides, amongst wild sage and thorn. In Elis and Achaia a yellow-berried mistletoe (*Loranthus europæus*) is found on every second oak.

The Valonia oak is also widely spread throughout Asia Minor¹ and Crete. According to Sir Joseph Hooker,² "it is very gregarious in Syria, never forming a bush or growth of underwood, but rising on a stout gnarled trunk 3 to 7 ft. in girth, to the height of 20 to 30 ft. Wherever we saw it, as on the hills east of Nazareth, on Tabor where it is abundant, to the east of Caifa, and on the north-east flank of Carmel, it forms scattered, rather round-headed, densely leafy trees, giving an open park-like appearance to the landscape. The wood is said to be excellent. The acorn often attains a very large size, some we gathered were $2\frac{1}{2}$ in. long and 3 in. in girth, but they vary extremely on the same tree, some being so small that I have had difficulty in distinguishing between them and large ones of *Q. pseudococcifera*. I have examples which if they had not been taken by myself from an *Ægilops* tree which also bore large acorns, I should have attributed to hybridisation between the two. When fully ripe the gland is still green, and in this state it germinates, the pericarp never hardening. They may be seen in all the bazaars, raw and boiled, in which state they are eaten by Turks and Arabs."

Gay says that in the Jardin des Plantes on 14th November 1862, he found the acorns of a chestnut brown colour and with a nutty flavour; and this was the case with acorns from Greece which I tasted, and found slightly astringent, but quite edible.

CULTIVATION

According to Loudon this species was introduced as long ago as 1731, but it has always been a rare tree, and probably requires more summer heat than our climate affords. The acorns are often sent from the Levant, but seem to lose their vitality quickly. I received some of remarkably large size in January 1909 from Mr. Wood, which have made nice young seedlings in pots.

In Gay's herbarium, at Kew, there is a specimen from a tree growing in the

¹ Balansa in a note preserved in Gay's herbarium says that in the neighbourhood of Ushak (or Oushag or Uschak), this oak forms vast forests, and the collection of the cupules was an important industry. At that time they were worth about 2d. a pound, one tree producing about ten pounds.

² In *Trans. Linn. Soc.* xxiii. 385 (1862).

kitchen garden at Milford House, dated September 1859, and a note to the effect that it was introduced by P. Barker Webb. I visited this place in 1909, but could find no trace of this tree, though a small stunted tree exists in another part of the grounds.

At Abbotsbury there is a tree measuring 45 to 50 ft. high by 4 ft. 4 in. in girth, which in 1908 produced half-matured acorns. At Devonshurst, Chiswick, Henry found a branching tree of no great height, but 4 ft. 3 in. in girth.

At Hardwick, near Bury St. Edmunds, I found a small tree about 30 ft. by 4 ft.

At Tortworth a tree is growing on the lawn below the house, which was planted about 1846 by the late Lord Ducie and transplanted when about 10 ft. high to its present situation. It is now about 40 ft. high and produces abortive acorns almost every year, but once produced a ripe acorn which was sent to Kew. At Blenheim, Mr. A. B. Jackson measured a tree 37 ft. by 3 ft. 6 in. dividing into two stems at about 5 ft. from the ground.

Sir C. T. D. Acland has raised plants at Holnicote, which now vary from 1½ to 5 ft. high, from acorns gathered at Patras which were sown in 1899.

At Lyndon Hall, Rutland, there is a fine healthy tree, 30 ft. by 5 ft. in 1909 (Plate 322).

At Syon a tree was reported by Loudon in 1838 to be 22 ft. high and 3 ft. in girth; the only others in England known to him were at Llanbedr Hall, near Ruthin, and at Finborough Hall, Suffolk; all of these seem to have disappeared.

Loudon mentions¹ a tree at Oriel Temple, in Ireland, 55 ft. high in 1838; but I could find no trace of it in 1908.

In France it is hardy at Les Barres, where a specimen² 33 ft. high and 5 ft. in girth rarely produces fertile acorns.

The Valonia oak was introduced³ into Algeria about 1860 by M. Hardy, but though trees are to be found there about forty years old and flourishing, no plantations on a commercial scale appear to have been made. The credit of the introduction⁴ of this tree into Australia is due to Mr. George Cunnack, tanner at Castlemaine, Victoria, who imported from Smyrna in 1879 two Wardian cases, one containing rooted young plants and the other acorns covered with earth. They both arrived in good condition, the acorns having sprouted during the voyage, and produced some hundreds of plants.

VALONIA, MANNA

Valonia⁵ is the name for the cups of the acorns of *Q. Ægilops*, which for many years have been imported from the Levant for tanning.

According to Loudon who quotes M'Culloch, in 1831-32 the import amounted

¹ *Arb. et Frut. Brit.* i. 109 (1838).

² Figured by Pardé, *Arb. Nat. des Barres*, 293, t. 29 (1906). The specimen which we have of a tree called *Q. macrolepis* at Les Barres agrees well with *Q. Pyrami*. Albert et Jahandiez, *Plant. Vasc. du Var*, 447, note 1 (1908), state that *Q. Ægilops* is cultivated in the department of Var, and is occasionally found in woods there in a semi-wild state.

³ Trabut, *Le Chêne Vélani*, issued as Bull. 27 by the Agricultural Department of Algeria in April 1901.

⁴ Maiden, *The Valonia Oak, New South Wales, Dept. Agric. Misc. Public. No. 313* (1899).

⁵ Sir W. Thiselton Dyer tells us that *valonia* takes its name from Avlona or Valona, a port in Albania, whence it is exported.

to 7500 tons per annum, worth £12 to £15 per ton. Consul Wood of Patras informs me that though the export from Greece alone in 1896 was over 8000 tons, the price has now fallen to £7 or £8, which scarcely covers the cost of collecting and cleaning. In 1906 the export had fallen to 3900 tons, and it seems as though it would die out altogether. He adds that the figures apply to the cupule alone and not to the acorn also, which is discarded before shipment.

Professor Procter of Leeds University informs me that the import has diminished owing to the competition of oak and chestnut extracts, and other tanning materials in the extract form. Valonia extract is now made at Smyrna and may have a considerable future. Greek valonia is well known in the trade and usually averages lower in price than the Smyrna article. As a rule it is less in strength, but good samples of Greek are often better than anything but the best Smyrna. The ripe valonia, either Greek or Smyrna, consists of cups only; but Greek *camata* and *camatina*, are unripe varieties valued for their colour. In *camatina* the acorn is completely enclosed by the unopened cup; in *camata* the acorn shows, but cannot be removed. He cannot say definitely whether any import comes from Syra or Crete, but Greek island valonia is a well-known commodity and often good.

The Valonia oak and an allied species, *Q. persica*, Jaubert et Spach, yield a kind of manna in Kurdistan. These trees are visited in August by immense numbers of a small white *coccus*, from the puncture of which a saccharine fluid exudes and solidifies in little grains. This exudation is collected by the wandering tribes of Diarbekir, who use it as food. A complete account of this peculiar substance is given by Flückiger and Hanbury.¹ (H. J. E.)

QUERCUS CASTANEÆFOLIA, CHESTNUT-LEAVED OAK

Quercus castaneæfolia, Meyer, *Verz. kauk. Pflz.* 44 (1831); Mathieu, *Flore Forestière*, 367 (1897).
Quercus Afares, Pomel, *Nouv. Mat. Flore Atlantique*, 391 (1874).

A tree, attaining 100 ft. in height and 10 ft. in girth. Bark deeply divided into longitudinal slightly scaly ridges. Young branchlets covered with a minute dense pubescence. Buds (Plate 78, Fig. 4) ovoid, pubescent, those near the apex of the branchlet surrounded by persistent long filiform pubescent stipules. Leaves (Plate 337, Fig. 47) deciduous in autumn, oblong-elliptical, acuminate at the apex, rounded and unequal or cuneate at the base, 3 to 6 in. long, 1½ to 2½ in. wide; with 8 to 14 pairs of lateral nerves, each ending in a mucronate triangular tooth; upper surface dark green, shining, with deciduous minute white stellate hairs; lower surface paler, coated with a minute tomentum; petiole ½ to ¾ in. long, pubescent.

Fruit ripening in the second year, solitary or rarely in clusters of two to six, on a stout short pubescent peduncle; acorn ovoid-cylindrical, ¾ to 1¼ in. long, glabrous, rounded at the apex, which is crowned by the tomentose style; cupule hemispheric,

¹ *Pharmacographia*, 415 (1879). Virgil, *Ecl.* iv. 30, refers to honeydew on oak, and not to manna, as alleged by Hanbury.

$\frac{3}{4}$ to 1 in. wide, with tomentose scales, reflexed from near their bases, long and linear in the upper ranks, ovate and short elsewhere, but very variable in length and shape.

This species has a remarkable distribution, occurring both in Algeria and in the eastern Caucasus and northern Persia. The characters, upon which Pomel tried to separate the Algerian tree as a distinct species, are unreliable. As seen, however, in cultivation and described by travellers in the wild state, the Caucasian or typical form is characterised by its short trunk and widely spreading horizontal branches, with a bark darker in colour and smoother than in the Algerian form. The latter is narrowly pyramidal in habit, with ascending branches, and with a deeply furrowed whitish bark.

This species is restricted in the Caucasus to the province of Talysch, where it grows in the forests from sea-level to 4000 ft. In Persia it is met with in the mountains south of the Caspian Sea. In Algeria it is less widely spread than *Q. Mirbeckii*, being confined to the forests in the mountains near the coast from Kabylia to the borders of Tunis. This oak near El Snab forms a wood at 600 ft. above sea-level; but elsewhere it is usually a tree of higher levels, occurring in the Akfadou forest between 3700 and 5000 ft., where it is mixed with *Q. Mirbeckii*, but is less abundant (Plate 323). On the northern slope of Mt. Babor, *Q. castaneæfolia* grows in company with *Abies numidica* and *Cedrus atlantica*.

Q. castaneæfolia is the southern representative of *Q. Cerris* in the same way as *Q. Mirbeckii* replaces *Q. sessiliflora*; and the mixed oak forests in Algeria closely resemble, in their composition, the forests in Servia where the Turkey oak and the sessile oak are mingled together.

In the forest of Akfadou and elsewhere, on the line of contact between the cork oaks of the lower elevations and the mixed forest of *Q. Mirbeckii* and *Q. castaneæfolia* higher up, the latter species and *Q. Suber* form hybrids which are readily distinguishable in winter, as in that season *Q. castaneæfolia* has lost its leaves, while the hybrids are subevergreen and are different from *Q. Suber* in their inferior corky bark and in the shape of the leaves. These hybrids,¹ which bear a striking resemblance to those of the Turkey oak and *Q. Suber*, are very variable in the character of the bark, in the period of fall of the leaves, and in the stature and growth of the trees. Those which are closest to *Q. castaneæfolia* in these characters have been named *Q. numidica*, Trabut;² those nearest to *Q. Suber*, *Q. kabylica*, Trabut.² (A. H.)

CULTIVATION

We can find no reliable information as to when or by whom this oak was introduced into England, but it was not known to Loudon except from description.

The only large tree we know of in England is a fine specimen at Kew, near the Palm House, which measured in 1909 about 60 ft. by 9½ ft. It produces fertile

¹ Certain cork oaks in this forest which lose their leaves in winter are also probably hybrids.

² In *Bull. Assoc. France Avance. Sc.*, 1886, p. 506, and *Bull. Soc. Bot. France*, xxxvi. 58, 61 (1889).

acorns in good seasons, from which I have raised seedlings, and these, though they grow slowly, seem perfectly hardy. It is supposed to have been planted about 1843.

A smaller tree, growing beside this, is probably the Algerian form, and measures 47 ft. by 3 ft. 1 in. This is perhaps of the same origin as a very thriving narrow pyramidal tree¹ in the oak collection, measuring 34 ft. by 3 ft., which was raised from acorns sent by Playfair from Algeria in 1869.

Another tree at Beauport, near Grinstead's Cottage, is about 35 ft. by 4 ft. 9 in. and has a short bole with rather corky bark, and a very spreading crown.

Henry was informed in Algeria that the wood of this species is similar in its properties to that of *Q. Cerris*, as it has an abundant sapwood and fails in durability. It is hard, heavy, easy to rive, but difficult to work, and is rejected by the railway companies who have been urged in vain by the forestry department of Algeria to use it for sleepers. Up to the present time it has been mainly used for firewood.

(H. J. E.)

QUERCUS MACEDONICA

Quercus macedonica, A. de Candolle, *Prod.* xvi. 2, p. 50 (1864).

Quercus Grisebachii, Kotschy, *Eichen*, 3 (1862) (name only); Baldacci, *Riv. Coll. Bot. Alb.* 72 (1892).

Quercus Egilops, Grisebach, *Spicil. Fl. Rum.* 333, excl. syn. (1844) (not Linnæus).

Quercus ostryæfolia, Borbas, in *Erdesz. Lap.* xxvi. 932 (1887).

A small tree or large shrub. Young branchlets with a minute scattered pubescence. Buds ovoid, $\frac{1}{8}$ in. long, with glabrous ciliate scales. Leaves (Plate 337, Fig. 41) deciduous late in the season, coriaceous, about 2½ in. long and 1 in. broad, ovate-lanceolate, auricled at the broad base, acute or acuminate at the apex, with nine to twelve pairs of lateral nerves each ending in a short mucronate tooth; margin wrinkled, with the teeth inflexed; upper surface dark green, with minute deciduous scattered brown pubescence; lower surface paler, with a similar pubescence; petiole $\frac{1}{8}$ in. long, minutely pubescent.

Fruit ripening in the second year, solitary, or two to three together, on a very short stout pubescent peduncle; acorn pubescent at the tip, enclosed in the lower half in a hemispherical cupule, about 1 in. in diameter with pubescent scales, the lowest ovate and appressed; the middle scales linear, hooked, and recurved; the uppermost narrow, erect, or incurved.

This species was discovered by Grisebach in Macedonia, in the mountains near Vodena, and occurs in Epirus, Albania, Montenegro, southern Herzegovina, and in south-eastern Italy on the coast between Bari and Gallipoli.²

In Herzegovina³ it is a rare tree, growing in mixture with *Q. Cerris* and *Q. conferta*, in the Dobrava forest near Stolac and in a few other localities. Farther

¹ It measured 24 ft. by 2 ft. in 1897.

² Schneider, *Laubholzkunde*, i. 180 (1904).

³ Cf. Beck, *Veg. illyr. Land*, 211 (1901).

south it is more common, as in the mountains between Lake Scutari and the sea, and throughout Albania, where it grows above the zone of littoral vegetation, in the lower region of the deciduous oak forests up to 2000 or 3000 ft. It forms pure woods of small extent, or is mixed with *Q. Cerris*, *Q. conferta*, *Carpinus orientalis*, *Ostrya*, and *Fraxinus Ornus*.

This species only attains a moderate size, and can scarcely be expected to form a large tree in England, where the best specimen known to us is at Tortworth, which measured in 1907 about 25 ft. high and 1 ft. 11 in. in girth. The only others we have seen are small trees at Kew, about 10 ft. high, which were raised from acorns sent by Beccari in 1890. Elwes raised a lot of seedlings from acorns sent to Kew in 1905, which seem to thrive on oolite soil, and endured the severe frost of 1908-9 better than *Q. Ilex*. It appears to be perfectly hardy not only in England, but in Germany,¹ where young plants raised at Gotha from acorns gathered by Dr. Perona at Gallipoli are thriving. (A. H.)

QUERCUS LIBANI

Quercus Libani, Olivier, *Voy. Emp. Oth.* ii. 290, t. 32 (1807); De Candolle, *Prod.* xvi. 2, p. 49 (1864); Carrière, in *Rev. Hort.* 1872, p. 155, f. 18; Boissier, *Fl. Orient.* iv. 1173 (1879).

A small tree or large shrub. Young branchlets minutely pubescent. Buds ovoid, acute, $\frac{1}{8}$ in. long, with ciliate, glabrous, or pubescent scales. Leaves (Plate 337, Fig. 39) deciduous in autumn, about 3 in. long and $\frac{3}{4}$ in. wide, lanceolate, acuminate at the apex, rounded and unequal at the base, with nine to twelve pairs of lateral nerves, each ending in a bristle-tipped inflexed² serration; both surfaces at first pubescent, usually becoming glabrous in summer, except on the midrib and nerves, where some pubescence is retained; petiole $\frac{1}{2}$ in. long, pubescent.

Fruit ripening in the second year, solitary on short stout pubescent stalks, very variable in size; acorn globose and only slightly projecting beyond the cupule, or cylindrical and half-enclosed by the cupule, depressed and tomentose at the apex; cupule campanulate, $\frac{3}{4}$ to $1\frac{1}{4}$ in. in diameter, covered with appressed tomentose ovate-rhombic scales.

This species is extremely variable³ in the amount of pubescence on the branchlets and leaves, and in the size of the acorn cup, which shows much variation in the size and shape of the scales. Leaves with irregular deep lobes sometimes occur on vigorous young branchlets; and extreme forms of this are *Q. squarrosa*, Kotschy,⁴ founded possibly on coppice shoots. *Q. Libani*, which was discovered by Olivier on Mt. Lebanon, is widely spread throughout the mountains of Syria, Asia Minor, and Armenia.

¹ Schneider, *Laubholzkunde*, i. 180 (1904).

² The margin is wrinkled on account of the inflexed teeth, but less so than in *Q. macedonica*.

³ *Quercus regia*, Lindley, *Bot. Reg.* t. 73 (1840); *Q. vesca*, Kotschy, *Eichen*, t. 11 (1862); and *Q. Tchihatchewi*, Kotschy, in Tchihatcheff, *As. Min.* ii. 468, t. 40, f. 1 (1860), are united with *Q. Libani* by Boissier, and are perhaps extreme forms of this very variable species.

⁴ Ex De Candolle, *Prod.* xvi. 2, p. 108 (1864).

The oldest plants in Europe were apparently raised at Paris, from acorns sent by Balansa in 1855. A healthy tree in the Jardin des Plantes at Paris produces acorns; and it is quite hardy at Les Barres. This species is extremely rare in England. The best is a grafted tree at Kew, about 25 ft. high, with a good leader, which was obtained under the name *Q. serrata pendula*, from Lee's nursery in 1880. A smaller tree, about 15 ft. high, obtained from Paris in 1883, bore a few acorns in 1909. There are also specimens at Tortworth, Grayswood, and Aldenham. The latter, a healthy young tree, produced ripe fruit in 1908. (A. H.)

QUERCUS SERRATA

Quercus serrata, Thunberg, *Fl. Jap.* 176 (1784); Franchet et Savatier, *Enum. Pl. Jap.* i. 447 (1875); Hooker, *Fl. Brit. India*, v. 601 (1888); Skan, in *Journ. Linn. Soc. (Bot.)* xxvi. 520 (1899); Shirasawa, *Icon. Ess. Forest. Japon*, text 51, t. 26, figs. 1-12 (1900); Gamble, *Indian Timbers*, 673 (1902).

A tree, attaining usually about 40 ft. in height. Young branchlets silky pubescent when young, soon becoming glabrescent; smooth and shining in the second year. Leaves (Plate 337, Fig. 46) deciduous in autumn, 4 to 8 in. long, 1 to 2 in. wide, oblong-lanceolate, acuminate at the apex, cuneate or rounded at the base, with ten to sixteen pairs of lateral nerves, each ending in a bristle-tipped serration; upper surface glabrescent; lower surface green, with deciduous appressed pubescence, glabrous in summer except for slight stellate-pubescent axil-tufts; margin non-ciliate; petiole $\frac{1}{2}$ to 1 in. long, with scattered pubescence.

Fruit ripening in the second year, solitary or in pairs, sub-sessile; acorn ellipsoid, glabrous, scarcely longer than the hemispherical cupule, which is $\frac{3}{4}$ to $1\frac{1}{4}$ in. in diameter, covered with tomentose scales, those at the base ovate-oblong, those above linear, $\frac{1}{2}$ to 1 in. long, more or less spreading.

This species is widely distributed, occurring in Japan, China, the Shan and Khasia Hills, and in the Himalayas, through Bhutan and Sikkim to eastern Nepal. In Japan, Sargent saw it growing on dry soil near the coast behind Yokohama, and on the foothills of central Hondo. Gamble states that it has been largely planted at the cinchona plantations near Darjeeling and succeeded admirably. It has also done well at Dehra Dun, where a tree felled in the garden of the Forest School showed a growth of two to three rings per inch of radius.

Gay¹ states that four plants of this species, about 3 ft. high, were growing in 1861 at Verrières, near Paris, where they had been raised from acorns sent from Manchuria by Montigny; but these do not appear to have survived.² Maximowicz in 1864 introduced *Q. serrata* from Japan into the St. Petersburg Botanic Garden.³

It is probable that this species was introduced into England by Oldham, who collected in Japan, China, and Korea in 1861-64, as a small tree in Kew Gardens, about 20 ft. high, is labelled with his name. Younger specimens, received from

¹ Note in Kew Herbarium.

² In *Hortus Vilmorinianus*, 55 (1906), mention is only made of young plants of this species, raised from Chinese acorns, obtained a few years ago.

³ Bretschneider, *Hist. Europ. Bot. Disc. China*, 609 (1898).

Veitch in 1893, appear to be more vigorous. At Beauport, Sussex, there is a good specimen, which measured about 40 ft. by 3 ft. 3 in. in 1905. At Bickton, a healthy specimen is about 35 ft. by 5 ft. There is also a good tree in Coombe Wood.

This is one of the oaks in China on which some species of wild silkworm feed; but Mayr,¹ who says that it is not hardy at Grafrath, states that the great expectations of its successful cultivation in southern Europe as food for the silkworm of *Saturnia Yama-mai* have not been fulfilled. (A. H.)

QUERCUS VARIABILIS

Quercus variabilis, Blume, in *Mus. Bot. Lugd. Bat.* i. 297 (1849); Shirasawa, *Icon. Ess. Forest. Japon*, text 54, t. 28, figs. 1-11 (1900); Mayr, *Fremdländ. Wald- u. Parkbäume*, 510 (1906).

Quercus chinensis, Bunge, *Enum. Pl. China*, 61 (1835) (not Abel); De Candolle, *Prod.* xvi. 2, p. 50 (1864).

Quercus acutissima, Carruthers, in *Journ. Linn. Soc. (Bot.)* vi. 33 (1861).

Quercus Bungeana, Forbes, in *Journ. Bot.* xxii. 83, 85 (1884); Skan, in *Journ. Linn. Soc. (Bot.)* xxvi. 508 (1899).

Quercus serrata, Thunberg, var. *chinensis*, Wenzig, in *Jahrb. bot. Gart. Berlin*, iv. 221 (1886).

A tree, attaining 80 ft. in height and 10 ft. in girth. Bark grey, thick, corky. Young branchlets as in *Q. serrata*. Leaves (Plate 337, Fig. 40) similar to those of that species, but covered beneath with a dense white tomentum. Fruit with smaller cupules, which have thicker shorter scales.

This species, which is very closely allied to, if not a mere variety of *Q. serrata*, is spread through Japan, Korea, and China, where it is very common about Peking, attaining in the western hills a height of 60 to 80 ft. The acorn-cups are used in China for dyeing purposes, and yield a considerable amount of tannin.

This tree produces cork very similar to that yielded by *Q. Suber* in Europe; and the Japanese have commenced to utilise its bark for this purpose. Mayr strongly recommends its cultivation for cork in localities where the common chestnut thrives.

Fortune,² in 1861, procured a large quantity of acorns at Peking, from which Standish raised young plants at Bagshot; but we have found no trees of this origin.

It was afterwards introduced by Dr. Bretschneider,³ who sent acorns from Peking, where the tree is very common, to Prof. Sargent in 1881, and to Kew in 1882, where there is a good specimen about 20 ft. high and growing vigorously. A smaller tree, raised from acorns sent by Regel, is probably of Japanese origin. Sargent⁴ says that this species is very hardy in the Arnold Arboretum, U.S.A., and of rapid growth, the leaves turning a bright yellow in November. He⁵ also collected acorns in Japan in 1892, from which young plants were raised.

QUERCUS DENTATA

Quercus dentata, Thunberg, *Fl. Jap.* 177 (1784), and *l.c. Pl. Jap.* dec. 5, t. 6 (1794); Franchet et Savatier, *Enum. Pl. Jap.* i. 445 (1875); Sargent, *Forest Flora Japan*, 67, t. 23 (1894); Skan, in *Journ. Linn. Soc. (Bot.)*, xxvi. 511 (1899); Shirasawa, *Icon. Ess. Forest. Japon*, text 52, t. 27, figs. 1-15 (1900).

Quercus obovata, Bunge, *Enum. Pl. China*, 62 (1835).

Quercus Daimio, Koch, *Dendrologie*, ii. 2, p. 45 (1873).

Quercus yunnanensis, Franchet, in *Journ. de Bot.* 1899, p. 146.

A tree, occasionally attaining 80 ft. in height and 10 ft. in girth. Young branchlets covered with a dense brownish or greyish tomentum, retained in the second year. Buds tomentose, the terminal one surrounded by persistent stipules. Leaves (Plate 337, Fig. 43) deciduous in autumn, 8 to 12 in. long, 3 to 6 in. broad, obovate, acute or rounded at the apex, cuneate or subcordate at the base, with six to nine pairs of small rounded lobes; margin ciliate; upper surface pubescent on the midrib and nerves, elsewhere glabrous or with scattered hairs; lower surface pale, sparsely covered with a minute stellate pubescence; petiole $\frac{1}{4}$ to $\frac{1}{2}$ in. long, tomentose.

Fruit ripening in the first year, clustered, sub-sessile or stalked; acorn sub-globose; cupule covered with long tomentose scales, those in the basal ranks ovate-oblong, obtuse, and spreading, those towards the rim linear, acute, and reflexed.

This species displays a considerable amount of variation in the wild state, and several varieties¹ have been distinguished, none of which are in cultivation. The following remarkable variety is cultivated in Japanese gardens, but does not seem to have been introduced:—

1. Var. *pinnatifida*, Matsumura.

Quercus pinnatifida, Franchet et Savatier, *Enum. Pl. Jap.* i. 445 (1875), and ii. 497 (1879).

Leaves deeply lobed, almost to the midrib.
