This species is a native of Japan, Korea, Chinese Manchuria, and China. In Japan, according to Sargent, it is found in central Hondo only on the high mountains, where it is not at all common; but in the extreme northern part of the island it appears in great numbers on gravelly slopes at no great height above the sea-level. In Yezo, where Elwes collected it at Asahigawa, it grows on low ground with *Q. grosseserrata*, and though it attains a height of 80 ft., is not a fine or imposing tree. Mayr mentions as remarkable its occurrence on volcanic sands, and states that its bark is the most valuable tanning material in Japan, and recommends it for planting on sand dunes. The wood, according to Sargent, is coarse-grained, porous, and brittle, and worthless except for firewood.

In China it is common on poor soil on low hills in the northern provinces, and

¹ Var. *M'Cormickii*, Skan, *loc. cit.*; var. *oxylola*, Franchet, in *Journ. de Bot.* xiii. 146 (1899). *Q. yunnanensis*, Franchet, *loc. cit.*, is also a peculiar form, occurring in Yunnan.

it extends on the high western plateaux as far south as Mengtze in Yunnan, nowhere, so far as I have observed, attaining considerable dimensions.

This tree was probably introduced into Europe by Siebold, who sent acorns of several Japanese oaks to Leyden in 1830. According to Loudon,¹ young plants were growing in 1842 in the Tooting and Epsom Nurseries. It has never thriven in this country, usually forming a low bushy tree, liable to injury by both spring and late frosts, and seldom displaying its fine foliage to advantage. At Syon, where a specimen is said to be over thirty years old, it has made but little growth. It appears to thrive better in the United States, where it is hardy as far north as eastern Massachusetts.²

(A. H.)

QUERCUS ALNIFOLIA

Quercus alnifolia, Poech, *Enum. Pl. Cypri*, 12 (1842); Boissier, *Fl. Orient.* iv. 1168 (1879); Schneider, *Laubholzkunde*, i. 183 (1904).
Quercus cypria, Jaubert et Spach, *Illust. Pl. Orient.* i. t. 56 (1843).

A shrub or small tree. Young branchlets densely covered with greyish stellate pubescence, retained in the second year. Leaves (Plate 338, Fig. 60) coriaceous, persistent two years, $1\frac{1}{2}$ to 2 in. long and broad, orbicular or obovate; rounded or acute at the apex; rounded or broadly cuneate at the base; with five to eight pairs of prominent lateral nerves, all but the lower one or two pairs, ending in a minute mucronate tooth; upper surface dark green with deciduous stellate hairs; lower surface covered with a dense orange or yellowish grey tomentum;³ petiole $\frac{1}{2}$ in. long, tomentose.

Fruit ripening in the second year, solitary or two to three on a short tomentose stalk; acorn $\frac{1}{2}$ to $1\frac{1}{2}$ in. long, surrounded at the base by a hemispherical cupule, covered with tomentose scales, the basal ranks ovate and appressed, the median scales lanceolate, and the upper linear scales long and recurved.

This species grows as underwood in the pine forests of the mountains of Cyprus at 1600 to 5000 ft. altitude. It is very rare in cultivation,⁴ the only specimens which we have seen being two small trees, about 7 ft. high, at Kew, which were raised from acorns sent by Sir Robert Biddulph in 1885. One of these is in the temperate house and the other is in the oak collection.

(A. H.)

¹ In *Gard. Mag.* xviii. 17, 41 (1842). Bretschneider, in *Hist. Europ. Disc. China*, 1061 (1898), states that he sent acorns from Peking to the Arnold Arboretum, Mass., from which plants were raised.

² Sargent, *Silva N. Amer.* viii. 10, note 41 (1895).

³ In native specimens the tomentum is orange in colour; but in the shrubs at Kew it is only slightly tinged with yellow.

⁴ Cf. *Gard. Chron.* xiv. 533 (1880), and xvii. 227 (1882); and *The Garden*, xviii. 486 (1880).

QUERCUS COCCIFERA, KERMES OAK

Quercus coccifera, Linnæus, *Sp. Pl.* 1413 (1764); Loudon, *Arb. et Frut. Brit.* iii. 1908 (1838); Mathieu, *Flore Forestière*, 387 (1897).
Quercus pseudococcifera, Desfontaines, *Fl. Atl.* ii. 349 (1799).
Quercus Mesto, Boissier, *Voy. Bot. Esp.* ii. 519, t. 166 (1845).
Quercus anodonta, Borbas, in *Erdesz. Lap.* xxvi. (1887).

A shrub, usually 6 to 12 ft. high, occasionally becoming a small tree, rarely exceeding 20 ft. in height. Young branchlets with scattered brown stellate pubescence. Buds brown, ovoid, minute, glabrescent. Leaves (Plate 338, Fig. 62) persistent two or three years, coriaceous, variable in size and shape, oval or oblong, 1 to $1\frac{1}{2}$ in. long and $\frac{7}{8}$ in. broad, acute or rounded at the apex, sub-cordate or truncate at the base, wrinkled in margin, and with the upper surface concave; with four to eight pairs of minute teeth, each ending in a cartilaginous bristle; glabrous and shining green above and below; petiole $\frac{1}{8}$ to $\frac{1}{4}$ in. long, stellate-pubescent.

Fruit ripening in the second year, solitary or in pairs, sessile or shortly stalked; acorn cylindrical-ovoid, about an inch long, glabrous, shining; cupule hemispheric, $\frac{1}{2}$ to $\frac{3}{4}$ in. wide, covered with tomentose spine-tipped scales, ovate to linear, and very variable in breadth, thickness, and curvature.

The above description applies to the typical form prevalent in the western part of the Mediterranean region, but considerable variation occurs in the size and shape of the leaves (which are occasionally entire) and of the cupules, cupule-scales, and acorns. These differences appear to depend upon the vigour of the plant, and are occasionally present upon the same individual; and the numerous varieties which have been named can scarcely be upheld. The following, however, are noteworthy:—

1. Var. *Auzandri*, De Candolle, *Prod.* xvi. 2, p. 53 (1864).

Quercus Auzandri, Grenier et Godron, *Fl. France*, iii. 119 (1855-6).

Leaves (Plate 339, Fig. 65) more or less stellate-pubescent beneath. Cupules small with scales flattened at the points. This is supposed by Fliche¹ to be a hybrid between *Q. Ilex* and *Q. coccifera*, and has been observed in the south of France and in Algeria.

2. Var. *pseudococcifera*, Boissier, *Flora Orientalis*, iv. 1169 (1879).

Var. *Calliprinos*, Boissier, *loc. cit.*

Quercus pseudococcifera, Labillardière, *It. Pl. Syria*, Dec. v. p. 9, t. 6 (1812), (not Desfontaines),²

J. D. Hooker, in *Trans. Linn. Soc.* xxiii. 381, tt. 36, 37 (1862).

Quercus Calliprinos, Webb, *It. Hisp.* 15 (1838).

The eastern form of the species, often a shrub, occasionally a large tree, Leaves flat, scarcely concave or wrinkled, usually larger than in the type. Fruit variable, but often larger than in the western form.

¹ In Mathieu, *Flore Forestière*, 389 (1897). Albert et Jahandiez, *Plant. Vas. du Var*, 445, pl. xv. (1908), distinguish four hybrids between *Q. Ilex* and *Q. coccifera*, all of which have been seen in the south of France.

² *Q. pseudococcifera*, Desfontaines, described from Algerian specimens, is absolutely identical with *Q. coccifera*.

The Kermes oak is a native of the Mediterranean region, occurring in northern Africa, Spain, and Portugal, the south of France, Italy, Dalmatia, Albania, Greece, Asia Minor, and Syria. It covers dry poor soils with a shrubby vegetation, being often mixed on limestone with *Q. Ilex*. Its bark, especially that of the roots, is much esteemed for tanning, whilst its branches are often covered with an insect (*Chermes Ilicis*) called Kermes in Arabic, which was formerly used like cochineal, as a scarlet dye. (A. H.)

In Asia Minor and Syria this species occasionally becomes a large tree, of which Hooker gives the following account:—"This is by far the most abundant tree throughout Syria, covering the rocky hills of Palestine especially with a dense brushwood of trees 8 to 12 ft. high, branching from the base, thickly covered with small evergreen rigid leaves, and bearing acorns copiously. Owing to the indiscriminate destruction of the forests in Syria this oak rarely attains its full size. We saw but few very good trees, one of which is the famous oak of Mamre called Abraham's oak, of which a portrait is given (Plate xxxvi.), and I saw other good ones at Anturah on the Lebanon. Abraham's oak is supposed to indicate the spot where grew the oak under which the patriarch pitched his tent, and is revered by Jews, Mahometans, and Christians. In general habit it much resembles *Q. Ilex* as grown in this country. The diameter of the foliage is given, no doubt correctly, by Porter as 90 ft., the girth of the trunk as 23 ft. In the winter of 1856-57 when in the streets of Jerusalem the snow fell deep and lay for many days, a great branch of Abraham's oak was broken off, and when cut up was sufficient to load seven camels." A more recent photograph in my possession shows that this tree has now been protected by a stone wall, and though its foliage is more scanty than as shown in Hooker's drawing, the tree is still a very fine one.

According to Loudon the species was cultivated as long ago as 1683, but is now rarely seen, except in botanic gardens. At Kew it is perfectly hardy, young Algerian specimens having survived the severe winter of 1860-61, and it occasionally bears fruit. We have specimens from Kew, Eastnor, the Heatherside Nursery near Bagshot, and Fota. At Bitton¹ it forms a bush about 20 ft. high, which was raised from an acorn gathered near Athens in 1854-55. It produces root-suckers freely.

According to Mouillefert,² it is hardy at Grignon near Paris, where it has borne a temperature of 5° Fahr. without injury, and thrives well on poor calcareous soil.

(H. J. E.)

¹ Canon Ellacombe, in *Gard. Chron.*, 1870, p. 1155, says that it produces acorns very freely, but these are nearly always abortive.

² *Ess. Forest.* 112 (1903).

QUERCUS ILEX, ILEX OR HOLM OAK

- Quercus Ilex*, Linnæus, *Sp. Pl.* 995 (1753); Loudon, *Arb. et Frut. Brit.* iii. 1899 (1838); Willkomm, *Forstliche Flora*, 415 (1887); Mathieu, *Flore Forestière*, 374 (1897).
Quercus Gramuntia, Linnæus, *Sp. Pl.* 995 (1753); Loudon, *Arb. et Frut. Brit.* iii. 1906 (1838).
Quercus sempervirens, Miller, *Gard. Dict.* ed. viii. No. 3 (1768).
Quercus calicina and *expansa*, Poirét, in Lamarck, *Dict. Suppl.* ii. 216 (1811).
Quercus ilicifolia, Salisbury, *Prod.* 392 (1796).
Quercus pseudoilex, Chatin, in *Bull. Soc. Bot. France*, xvi. 22 (1869).

A tree, attaining in favourable conditions 90 ft. in height and 20 ft. in girth; often shrubby or of small size in dry climates and on poor soils. Bark of older stems divided into small scaly plates. Young branchlets covered with grey tomentum, retained in the second year. Leaves (Plate 339, Fig. 69) coriaceous, persistent two or three years, very variable in size, shape, and margin, even upon the same tree; larger leaves, often 3 in. long and 1½ in. broad, occurring on vigorous branches and on trees growing in moist climates and in good soils; smaller leaves, often 1 in. long and ½ in. broad, being characteristic of branches of feeble growth and on shrubby trees growing in dry climates and on hot calcareous soils; larger leaves usually ovate or ovate-lanceolate, acuminate at the apex, and tapering at the base; smaller leaves usually oval, acute at the apex, and rounded at the base, but with many intermediate forms; margin entire or undulate on the upper branches of older trees, or with holly-like spine-tipped teeth on lower branches and on young trees; upper surface dark green, shining, with numerous stellate hairs; lower surface usually covered with a dense fine white or greyish tomentum, occasionally glabrescent and light green on branches of young trees; lateral nerves seven to ten pairs, ending in the teeth of dentate leaves, dividing and looping before reaching the margin of entire leaves; petiole ¼ to ¾ in. long, tomentose.

Fruit ripening in the first year, solitary or in pairs, on a short stout grey tomentose peduncle; acorns, very variable in size and shape, often slightly pubescent towards the apex, which is surmounted by a conical umbo, tomentose except for a glabrescent or glabrous narrow basal zone; cupule hemispheric or rarely turbinate, with closely appressed ovate grey tomentose scales, diminishing in size from the base to the margin of the cupule.

VARIETIES

Spread over a wide area, occurring in different soils and climates, and showing a large amount of variation in the individual tree, influenced by age, vigour of branchlets, etc.,—this species has numerous forms, impossible to define in the present state of our knowledge, and only a few conspicuous varieties¹ can now be alluded to.

¹ Albert et Jahandiez, *Plant. Vasc. du Var*, 439, Pl. xi., xii., xiii., xiv. (1908), enumerate and describe thirty-one varieties.

1. Var. *Ballota*, De Candolle, *Prod.* xvi. 2, p. 39 (1864).

Quercus rotundifolia, Lamarck, *Encyc. Méth.* i. 723 (1783).

Quercus Ballota, Desfontaines, in *Mém. Acad. Sc. Paris*, 1790, p. 394, t. 6, and *Fl. Atlant.* ii. 350 (1800); Webb, *Iter Hisp.* 14 (1838); Loudon, *Arb. et Frut. Brit.* iii. 1905 (1838).

Leaves variable, spiny-dentate or entire, usually rounded at the base and white beneath. Acorns large, sweet, edible.

This variety is the prevalent form in Spain and northern Africa, and occurs also in Portugal, where Coutinho¹ distinguishes another variety, with sweet acorns (var. *avellanæformis*), very small, sub-globose, and almost enclosed in the cupule. Webb says that the leaves in var. *Ballota* always have a round rather than an elliptic shape, and that toothed and entire leaves are mixed on the same branch; the down which clothes them is thicker, the branches stiffer, and the acorns besides being very sweet are much longer and more cylindrical. He also found it more tender² than the common form, and said that a specimen which he grew for twenty years in a warm situation only reached 6 ft. high in that time.

2. Var. *Gramuntia*, Loudon, *Trees and Shrubs*, 882 (1842).

Quercus Gramuntia, Linnæus, *Sp. Pl.* 995 (1753); Loudon, *Arb. et Frut. Brit.* iii. 1906 (1838).

Quercus Cookii, Loudon, *Arb. et Frut. Brit.* iii. 1926 (1838).

Leaves (Plate 339, Fig. 68) broadly oval, obovate, or almost orbicular, often sub-cordate at the base, 1 to 1½ in. long; margin wrinkled, with a few inflexed teeth, ending in long sharp spines.

This variety was described by Linnæus from a specimen growing in the wood of Gramont, near Montpellier, where, however, De Candolle afterwards failed to find it. A tree bearing this name was growing in 1838 at Purser's Cross. It was raised in 1835 in the Chiswick Garden from acorns procured from Gibraltar. It is probably a form in which the seedling characters are preserved, and was both by Loudon and by Cook confused with var. *Ballota*. It is a small tree, occasionally seen in gardens, as at Kew and at Osborne, where there was a tree, 36 ft. by 4 ft., in 1908, bearing the name of *Q. Ballota*.

3. Var. *Fordii*, Loudon, *Gard. Mag.* xix. 36 (1843).

Quercus Fordii, Koch, *Dendrologie*, ii. 2, p. 56 (1873).

Leaves narrow, lanceolate, 1 to 1½ in. long; margin wrinkled, undulate or with a few irregular teeth, without spiny points. This peculiar form originated many years ago in Lucombe and Pince's nursery at Exeter, and was named after Ford, one of the proprietors.

4. Var. *crispa*, Loudon. As seen at Kew, a monstrous form, with very small entire leaves, about ½ in. in length, with the edges rolled inwards and the under surface concave.

5. Var. *Smilax*, Nicholson, in *Kew Handlist, Trees*, 689 (1902).

Quercus Smilax, Linnæus, *Sp. Pl.* 994 (1753).

Leaves entire, narrow, lanceolate, long acuminate at the apex.

¹ In *Boll. Soc. Brot.* vi. 94 (1888).

² The seedlings which Elwes raised at Colesborne were killed by a frost, which left seedlings of the typical form in the same bed unhurt.

6. Var. *Genabii* and var. *latifolia* are forms with very large leaves, up to 5 in. long, and 2½ in. wide, usually dentate towards the apex.

7. In Afghanistan and the western Himalayas, a variety described as a distinct species, *Q. Baloot*, Griffith, *Itin. Notes*, 328 (1848), occurs at altitudes between 3000 and 8500 ft.¹ In western China, several peculiar varieties² have been found on the high mountains of Szechwan, Hupeh, and Yunnan. None of these Asiatic forms have been introduced into cultivation, and need not be here further alluded to.

HYBRIDS

Reputed hybrids between *Q. Ilex* and *Q. Suber* have been reported in France,³ Italy,⁴ Spain,⁵ and Portugal.⁶ This species also hybridizes with *Q. coccifera*. Cf. p. 1279.

Q. Turneri, supposed to be a hybrid between *Q. Ilex* and *Q. pedunculata*, is described on p. 1288. *Q. audleyensis*, possibly a hybrid with *Q. sessiliflora*, is described on p. 1291.

DISTRIBUTION

Q. Ilex is a native of the Mediterranean region, occurring in Spain and Portugal, France, Italy, Southern Tyrol, Istria, Dalmatia, Greece, the coast region of Syria, and in Morocco, Algeria, and Tunis.

In France, *Q. Ilex* occurs in the departments bordering on the Mediterranean, and ascends the valley of the Rhone to a point near Valence, spreading on the east along the valleys of its tributaries through Drôme, Basses-Alpes, and Hautes-Alpes, and being limited on the west by a line passing through the southern parts of Ardèche, Lozère, Aveyron, and Tarn, and including the greater part of Aude and Pyrénées Orientales, where M. Flahaut observed it in the valley of the Tet as high as 5000 ft. elevation. In south-eastern France this species is only met with on limestone, and is rarely seen except as coppice, its bark being a valuable tanning material. At low altitudes and in arid situations it is often mixed with *Pinus halepensis*, and at higher altitudes with *Quercus lanuginosa*. These coppices consist usually of scattered bushes separated by paths frequented by flocks of sheep. The most remarkable forest of this kind is that of Bédoin, on the southern slope of Mt. Ventoux, where *Q. Ilex* ascends from 300 to 2700 ft., occurring pure up to 2300 ft., and mixed with *Q. lanuginosa* between 2300 and 2700 ft. In this coppice is found the most esteemed kind of truffle, that of Périgord.⁷ In the south-west and west of France *Q. Ilex* is found here and there on limestone in small

¹ Cf. Hooker, *Fl. Brit. India*, v. 602 (1888).

² Cf. Skan in *Journ. Linn. Soc. (Bot.)* xxvi. 516 (1899). *Q. Ilex*, var. *phillyræoides*, Franchet, a native of Japan and western China, is very different and is treated by us as a distinct species. See p. 1298.

³ *Quercus Bertrandii*, Albert et Reynier in *Bull. Acad. Intern. Géog. Bot.*, 1902, ex Albert et Jahandiez, *Plant. Vasc. du Var*, 444, pl. xiv. (1908).

⁴ *Quercus Morisii*, Borzi, in *Nuov. Giorn. Bot. Ital.* xiii. 10, fig. 1 (1881). This hybrid is reported by Pereira in *Bull. Soc. Bot. France*, xiv. 69 (1892) to occur near Bastia, in Corsica.

⁵ Mentioned by Laguna, as occurring in Estremadura and Andalusia.

⁶ Coutinho reports this hybrid to be not uncommon in Alentejo.

⁷ Cf. Huffer, *Économie Forestière*, i. 386-390 (1904).

groups, in the Basses-Pyrénées, Gironde, Charente, around Nantes and Poitiers; and is reported as far north as Quimper. In France, though limited in the wild state to the milder regions, it bears a considerable degree of winter cold, having sustained without injury at Grignon a temperature of -23° Cent. in 1871; but in 1879 when the temperature fell to $-26\frac{1}{2}^{\circ}$ Cent. it was killed to the ground, but the root has since produced a vigorous shoot.¹

In Corsica, *Q. Ilex* is a common tree, and forms fine forests in the north-western part of the island. That of Piriò, near Calvi, occupies northern slopes between 600 and 2500 ft. altitude, and contains many large trees, up to 90 ft. in height. (A. H.)

In Italy, *Q. Ilex* is widely spread. Bunbury² says that "in the Cascine, near Pisa, mixed with stone pine and pinaster, it forms extensive woods on light sandy soil. The limestone mountains behind Spoleto are entirely clothed with the Ilex; so are those near Terni, around the famous falls of the Velino, and those bounding the valley of the Nar from Terni to Narni. There are many large trees of it on the banks of the Nar near the Bridge of Augustus. The superb Ilexes in the grounds of the Villa Borghese and Villa Pamfili at Rome are celebrated; but the finest trees of the kind that I remember ever to have seen are on the road between Castel Gondolfo and the Capuchin convent above the town of Albano. They are of vast size." I measured a very fine tree, said to be over 150 years old, in the garden of the Hotel Hassler at Naples, formerly belonging to the King of Naples. In March 1910 it was over 90 ft. high and $12\frac{1}{2}$ ft. in girth, and had borne many large acorns, some of which I brought home.

Q. Ilex is generally known in Spain as *encina*, but sometimes called *carrasca*, or *chapparro*; and in Portugal is named *azinho* or *azinheira*. It is an extremely variable tree found throughout Spain except perhaps in Galicia, most abundant in the south, where it ascends, near Ronda, to 1500, and in the Sierra Nevada to 2000 metres; and is a most characteristic tree of large tracts in Estremadura and Leon. Widdrington considered it distinct from the common *Ilex* grown in England, and says that he instantly recognised it in a bed of seedlings at Kensington, which on inquiry turned out to have been raised from acorns sent from Valencia by Lord Holland. He adds that it is less hardy, and would barely exist in the north of England, where the Italian form grew well.

In passing through the great open plains which lie between the Portuguese frontier and Ciudad Rodrigo this was almost the only tree that I saw scattered over the country for many miles as a sort of open forest, cultivated with wheat or rye between the trees, or grazed. The trees were heavily pruned like olive trees, to make them produce as many acorns as possible; and these acorns, known as *bellotas*, are looked on as good food for man and beast.

In Portugal the tree is not so common generally as *Q. Suber* and *Q. lusitanica* in the south, or as *Q. pedunculata* and *Q. Toza* in the north; and I saw none of great size; though a tree at Villa Nova de Baronia, in Alemtejo, is recorded by Gebhart as 3.35 metres in girth, with a crown 19 metres in diameter when less than 100 years

¹ Cf. Mouillefert, *Essences Forestières*, 104 (1903).

² *Arboretum Notes*, 112 (1889).

old, and was said to produce 1000 litres of acorns in one year. The flowering of the tree is earlier in Portugal than that of the cork oak, and so profuse that in April the trees had quite a golden appearance. The timber is valued for cart wheels and other farm implements, and preferred to that of the cork oak. It is also largely used for firewood and charcoal.

CULTIVATION

The Ilex or holm¹ oak as it was formerly called, was introduced into this country at a very early period, and was known to Clusius in 1581, who spoke of two trees then growing near London, one of which was old enough to bear acorns; and Evelyn² spoke of it as a tree which "thrives manifestly with us; witness his Majesty's privy garden at Whitehall, where once flourish'd a goodly tree of more than four-score years growth, and there was lately a sickly imp of it remaining. And now very many rais'd by me have thriv'd wonderfully, braving the most severe winters, planted either in standards or hedges, which they most beautifully become."

It ripens seed freely in the warmer parts of England, and reproduces itself where conditions are suitable; but pheasants are so fond of the acorns that few get a chance to grow; and they are better sown in a nursery or in pots, as the roots at first have very few fibres, and the tree, as Evelyn long ago remarked, is difficult to transplant. It is better to move them like hollies late in spring, or in August, if the autumn is moist and the climate mild. The Ilex undoubtedly likes sea air, and rarely grows as large inland as near the coast. It grows well on limestone, but also thrives in a good loamy soil, dry and well drained; and is sometimes killed by severe winters on wet and cold situations away from the coast.³

The tree varies extremely both in habit and foliage; and in a plantation at the Barton Farm, Osborne, I.W., where cork oaks and Ilex have been planted together, there are many seedlings which might be hybrids, though the bark of the older trees is always a good mark of distinction. In the Prince of Wales plantation, a little beyond the statue in Windsor park, I saw in 1909, a number of trees of very upright habit, which are said to have been planted in 1880, and are now in some cases over 40 ft. high.

REMARKABLE TREES

Among the largest and finest trees in England are those at Mamhead, of which Bradley⁴ wrote as follows: "That curious gentleman Robert Balle, Esq., F.R.S.,⁵

¹ Murray, *Eng. Dict.* v. 343 (1901), states that *holm* is a phonetic corruption of *holm*, from *holen*, *hollin*, the Old English equivalents of the modern word holly. *Holm* is used by Chaucer in the *Knight's Tale*, meaning holly tree. *Holm* was apparently first used for the evergreen oak by Cooper, *Elyot's Dict.* (1552),—"Ilex, a tree called by some holme." Holland, *Pliny* i. 495 (1601), says: "There is an holme growing in the Vatican, elder than Rome it selfe." *Ilex*, however, is so generally used, that it may now be considered an English word.

² *Silva*, 171 (1706).

³ In East Anglia, young trees twelve to twenty years old were killed in the severe winter of 1859-60; but old trees escaped with merely a browning of their leaves (cf. *Gard. Chron.*, 1869, p. 167). Many trees at Kew, but not all, were quite defoliated in the severe winter of 1908-9, when the temperature fell to 10° Fahr. on 30th December. Cf. *Kew Bull.*, 1909, p. 236.

⁴ Bradley, *Improvements of Planting*, 38 (1739).

⁵ In Polwhele's *History of Devonshire* (1793) it is said: "The woods and plantations of Mamhead were extensive; many of the trees were introduced by Mr. Thomas Ball, the last of that family (he died in 1749), who returning from the continent, brought with him a quantity of cork tree, Ilices, wainscot oaks (*Q. Cerris*), chestnuts, acacias, cedars, and other trees."

has, among other improvements for the good of his country, propagated a large parcel of these trees in England, some of which have in about thirty years grown to a considerable greatness of stature. This gentleman has raised some thousands of them from acorns, and to follow his method we must set the acorns in loam well sifted, in garden pots in February, and turn them out with the earth about their roots when they are two years old." Ellis¹ a year later says that "at Mamhead in a shallow sort of soil of but 9 in. deep, before a red rock appears, these trees had prospered so well that at forty years' end the diameter of their bodies measured above a foot each, and the height of one of them was above 50 ft., with a straight taper stem without a knot." R. Pince² of the Exeter Nursery gave the dimensions of some of the trees at Mamhead in 1835 as follows:—

	Height.	Girth.	
1. <i>Quercus Suber</i>	60 ft.	12½ ft.	
2. " "	50 ft.	11 ft. 3 in.	
3. <i>Q. Ilex</i>	85 ft.	11 ft.	One of a group on the confines of Haldon, about 600 ft. above sea-level.
4. " . . .	70 ft.	14 ft.	Detached in middle of park.
5. " . . .	55 ft.	22 ft.	In a sheltered place about 250 ft.
6. <i>Q. Cerris hybrida</i> , Fulham oak	80 ft.	13½ ft.	About 500 ft. elevation.
7. <i>Q. Cerris</i> , Turkey or wainscot oak	100 ft.	12 ft.	In a sheltered situation about 500 ft. elevation.
8. " . . .	90 ft.	15 ft. 3 in.	About 500 ft. elevation.
9. " . . .	80 ft.	14 ft. 1 in.	" exposed situation.

Of these I cannot now identify Nos. 3 and 6. No. 4 is probably a fine old tree (Plate 326) near the big cork oak, and, in 1908, was 17 ft. 10 in. in girth. No. 5 is probably a very spreading tree with a short bole, near the gardens, which in 1908 measured³ 21 ft. in girth. Besides these there is a group of very tall trees close to the Dawlish Lodge, which Sir R. Newman believes to be some of the earliest planted. The finest of these is at least 90 ft. high by 16½ ft. in girth.

At Tregothnan in Cornwall there are great numbers of this tree, which shade a beautiful drive along the shores of the harbour, but owing to the rocky soil do not attain any great size.

Perhaps the oldest-looking tree which I know of is at Wilton House, close to the mansion, and, though of no great height, its trunk measures no less than 18 ft. in girth, and its branches, which are supported by props, cover an area 90 paces round. Loudon states that in 1810 this tree was 10 ft. in girth.

At Frogmore, there is a large tree, having the leaves much larger than usual, and supposed to have been raised from Algerian acorns, though I can get no exact history of it. It measured about 50 ft. by 17 ft. in 1904; and another close by it with different leaves was 15½ ft. in girth.

¹ Ellis, *The Timber Tree Improved* (1740).

² Loudon, *Gard. Mag.* xi. 127 (1835).

³ The girth, 22 ft., recorded in 1835, may have been taken near the ground.

At Goodwood there are many fine trees in the grounds and in a belt north of the house. Here I measured in 1906 a tree 83 ft. by 7 ft. 7 in.

At Siston Court, Gloucestershire, there is a well-shaped and spreading tree which in 1908 was about 60 ft. by 17 ft. At Epping House, Hertford, Mr. H. Clinton Baker measured a tree 60 ft. by 16½ ft. in 1909.

At Godinton, near Ashford, the seat of G. Ashley Dodd, Esq., there is one of the finest that I have seen in England. This beautiful tree has a short bole 18 ft. 1 in. in girth, dividing into many large spreading branches which reach a height of about 75 ft., and spread over an area no less than 102 paces in circumference. It is a symmetrical tree, in perfect health, and must be considerably over 100 years old.

At Betteshanger, in the same county, Lord Northbourne showed me a tree of the same character, which measures about 50 ft. by 17 ft. at 3 ft. from the ground, and shows the suitability of this tree for a chalky soil, in the south-east of England.

At Cobham Park a beautifully shaped tree measured in 1905, 80 ft. by 15 ft., with a clean bole 20 ft. high. Lord Darnley thought it was surpassed by a tree at Faringford, Lord Tennyson's place in the Isle of Wight; but when I measured this in 1906, I found that, though it covered an area 94 paces round, its trunk, which consists of several stems fastened up by chains, was much inferior to the Cobham tree.

In Somersetshire, Sir C. T. D. Acland showed me a big *Ilex* at Holnicote, a stool with four trunks, about 70 ft. by 17 ft.

In the eastern counties near the coast this tree also thrives at many places, among which Holkham is pre-eminent for numbers and size. The *Ilex* seems to have been a very favourite tree with the late Earl of Leicester and his father, who planted in the park what is now the largest grove of evergreen oaks that I know. In this grove, known as the Obelisk Wood, I measured one in 1903, 75 ft. by 10½ ft., with a clean bole 28 ft. long; and another with a remarkable twisted trunk (Plate 324). A third tree on the outside of this grove, with wide-spreading branches, is shown in Plate 325. At Ken Hill near Snettisham, in Norfolk, the seat of Sir E. Green, there are two fine trees, the largest of which measures about 75 ft. by 19½ ft. at 2 ft. from the ground, dividing at 4 ft. into two main stems.

In Wales the finest I know of is a tree mentioned by Loudon at Stackpole Court, said to be 100 years old in 1838, and then 78 ft. high by 7½ ft. in girth. It is probably the same as one which in 1906 measured 80 ft. by 9 ft. 8 in., and though split to the ground, was kept together by a chain. The best *Ilex* now at Stackpole is a tree on the lawn measuring about 60 ft. by 14 ft. 5 in., whose trunk is curiously gnarled and distorted.

In Scotland the *Ilex* grows well on the south-west coast, especially in the Earl of Stair's grounds at Castle Kennedy, where there is a tree remarkable for its very weeping habit. This tree has five stems forking close to the ground, where it measures 12 ft. 8 in. in girth, and is about 47 ft. high. Another large tree is reported by Mr. Renwick to grow at Mount Stuart, in Bute, the seat of the Marquess of Bute, and to measure 10 ft. 5 in. in girth. At Fullerton House, near Troon, a tree is recorded by Paxton in *Remarkable Trees of Ayrshire*, 11 ft. 9 in. in girth.

As far north as Gordon Castle the *Ilex* is hardy near the coast; and I measured a tree there, which was 45 ft. by 10 ft. 10 in. in 1907.

Possibly the oldest if not the largest tree in Ireland, is one growing at Courtown on the Wexford coast, of which the Earl of Courtown has been good enough to send me a photograph. He believes that it may have been planted by Sir Walsingham Cook, whose mansion and garden were conveyed in 1648 to T. Jones, a sea-captain of Stepney: but in any case is a tree of very great age. In 1884 it was 66 ft. high, dividing into several large trunks close to the ground. At Rossanagh there is a very fine old tree 80 ft. high by 16 ft. 7 in. near the ground, dividing at 3 ft. into two big stems, one of which is 10 ft. 9 in., the other 8 ft. 8 in. in girth.

At Kilruddery Castle, Co. Wicklow, Henry measured two big trees in 1904, one 77 ft. by 14½ ft., the other 77 ft. by 11½ ft., with a bole about 25 ft. high. At Castlemartyr there are many fine old trees, one of which in 1908 measured nearly 100 ft. by 12 ft., with a bole of 30 ft. At Belgrove, near Queenstown, Mr. Gumbleton showed me a very handsome and well-shaped tree about 70 ft. by 14½ ft., the branches over 80 yds. round.

At Doneraile Court, Co. Cork, there is a tree with a short butt, 15 ft. 3 in. in girth, dividing into two main stems about 45 ft. high, with a spread of branches about 80 ft. across. At Cooper Hill, Limerick, Henry saw several very old trees of no great height, but of immense girth, one 21 ft., the other 18 ft., in 1907.

(H. J. E.)

QUERCUS TURNERI, TURNER'S OAK

Quercus Turneri, Willdenow, *Enum. Hort. Berol.* 975 (1809), and *Berlin. Baumz.* 339, t. 3, fig. 2 (1811); Loudon, *Arb. et Frut. Brit.* iii. 1922 (1838).

Quercus hispanica, var. γ , *le chêne Turnère*, Lamarck, *Encyc. Méth.* i. 723 (1783).

Quercus hybrida nana, Loudon, *Arb. et Frut. Brit.* iii. 1924 (1838).

A tree, attaining about 50 ft. in height and 8 ft. in girth, variable in bark and foliage, probably hybrid in origin, the supposed parents¹ being *Q. pedunculata* and *Q. Ilex*. Two distinct forms occur, one with short broad leaves, corresponding to the typical plant described by Willdenow; the other with larger narrower leaves, treated by us as a variety. These two forms are connected by trees intermediate in foliage; and a seedling, about 5 ft. high, raised at Kew in 1894 from an acorn, produced by the narrow-leaved form, has both broad and narrow leaves.

The typical form is characterised as follows:—Young branchlets covered with dense stellate pubescence, glabrescent in the second year. Leaves slightly coriaceous,

¹ The fruit on long peduncles, and the auricles often present at the base of the leaf indicate *Q. pedunculata* parentage. The subevergreen habit, the pubescence on the branchlets and leaves, and the mucronate teeth of the latter, suggest the influence of *Q. Ilex*. The bark usually resembles that of *Q. Ilex* more than the common oak.

falling early in spring, before the new leaves appear, about 3 in. long and 2 in. wide, obovate, rounded or acute at the apex, rounded or slightly auricled at the base, with five to eight pairs of lateral nerves, all but the lowest one or two pairs ending in a sinuate tooth, with a cartilaginous tip, long and bristle-like in young plants, short and blunt in old trees; upper surface dark green, with deciduous scattered stellate hairs; lower surface pale green, with white stellate hairs on the midrib and nerves, elsewhere glabrous or with scattered inconspicuous pubescence; petiole ¼ in. long, densely pubescent.

Fruit ripening in the first year, three to seven, of which only one or two develop, sessile on a slender tomentose peduncle, about 2 in. long; acorn ovoid, about ¾ in. long, with appressed long white hairs towards the apex, which is crowned by the conspicuous tomentose style; cupule about ½ in. in diameter, urceolate, covered with closely appressed grey tomentose ovate scales, reddish at the tips, and diminishing in size from the base to the constricted thin margin of the cupule.

Var. *pseudoturneri*.

Quercus glandulifera, Masters, in *Gard. Chron.* xiv. 714, fig. 134 (1880) (not Blume).

Quercus pseudoturneri, Schneider, *Laubholzkunde*, i. 200, fig. 126 g, h (1904).

Quercus aizoon, Koehne, in *Gartenflora*, liii. 657 (1904).

Usually a smaller tree than the typical form. Leaves (Plate 337, Fig. 45) usually longer and narrower, averaging 4 to 5 in. long and 1½ to 2 in. wide; teeth larger, with mucronate points often obsolete; under surface more pubescent than in the type; base rounded, auricled, or cuneate.

The earliest account of this oak is by Lamarck, who described it in 1783, from a specimen growing in the garden of the Trianon, as *le chêne Turnère*, said to have been found originally as a seedling in England, which was propagated by grafting. Messrs. Loddiges informed Loudon that it was a hybrid, "raised about 1795 or before, by Mr. Spencer Turner, in the Holloway Down Nursery, Essex, which was founded by him about 1787." The latter account is evidently inaccurate as regards dates; but it may be assumed that the oak was raised by Mr. Turner sometime before 1783, when it was well-known to Lamarck. Willdenow¹ founded his description on a plant of the broad-leaved form, growing at Berlin, which had been sent to him by Loddiges. The narrow-leaved variety appears to have been the form more generally propagated, especially by Rivers at the Sawbridgeworth Nursery, where Loudon states that there was a tree forty years old in 1838. It is possible that both forms of foliage occurred on the original tree in Turner's nursery.

In the Bristol Nursery, a tree was found in 1825 in a bed of seedling oaks, which Loudon describes as *Q. hybrida nana*, and this seems to have been a form of *Q. Turneri*, bearing both broad and narrow leaves. It is said by Loudon to have been a bush rather than a tree; but the original plant made fairly rapid

¹ Willdenow's statement that the tree came originally from Tibet is evidently due to a confusion between Spencer Turner, the nurseryman, and Samuel Turner, the famous traveller, who visited Tibet about 1786.

growth, having attained 9 ft. high in twelve years. This was propagated by Messrs. Loddiges, and may be the origin of some of the trees now in cultivation.

(A. H.)

REMARKABLE TREES

Of the typical form, we have identified the following, but it is probable that other trees exist which we have overlooked.

A tree at Ham Manor, Sussex, forking near the ground, and carrying its leaves until after mid-winter. In 1907 it was about 45 ft. high.

A tree at Nuneham Park, with bark like that of the common oak on which it is grafted, measured by Henry in 1907, 48 ft. by 4 ft. 4 in. A tree in the Wilderness at White Knights, grafted on the common oak and not showing much of the *Ilex* character in the bark, measured by me in 1907, when it was 52 ft. by 6 ft. 10 in. above the graft. At Bayfordbury a tree said to have been planted in 1837 with *Ilex*-like bark, 40 ft. by 3 ft. At Henham Hall, Sussex, a tree 50 ft. by 8 ft. At Lyndon, a tree 53 ft. by 6 ft. grafted near the ground on the common oak and showing no trace of the *Ilex* parentage in the bark.

A small tree in the Royal Botanic Garden, Edinburgh, is the only one we have seen in Scotland; but Mr. Bean mentions one 45 ft. high in 1906, which he saw at Kinfauns Castle, Perthshire.

In Ireland there is a tree at Oriel Temple with typical *Ilex*-like bark, which in 1908 was 48 ft. by 4 ft. with a bole about 20 ft. high.

Of the *pseudoturneri* form the best specimen we know of is at Syon, a tree 62 ft. by 4 ft. 4 in., having a clean bole of considerable height injured on one side. At Kew there are several trees of which the largest measures 37 ft. by 5 ft. Their history is unknown and they were unnamed before 1880. In the Sawbridgeworth Nursery there are two trees believed to have been propagated from the original tree by grafting on the common oak. The larger of these measured in 1908 about 50 ft. by 5 ft., and on June 4th had a good many of the previous year's leaves still on it. The other tree, growing in a beech hedge, is much more stunted, and had no old leaves left on it, but was flowering profusely. We have specimens of this form from trees growing at Eastnor Castle; from Alnwick sent by Miss Manders; and from Monreith. I also found a tree at Castlewellan in Ireland.

Judging from all that we know, this hybrid does not seem to have anything to recommend it as an ornamental tree, and is much inferior in size and beauty to the Lucombe oak.

(H. J. E.)

QUERCUS AUDLEYENSIS

Quercus Ilex × *Q. sessiliflora* (?)

At Audley End, Essex, there is a remarkable oak, which we have been unable to identify with any described species, and which is probably a hybrid between the evergreen oak and *Q. sessiliflora*. It is characterised as follows:—

Young branchlets slender, grey tomentose, the tomentum being retained in the second year. Buds $\frac{1}{5}$ to $\frac{1}{4}$ in., ovoid, obtuse, few-scaled, pubescent. Stipules persistent, linear, pilose, $\frac{1}{2}$ in. long, two at the base of each leaf. Leaves (Plate 338, Fig. 59) slightly coriaceous, falling late in the season, up to $3\frac{1}{2}$ in. long and 2 in. broad, very variable in shape on the same branch, narrow elliptical and entire or slightly undulate in margin, or obovate to obovate-oblong with 4 to 5 pairs of sinuate teeth or small lobes in the upper two-thirds, occasionally with one to three teeth near the apex; teeth with or without a minute projecting mucro; nerves five to eight pairs, ending in the teeth or dividing before reaching the margin when it is entire; apex rounded; base unequal, rounded or cuneate; both surfaces stellate pubescent when young, upper surface, when mature, dark green, shining, glabrous; lower surface pale green, retaining the pubescence on the midrib and basal part of the blade; petiole $\frac{1}{2}$ to $\frac{3}{4}$ in. long, with scattered stellate tomentum.

Fruit, imperfect, probably never developing, in pairs at the apex of a short erect tomentose axillary peduncle.

In favour of this oak being a hybrid, may be noticed the instability of form of the leaves on the same branch; some resemble the entire leaves of *Q. Ilex*; others are like the obovate lobed leaves of *Q. sessiliflora*. It agrees with both species in the nervation. The slender tomentose branchlets, minute mucros of the teeth, and the persistent stipules are like *Q. Ilex*, from which it may derive its subevergreen habit.

It resembles superficially some of the forms of *Q. lusitanica* in Portugal, but these have uniform leaves on the same branchlet and are different in venation.

This beautiful oak, the origin of which is unknown,¹ has bark somewhat resembling that of *Q. Ilex*, and measured in 1908, 86 ft. in height and 11 ft. 3 in. in girth (Plate 327). It was reported never to bear fruit; but a few imperfect acorns were formed in 1909.

(A. H.)

¹ Lord Braybrooke informs us that in a catalogue of trees at Audley End, made in 1834, he finds "Lucombe's Oak" mentioned; and as I saw no tree of that species, it is probable that it is the same as the one now described.

QUERCUS SUBER, CORK OAK

- Quercus Suber*, Linnæus, *Sp. Pl.* 995 (1753); Loudon, *Arb. et Frut. Brit.* iii. 1911 (1838); Willkomm, *Forstliche Flora*, 424 (1887); Coutinho, in *Bull. Soc. Brot.* vi. 82 (1888); Mathieu, *Flore Forestière*, 377 (1897).
Quercus suberosa, Salisbury, *Prod.* 392 (1796).
Quercus Bivoniana, Gussone, *Fl. Sicul. Syn.* ii. 604 (1844).

A tree, attaining 60 ft. in height and 20 ft. in girth, usually much smaller. Bark thick and corky, occasionally becoming a foot in thickness on old trunks, which are deeply fissured. Young branchlets covered with a dense greyish tomentum, retained in the second year. Leaves (Plate 339, Fig. 63) coriaceous, persistent two or three years, often convex above and concave beneath, about 2 in. long and $1\frac{1}{4}$ in. wide, variable in shape, ovate or oval, acute or rounded at the apex, unequal at the base; with about six pairs of lateral nerves, all but the lowest one or two pairs, ending in a minute mucronate tooth; upper surface bright green, glabrescent; lower surface covered with a dense grey tomentum; petiole, $\frac{1}{4}$ to $\frac{1}{2}$ in. long, tomentose.

Fruit in the typical form, ripening in the first year, solitary or in pairs on short stout grey tomentose axillary peduncles; acorn $\frac{3}{4}$ to 1 in. long, variable in shape, glabrous, with a tomentose apical umbo; cupule turbinate, $\frac{1}{2}$ to $\frac{3}{4}$ in. in diameter at the rim, covered with grey tomentose scales, reddish at the tips, ovate and short in the basal ranks, long linear and mostly erect in the upper half of the cupule.

Var. *occidentalis*.

- Quercus occidentalis*, Gay, in *Ann. Sc. Nat.* vi. 243 (1856), and in *Bull. Soc. Bot. France*, iv. 449 (1857); Mathieu, *Flore Forestière*, 384 (1897).

Leaves deciduous in June of the following year, when the next season's leaves are already developed. Fruit ripening in the second year; cupules hemispherical, with appressed ovate obtuse grey tomentose scales, red at their tips.

This variety is the only form of the cork oak in the south-west of France, and is also found on the coast of Portugal, where according to Coutinho,¹ the distinction between it and the type disappears, acorns of both kinds being found on the same tree. There the cork oaks flower continuously from January to April. The acorns produced by the first flowers either ripen in September or in October and November, two distinct crops being noticeable. The acorns produced by the last flowers of the season are stopped in their growth by the winter cold, and ripen in the following year, constituting a third crop. The latter, according to Coutinho, have cupules with scales similar to those of *Q. occidentalis* in the Landes.

This variety is, however, considerably hardier than the type, as plantations made in Brittany in 1826 with acorns from the Landes succeeded, while those made with

¹ Daveau, who had much experience in Portugal as well as in Provence, in a pamphlet, *Note sur le Q. occidentalis*, ex *Ann. Soc. Hort. Hérault* (Montpellier, 1899), confirms the opinions of Coutinho.

acorns from Catalonia soon perished. At Nancy, var. *occidentalis* resists the cold of ordinary winters, while the typical form always succumbs in the first winter after planting.

DISTRIBUTION

The cork oak is a native of the Mediterranean region, exclusive of the Levant, and occurs in France, Spain, Portugal, Corsica, Sardinia, Italy, Sicily, Istria, Dalmatia, and Albania; and in northern Africa, in Morocco, Algeria, and Tunis. It is usually found growing wild on granitic or slate soils, and is never seen on limestone formations, where it is replaced by *Q. Ilex*. It usually either forms pure and rather open woods, or is mixed with other oaks; but on sandy soil near the sea-coast is often found scattered in the forests of maritime pine.

In France there are three regions where it flourishes and is of commercial importance: in the Landes and in Lot-et-Garonne; in the Pyrénées Orientales, where it ascends to 1600 ft.; and along the Mediterranean coast from Toulon to Antibes, where it is confined to non-calcareous soils. In Corsica, though large woods are rare, it is widely spread and covers an estimated total area of 18,000 hectares. In Sardinia, nearly all the important woods, which were formerly very fine and of large extent, have been destroyed, except those in the valley of Tempio, where there are fine trees producing an excellent cork. The cork tree is of no great importance on the mainland of Italy, though widely distributed on the western coast; but in Sicily there are extensive forests, often composed of large trees, the most notable between Caltagirone and Terranova having an area of 40,000 hectares.

In Algeria, the principal forests where this species is met with are in the mountainous region close to the sea, from Dellys eastward to the Tunisian frontier, where the annual rainfall exceeds 24 in. Here three species of oak occur, often mixed; but as a rule *Q. Suber* and *Q. Mirbeckii* occupy northern aspects, the former growing on the slopes and crests of the mountains, and the latter in the better soil in the ravines; while *Q. castaneaefolia* is restricted to southern slopes. In Oran and the western part of the province of Algiers, the oak woods are small in extent, and are mainly composed of *Q. Suber*, *Q. Ilex*, and *Q. coccifera*. The total area covered by the cork oak in Algeria is estimated at 426,000 hectares; and the annual production of cork, steadily increasing, amounted in 1899 to about 16,000 tons.

In Tunis, the forests of this species occur in the north-east in the Khroumir mountains, and cover about 82,000 hectares, with an annual production of cork of 1200 to 1500 tons. In Morocco, there are large forests in the Riff mountains between Tetuan and Melilla; and scattered smaller woods are reported in the interior, as far south as Morocco and Agadir; but up to the present these have not been utilised, except in a trifling way.

In Spain, where the woods of *Q. Suber* are estimated to cover an area of 300,000 hectares, the most important are in Catalonia, in the hills close to the sea-coast, where this species is associated with *Pinus Pinea* and *Pinus Pinaster*. There are also extensive forests in Estremadura, and many scattered woods throughout Andalusia.

The Catalonian forests furnish the best quality of cork, that used for champagne bottles; and it was here that about 150 years ago, at San Lorenzo de la Muga, the trees were first artificially treated, so as to produce a better quality of cork than the natural bark affords. Throughout Spain, the forests are poorly treated; natural regeneration is rendered nearly impossible by grazing animals, and artificial plantations are unknown.

(A. H.)

In Portugal, where, according to Lefebvre, the largest amount of cork is produced, the forests are well cared for, and many new plantations are made. In central and southern Portugal the cork oak is one of the commonest and most widely cultivated trees, principally on account of the value of its bark, but also for its acorns. It is usually planted on the drier lands which are ploughed for wheat at intervals of two or three years, and are grazed by sheep and pigs at other times.

In the better cultivated districts it is barked at intervals of eight to ten years, and from about twenty-five to thirty years up to a hundred and fifty or more, when the quality of the cork begins to decline. The bark is taken off the trunk and lower branches down to about 6 in. in diameter, and the trees so treated have a very different appearance to wild or unbarked trees, being comparatively smooth and reddish brown in colour. In the woods near Cintra, on Sir Frederick Cook's property, there are many large and very picturesque trees, which are never barked, and have wide-spreading branches, but they do not here attain anything like the size that they do farther inland, where the soil is stronger and the climate drier.

On the property of Senhor Suares Mendes, near Abrantes, where the lower parts of the valleys running back into the plateau were full of splendid cork oaks, I measured a magnificent tree nearly 60 ft. high, with a trunk about 12 ft. in girth, dividing at about 12 ft. into twenty large branches, which covered an area 25 paces in diameter. Another, which some years previously had been severely lopped, was about 25 ft. in girth, and though of great age seemed to be perfectly sound. In this valley, which reminded me somewhat of the foothills in San Bernardino county, California, the cork trees were scattered at irregular intervals, as though self-sown, and gave the effect of old oaks in an English park. Their produce is very valuable, and I was told by Mr. Percy Ellis of Lisbon, who has a large cork factory, that there was much difference in the quality in different parts of the country, but that the cork of Alemtejo was perhaps equal, if not superior to any in the world. Specimens of the different qualities showing the injuries produced by various causes, which he was good enough to give me, are now in the Cambridge Forestry Museum.

I heard of still larger trees than those which I have mentioned; one between Niza and Povia de Meadas, in Alemtejo, supposed to be 300 years old and growing on granite soil, which seems to suit this tree best, was 18 metres high by 7.20 metres in girth, the diameter of the crown 28 metres; another at St. Anna de Malto in the commune of Concho, 5 metres in girth, produced in 1879, 1465 kilos, and in 1889, 1755 kilos (nearly two tons) of cork. A third, near the Chapel of San Gonçalo, on the road to Palonella, 10 miles south of Lisbon, of which a photograph is given in *Bull. Soc. Tosc. d'Hort.* ser. ii. vol. ii. p. 19 (1887), was 18 m. high by 9 m. in

girth, with bark 20 cm. thick, and supposed to be 400 years old. This tree has produced as much as 800 litres of acorns in one year. The cork tree is known in Portugal as *sobreiro*, and in Spain as *alcornoque* or *suro* in Catalonia, and *sobreiro* in Galicia.

I did not see or hear of any cork trees either in the south-west of France, or on the Riviera, which approached the dimensions above given. In the Esterel mountains between Cannes and Frejus, where it is abundant, the trees rarely exceed about 50 ft. in height and 10 ft. in girth. There is a large cork tree in the Botanic Garden at Florence, believed to have been planted in 1805. When I saw it in February 1910, it measured 80 ft. by 10½ ft., with a clean trunk about 20 ft. high, and a well-shaped spreading crown.

CULTIVATION

I am informed by M. Marc Bazille of Montpellier that all the attempts which have been made in the south of France to graft the cork oak upon the Ilex, with the object of extending its cultivation to the calcareous soils of Provence, have failed, and this is confirmed by Prof. Flahault.

The cork oak is said¹ to have been introduced in 1699 by the Duchess of Beaufort; but the present Duchess, who has been good enough to search the archives at Badminton, was not able to find anything relating to the introduction. Judging from the age of many existing trees it must have become fairly common early in the eighteenth century. It seems to have been usually grown from acorns, which are commonly produced in the warmer parts of the south of England and usually ripen in the second season.² Though it has in one place reproduced itself naturally, it is best to sow the acorns in pots or in a frame, as the seedlings require protection for two or three years at least.

In England the largest³ is the splendid tree at Mamhead Park near Exeter, the seat of Sir R. Newman, Bart., which is now about 60 ft. by 15 ft. 2 in. in girth (Plate 328). This noble specimen grows on red loam at an elevation of at least 400 ft., and is exposed on all sides. A second tree about 50 ft. by 11½ ft. grows near it. At Haldon House, near Exeter, there is a tree only second in size to the one at Mamhead, and even more perfect in shape. In 1908 it was 60 ft. by 9 ft. 4 in., and looked very healthy. At Sidmouth Miss Woolward has photographed a tree over 60 ft. high and 9 ft. 4 in. in girth; and at Powderham, Killerton, and other places in south Devonshire, there are trees nearly as large. At Tregothnan, Mr. A. B. Jackson measured a tree 58 ft. by 9 ft. in 1908.

At Sherborne Castle, Dorset, there is a tree in the walk, east of the old castle, which has been rather drawn up by other trees, and in 1909 was 59 ft. by 8 ft. 2 in. At Claremont there is another which is fast decaying, and of no great height, whose trunk measured in 1903 no less than 16 ft. in girth.

At Pains Hill, in Surrey, there is a fair-sized tree which has reproduced itself naturally from seed, and healthy seedlings were growing in the grass near it in 1903.

¹ Aiton, *Hort. Kew.* v. 289 (1813).² Judging from the few specimens, which we have seen, with ripe fruit.³ Cf. p. 1286.

But in the midland and northern counties the tree seems to suffer so much from exceptionally severe frosts and lack of summer heat, that we know of no good trees.

In the east of England the cork tree is also quite hardy, and at Linton Park, Kent, there is a fine tree, planted by Sir Horace Mann in 1778, which is 50 ft. by 9 ft. At Orwell Park, Suffolk, on the lawn, exposed to the east wind from the North Sea, there is a tree about 40 ft. by 8 ft. whose leaves were only just appearing on 23rd June 1905 when most of the old leaves had fallen. At Henham Hall, Suffolk, the seat of the Earl of Stradbroke, there is a healthy cork tree close to the house, which in 1909 measured about 40 ft. by 11 ft., and sometimes produces ripe acorns.

At Stout Hall, in Glamorganshire, Mrs. Nicholl tells me of a tree which is considered to be the largest in Wales, and which is 50 ft. high by 13 ft. near the ground, where it forks into five or six main stems.

In Scotland the only tree we have on record is one at Mount Stuart, Bute, which, when measured in 1903 by Mr. A. Renwick, was about 20 ft. by 3 ft. 10 in., with a bole 10 ft. high.

In Ireland the only tree we know of large size is one at St. Joseph's Cemetery, near Cork, which Henry measured in 1903, when it was about 50 ft. high, with a short trunk dividing into four stems which measured from $4\frac{1}{2}$ to 6 ft. in girth. The tree at Summerstown, near Cork, figured by Loudon, and said to be 30 ft. by 8 ft. 10 in. below the fork in 1828, has been dead for some years, although, when recently seen by Mr. R. A. Phillips, 6 ft. of the trunk, with the bark quite sound but the timber rotten, was still lying on the ground.

TIMBER. CORK

The timber of the cork tree seems to be little used except for firewood, and to some extent by wheelwrights in Portugal, probably because it is rarely cut until the tree is worn out and partly decayed, and I could not learn that it is ever exported. According to Mathieu, the wood is similar to that of *Q. Ilex*, but is not so homogeneous or fine in the grain, but is equally heavy and hard. A board which was sent me from a tree which died at Blaize Castle, showed very handsome grain when quartered, but the heartwood was discoloured.

The cork naturally produced, what is called in French natural, male, or virgin cork, is of little value on account of its hardness and brittleness, but is taken off the trees when young, which then begin to produce the cork of commerce called female or reproduced cork. This increases in thickness fastest between the second and sixth year, and is usually taken off after eight to ten years, the quality improving with the age of the tree, which may continue to produce marketable cork for 150 to 200 years or even more. When taken off, the slabs are scorched over a fire and pressed to flatten them.

Many details with regard to the commercial production and preparation of cork¹ are given at length by Loudon and other authors, but as the subject has no economic importance to British arboriculturists, we omit them. (H. J. E.)

¹ The best and latest account of the cork tree, with complete statistics of the production, export, and imports of cork throughout the world, is given by Lefebvre, *Forêts de l'Algérie*, pp. 135-326 (1900). Another monograph on the cork oak in its commercial aspect by E. A. Müller, published in *Abh. k.k. Geogr. Ges. Vienna*, 1900, may also be consulted.

QUERCUS SEMECARPIFOLIA

Quercus semecarpifolia, Smith, in Rees, *Cyclop.* xxix. No. 20 (1819); Hooker, *Fl. Brit. India*, v. 601 (1888); Skan, in *Journ. Linn. Soc. (Bot.)* xxvi. 520 (1899); Gamble, *Man. Indian Timbers*, 671 (1902); Brandis, *Indian Trees*, 625 (1906).
Quercus obtusifolia, Don, *Prod. Fl. Nepal*. 56 (1825).
Quercus Cassura, Don, *Prod. Fl. Nepal*. 57 (1825).

A tree, occasionally attaining in the Himalayas 100 ft. in height and 18 ft. in girth, usually considerably smaller. Young branchlets with scattered stellate pubescence. Leaves (Plate 338, Fig. 53) coriaceous, subevergreen, falling a month or two before the new leaves appear, very variable in size and margin; averaging 3 in. long and 2 in. broad; usually elliptical; rounded or rarely acute at the apex; cordate or rarely rounded at the base; margin on old trees undulate-entire, on young trees with spine-tipped serrations or teeth; lateral nerves six to ten pairs, forking before reaching the margin; upper surface dark green, with scattered stellate pubescence, retained on the midrib, soon deciduous elsewhere; lower surface pale, with scattered fine stellate pubescence; petiole $\frac{1}{16}$ to $\frac{1}{2}$ in., stellate-pubescent.

Fruit ripening in the second year, solitary or in pairs, on a short stout pubescent peduncle; acorns globose or ovoid, enclosed at the base in a hemispherical cupule, about $\frac{1}{2}$ in. in diameter, and covered with closely appressed tomentose scales.

This species, which has holly-like leaves, is readily distinguished from *Q. Ilex* by the subevergreen leaves, which have lateral veins always forked before reaching the margin.

It is a native of the Himalayas from Kumaon to Bhutan and Munnipore, occurring at altitudes of 6000 to 12,000 ft.; and also occurs in the mountains of China, in the provinces of Szechwan and Yunnan. Though mentioned by Loudon¹ as one of the Himalayan oaks worthy of a trial in this country, it appears not to have been introduced till lately. Mr. Gamble has raised two plants from acorns received in 1900 from Chakrata in the north-west Himalaya at 9000 ft. These have thriven in his garden at East Liss, Hants, and seem perfectly hardy, their present height being 10 ft. and 15 ft. (A. H.)

¹ *Arb. et Frut. Brit.* iii. 1935 (1838).

QUERCUS INCANA

Quercus incana, Roxburgh, *Hort. Bengal*, 104 (1813), and *Fl. India*, iii. 642 (1832); Hooker, *Fl. Br. India*, v. 603 (1888); Gamble, *Man. Indian Timbers*, 675 (1902); Brandis, *Indian Trees*, 626 (1906).

Quercus dealbata, Wallich, *List*, 2769 (1828-49).

Quercus lanata, Don, var. *incana*, Wenzig, in *Jahrb. bot. Gart. Berl.* iv. pt. i. 222 (1886).

A tree, attaining 80 ft. in height and 12 ft. in girth. Young branchlets white tomentose. Leaves (Plate 335, Fig. 18) coriaceous, persistent two years, 3 to 6 in. long, 1 to 2 in. wide, elliptic-lanceolate, acuminate at the apex, rounded or tapering at the base; with ten to fifteen pairs of lateral nerves, all but the lowest one to three pairs ending in a mucronate triangular serration; upper surface glabrous; lower surface densely covered with white tomentum; petiole $\frac{1}{4}$ to $\frac{1}{2}$ in. long, white tomentose.

Fruit ripening in the second year, solitary or clustered on very short tomentose stalks; acorn ovoid-conic, about an inch long, tomentose with a short cylindrical umbo, enclosed for half its length in a hemispherical cupule, $\frac{1}{2}$ in. in diameter, covered with closely appressed tomentose triangular scales.

This species is a native of the north-western Himalayas at altitudes between 4000 and 8000 ft.

The only specimen we have seen in cultivation is growing in the temperate house at Kew. Mr. Gamble has young plants at East Liss, Hants, which are kept alive with difficulty out-of-doors in winter. This oak has not, however, been tried in the south-west of England or in Ireland, where it would probably be hardy and worth cultivating on account of its handsome foliage. (A. H.)

QUERCUS PHILLYRÆOIDES

Quercus phillyræoides, A. Gray, in *Mem. Amer. Acad.* vi. 406 (1859); Masters, in *Gard. Chron.* i. 632 (1874); Franchet et Savatier, *Enum. Pl. Jap.* i. 446 (1875); Shirasawa, *Icon. Ess. Forest. Japon*, text 58, t. 31, figs. 1-12 (1900).

Quercus Ilex, Linnæus, var. *phillyræoides*, Franchet, in *Journ. de Bot.*, 1899, p. 152; Skan, in *Journ. Linn. Soc. (Bot.)* xxvi. 516 (1899).

A small tree, 20 to 30 ft. high, or a large shrub. Young branchlets densely covered with minute stellate pubescence, retained in part in the second year. Leaves (Plate 339, Fig. 66) coriaceous, persistent two years, $1\frac{1}{2}$ to 2 in. long, $\frac{3}{4}$ to 1 in. broad, oval or obovate-oblong, rounded or acute at the apex, rounded or sub-cordate at the base; lateral nerves inconspicuous, about eight pairs, dividing and looping before reaching the margin; occasionally entire, but usually with four

or five pairs of serrations in the apical half of the blade; upper surface dark green, stellate-pubescent on the midrib, elsewhere glabrescent; lower surface light green, glabrous except for dense pubescence on the base of the midrib, continuous with that on the very short stout petiole.

Fruit ripening in the second year, sub-sessile; cupule hemispherical, about $\frac{3}{8}$ in. in diameter, tomentose within, and covered externally with whitish tomentose closely appressed scales, dark red at the tips; acorn, $\frac{1}{2}$ to $\frac{3}{4}$ in. long, tomentose towards the apex.

This species is a native of Japan, where it was discovered near Simoda; and in recent years has been found in the high mountains of western China in the provinces of Szechwan and Yunnan.

In Kew Gardens, the only place where we have seen this species, it forms an elegant shrub, with dense bright green foliage, and is perfectly hardy. The oldest specimen, which has not yet produced acorns, is about 15 ft. high, and was introduced by Oldham, who made collections in Japan in 1861 and 1862. Smaller specimens, 2 to 6 ft. high, have been obtained since from Japan. (A. H.)

QUERCUS CHRYSOLEPIS

Quercus chrysolepis, Liebmann, in *Overs. Dansk. Vidensk. Selsk. Forhandl.* 173 (1854); Sargent, *Silva N. Amer.* viii. 105, tt. 398, 399 (1895), and *Trees N. Amer.* 257 (1905).

Quercus fulvescens, Kellogg, in *Proc. Calif. Acad.* i. 67 (1855).

Quercus crassipocula, Torrey, in *Pacific R. R. Rep.* iv. 1, p. 137 (1856).

A tree, occasionally attaining 50 ft. in height and 15 ft. in girth, with wide-spreading branches; often shrubby. Bark covered with small appressed scales. Young branchlets with scattered stellate pubescence. Leaves (Plate 338, Fig. 61) coriaceous, persistent three years, very variable in size and shape, often entire on old trees; on young trees, oblong ovate, about 2 in. long and $1\frac{1}{4}$ in. wide, acute and spine-tipped at the apex, broad and usually cordate at the base; margin with twelve to twenty spiny triangular small teeth; upper surface dark green with minute stellate pubescence; lower surface more or less covered with yellow appressed hairs and dotted with minute shining glands; petiole, $\frac{1}{8}$ in. long, pubescent, glandular.

Fruit ripening in the second year, solitary, sessile or sub-sessile; acorn ovoid, variable in length, slightly pubescent at the apex, enclosed at the base in a thick turbinate cupule, covered with triangular scales, hoary at their short free tips, or hidden in a dense yellow tomentum.

This species is extraordinarily variable both in foliage and fruit; and is most readily recognised by the glands on the lower surface of the leaf.

In var. *vacciniifolia*, Engelm., in *Trans. St. Louis Acad.* iii. 393 (1878), a low prostrate shrub, growing on sub-alpine slopes, the leaves are usually oval and entire, and scarcely exceed an inch in length.

This species is more widely distributed than *Q. agrifolia* and *Q. Wislizeni*, the

other Californian evergreen oaks with spiny leaves; as it extends northwards into southern Oregon, southwards to Mt. San Pedro Martir in Lower California, and eastward to the high mountains of southern Arizona, New Mexico, and the province of Sonora in Mexico. It yields valuable wood, which is used in the manufacture of waggon and agricultural implements.

The only specimens which we have seen in cultivation are plants at Kew, 2 to 3 ft. high, raised from acorns obtained from Meehan in 1904. There are also small plants at Coombe Wood.

(A. H.)

QUERCUS GLABRESCENS

Quercus glabrescens, Bentham, *Pl. Hartw.* 56, 348 (excl. syn. *Q. splendens*, Née) (1839); De Candolle, *Prod.* xvi. 2, p. 34 (1864); Liebmann, *Chênes Am. Trop.* t. 39 (1868); Hemsley, *Biol. Centrali-Amer. Bot.* iii. 172 (1882).

A small tree. Bark peeling off in thin quadrangular scales. Young branchlets slender, with scattered stellate pubescence. Buds minute, globose, surrounded by persistent linear pubescent stipules. Leaves (Plate 339, Fig. 67) coriaceous, persistent two years, 2 to 2½ in. long, ¾ to 1 in. broad, obovate-oblong, rounded or sub-cordate at the base, acute at the apex; margin thickened, revolute, with three to six pairs of gland-tipped small teeth above the middle; lateral nerves seven or eight pairs ending in the margin; upper surface dark green, shining, pubescent on the midrib, elsewhere glabrescent; lower surface yellowish, with scattered stellate pubescence; petiole stout, ¼ in. long, stellate-pubescent.

Fruit ripening in the first year, two or three on a pubescent peduncle; acorn ovoid, surrounded in its lower half by a hemispherical cupule, covered with appressed ovate pubescent scales.

This species is a native of the mountains of southern Mexico, and was first described by Bentham, from specimens collected by Hartweg, the locality being unknown, but supposed to be near Real del Monte. Liebmann afterwards, in 1841 and 1842, found it growing on the peak of Orizaba at 8000 to 9000 ft. altitude, and also at Chinantla, Cuesta de Lachopa, and Cerra Leon. It appears to be a small evergreen tree, but its dimensions are not stated. Amongst Liebmann's specimens at Copenhagen, there is an entire-leaved variety of this species, which I have not seen.

This appears to have been one of the trees introduced by Hartweg, who sent all his specimens of oaks, with acorns of some of the species, to the Horticultural Society; but Gordon,¹ in his account of the new plants introduced into the Chiswick Garden in 1840, states that the acorns of this species were presented by Mr. Strangways.

The only tree which survives, so far as we know, is growing in the Botanic

¹ In Loudon, *Gard. Mag.* xvi. 636 (1840). Cf. Loudon, *Trees and Shrubs*, 904 (1842).

Garden of Trinity College, Dublin, and is now about 25 ft. high, with a bole 9½ ft. in height and 2 ft. 5 in. in girth. Mr. S. G. Wild reports that it is healthy and vigorous, and not affected by the winter's cold. It produced acorns in 1905, which apparently did not ripen.

(A. H.)

QUERCUS ALBA, WHITE OAK

Quercus alba, Linnæus, *Sp. Pl.* 996 (1753); Loudon, *Arb. et Frut. Brit.* iii. 1864 (1838); Sargent, *Silva N. Amer.* viii. 16, tt. 356, 357, 358 (1895), and *Trees N. Amer.* 259 (1905).

A tree, attaining in America 150 ft. in height and 18 ft. in girth. Bark grey, on young trees broken into long thin loose irregular scales; on old trunks about 2 in. thick, and divided into broad flat scaly ridges. Young branchlets glabrous, shining. Buds ovoid, obtuse, reddish brown, ⅓ in. long. Leaves (Plate 336, Fig. 33) deciduous in winter, turning reddish before they fall, occasionally withering and persistent during winter, about 7 in. long and 4 in. broad, obovate, cuneate at the base, obtuse at the apex, with seven to nine lobes; terminal lobe truncate, sinuate, or with three lobules, of which the two lateral are unequal in size; lateral lobes oblong, usually entire, variable in width and depth; lateral nerves ending in some of the sinuses as well as in the lobes; upper surface dark green, glabrous; lower surface pale, covered with a very minute pubescence, only discernible with a strong lens, no conspicuous hairs being present on the midrib or nerves; petiole ½ in. long, glabrous.

Fruit ripening in the first year, sessile or on a slender stalk, both forms sometimes occurring on the same branch, single or in pairs; acorn edible, ovoid, rounded at the apex, shining, ¾ in. long, enclosed for one-quarter of its length in a hemispherical cupule, which is covered with tomentose scales thickened and tuberculate in the lower ranks, thin and membranous towards the rim. Individual trees, believed to be hybrids¹ of *Q. alba* with other oaks, have been observed in different parts of North America, the most noteworthy being that with *Q. macrocarpa*. See p. 1304.

The White Oak has a wide distribution, extending northward to lat. 46° in southern New Brunswick, south-western Quebec, and southern Ontario; westward through southern Michigan and Wisconsin to southern Minnesota, south-eastern Nebraska, and eastern Kansas; and southward to northern Florida and the Gulf States as far as the Brazos river in Texas. It is one of the most common oaks of the Mississippi basin and of the Atlantic states, growing both on fertile uplands and on alluvial soil, which is not too moist. It is abundant and of large size in Ontario and the northern borders of the United States, furnishing the "Canadian oak" exported to England, which is now supplemented by large supplies from Ohio and Indiana, and even from Kentucky and west Virginia, by way of the Great Lakes. The tree is most abundant and of its largest size in the alluvial lands of the lower Ohio basin,

¹ These are described and figured by Sargent, *Silva N. Amer.* viii. 18, tt. 359, 360, 361 (1895).

in the Carolinas, and on the western slopes of the Alleghanies in Tennessee, rarely ascending above 2000 ft. in the extreme south.

Prof. Mohr states that in the forests where the white oak originally formed one-fourth to one-half of the timber growth, it is associated with black and Spanish oaks, hickories, beech, black walnut, and tulip tree; towards the north and at high levels in the south, its companions are red oak, scarlet oak, and chestnut; and in the extreme south it is mixed with the Carolina hickory, *Q. Phellos*, *Q. Schneekii*, and *Magnolia acuminata*. The undergrowth is mostly *Cornus*, *Ostrya*, *Carpinus*, *Amelanchier*, and *Cercis*. Where the original forest has been cut down, white oak is scarcely seen in the second growth, the more aggressive species of the red oak group occupying almost exclusively its place. Owing to the difficulty and scarcity of its natural regeneration, together with the fact that forest land suitable for its growth is occupied by the farmer, Prof. Mohr considers that so far as economic interests are concerned, the final extinction of the white oak will take place at no distant date. Even the immense forests of Kentucky and Tennessee are becoming exhausted. Future supplies of white oak must come from the forests south of the confluence of the Ohio and Mississippi rivers, and the sawmills are being moved southwards. Nashville, until a few years ago, was the most important market. At present Memphis, Mobile, and New Orleans are becoming the main centres, where white oak is sawn and marketed.

(A. H.)

Ridgway gives many details of the size of white oak in the bottoms of southern Indiana and Illinois, the largest measured by Dr. J. Schneck in Wabash Co. being 150 ft. by 6 ft. in diameter with a clean bole 60 ft. long. The average of ten trees here was about 125 ft. in height by 4 ft. in diameter, whilst on the uplands in the same district the average height was only 100 ft. by 2'40 ft. in diameter.

In an article¹ on this tree by Sargent, good illustrations are given of the white oak in summer and winter from a tree growing in the grounds of Mr. Fearing, near Jobstown, New Jersey, which shows the form the tree assumes when grown in the open, like the park oaks of Great Britain; but though he says that the white oak in girth of stem and stoutness of branches is not second to its Old-World relative, the dimensions given by various writers do not show that any trees now exist which can rival our big English oaks. The tree in question is of no great height, and has a very short bole, 18 ft. in girth at 3 ft. from the ground. It is remarkable for its very wide-spreading and well-shaped crown, which covers a space 120 ft. in diameter.

Sargent also gives² a picture of a very beautiful and well-shaped tree at Shandy Hall, Maryland, which is 36 ft. in girth at the ground and 22 ft. just below the first limb at about 10 ft. The spread of the branches covers a circle 122½ ft. in diameter. In size, shape, and appearance, this tree is very similar to the Bourton Oak (Vol. II. Plate 93). In *Gard. Chron.* xxxiv. 51, figs. 19 and 20 (1903), some very large and old white oaks growing in the State reservation at Waverley, near Belmont, Massachusetts, are described and figured. The largest is about 80 ft. by 25 ft. in girth at 5 ft., and its age is estimated at 800 years, though there is no

¹ *Garden and Forest*, iv. 1, figs. 1, 2 (1891).

² *Ibid.* v. 254, fig. 50 (1892).

evidence that this species attains so great an age. It is said that during 100 years no seedling white oaks have come up in the reservation.

Prof. Sargent took me to see a fine white oak at Ponkapoug pond, near Boston, which was also very like an English park oak in habit, and measured about 60 ft. by 15 ft., with a spread of 40 paces. What was to my mind even more striking was the inhabited house of a settler dating from 1704, the white oak timbers and part of the weather-boarding of which was still quite sound, though unpainted for 200 years.

This oak has been repeatedly tried¹ in this country since its introduction in 1724, but has never thriven in our climate, the only specimens, except nursery plants at Kew, which we have seen² being a stunted tree at Tortworth, scarcely 20 ft. high, which was planted many years ago; and some plants at Aldenham, with sickly yellow foliage, planted eight years ago and reputed to be twenty years old from seed.

It seems to do rather better in France, where there are three trees at Les Barres in the old nursery, and some smaller ones which are not thriving. The best of them measure from 40 to 45 ft. high, and some produce acorns. At Verrières le Buisson, near Paris, in M. Philippe de Vilmorin's garden, there is a fairly healthy and well-grown tree, which, when I saw it last in 1905, measured 58 ft. by 4 ft. 2 in.

(H. J. E.)

QUERCUS LYRATA, OVERCUP OAK

Quercus lyrata, Walter, *Fl. Car.* 235 (1788); Loudon, *Arb. et Frut. Brit.* iii. 1871 (1838); Sargent, *Silva N. Amer.* viii. 47, t. 374 (1895), and *Trees N. Amer.* 268 (1905).

A tree, attaining in America 100 ft. in height and 9 ft. in girth, but usually smaller. Bark broken into scaly plates. Young branchlets glabrous. Leaves (Plate 336, Fig. 31) deciduous and turning scarlet in autumn, 6 to 8 in. long, 2 to 3 in. wide, obovate, cuneate at the base, obtuse or acute at the apex, with five to nine lobes, the upper two lateral lobes broad, emarginate, and much larger than the middle and basal triangular lobes; upper surface dull green, with quickly deciduous minute scattered pubescence; lower surface pale, covered throughout with a minute pubescence; petiole ¼ to ⅝ in. long, glabrous or with a few hairs.

Fruit ripening in the first year, sessile or on slender pubescent stalks; acorn pubescent in its upper half, almost or entirely enclosed in a nearly spherical thin cupule, pubescent within and covered with ovate tomentose scales, thick and twisted in the basal ranks, thinner and forming a ragged edge at the margin of the cupule.

This species is a native of river swamps and wet alluvial land, from Maryland

¹ Loudon, in *Gard. Mag.* xix. 124 (1843), states that hundreds, even thousands of pounds, had been spent fruitlessly in the importation of acorns from America. In 1843, 30,000 plants which had been sent from New York, packed with moss in barrels, were said to have been thriving in a favourable soil in Surrey, but doubtless these soon perished.

² Loudon's account in *Arb. et Frut. Brit.* iii. 1868 (1838), of white oaks of large size in England is erroneous. In *Gard. Mag.* xviii. 656 (1842), he admits that there was only one tree known to him in England, growing in Loddiges' nursery. This was probably a young specimen. A supposed *Q. alba* at Muswell Hill was cut down in 1839, and a tree bearing that name at York House, Twickenham, was ascertained to be *Q. Prinus* by Loudon. Henry visited York House in 1904, and found no trace of this American oak.

south to Florida, and westward through the Gulf States to Trinity river, Texas, ascending the Mississippi basin to southern Indiana and Illinois, most common and attaining its largest size in Louisiana.

The overcup oak was introduced¹ by Fraser in 1786, but Loudon only mentions in 1838 a small plant in Loddiges' nursery. Probably neglected by nurserymen, and unsuited for our climate, it is now nearly unknown in cultivation, the only specimens which we have seen being two trees in Kew Gardens, about 10 ft. high, which were obtained from the Arnold Arboretum in 1897. (A. H.)

QUERCUS MACROCARPA, BURR OAK

Quercus macrocarpa, Michaux, *Hist. Chênes Am.* No. 2, tt. 2, 3 (1801); Loudon, *Arb. et Frut. Brit.* iii. 1869 (1838); Sargent, *Silva N. Amer.* viii. 43, tt. 371, 372, 373 (1895), and *Trees N. Amer.* 267 (1905).

Quercus olivæformis,² Michaux f., *Hist. Arb. Am.* ii. 32, t. 2 (1812); Loudon, *Arb. et Frut. Brit.* iii. 1869 (1838).

A tree occasionally attaining in America 170 ft. in height and 20 ft. in girth. Bark, 1 to 2 in. thick, deeply furrowed, and broken on the surface into irregular flattened scales. Young branchlets stout, with a minute pubescence, gradually disappearing in summer. Buds ovoid, $\frac{1}{8}$ to $\frac{1}{4}$ in. long, greyish tomentose; the terminal bud surrounded by persistent stipules. Leaves (Plate 336, Fig. 29) deciduous in autumn, turning dull brown before they fall, 6 to 12 in. long, 3 to 6 in. wide, obovate, rounded or acute at the apex; variable in outline, usually with five to seven lobes, the terminal lobe large, ovate, and crenately toothed, the lower lobes smaller, oblong, and separated by deep sinuses; occasionally, more regularly divided into more numerous shallower lobes; upper surface yellowish green, with quickly deciduous scattered hairs; lower surface pale, covered with a minute appressed pubescence, disappearing in greater part before the end of summer; petiole stout, pubescent, $\frac{1}{2}$ to 1 in. long.

Fruit ripening in the first year, solitary or in pairs, sessile or long-stalked, variable in size and shape; acorn usually broad, ovoid, rounded or depressed at the apex, from $\frac{1}{2}$ in. long in the north to 2 in. long in the south; cupule usually hemispheric, thick, pubescent within, covered externally with grey tomentose scales, tuberculate below, prolonged into awn-like tips above, forming a fringed border to the cupule.

Q. macrocarpa is remarkable for the corky wings³ on the branchlets, sometimes an inch or more in width, when these are three or four years old.

A supposed hybrid⁴ between this species and *Q. alba* was first discovered by M. S. Bebb at Fountaindale, Illinois, and has since been found in other localities.

¹ Aiton, *Hort. Kew.* v. 295 (1813).

² This name was applied by Michaux to trees with deeply lobed leaves and small fruit; but the foliage is so variable on this species, even on the same individual, that it is doubtful if it can be maintained even as a varietal name.

³ Cf. Miss Gregory, in *Bot. Gaz.* xiii. 254, pl. xxii. (1888).

⁴ *Quercus Bebbiana*, Schneider, *Laubholzkunde*, i. 201 (1904).

A tree¹ of this kind is growing in the Arnold Arboretum, from the acorns of which Elwes has raised seedlings, which are not, however, growing vigorously at Colborne, where the summers are too short and cold for it. (A. H.)

This is one of the most widely distributed oaks in North America, and extends farther to the northward and westward than any other of the eastern species. Its natural range is from Manitoba, the eastern foothills of the Rockies in Montana, the Dakotas, Nebraska, central Kansas, Indian Territory, and eastern Texas, eastward to the Atlantic coast. In the north-western states and about the Great Lakes, it sometimes grows in pure stands, forming the characteristic "oak openings," which are an intermediate region between the prairie and the forest. It resisted well the fires which constantly swept over this country before it was settled. An excellent picture of the type of tree found here is given in *Garden and Forest*, iii. 407 (1890), representing an oak near Whitewater, Wisconsin. In Manitoba, according to Macoun,² it forms thickets and open forests in many parts, sometimes becoming a fine tree, but dies out west of the Assiniboine. In Nova Scotia, New Brunswick, and westward through the valley of the St. Lawrence to Ontario, it is not so common and does not attain as large a size as *Q. alba*. It is most abundant and most important in the low ground of the Mississippi basin, where it is associated with white oak, lime, white ash, poplar, black walnut, and hickories. The largest dimensions given by Ridgway are of trees in Wabash county, Illinois, measured by Dr. J. Schneck—165 ft. by 22 ft., with a trunk 72 ft. long; and 162 ft. by 20 ft. East of the Alleghanies it is rare and local; and in the northern and north-western limits of its distribution, where the climate is cold and very dry, it dwindles to a mere shrub.

This species was introduced into England in 1811, but was rare in Loudon's time. Like most of the white oaks from eastern North America, it cannot be said to thrive in this country. From acorns which I gathered from a tree of no great size near Ottawa, I raised seedlings which, at first, were more vigorous than any of the American oaks that I raised at the same time, except the hybrid between this species and *Q. alba*, but are now, like the latter, apparently suffering from the soil and climate.

The best specimen we have seen is a tree at Eastnor Castle, which was 40 ft. high by 3 ft. in girth in 1905. Smaller trees are growing at Hildenley, Yorkshire, in Kew Gardens, at Tortworth, Orton, Fota, and Castlewellan. It does not appear to ripen fruit in this country, but I collected specimens with ripe acorns in September 1907 from a tree in M. Allard's arboretum at Angers, France. At Les Barres it seems to endure calcareous soil better than other American oaks, and has attained 13 metres in height; but Pardé does not think it likely to have any value as a forest tree in France.

According to Pinchot,³ the burr oak is one of the most valuable hardwood trees in North America. The wood is heavy, hard, very strong, and durable; and in the market is not distinguished from white oak, and is used for the same purposes.

(H. J. E.)

¹ This tree is one of several raised in the Arnold Arboretum from acorns taken from a hybrid oak growing near Charle-ville, Vermont. They reproduce the foliage of the parent, and grow more rapidly than trees of *Q. alba* and *Q. macrocarpa* in the same plantation. Cf. Sargent, *Silva N. Amer.* viii. 18, note 3, t. 350 (1895).

² In *Proc. Roy. Soc. Canada*, xii. pt. 4, p. 12.

³ U.S. Forest Service Circular No. 56 (1907).

QUERCUS LOBATA, CALIFORNIAN VALLEY OAK

Quercus lobata, Née, *Ann. Cienc. Nat.* iii. 277 (1801); Sargent, *Silva N. Amer.* viii. 23, t. 362 (1895), and *Trees N. Amer.* 261 (1905).

Quercus Hindsii, Bentham, *Bot. Voy. Sulphur*, 55 (1844).

Quercus longiglанда, Frémont, *Geograph. Mem. Upper California*, 15, 17 (1848).

A tree, attaining in California 100 to 130 ft. in height, with a trunk often 12 ft. and occasionally 20 to 30 ft. in girth. Bark about an inch thick, with small loosely appressed scales. Young branchlets slender, minutely pubescent. Buds ovoid, acute, $\frac{1}{8}$ in. long, pubescent. Leaves (Plate 336, Fig. 30) deciduous in autumn, 2 to 3 in. long, 1 to $1\frac{1}{2}$ in. broad, obovate or oblong, cuneate or rounded at the base, obtuse at the apex, with seven to eleven lobes, separated by sinuses of varying depth, the lateral lobes truncate or bidentate at their broad apex or triangular-ovate; upper surface dark green, with scattered minute stellate pubescence; lower surface paler, with denser similar pubescence; margin ciliate; petiole $\frac{1}{8}$ to $\frac{1}{2}$ in. long, pubescent.

Fruit ripening in the first year, sub-sessile, solitary or in pairs; acorns conical, elongated, 1 to 2 in. in length; cupule hemispheric, tomentose, the scales towards the base thickened and tuberculate, the others with long acute ciliate tips, the uppermost forming a fringe-like margin to the cupule.

This splendid tree is found in the valleys of western California, between the Sierra Nevada and the ocean, from the upper Sacramento to Tejon Pass. Alone or mixed with *Q. Wislizeni* and *Q. Douglasii*, it forms large open park-like groves. The Ukiah valley a few years ago was a vast forest of oaks, many of which still survive and are of a large size, Carl Purdy¹ having measured here in 1897 one tree 132 ft. high and 23 ft. 9 in. in girth, and another 120 ft. by 19 $\frac{1}{2}$ ft. A heavy rainfall, rich soil, and sheltered situation have produced these surprising dimensions, unequalled by any other oaks on the Pacific Slope. Mr. Shinn² describes and figures a grove near Visalia, about 150 acres in extent, with trees 55 to 94 ft. in height and 11 to 15 ft. in girth. These grow on a heavy alluvial soil, rich in alkaline salts. Hilyard³ also notices the growth of this tree on slightly alkaline soil, as in the delta lands of the Kaweah valley, where it forms a dense forest.

Mr. F. R. S. Balfour tells us that these oaks are the most conspicuous landmarks in the great central valleys of Sacramento and San Joaquin. They now stand solitary and stately in the vast expanse of wheat and barley in the grain tracts of Fresno, Merced, and other counties, which are now under cultivation. These trees were left to give shade in former times, when these districts were devoted to cattle-raising. The wood is remarkably brittle, and can only be used for firewood.

The date of introduction into Europe is uncertain; but Koch⁴ had seen

¹ In *Garden and Forest*, x. 52, fig. 8 (1897).

³ *Soils*, 480 (1906).

² *Ibid.* x. 202, figs. 25, 26 (1897).

⁴ *Dendrologie*, ii. 2, p. 54 (1873).

specimens in 1873 from Simon-Louis's nursery at Metz. It is rare in cultivation,¹ the only specimens which we have seen being a tree at Tortworth, about 20 ft. high, and another at Kew, about 30 ft. The latter is a narrow pyramidal fast-growing tree, the date of planting of which is unknown. (A. H.)

QUERCUS BICOLOR, SWAMP WHITE OAK

Quercus bicolor, Willdenow, in *Neue Schrift. Gesell. Natfr. Berlin*, iii. 396 (1801); Sargent, in *Bot. Gaz.* xlv. 226 (1907).

Quercus platanoides, Sudworth, *Rep. Agric. U.S.*, 1892, p. 327 (1893); Sargent, *Silva N. Amer.* viii. 63, tt. 380, 381 (1895), and *Trees N. Amer.* 269 (1905).

Quercus Prinus, β *platanoides*, Lamarck, *Dict.* i. 720 (1783).

Quercus alba palustris, Marshall, *Arbust. Am.* 120 (1785).

Quercus Prinus, β *tomentosa*, Michaux, *Hist. Chênes Am.* t. 9 (1801); Loudon, *Arb. et Frut. Brit.* iii. 1876 (1838).

Quercus Prinus discolor, Michaux f., *Hist. Arb. Am.* ii. 46, t. 6 (1812).

Quercus Prinus, β *bicolor*, Spach, *Hist. Vég.* xi. 158 (1842).

A tree, attaining in America occasionally 100 ft. in height and 25 ft. in girth, usually much smaller. Bark of young trees separating into large membranous persistent scales, curling back and exposing the inner bark; on old trunks fissured into broad flat scaly ridges. Young branchlets glabrous. Buds ovoid, obtuse, pubescent, $\frac{1}{8}$ in. long. Leaves (Plate 336, Fig. 37) deciduous in autumn, 5 to 6 in. long, 2 to 4 in. broad, obovate, rounded or acute at the narrowed apex, cuneate at the base, with six to eight pairs of rounded or acute small lobes; nerves more numerous than the lobes; upper surface shining green, with quickly deciduous scattered hairs; lower surface pale, often silvery white, covered with a dense tomentum, velvety to the touch; petiole about $\frac{1}{2}$ in. long, slightly pubescent.

Fruit ripening in the first year, usually in pairs, on pubescent stalks; acorn edible, ovoid, about an inch long, pubescent at the apex, enclosed for one-third its length in a thick hemispherical cupule, covered with tomentose scales, those near the base thickened with twisted tips, those near the margin thinner and often forming a fringe-like rim.

A hybrid² between this species and *Q. alba* was discovered in 1894 by J. G. Jack at Chateaugay in Canada.

Q. bicolor is a native of Canada and of the northern and central parts of the United States, extending from the southern peninsula of Michigan, Ontario, southwestern Quebec and southern Maine, southwards to the District of Columbia and northern Kentucky; extending along the Alleghany mountains to northern Georgia; and westwards to Iowa, Missouri, and Arkansas. It usually grows in small groves on the borders of streams and swamps, in moist fertile soil, but is nowhere abundant, and attains its largest size in western New York and northern Ohio. (A. H.)

¹ Sargent, in *Silva N. Amer.* viii. 25, states that *Q. lobata*, like the other Californian oaks, does not succeed beyond the borders of its native state, and that attempts to establish it in eastern America and in Europe have not been successful.

² *Q. Jackiana*, Schneider, *Laubholzkunde*, i. 202 (1904).

An excellent account of this oak in *Garden and Forest*, iv. 241 (1891) says that in its young state, and until it has reached 20 to 30 ft. high, this species develops short stout branches which are very persistent and generally pendulous, as shown in the plate which accompanies the article. The bark separates into long thin papery scales, which remain long on the young trees, and give them a ragged appearance. I have noticed these peculiarities, in a minor degree, on some English-grown trees. The foliage of this oak when newly unfolded in spring is extremely beautiful, the upper surface being bronzed or green, and the lower side covered with white down. In autumn, however, they have no red or orange tints. Sargent says that the largest tree of this kind on record formerly grew at Wadsworth, on the Genesee river, New York, and measured 24 ft. in girth at the narrowest part of its trunk. As the timber is even more valuable than that of the white oak, and the trees bear transplanting better than that species, Sargent recommends planting it in deep moist soils.

In England, however, though introduced probably about 1800, the tree is very rare, and none of the specimens which we have seen look very thriving. Perhaps if it were planted on deeper and moister soils, free from lime, in the south of England, it might do better, but the seedlings raised from acorns collected in 1904 at Boston soon died at Colesborne. Loudon mentions no trees except small ones in the gardens of the Horticultural Society and of Loddiges.

The largest we know of is a tree at Syon, 59 ft. by 5½ ft., which seems healthy. Another at Arley Castle, planted about 1820, No. 36 of *Hortus Arleyensis*, was 50 ft. by 3 ft. 3 in. in 1904. A third at Corsham Court, growing in damp soil, measured 47 ft. by 3 ft. in 1905, and looked fairly healthy, though the twigs seemed to have been repeatedly cut back by frost. A small tree at Kew, with the bark scaling like that of a hickory, is healthy, but grows slowly. There is a well-grown tree in a rather cold and exposed situation at Lyndon Hall (Plate 329), 52 ft. by 4 ft. 3 in. This, when I saw it in 1909, had a large wound at 7 ft., nearly covered over by new wood, and though many young twigs were dead, there was still plenty of healthy foliage on 12th October.

In France the finest tree that I have seen is one at Verrières, 65 ft. by 6 ft. 1 in. in 1909. There is a tree about 35 ft. high in the collection at Les Barres, catalogued by Pardé as *Q. bicolor*, which was formerly named *Q. alba*. Prof. Sargent and Mr. Proctor, who saw it, considered it to be *Q. bicolor*, but Mr. Rehder, who saw it still later, thought that it was a hybrid between *alba* and *bicolor*.¹

(H. J. E.)

¹ Pardé, *Arb. Nat. des Barres*, 289, note 1 (1906).

QUERCUS PRINUS, CHESTNUT OAK

Quercus Prinus, Linnæus, *Sp. Pl.* 995 (1753); Loudon, *Arb. et Frut. Brit.* iii. 1872 (1838); Sargent, *Silva N. America*, viii. 51, tt. 375, 376 (1895), and *Trees N. America*, 272 (1905).
Quercus montana, Willdenow, *Sp. Pl.* iv. 440 (1805).
Quercus Castanea, Emerson, *Trees Mass.* 137, t. 5 (1846).

A tree, occasionally attaining in America 100 ft. in height and 20 ft. in girth, but usually much smaller. Bark on young trees smooth, thin, shining, purplish brown; on old trunks about an inch thick, dark in colour, and divided into broad rounded scaly ridges. Young branchlets stout, glabrous. Buds ovoid, pointed, about ¼ in. long, pubescent at the tip, with reddish brown glabrous ciliate scales. Leaves (Plate 336, Fig. 36) deciduous in autumn, turning a dull orange or rusty brown before they fall, averaging about 6 in. long and 3 in. broad, obovate or elliptical; usually unequal and cuneate, rarely rounded at the base; apex acute or shortly acuminate; lateral nerves 10 to 13, each ending in a rounded or acute oblique crenate tooth; upper surface dark green, shining, glabrous; lower surface pale, covered with a fine pubescence, disappearing in summer; petiole glabrous, ½ to 1 in. long.

Fruit ripening in the first year, on stout stalks about ¾ in. long, single or in pairs; acorn ovoid-oblong, about an inch long, shining, glabrous, enclosed nearly half its length in a thin hemispherical cup, pubescent within, and roughened or tuberculated externally, especially near the base, by the small appressed greyish pubescent scales, which are thickened in the centre and free at their tips.

This species closely resembles in foliage *Q. Mirbeckii*; but the leaves of the latter species are readily distinguished by the brown fluffy pubescence along the midrib on the lower surface.

The allied species, *Q. Michauxii*, Nuttall, formerly considered to be a variety of *Q. Prinus*, is not in cultivation, but is distinguished in the key, and figured on Plate 336, Fig. 34.

The chestnut oak ranges from southern Maine, the valley of the Genesee in New York, and the Bay of Quinte in Ontario, southwards to north-eastern Maryland, and along the Alleghany Mountains through the western portions of the Carolinas to northern Georgia and Alabama, becoming, however, in these two states small in size and confined to high altitudes, 2000 to 4500 ft. In the north, in Ontario and New England, it is rare and local and of no commercial importance. It is most abundant in the Alleghany Mountains from southern Pennsylvania, through Virginia, West Virginia, and Kentucky to central and eastern Tennessee. The tree is now found mostly on poor land, or on exposed hill-sides and high rocky ridges, where it often forms a quarter or a third of the hardwood forest in such situations, while on lower slopes and on alluvial land it seldom forms more than 5 per cent. It is mainly associated with *Q. velutina*, *Q. alba*, and hickories, and is slow in growth and intolerant of shade; and on this account tends to be excluded from the better soils and low altitudes, where hemlock, maple, and beech predominate.

A good illustration of the trunk and peculiar bark of this tree, taken from the Washington oak at Fishkill on the Hudson river, is given by Sargent,¹ who says that it may be eight or ten centuries old, and was 7 ft. in diameter in 1888.

This was one of the first American oaks introduced. Mentioned by Ray² in 1688, it was first figured and described by Plukenet³ three years later, and is included⁴ amongst the trees for sale in the Catalogue of the Society of Gardeners, published in 1730.

In Loudon's time it was a rare tree, as he only notices plants in Loddiges' nursery and in the Chiswick Garden. It apparently has not been successful in our climate, as the only specimens⁵ which we have seen are small trees at Kew and at Westonbirt.

According to Foster and Ashe,⁶ this species is becoming more valuable as a timber tree than formerly, as the wood is now used as a substitute for white oak. The best qualities are mixed with white oak and sold under that name. The wood is heavy, strong, tough, close-grained, and durable in contact with the soil, but is inclined to check in drying. It is dark brown in colour, with paler sapwood. Slightly softer than white oak, it does not take so high a polish. The medullary rays are not so broad as in the white oak, and when quarter-sawn the silver grain is not so pleasing. In western Virginia half the railway sleepers are now made of chestnut oak, where white oak was once the only wood accepted. In the northern factories it is now being put to uses for which only a few years ago white oak was considered essential, as for furniture, farm implements, tool handles, oil barrels, interior finish, and wagons. The inferior kinds are often marked with black specks, due to the burrowing of a minute larva.

Until about 1900 the great bulk of the chestnut oak was cut for the bark alone, the timber being abandoned in the forest. The bark is richer in tannin than any other of the eastern American oaks, and is still much used in local tanneries, and is also made into tannic acid for export.

(A. H.)

QUERCUS MUEHLENBERGII, YELLOW OAK

Quercus Muehlenbergii, Engelmann, in *Trans. St. Louis Acad.* iii. 391 (1878); Sargent, in *Bot. Gaz.* xlv. 226 (1907).

Quercus Prinus acuminata, Michaux, *Hist. Chênes Am.* No. 5, t. 8 (1801); Loudon, *Arb. et Frut. Brit.* iii. 1875 (1838).

Quercus acuminata, Sargent, in *Garden and Forest*, viii. 93 (1895), *Silva N. Amer.* viii. 55, t. 377, (1895), and *Trees N. Amer.* 273 (1905).

Quercus Castanea, Willdenow, *Neue Schrift. Gesell. Natfr. Berlin*, iii. 396 (1801) (not Née).

A tree, occasionally attaining in America 160 ft. in height and 12 ft. in girth above the broad and often buttressed base. It is mainly distinguished from

¹ In *Garden and Forest*, i. 511, fig. 81 (1888).

² *Historia Plantarum*, ii. 1801 (1688).

³ *Phytographia*, t. 54, f. 3 (1691).

⁴ Cf. Loudon, *Arb. et Frut. Brit.* i. 68 (1838).

⁵ The tree figured under this name in *Gard. Chron.* xiv. 617, fig. 101 (1893), is *Q. Mirbeckii*.

⁶ U.S. Forest Service Circular No. 135 (1908).

Q. Prinus by the narrower leaves (Plate 336, Fig. 35), 4 to 7 in. long and 2 to 3 in. wide, with long narrow or short broad apices; with eight to ten pairs of inflexed teeth, glandular at their tips; upper surface yellowish green, glabrescent; lower surface pale with scattered minute pubescence; petiole $\frac{1}{2}$ to 1 in. long, glabrescent.

Fruit smaller than in *Q. Prinus*; acorn broadly ovoid, $\frac{1}{2}$ to $\frac{3}{4}$ in. long; cupule hemispherical, pubescent within, covered with appressed ovate tomentose scales, the lower ranks thickened, those above with free tips forming a fringe-like margin to the cupule.

This is the most important of the chestnut oaks, being more widely distributed than *Q. Prinus*, extending farther westward to Nebraska, Kansas, Indian Territory, and the Guadalupe mountains, Texas. It is rare and local in the Atlantic States, where it is usually found growing on limestone soils, from the district of Columbia and the valley of the Potomac northwards to Lake Champlain and southern Ontario. It is very abundant west of the Alleghany mountains, attaining an enormous size in the luxuriant forest of the Wabash valley in Indiana and Illinois.

Ridgway says of this tree¹ that it may be recognised at a distance by its thin-scaled very light-coloured bark and tall slender growth, being probably the tallest in proportion to its diameter of any of the white barked species. The tallest, however, that he measured was 130 ft. high by 13 ft. in girth; another 122 ft. high and 84 ft. to the first fork, was only $3\frac{1}{2}$ ft. diameter on the top of the stump. He describes the acorns as very small and sweet, much resembling the nuts of *Castanea pumila* in appearance and taste. The wood is said to be tougher than that of *Q. alba*, and much used by wagon-builders.

This species, though said by Loudon to have been introduced in 1822, is one of the rarest oaks in cultivation in Europe. The only specimens which we know of are two trees, about 8 ft. high, at Aldenham, which were procured, under the name *Q. Esculus*, about eight years ago from a German nursery. The yellow-green leaves, turning scarlet or orange in autumn, are handsome and peculiar, owing to their wrinkled uneven margin, caused by the teeth being turned inwards and upwards.

(A. H.)

QUERCUS PRINOIDES

Quercus prinoides, Willdenow, in *Neue Schrift. Gesell. Natfr. Berlin*, iii. 397 (1801); Sargent, *Silva N. Amer.* viii. 59, t. 378 (1895).

Quercus Prinus humilis, Marshall, *Arbust. Am.* 125 (1785).

Quercus Prinus pumila, Michaux, *Hist. Chênes Am.* No. 5, t. 9, f. 1 (1801); Loudon, *Arb. et Frut. Brit.* iii. 1875 (1838).

Quercus Prinus Chincapin, Michaux f., *Hist. Arb. Am.* ii. 64, t. 10 (1812).

Quercus Chincapin, Pursh, *Fl. Am. Sept.* ii. 634 (1814).

Quercus Muehlenbergii, var. *humilis*, Britton, in *Bull. Torrey Bot. Club*, xiii. 41 (1886).

A shrub, 12 to 15 ft. high. Young branchlets glabrous. Buds ovoid, obtuse, glabrous, $\frac{1}{8}$ in. long. Leaves (Plate 336, Fig. 38) deciduous in autumn, turning

¹ *Proc. U.S. Nat. Mus.*, 1882, p. 82 (in separata).

orange and scarlet before falling, about 4 in. long and 2 in. broad, obovate or ovate, acute at the apex, cuneate at the base; with four to seven pairs of acute or rounded teeth; lateral nerves five to eight pairs; upper surface dark green, with scattered glandular hairs; lower surface pale, with scattered minute pubescence; petiole glabrous, $\frac{1}{4}$ to $\frac{1}{2}$ in. long.

Fruit ripening in the first year, clustered, sessile; acorn edible, ovoid, $\frac{1}{2}$ to $\frac{3}{4}$ in. long, white pubescent and rounded at the apex, enclosed for half its length in a hemispherical cupule, pubescent within, and covered with grey tomentose scales, large and thickened in the lower ranks, thin and forming a fringe-like rim at the upper margin of the cupule.

This is usually a low shrub, spreading by root suckers, and growing on rocky slopes and hill-sides. It is distributed from Massachusetts to North Carolina, extending westward to Nebraska, Kansas, Indian Territory, and eastern Texas, where it is often seen on the low undulating prairies.

It was introduced in 1823, but is very rare in cultivation, the only specimens which we have seen being at Kew and Tortworth, where it does not appear to bear fruit.

(A. H.)

QUERCUS OBTUSATA

Quercus obtusata, Humboldt and Bonpland, *Pl. Æquin.* ii. 26, t. 76 (1813); Loudon, *Arb. et Frut. Brit.* iii. 1942 (1838); De Candolle, *Prod.* xvi. 2, p. 27 (1864); Hemsley, *Biol. Centrali-Amer. Bot.* iii. 175 (1882).

Quercus pandurata, Humboldt and Bonpland, *Pl. Æquin.* ii. 28, t. 77 (1813); Loudon, *Arb. et Frut. Brit.* iii. 1942 (1838).

Quercus ambigua, Humboldt and Bonpland, *Pl. Æquin.* ii. 51, t. 93 (1813) (not Michaux).

Quercus Hartwegi, Benth., *Pl. Hartweg*, 56 (1839).

Quercus affinis, Martens et Galeotti, in *Bull. Acad. Brux.* x. 222 (1843).

Quercus nudinervis, Liebm., in Seemann, *Bot. Herald*, 334 (1852-57), and in *Overs. K. Dansk. Vidensk. Selsb. Forhand.*, 1854, p. 182.

A large tree in Mexico. Young branchlets with quickly deciduous scattered minute hairs. Buds ovoid, $\frac{1}{8}$ in. long, obtuse, with reddish brown glabrous ciliate scales. Leaves (Plate 333, Fig. 4), deciduous late in the season (January to March), coriaceous, averaging 4 in. long and 2 in. broad, obovate or obovate-oblong; narrowed and auricled at the base; usually rounded, rarely acute, at the apex; margin with irregular callous-tipped crenate inflexed teeth, variable in size and number, and often obsolete; lateral nerves, ten to twelve, mostly ending in the margin; upper surface dark green, glabrous; lower surface pale or greyish green, glabrous; petiole $\frac{1}{4}$ to $\frac{1}{2}$ in., stout, glabrous.

Staminate catkins, slender, filiform, $1\frac{1}{2}$ to 2 in. long, covered with white hairs; calyx pilose; anthers six, glabrous. Pistillate flowers two or three, on a slender densely pubescent stalk about $\frac{3}{4}$ in. long.

Fruit, ripening in the first year, solitary or two to three on a slender glabrescent stalk averaging $1\frac{1}{2}$ in. in length; acorn ovoid, $\frac{3}{4}$ in. long, glabrescent, with a pubescent umbo, enclosed for one-third its length in a hemispherical cupule, $\frac{1}{2}$ in. in diameter,

tomentose within, and covered with closely appressed tomentose scales, reddish at their apices, those at the margin of the cupule minute, gradually increasing in size and thickened towards the base.

The above description is taken from specimens in cultivation, which show considerable variation in the shape of the leaves. Herbarium specimens from Mexico show greater variation, and have been grouped by De Candolle into three forms, the type and two varieties, *pandurata* and *Hartwegi*.

This species appears to be widely spread in the mountains of southern Mexico, where it was discovered by Humboldt near Ario, at an elevation of 6000 ft. He describes it as a lofty tree, 3 to 4 ft. in diameter, with very thick deeply cracked bark, and very compact strong wood, susceptible of taking a fine polish. Galeotti found this oak in the woods and savannas of Mirador and Zacuapan at 2500 to 3000 ft. altitude. It was collected by Hartweg at Tuxpan near Anganguio, by Bourgeau near Santa Fé, and by Berlandier between Tula and Tampico. Seemann found it also on the Cerro de Pinal in northern Mexico.

Specimens of this oak, described by Benth. as *Q. Hartwegi*, were sent by Hartweg to the Horticultural Society in 1839; and seedlings probably were raised in the Chiswick Garden, though there is no definite record of its cultivation.

(A. H.)

The finest specimen which we have seen is a tree in the Cambridge Botanic Garden, which is grafted on the common oak. It retains its leaves till March or April, and does not appear to suffer from severe winters. In 1908, a favourable season, it bore well-formed acorns; but in 1909 none of the fruit ripened.

A small tree, about 12 ft. high, at Kew, was obtained from Smith of Worcester in 1873. It has long borne the label *Q. genuensis*; but this appears to be an abbreviation of *Q. rugosa*¹ *genuensis*, the name applied to a tree at Glasnevin, about 16 ft. high, which was obtained from the same firm in 1885.

At Kilmacurragh, Co. Wicklow, there is a good specimen, reported by Capt. Acton to be 36 ft. high and 2 ft. 8 in. in girth. Its history is unknown.

This species is also in cultivation at Westonbirt; where a number of uncommon oaks were planted in Silkwood by the late Mr. Holford, on soil too dry and thin to enable them to develop themselves.

(H. J. E.)

QUERCUS TOZA, PYRENEAN OAK

Quercus Toza, Bosc, in *Journ. Hist. Nat.* ii. 155 (1792); Mathieu, *Flore Forestière*, 359 (1897).

Quercus pyrenaica, Willdenow, *Sp. Pl.* iv. 451 (1805); Loudon, *Arb. et Frut. Brit.* iii. 1842 (1838).

Quercus Tauzin, Persoon, *Syn. Pl.* ii. 571 (1807).

Quercus stolonifera, Lapeyrouse, *Pl. Pyren.* 582 (1813).

A tree, attaining about 70 ft. in height and 10 ft. in girth, but usually smaller; producing root-suckers freely. Bark dark brown, fissured longitudinally. Young branchlets covered with a dense grey tomentum, persistent in part in the second and

¹ *Q. rugosa*, Née, *Ann. Cienc. Nat.* iii. 275 (1801), is a different Mexican species, identified by De Candolle with *Q. crassifolia*, Humboldt and Bonpland.

third year. Buds $\frac{1}{5}$ in. long, pale brown, ovoid, obtuse, pubescent. Leaves (Plate 335, Fig. 28) deciduous in autumn, 4 to 8 in. long, 3 to 4 in. wide, oval or obovate, variable in shape, acute or obtuse at the apex, cuneate or sub-cordate at the base; usually pinnatifid, with five or six pairs of deep, entire or sinuately-toothed lobes, either oblong, rounded at the apex, and with narrow sinuses, or triangular and acute with wide sinuses; upper surface dark green, stellate-pubescent; lower surface grey or whitish, covered with a dense soft tomentum; lateral nerves more numerous than the lobes; margin ciliate; petiole about $\frac{1}{2}$ in. long, tomentose.

Fruit ripening in the first year, two to four on a tomentose, usually erect, rarely pendulous stalk, $\frac{1}{2}$ to 2 in. long; acorn variable in size and shape, cylindrical, ovoid or globose, pubescent at the apex, elsewhere glabrous; cupule hemispheric, $\frac{1}{2}$ to $\frac{3}{4}$ in. in diameter, with tomentose scales, closely appressed, except near the margin of the cup, where they are occasionally slightly spreading at their tips.

Q. Toza varies extremely in the size and shape of the foliage, and in Portugal hybridises occasionally both with *Q. lusitanica*¹ near Coimbra, and with *Q. pedunculata* near Castello Novo, where Padre Tavares showed Elwes trees which he considered to be intermediate between them.

At Angers, where *Q. Toza* is found growing in the hedges with both *Q. pedunculata* and *Q. sessiliflora*, it forms occasional hybrids with these species, which have been described by Abbé Hy.²

A small tree at Tortworth appears to be a hybrid between this species and *Q. pedunculata*. Its leaves are variable in size and shape, usually more deeply lobed than *Q. pedunculata*, of which it has the auricles at the base; less deeply lobed than *Q. Toza*, and greyish tomentose beneath, as in the latter species. It bears fruit freely, intermediate in character between the two species, from which seedlings have been reared at Colesborne, which resemble the parent tree in foliage.

DISTRIBUTION

This oak is a native of south-western France, and of Spain and Portugal. In France it is more or less common in the departments of the Basses-Pyrénées, Gers, Landes, Lot-et-Garonne, Gironde, Dordogne, Charente, and Charente Inférieure; and scattered trees are met with as far north as Angers and Le Mans. Its distribution is thus confined to near the coast and to low altitudes; as it succumbs to the cold winters, which occasionally occur in the interior, a temperature of -4° Fahr. being fatal to it. In the Landes,³ a tenth of these oaks were killed in 1829-30, when the thermometer fell to 5° Fahr. A plantation⁴ of this species at Les Barres, made in 1829-34, was almost entirely destroyed by the severe winter of 1871-72. In France, it is usually a low tree, with a short and crooked stem, doubtless due to the bad soil where it is mainly found, as in favourable situations moderately tall trees with straight stems are met with. It commonly grows unmixed with

¹ Coutinho, in *Bull. Soc. Brotero*, vi. 57 (1886).

² *Q. Trabuti* and *Q. Guerangeri*, Hy, in *Bull. Soc. Bot. France*, xvii. 556, 557 (1895), are names given to supposed crosses with *Q. sessiliflora*. *Q. Rechini*, and *Q. andegavensis*, Hy, *op. cit.* 557, 558, are names applied to the hybrids with *Q. pedunculata*.

³ Dufour, quoted by Mathieu, *op. cit.* 360.

⁴ Pardé, *Arb. Nat. des Barres*, 288 (1906).

other trees on almost pure sand or on sandy clays; but is occasionally seen in mixture with *Q. pedunculata*. It is usually treated as coppice, as it regenerates freely from cut stools and from the roots; but is of little value except for its bark and for firewood. It produces fruit abundantly every year; and the woods in which this species occurs near Bayonne are celebrated for fattening pigs. (A. H.)

This is one of the common trees of the north of Spain and Portugal, extending from the Pyrenees through the Cantabrian mountains to Portugal; and according to Laguna¹ is found more or less in every province of Spain, occurring in the Sierra de Gredos up to 5000 ft., and in the Sierra Nevada to 6000 ft. In Galicia, according to Gadow,² it is abundant from about 1000 to nearly 3000 ft. Barros Gomes³ says that it is with the chestnut, the dominant tree in Beira Trasmontana, on the upper Lezera, the Côa, and the Serra de Montemuro, at an elevation of 200 to 1500 metres. I found it mixed with *Q. pedunculata* in the Serra do Gerez in north Portugal, at about 3000 ft., and abundantly near Castello Novo in Beira Baixa, where it varies very much in the shape and size of its foliage, and was in full leaf by the end of April.

It is known in Galicia as *cerquinho*, and in the Serra do Gerez as *carvalho cerquinho*, meaning little oak. In Portugal it is sometimes called *negral* or *carvalho negro*; near Santander, *roble negro* or *tocio*; and in the mountains of Cuenca, *melejo*. It is rarely allowed to become a large tree, the branches being lopped as fodder for goats and cattle, and it never seems to attain the size of the common and cork oaks, the largest that I saw or heard of, near Castello Novo, which, however, were not old trees, were about 70 ft. by $7\frac{1}{2}$ ft.⁴

It usually bears numbers of large galls, produced by *Cynips Tozae*, Bosc, which are also characteristic of *Q. lusitanica*, and are described and figured, with many other galls, in a valuable paper by Padre Joaquim da Silva Tavares.⁵

CULTIVATION

This species is said by Loudon to have been introduced in 1822, but the tree at Clonmannon is probably older than this date. It never seems to have been popular with nurserymen, and possibly is short-lived.

In England, the best tree appears to be one at Strete Raleigh, which Miss F. Woolward reports to be about 40 ft. high, but with the branches much broken by wind. There is a good specimen at Tortworth, and others at Kew, Syon, Melbury, and Westonbirt.

At Smeaton Hepburn, East Lothian, Sir Archibald Buchan-Hepburn, Bart., reports a tree which, although it has lost 12 ft. of its leader, is 35 ft. high and $4\frac{1}{2}$ ft. in girth. The branches are distinctly pendulous, but have been repeatedly broken by north-westerly gales.

The finest tree that we know of is at Clonmannon, Co. Wicklow, which, when seen by Henry in 1904, measured 66 ft. in height and 9 ft. in girth; but was beginning to be attacked by a fungus, a portion of the butt being unsound (Plate 330). There is no authentic information to be obtained concerning the date of planting

¹ *Flora Forestal Española*, 232 (1883). ² *Northern Spain*, 389 (1897). ³ *Journ. Sc., Acad. Sci., Lisbon*, v. 235 (1876).

⁴ A large tree in the forest of Bussaco is figured in *Bull. Soc. Dend. France*, 1905, p. 5.

⁵ *Broterid*, vi. t. vi. fig. 6 (Lisbon, 1905).

of this remarkable tree. A tree, 40 ft. by 2½ ft., in the same year, is thriving at Kilmacurragh in the same county. (H. J. E.)

QUERCUS CONFERTA, HUNGARIAN OAK

Quercus conferta, Kitaibel, in Schultes, *Östr. Fl.* i. 619 (1814); Masters, in *Gard. Chron.* v. 85, fig. 18 (1876).

Quercus farnetto, Tenore, *Cat. Pl. Hort. Neap.* 65 (1819).

Quercus apennina, Loiseleur, in *Nouv. Duham.* vii. 177 (1819) (not Lamarck).

Quercus hungarica, Hubeny, in *Gemein. Blätt. Ofn. u. Pesth. Zeitschr.* xx. 2, p. 754 (1830); Willkomm, *Forstliche Flora*, 412 (1887); Hempel u. Wilhelm, *Bäume und Sträucher*, ii. 71, t. 24 (1889); Beck, *Vegetationsverhält. illyrisch. Länd.* 210 (1901).

Quercus pannonica, Booth, *ex Gordon*, in Loudon, *Gard. Mag.* xvi. 637 (1840).

A tree, attaining 100 ft. in height and 12 ft. in girth. Bark less deeply fissured than that of *Q. sessiliflora*, broken on the surface into small square scaly plates. Young branchlets with scattered hairs. Buds (Plate 78, Fig. 5) ovoid, obtuse, ½ in. long, with pubescent ciliate scales. Leaves (Plate 335, Fig. 26) deciduous¹ in autumn, about 6 in. long and 4 in. broad, obovate, rounded at the apex, usually subcordate at the base, with six to eight pairs of oblong, entire or sinuately-toothed lobes, with sinuses extending about half way to the midrib; margin ciliate; upper surface dull green, with a quickly deciduous scattered minute pubescence; lower surface greyish or pale green, covered with a thin stellate tomentum; petiole ¼ to ½ in. long, pubescent.

Fruit ripening in the first year, three or four clustered on a short stout pubescent peduncle; acorn ½ to ¾ in. long, rounded at the apex; cupule hemispherical, ½ to ¾ in. broad, with tomentose loosely appressed scales.

This species is closely allied to *Q. Toza*; but has thinner, not so densely tomentose leaves, and almost glabrous branchlets. It is reported² to hybridize with *Q. sessiliflora*, *Q. pedunculata*, and *Q. lanuginosa*.

DISTRIBUTION

This oak is a native of south-eastern Europe, attaining its northern limit in the southern provinces of the Hungarian kingdom, where it is widely spread through Slavonia, Banat, and the adjoining districts to Transylvania. It extends southwards through the Balkan States, Bulgaria, and northern Greece; and is also found in southern Italy.

In Italy, according to Borzi,³ *Q. conferta* is not found north of lat. 42°, but is common, either pure in small woods, or mixed with *Q. sessiliflora* and *Q. Cerris*, in the hills of southern Latium, in the Terra di Lavoro, and in the southern part of the Abruzzi as far as the slopes of Mt. Gargano. Farther south it gradually becomes rare and sporadic, and is not seen in the extreme south of Calabria. Its occurrence in Sicily is doubtful, as it has not been found recently by Lojacano in the locality near Taormina, where specimens were gathered by Di Leo and sent to Borzi in 1884.

¹ M'Nab exhibited a branch of a tree, growing at Edinburgh, which retained its leaves fresh and green in January. This was probably a young tree. Cf. *Gard. Chron.* v. 113 (1876).

² Schneider, *Laubholzkunde*, i. 194 (1904).

³ *Fl. Forestal Ital.* 167 (1880), and in *Boll. R. Orto. Bot. Palermo*, iv. 48 (1905).

In southern Hungary and Servia, it is one of the constituents of the oak forests, found on the hilly land and the lower slopes of the mountains, its companions being *Q. sessiliflora* and *Q. Cerris*; and is not met with in the great oak forests of the alluvial plains, where *Q. pedunculata* is the sole species. It usually grows on dry slopes with a sunny aspect, for which it is well adapted by its pubescent leaves. These check evaporation of water; and on hot days in summer in the Drina valley, I observed the leaves on the upper part of the tree, exposed to the sun, turning their greyish under surfaces to the east in the morning and to the west in the afternoon. It occupies drier situations than *Q. sessiliflora*; but does not ascend on the hot exposed ridges, with shallower soil, to as great an altitude as *Q. Cerris*, which often forms pure forests at 3000 ft. elevation.

Q. conferta becomes less common west of the Drina valley, and is only met with in Bosnia in the mountains south of the Save, east of Brčka, and in the valleys of the Drina and Lim rivers.

In Herzegovina, *Q. conferta* occurs in a few localities in the Narenta valley, the most important being the large forest of Dobrava, south of Mostar and west of Stolac, which is composed of a mixture of this species with *Q. Cerris* and *Q. macedonica*. Similar woods are met with in Montenegro and in Albania.

In Roumania, according to Huffel,¹ it occasionally forms pure woods; but is more commonly mixed with *Q. Cerris*; and in rare cases grows on moist clay soil with *Q. pedunculata*.

The largest tree,² which I measured in an oak forest in the Drina valley at about 1000 ft. elevation, was 85 ft. high and 12 ft. in girth; and here it seemed to be outgrown by the Turkey oaks standing beside it, which attained about 100 ft. by 10 ft.; but I was informed that in many places it grew to a larger size, equalling *Q. sessiliflora* in height and girth.

Q. sessiliflora and *Q. conferta*, growing in the hills in Servia, produce timber which is practically indistinguishable and is exported under the same name. In Slavonia, this hill oak timber is sold, for similar sizes, at about two-thirds the price of the wood of *Q. pedunculata*. The latter, grown in the forests of the alluvial plain of the Save, in moist ground, exposed to floods, is claimed locally to be the best oak in the world; and sells in the forest, close to the railway, when of the best quality and over 3½ ft. in diameter, at about a shilling per cubic foot.

Huffel, speaking of the wood of *Q. conferta* in Roumania, says that it has the peculiar property of breaking transversely, when force is applied, as neatly as if cut with a saw; and that, on this account, it is unsuitable for building purposes; but he adds that it rends well, is beautifully figured, and not liable to crack or warp in drying. (A. H.)

CULTIVATION

Q. conferta was introduced into England shortly before 1838, as Loudon³ mentions, as a possible variety of *Q. Toza*, an oak, in the Horticultural Society's

¹ *Les Forêts de la Roumanie*, 4 (1900).

² A tree cut down in this forest, ninety-five years old, showed on a radius of 14 in., 11 in. of heartwood with 85 annual rings, and 3 in. of sapwood with 10 rings.

³ *Arb. et Frut. Brit.* iii. 1844 (1838).

Garden at Chiswick, which had been received from Pesth, under the name *Q. conferta*; and Gordon,¹ in a list of the plants cultivated at Chiswick in 1839, enumerates *Q. pannonica*, which had been obtained from Booth of Hamburg. Grafted plants² were sold soon afterwards in considerable quantity by Lawson of Edinburgh. The species is, however, quite rare in England, though it seems to grow well where it has been planted in the southern and midland counties.

The largest we know is at Orton Hall, which in 1905 measured 68 ft. by 8½ ft., and is apparently grafted on the common oak (Plate 331). At Beauport there is a fine tree 67 ft. by 7 ft. 3 in. in 1909. At Westonbirt a well-grown tree in the arboretum measured 53 ft. by 5 ft. in 1909. At Kew³ a fine young tree is about 45 ft. by 6 ft. At Tortworth a well-shaped and thriving specimen was 41 ft. by 3 ft. in 1904. At Osterley Park, there are two healthy young trees about 35 ft. high. Smaller ones are growing at Bicton, Grayswood near Haslemere, Liphook, Sawbridgeworth, and Aldenham.

In the Edinburgh Botanic Garden, a tree,⁴ planted in its present position by Sir W. Gibson Craig in 1866, measured in 1905, 39 ft. by 5 ft.; and another, planted by Dr. Masters in 1875, measured in 1905, 30 ft. by 3½ ft. (H. J. E.)

QUERCUS MIRBECKII, ALGERIAN OAK

Quercus Mirbeckii, Durieu, in Duchartre, *Rev. Bot.* ii. 426 (1847); Mathieu, *Flore Forestière*, 362 (1897).

Quercus lusitanica, Webb, sub-species *baltica*, De Candolle, *Prod.* xvi. 2, p. 19 (1864).

Quercus Prinus, Masters, in *Gard. Chron.* xiv. 617, fig. 101 (1893) (not Linnaeus).

A tree, attaining in Algeria 120 ft. in height and 20 ft. in girth. Bark thick, hard, dark coloured, and deeply fissured into narrow scaly plates. Young branchlets glabrous, or with a few scattered hairs. Buds (Plate 78, Fig. 6) ovoid, angled, pointed, about ¼ in. long; scales pubescent, ciliate. Leaves (Plate 337, Fig. 44) deciduous in January, February, and March, variable in size and shape, the wider obovate leaves averaging 4 in. long and 3 in. broad, the narrower oval leaves nearly as long, and about 2 in. wide; acute at the apex; truncate, rounded, or auricled at the base; with nine to fourteen pairs of lateral nerves, each, except the lowest one or two pairs, ending in a rounded or acute tooth or short lobe; upper surface dark green, glabrous, except for slight pubescence at the base of the midrib; lower surface paler or slightly glaucous, glabrous, except for a brown flocculent tomentum along the midrib, especially at its base; petiole, ½ to ¾ in. long, brown tomentose in part.

Fruit ripening in the first year, clustered, sessile; cupule nearly hemispheric, ¾ in. wide, with appressed tomentose scales, those at the base oval, thickened, and

¹ In Loudon, *Gard. Mag.* xvi. 637 (1840).

² Cf. Masters, in *Gard. Chron.* v. 85 (1876).

³ This tree is mentioned under the name *Q. sessiliflora pannonica*, by Hemsley, in *Gard. Chron.* iv. 455 (1875).

⁴ This tree was 20 ft. high in 1876, and was one of Lawson's original plants, which had been for some time in the garden in an unsuitable site. Cf. *Gard. Chron.* v. 86 (1876).

larger than the narrow triangular scales towards the thin margin; acorn ovoid, about an inch long, glabrous.

This species in Algeria varies¹ considerably in the size and shape of the leaves, the largest and most obovate forms occurring in the rainy districts near the coast; while small and narrow leaves are characteristic of the trees growing in the dry mountains of the interior, as in the cedar forest of Teniet-el-Hâad, where the specimens which I collected are scarcely half the size of those of the coast forest of Akfadou. In the driest regions of the western part of Algeria, where the soil is limestone, the leaves are not only small, but are covered beneath with a thin tomentum, constituting var. *tlemcensis*, Warion.²

Q. Mirbeckii also occasionally forms hybrids with *Q. Suber*, a tree of this kind with corky bark found in the forest of Tlemcen being *Q. Pseudosuber*, Desfontaines, *Fl. Atlant.* ii. 348 (1800) (not Santi). A similar tree has lately been found in the same forest by M. Trabut.

DISTRIBUTION

This species is a native of southern Portugal (where it seems to be rare,³ and confined to the province of Algarve), Morocco, Algeria, and Tunis. Little is known of its distribution in Morocco, where it was collected in the mountains near Tangier by Ball in 1862; while in Tunis it appears to be limited to and not abundant in the Khroumir mountains. In western Algeria and throughout the Atlas range, owing probably to the insufficient rainfall, *Q. Mirbeckii* grows only in a few localities, on the northern slopes of the mountains, as in the forest of Hafir, near Tlemcen, at Nesmoth, around Ténès, at Teniet-el-Hâad, Matmata, and Blida. At Teniet-el-Hâad it grows in company with the cedar, from 4700 ft. to the summit at 5900 ft., and forms wide-spreading branching trees often 12 ft. in girth. This oak is much more abundant and of considerable commercial importance in the extensive broad-leaved forests, which are situated in the mountains near the coast, in eastern Kabylia and in the province of Constantine, where the rainfall is heavy. The forest of Akfadou, near Bongie, which I visited in January 1907, is mainly composed of oaks, with a slight admixture of maples, willows, cherry, and holly. In the lower zone, between 1500 and 3000 ft., *Q. Suber* predominates, with a few scattered small trees of *Q. Mirbeckii*; above 3000 ft. the latter becomes the main species, and increases in size, the cork oak ceasing at about 3700 ft., and being replaced by *Q. castaneaefolia*. Above this level to the summit, about 5000 ft., the forest is an equal mixture of the latter species and *Q. Mirbeckii* (Plate 323). In this forest the largest *Q. Mirbeckii* is reported to be 17 ft. in girth; but I saw none exceeding 13 ft., and the tallest tree which I measured was 90 ft. by 8 ft. 4 in. M. Trabut informed me that the finest forest of this species, nearly pure, is at Ain-ma-beurd, near Djidjelli, where the trees rival in height and in density upon the ground those of *Q. sessiliflora* in the famous forest⁴ of Bercé, in France. The total annual yield of

¹ Cf. Trabut, in *Rev. Gén. de Bot.* iv. 1-6, figs. 1-3 (1892).

² Ex Battandier et Trabut, *Fl. Algér.* 821 (1890).

³ The only specimen which I have seen from Portugal, is one collected by Welwitsch, on the Serra da Picota in Algarve. This specimen is in the Kew herbarium.

⁴ Cf. vol. ii. p. 331.

timber of *Q. Mirbeckii* in the forests of eastern Algeria is said to be about 3,500,000 cubic feet.

The wood is very dense and heavy, sinking in water when green, and in the dry state having a specific gravity of 0.924. It is easy to rend, but is very liable to warp and split when drying. In structure it differs from the wood of the common oak in having smaller and fewer large pores in the zone formed in spring, these being represented by one, or at most two, rows, the greater part of the annual ring, that formed in autumn, being composed of fibrous tissue. The timber is valuable for building purposes, and for other uses similar to those of the common oak, but up to the present it has been mainly used in Algeria for railway sleepers.

(A. H.)

CULTIVATION

This species was introduced¹ about 1844 or 1845, when King Louis Philippe sent acorns, which had been procured in Algeria, to Queen Victoria, who distributed them amongst the ladies of the court. *Q. Mirbeckii* has handsome foliage, which is subevergreen, and thrives well in the warmer parts of England; and, though we have found no trees in Wales, Scotland, or Ireland, no doubt it would succeed there in many localities.

The largest tree we know of is at Bicton, where in 1902 I measured one 75 ft. high and 12 ft. 9 in. in girth, with a spreading crown 30 paces in diameter. At Tregothnan Mr. A. B. Jackson measured a tree about 60 ft. high and 6½ ft. in girth in 1908.

At Ham Manor, near Worthing, there are two fine trees, the largest of which in 1907 was 70 ft. by 8 ft. 3 in.; the other, close to it, was about 60 ft. by 7 ft.

On a lawn at Hursley Park, Winchester, there is a well-shaped specimen which in 1906 measured 62 ft. by 7½ ft. (Plate 332). I am informed by Colonel Heathcote that it is known as "The Speaker's Oak," because the late Lord Eversley, who was Speaker of the House of Commons from 1837 to 1857, and an intimate friend of the late Sir William Heathcote, then of Hursley, jumped over the tree when it was planted.

At Syon there is a tree 53 ft. by 5 ft. 3 in. in 1904, when it ripened a large number of acorns. Some of these which were sown at Colesborne have grown well, and carry their leaves until spring. An older tree, purchased under the name of *Q. afghanistanica*, has proved quite hardy at the same place, though planted in a situation very subject to spring frost, on a cold clay soil.

At Albury there is a small tree 24 ft. high, forking near the ground into two stems, each 2½ ft. in girth, which was figured in the *Gardeners' Chronicle*, xiv. 617 (1893) as *Q. Prinus*. At Melbury there is a tree about 40 ft. by 4 ft. in 1909. In the Victoria Park, Bath, another is about 50 ft. At Blenheim, Westonbirt, Tortworth, Howick in Northumberland, and in the Cambridge Botanic Garden there are trees of smaller size.

At Tockington Manor, Gloucestershire, Capt. H. Pomeroy Salmon has two trees

¹ See correspondence at Kew with Mr. J. W. Ford, of Enfield Old Park, Winchmore Hill, who gives an account of the origin of an old tree of this species which was cut down near Enfield in 1900.

24 ft. and 17 ft. high, which he raised from acorns collected in the Atlas mountains, where the Kabyles grind the acorns and mix the flour with barley meal to make cakes. He adds that the native name is *Abelude n'zān*, which has been corrupted by French authors into *zēn*. (H. J. E.)

QUERCUS PONTICA

Quercus pontica, Koch, in *Linnaea*, xxii. 319 (1849); De Candolle, *Prod.* xvi. 2, p. 49 (1864); Dieck, in *Gartenflora*, xl. 509, fig. 95 (1891); Albow, *Prod. Fl. Colch.* 219 (1895); Schneider, *Laubholzkunde*, i. 192, fig. 102 (1904).

A shrub, attaining 10 to 13 ft. in height. Young branchlets stout, glabrous. Leaves (Plate 339, Fig. 70) deciduous, elliptic, about 6 in. long and 3 in. broad, often larger on young plants, coriaceous, cuspidate or shortly acuminate at the apex, rounded at the base; with 15 to 20 pairs of parallel lateral nerves, prominent beneath, each ending in a large triangular incurved cartilaginous-tipped serration; upper surface dark shining green, glabrous; lower surface glaucous, glabrous except for a few scattered long hairs on the midrib and lateral nerves; petiole stout, swollen at the base, ¼ to ½ in. long, glabrescent.

Fruit not seen. Its affinities are probably with *Q. Mirbeckii*.

This species is readily distinguished by its remarkable buds, which are stout, ovoid, pointed, about ½ in. long; scales glabrous, green, with a brown ciliated margin.

This species was discovered by Koch in north-eastern Asia Minor, in the mountains of Lazistan, near the source of the river Asperos, where, in company with alder and beech, it forms a shrubby vegetation above the conifer region, from 5000 to 7000 ft. elevation.

It is also widely spread in the mountains of Caucasia, which border on the eastern shore of the Black Sea, where it has been found in numerous stations, in Abkhasia, Mingrelia, Imeritia, Adshuria, and Guria. It grows mainly in the subalpine zone of the forests, between 4000 and 7000 ft., often forming with hazel and birch the timber line. Alboff¹ describes it as a shrub 10 to 13 ft. in height, with very variable foliage as regards size and shape,—large broad leaves, 5 to 13 in. long and 2½ to 5 in. wide being characteristic of warm humid districts near the sea; while smaller narrow leaves are the prevalent form in the mountains near the central chain of the Caucasus.

It was seen by Dieck in 1890, who was unable to procure acorns, but brought back cuttings. It was first introduced into England by Lord Kesteven, who collected acorns in September 1905 in the mountains inland from Sukhum-Kaleh, a port on the Black Sea about 100 miles north of Batum. He raised three seedlings, which retained their foliage in March 1910, when they were about 12 to 18 in. high and very thriving. Schneider states that he has only found it in cultivation in the forest garden at Münden in Hanover; but Elwes has recently obtained living plants from the nursery of O. Poscharsky at Laubegast, near Dresden. (A. H.)

¹ In *Bull. Herb. Boissier*, i. 259 (1893). Cf. also Radde, *Pflanzenverb. Kaukasus*, 182, 188 (1899).

QUERCUS MACRANTHERA

Quercus macranthera, Fischer et Meyer, in *Bull. Soc. Nat. Mosc.* x. 260 (1838); De Candolle, *Prod.* xvi. 2, p. 13 (1864); Boissier, *Flora Orientalis*, iv. 1165 (1879); Schneider, *Laubholzkunde*, i. 192 (1904).

A tree, about 60 ft. in height. Young branchlets stout, covered with dense brown pubescence, retained in the second year. Buds pubescent, with persistent pubescent filiform stipules. Leaves (Plate 337, Fig. 42) deciduous in autumn, 4 to 5 in. long, 2 to 3 in. broad, obovate, acute at the apex, unequal and rounded or cuneate at the base, margin ciliate; with seven to eleven pairs of lateral nerves, each ending in a rounded, short, usually entire, rarely toothed lobe; upper surface dark green, with minute scattered brown hairs; lower surface pale, covered with dense tomentum; petiole $\frac{1}{4}$ to $\frac{1}{2}$ in., densely pubescent.

Fruits ripening in the first year, sessile or sub-sessile, crowded at the apex of the branchlet; acorns cylindrical-ovoid, nearly an inch long, glabrous, surrounded at the base by a hemispherical cupule, about $\frac{1}{2}$ in. in diameter, covered with loosely appressed pubescent scales, ovate in the basal ranks, and lanceolate towards the margin of the cupule.

This species, which is closely allied to *Q. Toza* and *Q. conferta*, is a native of the mountains of northern Persia and of the Caucasus, between 4000 and 7500 ft. altitude, where it often grows in subalpine meadows near the timber line. It has also been collected in Karabagh and in Armenia. According to Radde,¹ who gives a photograph of a large tree growing amidst tall grass, it attains a great age and considerable size, one tree being recorded as 425 years old, 2 $\frac{1}{2}$ ft. in diameter, and with 180 cubic ft. in the stem, exclusive of branches.

Q. macranthera, which is a very ornamental species, was introduced some time before 1873, as Koch² in that year mentions small trees in north-eastern Germany, which were perfectly hardy. Mayr³ says that it grows fast at Grafrath, near Munich. A tree in Kew Gardens, obtained from Späth in 1895, is about 20 ft. high, and has borne acorns during the last three years. There are also specimens at Westonbirt and Aldenham.

(A. H.)

QUERCUS LUSITANICA, PORTUGUESE OAK

Quercus lusitanica, Lamarck, *Encyc.* i. 719 (1783); Webb, *It. Hisp.* 11 (1838); Boissier, *Voy. Bot. Espagne*, ii. 575 (1839-45); Hooker, *It. Plant.* vi. t. 562 (1843); Coutinho, in *Bull. Soc. Brot.* vi. 66 (1888).

Quercus australis, Link, ex Loudon, *Arb. et Frut. Brit.* iii. 1925 (1838).

A tree, attaining 60 ft. in height and 10 ft. in girth. Bark thick, divided into small quadrangular scaly plates. Young branchlets tomentose. Buds ovoid, acute,

¹ *Pflanzenverb. Kaukas.* 204, 226 (1899).² *Dendrologie*, ii. 2, p. 44 (1873).³ *Fremdländ. Wald- u. Parkbäume*, 502 (1906).

$\frac{1}{6}$ to $\frac{1}{4}$ in. long, with ciliate scales. Leaves falling late in the season, coriaceous, variable in shape often on the same branch, averaging 3 in. long, 1 $\frac{1}{4}$ in. broad, obovate-oblong, usually rounded at the apex, unequal and cuneate or rounded at the base; lateral nerves seven to nine pairs; margin wrinkled, revolute, with irregular, mucronate, inflexed teeth; upper surface dark green, shining, glabrescent, except on the midrib, which remains pubescent; lower surface covered with a dense greyish tomentum; petiole tomentose, $\frac{3}{8}$ in. long.

Fruit ripening in the first year, two or three together on a tomentose peduncle; acorn ellipsoid, $\frac{3}{4}$ in. long, glabrous, enclosed to a variable height in a hemispherical or urceolate cup, narrowed at the orifice, and covered with appressed tomentose scales.

No species of oak is so variable as *Q. lusitanica*; and after examination of the abundant Spanish and Portuguese material in herbaria, and of the specimens collected by Elwes at Cintra in Portugal, and a fine series of variations obtained by him from Padre Tavares, I am unable to group the numerous forms into distinct varieties. Coutinho, in his valuable paper on the oaks of Portugal, states that the different forms of leaves graduate into each other, and are sometimes found on the same tree, and even on the same branch. The variations are mainly in the size, shape, and texture of the leaves, which have regular or irregular teeth, with or without a mucro at their apex. The dense grey tomentum on the under surface of the leaf and on the branchlets are constant characters, and serve to distinguish this species from the closely allied *Q. lanuginosa*, which has always deep and rounded lobes, not present in *Q. lusitanica*. The variation in some instances is due to the influence of soil, climate, and altitude; but in other cases is perhaps dependent on hybridisation with the other species of oak in the same region.

The principal forms are as follows:—

1. Var. *Broteri*, Coutinho. This is perhaps the typical form, and is described above, from specimens gathered from large trees near Cintra by Elwes. This usually is a large tree, making summer shoots, and characterised by large leaves, with rather irregular teeth.

2. Var. *faginea*, Boissier, *Voy. Bot. Espagne*, ii. 575 (1839-45).

Quercus faginea, Lamarck, *Encyc.* i. 725 (1783).

Quercus valentina, Cavanilles, *It. Fl. Hisp.* ii. 25, t. 129 (1793).

Usually a shrub. Leaves thin in texture, obovate or oblong, 1 $\frac{1}{2}$ to 2 in. long, $\frac{3}{4}$ to 1 $\frac{1}{4}$ in. wide, regularly toothed, with sharp mucros.

A common form, often a tree, is intermediate between var. *faginea* and var. *Broteri*, the leaves (Plate 335, Fig. 25) being small like the former, coriaceous like the latter; and the teeth, though regular, are without mucros.

3. Var. *alpestris*, Coutinho.

Quercus alpestris, Boissier, *Elenchus*, 83 (1838), and *Voy. Bot. Espagne*, ii. 576, pl. 164 (1839-45).

Leaves coriaceous, oblong, 2 to 3 in. long, nearly entire, the mucronate teeth being few, irregular, and inconspicuous. This occurs at high altitudes, and is oftener a shrub than a tree.

4. Var. *humilis*.

Quercus humilis, Lamarck, *Encyc.* i. 719 (1783) (not Miller); Webb, *It. Hisp.* 11 (1838); Masters, in *Gard. Chron.*, 1874, p. 112, f. 31.
Quercus fruticosa, Brotero, *Fl. Lusit.* ii. 31 (1804).

A low shrub, found in poor sandy soil. Leaves late in falling, 1 to 1½ in. long, obovate-elliptic, irregularly and acutely mucronate-toothed; petiole very short, about ⅛ in. long. According to Webb, this covers arid tracts in central and southern Portugal, and finds its most easterly station near Gibraltar.

5. At Tortworth there is a grafted tree, about 40 ft. high, which was procured from the Elvaston Nursery about forty-five years ago, under the name *Q. serratifolia*.¹ This has narrow leaves, with triangular mucronate teeth, a cuneate base and a long petiole, and is one of the forms assignable to var. *Broteri*. It bears fruit freely, from which seedlings have been frequently raised, said to resemble the parent in foliage. One of these seedlings, planted at Kew, has large obovate-oblong leaves, green and glabrous beneath, auricled at the base, and with a short petiole; and is intermediate between *Q. lusitanica* and *Q. pedunculata*. Its parent was probably pollinated by an adjoining common oak. (A. H.)

DISTRIBUTION

Q. lusitanica is a native of Spain and Portugal, being replaced in the Levant by the closely-allied species, *Q. infectoria*. The range of this species in Spain is very wide. According to Laguna and Avila it is found in all the provinces except Galicia, Asturias, and Biscay, but is commonest in Estremadura and Andalusia.

Captain Widdrington seems to have been the first to call special attention to it,² and says that it was a leading feature in the ancient forests of Spain. He found it from the southern part of Andalusia to the centre of Leon, almost to the watershed of Asturias, and from the western Sierra Morena to near Guadalaxara. He notices its extreme variability, and calls it a very beautiful deciduous tree, with shining green leaves varying from 1 to 4 in. in length, and proposed for it the name of *Q. Quexigo*. Laguna and Avila spell this—the common Spanish name—Quejigo.

In Spain it is usually so much cut for firewood that it is rarely seen as a large tree, but in Portugal it attains a great size; and in a paper by Gebhart, in the *Revue des Eaux et Forêts*, I find one recorded in the forest of Casal do Prado, which was 5.40 metres in girth, and with a crown 26 metres in diameter, which produced 840 litres of acorns in one year.

I saw this oak growing abundantly in central Portugal, especially in the Serra of Cintra. It is a medium-sized or large tree, usually attaining 50 to 60 ft. in height, and 8 to 10 ft. in girth; and in this mild and comparatively damp climate seems to be subevergreen, a few leaves remaining on most of the trees in the beginning of April. Its habit is spreading and branchy, very similar to that of the cork oak. The bark is more like that of *Q. Ilex* than that of *Q. pedunculata*, and never becomes corky.

¹ According to Koch, *Dendrologie*, ii. 2, p. 78 (1873), an oak with this name was introduced from Spain by Booth of Flottbeck, near Hamburg.

² *Spain and the Spaniards*, i. 385 (1844).

Coutinho describes and figures the leaves of supposed hybrids between this species and *Q. pedunculata* and *Q. Toza*, found near Coimbra and in other localities in Portugal.

CULTIVATION

This tree, which is very rare in cultivation, was introduced in 1835, when plants were raised in the Horticultural Society's garden at Chiswick, from acorns gathered in the neighbourhood of Gibraltar. These seedlings were named *Q. australis*, Link, and in their juvenile stage, according to Loudon's figure, closely resembled specimens gathered at Cintra in their foliage. A tree on the lawn near the gate of the Director's Office, Kew, grafted at about 3 ft., which measures about 35 ft. in height and 5 ft. 9 in. in girth, and ripened acorns in 1909, bears smaller leaves, somewhat intermediate between var. *Broteri* and var. *faginea*. At Lyndon Hall, Rutland, a low tree, about 6 ft. in girth, which recently died, bore similar foliage. Another tree at Kew, in the oak collection, near the bank of the Thames, about 30 ft. in height, and wide-branching from near the base, has much larger leaves, almost glabrescent in autumn, and is probably one of the forms of var. *Broteri*. (H. J. E.)

QUERCUS INFECTORIA

Quercus infectoria, Olivier, *Voy. Emp. Othm.* i. 252, tt. 14, 15 (1801); Loudon, *Arb. et Frut. Brit.* iii. 1928 (1838); J. D. Hooker, in *Trans. Linn. Soc.* xxiii. 383 (1861).
Quercus lusitanica, sub-species *orientalis*, De Candolle, *Prod.* xvi. 2, p. 18 (1864).
Quercus lusitanica, Boissier, *Fl. Orient.* iv. 1166 (1879) (not Lamarck).

This species, which is the representative of *Q. lusitanica* in the Levant, includes a great number of forms, presenting the same range of variation in the foliage as the Peninsular species; and differs¹ mainly from it in being less pubescent on the branchlets and leaves. The typical form is a shrub or small tree, with very scaly bark. Young branchlets tomentose or glabrescent. Leaves coriaceous, deciduous late in the season, ovate, oblong, or obovate-oblong, about 2 in. long and 1 in. broad; rounded or occasionally acute at the apex; unequal at the base; margin wrinkled, with about six pairs of sinuate teeth, with or without mucros; upper surface light green, shining, glabrous; lower surface pale green, with scattered stellate hairs, glabrescent towards the end of the season; petiole ½ in. long, glabrescent. Fruit similar to that of *Q. lusitanica*.

1. Var. *Boissieri*, De Candolle, *loc. cit.*

Quercus Boissieri, Reuter, in Boissier, *Diag. Ser.* i. 12, p. 119 (1842).

Leaves oblong, or obovate-oblong, larger than in the type, up to 3 or 4 in. long, with more numerous acute mucronate teeth.

2. Var. *petiolaris*, De Candolle, *loc. cit.* Leaves oblong, almost entire, or with

¹ Some specimens from Asia Minor have leaves tomentose beneath, and are indistinguishable from *Q. lusitanica*.

a few inconspicuous irregular teeth. This includes some remarkable forms, which are possibly distinct species.¹

Q. infectoria is widely spread throughout Syria, Asia Minor, Armenia, and Kurdistan; and occurs also in Turkey near Constantinople, and in Cyprus; but appears to be unknown in Greece.²

Sir Joseph Hooker saw it in great abundance on the east slopes of Lebanon, on the rocky hills of Galilee south of Safed, and on the summit of Carmel. It occurred as a small tree 15 to 20 ft. high, or more often, as a bush sparingly branched, with a rather slender rugged trunk, and grey deciduous foliage, white on the under surface, and was rendered very conspicuous by the abundance of spherical galls of a deep red brown colour and shining viscid surface.³ He also speaks of another gall, of smaller size, paler colour, and softer texture with several angular protuberances, found sparingly in Syria and, as he believed, also on this species. Neither of these galls is collected in Syria. The larger and commoner is probably not different from the Aleppo gall, though it may be inferior in quality. Hooker adds that the acorns are of a singularly elegant form and of a bright amber colour.

The galls of this species, known as Aleppo galls, of which a full account is given by Flückiger and Hanbury,⁴ are exported from Smyrna and Trebizond; and are used in medicine, for dyeing and tanning, for making tannic and gallic acids, and in the preparation of ink.

We are indebted to Consul H. Shipley of Erzeroum for some drawings of oak leaves and specimens of galls from Kurdistan, which in the absence of acorns cannot be certainly identified, but which, in Dr. Stapf's opinion, belong in part to *Q. pedunculata*. The galls, however, are extremely similar to those commonly found on *Q. lusitanica* in Portugal.

Loudon says that although, according to the catalogues, this tree was introduced into England in 1822, he had never seen a specimen. Apparently⁵ it was first cultivated in the Chiswick Garden in 1850, when seedlings were raised from acorns sent by Sir A. H. Layard from Kurdistan, where he had found the tree abundant, especially near Bitlis, which was the emporium for galls. Sir J. Hooker⁶ also brought home from Syria, in 1860, acorns in damp earth, from which plants were raised at Kew.

The only specimens that we have seen are at Kew, where a tree of the typical form, about 23 ft. by 2 ft. 3 in. in 1909, is probably one of Hooker's seedlings. Trees of similar size, belonging to var. *Boissieri*, were obtained in 1870 and 1873 from Booth of Hamburg. (A. H.)

¹ Cf. Schneider, *Laubholzkunde*, i. 191, fig. 120 (1904), who describes and figures, as *Q. veneris*, Kerner, an oak in the Botanic Garden at Vienna, which was raised from an acorn sent by Kotschy from Cyprus. This is identical with *Q. Pfaeffingeri*, var. *cypria*, Kotschy, in Unger and Kotschy, *Die Insel Cypern*, 492 (1865), who state that it once formed extensive woods of fine trees, of which only a few scattered individuals now remain.

² It is not mentioned as one of the oaks of Greece, by Halacsy, *Comp. Fl. Græcæ*, iii. 125 (1904).

³ Figured by Lambert, in *Trans. Linn. Soc.* xvii, t. 22 (1837).

⁴ *Journ. Hort. Soc. Lond.* viii. 132 (1853).

⁶ *Trans. Linn. Soc.* xxiii. 383 (1861).

QUERCUS GLANDULIFERA

Quercus glandulifera, Blume, in *Mus. Bot. Lugd. Bat.* i. 295 (1850); Skan, in *Journ. Linn. Soc. (Bot.)*, xxvi. 514 (1899); Shirasawa, *Icon. Ess. Forest. Japon*, text 50, t. 26, figs. 13-24 (1900).

A small tree, rarely attaining 50 ft. in height. Young branchlets slender, covered with quickly deciduous appressed pubescence. Buds ovoid, $\frac{1}{8}$ in. long, with ciliate glabrous scales. Leaves (Plate 335, Fig. 27) deciduous in autumn, 3 to 5 in. long, 1 to 2 in. broad, membranous, obovate or elliptical, acuminate at the apex, usually cuneate at the base; with eight to eleven pairs of lateral nerves, all but the lowest pair ending in a serration, tipped with a short glandular cartilaginous mucro; upper surface dark green, shining, with deciduous appressed silky pubescence; lower surface pale green, with similar but persistent pubescence; petiole $\frac{1}{4}$ to $\frac{1}{2}$ in. long, appressed, pubescent.

Fruit, ripening in the first year, solitary or clustered, on a glabrescent short peduncle; acorn $\frac{1}{2}$ in. long, surrounded at the base by a shallow cupule, $\frac{1}{2}$ in. broad, covered with lanceolate pubescent scales.

This species is widely spread throughout China, Korea, and Japan. There are four small trees at Kew, about 10 ft. high, which were obtained from the Arnold Arboretum in 1893; and a small specimen is also growing at Aldenham.

(A. H.)

QUERCUS GROSSESERRATA

Quercus grosseserrata, Blume, in *Mus. Lugd. Bot.* i. 306 (1850); Sargent, *Forest Flora of Japan*, 67 (1894); Shirasawa, *Icon. Ess. Forest. Japon*, text 53, t. 27, figs. 16-28 (1900).

Quercus crispula,¹ Blume, var. *grosseserrata*, Miquel, in *Ann. Mus. Bot. Lugd.* i. 104 (1863).

A tree, attaining 100 ft. in height and 12 ft. in girth. Branchlets and buds glabrous. Leaves (Plate 337, Fig. 49) deciduous in autumn, sub-sessile, membranous, 4 to 6 in. long, 3 to $3\frac{1}{2}$ in. broad, obovate, acuminate at the apex, tapering to a narrow auricled truncate base, with twelve to fifteen pairs of regular triangular non-mucronate teeth; upper surface dull, dark green, glabrous except for long hairs on the midrib; lower surface paler, glabrous, with long hairs on the midrib and lateral nerves, each of which except the lower one or two pairs ends in the apex of a tooth; petiole $\frac{1}{8}$ in., glabrous.

Fruit ripening in the first year, clustered at the ends of the branchlets, solitary or two to three on short peduncles; cupule hemispheric, about $\frac{1}{2}$ in. in diameter, with appressed grey tomentose ovate scales, enclosing about one-third of the ovoid acorn, which falls out of the cupule when ripe. (A. H.)

¹ *Quercus crispula*, Blume, in *Mus. Lugd. Bot.* i. 298 (1850), according to Sargent, is indistinguishable in foliage: but is said by Miyabe to have different fruit, the cupule being deeper and enclosing half the cylindrical acorn, cupule and acorn falling together when ripe. Shirasawa only mentions and describes one species, *Q. grosseserrata*.

*Q. grosseserrata*¹ is a native of Japan and the Kurile Isles, and is said to have a more northerly distribution than *Q. crispula*, though both, according to Sargent, grow together on the hills of central Yezo, forming large trees and producing timber of excellent quality. I collected this oak at Asahigawa, in this region, at 500 ft. elevation, where it was growing in open forests mixed with *Q. dentata*. Sargent reports *Q. crispula* to be common on the low ground and near the banks of streams in Yezo; and states that he saw fine forests of it on the Nikko mountains. It is known as *onara* in Japan, where the timber is largely used for sleepers. I believe that this tree produces the greater part of the oak timber which has lately been exported in quantity to Europe and to California, and is very favourably spoken of by Messrs. Marsh, Jones, and Cribb of Leeds, who have used it for furniture. When quarter sawn it shows a good figure, and is not easy to distinguish from Austrian oak.

Sargent collected acorns of this oak in Japan in 1892, from which plants were raised in the Arnold Arboretum. These are said by Rehder to be perfectly hardy and to bear handsome foliage. Some of these plants, sent to Kew in 1893, are about 10 ft. high, but do not look very thriving. Acorns sent to me by Prof. Miyabé from Sapporo in 1905 germinated, but grew badly on my soil, and are now dead.

(H. J. E.)

QUERCUS GLAUCA

Quercus glauca, Thunberg, *Fl. Jap.* 175 (1784); Franchet et Savatier, *Enum. Pl. Jap.* i. 448 (1875), and ii. 501 (1879); Hooker, *Fl. Brit. India*, v. 604 (1888); Skan, in *Journ. Linn. Soc. (Bot.)* xxvi. 515 (1899); Shirasawa, *Icon. Ess. Forest. Japon*, text 56, t. 30, figs. 13-24 (1900); Gamble, *Indian Timbers*, 677 (1902).

Quercus annulata, Smith, in Rees, *Cyclop.* xxix. No. 22 (1819); Loudon, *Arb. et Frut. Brit.* iii. 1921 (1838).

Quercus phullata, Buchanan-Hamilton, in D. Don, *Prod. Nep.* 57 (1825).

A large tree. Young branchlets pubescent at first, soon becoming glabrous. Leaves (Plate 338, Fig. 52) coriaceous, persistent two or three years, about 3 in. long and 1 in. broad, lanceolate, acuminate at the apex, rounded or cuneate at the base, margin mucronate-serrate in its upper half; lateral nerves about ten pairs, prominent beneath; upper surface green, glabrous; lower surface greyish or white, with scattered appressed silky hairs; petiole $\frac{1}{2}$ in. long, glabrous or with scattered hairs.

Fruit (section *Cyclobalanopsis*) ripening in the first year, one to three, sessile on a short stalk; acorn ovoid, acute, much exserted, similar to that of *Q. Vibrayeana*; cupule hemispheric, about $\frac{1}{2}$ in. wide, with grey tomentose scales, connate into four to eight concentric zones, the lower with crenate, the upper with entire margins.

¹ *Q. grosseserrata* is closely allied to *Q. mongolica*, Fischer, ex Turczaninow, in *Bull. Soc. Nat. Mosc.*, 1838, p. 101. The latter species is widely spread in Dahuria, Amurland, Manchuria, Mongolia, and northern China. The leaf, bud, and branchlet of *Q. mongolica* are figured in Plate 337, Fig. 48; and a small tree in Kew Gardens, sent by Sargent in 1893, under the name of *Q. crispula*, is possibly this species. As a rule, the plants usually found in cultivation under the name *Q. mongolica* are *Q. lanuginosa*.—(A. H.)

The above description applies to the Japanese form. The species is very variable in the wild state in foliage, and several varieties have been described. In Himalayan specimens the serrations of the leaves have long mucronate points.

The following peculiar variety probably originated in Japanese gardens:—

Var. *lacera*, Matsumura, *Shokubutsu Mei-I*, 243 (1895).

Quercus lacera, Blume, in *Mus. Lugd. Bat.* i. 306 (1850).

Leaves obovate, ovate, or lanceolate, with the apex prolonged into a long slender caudate acumen; margin deeply lobed, each lobe ending in a long cartilaginous point.

There is a small plant of this variety in Kew Gardens, introduced in 1907 from Yokohama.

Quercus glauca is widely spread in eastern Asia, occurring in the Himalayas from Kashmir to Bhutan at 3000 to 6000 ft., throughout the mountains of China, and in Japan and Formosa. Sargent¹ states that the acorns are eaten by the Japanese, and are of considerable commercial importance.

The Himalayan form was introduced in Loudon's time, as there were plants about 10 ft. high at Kew, Chiswick, and Loddiges' nursery; but none of these appear to have survived. The only specimen which we have seen is a small tree at Tortworth, probably of Japanese origin, which appears to be perfectly hardy, but has never borne fruit.

(A. H.)

QUERCUS VIBRAYEANA

Quercus Vibrayeana, Franchet et Savatier, *Enum. Pl. Jap.* i. 449 (1875), and ii. 498 (1879); Skan, in *Journ. Linn. Soc. (Bot.)* xxvi. 522 (1899); Shirasawa, *Icon. Ess. Forest. Japon*, text 55, t. 29, figs. 16-31 (1900).

Quercus bambusifolia, Fortune, in *Gard. Chron.*, 1860, p. 170; Masters,² in *Gard. Chron.* i. 632 (1874). (Not Hance.)

Quercus acuta, Thunberg, var. *bambusifolia*, Masters, in *Kew Handlist, Trees*, 181 (1896).

A tree, attaining about 50 ft. in height. Young branchlets slender, glabrous. Buds ovoid, minute, glabrous. Leaves (Plate 338, Fig. 55) coriaceous, persistent two years, 3 to 4 in. long, 1 to $1\frac{1}{4}$ in. broad, often larger on young plants, lanceolate, cuneate at the base, long acuminate at the apex, which is often tipped with a mucro; lateral nerves, nine to twelve pairs, slender, inconspicuous; margin minutely serrate in the upper half of the blade; upper surface dark green, shining, glabrous; lower surface pale green, glaucescent, glabrous; petiole $\frac{1}{4}$ to $\frac{1}{2}$ in. long, glabrous.

Fruit (section *Cyclobalanopsis*) ripening in the first year, two to four, sub-sessile on a slender peduncle, about 2 in. long, the upper part of which has fallen, bearing with it the unripened pistillate flowers; acorn ovoid, pubescent towards the tip, which is marked with a lamellate umbo, crowned by the persistent style; cupule

¹ *Silva N. Amer.* viii. 11, note 48 (1895).

² The plant here described by Masters is incorrectly excluded from *Q. Vibrayeana* in *Journ. Linn. Soc. (Bot.)* xxvi. 522 (1899).

hemispheric, about $\frac{2}{3}$ in. in diameter, with grey tomentose scales, connate into seven or eight concentric zones.

This is a rare tree, occurring in Japan, where it was found near Nikko by Savatier, and in the mountains of Chekiang, in China, whence it was introduced¹ into cultivation, under the name *Q. bambusifolia*, by Fortune in 1854. Fortune² saw trees 30 to 50 ft. in height; but, as far as we have seen, it has remained shrubby in this country. There are specimens at Kew, Eastnor, and Syon. (A. H.)

QUERCUS ACUTA

Quercus acuta, Thunberg, *Fl. Jap.* 175 (1784); Shirasawa, *Icon. Ess. Forest. Japon*, text 60, t. 32, figs. 1-13 (1900).

Quercus Buergerii, Blume, in *Mus. Lugd. Bat.* i. 299 (1850).

Quercus marginata, Blume, in *Mus. Lugd. Bat.* i. 304 (1850).

A small tree; young branchlets covered with a dense brownish tomentum, speedily deciduous, though traces of it persist near the tip of the branchlet and above the insertions of the leaves. Buds spindle-shaped, $\frac{1}{3}$ in. long, with reddish glabrous scales. Leaves (Plate 338, Fig. 56) coriaceous, persistent for two years, 4 to 5 in. long, $1\frac{1}{2}$ to 2 in. wide, elliptical; gradually tapering at the base, and prolonged as a narrow wing on each side of the petiole; abruptly contracted into an acuminate apex; entire in margin or with undulate slight crenations towards the apex; lateral nerves about nine pairs, dividing and looping before reaching the margin; glabrous on both surfaces, dull or yellowish green below; petiole $\frac{1}{2}$ to 1 in., glabrous.

Fruit (section *Cyclobalanopsis*) ripening in the second year, clustered on a tomentose peduncle; acorn ovoid, with a laminate pubescent umbo; cupule hemispheric, with tomentose scales connate into about six concentric zones.

This species, which is a native of Japan, was introduced into England by Maries in 1877. It forms a large bush in this country, where it is perfectly hardy, the finest specimen probably being one at Coombe Wood,³ growing on a cold clay soil in an exposed position, and about 20 ft. in height. Seedling plants vary much in habit.

A specimen at Kew, from Holker Hall, bears immature fruit. (A. H.)

¹ Cf. F. B. Forbes, in *Journ. Bot.* xxii. 85 (1884).

² *Gard. Chron.*, 1860, p. 160. In the Cambridge Herbarium there is a specimen dated 1860, from a plant in Glendinning's nursery, raised from acorns sent by Fortune, and labelled *Q. bambusifolia*. The leaves of this specimen, like most of the plants in cultivation, have smaller serrations than those which occur on native adult trees.

³ *Hortus Veitchii*, 405 (1906). Cf. also *Woods and Forests*, 1884, p. 85, and *The Garden*, xix. 285, fig. (1881).

QUERCUS DENSIFLORA

Quercus densiflora, Hooker and Arnott, *Bot. Voy. Beechey*, 391 (1849); Hooker, *Icon. Plant.* t. 380 (1841); Sargent, *Silva N. Amer.* viii. 183, t. 438 (1895).

Quercus echinacea, Torrey, *Pacific R. R. Rep.* iv. 1, p. 137, t. 14 (1856).

Pasania densiflora, Oersted, in *Kjoeb. Vidensk. Medd.*, 1866, p. 83; Schneider, *Laubholzkunde*, i. 161 (1904); Sargent, *Trees N. Amer.* 225 (1905).

A tree, attaining in California 80 or 90 ft. in height, and 18 ft. in girth. Bark divided by narrow fissures into broad rounded scaly ridges. Young branchlets with a dense stellate tomentum, partly retained in the second year. Leaves (Plate 338, Fig. 54) coriaceous, persistent two or three years, 3 to 4 in. long, 1 to 2 in. broad, oblong or ovate-oblong, acute or rounded at the apex, rounded at the base; with about twelve pairs of prominent lateral nerves, all but the lower one or two pairs ending in a cartilaginous-tipped serration; margin revolute; upper surface shining green, glabrous; lower surface rusty pubescent at first, ultimately becoming glabrous and whitish or greyish, some pubescence being often retained on the midrib near the base; petiole $\frac{1}{2}$ to $\frac{3}{4}$ in. long, tomentose.

Fruit (section *Pasania*) ripening in the second year, solitary or in pairs on a stout tomentose peduncle; acorn about 1 in. long, enclosed at the base in a shallow cupule, $\frac{3}{8}$ in. in diameter, with scattered long hairs within; and covered externally with spreading or recurved, long linear rigid stellate-pubescent scales, usually tipped with a reddish gland.

Var. *echinoides*, Sargent,¹ is a shrubby form, with small entire leaves, growing at high elevations in the Siskiyou mountains and the northern part of the Sierra Nevada.

Q. densiflora is distributed from the valley of the Umpqua river in Oregon, southwards through the coast ranges to the Santa Inez mountains in California, and along the western slope of the Sierra Nevada, below 4000 ft. elevation, to Mariposa County. It is abundant in the coast region north of San Francisco bay, and attains its largest size in Napa and Mendocino Counties. Sargent² gives a good illustration of a fine tree near San Francisco. This species has been much cut down on account of its bark, which contains a large amount of tannin; but owing to the vigorous way in which the stumps produce coppice shoots, there is little danger of its extinction.

This tree is apparently unknown in cultivation in Europe, except at Kew, where there are two healthy trees, which scarcely suffered³ from the severe winters of 1879-80, and 1880-81. One in the oak collection measures 21 ft. high by $14\frac{1}{2}$ in., the other, near the flagstaff, is 18 ft. by 1 ft. These were raised from acorns sent to Kew by Prof. Sargent in November 1874. (A. H.)

¹ *Silva N. Amer.* viii. 183, note.

² *Garden and Forest*, v. 517, fig. 89 (1892).

³ Cf. *Gard. Chron.* xvii. 228 (1882).

QUERCUS GLABRA

Quercus glabra, Thunberg, *Fl. Jap.* 175 (1784); Franchet et Savatier, *Enum. Fl. Jap.* i. 447 (1875); Masters, in *Gard. Chron.* xiv. 784, fig. 153 (1880).

Pasania glabra, Oersted, in *Kjoeb. Vidensk. Medd.*, 1866, p. 81; Shirasawa, *Icon. Ess. Forest. Japon.*, text 61, t. 32, figs. 14-24 (1900); Schneider, *Laubholzkunde*, i. 160, fig. 95 (1904).

A small tree with smooth bark. Young branches glabrous. Leaves (Plate 338, Fig. 50) coriaceous, persistent for two or three years, 4 to 5 in. long, 1 to 1½ in. broad, lanceolate or elliptical, tapering at the base and prolonged as a narrow wing on each side of the petiole; apex acute or contracted into a short acumen, rounded at the tip; margin entire, revolute; upper surface shining, glabrescent; lower surface pale, glabrous, with numerous shining minute dots; lateral nerves about ten pairs, dividing and looping before reaching the margin; petiole glabrous, ¼ to ¾ in. long.

Fruit (section *Pasania*) ripening in the second year, grouped in threes and numerous, but only a few developing, on an erect spike about 4 in. long; acorn ovoid, about an inch long, pointed, glabrous, surrounded at the base by a shallow cupule, ½ in. in diameter, covered with appressed grey tomentose ovate acuminate scales.

Q. glabra is a native of Japan, and was introduced¹ into cultivation in England in 1842, when plants were raised in the Tooting and Epsom Nurseries. We have not been able to separate as distinct var. *latifolia*² introduced by Maries in 1877. This species does not appear to be quite so hardy as *Q. acuta*, and remains a large bush, often seen in gardens in the south and west of England, and in Ireland, where it ripens fruit.³ There are specimens in the oak collection at Kew. (A. H.)

QUERCUS CUSPIDATA

Quercus cuspidata, Thunberg, *Fl. Jap.* 176 (1784); Franchet et Savatier, *Enum. Pl. Jap.* i. 449 (1875); Masters, in *Gard. Chron.* xii. 232, f. 38 (1879); Skan, in *Journ. Linn. Soc. (Bot.)* xxvi. 510 (1899).

Pasania cuspidata, Oersted, in *Kjoeb. Vidensk. Medd.*, 1866, p. 81; Shirasawa, *Icon. Ess. Forest. Japon.*, text 62, t. 34, figs. 1-13 (1900); Schneider, *Laubholzkunde*, i. 160 (1904).

A large tree. Bark smooth on young stems, deeply fissured on old trunks. Young branchlets glabrescent. Leaves (Plate 338, Fig. 51) coriaceous, persistent two or three years, 2 to 3 in. long, ¾ to 1 in. broad, elliptical; base tapering

¹ Loudon, *Gard. Mag.* xviii. 17, 41 (1842). Gay, in *Bull. Soc. Bot. France*, v. 32 (1858), mentions a small plant at Verrières in 1858; but this is not referred to in *Hortus Vilmorinianus*, published in 1906.

² Veitch, *Cat. Trees and Shrubs*, 1881-82, p. 22, and *Hortus Veitchii*, 405 (1906).

³ It ripened fruit in 1852 at Bishopstoke, Hants, according to *Gardeners' Chronicle*, 1852, p. 695.

and prolonged as a narrow wing on each side of the petiole; apex long acuminate, rounded at the tip; margin entire, revolute; lateral nerves about eight pairs, inconspicuous, dividing and looping before reaching the margin; upper surface shining, dark green, glabrous; lower surface pale, with deciduous minute appressed pubescence, and showing under the lens shining dots; petiole ¼ in., with scattered minute pubescence.

Fruit (section *Pasania*) ripening in the second year, six to ten alternate and sessile on an erect peduncle; cupule ovoid, acute, ¾ in. long, composed of several rows of coalesced tomentose scales, completely enclosing the acorn, which is set free by the irregular splitting of the cupule into two to four valves.

This species is a native of Japan, Formosa, Korea, and central and southern China. According to Sargent,¹ it is the most widely distributed evergreen oak of Japan, often forming extensive forests in southern Hondo. Its acorns are edible when cooked and are sold in the Japanese markets. The most valuable mushroom of Japan is artificially cultivated upon pieces of the bark of this tree.²

Siebold³ sent acorns of this and other Japanese oaks to Leyden in 1830; but it appears to have been first introduced into England in 1879 by Maries.⁴ The only specimens which we have seen, those at Coombe Wood and at Kew, are shrubby in habit. Maries also sent home from Japan a variegated form (var. *variegata*),⁴ which does not seem to be now in cultivation. (A. H.)

NOTICE TO SUBSCRIBERS

ON publishing the Fifth Volume of this work, we desire to explain the unavoidable delay which has taken place in its publication, by saying that we could not foresee the amount of time and work which its preparation required. In the five volumes now issued, we have given subscribers 340 pages and 40 plates more than was promised; yet the vast amount of new material which has come to light since the original prospectus was issued in 1906 compels us to add a Sixth Volume, the materials for which are now ready. As this will be a thick volume, we think that a complete Index to the work will be more convenient to use if printed and bound separately. A few plates of remarkable trees, of kinds described in previous volumes, but not then known to us, will be added; and these may, if desired, be interpolated when the volumes are bound. Another notice will be issued as soon as an estimate can be made of the cost of the Sixth Volume.

We wish to thank most cordially the large number of correspondents and friends who have so greatly assisted us in various ways since we commenced our work; and though we have spared neither time, trouble, nor expense on the Illustrations, we trust that subscribers will forgive any imperfections due to the great difficulty of obtaining successful photographs of trees scattered in remote places throughout the whole of Great Britain and Ireland.

As it is our desire that this work shall be available for reference in public libraries, we would call the attention of librarians to the fact that only a small number of copies remain unsubscribed for.

NOTICE TO SUBSCRIBERS

THE favourable manner in which the Notice to Subscribers issued with the Fifth Volume of this work (*The Trees of Great Britain and Ireland*) was received, leads us to hope for their approval of the course we are now about to adopt, after consultation with some of our best supporters.

In consequence of the great additions to our knowledge, and the extreme difficulty of some of the genera described, the last part of the work has increased to over 500 pages, which, if published in one volume, would far exceed in size and cost those hitherto published. We have therefore decided to complete the work in two volumes. Vol. VII. will be issued, together with a general Index to the whole work, before the end of the year. In accordance with what was indicated in our last Notice to Subscribers the cost of these two volumes and the Index will be Five Guineas.

H. J. ELWES.

A. HENRY.

PICEA

THE characters of the Genus *Picea* and of the two sections into which it is divided have been given in Vol. I. pp. 75-76, with a description of the species belonging to the section *Omorica*. At that time the Sikkim spruce (*P. spinulosa*), one of this section, was imperfectly known, and a full account of it is now given at the end of this article. See p. 1392.

In the section *Eu-picea*, the leaves are quadrangular or rhombic in section, and bear stomatic lines on all their four sides. About fifteen species of quadrangular-leaved spruces are known,¹ which may be readily distinguished by the following key, based on the characters of the branchlets, buds, and leaves.

KEY TO SECTION EU-PICEA

I. *Branchlets quite glabrous.*

* *Leaves on lateral branches radially arranged, spreading uniformly on all sides.*

1. *Picea Smithiana*, Boissier. Western Himalayas. See p. 1366.

Branchlets pendulous, grey. Buds large, resinous, pointed. Leaves slender, about $1\frac{1}{2}$ in. long.

2. *Picea Maximowiczii*, Regel. Japan. See p. 1374.

Branchlets not pendulous, reddish brown. Buds small, resinous. Leaves, $\frac{3}{8}$ to $\frac{1}{2}$ in. long.

** *Leaves on lateral branches in an imperfect radial arrangement, not pectinate in two sets on the lower side of the branchlets, which are not pendulous.*

3. *Picea Schrenkiana*, Fischer and Meyer. Central Asia, in the Alatau and Thianshan ranges. See p. 1364.

Branchlets ashy grey. Terminal buds subglobose, girt with a ring of keeled pointed pubescent ciliate scales. Leaves rigid, sharp-pointed, $\frac{3}{4}$ to $1\frac{1}{4}$ in. long.

4. *Picea pungens*, Engelmann. Wyoming, Colorado, Utah, New Mexico. See p. 1389.

Branchlets at first glaucous, becoming reddish brown. Buds with the tips of their upper scales usually loose and reflexed. Leaves stout, rigid, with a hard sharp-pointed apex, $\frac{3}{4}$ to $1\frac{1}{4}$ in. long.

¹ Not including the spruces of China, of which two or three species introduced by Wilson are in cultivation at Coombe Wood, but are too young to describe.

5. *Picea polita*, Carrière. Japan. See p. 1370.
Branchlets yellow. Buds shining reddish brown, with closely imbricated scales. Leaves rigid, stout, curved, ending in a spine-like point.

*** Leaves on lateral branches, imbricated on the upper side of the branchlet; those below, pectinate and spreading laterally in two sets.

6. *Picea alba*, Link. North America. See p. 1380.
Branchlets greyish or pale brown, usually glaucous. Buds with glabrous non-ciliate bifid scales. Leaves disagreeable in odour when bruised, about $\frac{1}{2}$ in. long.
7. *Picea bicolor*, Mayr. Japan. See p. 1372.
Branchlets yellow, glabrous on lateral branches, pubescent in the furrows on leading shoots. Buds with scarious scales. Leaves, with two conspicuous white stomatic bands, each of five to six lines, on the two dorsal sides, and two bands of two lines on the two ventral sides.

II. Branchlets¹ variable, quite glabrous or with slight scattered pubescence.

8. *Picea excelsa*, Link. Europe. See p. 1337.
Branchlets reddish, usually quite glabrous, or with slight pubescence often confined to the grooves between the pulvini. Terminal buds conical, acute, without resin, girt with a ring of keeled pubescent ciliate pointed scales. Leaves, usually $\frac{3}{4}$ to 1 in. long, with two to three stomatic lines on each of the four sides.
9. *Picea albertiana*, Stewardson Brown. Alberta, British Columbia, Montana, Wyoming. See p. 1385.
Branchlets greyish yellow, either glabrous or with minute pubescence usually confined to the pegs from which the leaves arise. Buds slightly resinous with rounded entire scales. Leaves, in an imperfect radial arrangement on the lateral branches, $\frac{1}{2}$ to 1 in. long.

III. Branchlets always plainly pubescent. Leaves arranged on lateral branches, as in *P. excelsa*.

* Terminal buds with a ring of conspicuous long subulate scales.

10. *Picea nigra*, Link. North America. See p. 1375.
Branchlets covered with dense short glandular pubescence. Leaves bluish or glaucous green, about $\frac{1}{2}$ in. long.
11. *Picea rubra*, Link. North America. See p. 1377.
Branchlets, as in *P. nigra*. Leaves yellowish green or dark green, not glaucous, $\frac{1}{2}$ to $\frac{5}{8}$ in. long.
12. *Picea Glehnii*, Masters. Saghalien, Yezo. See p. 1369.
Branchlets reddish, with short non-glandular pubescence, confined to the furrows between the pulvini. Leaves slender, $\frac{1}{3}$ to $\frac{1}{2}$ in. long.

¹ Cf. *P. bicolor*, No. 7, which has pubescent leading shoots and glabrous lateral branches.

** Terminal buds without long subulate scales.

13. *Picea orientalis*, Carrière. Asia Minor, Caucasus. See p. 1362.
Branchlets slender, pale brown, covered with dense short non-glandular pubescence. Leaves, $\frac{1}{4}$ to $\frac{2}{5}$ in. long, shining dark green, blunt and bevelled at the tip.
14. *Picea Engelmanni*, Engelmann. Western North America. See p. 1387.
Branchlets greyish yellow, with a sparse minute glandular pubescence. Leaves disagreeable in odour when bruised, bluish green, $\frac{7}{8}$ to 1 in. long.
15. *Picea obovata*, Ledebour. Northern Scandinavia, Russia, Siberia; sporadic at high altitudes in the mountains of Central Europe. See p. 1359.
Branchlets reddish brown, covered with a dense minute non-glandular pubescence. Leaves, $\frac{2}{5}$ to $\frac{3}{8}$ in. long, short-pointed, with three to four stomatic lines on each side.

- Picea Abies*, Karsten, *Pharm. Med. Bot.* 324 (1881).
- Pinus Abies*, Linnæus, *Sp. Pl.* 1002 (1753).
- Pinus Picea*, Du Roi, *Obs. Bot.* 37 (1771) (not Linnæus).
- Pinus excelsa*, Lamarck, *Fl. Franc.* ii. 202 (1778).
- Abies Picea*, Miller, *Dict.*, 8th ed., No. 3 (1768).
- Abies excelsa*, De Candolle, in Lamarck, *Fl. Franc.* iii. 275 (1805); Loudon, *Arb. et Frut. Brit.* iv. 2293 (1838).
- Abies carpatica*, Lawson, *Pinet. Brit.* ii. 137, t. 20 (1867).

A tree, often attaining in Britain 120 to 140 ft. in height and 10 to 12 ft. in girth, in central Europe attaining 200 ft. high and 15 to 20 ft. in girth. Bark on young stems brownish, thin, smooth; on older trees thick, and scaling off on the surface in thin small scales. Young branchlets, reddish or yellowish brown, glabrous or with a minute scattered non-glandular pubescence, often confined to the furrows between the pulvini. Buds conical, acute, reddish brown, without resin, with rounded scarious scales; terminal bud girt with a few acuminate keeled pubescent ciliate scales.

Leaves on erect shoots radially spreading, more or less appressed to the twigs with their tips directed upwards: on lateral branches, pectinate below, the lower side of the twig being laid bare, most of the leaves being directed forwards and outwards; while on the upper side of the twig, the leaves in the middle line are more or less

¹ Dietrich's name and description apply to the common European spruce, and not to the American red spruce, as is often erroneously supposed.

appressed, with their tips directed forwards and slightly upwards. Leaves, variable in size, usually $\frac{1}{2}$ to $\frac{3}{4}$ in., occasionally 1 in. long, rigid, straight or curved, ending in a short callous point, rhombic in section, with two or three stomatic lines on each of the four sides; resin-canals variable, occasionally absent or only one present, usually two, one at each end of the transverse axis of the rhomb, close to the epidermis.

Staminate flowers solitary in the axils of the leaves of the branchlets of the preceding year, rarely terminal on lateral branchlets, ovoid, about an inch long; stamens numerous, spirally arranged, reddish, each with two pollen-sacs directed downwards and dehiscing longitudinally, and a prominent denticulate connective; pollen grains, each with two air-vesicles.

Pistillate flowers, appearing in summer as brown buds at the tips of the branchlets of the current year, developing in the following spring, about 2 in. long; sessile, erect, cylindrical, purplish red; scales carmine red, oval, with a truncate erose apex; bracts about half the length of the scales, not increasing in size after the time of flowering, ovate-lanceolate, denticulate, with a long acuminate apex. After fertilisation the young cones leave the erect position, and gradually become pendulous, their scales becoming closely imbricated, and in the usual form of the species green in colour.

Cones ripe in October, when they turn brownish; cylindrical, pendulous, variable in size, about 4 to 6 in. in length; usually opening in spring and letting the seeds escape when a dry east wind is blowing; falling from the tree in the subsequent summer or autumn; scales thin and flexible, rhombic, with a truncate emarginate or dentate apex, variable in size, $\frac{5}{8}$ to $\frac{3}{4}$ in. wide, 1 to $1\frac{1}{4}$ in. long, pale brown and glabrous on the exposed part, dark reddish brown and minutely pubescent on the concealed part; bract about $\frac{1}{5}$ in. long, lanceolate, denticulate at the acute or acuminate apex. Seed about $\frac{1}{6}$ in. long, dark dull brown; seed with wing about $\frac{3}{8}$ in. long; wing broadest near the obliquely rounded denticulate apex.

Seedling.—Seeds sown in spring germinate in four or five weeks, the radicle first making its way out of the seed coats, and the caulicle carrying up the cotyledons, which are at first enveloped as with a cap by the albumen of the seed. The cap is soon cast off, and the cotyledons spread in a whorl. The cotyledons are six to ten in number, united at their base by a sheath, about $\frac{1}{2}$ in. long, triangular in section, with the upper edge faintly serrate, without resin-canals, stomatic on the two inner surfaces, deciduous at the end of the second year. The plant at the end of the first year is about 2 to 3 in. high, the young stem bearing, in addition to the whorl of cotyledons, spirally arranged primary needles, which are rhomboidal in section, serrulate on the four angles, with two resin-canals, and inserted on raised pulvini. Branching occurs in the third or fourth year, when the leaves assume their adult form, being entire and not serrulate. No tap root is formed, the root dividing into numerous branches spreading in all directions. Throughout the life of the tree the absence of the tap root, seen in the seedling, persists; and the roots of the spruce are usually spreading and do not penetrate the soil to any great depth.

The spruce is normally monœcious, but instances have been known of

individuals which always bear staminate flowers; and hermaphrodite flowers have been observed. The flowers are pollinated by the wind, the pollen being carried to an immense distance; as far as eight miles in a case which was noticed near Munich. In the vicinity of spruce forests the pollen often descends in enormous quantity, covering the ground and the surface of lakes and rivers with yellow patches.

I. The following variations occur in the form of the scales of the cone:—

1. Var. *europæa*, Schröter, *op. cit.* 142 (1898).

Var. *montana*, Ascherson and Graebner, *op. cit.* 198 (1897).

Picea vulgaris, Link, var. *europæa*, Teplouchoff, in *Bull. Soc. Nat. Mosc.*, xli. pt. ii. 249 (1869).

Cone-scales rhombic, gradually narrowing in the upper third to a truncate, slightly inflexed, emarginate or denticulate apex. This is the common form of *P. excelsa*, widely distributed throughout central Europe, and also occurring in southern Sweden. In the Alps it is rarely found over 5000 feet elevation.

2. Var. *acuminata*, Beck, in *Ann. Nat. Hofm. Wien*, ii. 39 (1887).

Cone-scales, contracted suddenly into a long bifid recurved undulate apex. This variety is of rarer occurrence in central Europe than the preceding; but is found in the Jura¹ and the Alps, and is said to be common in eastern Prussia and in southern Sweden.

3. Var. *triloba*, Ascherson and Graebner, *op. cit.* 199 (1897).

Scales of the cone trilobed at the apex. This is a much less common variation, which has been noticed in a few trees growing at Blankenburg² in the Harz Mountains, at Soglio³ to the north of Lake Como, and in Moravia.⁴

II. There appear to be two races of the common spruce in the continental forests, which are mainly distinguishable by the colour assumed by the unripe cones in August.

4. Var. *chlorocarpa*, Purkyne, in *Allg. Forst. u. Jagdzeit*, liii. 1 (1877). Cones remaining green in August.

5. Var. *erythrocarpa*, Purkyne, *loc. cit.* Cones becoming dark violet in August.

Purkyne considered that important differences in the growth of the tree, in the character of the wood, in the staminate and pistillate flowers, and in the soil occupied by each form, were correlated with the differences in the colour of the cones; but Schröter considers that these are not established, and suggests further investigation.

III. The spruce varies much in habit in the wild state, and several remarkable sports have been described.

6. Var. *viminalis*, Caspary, in *Schr. Phys. Oekon. Ges. Königsberg*, xiv. 126 (1873).

Pinus viminalis, Sparrman, ex Alstroemer, in *Vet. Ac. Handl. Stockh.* xxxviii. 310 (1777).

Pinus hybrida, Liljeblad, in *Svensk Fl.* (1792).

¹ Cf. Aubert, *Flore de la Vallée de Joux*, 345 (1900).

² A. Braun, in *Verh. Bot. Verein Prov. Brandenburg*, xviii. Sitzb. 13 (1876).

³ Ascherson and Graebner, ex Schröter, *op. cit.* 204, fig. 31 (1898).

⁴ Wilhelm, in *Oesterr. Forstzeit.* 1838, p. 169.

Branches in remote almost horizontal whorls, with very long and slender branchlets (often 10 ft., occasionally 20 ft. long) without or with very few lateral branchlets. Leaves radially spreading.

This remarkable form of the weeping spruce was considered by Linnæus¹ to be a hybrid between the spruce and *Pinus sylvestris*. It has been observed in about twenty places in Sweden, where it is vulgarly called *Tysk gran* or German spruce, in about the same number of localities in Norway, and in isolated cases in Livland, East Prussia, Poland, Thuringia, Tyrol, Styria, Carinthia, Carniola, and Switzerland.² When sown, the peculiar habit is occasionally reproduced.³

7. Var. *pendula*, Jacques and Hérincq, *Man. Gén. Plantes*, iv. 340, 341 (1857).

A remarkable form of the weeping spruce, narrow and columnar in habit, with pendulous branches almost appressed to the stem. Conwentz⁴ has described this form, known to him as a single tree⁵ in the Stellan forest near Elbing in West Prussia, another⁶ at Jegothen, near Heilsberg in East Prussia, and two others⁷ near Schierke in the Harz Mountains. Kraemer⁸ found another in a forest near Kreut in Bavaria. Solitary examples have also been found in Switzerland,⁹ in northern Hungary,¹⁰ and in the Bukowina.¹¹ The seed of the weeping spruce near Jegothen, when sown by Conwentz,⁴ gave twelve trees, only one of which showed a tendency to the weeping habit.

A similar tree with longer leaves, lighter in colour than the typical form, was discovered¹² about the year 1860 by Mr. R. Smith Carrington in a plantation near Kinlet Hall, Shropshire, which was propagated by R. Smith and Company, Worcester, who sold it under the name *Abies excelsa inverta*,¹³ Gordon, *Pinet. Suppl.* 4 (1862), a name scarcely worth keeping distinct from var. *pendula*, Jacques and Hérincq, which antedated it a few years. A fine example, about 30 ft. high, was growing¹⁴ in 1897 at Ide Hill, Sevenoaks, Kent; and a good specimen exists at Murthly Castle. There is also a good example¹⁵ at Barbier's nursery, Orleans.

Other kinds of weeping spruce, probably including *Abies excelsa pendula*, Loudon, a form introduced by Booth, are irregular in habit and much more spreading. A very fine example occurs at Durris.

¹ Linnæus refers to it as *Abies procera viminalis* in *Fl. Suec.* 288 (1745).

² Cf. Schröter, *op. cit.* 151, who draws attention to the fact that *P. Breweriana*, of the Siskiyou Mountains, has this habit as a constant specific character.

³ Cf. Wilhelm, in *Verh. K. K. Zool. Bot. Ges. Wien*, xxxvii. (1887).

⁴ *Beob. Seltene Waldbäume W. Preussen*, 135 (1895).

⁵ Figured in *Gartenflora*, 1899, p. 618, fig. 86; and by Conwentz, *op. cit.* 141, figs. 12, 13.

⁶ Figured by Conwentz, *op. cit.* 147, fig. 14.

⁷ Figured in *Gartenflora*, 1901, p. 315, figs. 48, 49; and by Conwentz, *op. cit.* 150, 152, figs. 15, 16.

⁸ In *Flora*, 1841, p. 700.

⁹ Schröter, *op. cit.* 156 (1898).

¹⁰ Schilberszky, in *Kertészeti Lapok*, vii. (1892), describes a weeping spruce near Leutschau.

¹¹ Cf. *Oesterr. Forst. u. Jagdzeit.* 1897, p. 356.

¹² Nicholson, in *Woods and Forests*, 1884, p. 691; and *The Garden*, xxv. 229 (1884).

¹³ *Picea excelsa inversa*, Beissner, *Nadelholzkunde*, 361 (1891).

¹⁴ *Gard. Chron.* xxii. 368, fig. 109 (1897). Cf. also *Gard. Chron.* xxix. 263, fig. 98 (1901).

¹⁵ Figured in *Gartenflora*, 1899, p. 617, fig. 87; and by Conwentz, *op. cit.* 163, fig. 17.

The "Cornish fir" which was mentioned by Hayes¹ as growing in 1794 at Avondale in Co. Wicklow, was pendulous in habit and bore large cones, sometimes nearly a foot in length. The remarkable pendulous spruce² at Shelsley Walsh, in the Teme Valley in Worcestershire, bears cones 9 in. in length, and appears to be identical with Hayes' variety.

8. Var. *columnaris*, Carrière, *Conif.* 248 (1855). Narrowly columnar in habit, with short horizontal branches, clothed with dense short branchlets and foliage.

This form, which has been known a long time in cultivation, exists in the wild state in Switzerland, where six trees are known by Schröter in the five localities of Stanserhorn, Stockhorn, la Brévine, Chavannes, and la Berboleuse, all at high altitudes between 4000 and 5800 ft.

The columnar spruce³ is to be carefully distinguished from the narrow spruce, known as the *spitzfichte*,⁴ in which the habit does not result as a sport, but is due to a severe climate, which checks the growth of the branches. The *spitzfichte* is similar to the columnar spruce in form, being narrowly cylindrical, but the stem is sparingly clad with short branches, wide apart, and forming a thin crown of foliage. The *spitzfichte* is never seen at low levels in the Alps and Jura, but occurs near the timber line, often forming small groves in exposed situations. This climatic form is much more common in *P. obovata* in Lapland, Finland, and northern Scandinavia.

9. Var. *pyramidata*, Carrière, 247 (1855).

Var. *stricta*, Schröter, *op. cit.* 158 (1898).

Branches ascending at a narrow angle, forming a nearly fastigiate tree. Trees of this kind are occasionally seen in the forests of central Europe, and are rarely found in the seed bed in nurseries.

10. Var. *strigosa*, Christ, in *Garden and Forest*, ix. 252 (1896).

A form with numerous slender horizontal branchlets, spreading from all sides of the branches, giving the tree the habit of the common larch. This variety occurs in one locality in the canton of St. Gall in Switzerland.

11. Var. *eremita*, Carrière, in Jacques and Hérincq, *Man. Gén. Plantes*, iv. 341 (1857).

A tree of slender pyramidal habit with numerous branches, directed upwards at a small angle with the stem, short stout branchlets, large buds, and distant short thick sharp-pointed needles.

Var. *Remonti*, said by Kent⁵ to be a dwarf modification of this, is described by Masters⁶ as of dense compact pyramidal habit, recalling that of *Cupressus Lawsoniana*, var. *erecta viridis*.

¹ *Planting*, 165 (1794). It is first mentioned apparently in *London Catalogue of Trees* (1730), as the long-coned Cornish fir, said to have been "brought from America some years previously and planted in Devon and Cornwall."

² Erroneously referred to *P. Smithiana* (as *P. Morinda*) in *Gard. Chron.* 1869, p. 713, and xix. 132 (1896).

³ Dr. Christ, in *Garden and Forest*, ix. 252 (1896), uses the term columnar spruce for the *spitzfichte*, which is not strictly accurate.

⁴ First named and described by Berg, in *Jahrbuch K. Sächs. Akad. Forst. Tharand.* xiii. 83 (1859).

⁵ Veitch's *Man. Conif.* 433 (1900).

⁶ In *Gard. Chron.* vii. 578 (1890).

12. Var. *virgata*, Caspary, *op. cit.* xiv. 125 (1873).

Abies excelsa, De Candolle, var. *virgata*, Jacques, in *Ann. Soc. Hort. Paris*, xlv. 653 (1853).

Abies excelsa Cranstonii, Knight and Perry, *Syn. Conif.* 36 (1850).

Picea excelsa, Link, var. *denudata*, Carrière, in *Rev. Hort.* iii. 102, fig. 7 (1854).

Branches very few and usually not in whorls, elongated, straight or curved, with very few or without branchlets. Leaves radially arranged, either longer or shorter than in the common spruce, persistent ten or twelve years.

This variety,¹ which is known as the snake spruce, owes its peculiarities to the arrest of nearly all the buds, which do not develop. Most of the examples recorded are young trees, but one² forty years old at Buttes, near Neuveville in the Swiss Jura, was 40 ft. high in 1898. The snake spruce is not uncommon in Norway, where Schübeler found it in seventeen localities between lat. $59\frac{1}{2}^{\circ}$ and $61\frac{1}{2}^{\circ}$; and also occurs here and there in Sweden between lat. 58° and 63° . Isolated examples are reported from Finland, Livland, and Courland which are probably *P. obovata*; and others occur in different parts of Germany. It is common in Bohemia; and one example is known in Moravia. Schröter mentions seventeen trees growing in ten localities in Switzerland. Carrière knew only one example, growing in Cochet's nursery at Suynes, near Brie-Comte-Robert, in Seine-et-Marne.

Varieties intermediate between the snake spruce and vars. *pendula*, *monstrosa*, and *viminalis* also occur, but are very rare.

13. Var. *monstrosa*, Schröter, *op. cit.* 170 (1898). (Not Carrière.³)

Abies excelsa, De Candolle, var. *monstrosa*, Loudon, *Arb. et Frut. Brit.* iv. 2295 (1838).

Abies adada, Salvi, in *Flora*, 1844, p. 519.

Picea excelsa, Link, var. *monocaulis*, Nördlinger, *ex Willkomm, Forstl. Flora*, 76 (1887).

This variety, which never develops any lateral branches, has a single thickened stem, bearing leaves near the apex, persistent for many years, and about $1\frac{1}{3}$ in. in length.

This variety was first described by Loudon, who mentions a single specimen growing in the Chiswick garden, twelve years planted, and about 3 ft. in height. A specimen at High Canons, Hertford, produced cones of the ordinary form in⁴ 1907. Salvi found in 1842 four specimens, growing wild in the Euganean Hills, west of Padua. One of these which was transplanted to Isola Bella in Lake Maggiore, where I saw it in 1909, is attached to a bamboo, and trained up the wall of the château; it measures about 30 ft. in height and is nearly as thick ($1-1\frac{1}{2}$ inch) at the top as at the bottom, bearing leaves with very sharp points only on the upper two feet of the stem. Schröter records another specimen at Stockach in Baden, another in Bohemia, and another at Ansbach in Bavaria. A form of this variety is recorded

¹ An analogous form of the common silver fir, *Abies pectinata*, var. *virgata*, Caspary, in *Bot. Zeit.* 778, t. ix. (1882), occurs; but only four examples are known—two in Alsace, one in the Bohemian forest, and another in the Swiss Jura near Neuveville. The latter is described and figured by Schröter, *op. cit.* 168, fig. 15 (1898). Cf. vol. iv. p. 722.

² The oldest known to Schröter was one near Dorpat, in Livland, said by Berg, in *Schrf. Naturf. Ges. Univ. Dorpat*, ii. t. 2 (1887), to be sixty years old.

³ Carrière, *Conif.* 248 (1855), wrongly applied the name *monstrosa* to var. *virgata*, Caspary.

⁴ According to *Gard. Chron.* xxv. 146 (1886), var. *monstrosa* at Lucombe, Pince and Co.'s Nursery, Exeter, produced cones in 1886 which were similar to those of the ordinary spruce.

from Silesia and Thuringia, which bears a few undivided branches at the base, the upper part being without branches.

14. Var. *globosa*, Berg, in *Schrift. Naturf. Ges. Univ. Dorpat*, ii. 19, 20 (1887).

In this variety, normal growth is replaced by numerous close branches, irregularly dividing into a great number of branchlets, similar to a witches' broom, and forming either a globose bush without any leader, or a conical bush with a leader arising out of a globose base. I saw a remarkable example of the globose spruce in 1909 at the Forestry Experimental Station, Zurich. Seedlings had been raised, one quarter of which had reverted to the habit of the ordinary spruce, the others being very various in appearance and intermediate between the parent form and the normal habit of the species.¹

In the true dwarf forms² of the spruce, the branching is regular, but the growth of the shoots is very small, and the needles are very short. The most important are:—

15. Var. *Clanbrassiliana*, Carrière, in Jacques and Hérincq, *Man. Gén. Plantes*, iv. 341 (1857).

Abies excelsa, De Candolle, var. *Clanbrassiliana*, Loudon, *Arb. et Frut. Brit.* iv. 2294 (1838).

A compact low dense globose bush, seldom higher than 5 or 6 ft.; branches and branchlets, much shortened; leaves about $\frac{1}{4}$ to $\frac{1}{2}$ in. long; buds very red in colour. This is supposed to have been found on the Moira estate, near Belfast, about the end of the eighteenth century, when it was introduced into England by Lord Clanbrassil. This dwarf form has been found growing wild in Thuringia, and near Stockholm, and in Jemtland in Sweden. It is always sterile, and is propagated by cuttings.

Elwes found at Tullymore Park, Co. Down, a large bush of this form measuring 10 ft. high and 28 ft. in circumference, which he was informed was either the original or a part of it, and was supposed to be about one hundred and fifty years old. A specimen at Aldenham has reverted to the normal type, and is now growing rapidly into an erect tree.

16. Var. *tabulaformis*, Carrière, *Product. et Fixat. Variétés*, 52 (1865), *Conif.* 333 (1867).

A prostrate form, with slender branchlets spreading horizontally over the ground. This is said by Carrière to have been taken, probably as a cutting, from a witches' broom, growing on an ordinary spruce in the Trianon. Torssander³ found a similar plant in Södermanland in Sweden, thirty years old, and only 20 in. high.

17. Other dwarf forms have been named, as vars. *pumila*,⁴ *pygmaea*,⁵ *Gregoryana*,⁶ *Maxwelli*,⁷ etc.

¹ Cf. Engler, in *Mitt. Schweiz. Forst. Versuch.* viii. pt. ii. 117, figs. 8, 9 (1904).

² See under *Witches' Brooms*, p. 1345.

³ In *Södermanland Botan. Notiser*, 1897, p. 169.

⁴ Beissner, *Nadelholzkunde*, 365 (1891).

⁵ Loudon, *op. cit.* 2295 (1838).

⁶ Said by Gordon, *Pinetum*, 9 (1875) to have been raised in the Cirencester Nursery.

⁷ Originated as a seedling in Messrs. Maxwell's nursery, Geneva, New York. Cf. *Woods and Forests*, 1884, p. 502, and Rehder, in Bailey, *Cycl. Amer. Hort.* iii. 1333, fig. 1798 (1901).

IV. Several varieties are known in which the leaves are coloured :—

18. Var. *aurea*, Carrière, *Conif.* 246 (1855).

Leaves yellowish white, shining. The golden spruce has been found wild in Carinthia.

19. Var. *finedonensis*, Gordon, *Pinet. Supp.* 4 (1862).

Leaves pale yellow at first, changing to a bronze colour, and ultimately becoming green.¹ This originated at Finedon Hall, Northamptonshire, where it came up accidentally in a bed of common spruce. It often loses its colour in cultivation, and at Colesborne has entirely reverted to the normal green. Var. *mutabilis*² has the young shoots creamy yellow in colour, changing to green by the end of the season. Mr. Bean³ saw in Hesse's nursery, Weener, Hanover, a very beautiful variety, with creamy white young shoots, which is called var. *argenteo-spica*.

20. Var. *variegata*, Carrière, *Conif.* 246 (1855).

Leaves variegated with pale yellow. A variegated form is mentioned by Loudon; and Wittrock⁴ found a tree with leaves variegated white at Helsingfors.

V. The colour of the bark of the common spruce varies from whitish grey to brown, probably due to influence of soil and climate. The following sports have been observed.

21. Var. *corticata*, Schröter, *op. cit.* 184 (1898).

Bark thick, up to $3\frac{1}{2}$ in., longitudinally fissured, and resembling that of a pine in external appearance, though in microscopical structure like the ordinary spruce. Schröter knew in 1898 only six spruces with thick bark, occurring in Austria, Bohemia, Hesse, Bavaria, and Switzerland; but more than twenty are now known⁵ in the latter country alone.

22. Var. *tuberculata*, Schröter, *op. cit.* 190 (1898).

Lower part of the stem covered with corky excrescences, projecting about an inch above the surface of the bark, where side branches are given off.⁶ Four examples only were known to Schröter in 1898, two in Austria, one in Bavaria, and one in Switzerland; but Badoux⁵ states that many more have since been found in Switzerland.

VI. In addition to the varieties and sports just described, which are of unknown origin, there are many peculiar forms of the spruce which are due to external influences, and which cannot, properly speaking, be named varieties or sports.

1. The candelabra spruce is often produced, when the leading shoot is broken off by the force of the wind or by other causes. A whorl of secondary branches becomes erect below the broken part of the stem, and forming a series of leaders, grows up, giving the tree a candelabra-like appearance.

2. Dwarf spruces,⁷ which are mere bushes, with irregular branches, dense

¹ Fowler, in *Gard. Chron.* 1872, p. 76, speaks of the inconstancy of the colour in different parts of the tree.

² Cf. Masters, in *Gard. Chron.* vii. 578 (1890).

³ *Kew. Bull.* 1908, p. 391.

⁴ In Hartman, *Skand. Flora*, 35 (1889).

⁵ Badoux, in *Journ. Forest. Suisse*, 1907, quoted by Beissner, in *Mitt. Deut. Dend. Ges.* 1910, p. 122.

⁶ Cf. Cieslar, in *Centralblatt Gesamte Forstwesen*, xx. Heft 4, pp. 145-149 (1894). Schröter compares these corky excrescences with those developed on the stems of *Zanthoxylum*, studied by Barber, in *Ann. Bot.* vi. 155 (1892).

⁷ *Picea ellipsoconis*, Borbas, *Magyar Bot. Lapok*, i. 26 (1902), a shrub-like spruce growing as scrub near tree-limit in the western Carpathians, with short broad cones, is considered by Pax, in *Pflanzenverw. Karpathen*, ii. 177 (1908), to owe its peculiarities to the high altitude, similar shrubs being recorded for the eastern Alps by Beck.

foliage, and numerous leaders occur in alpine regions, and are due either to the severe climate or to constant cropping by goats and sheep.

3. Witches' brooms on the spruce have hitherto been supposed to be due to the irritation of fungi, bacteria, or mites. Tubeuf,¹ in January 1907, sowed seed which he obtained from a witches' broom that had borne cones. The greater part of the seedlings are normal, but a certain number are dwarf and bushy. Tubeuf supposes that some of the former will in time develop witches' brooms on some of their branches, and that the latter will probably remain dwarf, resembling the varieties² *Clanbras-siliana*, *pumila*, etc., already referred to as of unknown origin.

4. Masters³ gives a figure of a remarkable branch of a spruce, in which the leading shoot had split into two portions for some distance, re-uniting above to form again one stem.

DISTRIBUTION

P. excelsa is a native of Europe, extending from the Pyrenees, Alps, and Balkans northward through south Germany and east Prussia to Scandinavia, and eastward through the Carpathians and Poland to western Russia.

In France, the spruce occurs in the mountains, mixed with the silver fir, and in the zone above it, the lower limit in the Vosges and Jura being about 2000 ft. It is not at all abundant in the Vosges, where it ascends to 4300 ft.; but in the Jura covers large areas, and reaches 5000 ft. altitude. It attains its greatest importance in Savoy, which is the only region in France where the spruce is the dominant tree, forming one half of the whole area occupied by forests. The forest of Thônes,⁴ near Annecy, which I visited in 1904, is one of the best examples of a spruce forest in France; and is treated on the selection system. It contains about 320 acres, lying between 2500 and 4300 ft. elevation on a steep slope, and is a mixture of two-thirds spruce and one-third silver fir. The standing timber is estimated at 7000 cubic ft. per acre, the annual felling averaging 53 cubic ft., with a revolution fixed at 144 years.

The spruce is absent in the Cévennes, and is extremely rare on the north side of the Pyrenees, where it is replaced by fine forests of *Pinus montana*. Willkomm records it for the Pyrenees of Catalonia and Aragon, where it is not at all common. Its most southerly point in western Europe is the forest of La Cinca, south of Mt. Maladetta in lat. 42° 30'.

In Germany, the northern limit of distribution, beginning in the Vosges, passes through the Pfalz, and after crossing the Rhine at lat. 50°, makes a bend to the westward through Westphalia, and reaches the Weser Mountains, where, near Minden, the spruce attains its most northerly point as a wild tree in western Germany, lat. 52° 20'. From here the limit passes through Hildesheim, Wolfenbüttel, Walbeck near Magdeburg, and Halberstadt to Altenburg; whence, taking a north-easterly direction, it is continued through Spremburg and Soran to Ostrowo, reaching the Russian frontier at lat. 52°. It then passes northward, parallel with the frontier, to

¹ Cf. Prof. Somerville, in *Quart. Journ. Forestry*, iv. 309 (1910).

² Cf. var. *tabulaformis*, Carrière, *ante* p. 1343.

³ In *Gard. Chron.* xxiii. 274, fig. 52 (1885).

⁴ Cf. *Bull. Soc. Forest. Franche-Comté*, vii. 630 (1904).

Gilgenberg in the province of East Prussia, and reaches the Gulf of Danzig at Elbing. In southern Germany it is scattered, or in small woods in the plains and valleys, being probably planted;¹ and as a wild tree is nearly confined to the mountains, where it occupies a distinct zone, with clearly defined upper and lower limits. The largest pure forests in Germany occur in the Harz mountains, which are almost entirely covered with spruce, ascending to 3300 ft., and in the Iser and Riesen mountains, up to 3900 ft. In the other great forest regions of Germany, as in the Thuringian, Bavarian, and Bohemian forests, the Fichtel and Erz mountains, central Saxony, etc., the spruce, in mixture with the silver fir, covers immense areas. In the province of East Prussia, there are very large forests on the plain, in which the spruce grows in company with the common pine, birch, alder, and willows; but it is absent on pure sandy soils, where the common pine reigns supreme.

The spruce is met with throughout the Alps in Switzerland and Italy, ranging in Tessin between 2700 and 6000 feet, and occupying a small outlying area in the Euganean hills in Lombardy. It is quite unknown in the Apennines.

In Austro-Hungary, extensive forests of spruce, often almost pure, occur in the Carpathians from Silesia to Bukowina, and in the Transylvanian mountains. The largest spruce recorded² is one which grew in the Carpathians, measuring 226 feet in height and 11½ feet in girth at breast height.

In the Balkan peninsula³ the spruce reaches its most southerly limit, a line extending from the mountains of northern Albania to the Kopaonik mountain in Servia, whence it is prolonged eastward to the Rhodope mountains in Rumelia about lat. 42°. In Bosnia, Servia, Montenegro, Croatia, and Herzegovina, the spruce usually grows in mixture with the beech and silver fir, occupying a zone on the mountains between 3000 and 6000 feet; but in northern Albania the lower limit rises to 4000 ft. Huffel⁴ states that in Roumania, the spruce attains enormous dimensions, a tree, which was cut down in 1888 in the forest of Tarcau, measuring 195 ft. in height by 3 ft. 3 in. in diameter at breast height; it was 392 years old. The spruce is much less common in Roumania than the silver fir, ascending to 6000 ft. in Wallachia and to 5000 feet in Moldavia; while in Bukovina the spruce is more abundant than the silver fir, and occupies a zone between 2600 and 5200 ft.

In Russia the southern limit of the spruce (including *P. obovata* and *P. excelsa*) extends from the frontier of Galicia, at lat. 50°, eastwards through northern Volhynia and Starodul in the government of Chernikof, crossing the river Oka at lat. 53° or 54°, to the southern boundary of the government of Kazan. From this northwards to the Arctic circle, the spruce is prevalent; but the exact boundary of the two species is unknown. So far as I have seen specimens, the spruce in Finland and near St. Petersburg is *P. obovata*, which all authors agree is the only spruce found in north-eastern Russia, as nothing like *P. excelsa* is seen to the eastward of the rivers Dwina

¹ It is supposed never to be native in situations below 1300 ft., though it thrives when planted. Left to nature the beech speedily supplants it on all soils at low elevations in southern Germany.

² Wessely, quoted by Mathieu, *Fl. Forestière*, 541 (1897). I have not been able to verify this record; but Schröter and Kirchner, *op. cit.* 115 (1906) state that Enderlin measured in the Grisons two trees as follows:—one, 143 ft. high, 6 ft. 3 in. in diameter, with a volume of 1300 cubic feet; the other, 152 ft. high, 4 ft. 11 in. in diameter, with a volume of 1150 cubic feet.

³ Beck von Mannagetta, *Veg. Illyrisch. Länd.* 287 (1901).

⁴ *Extrait Bull. Minist. Agric. Paris*, 1890, p. 6.

and Viatka. Korsinsky states¹ that the typical form of *P. excelsa* occurs only in western Russia in the region adjoining the German plain; and the varieties which he describes as occurring in central and northern Russia, and linking *P. obovata* with *P. excelsa*, seem to me to be simply *P. obovata* with cones slightly larger than those occurring in the Ural range.

Von Sievers² says that the spruce is the only shade-bearing tree in the Baltic provinces, and attains in favourable situations a height of 160 feet. It occurs naturally on better soil than the pine (which occupies poor sandy soil) and competes with the birch and alder on clay, thriving well on deep peat, if this is rich in mineral salts.

The original conifer of Norway was *Pinus sylvestris*, the remains of which are found everywhere in peat mosses. The spruce is a late emigrant from Sweden and Lapland. It occupies in Norway three distinct regions:³—

A. The spruce is found in the far north in isolated stations, as on the Varangerfjord, lat. 69° 30', at Karasjok, lat. 68° 30', and at Saltdalen, on the west coast, lat. 67° 10'.⁴ The spruce here is *P. obovata*, these stations being outposts of the north Russian spruce, which extends eastwards through Enara Lapland to the Kola peninsula, and through Swedish Lapland from Sulitjelma to Palojuensun on the Muonio river.

B. In the Trondhjem district the spruce reaches the coast, and is connected with the northern Swedish spruce, through four passes in the range separating Norway from the Swedish province of Jemtland. This spruce is *P. obovata*.⁵

C. In southern Norway the spruce, which appears to be *P. excelsa*, occupies a distinct area, separated from the last by the Dovrefjeld, and continuous with the spruce forests of south Sweden, there being no high mountains intervening between the two countries for a considerable distance north of Svinesund. Throughout this region, no remains of the spruce have been found in peat mosses, though those of the common pine are plentiful; and the spruce is evidently a late emigrant, not having yet reached the west coast. Through Romsdal, Bergenhus, and Stavanger provinces, and the district of Lister, the area covered by forest is not extensive, the principal trees being pine and birch, while the spruce is rarely if ever found wild, except in the inland district of Voss, situated about 40 miles east of Bergen. According to Schübeler, the spruce ascends on the Jotunfjeld to 3250 feet, and in Hallingdal to 3400 feet. South and east of the mountains, the greater part of the very extensive forest area consists of spruce, mixed to some extent with pine and birch. The Norwegian spruce is said to contain a relatively small amount of resin, and is therefore largely used in the production of mechanical and chemical wood-pulp, an industry, which in some places has begun to threaten the continued existence of the spruce forests. The spruce bark is also used for tanning.

² *Forst. Verhüll. Balt. Prov.* 18 (1903).

³ Cf. Semander, in Engler, *Bot. Jahrbüch.* xv. 3 (1893).

⁴ Elwes found it here in 1903 only as a rare isolated tree, and was told that the Rancenfjord, 50 miles south was its real northern limit.

⁵ Specimens collected at Trondhjem and at Bräcke in Sweden are identical, and are indistinguishable from specimens gathered in Perm in north-eastern Russia.

In Sweden the exact limits¹ between *P. obovata* and *P. excelsa* are unknown to me; but there is no doubt that in the northern part of the country, from Jemtland northwards, *P. obovata* is the sole species. In southern Sweden, the tree appears to be *P. excelsa*,² and its distribution³ is peculiar, as it does not extend to the extreme south, not occurring in Skåne north of lat. 56° 10', and not extending to nearer the west coast, from Strömstad to Halmsted, than fifteen miles at any point. Its remains have not been found in the peat mosses south of Jönköping on Lake Wetter; and it is supposed to have spread southward of this point in quite recent times; and this is confirmed by ancient maps of North Skåne, which show that there were no spruce forests in this district at the beginning of the 17th century. (A. H.)

In Scandinavia the spruce is called *gran*, or *rödgran*. From what I have seen in the forests of north and south Trondhjem it is usually found on the better class of land, and even there does not grow so large as farther south, ascending to about 2000 ft. in Tydal and Stordal, and attaining about 100 ft. in height by 8 to 10 ft. in girth. I have not noticed, even near the coast, that the trees are browned by the west wind, as they are sometimes even, far inland, in England, but the tree is rarely seen on the exposed parts of the coast, or on the islands, where the Scots pine grows alone. Schübeler, *Viridarium Norvegicum*, figs. 66, 68, 69, figures three trees remarkable for their habit, one having the branches very short and crowded on the upper part of the stem, and another a good example of the snake spruce, var. *virgata*, Caspary. Figures 73, 74, and 75 show instances of natural layering; and figures 76 and 77, trees grown from a fallen stem. Figure 78 shows a candelabra-shaped tree growing near Horten in the Christiana fjord.

It is stated that the varieties known in cultivation as vars. *nana*, *inverta*, and *Clanbrassiliana* have all been found wild on the coast of Norway.

The tallest spruce mentioned in Norway by Schübeler was in Hurdalen (lat. 60° 24'), and measured 130 ft. high by 3 ft. 5 in. in diameter; and I am informed of one recently cut in South Rendalen, which was 125 ft. high, and 15 in. in diameter at 80 ft. from ground, and 25 in. at 20 ft. Five logs over 20 ft. long were cut from this one tree.

The largest spruce I have heard of in Sweden is mentioned by Schübeler (p. 409). It grew in Oster Gotland (lat. 58°) and measured 150 Swedish feet (44.54 m.), with a diameter of 6 ft. (1.78 m.).

In Professor Göppert's memoir⁴ on the *Primeval Forests of Silesia and Bohemia* there are many illustrations of the remarkable forms which the spruce assumes when left absolutely in a state of nature, in regions where the snow lies long and deep. These forests are not described in detail, but are above the region of deciduous trees, and consist mainly of spruce and silver fir, with *Sorbus Aucuparia*, *Salix silesiaca*, and *Lonicera nigra* as underwood. Many of the fallen and rotting

¹ Wittrock, in *Act. Hort. Berg.* iv. No. 7, p. 69 (1907), agrees with me in laying stress on the character of the twigs in the discrimination of the two species, *P. obovata* and *P. excelsa*, which he considers to exist in Sweden. Cf. his article in Krok, Hartman's *Skand. Flora*, 1889, p. 34.

⁴ Göppert, *Skizzen zur Kenntniss der Urwälder Schlesiens und Böhmens*, in *Nova Acta Acad. Leop. Carol. Nat. Cur.* xxxiv. (1868).

stems are covered with trees which have sprung from seeds germinating in the moss on these trunks. Göppert mentions one about 50 ft. long on which he counted thirty-six living trees of various ages from 4 ft. to 80 ft. high. On another 70 ft. long, there were thirty-two trees from eighty to one hundred years old, all of which had their roots resting on the fallen tree which had given them birth. Such examples are figured in his plates vii., viii., and ix.

Another form is shown in plate ii., figs. 7, 8, and 9, which illustrate trees which have grown from seeds falling on stumps of broken or dead trees at a considerable height from the ground, and which have forced their roots down through the decaying wood, in one case from a height of 16 feet, to the ground. When the stump decayed the roots were strong enough to support the young tree, which eventually was left standing like a Pandanus on a pyramid of its own roots.

In some cases, as shown in plate iv., fig. 11, two trees which had originated separately on the same stump became perfectly inarched at the root. Plate iv., fig. 12, shows a remarkable instance of a stump no less than 6 ft. in diameter, which had become covered with a thick layer of moss, and assumed the appearance of a gigantic mushroom, on the top of which no less than seven young spruces from 2 to 40 ft. high were growing without their roots having reached the ground at all.

Plate ix., fig. 22, proves, according to Göppert, the immense period which may elapse in these forests before the fallen trees are absolutely decayed and resolved into humus. It shows, *A*, a fallen tree, of which the wood was nearly all dissolved into long brown pieces, only held together by the overgrowing thick moss, into something like the original shape of the trunk; *B* is a tree which had fallen on the top of it at a later period, and was decayed about half through; *C* is a living tree estimated at 300 years old, which had germinated on *B*, and buried its roots partly in and partly on one side of it. Göppert believes that from 1000 to 1200 years may have elapsed since the germination of the lowest tree, *A*; but it seems to me that even if it was 400 years old when it fell, the second, *B*, may have fallen soon afterwards, and owe the slower decay of its wood to the comparative dryness of its position above *A*. Still it proves that the decay of such a comparatively soft wood as spruce or silver fir (the species is not in this case specified) is extraordinarily slow under the conditions prevalent in these forests.

As a proof of its slowness of growth in some instances Forstmeister John remarked that the spruce in the densest parts of the forest attained an age of 120 to 160 years without exceeding 5 to 7 in. in diameter. I have myself cut in Norway a spruce which showed over forty annual rings, and was still thin enough to serve as a walking-stick, which I used through three seasons of elk-hunting before it broke under my weight.

In the Böhmerwald the spruce comes to perfection at a higher level than the beech and silver fir, from 3000 to 3400 feet; and in the Kubany forest there are thousands of trees from 120 to 150 ft. high, and 12 to 16 ft. in girth. It attains a greater age than the silver fir, some trees showing no less than 700 annual rings, though still quite sound. From 3600 ft. up to the highest peaks, which in this range of mountains attain little over 4500 ft., the spruce changes its habit, the stems

becoming shorter and the branches more spreading and drooping on account of the heavier snowfall, so that when adult they assume a regular pyramidal or conical shape. At 3500 ft., a tree 3 ft. in diameter showed 420 rings; and on the top of Kubany at 4100 ft., another with a diameter of 2 ft. had 235 rings. On the Arber mountain, the highest peak of all, at 4200 ft., Göppert saw a tree 3 ft. thick, but only 40 ft. in height; but even at this elevation the majority of the trees are neither crippled nor diseased, as is often the case near the limit of trees in the Alps and Riesengebirge, where they are covered with lichens.

Above these altitudes the lower branches often spread on the ground and form natural layers, which grow upright and make a colony of small trees around their parent. Such an instance is shown in plate i. fig. 2, and another even more curious on fig. 3, where the main trunk of a tree about 5 ft. in girth curved to one side and threw up a secondary straight stem from the nearly horizontal part of its bole. Figure 4 shows a fallen stem 32 ft. long, which remained living and bore no less than five erect trees from 10 to 37 ft. high, which apparently drew the whole of their nourishment from the original roots of the parent tree.

Another peculiarity which occasionally appears in these forests are trees with immense swellings on their trunk, in the form of irregular burrs equally developed all round the trunk. Plate i. fig. 5, shows a spruce 18 in. in diameter at the ground, which has a regular swelling, shaped like a flattened orange, no less than 12 ft. in diameter, and from the centre of which the straight trunk again emerges with a diameter of 16 in. Göppert saw in Silesia an even more extraordinary tree (plate i. fig. 6), which was 45 ft. high and 2 ft. in diameter near the ground. At 7 ft. a regular swelling suddenly began (which is described as covered with many branches, but in the drawing shows none on one side) with a diameter of 10 to 12 ft. and 23 ft. high, above which it tapers off into a normal stem. No disease could be found in the bark or wood, which appeared completely sound, and the upper part of the tree is shown crowded with healthy branches.

A remarkable group of four spruces growing at timber line (about 1850 metres altitude), on the north side of the Great Scheidegg, is figured by Dr. Klein,¹ which from their position appear to have all sprung from seeds which have grown on a rotting trunk. Another remarkable illustration of the effect of wind on the growth of the spruce at high elevations is shown in plate 54 of the same work. A group of trees growing at about 4600 ft. on the Feldberg in the Black Forest, from 10 to 16 ft. high, have the branches cut off clean on the west side, which is attributed by Dr. Klein not alone to the drying effect of the wind in winter and spring, but also to the heating of the branches on one side only by the sun. In the same work are several illustrations of the dense spruce bushes, called "feisstannli" by the Swiss, which are common in alpine regions, and are caused by the constant cropping of goats and sheep.

In the virgin forests of the Capella Mountains in Croatia I saw, in 1910, some spruce of immense height;² and measured one of about 170 ft. by 12½ ft. I was informed that, in this forest, spruce had been felled 190 ft. high and about 12 ft. in

¹ Karsten and Schenck, *Vegetationsbilder*, 11, t. 38 (1905).

² Cf. *Quart. Journ. Forestry*, v. 31 (1911).

girth, and that about 300 years is the maximum age at which this tree remains sound.

The spruce is not a native of Britain at the present epoch; but remains of it have been found in pre-glacial beds at Cromer, Mundesley, Bacton, and Happisburgh in Norfolk.¹

CULTIVATION

It appears to have been introduced early in the sixteenth century, as Turner includes it in his *Names of Herbes* published in 1548; and both Gerard and Parkinson state that it was found in different parts of Britain.

The spruce is easy to raise from seed, but the seedlings grow very slowly for the first three or four years, and are rarely large enough to plant out until they are four to six years old. I have noticed a great deal of variation in the time at which their new growth appears, and it is well to separate the earliest, which are very liable to be injured by spring frost, whilst those which do not start into growth till June remain uninjured. Few conifers are easier to transplant either in spring or autumn, provided the roots are not allowed to become dry; but if exposed to the air in dry or cold weather a good many will die, or languish for two or three years after planting.

The tree grows on almost any soil, but requires a sheltered situation to attain a great height and only comes to perfection where the soil is moist and not liable to dry up in summer. Grown in dense woods, the spruce is liable to be blown down by the wind; but isolated trees make much stronger roots and are moderately storm-firm. In places near the sea the foliage is often injured by the salt contained in the air, and even as far as forty miles from the Bristol Channel I have seen the spruce completely browned on the side exposed to the wind in March.

Though the seed ripens freely in most seasons and germinates readily, the spruce rarely reproduces itself from seed in England owing to its slow growth at first and the weak hold of its young roots on the soil, which cause the seedlings to wither up in summer or to be thrown out of the ground in winter. I only know a few places on my estate where self-sown spruce can be found; and the seedlings have grown so slowly that I am convinced it is not an economic practice to reproduce spruce by seed, except in places where the ground is under snow for a long period. In the Highlands among heather self-sown seedlings are much commoner; and on the shores of Loch Rannoch and in some of the old pine woods at Castle Grant there are considerable numbers of self-sown seedlings, but nothing like the number seen in Scandinavia or in the German forests, where they are protected by deep snow for a long period in winter.

The spruce is a tree which has been planted more largely in England than it deserves to be; for though it will, when established, grow on poor ill-drained soil faster than most conifers, yet the value of its timber when felled is less than that of almost any other tree; and it is, on account of its shallow rooting habit, very likely to be blown down if the wind once gets into the plantation.

¹ C. Reid, *Origin of British Flora*, 151 (1899).

As a nurse it is, on land unsuitable for Scots pine, one of the best we have, if not allowed to overcrowd the hardwoods planted with it; because its branches protect the ground from frost and drought, and its rapid growth acts as a wind-break and draws up the other trees. Its roots are more superficial than those of larch or Scots pine; and it is much cheaper to plant and less liable to injury from frost than silver fir. Loudon quotes (*Arb. et Frut. Brit.* p. 2305) the experience of W. Adam, Esq., of Blair, Kinross-shire, who was a great advocate of planting spruce as a nurse to oak and elm; but it must be cut out or its lower branches lopped before it becomes large.

In the east and north-east of Scotland the tree seems more promising as a forest tree; and in the opinion of Mr. Crozier may produce a more valuable crop than either larch or Scots pine at considerable elevations. He gives me particulars of a plantation of 400 acres on the Durriss estate, at an elevation of over 800 ft., which was marketed under his own supervision. The age of the trees was sixty years, the number per acre 560, averaging 10 cubic feet each. Sold standing at 5d. per foot they realised £116 per acre. Some parts of this plantation planted with Scots pine only made £15 per acre, and the best of it under larch was estimated at £70 per acre. In this plantation the spruce was planted in patches, none over three or four acres, usually on sites unsuitable on account of excessive moisture for larch or Scots pine. The greater parts of the area, however, might well have been planted with spruce, as the locality is favourable to its growth, and similar results to the above are the rule rather than the exception on the whole estate. I have lately received from Mr. D. Munro of Banchory a photograph (Plate 371) of this plantation, most of the trees in which were blown down after it was sold. Mr. Crozier states that there is a large demand for home-grown spruce boards for box-making in Scotland, but that the wood must be fairly free from knots and discoloration; and he considers it one of the most useful timbers for house-building. He adds that when planters realise that the limit of altitude for spruce planting lies above the pine belt, and not below it as seems to have been the general idea, and that it must be grown thicker than larch or Scots pine, its economic merits will become more evident than they are at present.

In confirmation of Mr. Crozier's opinion that spruce is a valuable tree for planting for profit at a high elevation, I may refer to Messrs. Robinson and Watt's very full report¹ on the Coombe Plantation, which lies between 900 and 1500 ft. altitude near Keswick in Cumberland. This plantation, which was sixty-one years old in 1910, consists mainly of larch, with a mixture of spruce, amounting to only one or two per cent at the lower levels, but to ten per cent at over 1250 ft. These authors state that here "spruce grows well at all elevations, and everywhere attains a greater volume than larch under the same conditions." At the higher altitudes it much exceeds the larch in volume. The influence of altitude and exposure on the spruce itself is shown in the following table:—

¹ *Journ. Board of Agric.* xvii. 273, 360 (1910).

Elevation : feet.	Height of tree in feet.	Quarter-girth measurement, in cubic feet.
900	80	44
1150	not stated	32
1250	"	26
1450	48	8
1520	35	4

I have failed to obtain any other exact and reliable figures as to the value of a crop of spruce grown in England, except on such small and isolated patches of land, that they would give no fair criterion.

As a shelter tree it makes a good edging to the roads in a plantation, and can be headed down or clipped when it has grown tall enough to keep the wind out. It bears clipping well and makes a good dense hedge on soils not liable to drought.

Sargent¹ states that as an ornamental tree in America, it loses vigour at twenty-five to thirty years old, except in the most favourable situations; and he only recommends it as a nurse for other trees, as it is very hardy and grows rapidly at first. As a proof, however, of the extremely vigorous growth of the spruce in America, I may say that the tallest tree in Mr. Hunnewell's Pinetum at Wellesley, Mass., which I had the pleasure of visiting with Professor Sargent in 1904, was a Norway spruce which was planted about 1852, and was in 1894 80 ft. high with branches spreading over a circle 60 ft. in diameter. When I saw it, it had increased little in height, but its lower branches had spread to 75 ft. diameter and some of them had rooted; flowers were just showing on May 9, and cones were produced on branches close to the ground, which is rarely the case in Europe. This tree is figured on Plate 340.

According to Pinchot,² it thrives throughout the entire north-east of the United States and southward at the higher elevations; but in the west, favourable results have been attained only as far as the eastern part of the prairie region, and then only in the more protected localities. He considers that it should be planted on a large scale in the cut-over land in the north, where the tree will provide a future supply of wood pulp, as it is in every way superior to the native spruces.

REMARKABLE TREES

If I could trust the measurements which have been given me I should say that the tallest spruce in this country is a tree at Rooksbury Park, Hants, the seat of J. C. Garnier, Esq. It is in a densely crowded thicket of rhododendron, surrounded by beech, and was said by Mr. A. Arnold to measure no less than 178 ft.; but after seeing it twice I could not believe that it was over 150 ft., and, owing to its position, could not measure it myself.³

In Oates Wood at the top of Cowdray Park, near the superb silver fir figured

¹ *Silva N. Amer.* xii. 24, note (1898).

² *U.S. Forest Service, Planting Leaflet*, No. 20 (1908).

³ At my request Mr. Arnold has recently re-measured this tree with a theodolite, and informs me that though he could not get a clear view of its top, he now estimates it at 149 feet.

on Plate 208, there are two remarkably tall trees, which in 1903 I estimated at 140 to 150 ft., but owing to the steep slope on which they grow, and to the adjoining trees, I could not measure a base line. They were 11 ft. 6 in. and 10½ ft. in girth in 1906. Mr. Harold Pearson has recently had these measured by Mr. T. Roberts, forester at Cowdray, who informs me that he levelled a base line, and found the height in January 1911 to be 153 ft.; but this tree which has three leaders is not so handsome as the other, which he thought was about 148 ft. high.

The tallest which I have myself measured are two trees growing on the edge of the lake near Fountains Abbey, Studley Royal, Yorkshire, which Loudon describes as the tallest spruces known to him, and says were 132 ft. high. When I saw them in 1905 I found one to be 140 ft. by 12 ft. 10 in., and the other 137 ft. by 11 ft. They are free from branches for 30 to 40 ft., and seemed in excellent health, though probably over 150 years old (Plate 341).

In Earl Bathurst's woods at Cirencester there are two narrow avenues of spruce known as the Cathedral firs, because they resemble the cross aisles of a cathedral. Of these Plate 342, from a negative taken by Mr. T. E. Gerald Strickland, gives an excellent picture as they were four years ago, but since then several have been blown down, one of which was over 100 ft. high, and showed on the stump 134 annual rings. Those standing average from 110 to 120 ft. high by 8 to 10 ft. in girth.

On my own land at Lyde near Colesborne, in a deep sheltered valley, there is a tree about 125 ft. by 8 ft., but this is beginning to decay at the base, though not much over 100 years old.

At Bowood, Wilts, I saw a very fine tree which measured, in 1908, 125 ft. by 10 ft. 8 in.; but there may be better ones here.

On the Earl of Powis's estate at Walcot, Shropshire, there is a wood of spruce about 100 years old on a steep hill-side next to the Plassey plantation, a photograph of which has been reproduced in the *Quarterly Journal of Forestry*, iii. p. 358. I have seen no spruce plantation in England which equals this, and am indebted to Mr. R. H. Newill, agent for the estate, for the following account:—

“When I came to measure up an area in the Spruce Plantation, near Plassey, I found it difficult to find a piece without any gaps in it, as the wind has been busy of late years, and has blown down many trees. Eventually I chose a piece near the top and squared 1½ chain along the bank and 1 chain down it, an area of 0.15 acre. On this were twenty-two trees standing, of which I enclose measurements.¹

No.	Length, Feet.	Quarter-girth, Inches.	Cubic Feet.	No.	Length, Feet.	Quarter-girth, Inches.	Cubic Feet.	No.	Length, Feet.	Quarter-girth, Inches.	Cubic Feet.

8	83	9½	52.		12	6½	3.6	21	75	9	42.2
								22	74	10	51.4

Total 22 trees, 1401 cubic feet.

These vary from 19 to 103 cubic feet, and average 63.7 cubic feet. I found stumps of seven more trees on the area, and taking them at the same average there would be about 1849 feet; or about 193 trees measuring 12,326 cubic feet per acre.

The age of the trees is about 100 years; the rings are well marked to eighty-five years, afterwards so very close together that it is difficult to count them. All the trees are going back very fast, I believe every one is decayed at the butt; and in the lower part of the plantation many are blown down or broken off each year. We could only obtain 3d. to 4d. per foot for this class of timber, and it was in order to turn it to a more profitable use, that I put down the creosoting plant.”

Assuming that this plantation had been clean felled at eighty years of age and that it had then contained 10,000 cubic feet per acre, the annual increment would have been 125 feet per acre; and taking the price at 4d. per foot standing the value of the crop would have been £166 per acre.

The trees are facing north-east at an elevation of 600 to 900 ft., and the old red sandstone here seems to suit all kinds of trees, both hardwoods and conifers, as well as any soil in England.

At Kyre Park there is a remarkable old spruce of the candelabra type which has an immense rugged bole broken off at about 30 ft., and 15 ft. 9 in. in girth. One of its upright branches is no less than 10 ft. 4 in. in girth, and twelve others have naturally layered themselves in a circle 64 ft. in diameter, and grown up into trees, two of which are 90 ft. high by 8 ft. in girth.

Another remarkable instance of layering in the spruce is at Langley Park, Slough, where a tree on the lawn has been broken off at about 20 ft. and whose lower branches have formed a complete bower, resembling on a smaller scale that formed by the Whittingehame yew. Some of the small branches, only one to three inches thick, have formed a woody mass and thickened enormously at the point where they have taken root.

In Wales the finest spruce we have seen are in a wood above Gwydyr Castle, where in 1905 I measured two trees in a grove round the bowling green, which were about 125 ft. high by 9 ft. 8 in. and 6 ft. 10 in. in girth. In this grove, which is shown in Plate 343, the spruce seems to clean itself better than in England, and I estimated that there might be 8000 to 10,000 cubic ft. per acre. Mr. Richards, forester to Lord Penrhyn, informed me that at Tyn-y-Coed in the same district of North Wales, a spruce plantation was felled in 1902 and sold to Mr. J. Jones of Liverpool, a tree in which is said to have been 149 ft. high, and that 158 trees in this wood contained 11,937 cubic ft., an average of over 75 cubic ft.; two of them measuring respectively 80 ft. by 23 in. quarter-girth = 294 cubic ft., and 67 ft. by 27 in. = 338 cubic ft. It is evident from these figures that even if the value of the timber is low as compared with imported spruce, yet that it may pay well in this particular district, provided the trees are grown thickly enough.

In Scotland the largest spruce of which we have any record grew at Blair Atholl, and was visited by the Scottish Arboricultural Society in 1879. It was then said to measure 142 ft. high, and to contain over 420 cubic ft. of timber.¹ I

¹ Hunter, *Woods of Perthshire*, 60 (1883).

was informed by the late Mr. Pitcaithley, forester to the late Earl of Mansfield, that this tree was blown down about 1893, when the height above given was verified.

The tallest that we now know of, are probably some trees on the banks of a deep glen at Dupplin Castle, which I saw in 1907, and on account of their leaning to one side could not measure accurately, but thought must be from 130 ft. to 140 ft. high. A fine tree in the same place, dividing into two stems at thirty feet from the ground, measured about 100 ft. by 12 ft. 10 in.

At Methven, Henry measured a tree in 1904 as 125 ft. by 8 ft. 3 inches.

At Inveraray I saw trees over 120 ft. by 8 to 10 ft., and the forester, Mr. Campbell, told me that he had measured one blown down on Ben-y-Cuach 130 ft. long. In the woods of Glenarary the spruce seems to grow very well, being sheltered from the westerly gales; but I do not remember to have seen such large or thriving trees elsewhere on the west coast of Scotland.

In the east of Sutherlandshire, I am told by Mr. Gillanders that spruce grows well and cleans itself better than in the south.

In Ireland we have not seen any trees of extraordinary size, and as a rule the climate is not adapted to the production of high-class spruce timber. But Mr. A. E. Forbes has sent me an account of a remarkable plantation near Fermoy, which I reproduce verbatim, and am indebted to Lieut. and Quartermaster T. Smith, R.E., for a negative which gives a good idea of this plantation (Plate 344).

"A very fine clump of common spruce is growing in Glenshiskin Wood, which forms part of the property purchased by the War Department a few years ago near Kilworth. This wood occupies a valley running into the Kilworth mountains, a low range of hills formed from the Old Red Sandstone formation. A small mountain stream flows down the centre of this valley, and at one point, about 300 feet above sea-level, an alluvial deposit has been formed along its course of about an acre in extent. In this deposit a clump of almost pure spruce was planted about eighty years ago, and judging from appearances was never thinned or attended to in any way. From time to time poles were doubtless removed from it as required; but no systematic thinning could have been carried out, as many of the trees still stand within four or five feet of each other.

"This clump probably presents as fine an example of spruce growth in Britain as can be found anywhere. The trees vary in height from 90 to 110 ft., and form long clean poles with little taper, and ranging from 8½ to 18 in. quarter-girth at 4½ ft. from ground. The trees in two-thirds of an acre were carefully measured by Mr. M'Rae, forester at Dundrum, Co. Tipperary, in the spring of 1910, and the summary of the results obtained is given below:—

	No.	Age.	Average Height.	Average Quarter-girth at 4½ ft.	Total Cubic Contents.
Spruce	161	78 years	98 feet	12½ in.	8050
Larch	11	"	99 "	12½ in.	550
Stumps of Felled Trees	110
					8600

"By dividing the trees into three stem classes, a volume of 9600 cubic feet was obtained. Assuming the estimate of 8600 ft. to be correct, the average contents of the trees is about 50 ft., and the total yield per acre would be over 12,000 cubic ft., which for the period of eighty years is higher than anything I have heard of in Great Britain.

"Within recent years, trees similar in size to those still standing have been removed, and the stumps still exist. It is quite possible, therefore, that the existing crop is smaller in volume than that which stood on the ground a few years ago. The high yield is, of course, largely due to the exceptionally favourable soil and situation of the site on which the trees were grown. A fine, rich, and well-drained soil, well provided with soil and atmospheric moisture, and a situation sheltered from all winds, provide ideal conditions for the growth of spruce or any other tree able to thrive with a moderate amount of summer heat. Oak and beech growing in the immediate vicinity of these trees are very poorly developed and covered with lichen and moss, indicating the cool and humid conditions which prevail."

TIMBER

Next to that of the Scots pine, the wood of the spruce is the largest import from the Baltic; and from Norway the proportion of spruce timber is probably greater. On account of climatic and economic causes, it seems probable that this will always be the case, though in the west coast ports American spruce takes its place. For scaffold and ladder poles, small spars and masts, and oars, we cannot hope to compete with the north of Europe; whilst for flooring, joists, and almost all purposes except those for which knotty boards are not objected to, it seems equally hopeless for British growers to attempt to compete with the well-known white deal of commerce.

The reasons why the value of home-grown spruce timber is so low are, first, its very knotty character, caused by the persistence of the branches, which die more slowly than those of other conifers; and, secondly, its want of strength and durability as compared with larch. Continental foresters tell us that the first defect may be obviated by close planting, and cite the large profit which is derived from this tree in Germany and Scandinavia. I have inquired of many of our best practical foresters; but I have never been able to find any plantation in England, and only very small areas in Scotland, Wales, and Ireland, where spruce, which stood close

enough to kill the branches, have attained a considerable size, or where a spruce plantation has been a really profitable investment.

My own experience is, that land where spruce may be well grown is fit to produce a much more valuable timber, and that on ordinary land it will starve to death before it will clean itself from branches. The late Mr. Philip Baylis, Deputy-Surveyor of Dean Forest, told me that spruces there, 50 to 60 ft. high, and so thickly planted that no vegetation would exist under them, still retained the dead branches to within 5 or 6 ft. from the ground; and I think that this will apply to most places in England and Scotland.

When the tree is of large size it usually becomes rotten at the heart near the ground; and the top is often broken by the wind. Though the timber may be worth 4d. to 6d. per cubic foot for rough boarding or packing-cases, or for temporary sleepers and pit props in collieries or railways under construction, yet in quantity it is the most unsaleable wood we have. When, as often happens, large quantities are blown down by a heavy gale, I have known cases where no one would go to the expense of cutting up and removing the trees if they had them for nothing, and the proprietor has had considerable expense in doing so without any return whatever. When blown down, the shallow spreading roots tear up the ground for some distance round the tree and are very costly to get rid of, or if left leave the ground in a bad state for re-planting.

Where, however, the soil and climate allow the spruce to be crowded closely enough to clean itself, before it becomes rotten at heart or is blown down, spruce timber may be used for estate building purposes, if not with actual economy, yet in many cases more advantageously than by selling it. Sixpence per foot is something like the average price, though 3d. to 4d. often has to be accepted.

On shallow and dry soils the spruce often begins to decay at the heart for some feet from the ground at the age of fifty to seventy years, and on such soils should not be planted at all. Its spreading roots, which are extremely tough and elastic, are used in Scandinavia for the knees of boats, though rarely so utilised in England. The tough and durable branches made into a wattled fence will last for a long period, and are the common farm fence in many parts of Norway and in the Alps.

When facilities exist for creosoting, spruce may be used for fencing and other outside work, such as sheds and outbuildings; but unless treated with some preservative it soon decays when exposed to wet and dry.

The spruce trees which produce the *bois de resonance*, used for sounding-boards in musical instruments, grow at high elevations in the Alps, the Jura, and in the Bohemian and Bavarian forests. These are very old trees, the growth of which has been extremely slow and very uniform, the annual rings not exceeding $\frac{1}{2}$ in., and containing only a slight amount of autumn wood. These trees are usually covered with lichens, and their selected timber sells at very high prices, as much as 9s. to 12s. per cubic foot.

Burgundy pitch is a resinous product of the spruce, well known under the name of *Burgony Pitch* and *Pix Burgundica* as long ago as 1640. It was formerly

produced in the Vosges Mountains, but now, according to Flückiger and Hanbury,¹ mainly in Finland, the Black Forest, Austria, and Switzerland. Flückiger states that at Oppenau, in Baden, the principal place of its manufacture in Germany, it is mixed with French turpentine from Bordeaux and with rosin from N. America; and the tapping of the trees in Government forests in Baden and Württemberg is now prohibited on account of the injury caused thereby to the timber. It is very generally adulterated in England, and is mainly used as an ingredient in plaisters.¹

Picea excelsa, Link, var. *obovata*, Schröter, in *Viertelj. Naturf. Ges. Zürich*, xliii. 138 (1898).
Pinus Abies, Pallas, *Fl. Ross.* i. 6 (1784) (not Linnæus).
Pinus obovata, Antoine, *Conif.* 96 (1840-1847).
Pinus orientalis, Ledebour, *Fl. Ross.* iii. 671 (in part) (1847-1849) (not Linnæus).
Abies obovata, Don, *ex Loudon, Arb. et Frut. Brit.* iv. 2329 (1838).

A tree, attaining in Russia and Siberia the dimensions of *P. excelsa*, which it resembles in habit of growth and in bark. Young branchlets reddish brown, covered with a dense minute pubescence, which is retained for several years, the older branchlets becoming greyish yellow. Buds, about $\frac{1}{2}$ in. long, conic, composed of closely appressed scales, rounded at their apices; terminal bud girt with a ring of keeled acuminate ciliate scales, and closely surrounded at the base by the uppermost leaves. Leaves, arranged as in *P. excelsa*, deep green in colour, $\frac{2}{3}$ to $\frac{3}{4}$ in. long, ending in a short point, quadrangular in section, with three to four stomatic lines on each side.

Cones $2\frac{1}{2}$ to $3\frac{1}{2}$ in. long, $1\frac{1}{4}$ to $1\frac{1}{2}$ in. in diameter when open, shining brown when ripe; scales numerous, thin, tough, flexible, longer than broad, $\frac{6}{10}$ to $\frac{7}{10}$ in. wide, and $\frac{7}{10}$ to $\frac{9}{10}$ in. long, fan-shaped, widest near the upper edge, tapering to the base on each side; upper margin thin, undulate, rounded or with a slightly projecting occasionally bifid apex; exposed part pale brown, glabrous; concealed part reddish brown, minutely pubescent; flat or slightly concave internally from side to side; bract $\frac{1}{2}$ in. long, lanceolate, narrowing to an acute denticulate apex. Seed $\frac{1}{2}$ in., brownish black; seed with narrow wing $\frac{2}{3}$ to $\frac{3}{4}$ in. long, broadest near the rounded denticulate apex.

The description of *P. obovata* given above is drawn up from specimens procured from Siberia, and from Perm in Russia, by Mr. H. Clinton-Baker, from specimens collected in Finland by Mr. M. P. Price, and from specimens which I gathered in

¹ *Pharmacographia*, 616 (1879).

northern Sweden, near Bräcke, and in Norway, near Trondhjem; all agreeing in the character of the cones, branchlets, buds, and leaves, and constituting, in my opinion, a species distinct from *P. excelsa*, of which *P. obovata* is generally considered to be a variety by Schröter and other modern botanists. These authorities have apparently paid no attention to the characteristic pubescence of *P. obovata*, a matter of importance, as in the genus *Picea* the presence or absence of pubescence on the branchlets is one of the most diagnostic features in the discrimination of the different species. The cones, moreover, are amply distinct in the two species.

P. obovata varies somewhat in the size of the cones and in the shape of their scales; and two main varieties have been distinguished, which are, however, connected by intermediate gradations. These varieties are: (a) the typical form described above, which is characterised by the scales of the cone being entire on margin; and (b) var. *fennica*.

1. Var. *fennica*, Henry.

Picea excelsa, Link, var. *fennica*, Schröter, in *Viertelj. Naturf. Ges. Zürich*, xliii. 138 (1898).

Picea excelsa, Link, var. *medioxima*, Willkomm, *Forst. Fl.* 75 (1887).

Picea vulgaris, Link, var. *uralensis*, Teplouchoff, in *Bull. Soc. Nat. Mosc.* xli. pt. ii. 250 (1869).

Pinus Abies, Linnæus, var. *fennica*, Regel, in *Gartenflora*, xii. 95 (1863).

Pinus Abies, Linnæus, var. *medioxima*, Nylander, in *Bull. Soc. Bot. France*, x. 501 (1863).

Pinus Picea medioxima, Christ, *Flore de la Suisse*, 254 (1883).

Abies medioxima, Lawson, *Pinet. Brit.* ii. 159 (1867).

Cone-scales, with their upper margins rounded and finely denticulate. Leaves dark green in colour.

According to Schröter this variety occurs sporadically in Amurland and Siberia, and is the common form in the Ural range and throughout Russian Lapland, northern Sweden, and northern Norway, occurring with less frequency in Finland, Livland, Kazan, and Poland. Solitary trees with cones similar to this variety have also been recorded from numerous stations in the mountains¹ of central Europe, from the Vosges and Jura throughout the Alps to the Carpathians and Bosnia.

2. Var. *alpestris*, Henry.

Picea alpestris, Stein, in *Gartenflora*, xxxvi. 346 (1887).

Picea excelsa, Link, var. *alpestris*, Schröter, *op. cit.* 141 (1898).

Abies excelsa alpestris, Brügger, in *J. B. Naturf. Ges. Graubundens*, xvii. 154 (1874), and xxix. 122 (1884).

Abies excelsa medioxima, Heer, in *Verh. Schw. Nat. Ges.* 1869, p. 70 (not Nylander).

Cones 3 to 5 in. long, with scales rounded and entire in upper margin. Leaves short, $\frac{1}{2}$ to $\frac{2}{3}$ in. stout, very glaucous.

Trees with a whitish grey bark, and with remarkable bluish white foliage, which have been found at high elevations (between 4400 and 6400 ft.) in a few localities in the Swiss Alps, from Landbeck in the Tyrol² to Engstelnalp in the Bernese Oberland, and from Lake Walen to Lake Como. These trees were first investigated by Heer and Brügger on account of the special name given to them by

¹ Cf. Christ, in *Garden and Forest*, ix. 273 (1896).

² Beissner, in *Mitt. Deut. Dend. Ges.* 1905, p. 143, describes trees like var. *alpestris* in the Engadine.

the peasants, *aviez selvadi*, or wild silver fir, the common spruce being known as *pign*. I have seen no specimens, but apart from the glaucous foliage, which is a trivial and inconstant character in conifers, *P. alpestris* would seem to be identical with *P. obovata*.

A vast amount of literature¹ has been written on the relationship of *P. obovata* to *P. excelsa*, the general result of which shows that a complete series of transitional forms connecting the two species may be found; but these are only met with in the regions where the two spruces come in contact—elsewhere they are quite distinct and easily recognisable. It is possible that these transitional forms are due to hybridisation; and further study by experimental sowings is needed to clear up the matter.

P. obovata is the most widely distributed of all the spruces, extending over the vast northerly region of eastern Europe and Asia, where the climate is severe in winter and continental in character. It occurs in northern Scandinavia, Lapland, Finland, northern and eastern Russia, throughout Siberia to the Sea of Ochotsk and Kamtschatka,² and in Manchuria. It extends far to the northward, reaching lat. 67° in the Kola peninsula, lat. 68° in the Ural range, attaining its most northerly point in Siberia on the Yenisei at lat. 69° 5', and crossing the Stanovoi mountains at lat. 64°, where it comes in contact with *P. ajanensis*. According to Komarov³ it is abundant throughout the wooded parts of Manchuria, where it grows along the banks of rivers, either forming pure woods or scattered amidst other trees. Its eastern and southern limits in Asia are imperfectly known, but it forms great forests in the mountains of Dahuria and in the Altai and Sayan ranges. Seebohm⁴ describes it as extending on the Yenisei "nearly as far north as the larch, where it is a very important tree for commercial purposes. Its wood is white, of very small specific gravity, extremely elastic; and it is said not to lose its elasticity by age. It makes the best masts for ships, and is for oars the best substitute for ash. Snow-shoes are generally made of this wood. The quality is good down to the roots, and it makes the best knees for shipbuilding."

In European Russia its southern limit is the northern edge of the Orenburg steppe; and it forms vast forests in the governments of Perm, Vologda, Ekaterinburg, Ufa, Viatka, and Kama, that are either pure or mixed with larch, *Pinus Cembra*, *Abies sibirica*, and birch. It appears to be the spruce prevalent in Finland and in the Baltic provinces; but in western Russia is mixed with *P. excelsa*, the limits between the two species being undefined, owing to the occurrence of transitional forms. Similarly in Scandinavia⁵ it is the common spruce in the north, while in the south *P. excelsa* appears to be the prevalent form. Its occurrence as a sporadic tree in the mountains of central Europe, under the form described as *P. alpestris*,

¹ Cf. Teplouchoff, *loc. cit.* Korshinsky, in *Tentamen Fl. Ross. Orient.* 493 (1898), admits that cones like those of *P. excelsa* are never seen in eastern Russia. At the junction of the rivers Kama and Viatka the woods are said to be composed of both species. Cf. Kihlman, *Pfl. Stud. Russ. Lapland*, 143 (1890), on the variation of the spruce in Finland, Lapland, and northern Scandinavia. Dammer, in *Gard. Chron.* iv. 480 (1888), may also be consulted, as well as the numerous authorities quoted by Schröter, *op. cit.* 240 (1898).

² It is a doubtful native of the Kurile Isles, according to Miyabe in *Mem. Boston Soc. Nat. Hist.* iv. 261 (1894).

³ *Flora Manshuriae*, i. 197 (1901).

⁴ *Siberia in Asia*, 233 (1882).

⁵ Cf. under *P. excelsa*, pp. 1347, 1348.

is peculiar; but may be explained as a remnant of the pre-glacial forests.¹ In habit, *P. obovata* is usually more columnar than *P. excelsa*; but little reliance can be placed on this character as a mark of distinction.

This species had not been introduced into England in Loudon's² time; and it is very doubtful if it occurs in cultivation in this country, except at Bayfordbury, where seedlings were raised in 1908 from seed brought from Siberia by Mr. C. F. H. Leslie. According to Kent,³ "the Siberian spruce soon perishes under the stimulus of the high temperature of this country." Small trees in botanic gardens reputed to be this species appear to me to belong to the transitional form between *P. excelsa* and *P. obovata*, which has less pubescence on the branchlets. Plants raised from Finnish seed, procured from Rafn, are much slower in growth at Colesborne than common spruce.

In Germany, according to Mayr,⁴ it is slower in growth than the native spruce, and is not more hardy. It appears⁵ also to be equally slow in growth in the Arnold Arboretum, U.S.A. (A. H.)

PICEA ORIENTALIS, CAUCASIAN SPRUCE

Picea orientalis, Carrière, *Conif.* 244 (1855); Boissier, *Fl. Orient.* v. 700 (1884); Masters, in *Gard. Chron.* xxv. 333, fig. 62 (1886), and iii. 754, fig. 101 (1888); Kent, Veitch's *Man. Conif.* 443 (1900); Clinton-Baker, *Illust. Conif.* ii. 44 (1909).

Pinus orientalis, Linnæus, *Sp. Pl.* 1421 (1763); Lambert,⁶ *Genus Pinus*, i. t. 39, fig. a (1803).

Abies orientalis, Poiret, in Lamarck, *Dict.* vi. 518 (1804); Loudon, *Arb. et Fruit. Brit.* iv. 2318 (1838).

A tree, attaining in the Caucasus 180 ft. in height and 12 ft. in girth. Bark brown, fissuring irregularly on old trees into thin scales. Young branchlets pale brown, slender, densely covered with a short pubescence, retained in the second and third years. Buds conical, acute, about $\frac{1}{5}$ in. long, brown; terminal buds girt at the base with a few keeled acuminate scales. Leaves, on lateral branches arranged as in *P. excelsa*, very short, $\frac{1}{2}$ to $\frac{2}{5}$ in. long, dark green, shining, bevelled and obtuse at the apex, quadrangular in section, with one to four lines of stomata on each of the four surfaces.

Staminate flowers, cylindrical, $\frac{1}{2}$ in. long, carmine red in colour; anther connective suborbicular, minutely denticulate.

Cones, 3 to 4 in. long, $\frac{3}{4}$ to 1 in. in diameter when closed, cylindrical but tapering to a narrow apex, violet coloured⁷ when growing, brown when ripe; scales

¹ Christ, *Flore de la Suisse*, 197 (1883), compares the distribution of this spruce with *Pinus sylvestris*, var. *engadinensis*, the pine on the Engadine, which he considers to be identical with *Pinus lapponica*, Mayr, the form of the common pine that occurs in northern Scandinavia and Lapland. Cf. *ante*, vol. iii. 573.

² Cf. Loudon, *Trees and Shrubs*, 1030 (1842).

⁴ *Fremdländ. Wald- u. Parkbäume*, 333 (1906).

³ Veitch's *Man. Conif.* 442 (1900).

⁵ Sargent, in *Garden and Forest*, x. 481 (1897).

⁶ The cones figured by Lambert in this edition, t. 29, fig. b, were from China, and are possibly those of *P. ajanensis*. Lambert, in his second edition, t. 39 (1832), gives a new and coloured drawing of leaves and cones, collected by Sir Gore Ouseley near Tiflis, repeating also the figures of the cones from China.

⁷ The scales of young cones are green, with a narrow carmine-coloured margin.

obovate with a cuneate claw, $\frac{1}{2}$ to $\frac{3}{8}$ in. wide, rounded entire and slightly bevelled in the upper margin; bract $\frac{1}{4}$ in. long, with a narrow claw and a rectangular lamina, truncate at the apex. Seed dark coloured, $\frac{1}{8}$ in. long, with the wing $\frac{1}{2}$ in. long; wing broadest about the middle, upper margin rounded.

This species is readily distinguished by its very short blunt leaves, and pale brown pubescent branchlets.

DISTRIBUTION

The oriental spruce is a native of Asia Minor and the Caucasus. It is widely spread in most of the mountain ranges of Asia Minor, being recorded for Troas, Mysia, Galatia, and Phrygia, where it generally occurs between 3000 and 7000 feet elevation. It is also met with in the valleys of the Antitaurus. It is, however, much more common, forming large forests, in the mountains between Trebizond and Erzerum, where it was discovered by Tournefort¹ at the beginning of the eighteenth century. In the Caucasus it is generally associated with *Abies Nordmanniana*, and occurs in Georgia between 2500 and 7500 feet. In the Lesser Caucasus its eastern limit is the meridian of Tiflis, being totally absent to the eastward and in the province of Talysch. As a rule it ascends higher than *Abies Nordmanniana*, occasionally forming the timber line at 7500 feet. The largest tree recorded by Radde,² measured, when felled, 184 ft. in height, with a diameter of stem of 4 ft. 1 in., and a cubic content of 925 ft.; it was 390 years old.

CULTIVATION

The species, according to Beissner,³ was introduced into Europe in 1837, but Loudon, writing in 1838, speaks of it as not in cultivation; and it appears⁴ to have come into this country in 1839. It has been in cultivation in the United States⁵ since about 1850, where it has proved hardy as far north as eastern Massachusetts, and is one of the most beautiful of all the exotic conifers that have been planted in the neighbourhood of Boston. (A. H.)

REMARKABLE TREES

None of the spruces seems more generally successful in cultivation than this; and though it does not grow so fast as the common or the Sitka spruce, it is a really good ornamental tree, hardy in all parts of Great Britain, and ripening seed in most places. We have measured many specimens of from 60 to 70 ft. high and a few taller, among which the following may be mentioned:—

At Dogmersfield Park, Hants, the seat of Sir H. Mildmay, a fine tree with many cones, 78 ft. by 7 ft. 8 in. in 1907. At Strathfieldsaye a handsome specimen 76 ft. by 7 ft. 8 in. At Highnam a tree about 67 ft. by 7 ft. in 1905. At Penrhyn a tree recorded⁶ as 58 ft. high in 1891, which was, when measured by me in 1906, 75 ft. by 5 ft. 10 in.

¹ *Voyage au Levant*, 288 (1717).

² *Kaukasuslindern*, 223 (1899).

³ *Nadelholzkunde*, 374 (1891).

⁴ Lawson, *Pinet. Brit.* ii. 163 (1865). Loudon, in *Trees and Shrubs*, 1029 (1842) says: "Of late many plants have been raised in Knight's exotic nursery, from seeds received from Mingrelia and the neighbourhood of Tiflis."

⁵ Sargent, *Silva N. Amer.* xii. 22, note (1898), and in *Garden and Forest*, 1895, p. 55.

⁶ *Journ. R. Hort. Soc.* xiv. 485 (1892).

In Canon Ellacombe's garden at Bitton there is a dwarf bush of considerable age, which when covered with young cones is very ornamental. From it I have raised seedlings which grow very slowly.

In Scotland the finest tree we know of is at Durris, which in 1904 was 61 ft. by 6 ft. 3 in.

In Ireland Henry measured at Fota one which in 1903 was about 67 ft. by 6 ft. (H. J. E.)

PICEA SCHRENKIANA, SCHRENK'S SPRUCE

Picea Schrenkiana, Fischer and Meyer, in *Bull. Acad. Sci. St. Petersb.* x. 253 (1842); Regel, in *Gartenflora*, xxvi. 69 (1877), and xxix. 49 (1880); Fedtschenko, in *Bull. Herb. Boissier*, vii. 189 (1899); Kent, Veitch's *Man. Conif.* 451 (1900); Clinton-Baker, *Illust. Conif.* ii. 48 (1909).

Picea tianschanica, Ruprecht, in *Mém. Acad. Sci. St. Petersb.* xiv. No. 3, p. 72 (1870).

Picea obovata, Ledebour, var. *Schrenkiana*, Masters, in *Journ. Linn. Soc. (Bot.)* xviii. 506 (1881).

Pinus Schrenkiana, Antoine, *Conif.* 97 (1840-1847).

Pinus obovata, Antoine, var. *Schrenkiana*, Parlature, in De Candolle, *Prod.* xvi. 2, p. 415 (1868).

Pinus orientalis, Linnæus, var. *longifolia*, Ledebour, *Fl. Ross.* iii. 671 (1847).

Abies Schrenkiana, Lindley and Gordon, in *Journ. Hort. Soc. Lond.* v. 212 (1850).

A large tree, attaining in Turkestan the dimensions of *P. obovata*. Young branchlets ashy grey, stout, glabrous. Buds dome-shaped or sub-globose, $\frac{1}{3}$ in. in length, rounded at the apex, light brown, with scarious scales; terminal bud girt with a ring of acuminate keeled pubescent ciliate scales and closely surrounded at the base by the uppermost leaves of the branchlet.

Leaves in an imperfect radial arrangement, dense and pointing forwards on the upper side of the branchlet, spreading with a few leaves pointing forwards and not truly pectinate on the lower side of the branchlet; $\frac{3}{4}$ to $1\frac{1}{4}$ in. long, straight or curved, rigid, gradually tapering at the distal end to a long fine sharp-pointed apex¹; obscurely quadrangular in section, with three to four lines of stomata on each of the four sides.

Cones, 3 to 4 in. long, cylindrical, narrowing towards the obtuse apex, shining dark brown when ripe; scales numerous, closely imbricated, longer than broad, about $\frac{1}{2}$ in. wide, obovate-cuneate, with the upper exposed part thin and glabrous, concealed part thicker and minutely pubescent; upper margin rounded, entire, undulate; bract $\frac{1}{5}$ in. long, ovate. Seed, light brown, $\frac{1}{8}$ in. long; seed with wing $\frac{1}{2}$ in. long; wing narrow, widest near the rounded apex.

This species was discovered in 1840 by Schrenk, and is widely distributed in Central Asia, occurring mainly in the Alatau mountains and in the Thianshan² range in Turkestan, where, according to Fedtschenko, it forms vast forests, now rapidly disappearing, as far south as lat. 41°, at 4000 to 8000 ft. altitude towards the north, and at 8000 to 10,000 ft. towards the south. It does not appear to

¹ In wild specimens from old trees, the leaves end in a short acute callous tip.

² Both Regel and Komarov agree that the spruce in the Thianshan range, considered by Ruprecht to be a distinct species (*P. tianschanica*), is identical with *P. Schrenkiana* in the Alatau range.

occur in the mountains uniting the Thianshan range with the Pamirs; and its western limit is probably the Alexandrovoski mountains in Russian Turkestan. Its eastern limit is not as yet clearly known;¹ but Przewalski found extensive woods of it, not only in the Thianshan range, but also in the upper course of the Yellow River in Mongolia, near Lake Kokonor, and in the adjoining Nan-Shan range.²

Mr. M. P. Price informs us that its most northerly point appears to be in the Barluk mountains, lat. 46°, where there are a few scattered forests in the higher valleys. He observed this tree at 9200 feet altitude in the pass between the valley of the river Baratala and the plateau of Lake Sairam. It bears the greatest extremes of heat and cold in these regions. Most of the trees, which he saw, scarcely exceeded 50 to 70 ft. in height and 7 to 8 ft. in girth. On a section 2 ft. 10 in. in diameter from the base of a tree, which had grown in the vicinity of Lake Issik Kul and was preserved in the museum at Vernoe, he counted 296 annual rings. The wood is used for building houses in Russian Turkestan; but is of little economic importance on account of the inaccessibility of the forests.

In the eastern part of the Thianshan range, where the climate is very severe, and the thermometer sinks at least 7° F. below freezing every night during summer, *P. Schrenkiana*, nevertheless, forms open woods at about 8000 ft. elevation, which are remarkable for the peculiar narrow columnar form of the trees. This is well shown by two photographs, taken by Baron von Dungern, which are reproduced in *Mitt. Deut. Dend. Ges.* 1910, pp. 227, 229. He explains the cypress-like habit as due to the fact that the shoots of the lateral branches are almost invariably frozen, soon after their production in early summer; whilst those of the leading branches, which are later in the season in emerging from the bud, escape destruction by the severe frosts.

This species was distributed by the St. Petersburg Botanic Garden after its re-discovery in 1877 by Regel in Turkestan. It has never become common in cultivation. There are two trees at Kew, 8 and 10 ft. high, obtained from Messrs. Veitch in 1882; and smaller specimens at Bayfordbury and in other private collections. It appears to be hardy, though slow in growth, and is very distinct in appearance, most of the branches being rigid and ascending. (A. H.)

¹ The spruce collected in Kansu, in north-western China, by Futterer and Holderer, identified with *P. Schrenkiana* by Diels, *Flora von Central-China*, 217 (1901); and another, collected by Bretschneider, near Peking, similarly identified by Masters, in *Journ. Linn. Soc. (Bot.)* xxvi. 554 (1902), appear to be identical with *Picea Mastersii*, Mayr, *Fremdländ. Wald- u. Parkbäume*, 328, figs. 105-107 (1906).

² Cf. Köppen, *Holzgewächse Europ. Russlands*, ii. 538 (1889). Regel, in *Act. Hort. Petrop.* vi. 485 (1880), states that it grows not only in the high mountains, but also along the rivers Baratala, Kash, and Yuldus.

PICEA SMITHIANA, WESTERN HIMALAYAN OR MORINDA SPRUCE

Picea Smithiana, Boissier, *Fl. Orient.* v. 700 (1884); Kent, Veitch's *Man. Conif.* 454 (1900).

Pinus Smithiana, Wallich, *Pl. Asiat. Rar.* iii. 24, t. 246 (1832).

Pinus Khutrow, Royle, *Illust. Him. Plants*, 353, t. 84 (1839).

Abies Smithiana, Lindley, in *Penny Cycl.* i. 31 (1833); Loudon, *Arb. et Frut. Brit.* iv. 2317 (1838).

Abies Khutrow, Loudon, *Trees and Shrubs*, 1032 (1842).

Abies Morinda, Nelson (Senilis), *Pinaceae*, 49 (1866).

A tree, attaining in the Himalayas over 200 ft. in height and 20 ft. in girth. Bark greyish brown, divided by shallow fissures into small rounded or quadrangular scales. Young branchlets grey, shining, glabrous. Buds about $\frac{1}{2}$ in. long, spindle-shaped or ovoid, acute at the apex, brownish, resinous; scales numerous, densely imbricated, rounded at the apex; terminal bud girth at the base with a ring of acuminate keeled scales. Lateral branches always pendulous, with the leaves radially arranged and directed outwards and towards the apex of the branchlet at an acute angle. Leaves long and slender, about $1\frac{1}{2}$ in. long and $\frac{1}{2}\frac{1}{5}$ in. broad, incurved, tapering towards the apex, which ends in a slender cartilaginous point; obscurely 4-angled, with about two lines of stomata on each of the four sides.

Staminate flowers, about 1 in. long and $\frac{1}{2}$ in. in diameter, cylindrical, obtuse, light yellow; anther connective orbicular, crenate.

Cones, 4 to 6 in. long, $1\frac{1}{2}$ to 2 in. in diameter, cylindrical, narrowed towards the base, obtuse at the apex; bright green and smooth when growing; shining brown when mature; scales about an inch wide, broadly obovate from a cuneate base, smooth, convex, rounded and entire in margin; bract obsolete. Seed dark brown, $\frac{1}{4}$ in. long, with the wing $\frac{3}{4}$ in. long; wing spatulate, broadest near the truncate denticulate apex.

P. Smithiana occurs throughout the western Himalayas, between 7000 and 11,000 ft. elevation, being common from Garhwal to Kashmir, and also occurring in Gilgit, Chitral, and Kafiristan. It extends westwards to Afghanistan, where Aitchison found it in the Kuram and Hariab district, between 8000 and 11,000 ft., occasionally extending as high as 12,000 ft., where it struggles for existence with *Pinus excelsa*. According to Gamble, it is a very fine tree in the Himalayas, often attaining a greater height than the deodar, but probably never equalling the latter in girth. Large trees measured near Mundali in Jaunsar were 175 to 215 ft. in length and 19 to 23 ft. in girth.¹ It forms mixed forests with *Abies Pindrow*, which cover mainly the northern and western slopes of the mountains, usually between 7500 and 8500 ft. In these forests the spruce is more common on the drier ridges, the silver fir growing in the moister ravines. *P. Smithiana* also forms mixed forests

¹ I am informed by Sir G. Watt that a tree, recorded by Sir E. Buck, near Nagkunda, measured no less than 250 ft. high. Cf. Frontispiece of Vol. V.—H. J. E.

with the deodar. Grown in dense forest the stems are often free from branches to a great height, crowned by a conical pyramid of foliage with pendulous branches. In this condition, it produces seed at intervals of three or four years, and in small quantity. The rank undergrowth consists of *Strobilanthes*, small bamboos, raspberries, balsams, and other plants, which render natural reproduction of seedlings rare and difficult. Clear cutting and artificial regeneration have been found to be the most successful modes of treating these forests. This spruce is attacked in the Himalayas by the aphid, *Chermes abietis*, which is common on the European spruce, and produces cone-like excrescences on the twigs. A fungus, *Peridermium incarcerans*, Cooke, often occurs as curious tassel-like orange bunches on the branchlets. The leaves are attacked by another fungus, *Aecidium Thomsoni*.¹ (A. H.)

CULTIVATION

P. Smithiana was introduced into cultivation in 1818 by Dr. Govan of Cupar, who gave the seed to the Earl of Hopetoun, from which the first trees were raised at Hopetoun House, near Edinburgh. It is a thriving tree in many parts of the British Isles; and though the young shoots are liable to be nipped by frost, this does not seem to do the tree permanent injury. It does not, however, seem to succeed on limestone soil.

The tallest specimen² I have seen in England is at Melbury, where, in 1906, I measured one 85 to 90 ft. high and 8 ft. 10 in. in girth. (Plate 345.)

At Cardew a tree was reported³ in 1891 as 80 ft. high, but when I measured it in 1905 it was 86 ft. by 7 ft. 9 in. At Pencarrow Mr. Bartlett measured a perfect specimen planted by Sir W. Molesworth about 1850, which in 1907 was 57 ft. by 6 ft. 7 in. At Bicton in 1902 I measured one 65 ft. by 6 ft. 9 in. At Redleaf, Kent, in 1907 a tree 75 ft. by 9 ft. had many cones on the lower branches, which rested on the ground. At Walcot there is a fine tree 60 ft. by $5\frac{1}{2}$ ft.

At Barton, Bury St. Edmunds, there are two fine trees, one of which was 84 ft. high by 7 ft. 1 in. in girth in 1904, the other 77 ft. by an inch less in girth. These trees were raised from seeds sent by Lady Napier, to whom they had been given by Wallich, and the seedlings were planted out in 1843. The trees were not injured in the least by the severe winter of 1860-1861, and commenced to bear cones for some years before 1869, having a very abundant crop in that year.⁴ A tree at Hardwicke House, Suffolk, planted later than those at Barton, was measured by Sir Hugh Beevor in 1904 as 73 ft. by 7 ft.

In Wales the largest I have seen, a tree at Margam Park, was 81 ft. by $6\frac{1}{2}$ ft. in 1907.

In Scotland there are many good specimens, of which those at Hopetoun are the oldest, having been raised from seed sent to the Earl of Hopetoun by

¹ Described and figured by Berkeley in *Gard. Chron.* 1852, p. 627.

² The *Picea Smithiana* reported in *Gard. Chron.* 1869, p. 713, to be growing at Shelsley Walsh in the Teme Valley in Worcestershire, is *P. excelsa*. Cf. p. 1341.

³ *Journ. R. Hort. Soc.* xiv. 488 (1892).

⁴ Bunbury, *Arboretum Notes*, 134.

Dr. Govan in 1818. When I saw them in 1904 the best of these was about 70 ft. by 8½ ft. Fowler¹ states that the two trees at Hopetoun House were planted in their present position in 1824, one being a seedling, the other a grafted plant worked on the common spruce, four feet above the ground. In 1871 the graft had outgrown the stock all round for 2 to 3 inches. The seedling tree in that year was 60 ft. high by 7 ft. in girth at four feet from the ground, the grafted tree being scarcely so tall. Mr. T. Hay, gardener at Hopetoun, remeasured these trees in January 1911, and informed me that the grafted tree is still in fair condition, and measures 70 ft. high. Its girth below the graft is 6 ft. 2 in., and above it 7 ft. 2 in. The seedling tree is more healthy and measures 75 ft. by 8 ft. 8 in. at 4 ft. from the ground.

At Smeaton Hepburn, a tree, planted in 1840, was measured by Henry in 1905 as 67 ft. by 6 ft. 5 in.

In Ireland this species thrives remarkably well, and there are many fine specimens. At Woodstock, Kilkenny, in 1909 I measured a tree 72 ft. by 8½ ft. At Mount Shannon near Limerick, a tree measured, in 1905, 69 ft. by 8½ ft. in girth. At Fota, Queenstown, there is a fine tree, which was, in 1903, 63 ft. by 8 ft. At Glenstal, Co. Limerick, in the same year, a tree was 11½ ft. in girth with an estimated height of 70 ft. At Bessborough in Co. Kilkenny, a tree, which was figured in the *Gardeners' Chronicle*, May 21, 1904, is, we are informed by Viscount Duncannon, 60 ft. high by 6 ft. 9 in. in girth. Another at Emo Park, Portarlinton, was 60 ft. by 8 ft. in 1907; and one at Coollatin was 59 ft. by 4 ft. 8 in. in 1906.

In the United States,² the tree is too tender for the climate of Boston, and does not do well even at Washington. There are no large trees of this species in the United States.

TIMBER

According to Gamble, the rate of growth in India is fairly fast, averaging about 11 rings per inch of radius, or 125 years to a girth of 6 ft. The wood is similar to that of the European spruce, and affords excellent planking for floors, walls, and ceilings. It is used for shingles, for packing cases, for building huts, for water-troughs, etc. In some places it is utilised for making tea boxes. It averages in weight 30 lbs. to 32 lbs. per cubic ft. The bark was formerly used extensively by the shepherds for roofing their huts, but this practice has been stopped in the Government forests. On account of the expense of transport, it is never likely to be exported.

(H. J. E.)

PICEA GLEHNII

Picea Glehnii, Masters, in *Gard. Chron.* xiii. 300, fig. 54 (1880), and in *Journ. Linn. Soc. (Bot.)*, xviii. 512, fig. 13 (1881); Mayr, *Abiet. Jap. Reiches*, 56, 102, t. 4, fig. 11 (1890), and *Fremdländ. Wald- u. Parkbäume*, 327 (1906); Kent, Veitch's *Man. Conif.* 437 (1900); Shirasawa, *Icon. Ess. Forest. Japon.* ii. t. 3, figs. 19-42 (1907); Clinton-Baker, *Illust. Conif.* ii. 39 (1909).

Abies Glehnii, Schmidt, in *Mém. Acad. Imp. Sc. St. Pétersb.* xii. 176, t. 4 (1868).

A tree, attaining in Yezo over 100 ft. in height. Bark different from any of the other spruces, reddish in colour, and fissuring into broad thin loose plates. Young branchlets slender, reddish, with dense short pubescence in the furrows between the pulvini, not spreading over the surface of the latter. Buds ovoid, brown, ⅛ in. long, composed of a few glabrous scales; terminal buds girt with a ring of scales ending in long subulate points. Leaves arranged on the branchlets as in *P. excelsa*, ⅓ to ½ in. long, slender, ending in a short cartilaginous point; rhombic in section, with about two stomatic lines on each of the two upper sides, and a single line on each of the lower sides.

Cones, about 2 in. long by 1 in. in diameter when closed; violet, with a red edge to the scales when growing, shining brown when ripe; cylindrical, with an obtuse narrowed apex; scales, when ripe, spreading from the axis at a right angle, suborbicular, with a cuneate claw, about ½ in. wide, with the thin upper margin entire, slightly erose, or faintly denticulate; bract spatulate, ⅓ in. long, denticulate at the apex. Seed blackish, ⅓ in. long, with wing ⅔ in. long; wing broadest about the middle, rounded at the apex, outer margin denticulate.

This species is readily distinguishable from the other short-leaved spruces by the reddish branchlets, with the pubescence confined to the furrows. It resembles *P. orientalis* in the colour of the foliage, but is very distinct in the terminal buds, which have a ring of subulate scales, similar to *P. nigra* and *P. rubra*.

DISTRIBUTION

*P. Glehnii*¹ was discovered in Saghalien in 1861 by Glehn, the comrade of F. Schmidt on the expedition sent out by the Russian Geographical Society to Eastern Asia. It was subsequently found in Yezo by Maries in 1877.

In Saghalien, this species is confined to the southern half of the island, where it grows on the plains and in the valleys, never attaining, according to Schmidt, a great size, being seldom over a foot in girth. According to Mayr, it is probably absent from the Kurile Isles,² as it was not noticed by him on Shikotan; according to Komarov,³ it does not occur in Russian Manchuria.

(A. H.)

¹ The Formosan spruce, identified with *P. Glehnii* by Matsumura in *Tokyo Bot. Mag.* xv. 141 (1901), is quite distinct, and has been named *P. morrisonicola*, Hayata, in *Journ. Coll. Sci. Tokyo*, xxv. 220 (1908).

² Miyabe does not include it in his *Flora of the Kuriles*.

³ *Flora Manchuria*, i. 200 (1901).

P. Glehnii attains its maximum development in Yezo, where, according to Mayr, it is much commoner in the west of the island than in the east. In western Yezo it forms mixed forests in company with *P. ajanensis*, chiefly on the cooler parts of the mountains, the trees reaching on an average nearly 120 feet in height. Mayr mentions a peculiar forest of this species, which occurs on the volcanic Iwo-san (1500 feet elevation) east of Lake Kucharro. In the eastern part of the island, it forms pure forests in the river valleys in swampy situations, which are often several hundreds of acres in extent; but the trees are of no great size, averaging only 80 ft. in height. This species is known to the Japanese as *Shinko matsu* or *Aka-eso*.

According to Miyabe, it is rare near Sapporo and only found at high elevations mixed with *P. ajanensis*. Near Lake Shikotsu at 1500 feet elevation, I found it much less abundant than *P. ajanensis*, and could not procure any fruiting specimens. A self-sown seedling which I brought from here is growing very slowly at Colborne and is now only 1 foot high.

I could not learn whether the wood of the tree is distinguished from that of the common Yezo spruce. Some very broad clean pieces which I saw in the saw-mill at Sunagawa had a close grain and a shiny satiny surface when planed, making it suitable for interior work where strength is not required.

CULTIVATION

According to Beissner¹ seeds of this species arrived in Germany before 1891, from which young plants were raised. It is scarcely known in cultivation in England. There are young plants at Kew, about 2 ft. high, which are thriving; and small specimens at Bayfordbury and Brickendon Grange, Herts, and in the Cambridge Botanic Garden. It is too soon as yet to form any opinion as to the suitability of this species to our climate; but I do not expect that it will attain any size.

(H. J. E.)

PICEA POLITA

Picea polita, Carrière, *Conif.* 256 (1855); Masters in *Gard. Chron.* xiii. 233, fig. 44 (1880), and *Journ. Linn. Soc. (Bot.)* xviii. 507, pl. 19 (1881); Mayr, *Abiet. Jap. Reiches*, 46, t. 3, f. 7 (1890), and *Fremdländ. Wald- u. Parkbäume*, 335 (1906); Kent, Veitch's *Man. Conif.* 446 (1900); Shirasawa, *Icon. Ess. Forest. Japon.* ii. t. 2, figs. 18-29 (1907); Clinton-Baker, *Illust. Conif.* ii. 45 (1909).

Picea Torano, Koehne, *Deutsche Dendrologie*, 22 (1893).

Abies Torano,² Siebold, in *Verhand. Batav. Genoot. Konst. Wet.* xii. 12 (1830).

Abies polita, Siebold et Zuccarini, *Flor. Jap.* ii. 20, t. 111 (1842).

Pinus polita, Antoine, *Conif.* 95 (1840-1847).

A tree, occasionally attaining in Japan 120 ft. in height, but usually considerably smaller. Bark fissuring into small scales, exposing the yellowish brown cortex

¹ *Nadelholzkunde*, 377 (1891).

² This specific name is uncertain, as it was unaccompanied by any description, and cannot be adopted.

beneath. Buds ovoid, acute at the apex, up to $\frac{5}{8}$ in. long, shining reddish brown; scales closely imbricated, ovate, rounded at the apex. Young branchlets stout, glabrous, shining, pale yellow. Leaves on lateral branchlets in an imperfect radial arrangement, all directed outwards with their tips curving upwards; about $\frac{3}{4}$ to $\frac{7}{8}$ in. long, $\frac{1}{16}$ in. wide, very rigid, stout, curved, ending in a sharp spine-like point; compressed rhomboidal in section, with 4 to 6 lines of stomata on each of the four surfaces.

Cones, about 3 to 4 in. long, $1\frac{1}{2}$ in. in diameter when closed, yellowish green when growing, shining chestnut brown when mature; ovoid-cylindrical, obtuse at the apex; scales obovate, with a cuneate base, about $\frac{1}{10}$ in. wide; upper margin rounded, with a few irregular denticulations; bract oblong, $\frac{1}{4}$ in. long, slightly narrowed at the denticulate apex. Seed mottled grey, about $\frac{1}{8}$ in. long, with wing $\frac{7}{8}$ in. long; wing broadest near the truncate denticulate apex.

The very rigid sickle-shaped leaves, ending in prickly spines, and arranged radially on the branchlets, are unlike those of any other spruce.

P. polita is confined to the main island of Japan, having nearly the same distribution as *P. hondoensis* and *P. bicolor*, extending from about lat. $35\frac{1}{2}^{\circ}$ to lat. 38° , and not reaching the extreme north of the island. It is found in warmer situations than the other two spruces, and, unlike them, never forms pure woods. It always occurs as isolated trees or in small groups, scattered through the broad-leaved forest. It is the tallest of the three, the largest specimens seen by Mayr being nearly 120 ft. high; and is a much rarer tree, of no economic importance in Japan, where it is known as *hari-momi*.

This species was introduced into cultivation by J. Gould Veitch in 1861, and is perfectly hardy; but it has nowhere attained considerable dimensions. Kent states that the best specimens occur in Devon and Cornwall; but the largest which we have seen is one at Highnam, Gloucester, 30 ft. by 2 ft. in 1910. There is also a healthy specimen at Bayfordbury, planted in 1879, which has borne cones; and another at Hatfield, very thriving. A tree at the Heatherside Nursery, Farnborough, about 20 ft. high, bore cones in 1909. There are two good young trees at Castle Kennedy. A fine specimen at Castlewellan, planted in 1884, was about 25 ft. high in 1907.

According to Mayr this species, with *P. bicolor* and *P. pungens*, are the latest to grow in Germany, not opening their buds until June. It is much injured by squirrels, and will probably be of no economic value, either on the Continent or in England.

(A. H.)

PICEA BICOLOR

Picea bicolor, Mayr, *Abiet. Jap. Reich.* 49, t. 3, fig. 8 (1890), and *Fremdländ. Wald- u. Parkbäume*, 323 (1906); Shirasawa, *Icon. Ess. Forest. Japon.* i, text 19, t. 4, figs. 1-14 (1900).

Picea Alcockiana, Carrière, *Conif.* 343 (1867); Masters, in *Gard. Chron.* xiii. 212, figs. 41, 43 (1880), and in *Journ. Linn. Soc. (Bot.)* xviii. 508, figs. 7-9 (1881); Hennings, in *Gartenflora*, xxxviii. 216, fig. 40 (1889); Kent, *Veitch's Man. Conif.* 429 (1900); Henry, in *Trees of Great Britain*, i. 89, 90 (1906).

Picea japonica,¹ Regel, *Index Sem. Hort. Petrop.* 33 (1865).

Picea acicularis, Beissner, *Nadelholzkunde*, 380 (1891).

Abies bicolor, Maximowicz, in *Mél. Biol.* vi. 24 (1866).

Abies acicularis, Maximowicz, in *Index Sem. Hort. Petrop.* 74 (1868).

Abies Alcockiana, Gordon, *Pinetum*, 4 (1875) (not Lindley).

Pinus Alcoquiana, Parlatore, in De Candolle, *Prod.* xvi. 2, p. 417 (1868).

A tree, attaining in Japan 80 ft. in height. Bark greyish brown, fissuring into small scales. Young branchlets yellowish, glabrous on the lateral branches, but pubescent in the furrows between the pulvini on strong leading shoots; older branchlets shining reddish brown. Buds, about $\frac{1}{8}$ in. long, conic, rounded at the apex, without resin, and with few scales, scarious in margin. Leaves, on lateral branches arranged as in *P. excelsa*, about $\frac{3}{4}$ in. long, rigid, curved, ending in a short cartilaginous point, rhombic in section, with two conspicuous white stomatic bands on the upper two sides, each of 5 or 6 lines, and two bands of about 2 lines each on the two lower green sides.

Cones, averaging $3\frac{1}{2}$ in. long and 1 in. in diameter when closed; bluish red with green margins to the scales when growing, brownish when mature; ovoid-cylindrical: scales obovate with a cuneate base, about $\frac{3}{8}$ in. broad, thin and faintly denticulate in the upper rounded margin; bract $\frac{1}{8}$ in. long, spatulate, with a slightly expanded denticulate lamina. Seed, $\frac{1}{8}$ to $\frac{1}{4}$ in. long, brown; seed with wing $\frac{3}{8}$ in. long; wing widest about the middle, rounded and faintly denticulate at the apex.

This species, as its name implies, differs from the other quadrangular-leaved spruces, in the conspicuous white broad stomatic bands on the upper surface of the leaf, contrasting with the green lower surface, and in this respect it simulates the flat-leaved spruces, and has been confused² with *P. hondoensis* and *P. ajanensis*. The leaves of the latter are flat and not rhombic in section, and are devoid of the faint stomatic lines on their lower surface, which are readily seen in *P. bicolor*.

HISTORY

This species was discovered in 1860 on Fujiyama by J. G. Veitch, who collected cones of it, unfortunately mixed with twigs of *P. hondoensis*. Lindley, in 1861, described a mixture of the two species, and his name, *Abies Alcoquiana*, Veitch,³

¹ A name without any description. It is identified in *Index Sem. Hort. Petrop.* 3 (1866) with *Abies bicolor*, Maxim. Seeds were sent from Japan in 1865 by Tschonoski.

² Cf. Vol. I. p. 90.

³ Ex Lindley, in *Gard. Chron.* 1861, p. 23. Lindley's description comprises the leaves of *P. hondoensis* and the cones of *P. bicolor*. The type specimen, in which both these are mixed in one packet, is in the herbarium at Cambridge.

cannot stand. Maximowicz gave a correct description of the species under the name *Abies bicolor* in 1866.

As explained in our article¹ on *P. hondoensis*, seeds of both species were early distributed as *P. Alcockiana*; and in gardens most trees named *P. Alcockiana* are in reality *P. hondoensis*.

This species was introduced into the St. Petersburg Botanic Garden by seeds sent from Japan in 1868 by Tschonoski under the name *Abies acicularis*,² Maximowicz.

DISTRIBUTION

This species occurs only in the main island of Japan, where, like *P. hondoensis* and *P. polita*, it is confined to the central ranges between lat. $35\frac{1}{2}^{\circ}$ and lat. 38° . It forms part of the coniferous forest, which covers these mountains at varying altitudes from south to north, usually above the zone of broad-leaved trees; but occasionally scattered trees are met with in the upper limits of this zone. Mayr never saw any trees over 80 ft. in height, though he thinks that it occasionally attains greater dimensions.

This species is rare in collections, the largest we have seen being at Kew, where there are two trees, 25 and 30 ft. high, one of which bore cones in 1900. There are also specimens at Westonbirt, Pencarrow, Murthly, Castle Kennedy, and Glasnevin. Mr. H. Clinton Baker collected cones from the tree at Pencarrow in August 1908; and I saw at Castlewellan in 1907 a tree about 20 ft. high bearing cones.

The tree at Blackford Park, Edinburgh, mentioned by Kent, was planted about 1882-1884, and measured 20 ft. by 1 ft. 7 in. in 1906. The gardener, Mr. Small, states that it is late in starting into growth in the spring, and in consequence escapes late frosts.

Probably the finest tree in cultivation is growing in Mr. Hunnewell's pinetum at Wellesley, Mass., U.S.A. It bears cones freely, some of which I gathered in 1906, when the tree measured about 36 ft. high by 3 ft. in girth.³ (A. H.)

¹ Vol. I. p. 90.

² Young plants with slender sharp-pointed needles were distributed under this name.

³ Cf. Sargent, *Pinetum at Wellesley*, 1905, p. 11.

PICEA MAXIMOWICZII

Picea Maximowiczii, Regel, in *Index Sem. Hort. Petrop.* 33 (1865); Carrière, *Conif.* 347 (1867); Masters, in *Gard. Chron.* xiii. 363 (1880), and *Journ. Linn. Soc. (Bot.)* xviii. 507 (1881); Mayr, *Abiet. Jap. Reiches*, 98 (1890).

Picea obovata, Ledebour, var. *japonica*, Beissner, *Nadelholzkunde*, 370 (1891).

Picea Tschonoskii, Mayr,¹ *Fremdländ. Wald- u. Parkbäume*, 339 (1906).

Abies obovata, Loudon, var. *japonica*, Maximowicz, in *Index Sem. Hort. Petrop.* 1 and 3 (1866); Franchet, *Enum. Pl. Jap.* i. 466 (1875).

Abies Maximowiczii, Neumann, *Cat.* 1865, ex Parlatores, in De Candolle, *Prod.* xvi. 2, p. 431 (1868); Veitch, *Man. Conif.* 80 (1881).

A small tree. Young branchlets reddish brown, glabrous, with the apices of the pulvini all directed outwards and forwards. Buds about $\frac{1}{2}$ in. long, ovoid, acute, with glabrous rounded resinous scales. Leaves on lateral branches radially spreading on all sides at nearly a right angle to the branchlet, but with their tips pointing slightly forwards; $\frac{3}{8}$ to $\frac{1}{2}$ in. long, rigid, tapering near the apex which is tipped with a short blunt point; green, quadrangular in section, with three to five stomatic lines on each surface; resin-canals two, lateral, close to the epidermis.

Cones, $1\frac{3}{4}$ to 2 in. long, 1 in. in diameter when open, shining brown when ripe, cylindrical, but tapering at both ends: scales numerous, obovate with a cuneate claw, $\frac{1}{2}$ in. wide; rounded, entire, and bevelled in the upper margin: glabrous in the exposed part, elsewhere covered with a minute reddish pubescence: bract about $\frac{1}{8}$ in. long, oblong, with a rounded faintly denticulate apex. Seeds, not extending to the upper and lateral margins of the scale, $\frac{1}{8}$ in. long, dark brown mottled with lighter streaks; seed with wing $\frac{1}{2}$ in. long; wing widest near the upper rounded denticulate margin.

This species is readily distinguishable by its short leaves radially arranged, and its resinous buds. At Kew it produces new shoots a month earlier than *P. bicolor*.

This spruce is a native of Japan, where it was collected in 1864 on Mt. Fujiyama by Tschonoski,² a young Japanese collector in the employment of Maximowicz. One of the original specimens from this locality is preserved at Kew, where there is also an imperfect specimen,³ collected in the same year in the province of Senano by Tschonoski, which was recognised by Maximowicz to be the same species.⁴ It appears to be very rare, and has not since been found by Japanese botanists. Maximowicz considered it to be a variety of *P. obovata*, from which it is clearly distinct; but it is rather related to *P. bicolor*, though differing much in foliage and in cones.

¹ Mayr erroneously considered that the tree cultivated as *P. Maximowiczii* was different from Tschonoski's Fujiyama specimen. He identified the latter with *P. bicolor*, and proposed a new name, *P. Tschonoskii*, for the former.

² Maximowicz, in *Rhamn. As. Or.* 17 (1866), gave an account of Tschonoski, who was a Japanese and not a Russian as some authors have supposed. He gathered about 800 species of Japanese plants, and sent seeds of many kinds to St. Petersburg.

³ Consisting of a cone and a single leaf. The cones on the Grignon tree, about 2 in. long, are intermediate in size between those of the Fujiyama tree (which are $1\frac{3}{4}$ in. long) and those of the Senano specimen (about $2\frac{1}{2}$ in. long).

⁴ The Senano specimen is labelled *Abies obovata*, Loudon, var. *japonica*, Maximowicz; and the Fujiyama specimen is named *Picea Maximowiczii*, Regel.

Seeds sent to St. Petersburg by Tschonoski in 1865 were distributed by Regel to various botanic gardens on the Continent. The best specimen that I have seen is a tree with ascending branches at the Agricultural School of Grignon near Paris, which is about 30 ft. in height by 19 in. in girth; but M. Hickel¹ tells me that there are still finer trees elsewhere in France.

A smaller tree in the Arnold Arboretum, U.S.A., also bears cones, smaller in size than those on the tree at Grignon. Another in Mr. Hunnewell's pinetum at Wellesley, Mass., was 11 ft. high in 1905. There is also a small specimen² in the spruce collection at Kew, a bush about 4 ft. high; and two trees at Handcross Park, Sussex, the taller of which was 32 ft. by 2 ft. 5 in. in 1911. These were planted about thirty years ago, and have not as yet borne cones. (A. H.)

PICEA NIGRA, BLACK SPRUCE

Picea nigra, Link, *Handb.* ii. 478 (1831); Kent, Veitch's *Man. Conif.* 438 (1900); Clinton-Baker, *Illust. Conif.* ii. 41 (1909).

Picea Mariana, Britton, Sterns, and Poggenburg, *Cat. Pl. N. York*, 71 (1888); Sargent, *Silva N. Amer.* xii. 28, t. 596 (1898), and *Trees N. Amer.* 39 (1905).

Picea brevifolia,³ Peck, *Spruces of the Adirondacks*, 13 (1897), and in *Bull. Torrey Bot. Club*, xxvii. 409 (1900).

Abies Mariana, Miller, *Dict.* ed. 8, No. 5 (1768).

Abies nigra, Du Roi, *Harbk. Baumz.* ii. 182 (1800); Loudon, *Arb. et. Frut. Brit.* iv. 2312 (1838).

Abies denticulata, Michaux, *Fl. Bor. Amer.* ii. 206 (1803).

Pinus Mariana, Du Roi, *Obs. Bot.* 38 (1771).

Pinus nigra, Solander, in Aiton, *Hort. Kew.* iii. 370 (1789).

A tree, attaining in America 100 ft. in height and 9 ft. in girth, but usually much smaller. Bark brownish, fissuring into irregular thin appressed scales. Buds small, ovoid, acute; the terminal buds surrounded at the base by ciliate pubescent scales with conspicuous long subulate points. Young branchlets brownish, with dense short erect glandular pubescence, retained on the dark-coloured branchlets of the second year. Leaves, arranged on lateral branches as in the European spruce, about $\frac{1}{2}$ in. long, bluish or glaucous green, slightly incurved, ending in a short cartilaginous point, quadrangular in section, with four lines of stomata on each of the two sides turned towards the branchlets, and with one to two lines on each of the other sides.

Cones persistent on the branches for several years, ovoid, acute at the apex, $\frac{3}{4}$ to $1\frac{1}{2}$ in. long, dark purple when growing, dull brown when ripe; scales rigid, woody, pubescent, about $\frac{2}{8}$ in. wide, rounded or rarely pointed at the apex, denticulate

¹ M. Hickel informs me that the older trees in France, which were planted about 1868, were originally raised in Thibaut and Keteleer's nursery at Sceaux, from seed given them by Carrière, which he received from Regel. Of late years this spruce has been propagated by grafting.

² This is perhaps the same shrub as that from which a specimen in the Kew Arboretum herbarium was taken in 1882, labelled "low bush, 1 to 2 ft. (rounded). Pinetum, Aug. 3, 1882. J. D. Hooker." The low stature of the shrub at Kew indicates probably an alpine origin for the seed from which it was raised.

³ This is the ordinary stunted form of *P. nigra*, growing on swamps and exposed mountain summits, and is not distinguishable even as a variety by Sargent, or by Britton and Shafer, *N. Amer. Trees*, 57 (1908); Rehder, in Bailey, *Cyc. Am. Hort.* iii. 1334, fig. 1794 (1901), and in *Rhodora*, ix. 109 (1907), has distinguished it as var. *brevifolia*.

in margin. Seeds dark brown, about $\frac{1}{8}$ in. long, with pale brown wings broadest above the middle and very oblique at the apex.

Dwarf and fastigate forms,¹ and varieties in which the foliage is variegated with white or golden yellow in colour are mentioned by Beissner.

Var. *Doumetii*, Carrière, *Conif.* 242 (1855). This variety was first noticed about 1835 in the garden of the Château de Baleine² near Moulins in France. It is a small tree or large shrub, with short numerous branches, forming a dense conical pyramid of foliage. The leaves are very crowded, thin and sharp-pointed. As seen at Kew this variety is very distinct in appearance.

There are remarkable black spruces³ in the Wilhelmshöhe and Karslane parks at Cassel in Germany, which are pyramidal in habit and bluish in foliage. Self-layering occurs, and numerous colonies of young plants are produced round the parent trees.

DISTRIBUTION

The black spruce is widely spread throughout the Dominion of Canada, occurring as far north as Labrador on the Atlantic coast, and reaching lat. 65° in the valley of the Mackenzie River, whence, crossing the Rocky Mountains, it spreads in the interior of Alaska to the valley of the White River.⁴ Farther south, it is restricted to the eastern side of the Rocky Mountains, extending throughout Alberta, Assiniboia, northern Saskatchewan, and northern Manitoba (where it attains its largest size) to central Wisconsin and Michigan. It is common in Newfoundland and all the eastern provinces of Canada, except southern Ontario; and spreads in the north-eastern United States to Pennsylvania, reaching its most southerly point in the Alleghanies in southern Virginia.

Towards the northerly part of its range it is abundant, and grows on well-drained alluvial soils and on the stony slopes of barren hills; while towards the south it is almost entirely restricted to bogs and swamps. Mr. H. E. Ayres in *Garden and Forest*, vii. 504, fig. 80 (1894), describes and figures it under these conditions in Minnesota, as the "Muskeag" spruce, this being the name by which the sphagnum bogs so common in North America are known. He states that in these swamps the trees grow slowly to a height of 60 ft. with very drooping branches, the trunks never exceeding about 10 in. in diameter. The cones are densely crowded at the summit of the tree, and are sometimes produced on trees only 3 ft. high.

(A. H.)

CULTIVATION

The black spruce was introduced⁵ into England by Bishop Compton about 1700; but Sir W. Watson, who gave a list of the principal trees which he found in the Fulham Palace gardens in 1751, does not include it.

¹ For *Picea nigra*, var. *virgata*, Rehder, see under *P. rubra*, p. 1378.

² When I visited this place in 1909, I found that the original specimen, a tree about 30 ft. high, was dead; but two plants grown from its layers are now about 15 ft. high, with pointed tops; while others, which were raised from cuttings, form dense dwarf bushes.—(H. J. E.)

³ See *Gard. Chron.* xi. 81, *Suppl. Illust.* (1892). The black spruce appears to layer frequently; and Loudon figures an instance which was noticed in 1828 at Braco Castle, Perthshire.

⁴ Cf. Sargent, *Silva N. Amer.* xiv. 106 (1902).

⁵ Aiton, *Hort. Kew.* iii. 371 (1789).

It is common in cultivation and usually sold in nurseries under the name of blue spruce, but it never attains large dimensions and is of no economic importance. It has been recommended for planting in boggy and marshy situations, but is always much surpassed in growth by *Picea sitchensis*, and seems to be a short-lived tree in this country.

One of the best specimens we know of is the one figured in Plate 346, which grows on the north edge of a plantation of common spruce at Lyde, near Colesborne, on my property. This tree has been favoured by a moist clay soil, a sheltered position and a cold damp climate; and has attained at about fifty-five years old a height of 56 ft. with a girth of 2 ft. 10 in. As the figure (Plate 346) shows, it has become self-layered under the shade of a hedge, which was cut away to show it; and one of the lower branches has already attained half the height of the parent stem. Though it has not increased much in the last ten years, this tree is in good health, but several others, planted at the same time on dry land, are not half the size and dead or dying. As usual in England it bears cones in abundance near the top of the tree. I have seen a tree at Woburn about 60 ft. by 4 $\frac{1}{2}$ ft.; and there is one at Merton which was about 40 ft. by 5 ft. 10 in. in 1905.

In the west of Scotland it grows well, but so far as we have seen never attains a large size; the tallest recorded¹ in Scotland in 1891 was 46 ft. by 3 ft. 5 in. at Mount Stuart. Of the numerous trees planted in two groups in 1832 at Keillour, Perthshire, at the lower end of a peat-bog, Henry only found a few surviving in 1904, none exceeding 40 ft. in height. At Dawyck, a tree was 37 ft. by 2 $\frac{1}{2}$ ft. in 1911.

In Ireland the best we have seen was measured by Henry at Fota in 1903, when it was 60 ft. by 4 ft. 10 in. (H. J. E.)

PICEA RUBRA, RED SPRUCE

Picea rubra, Link, in *Linnaea*, xv. 521 (1841) (not Dietrich²); Gorrie, in *Trans. Bot. Soc. Edin.* x. 353 (1870); Kent, Veitch's *Man. Conif.* 450 (1900); Sargent, in *Bot. Gaz.* xlv. 226 (1907); Clinton-Baker, *Illust. Conif.* ii. 47 (1909).

Picea nigra, Link, var. *rubra*, Engelmann, in *Gard. Chron.* xi. 334 (1879).

Picea rubens, Sargent, *Silva N. Amer.* xii. 33, t. 597 (1898), and *Trees N. Amer.* 41 (1905).

Pinus rubra, Lambert, *Genus Pinus*, i. 43 (1803) (not Miller³).

Picea acutissima, Jack, in *Garden and Forest*, x. 63 (1897).

Abies rubra, Poiret, in Lamarck, *Dict.* vi. 520 (1804); Loudon, *Arb. et Frut. Brit.* iv. 2316 (1838).

A tree, attaining in America 100 ft. in height and 9 ft. in girth. Bark, branchlets, and buds, similar to *P. nigra*. Leaves yellowish or dark green, not glaucous, about $\frac{5}{8}$ in. long, incurved, acute or rounded at the apex, quadrangular in section, marked on each of the two upper sides by about four stomatic lines, and on each of the two lower sides by two to three stomatic lines.

¹ *Journ. Roy. Hort. Soc.* xiv. 506 (1892).

² *Picea rubra*, Dietrich, *Fl. Berol.* ii. 795 (1824) is the common European spruce, *Picea excelsa*.

³ *Pinus rubra*, Miller, *Gard. Dict.* No. 3 (1795) is the common European pine, *Pinus sylvestris*.

Cones, ovoid-oblong, $1\frac{1}{4}$ to 2 in. long, green or purplish green when growing, shining reddish brown when mature, usually falling in the second summer: scales $\frac{2}{5}$ in. broad, rounded entire or denticulate at the thin upper margin: bract inconspicuous, oblanceolate, about $\frac{1}{8}$ in. long. Seeds mottled dark brown, about $\frac{1}{8}$ in. long, with wings broadest near the rounded apex, the total length of seed and wing being about $\frac{2}{5}$ in.

VARIETIES

1. *Picea australis*, Small, *Flora S.E. United States*, 30 (1903), is probably a variety¹ of the red spruce, which differs in bearing small cones that are said to fall directly after shedding their seed. Large trees of this kind, attaining 130 ft. in height, are reported to occur on the summits and rocky slopes of mountains in Virginia and North Carolina.

2. A solitary red spruce,² with snake-like branches, similar in habit to *P. excelsa*, var. *virgata*, was discovered in 1892, near Williamstown, in north-western Massachusetts. From it young plants were raised by grafts in the Arnold Arboretum.

DISTRIBUTION

The red spruce has a much more southerly distribution than the black spruce,³ and does not extend farther north than Prince Edward Island and Nova Scotia. It is widely spread in New England,⁴ through Maine, New Hampshire, Vermont, and northern Massachusetts; but is not known in Rhode Island and Connecticut. In New York, especially in the Adirondacks, it forms extensive forests; and extends through the Alleghany Mountains southward through Pennsylvania and West Virginia to the high peaks of North Carolina. Pinchot⁵ has given a complete account of this species, which provides the only merchantable spruce timber in the United States; and states that it is remarkable for its tolerance of dense shade and its capacity for recovering after years of suppression. In the Adirondacks, it ascends to 4500 ft., and is often seen on steep southern slopes; but elsewhere is mixed with balsam fir, hemlock, white pine, birch, maples, and beech. (A. H.)

CULTIVATION

The red spruce was first accurately described and figured by Lambert from a tree growing in England, which was said to have been brought from Newfoundland. According to Aiton,⁶ it was cultivated near London by Miller before 1755; but it is doubtful if this tree was distinguished from the black spruce at that date.

P. rubra is rare in collections, the only large trees which we have seen being

¹ Cf. Britton and Shafer, *North American Trees*, 58 (1908).

² Figured in *Garden and Forest*, viii. 45, fig. 7 (1895). This is identical with *Picea nigra*, Link, var. *virgata*, Rehder, in Bailey, *Cycl. Am. Hort.* iii. 1334 (1901), corrected to *P. rubra forma virgata*, Rehder, in *Rhodora*, ix. 110 (1907). Cf. *Mitt. Dent. Ges.* 1907, p. 116.

³ Keiler, *Our Native Trees*, 470 (1907) says: "Black spruce is a tree of the far north, existing but precariously south of the northern boundary of the United States; while red spruce is an Appalachian tree, attaining its greatest dimensions in northern New Hampshire and Pennsylvania."

⁴ Dame and Brooks, *Trees of New England*, 14 (1902).

⁵ *The Adirondack Spruce*, pp. 1-157 (1898).

⁶ *Hort. Kew.* v. 319 (1813).

one at Stanage Park, Herefordshire, which measured in 1911, 72 ft. by 5 ft. 9 in.; and another at Merton, Norfolk, 63 ft. high and 4 ft. 7 in. in girth in 1909.

The large trees reputed¹ to be of this species at Dropmore are undoubtedly *P. excelsa*.

The only place I know where this tree has been planted in quantity is on the drive of the Rhinefield enclosure in the New Forest, where there are a number of red and white spruce along the south end of the main avenue. The largest of the former was on the north side of the first cross ride on the west and measured 40 ft. by 4 ft. in 1906; most of the trees had old and new cones, low down on the ends of the branches, from which I have raised seedlings. The largest of the white spruce at the corner of the second cross ride on the west was 56 ft. by 5 ft. 4 in., and I found cones on only one of the trees.

Some small trees sent from America grow very slowly at Colesborne.

In 1870 Gorrie² found a few trees of this species, about 12 to 18 ft. in height, and bearing cones, which were growing on the railway bank near Tynehead in Midlothian at 800 ft. elevation. They had been raised about fifteen years previously from seed obtained in Newfoundland. Some of the seedlings which had been planted two or three miles off in a dry heavy soil had dwindled and died. Dr. A. W. Borthwick visited this place in 1906, and sent me specimens from these trees, from the cones of which I have raised seedlings. The trees are now about 35 ft. in height, growing mixed with common spruce, but not so large as white spruce at the same place. Gorrie also reported in the same year trees about 15 to 20 ft. high growing in Dunmore Park, near Stirling. We have not been able to discover whether these are living.

At Avondale, in Ireland, there is an experimental plot, covering about two acres, which was planted in 1907 with red spruce, mixed with a small proportion of white and black spruce. The red spruce in this plot is extremely thriving, being about 6 ft. high in January 1912, and exceeding in vigour a plot of European spruce beside it.

In France the species seems to grow remarkably well at Les Barres, according to Pardé, who figures³ a group of three trees about 45 ft. by 4 ft. There are others even larger planted in 1832 which have produced several natural seedlings. Beissner says that there are fine specimens in the Karls-aue at Cassel, at Herrenhausen in Hanover, and at Worlitz. (H. J. E.)

In 1908 I visited in the Hertogenwald in Belgium, a plantation of red spruce consisting of five acres in two separate plots at an elevation of 1250 ft. The soil here is a loamy clay, on which the European spruce thrives remarkably well. The plots had been accurately measured in 1907, when the trees were fifty-five years old with the following results:—

Number of trees per acre, 950.

Total volume in the round per acre, 3265 cubic ft.

Annual increment, about 60 cubic ft. per acre.

¹ Kent, Veitch's *Man. Conif.* 451, note (1900).

² In *Trans. Bot. Soc. Edin.* x. 353 (1870).

³ *Arb. Nat. des Barres*, 102, pl. 46 (1906).

The two best trees were, in 1908, 50 ft. high and 10 in. in diameter at five feet from the ground. The plantation had not been properly thinned at an early period.

The European spruce in the same district, at a higher elevation, about 1800 ft., averaged at forty-five years old 445 trees per acre, with an annual increment of 136 cubic ft. per acre; and the best trees were 60 ft. high by 12½ in. in diameter.

The red spruce had a redder and more scaly bark than the common spruce; and was more densely clothed with foliage, the improvement of the soil due to the decay of the fallen leaves being well marked. The trees bear cones about every two years; and I noticed several seedlings in the open ground adjoining the plantation. One of the trees had a sucker from its roots about 3 ft. high. (A. H.)

PICEA ALBA, WHITE SPRUCE

Picea alba,¹ Link, *Handb.* ii. 478 (1831), and in *Linnaea*, xv. 519 (1841); Kent, Veitch's *Man. Conif.* 427 (1900); Clinton-Baker, *Illust. Conif.* ii. 34 (1909).

Picea canadensis, Britton, Sterns, and Poggenburg, *Cat. Pl. N. York*, 71 (1888); Sargent, *Silva N. Amer.* xii. 37, t. 598 (1898), and *Trees N. Amer.* 42 (1905).

Picea laxa, Sargent, in *Garden and Forest*, ii. 496 (1888); Jack, in *Garden and Forest*, x. 63 (1897).

Abies canadensis, Miller, *Dict.* 8th ed. No. 4 (1768).

Abies alba, Michaux, *Fl. Bor. Amer.* ii. 207 (1803) (not Miller); Loudon, *Arb. et Frut. Brit.* iv. 2310 (1838).

Abies curvifolia, Salisbury, in *Trans. Linn. Soc.* viii. 315 (1807).

Abies laxa, Koch, *Dendrologie*, ii. 2. p. 243 (1873).

Pinus canadensis, Du Roi, *Obst. Bot.* 38 (1771) (not Linnæus).

Pinus laxa, Ehrhart, *Beiträge*, iii. 24 (1788).

Pinus alba, Solander, in Aiton, *Hort. Kew.* iii. 371 (1789); Lambert, *Genus Pinus*, i. 39, t. 26 (1803).

A tree, attaining in America 70 to 100 ft. in height and 6 to 8 ft. in girth. Bark ¼ to ½ in. thick, with thin greyish plate-like scales. Young branchlets slender, glabrous, glaucous; becoming greyish or pale brown in the second year. Buds, ¼ in. long, ovoid, rounded or obtuse at the apex; with glabrous scales, non-ciliate, rounded and bifid at the tip, and usually loosely imbricated. Leaves on lateral branches arranged as in the common spruce, usually with a disagreeable odour² when bruised, bluish,

¹ The oldest specific name (*canadensis* of Miller) for this species is not available, as it was previously used by Linnæus for the eastern hemlock, his *Pinus canadensis* being *Tsuga canadensis*. Moreover, Jack, in *Garden and Forest*, x. 63 (1897), gives some reasons for supposing that Miller indicated the red spruce by his name *Abies canadensis*; and on this account Jack proposes the name *Picea canadensis* for the red spruce, and *Picea laxa* for the white spruce. The latter name is based on Ehrhart's *Pinus laxa*, which is earlier than Solander's *Pinus alba*. Voss, in *Mitt. Deut. Dend. Ges.* 1907, p. 93, proposes *Picea glauca* for the white spruce, based on *Pinus glauca*, Moench, which is earlier than any name except Miller's, but was applied to the glaucous variety. In the midst of the confusion, in which the nomenclature of the American black, white, and red spruces is involved, it is most convenient to adopt for them the names *Picea nigra*, *Picea alba*, and *Picea rubra*, which were first used in combination by Link, and which have been in common use for a great number of years. Moreover, these names are unambiguous, as they have always been applied in each case to the same species.

² Hence the name cat or skunk spruce often given to the tree in America. Usually the odour is only perceived when the leaves are bruised, but in certain states of the air it can be detected at some distance from the tree. Cf. *Garden and Forest*, x. 63 (1897).

about ½ in. long, incurved, ending in a rounded or acute (not acuminate) cartilaginous tip; quadrangular in section, with three to four rows of stomata on each side.

Cones, deciduous in the autumn or winter of the first year after the escape of the seeds, sessile or shortly stalked; slender, cylindrical but tapering at both ends, about 2 in. long and ½ in. in diameter, green when growing, shining pale brown when ripe: scales few, loosely imbricated, thin and flexible, so that the cone can be easily crushed by the hand, orbicular or oval, ⅓ in. broad, rounded or truncate at the entire anterior margin: bract about ⅓ in. long, oblong with a slightly enlarged ovate denticulate lamina. Seed, ⅓ in. long, brown, partly embraced by the inflexed margins of the base of the narrow pale wing, which is broadest near the rounded denticulate apex; seed with wing, ⅔ in. long.

The three American species are often confused, though they have been clearly recognised by botanists in Europe since Lambert's time. In America the younger Michaux and Asa Gray united *P. rubra* with *P. nigra*; but all modern American botanists and foresters keep the three species distinct. The best account of their history is given by Dr. G. Lawson of Halifax, Nova Scotia, in *Proc. Canad. Institute*, 1887, pp. 169-179. Formerly the white spruce was considered to be a native of the Rocky Mountains, but the tree inhabiting Alberta, British Columbia, and Montana is now considered to be distinct, and has been named *P. albertiana*.

P. alba is readily distinguished by its bluish disagreeably smelling foliage and glabrous branchlets, and cannot be confused with *P. nigra* and *P. rubra*, which have pubescent branchlets and peculiar buds with long subulate scales. The cones of the white spruce are easily crushed by the hand on account of their thin flexible scales, and are very different in shape from those of the other two species, which have firm rigid scales.¹

VARIETIES

1. Var. *arctica*, Kurz, in *Bot. Jahrb.* xix. 425 (1895).

Abies arctica, Murray, in *Journ. Bot.* v. 253, t. 69 (1867).

Pinus alba, var. *arctica*, Parlatore, in De Candolle, *Prod.* xvi. 2, p. 414 (1868).

Towards the northern limit of its area the white spruce has thicker leaves and smaller cones, with more concave scales and bracts slightly different in shape. This form was first collected by Seemann in north-western Alaska. According to Sargent² the branchlets of the white spruce in the interior of Alaska are sometimes slightly pubescent, and in all probability this variety is a connecting link between *P. alba* and *P. albertiana*.

A few peculiar forms have arisen in cultivation:—

2. Var. *nana*, Loudon. A round compact bush, rarely exceeding 6 ft. in height.
3. Beissner mentions fastigiata, pendulous, and variegated forms, which we have not seen in England.

¹ Trelease, in *Bot. Gaz.* xxix. 196 (1900) describes remarkable burrs, almost globose in shape and covered with smooth bark, which are occasionally seen on the trunk and branches of the white spruce in the United States.

² *Silva N. Amer.* xii. 38, note (1898).

4. Var. *cærulea*, Carrière, *Conif.* 320 (1867).*Pinus glauca*, Moench, *Bäume Weiss.* 73 (1785).*Abies rubra cærulea*, Loudon, *Arb. et Frut. Brit.* iv. 2316 (1838).*Abies cærulea*, Forbes, *Pin. Woburn.* 99 (1839).*Picea cærulea*, Link, in *Linnaea*, xv. 522 (1841).*Pinus rubra violacea*, Endlicher, *Syn. Conif.* 114 (1847).*Picea canadensis glauca*, Sudworth, in *U.S. Forestry Bulletin*, No. 14, p. 37 (1897).

A small tree of dense pyramidal habit, with very glaucous leaves closely pressed against the branchlets. This variety, which according to Carrière frequently arises in the seed-bed, appears to have been known since 1785, and is unquestionably a form of *P. alba*, though it has been by various authorities ascribed to *P. rubra*.

(A. H.)

DISTRIBUTION

The white spruce is a native of eastern Canada and the northern part of the United States, extending southward to the Black Hills of Dakota, the northern parts of Minnesota, Wisconsin, and Michigan, New York, Vermont, northern New Hampshire, and the coast of Maine as far south as Casco Bay. It is recorded¹ for a few stations in Massachusetts, its most southerly limit.

Its westerly distribution in the Dominion of Canada is uncertain; but according to Dr. Lawson, the white spruce is essentially a maritime species, growing along the Atlantic and northern coasts of Canada, and extending by way of the St. Lawrence to the great lakes, as far as Lake Winnipeg. It is common in Newfoundland, Nova Scotia, and New Brunswick, and on the streams which flow from the north into the St. Lawrence, ranging westward through Ontario to the treeless plains of Manitoba, where it occupies sandhills and the dry slopes of river banks. In Labrador it is widely but not generally distributed, growing in the south in well-watered valleys and ascending rocky hills to elevations of 2000 ft. West of Hudson Bay it grows to a large size on river terraces to the borders of the barren lands; and its stems choke the mouths of every arctic American river, strewing the shores with driftwood and testifying to its abundance on their shifting banks.²

CULTIVATION

The white spruce was first described by Miller in 1731, and is said by Loudon to have been introduced into England by Bishop Compton in 1700.

Though the name is often found in nursery catalogues and it has no doubt been planted in many places, yet it is nowhere in England so far as we have seen of any special value, either as a timber or an ornamental tree. In some parts of Denmark, however, it has been largely planted as a shelter tree on poor sandy land, in alternate rows with *Pinus montana*, as it is found to grow on poorer soil and to bear salt sea

¹ Dame and Brooks, *Trees of New England*, 17 (1902).² E. T. Seaton, *Arctic Prairies*, 329 (1912), measured a tree near Fort McKay 118 ft. high. A log here, 84 ft. long, was 22 in. in diameter at the butt and 15 in. at the small end. At tree limit on the eastern shore of Artillery Lake, a tree, 8 ft. high and 1 ft. in diameter at the butt, showed 300 annual rings.

wind better than common spruce. From what I saw, however, during our visit to Denmark in 1908,¹ it is not likely to become a timber tree of any value here.

In a paper on the "Reclamation of Moors in Belgium,"² Mr. A. P. Grenfell says that it forms an excellent mixture with common spruce on poor soils, and in exposed situations in that country, and that it is more windfirm than common spruce.

The white spruce is extremely hardy, and will thrive in exposed situations on high hills, where the common spruce succumbs to the continued action of cold winds in spring. Annand³ gives an instance of its success on poor peaty soil at a high elevation in the north of Scotland, and recommends it for planting as a wind-break. He tells us that at Carragill in Cumberland, where it has been planted in perhaps the most exposed situation in England, it continues to grow as a low tree between 1600 and 2000 feet, where there is practically no soil, and above the zone in which the common spruce can exist. He considers it specially valuable on wet soils; and says that it has been planted for shelter to a considerable extent in the Moorfoot hills in Midlothian, and in hilly districts in Peeblesshire, Aberdeenshire, and Caithness. At Durris,⁴ however, *P. sitchensis* far surpasses it in growth in such conditions, and appears to be equally hardy. In the Hertogenwald in Belgium *P. alba* has been planted with some success in the wettest parts of the peat mosses at high altitudes.

At Weston Hall, Staffordshire, on good alluvial soil, a plantation was made of the common spruce in 1868, amongst which are scattered a few *P. alba*. The best of the white spruce was 45 ft. by 2 ft. 9 in. in 1909, while the European spruce averaged 60 ft. by 5 ft. 3 in.

The tallest white spruce in England is probably one at Woburn, which measured in 1909 72 ft. by 4 ft. 6 in. There are two fine trees at Powis Castle, the best of which measured 56 ft. by 5 ft. 3 in. in 1906. At Eastnor, a white spruce measures 46 ft. by 2 ft. 10 in.

In the Keillour pinetum, Perthshire, which was planted in 1832, the best *P. alba* measured 52 ft. by 5½ ft. in 1905. In this poor boggy soil, the West American conifers much surpass both *P. alba* and *P. nigra* in growth, the growth of *P. sitchensis* and *Abies grandis* being astonishing.⁵ Kent mentions a tree, 45 ft. high, growing on light loam at Dolphinton, Lanarkshire.

At Fota, a white spruce was 45 ft. by 5 ft. in 1907.

TIMBER OF THE BLACK, RED, AND WHITE SPRUCES

In the United States, only the red and white spruce yield merchantable timber, the black spruce never attaining large enough dimensions. In Canada the red spruce is never mentioned by foresters or lumbermen, and only the white and black spruces are said to produce lumber. According to Dr. Lawson, the black spruce is

¹ *Quarterly Journal of Forestry*, iii. 75 (1909).² In *Trans. Roy. Scot. Arb. Soc.* xvi. 473 (1901).³ Cf. Crozier's account in *Trans. Roy. Scot. Arb. Soc.* xxiii. 7-16, plate 1 (1910), and in our Vol. I. p. 95.⁴ Cf. our account of the pinetum at Keillour, in Vol. I. p. 96. Complete details of the original planting operations in 1832 at Keillour are given in *Proc. Hort. Soc.* iii. 297 (1863).⁵ *Ibid.* ii. 273 (1908).

famed amongst the Canadian lumbermen as a tree yielding sound, strong, and lasting timber; while red spruce produces softer wood, less durable "under exposure to the open air, as is known from experience; every year the red spruce poles have to be replaced more frequently than the black in fences."¹

Langelier² states that the black spruce is the prevailing coniferous tree in northern Quebec, where the forests are estimated to be capable of supplying 400,000,000 cords of pulp wood. White spruce is less abundant in this region, but attains a larger size, and is utilised for lumber, only the tops being converted into pulp wood. In the southern section of the Abitibi territory white spruce attains splendid dimensions over an area of 15,000,000 acres, and Mr. H. O'Sullivan has seen trees over 100 ft. in height and 20 in. in diameter. Dr. Bell is quoted as saying that "white spruce is perhaps the most valuable tree of the district. It grows to a great size everywhere along the rivers and lakes, where it often girths upwards of 6 ft. The timber is sound; as a rule the trunks run to a great height, and in every respect the white spruce ranks among the very best timber for the manufacture of first-class saw-logs."

J. M. Macoun, in *Forest Wealth of Canada*, says that the wood of the three species is not separated commercially, and that they are used for the same purposes. The black spruce is perhaps the best suited for masts or spars. Of the white spruce he says that the wood is tougher, stronger, and more elastic than that of pine, and is very largely used as lumber, and for railway ties, fence-posts, piles, and telegraph poles.

The wood of these Canadian spruces now supplies the greater part of the material used for pulp-making, which has recently become one of the great industries of Canada. According to a paper on *Pulp Wood in Canada*, by George Johnson, which was printed for the Minister of Agriculture at Ottawa in 1904, no less than 15,000,000 to 20,000,000 dollars are now invested in this manufacture; and as it is estimated that no less than 450,000,000 acres of land in Canada are covered more or less densely with spruce which reproduces itself very rapidly when cut, there is no risk of the supply failing. Great Britain and the United States are said to consume about 900,000 tons of pulp wood annually, the product of about 90,000 acres.

The black spruce is considered better than the white for this purpose and grows mostly on the hills and rocky ground, whilst white spruce loves valleys, where there is more soil.

To show the rapid increase in the value of these timber lands it is stated that in 1892 spruce limits were sold in the province of Quebec as low as eight dollars per square mile, whereas in 1899 similar limits realised 150 dollars per mile, and the price has risen higher lately.

English papermakers are said to have found out that Canadian spruce pulp makes a stronger and better newspaper than Scandinavian pulp; and the immense water-power of the Dominion makes both the transport of the logs and the manufacture cheaper than in most parts of Europe.

PICEA ALBERTIANA, ALBERTA WHITE SPRUCE

Picea albertiana, Stewardson Brown, in *Torrey*, vii. 126 (1907); Rehder, in *Mitt. Deut. Dend. Ges.*, 1907, p. 69; Britton and Shafer, *N. Amer. Trees*, 58 (1908).

Picea columbiana, Rydberg, in *Mem. New York Bot. Garden*, i. 11 (1900) (not Lemmon¹); M. E. Jones, in *Montana Botany Notes*, 10 (1910).

Picea alba, Mayr, *Fremdländ. Wald- u. Parkbäume*, 319 (in part), fig. 101 (1906) (not Link).

A tree, attaining in western North America 160 feet in height. Bark thin, greyish white, scaling off in small quadrangular plates, furrowed at the base of old trunks. Young branchlets greyish or light yellow; yellow or orange in the second year; glabrous or more usually with a minute pubescence on the pegs (from which the leaves arise), which is occasionally scattered over the rest of the surface of the pulvini. Buds about $\frac{1}{3}$ in. long, ovoid, slightly resinous, with scarious scales rounded and entire in margin; terminal buds girt at the base with acuminate ciliate keeled scales. Leaves bluish green, in an imperfect radial arrangement on the lateral branches, but more crowded on the upper side of the branchlets; $\frac{1}{2}$ to 1 in. long, soft or rigid, curved, ending in a short point, quadrangular in section, with three to five stomatic lines on each side.

Cones, 1 to 2 $\frac{1}{4}$ in. long, cylindrical, obtuse at the apex, sessile, about 1 in. wide when open, shining light brown when ripe: scales numerous, thin, and flexible, fan-shaped, wide, and rounded anteriorly, cuneate on the sides, flatter than those of *P. alba*; upper margin thin, undulate, or faintly denticulate; light brown and glabrous on the exposed part, minutely pubescent and reddish brown on the concealed part: bract $\frac{1}{5}$ in. long, with an oblong claw, slightly expanded into a denticulate lamina, which is either emarginate or rounded at the apex. Seed $\frac{1}{8}$ in. long, mottled dark brown; seed with wing $\frac{1}{2}$ in. long; wing contracted just above the seed, widest in the upper two-thirds, ending in an oblique denticulate apex.

This species is very variable in the amount of pubescence on the branchlets, which is occasionally absent both in specimens from Montana² and from Alberta. The cones are also variable in size, and in the faint denticulation of the margin of the scale. It is most closely allied to *P. alba*, of which it may be considered the Rocky Mountain form. In *P. alba* the branchlets are always perfectly glabrous, with less prominent pulvini; and the leaves are differently arranged in the two species. The buds of *P. alba* are non-resinous, with scales emarginate or two-lobed, and not entire as in *P. albertiana*. The cones of *P. alba* are less rigid, being easily crushed by the hand, and have very fragile scales, entire in margin, more concave internally from side to side, and more reddish brown in colour than those of *P. albertiana*. The seeds are similar in the two species, but those of *P. alba* have shorter wings.

¹ *P. columbiana*, Lemmon, is imperfectly described, and is referred by Sargent and by Britton to *P. engelmanni*. Lemmon's description may have partly included *P. albertiana*; but the latter name, being quite certain, must stand for the species now treated here. Cf. p. 1388.

² Three trees growing together in a clump at 3300 ft. altitude, near Belton in Montana, which I examined in 1906, were precisely alike in size, bark, and habit. One had perfectly glabrous branchlets, silvery leaves, and large cones. Another had very pubescent branchlets, green leaves, and small cones. The third was intermediate.

This species, the exact distribution of which has not yet been clearly defined, ranges from Wyoming¹ and western Montana northward to Alberta and British Columbia. It occurs in the Rocky Mountains at lower elevations than *P. Engelmanni*, extending from 3000 to 5000 ft. The type specimen was collected at Bankhead, Alberta, by Stewardson Brown; and I have received from Macoun specimens from the neighbourhood of Banff, in the same province. Rehder states that this spruce near Banff occasionally attains 160 ft. in height, and forms extensive forests, in one of which he took a fine photograph, which shows well the habit of the tree, and is reproduced by Mayr² in his article on the white spruce. *P. albertiana* is the white spruce referred to by Sargent³ as a native of "the Rocky Mountains of Alberta, British Columbia, and northern Montana, where it lines the banks of streams and lakes up to 5000 ft. elevation, attaining a large size, and sending up tall spire-like heads of dark foliage."

In Montana this spruce is not found on the east side of the continental divide, but is common in the Flathead⁴ region, where it forms a low tree in marshy situations; but on moist alluvial soil, in mixture with the Douglas fir, western larch, and *Thuja plicata*, it attains large dimensions. It usually occurs in small groups in these mixed forests, occupying the moister ground, and bearing considerable shade. The largest tree which I measured, growing near Nyack on the Northern Pacific railway, was 150 ft. by 10 ft. A tree 114 ft. by 4 ft. 9 in. showed, when cut down, 114 annual rings; another, 15 in. in diameter, showed 160 rings, the bark being only $\frac{1}{4}$ in. thick.

It is possible that the trees referred to *P. Engelmanni*, in Idaho, Washington, and Oregon, may wholly or in part belong to *P. albertiana*; and a further study of the spruces in western America is desirable, as the variability in *P. albertiana* points possibly to hybridisation with Engelmann's spruce.

This spruce is the finest species in North America, except *P. sitchensis*, and is worth a trial as an ornamental tree. It was introduced into England by Elwes, who received seeds from Mr. J. M. Macoun of Ottawa in 1906, which have produced plants, the largest of which in 1912 were about 18 in. high, and which have been distributed to several places in England and Scotland. According to Rehder, it was sent by Baron von Fürstenberg to Germany in 1907. (A. H.)

¹ Britton and Shafer, *N. Amer. Trees*, 58 (1908), give Wyoming as a habitat; but I have seen no specimens.

² *Fremdländ. Wald- u. Parkbäume*, fig. 101 (1906). This photograph is also reproduced in Möller's *Deut. Gärtn. Zeit.* 1905, p. 117.

³ *Silva N. Amer.* xii. 39 (1898).

⁴ The spruce described as *P. Engelmanni* by Whitford, in *Bot. Gaz.* xxxix. 196 (1905).

PICEA ENGELMANNI, ENGELMANN'S SPRUCE

Picea Engelmanni, Engelmann, in *Trans. St. Louis Acad.* ii. 212 (1863), and in *Gard. Chron.* 1863, p. 1035; Sargent, *Silva N. Amer.* xii. 43, t. 599 (1898), and *Trees N. Amer.* 43 (1905); Kent, Veitch's *Man. Conif.* 431 (1900); Britton, *N. Amer. Trees*, 59 (1908); Clinton-Baker, *Illust. Conif.* ii. 37 (1909).

Picea columbiana, Lemmon, in *Garden and Forest*, x. 183 (1897).

Picea pseudopungens, Dieck,¹ *Verkaufs-Verzeichniss Zöschchen*, 28 (1904).

Abies Engelmanni, Parry, in *Trans. St. Louis Acad.* ii. 122 (1863).

Abies commutata, Murray, in *Gard. Chron.* iii. 106 (1875).

Pinus commutata, Parlatore, in De Candolle, *Prod.* xvi. 2, p. 417 (1868).

A tree with disagreeably smelling foliage, attaining in America 150 ft. in height and 15 ft. in girth, though usually considerably smaller. Bark reddish, exuding resin, with thin loose scales. Young branchlets greyish yellow, with a sparse minute erect glandular pubescence. Buds conical, about $\frac{1}{2}$ in. long, obtuse at the apex; the terminal bud closely surrounded at the base by the uppermost leaves; scales scarious, rounded, without resin.

Leaves, arranged on lateral branches as in *P. excelsa*, $\frac{3}{8}$ to 1 in. long, soft and flexible, tapering towards the apex, which ends in a sharp point; bluish green in colour, with a cat-like odour when bruised; quadrangular in section, with four to five stomatic lines on each side.

Cones horizontal at first, ultimately pendulous, sessile, green tinged with scarlet when growing, light brown when ripe, cylindrical but narrowed at both ends; very variable in size, $1\frac{1}{2}$ to 3 in. long: scales numerous, thin and flexible, rhombic or ovate, minutely pubescent in the lower half, longer than broad, $\frac{2}{3}$ in. wide, with their upper margin truncate or rounded and lacerate: bract $\frac{1}{4}$ in. long, with an oblong claw, and an oval expanded denticulate lamina. Seed about $\frac{1}{10}$ in. long, dark brown; seed with wing $\frac{3}{10}$ in. long; wing broadest near the rounded oblique faintly denticulate apex.

This species resembles *P. alba* in the peculiar odour of the leaves, but is readily distinguishable by the very sparse minute pubescence on the branchlets.

VARIETIES

1. Forms with glaucous or silvery foliage appear in the seed-bed, and are known as var. *glauc*a and var. *argentea*. The tree, however, usually cultivated under the name *P. Engelmanni glauca* is a form of *P. pungens*, agreeing with the latter species in having glabrous branchlets and peculiar buds with reflexed scales.

2. Var. *microphylla*, Hesse. A dwarf form with short leaves, mentioned by Beissner, *Nadelholzkunde*, 345 (1891).

3. Var. *Fendleri*, Henry (var. *nova*).

At Kew one of the tallest spruce trees has long been labelled *P. Engelmanni*, but differs remarkably from that species in habit. Young branchlets pendulous,

¹ Dieck, *Neuh. Offert. Zöschchen*, 1892, p. 38, mentions *Abies Engelmanni*, var. *pseudopungens*, as a supposed new variety, raised from seed collected by Purpus north of Lytton in British Columbia.

brownish yellow, densely covered with minute erect glandular pubescence, retained for several years. Leaves disagreeable in odour when bruised, radially spreading from the branches equally on all sides, long and slender, about $1\frac{1}{8}$ in. long, bluish in tint, sharp pointed, quadrangular in section, with four stomatic lines on each of the inner two sides, and two lines on each of the outer two sides. This tree has never borne either flowers or cones.

In the pendulous branches and the radial arrangement of the leaves it resembles *P. Smithiana*; but differs entirely from this species in branchlets and buds. The tree at Kew, the history of which cannot be ascertained, now measures 40 ft. high by 3 ft. in girth.

It is probably identical with a specimen, preserved in the Kew Herbarium, which was gathered by Fendler in 1847 in New Mexico. This specimen, which bears no cones, has similar branchlets and buds, and leaves similar in length and stomatic lines, but somewhat stouter. Engelmann has marked this specimen in pencil: "vigorous long-leaved form, young tree"; but in all probability it is a distinct species. Until the tree at Kew bears cones, the identification must remain doubtful. The seed was perhaps sent home by Roetzl, who collected in this region.

DISTRIBUTION

Engelmann's spruce is an alpine tree, widely distributed in western North America, extending in the Rocky Mountains from Alberta¹ to southern New Mexico and Arizona, and westwards to the Selkirk and Cascade Mountains of British Columbia, Washington, and Oregon. Towards the south it occurs at 8000 to 11,500 feet elevation, while farther north it descends to 5000 feet. It attains its largest size and forms a great part of the forests on the high mountains of southern Alberta, and is a common tree in Montana and Idaho. Westward, on the Cascades and Blue Mountains of Washington and Oregon, it is smaller in size, and is usually scattered amongst other trees; and on account of its slightly different habit, was distinguished by Lemmon as *P. columbiana*²; but both Sargent and Britton are unable to separate this even as a distinct variety. It is common on the Yellowstone plateau in Wyoming, and forms extensive forests in Colorado, Utah, eastern Nevada, and the San Francisco peaks of northern Arizona, reaching its most southerly point on the summit of the Mogollon Mountains in New Mexico.

(A. H.)

This tree is a conspicuous feature in the alpine forest of Alberta, where I often camped under its shelter in 1895. It grows from the foothills of the Rocky Mountains up to nearly timber line, which is here about 7000 feet. It seems to be a very slow-growing tree, for Wilcox³ counted 400 rings on an old stump near Lake Louise, which was less than 3 ft. in diameter.

¹ A good photograph of a forest of this tree at Laggan is reproduced by Mayr, *Fremdländ. Wald- u. Parkbäume*, 325, fig. 103 (1906).

² The tree in Montana ascribed to this species by M. E. Jones, *Montana Botany Notes*, 10 (1910), is *P. albertiana*.

³ *The Rockies of Canada*, 62 (1900).

Mr. F. R. S. Balfour, who saw it in the same region, writes to me as follows:—"This alpine spruce covers immense tracts in the Rockies at high altitudes. The finest I have seen are near Lake Louise, where it grows to a height of 140 ft., mixed with *Abies lasiocarpa*. Indeed the two are singularly alike and difficult to distinguish, except for the red drooping cones of the *Picea*, and the small black erect ones of the *Abies*. The barks of these trees are very similar, of a grayish red broken into large loose scales. The leaves when crushed have a rather unpleasant smell. Wherever I have seen this tree, it has an arrowy appearance from the shortness of its branches. This is doubtless due to the weight of frozen snow which covers them in winter, and prevents lateral growth. The tree often fruits profusely when quite young and small, the leader then becoming bent with the weight of cones surrounding it. These are about two inches long and of a warm crimson when fully grown. The branches are produced in very regular whorls; and when young the bark is smooth and silvery before it becomes scaly."

This spruce was first distinguished by Dr. C. C. Parry, who found it in 1862 on Pike's Peak in Colorado, and sent seeds in the following year to the Botanic Garden of Harvard University, where the tree was first cultivated. It is said to have been introduced¹ into England in 1864; but the tree seems quite uncommon in this country. We have found no trees which are probably so old as this, except one at Highnam, which was bearing cones in 1909 and measured 38 ft. by 3 ft. 2 in. The bark of this separates into regular small scales. A thriving tree at Hatfield, Herts, which was planted in 1893, measured 21 ft. by 1 ft. in 1908. There are smaller trees in the same county at Bayfordbury, High Leigh, and Brickendon Grange.

(H. J. E.)

PICEA PUNGENS, COLORADO SPRUCE

Picea pungens, Engelmann, in *Gard. Chron.* xi. 334 (1879) and xvii. 145 (1882); Masters, in *Gard. Chron.* xx. 725, fig. 130 (1883), and x. 547, figs. 73, 74 (1891); Kent, Veitch's *Man. Conif.* 448 (1900); Britton and Shafer, *N. Amer. Trees*, 60 (1908); Clinton-Baker, *Illust. Conif.* ii. 46 (1909).

Picea Parryana, Sargent, *Silva N. Amer.* xii. 47, t. 600 (1898), and *Trees N. Amer.* 44 (1905).

Picea Menziesii, Engelmann, in *Trans. St. Louis Acad.* ii. 214 (1863) (not Carrière); Sargent, in *Bot. Gaz.* xlv. 227 (1907).

Abies Menziesii, Engelmann, in *Amer. Journ. Science*, xxxiv. 330 (1862) (not Lindley), and in *Gard. Chron.* vii. 790 (1877); André, in *Gard. Chron.* vii. 562 (1877).

Abies Menziesii Parryana, André, in *Illust. Hort.* xxiii. 198 (1876), and xxiv. 53, 119 (1877).

A tree, attaining in America 150 ft. in height and 9 ft. in girth, usually considerably smaller. Bark reddish grey, fissuring on young stems into small oblong plates, on old trunks deeply divided into broad rounded scaly ridges. Young branchlets, stout, rigid, glaucous at first, gradually becoming orange brown. Buds $\frac{1}{4}$ to $\frac{5}{8}$ in. long, ovoid, rounded at the apex, with the tips of the upper scales rounded

¹ Veitch, *Man. Conif.* 69 (1881).

and scarious and usually reflexed; terminal buds girt with a ring of keeled acuminate scales. Leaves on lateral branches in an imperfect radial arrangement, more crowded on the upper than on the lower side of the branchlet, all spreading forwards as well as outwards; $\frac{3}{4}$ to $1\frac{1}{4}$ in. long, stout, rigid, incurved, tapering towards the hard sharp-pointed apex; varying greatly in colour on different trees, bright green, bluish or silvery white; quadrangular in section, with four to seven stomatic lines on each side.

Cones sessile, usually persistent till the second winter, about 2 to 4 in. long, 1 to $1\frac{1}{2}$ in. in diameter, cylindrical but slightly narrowed at both ends; green tinged with red when growing, pale shining brown when mature: scales numerous, like those of *P. Engelmanni*, thin, tough and flexible, rhomboidal, narrowing towards the truncate denticulate apex, longer than broad, about $\frac{1}{2}$ in. wide: bract about $\frac{1}{8}$ in. long, with a denticulate ovate lamina. Seed blackish, $\frac{1}{8}$ in. long; seed with wing $\frac{2}{3}$ in. long; wing broadest near the truncate lacerate apex.

This species is readily distinguished by its radially arranged, rigid, sharp-pointed leaves, by its glabrous branchlets, and by the loose reflexed tips of the bud-scales.

VARIETIES

Seedlings differ very much in the colour of the foliage, which varies from almost a pure green to a silvery white. Trees with very blue glaucous foliage are distinguished as var. *glauca*, Regel,¹ and are much more ornamental than the green form, var. *viridis*, Regel,¹ which is less common in cultivation. Var. *argentea*, Waterer,² is a form with silvery foliage, which has longer and more slender needles than usual; and on this account it is often erroneously known in gardens as *Picea Engelmanni glauca*,³ from which species it is readily distinguished by its glabrous branchlets and peculiar buds with reflexed scales.

Var. *Kosteriana*⁴ (var. *glauca pendula*⁵). This is a form with very pendulous branches and fine bluish foliage, which originated in Messrs. Koster's nursery at Boskoop in Holland.

Another variety, said to be vigorous in growth, and characterised by shining leaves, silvery white in colour and broader and longer than in the type, originated in the nursery of Herr Weise at Kamenz in Saxony, who sent it out as var. *König Albert von Sachsen*.⁶

Beissner describes two prostrate forms, var. *prostrata*⁷ and var. *tabuliformis*.⁸ According to Rehder,⁹ a dwarf compact form originated about 1890 in the Arnold Arboretum, U.S.A.

DISTRIBUTION AND CULTIVATION

P. pungens is very restricted in its area of distribution, and is nowhere abundant, growing usually as isolated trees or in small groves on the banks and terraces of streams at 6500 to 10,000 ft. elevation. It is met with in Colorado, eastern Utah, New Mexico,¹ and in Wyoming, extending in the latter state as far north as the Wind River mountains.

This species was discovered² in 1862 on Pike's Peak in Colorado by Dr. C. C. Parry, who sent seeds in the following year to the Botanic Garden of Harvard University. One of the earliest plants³ raised had attained in 1883 16 ft. in height in Prof. Sargent's garden at Brookline, Massachusetts. Waterer⁴ in 1877 took cuttings from this tree, which were propagated in his nursery at Knap Hill; and, doubtless, from these are derived most of the older specimens growing in England. Seeds⁵ were again collected in Colorado by Roehl, from which some of the trees on the Continent may have originated.

It has been largely planted on account of its beautiful foliage; but has nowhere, so far as we know, attained large dimensions, and seems only suitable as an ornament in gardens. It has lately been attacked by a fungus.⁶

There are good specimens, about 30 ft. high, of both the green and glaucous varieties at Highnam, which were bearing cones in March 1910. A glaucous tree at Aldenham also bore cones in 1909. Mr. A. B. Jackson in 1911 reported two good trees, 35 and 33 ft. high, at Yattendon Court, Berks.

According to Schwappach,⁶ this tree may prove valuable for planting in northern Germany, where it not only supports the cold of winter without injury, but is hardier⁷ against late frosts than any other conifer. It grows well on moist soils, and thrives even on wet soils, which are unsuitable for *P. excelsa* or even for *P. sitchensis*; and on account of the sharp-pointed needles, it is not attacked by deer or squirrels. It has been tried at nineteen stations, the total area of the experimental plots being fifteen acres. It grows slowly at first, averaging in the fifth year 12 to 20 in. high, and in the tenth year $2\frac{1}{2}$ ft. to 4 ft. 8 in.

According to Sargent, it has been much planted in the United States as an ornamental tree, on account of its handsome pyramidal habit; but trees with bluish foliage lose in a few years much of their colour, and the older trees, 30 to 40 ft. in height, are losing their lower branches, so that their pyramidal habit is spoiled.

(A. H.)

¹ Britton and Shafer, *N. Amer. Trees*, 60 (1908), give New Mexico as a habitat for this species; but I have seen no specimens.

² According to Sargent in *Gard. Monthly*, quoted in *Woods and Forests*, 1885, p. 53, trees of this species were transplanted from Colorado to Iowa in 1860, and proved very hardy.

³ *Gard. Chron.* xx. 725, fig. 130 (1883).

⁴ *Gard. Chron.* vii. 48 and 562 (1877).

⁵ Borthwick, in *Trans. Bot. Soc. Edin.* xxiii. 232 (1906), and *Notes R. Bot. Gard. Edin.* 1909, p. 260, plate 50, states that this fungus, which he names *Cucurbitaria piceae*, attacks the buds, and produces large black conical swellings, in which numerous fructifications of the fungus occur. The bud is either immediately destroyed, or it may produce a twisted cankered shoot which frequently dies off at an early period.

⁶ *Anbauversuche mit Fremdländ. Holzarten*, 49 (1901).

⁷ This is also the case in my experimental ground at Colesborne, where late frosts have severely injured all the other spruces.—H. J. E.

PICEA SPINULOSA, SIKKIM SPRUCE

- Picea spinulosa*, Henry, in *Gard. Chron.* xxxix. 219 (1906); Beissner, in *Mitt. Deut. Dend. Ges.* 1906, p. 83; Clinton-Baker, *Illust. Conif.* ii. 50 (1909).
Picea morindoides, Rehder, in Sargent, *Trees and Shrubs*, i. 95, t. 48 (1903); Henry, in *Gard. Chron.* xxxix. 132, 219 (1906), and in *Trees of Great Britain*, i. 77 (1906); Masters, in *Gard. Chron.* xxxix. 218, fig. 84, and 274, fig. 113 (1906), and xli. 388 (1907); Brandis, *Indian Trees*, 720, 721 (1906); Stapf, in *Bot. Mag.* t. 8169 (1907).
Picea Alcockiana, Carrière, var. *morindoides*, Mottet, *Conif. et Taxac.* 273 (1902).
Abies spinulosa, Griffith, *Journals*, 259 (1847), and *Itin. Notes*, 145 (1848).
Abies Morinda, Lindley, in *Gard. Chron.* 1855, p. 334 (not *Picea Morinda*, Link).
Abies Smithiana, Hooker, *Himalayan Journals*, ii. 32 (1854) (not Lindley).
Pinus spinulosa, Griffith, *Icon. Pl. Asiat.* t. 363 (1854).

A tree, attaining in the eastern Himalayas over 200 ft. in height. Bark rough and scaling off in small quadrangular plates. Young branchlets slender, glabrous, yellowish grey. Buds, about $\frac{1}{4}$ in. long, ovoid, obtuse at the apex, brown, scarcely resinous, with glabrous obtuse scales. Leaves, in an imperfect radial arrangement, covering in closely imbricated ranks the upper side of the branchlets, those on the lateral sides directed outwards and forwards, those on the under side pointing downwards and forwards; $\frac{3}{4}$ to $1\frac{1}{4}$ in. long, $\frac{1}{20}$ in. broad, slender, acute at the apex, which is tipped with a sharp point; flattened, but keeled on both surfaces, so that the section is rhomboid-elliptic; ventral surface green without stomatic lines and directed towards the light; dorsal surface with two stomatic bands, each of 4 to 6 lines; resin canals, two (occasionally absent), dorsal, near the edges and close to the hypoderm.

Staminate flowers pink, $\frac{3}{4}$ in. long; connective with an orbicular denticulate appendix. Cones, about $2\frac{1}{2}$ in. to 3 in. long on cultivated trees, up to 4 in. long on wild trees, 1 to $1\frac{1}{2}$ in. in diameter, cylindrical, obtuse at the apex, green with a purple border to the scales when growing, shining brown when mature: scales thin and flexible, suborbicular with a cuneate base, about $\frac{1}{2}$ to $\frac{5}{8}$ in. wide, bevelled in the upper margin, which is rounded,¹ entire, undulate, or slightly denticulate: bract ovate, acute, $\frac{1}{8}$ in. long. Seed, $\frac{1}{8}$ in. long, greyish brown; seed with wing $\frac{1}{2}$ in. long; wing broadest above the middle, rounded and denticulate at the apex.

This species is distinguishable from the other flat-leaved spruces with glabrous branchlets,—by the leaves somewhat radially arranged, distinctly keeled on both surfaces, slender, and ending in a sharp point. The leaves of *P. sitchensis*, which are similar in appearance, are arranged on the lateral branches as in the common spruce.

This species appears to be the only spruce occurring in the eastern Himalayas, where it has been found in Sikkim and Bhutan, at 8000 to 10,000 ft. altitude. There are no specimens of *P. Smithiana* from this region in the Calcutta and Kew herbaria.²

¹ In some wild specimens the scales are truncate in the upper margin.

² The specimens in the Calcutta Herbarium, which were sent on loan to Kew in 1910, comprise the following:—

“Sikkim, chief forest tree in Rinchingung; King, 1875.”

“Sikkim, Lachen; King's collector in 1885.”

“Sikkim, Lachung; Gammie, 1892.” Referred to as *P. Morinda* in *Rec. Bot. Survey India*, i. No. ii. pp. 11, 19.

“Chumbi; Gamble, 1880.”

“Chumbi; King's collector, 1884.”

There are no specimens from Bhutan, either in the Kew or Calcutta herbarium.

It was discovered by Griffith, who found it growing on the slopes of the Rodoola Pass and in the Tung-chiew valley in northern Bhutan (about $91\frac{1}{2}^{\circ}$ long. and almost 150 miles east of the Sikkim frontier). He described it as a tree usually of moderate size, but occasionally attaining 80 ft. in height, and growing in groups between 8500 and 10,000 ft. elevation. It resembled at a distance a larch in habit, with the lower branches deflexed and the upper branches spreading. He named it *Abies spinulosa*, and there is no doubt possible as to its identity. He refers to the pulvini from which the leaves arise, showing that it was a spruce and not a silver fir. His statement¹ that “the lower surface of the leaf is glaucous, but that probably this was the true upper surface turned downwards” is characteristic of the section *Omorica*, to which *P. spinulosa* belongs.

Sir Joseph Hooker found this spruce again in 1849 in the Lachen valley, at 9000 ft. altitude, in Sikkim; and Elwes saw it in the same place on 1st October 1870; but neither Hooker nor Elwes noticed it elsewhere in Sikkim. Hooker identified it with Griffith's *Abies spinulosa*; but, unfortunately, afterwards combined it with *Picea Smithiana*.²

It was again found at 9000 to 10,000 ft. altitude, in 1887, in the drier climate of the Chumbi valley (on the north-eastern frontier of Sikkim) by a native in the employment of the late Sir J. Ware Edgar, then Deputy Commissioner of Darjeeling. It has lately been rediscovered in this locality by Mr. E. H. C. Walsh, who accompanied the military expedition to Lhasa. There are also specimens in the Kew Herbarium collected at Yatung ($27^{\circ} 51' N. lat., 88^{\circ} 35' E. long.$) by Mr. H. E. Hobson.

Sir George King, who considered the Chumbi valley specimens to be a new species, which, however, he left undescribed, sent seeds in 1877 or 1878 to various botanical establishments in Europe; and a tree probably raised from this seed is now growing in the arboretum of M. Allard, at Angers in France. It was found here by Mr. Rehder, who described it as a new species of unknown origin, under the name *P. morindoides*. It bore cones which I gathered in 1906, and was then about 20 ft. high. M. Allard obtained it about 1891 from Van Houtte.

(A. H.)

Though I saw this tree in the Lachen valley of Sikkim during my first journey to the Tibetan frontier in 1870, I did not take special notice of it at the time, and certainly saw no such wonderful trees as are described by Mr. J. Claude White in his recently published book.³ These grow in the Sebu valley, a tributary of the Lachung, and must be among the tallest trees in India. Mr. White says: “One fallen giant, a spruce that I measured, was 220 ft. from the roots to where it had broken off short, and there it measured 6 ft. in girth. What had become of the top I do not know, but it was a magnificent specimen.”

¹ Griffith's MS. description at Kew, which is mutilated in the printed *Itin. Notes*, reads: “Ramulis fere omnibus deflexis, verrucis e quibus folia oriuntur exasperatis; folia undique patentia, linearea, mucrone spinulosa terminale, pungentia; pagina inferior glauca, superior an resupinata. Conis terminalibus, pendentibus, oblongis, fere cylindraceis, castaneo brunneis; squamis latiformis, obtusissimis, laevibus.”

² *Flora Brit. India*, v. 653 (1888) under *P. Morinda*. Hooker gives on a drawing at Kew the height of the tree as 80 ft., and the locality, Lachen, 8000 to 10,000 ft. altitude.

³ *Sikkim and Bhutan*, 79 (1909).

To confirm this, I may say that I have since heard from Mr. A. D. Hickley, who visited and re-measured the same tree. He informs me that it grew at a place called Chu-par-rab-dong on the left bank of the river just opposite Yakchi, at an elevation of about 10,000 ft. Five lengths of the fallen stem were missing, having been probably used by the natives; but without counting these he made the length 207 ft., and the girth as follows:—at the base, 12 ft. 7 in.; at 50 ft., 13 ft.; at 100 ft., 12 ft.; at 139 ft. (the place where the tree was first broken in its fall), 9 ft. 4½ in. The thinnest piece, without the bark, was 5 ft. 2 in. in girth. In the same valley not far away Mr. Hickley measured another spruce, also with the top broken, 197 ft. long; and there were many like it still standing. A silver fir (*Abies Webbiana*) in this valley girthed 15½ ft. at four feet from the ground; and a larch (*Larix Griffithii*) growing between two spruces, of which he sends me a photograph, was well over 125 ft., and very much taller than any previously recorded. The photograph, unfortunately, is not good enough for reproduction in this work, and I have vainly endeavoured to obtain a better one.

This species was first detected by Henry in cultivation in this country at Castlewellan, where there are three or four trees, which were raised by the late Earl Annesley from seed sent by the Calcutta Botanic Garden in 1890. The largest tree¹ was 22 ft. high and 18 in. in girth in 1906, and produced cones for the first time in 1907. It is a handsome tree (Plate 347), remarkably distinct in appearance, and perfectly hardy. Specimens have been sent from Castlewellan to the Botanic Gardens at Kew, Glasnevin, and Cambridge.

There are three trees at Leonardslee, Horsham, which produced cones in 1906 and 1907. Sir Edmund G. Loder informs me that these were planted by a former owner, and that their origin is unknown. The largest in 1910 measured 31 ft. 9 in. by 2 ft. 5 in. From the seed of these trees seedlings have been raised each year since 1908. Mr. H. Clinton-Baker found a tree about 25 ft. high at Menabilly, in August 1908, which was bearing cones. Seedlings were raised from their seed at Bayfordbury. In Mr. J. M. Robb's garden at Chiltley Place, Liphook, Hants, there is a tree with two stems about 26 ft. high, which was bearing young and old cones in June 1912. This is supposed to have been planted about twenty-five years ago; but has been crowded by other trees. A smaller specimen with a single stem, about twenty years old, is more thriving. I found another tree at Melbury, about 15 ft. high, which was bearing cones in September 1909. It is said to have been planted about ten years ago. (H. J. E.)

¹ Figured in *Gard. Chron.* xxxix. 274, fig. 113 (1906).

JUNIPERUS

Juniperus, Linnæus, *Gen. Pl.* 311 (1737); Endlicher, *Syn. Conif.* 7 (1847); Parlato, in De Candolle, *Prod.* xvi. 2, p. 475 (1868); Bentham et Hooker, *Gen. Pl.* iii. 427 (1880); Masters, in *Journ. Linn. Soc. (Bot.)* xxx. 12 (1893); Hickel, in *Bull. Soc. Dend. France*, 1911, p. 31. *Sabina*, Haller, in Ruppert, *Fl. Jen.* 336 (1745); Garcke, *Fl. Deutschl.* 387 (1849); Antoine, *Cup. Gatt.* 35 (1857).
Thuicarpus,¹ Trautvetter, *Pl. Imag. Flor. Ross.* 11, t. 6 (1844).
Arceuthos, Antoine and Kotschy, in *Oestr. Bot. Wochenbl.* 1854, p. 249.

EVERGREEN shrubs or trees, belonging to the division Cupressineæ of the order Coniferae. Bark usually thin, and scaling in longitudinal strips. Leaves on young plants always spreading and acicular; on adult plants acicular, or appressed and scale-like, different in the sections of the genus, where they are described.

Flowers monœcious or diœcious. Staminate flowers composed of numerous stamens on a central axis, with ovate or peltate scale-like connectives, each bearing two to six globose pollen-sacs. Pistillate flowers, surrounded at the base by minute scale-like bracts, which persist unchanged under the fruit; composed of three to eight opposite or ternate pointed scales, bearing either at their base or alternate with them one to two ovules. Fruit a succulent berry-like indehiscent strobile, composed of three to eight fleshy scales united together, covered by a membranous epidermis; ripening in the first, second, or rarely in the third year. Seeds, variable in number (one to twelve) and in shape; usually free, but in one species coalesced. Cotyledons two, or four to six.

The genus comprises about thirty-five species distributed over the northern hemisphere from the Arctic Circle to Mexico and the West Indies, Azores and Canary Islands, Northern Africa, Abyssinia, and the mountains of East Tropical Africa,² Himalayas, China, and Formosa.

The genus is divided into three sections:—

I. Leaves always acicular, spreading in whorls of threes, jointed at the base. Buds distinct, and with scale-like leaves. Flowers axillary, diœcious.

§ I. OXYCEDRUS, Endlicher, *Syn. Conif.* 9 (1847).

Leaves always spreading, never appressed, linear, rigid, usually sharp-pointed, convex and green beneath, whitened above with one or two stomatic bands, entire in margin, without glands, not decurrent on the branchlets, which are glabrous and triangular in section.

Flowers solitary in the axils of the leaves. Staminate flowers, surrounded at

¹ Founded on a cultivated specimen of *J. communis*, L., var. *oblonga*, with abnormal fruit.

² Here extending south of the equator into the southern hemisphere.

the base by a few scales; stamens in ternate whorls, with oval connectives. Pistillate branchlets, composed of five to eleven ternate whorls of scales, with usually only the apical whorl fertile, each of its scales alternating with one of the three ovules, the tips of which protrude at the apex of the branchlet. Fruit, composed of three or six scales, marked at the apex by three radiating lines or furrows. Seeds, normally three, free and radially disposed in the centre of the berry, with depressions for large resin-glands.

A. *Leaves with one white stomatic band above.*

1. *Juniperus communis*, Linnæus. Europe, North Africa, Extratropical Asia, Canada, and the United States. See p. 1400.

Leaves, $\frac{2}{5}$ to $\frac{3}{5}$ in. long, slightly concave above, no trace of a green midrib being present except in rare cases near the base. In var. *nana*, leaves shorter, $\frac{1}{6}$ to $\frac{1}{3}$ in. long.

2. *Juniperus rigida*, Siebold and Zuccarini. Japan, Korea, Manchuria. See p. 1408.

Leaves $\frac{1}{2}$ to $\frac{3}{4}$ in. long, very slender, deeply concave above with the margins inflexed, forming a narrow median groove.

B. *Leaves with two white stomatic bands above.*

* *Shrubs, with leaves spreading horizontally outwards; branchlets usually not pendulous.*

3. *Juniperus Oxycedrus*, Linnæus. Mediterranean Region, Caucasus, Persia, Madeira. See p. 1409.

Leaves $\frac{1}{2}$ to $\frac{3}{4}$ in. long, gradually tapering from the middle to the sharp-pointed acuminate apex; upper surface with a conspicuous midrib, about half the width of the white bands, which are equal in width to the marginal green bands.

4. *Juniperus macrocarpa*, Sibthorp and Smith. Mediterranean Region. See p. 1412.

Leaves $\frac{3}{4}$ to 1 in. long, tapering from the base to the sharp-pointed acuminate apex; upper surface with a conspicuous midrib, less than half the width of the white bands, which are broader than the marginal green bands.

5. *Juniperus brevifolia*, Antoine. Azores. See p. 1413.

Leaves, oval-linear, very short, $\frac{1}{4}$ to $\frac{1}{3}$ in. long, with a rounded or acute and not acuminate apex; upper surface with a conspicuous midrib, and white bands broader than the green bands.

** *Trees, with leaves directed forwards towards the apices of the pendulous branchlets.*

6. *Juniperus Cedrus*, Webb and Berthelot. Canary Islands. See p. 1414.

Leaves, $\frac{1}{2}$ to $\frac{3}{4}$ in. long, with a conspicuous midrib above, about half the width of the white bands, which are equal in width to the marginal green bands.

7. *Juniperus formosana*, Hayata. China, Formosa. See p. 1415.

Leaves, $\frac{1}{2}$ to $\frac{3}{4}$ in. long; upper surface with a midrib much narrower than the white bands, which are broader than the marginal green bands.

§ 2. *CARYOCEDRUS*, Endlicher, *Syn. Conif.* 8 (147).

Leaves as in § *Oxycedrus*, but decurrent on the branchlets, which show between the whorls three raised pulvini, separated by grooves.

Staminate flowers, three to six in a head, on a scaly stalk arising in the axil of a leaf; stamens nine to twelve in each flower. Fruit, much larger than in the other sections, composed of six or nine ternate scales. Seeds consolidated into a thick globose three-celled bony mass. This section includes only one species.

8. *Juniperus drupacea*, Labillardière. Greece, Asia Minor, Syria. See p. 1417.

Leaves $\frac{1}{2}$ to $\frac{7}{8}$ in. long, widely spreading, very rigid, sharp-pointed; upper surface with a broad green midrib, deeply furrowed near the base, and two white bands, which are much broader than the marginal green bands.

11. Leaves (a) all scale-like and appressed, or (b) all acicular, or (c) often mixed; never jointed at the base, always adnate to the branchlet. No distinct leaf-buds. Flowers monœcious or diœcious, terminal on short axillary branchlets.

§ 3. *SABINA*, Spach, in *Ann. Sci. Nat.* xvi. 291 (1841).

Branchlets in most species like those of a *Cupressus*, terete or tetragonal in section, densely clothed with closely appressed imbricated scale-like leaves, which are usually in four ranks in decussately opposite pairs, or rarely ternate in six ranks, oval or triangular, adnate in the basal half, more or less free at the apex, glandular or marked with a depression on the back, entire or denticulate in margin.

In young plants of all the species, on occasional branches of adult trees of most species, and on all the branches of two species, acicular foliage occurs:—leaves linear-lanceolate, sharp-pointed, nearly appressed or more or less spreading, in whorls of threes or in opposite pairs, whitened on the ventral surface.

Staminate flowers with usually the stamens in opposite pairs, rarely ternate. Pistillate flowers, with usually opposite or rarely ternate scales, each of which bears one or two ovules. Fruit, with usually opposite or rarely ternate scales. Seeds, one to twelve, generally ovoid, with a broad base marked by a large hilum.

A. *Leaves on adult plants always acicular.*

9. *Juniperus recurva*, Buchanan-Hamilton. Himalayas. See p. 1419.

A tree with curved and pendulous branchlets. Leaves in threes, loosely appressed, $\frac{1}{8}$ to $\frac{1}{4}$ in. long, sharp-pointed, greyish green on the dorsal surface, which is channelled in the middle line near the base.

10. *Juniperus squamata*, Buchanan-Hamilton. Afghanistan, Himalayas, China, Japan, Formosa. See p. 1420.

A prostrate shrub. Leaves in threes, appressed or spreading, broader and shorter than in *J. recurva*, green on the dorsal surface, which is channelled from the base to near the apex.

J. procumbens, Siebold, is similar, but has larger leaves, which like the branchlets are glaucous in tint. See p. 1422.

B. Leaves on adult plants scale-like, except on occasional branches.

* Leaves denticulate¹ in margin.

(a) Acicular leaves usually in whorls of threes.

11. *Juniperus Wallichiana*, J. D. Hooker. Himalayas. See p. 1423.

Ultimate branchlets, tetragonal, $\frac{1}{25}$ in. in diameter; leaves closely appressed, narrowly ovate, acute, with a conspicuous linear furrow on the back from base to apex. Acicular foliage usually present, similarly furrowed on the back. Fruit blue, ovoid, with one very large seed.

12. *Juniperus phœnicea*, Linnæus. Mediterranean Region, Crimea, Canary and Madeira Islands. See p. 1424.

Ultimate branchlets, terete, $\frac{1}{25}$ in. in diameter; leaves closely appressed, ovate-rhombic, blunt, with an inconspicuous oval depression on the back. Acicular foliage rare on adult trees. Fruit, yellow or reddish brown, with fibrous yellow flesh, and three to nine seeds.

13. *Juniperus flaccida*, Schlechtendal. Texas, Mexico. See p. 1426.

A tree with long pendulous branches. Leaves ovate-lanceolate, slightly spreading, $\frac{1}{2}$ in. long, sharp-pointed, with a linear sunken gland, exuding resin. Acicular foliage usually present, similarly glandular, mostly ternate, rarely in pairs. Fruit reddish brown, minutely tuberculate, with six to twelve seeds.

14. *Juniperus pachyphlœa*, Torrey. Arizona, Texas, New Mexico, Mexico. See p. 1429.

Tree with thick bark, divided into small square scaly plates, unique in the genus. Ultimate branchlets, tetragonal, $\frac{1}{25}$ in. in diameter; leaves appressed, ovate-rhombic, with a depressed oval gland, often exuding resin. Acicular leaves often present. Fruit reddish brown, tuberculate on the surface, with four seeds.

(b) Acicular leaves in opposite pairs.

15. *Juniperus thurifera*, Linnæus. France, Spain, Portugal, Sardinia, Morocco, Algeria. See p. 1427.

Ultimate branchlets, $\frac{1}{10}$ in. in diameter; leaves ovate, appressed but free at their acute or acuminate tips, with a conspicuous glandular depression on the back. Acicular foliage often present. Fruit blue, with two to four seeds.

** Leaves entire in margin.

(a) Acicular leaves usually in whorls of threes.

16. *Juniperus chinensis*, Linnæus. China, Japan. See p. 1430.

Ultimate branchlets, $\frac{1}{25}$ in. in diameter, marked with white crosses, due to the pale margins of the leaves, which are appressed, rhombic, obtuse, with an inconspicuous dorsal gland. Acicular foliage usually present, either ternate or in pairs. Fruit brown, covered with a white mealy bloom, subglobose, but widest and depressed at the summit, with usually two or three seeds.

17. *Juniperus bermudiana*, Linnæus. Bermuda. See p. 1434.

Ultimate branchlets, tetragonal, $\frac{1}{10}$ in. in diameter; leaves closely appressed, ovate, obtuse at the incurved apex, with a conspicuous dorsal furrow. Acicular leaves usually present, furrowed on the back. Fruit dark blue, covered with a glaucous bloom, with two or three seeds.

¹ The denticulations on the leaves are very minute, and can only be seen with a considerable magnifying power.

(b) Acicular leaves in opposite pairs.

18. *Juniperus virginiana*, Linnæus. North America. See p. 1435.

A tree. Ultimate branchlets very slender, $\frac{1}{30}$ in. in diameter; leaves appressed, ovate, acute or acuminate, with often a small oval depression on the back. Acicular foliage usually present. Fruit bluish, very small, $\frac{1}{4}$ in. in diameter, with one or two seeds.

19. *Juniperus Sabina*, Linnæus. Europe, Caucasus, North America. See p. 1443.

A shrub, distinguishable by the strong disagreeable odour of the foliage, when bruised. Ultimate branchlets very slender, $\frac{1}{30}$ in. in diameter; leaves appressed, ovate, acute or acuminate, with a conspicuous depressed dorsal resin-gland. Acicular foliage often present. Fruit bluish, very small, $\frac{1}{5}$ in. in diameter, with usually two seeds.

20. *Juniperus excelsa*, Bieberstein. Balkan States, Crimea, Syria, Asia Minor, Caucasus. See p. 1446.

A tree. Ultimate branchlets very slender, $\frac{1}{30}$ in. in diameter; leaves appressed, ovate-rhombic, acute or obtuse, marked on the back with a depressed gland. Acicular foliage rarely present. Fruit dark purplish brown, $\frac{1}{3}$ to $\frac{1}{2}$ in. in diameter, with about six seeds.

The following species, of which I have seen no living adult specimens in cultivation, may be briefly mentioned, on account of their economic importance.

- I. *Juniperus procera*, Hochstetter, ex Endlicher, *Syn. Conif.* 26 (1847).

A tree, widely spread throughout Abyssinia, Somaliland, and the highlands of equatorial Africa. In botanical characters it closely resembles *J. excelsa*. Hutchins¹ gives a good account of this species in British East Africa, where it is called cedar and is a timber tree of great value, occasionally attaining an enormous size. He figures a very old tree dividing into two stems, the largest of which is 110 ft. high and 12 ft. in diameter. The wood is now imported into Hamburg in considerable quantity (about 2500 tons in 1911 from German East Africa), and is used for the same purposes as *J. virginiana*, selling in London at about 4s. per cubic foot. *J. procera* is occasionally seen in the juvenile stage in conservatories in botanic gardens; but is not hardy in the open air in Britain. Koch² mentions a reputed tree of this species, growing in 1873, in Simon-Louis's nursery at Metz, which we cannot now identify.

- II. *Juniperus occidentalis*, W. J. Hooker, *Fl. Bor. Amer.* ii. 166 (1839).

A tree, attaining 60 ft. in height, and 9 ft. in girth, readily distinguishable by the stout ultimate branchlets, covered with closely appressed scale-like leaves, arranged in six ranks, in whorls of threes, denticulate in margin, and conspicuously glandular on the back. Fruit subglobose, $\frac{1}{3}$ in. long, bluish with a glaucous bloom, with resinous juicy flesh, containing two or three seeds.

This species occurs on mountain slopes and high prairies in western North America from Washington and Idaho to the Sierras of California.

I have seen no specimens of this species in the living state in England; and

¹ Report of the Forests of British East Africa, 20, 145 (1909), and Scot. Geog. Mag. 1909, p. 351.

² Dendrologie, ii. pt. ii. 132 (1873).

it is doubtful if it has ever been introduced, as Carrière states¹ that all the reputed plants of *J. occidentalis* which he saw were very doubtful; and Kent² does not appear to have recognised this species. (A. H.)

JUNIPERUS COMMUNIS, COMMON JUNIPER

Juniperus communis, Linnæus, *Sp. Pl.* 1040 (1753); Loudon, *Arb. et Frut. Brit.* iv. 2489 (1838); Parlatore, in De Candolle, *Prod.* xvi. 2, p. 479 (1868); Bentley and Trimen, *Medicinal Plants*, iv. t. 255 (1880); Boissier, *Flora Orientalis*, v. 707 (1881); Willkomm, *Forstliche Flora*, 261 (1887); J. D. Hooker, *Fl. Brit. India*, v. 646 (1888); Köppen, *Geog. Verbreit. Holzgewächse Russlands*, ii. 396 (1889); Jack, in *Bot. Gaz.* xviii. 369, pl. 33 (1893); Sargent, *Silva N. Amer.* x. 75, t. 516 (1896), and *Trees N. Amer.* 86 (1905); Mathieu, *Flore Forestière*, 514 (1897); Ascherson and Graebner, *Syn. Mitteleurop. Flora*, i. 243 (1898); Franchet, in *Journ. de Bot.* 1899, p. 264; Kent, *Veitch's Man. Conif.* 170 (1900); Brandis, *Indian Trees*, 694 (1906); Kirchner and Schröter, *Lebensgesch. Blütenpfl. Mitteleuropas*, i. 287 (1906).

A shrub or low tree, occasionally, however, attaining 40 ft. or more in height. Bark reddish brown, at first smooth, ultimately peeling in thin papery shreds. Young branchlets slender, triquetrous, with three projecting narrow ridges between the whorls of leaves. Buds about $\frac{1}{8}$ in. long, with a few loose ovate acuminate green scales. Leaves all acicular, persistent for three years, sessile, spreading, variable in length, averaging $\frac{2}{8}$ to $\frac{3}{8}$ in. long, linear-subulate, gradually tapering from near the jointed and swollen base to the slender spine-like apex; upper surface concave, with usually a single continuous broad white longitudinal stomatic band, no green midrib being present, except occasionally near the base, in which case the stomatic band is divided into two parts for a short distance; lower surface bluntly keeled, with usually a slight furrow in the middle line; resin-canal solitary, situated in the substance of the leaf below the central fibro-vascular bundle.

Flowers dioecious, rarely monœcious, formed in autumn in the axils of the lower whorls of leaves on the current year's shoot, opening in the following spring. Staminate flowers solitary, cylindrical, $\frac{1}{8}$ in. long, yellow; stamens in five or six whorls, three in each whorl, with ovate acute connectives, each of which bears three or four pollen-sacs. Pistillate flowers solitary, green, $\frac{1}{12}$ in. long; scales in six or seven whorls, three in each whorl; the upper three scales minute at the time of flowering, and alternating with three fleshy tubular ovules; the lower scales larger, ovate-acuminate, empty.

Fruit³ ripening in the second or third year,⁴ small and green in the first year; when mature, bluish or almost black, covered with a slight bloom, globose or slightly longer than broad, $\frac{1}{3}$ in. in diameter, on a short scaly stalk; smooth, marked at the summit by three very short radiating lines, below which are three shallow depressions overhung by three minute mucros, indicating the three scales of which

¹ *Conif.* 40 (1867).

² *Veitch's Man. Conif.* 178 (1900).

³ Occasionally the three scales, of which the fruit is composed, do not unite at the summit of the fruit, but gape, showing the seeds inside. This abnormality, var. *thiocarpus*, Ascherson and Graebner, *op. cit.* 245, was described as a distinct genus, *Thuiocarpus juniperinus*, by Trautvetter, *Imag. Pl. Ross.* 11, t. 6 (1844).

Another abnormality, var. *coronata*, Sanio, in *Deut. Bot. Monatsschr.* i. 51 (1883), is occasionally met with, when the points of the scales unite together and form a projection at the summit of the fruit.

⁴ Cf. Jack, in *Bot. Gaz.* xviii. 369-375, plate 33 (1893), who states that in America this species does not ripen its fruit till the autumn of the third year after blossoming.

the fruit is composed. Seeds usually three, rarely two, immersed in a soft resinous mealy sweet pulp; light-brown, elongated-ovoid, triquetrous, narrowed at the summit, which is compressed into a thin transverse ridge; broad at the base, above which on the sides are a few large depressions for resin-glands. Seedling, with two cotyledons, the primary leaves and those of the second year being arranged in whorls of fours.

VARIETIES

The common juniper in the wild state displays a considerable amount of variation in the length and breadth of the leaves, and in the size and shape of the fruit; and numerous varieties based on these characters have been named by Ascherson and Graebner and other botanists, most of which need not be even mentioned here. The most remarkable varieties are the following:—

1. Var. *nana*, Loudon, *op. cit.* 2489 (1838); Ascherson and Graebner, *op. cit.* 246 (1898); Kirchner and Schröter, *op. cit.* 303 (1906).

Var. γ , Linnæus, *Sp. Pl.* 1040 (1753).

Var. *saxatilis*, Pallas, *Fl. Ross.* ii. 12, t. 54 (1788).

Var. *montana*, Solander, in Aiton, *Hort. Kew.* iii. 414 (1789).

Var. *alpina*, Gaudin, *Fl. Helv.* vi. 301 (1830).

Var. *depressa*, Pursh, *Fl. Amer. Sept.* ii. 646 (1814).

Var. *sibirica*, Rydberg, in *Contrib. U.S. Nat. Herb.* iii. 533 (1896).

Juniperus sibirica, Burgsdorf, *Anleit.* ii. No. 272 (1787), and ii. 127 (1790).

Juniperus nana, Willdenow, *Berl. Baumz.* 159 (1796), and *Sp. Pl.* iv. 854 (1805).

Juniperus alpina, J. E. Gray, *Nat. Arr. Brit. Pl.* ii. 226 (1821).

Juniperus depressa, Rafinesque, *Medic. Pl.* ii. 13 (1830).

Juniperus canadensis, Loddiges, *Cat.* 1836, p. 47; Loudon, *op. cit.* 2490 (1838).

Juniperus pygmaea, Koch, in *Linnæa*, xxii. 302 (1849).

A low prostrate spreading shrub, seldom more than a foot in height. Branchlets stouter than in the type. Leaves shorter, less spreading, $\frac{1}{8}$ to $\frac{1}{3}$ in. long, $\frac{1}{4}$ to $\frac{1}{2}$ in. broad, linear-subulate, gradually tapering to the spine-like apex; upper surface very concave, with a continuous white stomatic band; lower surface convex, bluntly keeled. Fruit blue, glaucous, globose, $\frac{1}{8}$ in. in diameter; seeds one, two, or three, smaller than in the type.

This, which is the alpine and arctic variety¹ of *J. communis*, is considered by many botanists to be a distinct species; but Kirchner and Schröter adduce good reasons for supposing it to be only a form, due to climatic conditions. Connecting links² between the type and var. *nana* are found both in the Alps and in Lapland; and experimental sowings of the latter at Berlin and Zurich gave seedlings which resembled the common juniper in all respects. Similarly plants of common juniper from Fontainebleau, which were cultivated by Bonnier³ on Mont Blanc at 6800 feet, assumed the habit of var. *nana* in three years.

¹ *J. dealbata*, Douglas, *ex Gordon*, in *Gard. Chron.* 1842, p. 652, is *J. communis*, var. *nana*. Cf. p. 1436, note 2.

² These have been distinguished as var. *intermedia*, Sanio, in *Deut. Bot. Monatsschr.* i. 51 (1883); and as *J. intermedia*, Schur, in *Verh. Siebenb. Naturw.* v. ii. 169 (1850).

³ *Assoc. Franc. Avanc. Sci., Compt. Rend.* 1892, pt. ii. 521.

2. Var. *hemisphaerica*, Parlature, *Fl. Ital.* iv. 83 (1867).

Juniperus hemisphaerica, Presl, *Delic. Pragens.* 142 (1822).

Resembling var. *nana* in habit, but with longer leaves and larger fruits. It is said by Parlature to occur on Mount Etna, where it grows¹ on sterile soil between 5000 and 7000 ft. elevation; in the mountains of Calabria and Greece; and on the Djurdjura range in Algeria.

Var. *echiniformis*,² which was introduced into gardens by Rinz of Frankfort, is usually identified with var. *hemisphaerica*, but this is extremely doubtful. This cultivated variety, which is commonly known as the "hedgehog juniper," forms a globose bush, 1 to 2 ft. high, with densely crowded branches, branchlets, and leaves.

3. Var. *suecica*, Aiton, *Hort. Kew.* v. 414 (1813).

Var. β , Linnæus, *Sp. Pl.* 1070 (1753).

Var. *fastigiata*, Parlature, in De Candolle, *Prod.* xvi. 2, p. 479 (1868).

Juniperus suecica, Miller, *Gard. Dict.* ed. 8, No. 2 (1758).

Juniperus hibernica, Loddiges, *ex Loudon, op. cit.* 2489 (1838).

Fastigiata in habit, with ascending branches, short leaves, and oblong fruit. This is occasionally found wild in the forests of Scandinavia and of east Prussia, where it often is a tree, 30 ft. to 40 ft. in height, resembling in appearance the fastigiata Mediterranean cypress. So far as I can learn, it has not been noticed³ in the British Isles; but many wild Junipers have a narrow columnar habit.

In gardens the fastigiata juniper is often seen under the name of Irish juniper, perhaps so called because it has the habit of the Irish yew. It is a neat shrub until it becomes thin and shabby in foliage, and often attains 10 to 15 ft. in height. The best specimen which we have seen is one at Westonbirt, about 25 ft. high in 1910. Another at Abercairney was about 20 ft. high in 1911.

4. Var. *compressa*, Carrière, *Conif.* 22 (1855).

Fastigiata, with short branches, and densely crowded very short leaves, forming a small bush, rarely exceeding 3 ft. in height. This is said to be tender, and is possibly of southern origin, as it was identified by Koch⁴ with *J. hispanica*,⁵ which was introduced into cultivation by Booth of Hamburg.

5. Var. *oblonga*, Loudon, *Arb. et Frut. Brit.* iv. 2489 (1838).

Var. *caucasica*, Endlicher, *Syn. Conif.* 16 (1847).

Juniperus oblonga, Bieberstein, *Fl. Taur. Caucas.* ii. 426 (1808) and iii. 634 (1819).

Leaves $\frac{3}{4}$ in. long. Fruit small, $\frac{1}{8}$ in. in diameter, oblong; seeds solitary or two. This variety has been found growing wild in the Caucasus, and scarcely deserves mention, as individuals with the same characters are not uncommon elsewhere. According to Loudon, it was introduced from Paris into the Horticultural Society's Garden at Chiswick about 1826, and formed a bush 4 ft.

¹ Schouw, in *Ann. Sc. Nat.* iii. 243 (1845).

² *J. Oxycedrus echiniformis*, Knight, *Syn. Conif.* 11 (1850). Cf. also Koch, *Dendrologie*, ii. pt. ii. p. 115 (1873).

³ Mr. R. A. Phillips has never seen the fastigiata form growing wild in Ireland, and knows of no records of its existence.

⁴ *Dendrologie*, ii. pt. ii. p. 115 (1873).

⁵ *J. hispanica*, Booth, *ex Endlicher, Syn. Conif.* 15 (1847).

high after being planted twelve years.¹ It has not been recognised by us as now in cultivation.

6. Var. *variiegata aurea*, Carrière, *Conif.* 19 (1867).

Young shoots golden yellow, becoming green in the following year.

7. Var. *cracovia*, Knight, *Syn. Conif.* 11 (1850).

Juniperus cracovia, Loddiges, *ex Loudon, op. cit.* 2490 (1838).

This,² which was said to have been introduced from Poland, was described as a robust plant, with pendulous terminal branchlets. It appears to be very rare in England, the only specimen which we have seen being a tree at Bicton, about 25 ft. high, which has been much broken by the wind.

DISTRIBUTION

The common juniper is more widely distributed than any other tree or shrub in the northern hemisphere. In Europe it is common throughout the northern and central part of the continent, and occurs in the mountains of the countries bordering on the Mediterranean; while the alpine form is reported³ to exist on the Djurdjura range in Algeria. Eastwards *J. communis* spreads through Siberia to Kamtschatka and the Kurile Isles, and through Turkestan to the Thianshan range in Mongolia; but it is not found in Japan,⁴ where it is represented by *J. rigida*. It is also met with in Asia Minor, the Caucasus, Persia, Afghanistan, and the western Himalayas, as far east as Garhwal and Kumaon. In North America it extends from far north in Alaska and in Canada, southwards on the east to New Jersey, Pennsylvania, Michigan, and western Nebraska; in the Rocky Mountains, to New Mexico; and on the Pacific coast, to northern California; and, according to Sargent, only becomes a tree on the limestone hills of Illinois.

Kirchner and Schröter attempt to distinguish with great accuracy the limits of distribution of the common juniper and its var. *nana*; but the altitudes given show that the records of the two forms are much confused. In a general way, it may be stated that var. *nana* extends farther to the north in the plains of the holarctic region, and ascends higher in the mountains to the southward. It is said to occur at the following altitudes: in the Sierra Nevada, between 5400 and 9700 ft.; in the Alps, usually between 6000 and 8000 ft., attaining its highest point on Mt. Rosa at 11,900 feet; in the Caucasus, between 7600 and 9400 feet; in the western Himalayas, between 4300 and 12,000 feet.

J. communis, while widely distributed throughout Russia, is totally absent from the south, in the provinces where the "black earth" formation prevails; and is most common in the Baltic provinces, where in Courland, north-west Livland, Esthonia, and the islands of Oesel and Dagö, it covers large tracts of peaty sand. Kerner⁵

¹ Gordon, in *Gard. Chron.* 1842, p. 652, says that this variety is a robust spreading plant, 2 ft. or 3 ft. high, with leaves like the common juniper, but long and slender; fruit dark purple when ripe, and very small.

² Gordon, in *Gard. Chron.* 1842, p. 652, says that this variety is not different from *J. communis*.

³ Chabert, in *Bull. Soc. Bot. France*, xxxvi. 30 (1889), who also states that the common form, 6 to 8 ft. in height, occurs, but is very rare, in Kabylia.

⁴ Kawakami, in *Tokyo Bot. Mag.* 1900, p. 111, records it, however, for Rishiri Island, on the west coast of Yezo.

⁵ *Pflanzenleben der Donauland* (1863).

long ago described a remarkable juniper forest in Hungary, between the Danube and the Thies, north of the Bacser Canal, where on loose sand it forms extensive thickets of bushes, about 6 ft. in height. The juniper is also widely spread in certain regions as undergrowth in the pine forests, as in those of *P. sylvestris* in the Alps, of *P. austriaca* in Austria, Bosnia, and Servia, and of *P. Peuke* in Macedonia. It is very common on all kinds of heath land in northern Germany; and is elsewhere found on sunny rocky mountain slopes, as in the Jura, the Alps, etc. (A. H.)

The juniper in Norway attains a very much larger size than it ever does in this country, many remarkable trees being mentioned by Schübeler, *Virid. Norv.* i. pp. 357-369. The cypress-like form, var. *suecica*, is not uncommon in a wild state; and he gives excellent illustrations of it, and mentions a tree found by Prof. Sexe in the Hardanger Fjord which was 40 ft. high. He figures a tree leaning very much on one side, which has the habit of a stunted spruce, growing near Vossevangen, which was 38 ft. high. Even as far north as Saltdalen (lat. $67\frac{1}{2}^{\circ}$) it attains very large dimensions. Forstmeister Niewjaar told me that he had sent one from there to the Paris Exhibition in 1878 of great size, and knew of one still living which was eleven metres high and about one metre in girth. Schübeler figures a tree with a short thick stem 7 ft. 1 in. in girth, and a spread of branches 26 ft. in diameter, at Hohl, near Christiania, and another with a beautiful straight clean trunk dividing into three stems.

Such trees as those above mentioned are of great age; some of which the rings were counted were as follows:—

- (1) 130 years old; longest diameter, 17 in.; shortest diameter, $14\frac{1}{2}$ in. at the base.
- (2) 114 years old; longest diameter, $14\frac{1}{2}$ in.; shortest diameter, $11\frac{1}{2}$ in. at the top of the log.
- (3) 150 years old; 33 ft. long; 4 ft. 3 in. in girth at the base, 3 ft. 3 in. at 5 ft., 2 ft. 8 in. at 10 ft., 2 ft. 1 in. at 15 ft., 1 ft. 6 in. at the top, where there were 47 annual rings; the total height of this tree was 37 to 38 ft.
- (4) 216 years old; 14 in. in diameter.
- (5) 300 years old; $12\frac{1}{2}$ in. in diameter.

Schübeler, *Tillæg til Virid. Norv.* 102 (1891) states that Lensmand Lund of Stryn parish, in North Bergenhus district ($61^{\circ} 55'$ lat.) sent him a sketch of a juniper supposed to be the tallest and thickest in Norway. It grows at an elevation of 1200 to 1500 ft., and is 45 ft. high, with the trunk 6 ft. 3 in. in girth, and the crown $9\frac{1}{2}$ ft. in diameter. It is supposed to be 195 years old.

In the Swedish forestry journal, *Skogsvårdsfor. Tidskrift*, 1911, p. 132, fig. 1, a photograph is reproduced of a remarkable fastigiata juniper, growing in the parish of Tyrserum, south of Linköping in Sweden, which is 37 feet high.

Wittmack,¹ quoting from the *Tägl. Rundschau*, says that a juniper, one of the oldest trees in the world, grew in Kokenberg parish in Livland. It was so large that two men were unable to span it near the base. The stem when cut down was deposited in the Riga Museum, and is said to have shown 2000 annual rings.

¹ *Gartenflora*, xxxvi. 139 (1887). Willkomm, *Forstliche Flora*, 263 (1887) quotes the same account—except that the name of the parish is given as Ermas—from *Oesterr. Forstzeitung*, 1885, p. 137.

According to Koernicke and Roth¹ the juniper is the characteristic conifer of the Eifel Mountains at an elevation of 1000 to 2000 ft. Here it grows on all kinds of soil, but best on the heaths of grauwacke, where it often forms large groups and attains about 25 ft. in height. The plates show how variable is the form of the tree here, some being round bushes, and some narrow pyramids. Prof. T. Schube, of Breslau,² figures a tree in a forest meadow at Kuchelberg, about 23 ft. high, and 5 ft. 5 in. in girth at a foot above the ground, which he thinks is the finest wild juniper in Silesia.

CULTIVATION

Though it has now been to a great extent displaced by modern introductions, the juniper was a great favourite as a garden shrub in former times, and according to Evelyn³ may be formed into most beautiful and useful hedges. He says: "The discreet loosening of the Earth about the Roots also, makes it strangely to prevent your Expectations, by suddenly spreading into a bush fit for a thousand pretty Employments. My Brother having cut out of one only tree, an Arbour capable for three to sit in; it was at my last measuring seven foot square, and eleven in height, and would certainly have been of much greater altitude and farther spreading, were it not continually kept shorn. But what is most considerable, is the little time since it was planted, being yet hardly ten years, and then it was brought out of the Common a slender bush of about 2 ft. high." He adds: "I have raised them abundantly of their seeds (neither watering nor dunging the soil) which in two months will peep." My experience in raising the seeds of juniper, which agrees with that of Boucher, and also with Loudon's statement, is that the seeds lie for one year before germinating, even when freshly sown. They keep for some years in the berry without losing their vitality.

REMARKABLE TREES

Though the common juniper seldom in Scandinavia and never in Great Britain attains the size of a timber tree, yet it is so striking a feature in the vegetation of some English hillsides that it cannot be passed by in silence. One of the best instances of its growth is seen on a dry oolite hillside at Hilcot, about two miles from Colesborne, on my own property. (Plate 348.) How old these trees are and how they originated, it is impossible to say; and though the juniper is indigenous in the Cotswold hills, this is the only hillside I know of in the county where it is abundant, and as the trees have not perceptibly increased in size during the last fifty years, they must be of great age. The largest are 20 to 25 ft. high, but none have developed a single stem thicker than 6 to 9 in. in diameter, and though they produce berries freely, natural reproduction is entirely prevented by rabbits. In young plantations, however, protected by wire-netting, not far away, there are seedlings in the grass, which have grown from seeds dropped by birds. On many of the chalk-hills of the Chilterns, the South Downs, and in Surrey and Hants, scattered

¹ In Karsten and Schenck, *Vegetationsbilder*, v. tt. 5, 6 a and b (1908).

² *Mitt. Deut. Dend. Ges.* 1910, p. 47.

³ *Silva*, 136 (1679).

bushes of juniper mixed with yew, holly, and thorn appear, but rarely exceed 8 to 10 ft. in height, and natural reproduction is in my own experience seldom found. Mr. Dykes informs us that many junipers grow on Shackleford Heath, and on the south side of the Hog's Back near Puttenham.

In a valley called Juniper Valley, about three miles east from Godalming, formerly the property of Col. H. H. Godwin-Austen, the juniper attains a greater size than I have seen it anywhere else in a state of nature in Great Britain. Col. Godwin-Austen tells me that a map in his possession shows the land to have been a sheep walk in 1733. The soil is a deep sand on the lower greensand formation, at an elevation of 350 ft., and is overgrown with rank ling and bracken. The trees are mostly branched near the ground, and attain 15 to 30 ft. in height, some having a fastigiate habit like the Irish juniper. They are mostly damaged and broken by heavy snow; and I could find no young seedlings.

H. Speight, *Romantic Richmondshire*, 239 (1897), states that "Down to the beginning of the last century there were many hundred acres of juniper and briar in the townships of Reeth, Helalough, and Muker. The chips at one time were extensively used for fumigating, and during seasons of plague and sickness no house was found without them. The berries were used as a spice. The plant grows best on open elevated limestone country, and flourished amazingly in upper Swaledale. There are acres of it about Harkeside, above Marden Castle, and elsewhere. In Wensleydale it occurs but sparingly."

At Merton, Norfolk, there is a remarkable plantation of juniper which covers 14½ acres, and consists of numerous shrubs very variable in appearance, and averaging about 20 ft. high. The smallest are about 7 ft. high, while the majority range from 15 to 20 ft.; the tallest being 25 ft. This was planted about 1845. In a neighbouring plantation there is a fine specimen 35 ft. high.

The largest recorded juniper in England is one which grew at Farnham Castle, Surrey, and was said by Loudon to be of the Swedish variety, and 40 ft. high, but on a recent visit to Farnham I could find no trace of this tree. Loudon¹ figures a tree growing in a birch wood near Farningham which was 20 ft. high and 4 ft. in girth in 1838; but of this also I can find no trace.

At Langley Park, Norfolk, I measured a very fine bush about 20 ft. high, and 43 paces round the branches; and at Westonbirt there is the finest specimen I know of the fastigiate form, measuring 26 ft. high in 1909.

In Scotland the juniper is less common in a wild state than formerly, but in certain districts is still abundant. Mr. T. Cathie, forester at Aberuchill, Comrie, Perthshire, informs me that a tree no less than 40 ft. high was blown down near there in 1904, but that the tallest now living were only 17 ft. high.

The finest I have seen wild in Scotland are in the forest of Guisachan, near the house of the forester Donald Kennedy, who told me that thirty years ago some of the thickets of juniper were so dense that he could not pass through them. Now, however, many are broken down by the snow, and injured or killed by the stags cleaning their horns on them; and the tallest that I saw, on a grassy mound,

¹ *Arb. et Frut. Brit.* iv. 2492 (1838).

were not over 20 ft. high. A specimen log in the Forestry Museum, Cambridge, sent by the Earl of Portsmouth, shows a section about 7 in. in diameter at five feet from the ground, displaying 120 annual rings. Owing to decay, the rings at the base could not be counted. In Glen Urquhart there are large thickets of scrubby junipers, which in Gaelic are called *asten*, but I saw no tall ones in this locality. In Perthshire it is local and, according to Buchanan White,¹ commonest between Dunkeld and Ballinluig. It ascends to 2600 ft. in Breadalbane.

On Ford, a farm occupied by Mr. Wallace, near Capenoch, Dumfriesshire, there is a hillside facing south, on the Silurian formation, covered with junipers over an area of thirty to forty acres, which, as I was told by Mr. Hugh Gladstone who showed them to me, have been in their present condition as long as any one can remember. Prof. R. Wallace tells me that an old man, who died last year at a great age, said that he could remember them when they were quite small; and Mr. Paterson of Craigdarroch says that no class of stock would eat juniper, though Herdwick sheep are said to do so when they can get no other food. At Capenoch, though the ground is grazed by sheep and cattle, there are many young seedlings coming up among the heather. The largest bushes here were 15 to 18 ft., but the majority were 6 to 10 ft. high, and some had the fastigiate habit of the so-called Irish juniper. Except a few ash, holly, and rowan, I noticed no other trees but juniper on this hillside. Col. Kennedy of Milton Park Lodge, Dalry, Kirkcudbrightshire, says that juniper is very scarce in that district, and that in Inverness-shire, where it is common near Kingussie, grouse are very fond of taking shelter in it in hot weather.

The juniper is common as a wild plant in the west of Ireland, being recorded by Praeger² for Donegal, Sligo, Mayo, Galway, Tipperary, and Kerry, where it is confined to the mountains and lake shores. Mr. R. A. Phillips writes to us as follows:—"I doubt if var. *nana*³ is really a variety or only a prostrate state of *J. communis*. In east Galway, on the limestone at Gort, and on the shores of Loch Derg near Portumna, where the species is abundant, it is an upright bushy plant when growing in fairly deep soil or in sheltered hollows; but close by on exposed rocks or bare ground it is perfectly prostrate. I have always failed in these localities to distinguish any difference in the leaves or fruits of the two forms. On the non-calcareous mountains of west Galway, Cork, and Kerry, principally Old Red Sandstone, the juniper is usually prostrate, and here its leaves are broader and more imbricate, with sometimes oval fruit, than the plant of the limestone; but even this form is in some sheltered lowland spots an upright bush. So far as I have seen, the juniper will not live in shade, and never forms undergrowth. Near Gort, the prostrate form covers large areas; and near Portumna, the upright form occurs in small groves, but never in such quantity as to deserve the name of a wood. The largest specimens which I have seen were about 12 to 15 ft. high, girthing near the ground 18 to 24 in." The finest that I have seen in Ireland is in the grounds of

¹ Buchanan White, *Flora of Perthshire*, 282 (1898).

² In *Proc. Roy. Irish Acad.* vii. 288 (1901).

³ Mr. Phillips is inclined to think that in Ireland, typical *J. communis*, as regards leaves and fruit, is a *calcicole*; whereas var. *nana* is a *calcifuge*.

Woodstock, Kilkenny, where in 1909 I measured a tree with four stems each measuring 3 to 4 ft. in girth and about 30 ft. high.

TIMBER

The wood of the juniper is whitish brown, hard, and takes a very good polish, but owing to its being usually too small for any but local uses is not often seen. It is, however, so strong and durable that the stems are commonly used for railway and other fences in Norway and Sweden, and are exported to Denmark from Sweden for the same purpose.

The fence of the Dyrhave or Royal Deerpark, near Copenhagen, is made from straight juniper poles about 3 to 4 in. in diameter, fixed on oak posts and rails. When I saw this fence in 1887, I was informed by the late Mr. O. Benson of Copenhagen that it had been erected about 100 years. I was so much struck by its appearance and durability that in 1904 I imported, through the kind assistance of Mr. E. Nilson of the Swedish Royal Forest Service, 1000 juniper poles, 2 metres long, at a cost of £15 free on board, and have put them up to fence off a part of my own deerpark for planting. The fence is made with stout oak posts, 4 yards apart, and the poles are kept in place by three strands of strained galvanised wire without crossbars, strong wire netting being fixed on the lower half to keep rabbits out and deer from getting their heads between the poles. It forms a strong, cheap, and probably a very durable deer fence.

Though the berries of the juniper are not now valued in medicine as much as they were in Evelyn's time,¹ yet they are still used for flavouring gin,² which owes its diuretic quality to them. An essential oil is also distilled from them. The berries are largely collected in the south-east of France and in Hungary for the wholesale druggists.³

(H. J. E.)

JUNIPERUS RIGIDA

Juniperus rigida, Siebold and Zuccarini, *Fl. Jap.* ii. 56, t. 125 (1844); Franchet and Savatier, *Enum. Pl. Jap.* i. 471 (1875); Masters, in *Journ. Linn. Soc. (Bot.)* xviii. 496 (1881), and xxvi. 543 (1902); Kent, Veitch's *Man. Conif.* 188 (1900); Shirasawa, *Icon. Ess. Forest. Jap.* i. t. 12, figs. 1-13 (1899); Komarov, *Fl. Mansh.* i. 207 (1901).

A small tree, attaining in Japan 20 to 30 ft. in height, often a low spreading bush. Bark thin and scaly. Young branchlets triquetrous, with three projecting ridges, becoming terete and scaly in the fourth year. Leaves all acicular, persistent three or four years, spreading, in whorls of threes, linear-subulate, $\frac{1}{2}$ to $\frac{3}{4}$ in. long, about $\frac{1}{5}$ in. broad, tapering from the middle to the very sharp cartilaginous apex, swollen

¹ Evelyn, *Silva*, 130 (1670) says:—"The berries afford (besides a tolerable pepper) one of the most universal remedies in the world to our crazy forester. The berry swallowed only, instantly appeaseth the worst collique, and in decoction most sovereign against an inveterate cough. They are of rare effect being steeped in beer. The water is a most singular specific against the gravel in the reins."

² Bentley and Trimen, *Medicinal Plants*, t. 255 (1880), give a good account of the medicinal uses of juniper, and state that the gin ordinarily distilled in England is flavoured with oil of turpentine, whereas gin, made in Holland, is slightly flavoured with juniper berries, two pounds of berries being used to 100 gallons of gin.

³ Flückiger and Hanbury, *Pharmacographia*, 626 (1879).

and jointed at the base; upper surface deeply concave with the margins inflexed, the narrow median groove whitened with a stomatic band scarcely so wide as the green margins on each side of it; lower surface green, prominently keeled, without glands. Buds ovoid, minute, with sharp-pointed scales, which persist brown and withered at the ends of the branchlets of the second year; lateral buds about $\frac{1}{5}$ in. long.

Flowers dioecious. Fruit ripening in the second year, globose, $\frac{1}{3}$ in. long, with six bracts in two whorls at the base, on a very short stalk, scarcely $\frac{1}{2}$ in. long; smooth, purplish brown, composed of three scales, separated at the apex by three radiating lines, each scale glaucous and with a minute mucro near the top. Seeds usually three, rarely two, in each berry, triquetrous, with three sharply angled sides, converging to a narrow apex, and marked near the base with three or four deep pits containing resin.

This species is a native of Japan,¹ where, according to Sargent,² it is usually a small tree or spreading bush. It is common on the barren land near Gifu, and is generally distributed at low elevations in central Japan, but usually is only found growing on dry sterile gravelly soil. Elwes saw it on dry hillsides in Kiushu, where it did not exceed 15 to 20 feet in height, and had usually a fastigate habit. It is much cultivated by the Japanese, especially in temple gardens. *J. rigida* also occurs in Korea and in the provinces of South Ussuri and Kirin in Manchuria, where it often grows isolated in rocky situations; but it does not seem to occur in China.¹ It was introduced³ into England in 1861 by J. Gould Veitch, who found it in the Hakone Mountains. Maximowicz⁴ sent living plants in 1864 to the botanic garden at St. Petersburg, of a form, which he called var. *filiformis*; but this, if distinct and not a mere juvenile state, is unknown in England.

This species appears to be rather rare in gardens; but there are specimens at Kew, Tortworth, Casewick, Chipping Campden, Highnam, and other places in England, and at Hamwood and Glasnevin in Ireland. It nowhere attains more than 20 ft. in height, but it often produces fruit abundantly. (A. H.)

JUNIPERUS OXYCEDRUS

Juniperus Oxycedrus, Linnæus, *Sp. Pl.* 1038 (1753); Loudon, *Arb. et Frut. Brit.* iv. 2494 (1838); Parlatore, in De Candolle, *Prod.* xvi. 2, p. 477 (1868); Boissier, *Fl. Orient.* v. 707 (1881); Mathieu, *Fl. Forest.* 516 (1897); Ascherson and Graebner, *Syn. Mitteleurop. Fl.* i. 247 (1898); Kent, Veitch's *Man. Conif.* 179 (1900); Rikli, in Kirchner, Loew, and Schröter, *Lebenges. Blütenpfl. Mitteleurop.* i. 309 (1906).
Juniperus tenella, Antoine, *Cupress. Gattung.* 20, tt. 27, 29 (1857).
Juniperus Marschalliana, Steven, in *Bull. Soc. Nat. Mosc.* xxix. 244 (1856), and xxx. 397 (1857).
Juniperus heterocarpa, Timbal-Lagrave, ex Loret et Barrandon, *Fl. Montpellier.* ii. 610 (1876).
Juniperus Biebersteiniana, Koch, *Dendrologie*, ii. pt. ii. 112 (1873).

¹ The plant, collected by David in the Ourato Mountains in Mongolia, and referred to *J. rigida* by Franchet, *Pl. David.* i. 295 (1884), is considered by M. Hickel to be *J. communis*. Wilson's No. 370, collected in Hupeh, and referred to *J. rigida* by Masters, in *Journ. Bot.* xli. 268 (1903) is *J. formosana*. A plant, collected by Giralddi in Shensi, and referred to *J. rigida* by Beissner, in *Mitt. Deut. Dend. Ges.* 1897, p. 216, is also probably *J. formosana*.

² *Forest Flora of Japan*, 78 (1894).

³ *Hortus Veitchii*, 340 (1906).

⁴ Bretschneider, *Hist. Europ. Bot. Disc. China*, i. 610 (1898).

A shrub or small tree, occasionally attaining 30 ft. in height and 10 to 12 ft. in girth. Branchlets angled, becoming pale brown and scaly in the third year. Leaves all acicular, in alternate whorls of threes, spreading, linear, $\frac{1}{2}$ to $\frac{3}{4}$ in. long, $\frac{1}{8}$ to $\frac{1}{6}$ in. broad, gradually tapering from the middle to the acuminate cartilaginous point, swollen and jointed at the slightly narrowed sessile base, entire in margin; upper surface with a narrow elevated green midrib, on each side of which is a white stomatic furrow, bounded externally by a narrow green band; lower surface green, convex, with a projecting sharp keel.

Flowers dioecious. Staminate flowers solitary in the axil of a leaf, two or three in each whorl, sessile, ovoid, about $\frac{1}{5}$ in. long. Fruit ripening in the second year, solitary in the axils, on short stalks about $\frac{1}{8}$ in. long, globose, $\frac{3}{8}$ to $\frac{1}{2}$ in. in diameter; shining reddish brown when ripe, with or without a partial glaucous bloom; composed of three or six scales, each indicated by a minute mucro, the apex of the fruit having three radiating lines. Seeds normally three, radially disposed in the centre of the fleshy resinous pulp, reddish brown, triquetrous-oblong, with two sharp lateral edges; the upper edge usually thin, rounded, broad and emarginate, occasionally narrow and pointed; with two resin-glands at the base which occasionally mark the surface with depressions.

Both *J. Oxycedrus* and *J. communis* are frequently attacked¹ by the parasitic *Arceuthobium Oxycedri*, Bieberstein, a plant allied to the mistletoe, which is common in the Mediterranean region.

This species is very variable in the wild state, differences occurring in the size and shape of the fruit and of the leaves. It usually forms a compact shrub, with ascending or spreading branches and branchlets; but large trees occur on the Riviera, which bear long pendulous branches, and are similar in habit to *J. Cedrus*.

VARIETIES

The following varieties have been described:—

1. Var. *viridis*, Pospichal, *Fl. Oest. Küstenl.* i. 30 (1897). Fruit dull green when ripe. Has only been seen on the north bank of the Canal di Leme, near Rovigno in Istria.

2. Var. *umbilicata*, Rikli, *op. cit.* 315 (1906).

Juniperus macrocarpa, Tenore, *Syll. Fl. Neap.* 483 (1831) (not Sibthorp and Smith).

Juniperus umbilicata, Grenier et Godron, *Fl. de France*, iii. 158 (1855).

Fruit when young, glaucous and covered with a bluish bloom; when ripe, larger than in the type, chestnut brown, very variable in shape, often umbilicate at the base. This is considered by Rikli to be a variety of *J. Oxycedrus*; but by Ascherson and Graebner to be a variety of *J. macrocarpa*. It occurs in Italy, and is perhaps a hybrid between the two species.

¹ Prof. Ed. Henry in *Bull. Soc. Bot. France*, xvii. 260 (1900) mentions an instance in which a branch of *J. communis*, attacked by this parasite, developed scale-like leaves, similar to those normally borne by *J. phoenicea*. Cf. also *ibid.* 155 (1900), where an instance is recorded of *J. phoenicea* being also attacked by *Arceuthobium Oxycedri*.

3. Var. *brachyphylla*,¹ Loret, in Billot, *Annot. Fl. France et Allemagne*, 282 (1855).

Juniperus heterocarpa, Timbal, *ex Loret et Barrandon, Fl. Montpellier*, ii. 610 (1876).

Leaves short, almost obtuse at the apex. Fruit large, pinkish, glaucous. Found on limestone rocks at Saint Béat in Haute Garonne.

4. Var. *maderensis*, Menezes, in *Bull. Acad. Internat. Géog. Bot.* xvii. Nos. 227-228, p. xii (1908).

Leaves very slender, $\frac{1}{3}$ to $\frac{2}{5}$ in. long, $\frac{1}{30}$ in. broad, rounded or acute and not mucronate at the apex. Fruit similar to the type in shape and size, brown with a glaucous tinge.

This is very rare, growing wild in Madeira at elevations of over 1500 feet, on the Serra do Faial, and on rocky slopes near Curral das Freiras. Menezes says that it is cultivated in the villages of Monte Camacho and Santo Antonio da Serra. Dr. Michael Grabham, from whom I obtained specimens,² says that it is an elegant small tree with pendulous branches, 20 to 30 ft. in height, and with a stem 15 in. in diameter. It is very distinct in appearance from *J. Cedrus*; and appears to be closely allied to a form of *J. Oxycedrus*, occurring in Portugal, of which I received a fruiting branch from Mr. H. Clinton-Baker. The latter has short and rather broad leaves.

DISTRIBUTION

This species³ is widely distributed throughout the Mediterranean region, extending eastwards through Syria, western Asia Minor, the south coast of the Crimea, and the Caucasus to Armenia and the Elburz Mountains in northern Persia. It is very common in the shrub-covered waste called *maquis*, which is characteristic of much of the region where it is prevalent; and appears to be indifferent to the chemical nature of the soil, as it grows on limestone, sand, and other formations; but it thrives in warm arid soils, where larger trees do not succeed.

In Algeria and Tunis, it forms undergrowth in the forests of Aleppo pine and cedar, ascending to 5000 ft. on Teniet-el-Hââd. It is widely spread throughout Spain, extending to Traz os Montes in Portugal, and ascends in the woods of *Pinus sylvestris* on the Sierra Nevada to 6600 feet. It occurs throughout Italy, Sicily, and Sardinia, and is not uncommon in the mountains of Corsica. On the eastern coast of the Adriatic, it is the commonest shrub in Istria and Dalmatia, extending inland to Herzegovina, where in the Dinaric Alps it grows to 3000 ft. elevation, and ascends the Narenta valley to Stolac. Its most northerly point is in Servia, in the western branch of the Morava valley. On the Rhodope Mountains it ascends to 3600 feet; and southwards it is common in Albania, Macedonia, Greece, and the Ægean archipelago. (A. H.)

In France it is common in the departments bordering on the Mediterranean, as

¹ This variety is referred to *J. macrocarpa*, by Loret, in *Bull. Soc. Bot. France*, vi. 446 (1859).

² Through Dr. Herbert Watney.

³ The distribution of the species and of *J. macrocarpa* is difficult to separate, both occurring in the same regions, but apparently occupying different altitudes. See under *J. macrocarpa*, p. 1412.

around Montpellier and on the Riviera; but it has been found inland in Aveyron and Ardèche. It is usually seen as a shrub, but is capable of becoming a tree in favourable situations, one recorded by Mathieu near Corbières being 11 ft. in girth. When I was at Montpellier in 1909, M. Marc Bazille showed me the largest tree known to exist in France. This grows on the Ferme de la Rouvière, in the commune of Salinzelles (Gard), twenty miles east of Montpellier. It stands on dry rocky soil covered with scrub of *Quercus Ilex* and *Q. coccifera*, and though a very old tree, is in a good healthy condition. It measured about 35 ft. high, with a trunk 8 ft. long, and 13 ft. 4 in. in girth, dividing into six or eight large limbs which spread over a space 58 paces round. According to M. Pardé,¹ this species will not endure the severe winters of Paris, but it is cultivated at Les Barres.

It was cultivated as early as 1739 in the Physic Garden at Chelsea; but we have seen no specimens of considerable size in England. The largest which we have seen is a shrubby tree at Glasnevin in Ireland, evidently of great age and about 18 ft. high. (H. J. E.)

JUNIPERUS MACROCARPA

- Juniperus macrocarpa*, Sibthorp and Smith, *Fl. Græc. Prod.* ii. 263 (1813); Loudon, *Arb. et Frut. Brit.* iv. 2494 (1838); Boissier, *Fl. Orient.* v. 706 (1884); Kent, Veitch's *Man. Conif.* 181 (1900); Parlato, in De Candolle, *Prod.* xvi. 2, p. 476 (1868).
Juniperus Oxycedrus, Linnæus, sub-species *macrocarpa*, Ascherson and Graebner, *Syn. Fl. Mitteleurop.* i. 248 (1898); Rikli, in Kirchner, Lœw, and Schröter, *Lebenges. Blütenpfl. Mitteleurop.* i. 315 (1906).
Juniperus Biasoletti, Link, in *Atti V. Riun. Sc. Ital. Napoli*, 878 (1845).
Juniperus attica, Orphanides, in Heldreich, *Nutzpfl. Griechen.* 13 (1862).
Juniperus Lobelii, Gussone, *Syn. Fl. Sicul.* ii. 635 (1844).
Juniperus sphaerocarpa, Antoine, *Cupress. Gattung.* 11, t. 10 (1857).

This species is closely allied to *J. Oxycedrus*, with which it has been united as a sub-species by Rikli and by Ascherson and Graebner. It differs in the longer and broader leaves, $\frac{3}{4}$ to 1 in. long, about $\frac{1}{2}$ in. broad, which gradually taper from the base to the acuminate sharp-pointed cartilaginous apex. Fruit larger than in *J. Oxycedrus*, glaucous blue, turning purplish brown after ripening, about $\frac{1}{2}$ in. broad, and $\frac{5}{8}$ in. long, on a short stalk less than $\frac{1}{8}$ in. long; seeds similar to, but larger than in *J. Oxycedrus*. The fruits are either globose; or more commonly pyriform in shape, gradually tapering to the base, constituting var. *ellipsoidea*, Neilrich, *Veget. Croat.* 52 (1868), and identical with *J. Lobelii*, Gussone.

This species has a similar distribution to that of *J. Oxycedrus*, extending throughout the Mediterranean region from Spain to Syria, and also occurring in Bulgaria. It does not appear to be a native of southern France. It grows on low hills, and in sandy tracts close to the sea-coast; whereas, as a rule, *J. Oxycedrus* occupies more inland and higher elevated regions.²

¹ *Arb. Nat. des Barres*, 49 (1906). It is commonly known in France as *genévrier cade* or *cadier*, and yields an oil, called *huile de cade*, which is much used in veterinary practice. Cf. Legre, in *Bull. Soc. Bot. France*, xlviii. 129 (1901).

² This distribution of the two species is confirmed for Greece by Halacsy, *Consp. Fl. Græca*, iii. 455 (1904), and for Algeria, by *Rev. Hort. de l'Algérie*, iv. 176 (1900).

J. macrocarpa was introduced about 1838 by Strangways from Italy; but does not appear to have succeeded in our climate. Rikli says that even on the coast of Istria it is often much injured in severe winters. (A. H.)

JUNIPERUS BREVIFOLIA

- Juniperus brevifolia*, Antoine, *Cupress. Gattung.* 16, tt. 20-22 (1857); Parlato, in De Candolle *Prod.* xvi. 2, p. 478 (1868); H. C. Watson, in *London Journ. Bot.* ii. 7, 9, 398, 401, 408 (1843) and iii. 606 (1844), and in Godman, *Nat. Hist. Azores*, 224 (1870); Trelease, in *Missouri Bot. Gard. 8th Ann. Rep.* 169 (1897); Kent, Veitch's *Man. Conif.* 180 (1900).
Juniperus Oxycedrus, Linnæus, var. *brevifolia*, Hochstetter, in Seubert, *Fl. Azorica*, 26 (1844).
Juniperus rufescens, Link, var. *brevifolia*, Endlicher, *Syn. Conif.* 11 (1847).

A shrub or small tree in the Azores, with a stem often 3 to 4 ft. in girth. Branchlets numerous, short, densely clothed with foliage. Leaves all acicular, in alternate whorls of threes, very short and broad, $\frac{1}{4}$ to $\frac{1}{3}$ in. long, about $\frac{1}{2}$ in. wide, oval-linear, jointed and swollen at the slightly narrowed base, widest about the middle, whence they taper to a rounded or acute (non-acuminate) apex; upper surface with a narrow green midrib not extending to the apex, on each side of which is a broad white stomatic furrow, bounded by an external green band; lower surface green, with a prominent midrib; margin entire.

Flowers diœcious. Fruit sub-globose, $\frac{1}{3}$ in. in diameter, on scaly stalks about $\frac{1}{16}$ in. long, dark reddish brown when mature; scales three, separated at the apex by three radiating prominent lines, and each marked by a minute mucro. Seeds three, embedded in a scanty pulp, ovoid, triquetrous, broadest at the base, gradually tapering to an acute apex, light brown; outer surface convex with two or three longitudinal furrows, not separated from the inner surface by a winged thin margin, as in *J. Oxycedrus*.

This species is remarkably distinct in the very short glaucous leaves; and its seeds differ from those of the allied species.

This species is limited to the Azores, where it occurs on the islands of Corvo, Flores, Fayal, San Miguel, and Pico, ascending to 5000 ft., and rarely descending below 1000 ft. It is locally known as *cedro*, and is usually a compact shrub or small tree, becoming a prostrate bush with interlacing branches on exposed hill summits. Formerly it appears to have been a tree of considerable size, as large logs have been found deeply buried under the secondary volcanic debris in the Grotto do Enferno of the large crater known as Caldeira des Sette Cidades. A slab of this was presented to the Kew Museum by Dr. Goeze, which was reported to have been excavated from a depth of 100 metres.¹

So far as we know this beautiful species has not been introduced² into cultivation in England. (A. H.)

¹ Cf. Goeze in *Card. Chron.* 1867, p. 929, and Masters in *Journ. R. Hort. Soc.* xvii. 3 (1894), who identified this wood with *Cupressus lusitanica*. The slab at Kew is undoubtedly the wood of this species of juniper. Cf. our Vol. V. 1179, note 1.

² Gordon, *Pinetum*, 131 (1880), says it is tender in England; but he gives no particulars as to its introduction.

JUNIPERUS CEDRUS

Juniperus Cedrus, Webb and Berthelot, *Hist. Nat. Isles Canar.* iii., *Phytog. Canar.* ii. 277, t. 217 (1840); Antoine, *Cupress. Gattung.* 14, tt. 16-19 (1857); Parlato, in De Candolle, *Prod.* xvi. 2, p. 478 (1868); Kent, *Veitch's Man. Conif.* 180 (1900).

Juniperus Oxycedrus grandifolius, Buch, *Phys. Besch. Can. Inseln*, 109, 159 (1825).

Juniperus canariensis, Knight, *Syn. Conif.* 13 (1850).

Juniperus Webbii, Carrière, *Conif.* 13 (1855).

A tree, attaining a large size in the Canary Islands, with wide-spreading branches and long pendulous branchlets. This is an insular form of *J. Oxycedrus*, differing mainly from the Mediterranean tree in habit and not in technical characters. Leaves directed towards the apex of the branchlet, and not widely spreading, resembling in this respect *J. formosana*, thinner in texture than in *J. Oxycedrus*, and becoming acute or rounded at the apex in adult trees; glaucous and not bright green on the lower surface, the glaucous tint being present on the narrow midrib and the borders external to the white stomatic bands of the upper surface. Fruit similar to that of *J. Oxycedrus*, with two or three seeds, which are often acute and not broad and emarginate at the apex, the resin-pits being usually more developed than in the Mediterranean species.

Copious specimens received from Dr. Perez show that this tree is scarcely separable as a distinct species from *J. Oxycedrus*; and trees of the latter, with pendulous branchlets, which occur on the Riviera, are very similar to, if not identical with *J. Cedrus*.

J. Cedrus is a native of the Canary Islands, where it has been nearly exterminated by the inhabitants, who value its timber highly. It still exists on Teneriffe, Grand Canary, and Palma, but is extinct on Gomera.¹ Dr. Perez writes that it was common on Teneriffe at the end of the eighteenth century,² as Humboldt mentions it as occurring all the way up from Orotava to the *cañadas*, growing with *Pinus canariensis*; but only a few stunted specimens now survive, which grow on inaccessible rocks about the *cañadas*, from 7000 to 9000 ft. altitude. Schenck,³ who gives the latest published account, quotes Fritsch,⁴ who mentions a noble juniper, which formerly grew on the south-west side of the Peak at 8000 ft. elevation. This tree was 18 ft. in girth and nearly 100 ft. high.

It also occurs in the crater of Tirijana on Grand Canary, but seems to be most abundant now on Palma,⁵ where it grows on the inaccessible inner walls of the crater, and outside it to the north-east on isolated rocks at 7000 ft. elevation. Dr. Burchard⁶

¹ Dr. Christ, in Engler, *Bot. Jahrb.* vi. 487, 500 (1885).

² Buch, *Phys. Besch. Canar. Inseln*, 109 (1825), mentions a few trees which were then growing at 9000 ft. altitude amidst the lava at the foot of the last cone of the Peak.

³ *Wiss. Ergeb. Deut. Exped. 'Valdivia'*, ii. pt. 1, p. 375, figs. 63, 64 (1907).

⁴ *Reisebilder*, 6 (1879).

⁵ Bornmüller, in Engler, *Bot. Jahrb.* xxxiii. 398 (1904), states that he found trees also on the south side of the crater, in the Barranco de las Angustias at 1300 and 2700 ft. elevation; and at Cumbrecita at 4700 ft.

⁶ In *Mitt. Deut. Dend. Ges.* 1911, p. 296, fig.

says that these trees have trunks almost completely bare of bark, and over a metre in diameter; and reproduces the photograph of a fine old female tree, which he took in June 1910. Schenck¹ also figures a very old tree, with a short bole, a few snaggy branches, and very little foliage. (A. H.)

It is doubtful if this plant was introduced until recently, as it was not mentioned by Loudon² in 1838, and was included by Knight and Perry in 1850 amongst the kinds of juniper of which little was known. Kent says that it is not hardy in England; and the only plant now living at Kew is one in the Temperate House, about 7 ft. high, raised from seed sent by Sir Daniel Morris in 1893. Sir John Ross-Bladensburg, K.C.B., however, informs me that a plant in his garden at Rostrevor survived without protection the winter of 1909-1910, which was exceptionally severe in the north of Ireland. As it grew well during the following summer, he looks upon it as hardy; in December 1911 it was 6 ft. high with a good leader, and slightly pendulous branches. A small plant at Glasnevin bore last winter 12° of frost without injury.

J. Cedrus is readily propagated by cuttings at Kew; but there seems to be a great difficulty in raising it from seed.³ Beissner,⁴ however, has raised young plants from seed which I saw in his collection at Bonn in 1908. (H. J. E.)

JUNIPERUS FORMOSANA

Juniperus formosana, Hayata, in *Journ. Coll. Sci. Tokyo*, xxv. art. 19, p. 209, pl. 38 (1908).

Juniperus oblonga pendula,⁵ Knight and Perry, *Syn. Conif.* 11 (1850); Carrière, *Conif.* 20 (1867).

Juniperus taxifolia, Masters, in *Journ. Roy. Hort. Soc.* xiv. 215 (1892), and *Journ. Linn. Soc. (Bot.)* xxvi. 543 (1902) (in part); and in *Journ. Bot.* xli. 268 (1903) (not Hooker and Arnott); Kent, *Veitch's Man. Conif.* 191 (1900).

A tree, attaining in China 40 ft. in height. Branchlets triquetrous, with three narrow ridges, yellowish green in the first year, reddish brown in the second year. Leaves all acicular, spreading, in whorls of threes, linear-subulate, about $\frac{1}{2}$ in. long and $\frac{1}{20}$ to $\frac{1}{12}$ in. broad, jointed and swollen at the base, ending in a sharp spine-like

¹ *Beit. Kennt. Veget. Canar. Inseln*, fig. 63, in *Wiss. Ergeb. Deut. Exped. 'Valdivia'*, 1898-1899 (1907). This figure is a reproduction of a photograph taken by Prof. Simony. A figure of a similar tree, also growing on Palma, is given by Webb and Berthelot, *Hist. Nat. Isles Canar.*, Atlas, t. 8 (1838). ² Cf. note 5 below.

³ Dr. Geo. V. Perez of Orotava, Teneriffe, wrote in *Gard. Chron.* xl. 14 (1906), and xli. 134 (1907), that none of the seed which he sent to Kew and elsewhere germinated. He finds that seeds, soaked in water at 70° Fahr. for 15 to 30 days, germinate freely in about six weeks. Probably germination occurs, under ordinary conditions, in the second year after sowing, or in the wild state after the seeds have been eaten and voided by birds. Correvo, in *Gard. Chron.* xlii. 209 (1907), reports that seeds, which had been soaked in a weak solution of acetic acid, germinated well at Geneva.

Dr. Perez informs me that Mr. Lister has raised, from seed sent from Orotava, eight plants in the Government nursery at Pretoria, which are now 4 ft. high.—(A. H.)

⁴ *Mitt. Deut. Dend. Ges.* 1906, p. 91.

⁵ Knight and Perry's plant is undescribed, but is stated to have come from China and Japan, and is evidently the Chinese species here described, as is confirmed by Carrière's description. It is apparently not the same plant as *J. communis oblonga pendula*, Loudon, *Arb. et Frut. Brit.* iv. 2489, fig. 2345 (1838), applied to a shrub at Kew, then 5 ft. high, with fastigate branches and pendulous branchlets. Gordon, in *Gard. Chron.* 1842, p. 652, describes the latter as: "Trained to a single stem, if left to nature, it will not rise more than three feet, but will spread over a large space of ground. It is quite hardy and a native of the Caucasus." Webb, *Phyt. Canar.* ii. 277 (1840), identified this plant with *J. Cedrus*, which is, however, not hardy at Kew. It is impossible now to identify Loudon's plant, but in all probability it was a pendulous variety of *J. communis*.

point; lower surface convex, keeled; upper surface concave, with two broad white stomatic bands, separated by a very narrow green or glaucous midrib, extending from the base to near the apex, where the white bands coalesce.

Fruit globose, $\frac{1}{3}$ in. in diameter, ripening in the second year, shining dark reddish brown when ripe; smooth on the surface, with three deep radial furrows at the summit, in the centre of each of which is a dark line, showing the separation of the three scales of which the fruit is composed; outer edge of each furrow with a thin mucro, overhanging a slight depression; base of the fruit hollowed out at the insertion of the short scaly stalk. Seeds three, elongated-ovate, triquetrous, mucronate at the narrow thin apex, with several circular resin-pits at the base, above which on the outer surface are three or four larger elongated oval pits.

In cultivated specimens in Europe the branches are ascending, but the branchlets are very pendulous, giving a weeping appearance to the tree. In China it assumes various habits, but is often very pendulous, and occasionally shrubby.

The Chinese species now described, as pointed out by Hayata, is distinct from *J. taxifolia*,¹ Hooker and Arnott, with which it has been confused. The latter, so far as we can learn, has never been introduced into cultivation, and is confined to Bonin Isle, where it was discovered by Capt. Beechey in 1827, and to the Liu Kiu Islands. I cannot find any particulars of the size and habit of this species.

J. formosana is widely spread throughout the mountains of China, and is also commonly cultivated in temple grounds, being known as the *Tz'e Poh*, or "prickly cypress." It is represented in the Kew herbarium by numerous wild specimens from the provinces of Szechwan, Hupeh, Chekiang, and Fokien; and was collected in Shensi by Père Giraldi. It has lately been found on Mt. Morrison and the adjacent ranges in Formosa, between 8000 and 13,000 ft. altitude.²

This species, which is usually known in cultivation as *J. oblonga pendula*, is stated by Kent to have been introduced from China by Fortune in 1856; but this is incorrect as regards the date. It was for sale in Knight and Perry's nursery in 1850, and was probably one of the plants sent home by Fortune in 1844. Knight and Perry describe it as a very elegant drooping shrub from China and Japan, which they supposed to be possibly identical with *J. rigida*; but the latter was not introduced till 1861.

J. formosana is now rare in collections, the best specimen that we have seen being a tree at Bicton, 30 ft. by 2 ft. A vigorous tree at Eastnor Castle is about 28 ft. high. A smaller specimen at Bayfordbury is reputed to have been planted

¹ *Juniperus taxifolia*, Hooker and Arnott, *Bot. Cap. Beechey's Voyage*, 271 (1841); Siebold and Zuccarini, in *Abh. Akad. Wiss. München*, iv. 3, p. 233 (1846); Miquel, *Prod. Fl. Japonica*, 331 (1867); Parlatores, in De Candolle, *Prod.* xvi. 2, p. 481 (in part); Masters, in *Journ. Linn. Soc. (Bot.)* xviii. 496 (1882); Hayata, in *Journ. Coll. Sci. Tokyo*, xxv. art. 19, p. 210, fig. 6 (1908).

Apparently a shrub. Leaves thicker than those of *J. formosana*, rounded or acute at the apex, and not ending in a spine-like point, about $\frac{5}{8}$ in. long; upper surface with two white stomatic bands, separated by an elevated green midrib from base to apex. Fruit globose, $\frac{1}{3}$ in. in diameter, yellowish, rugose on the surface, with three prominent radial ridges at the apex, overhanging three furrows, external to each of which is a mucro. Seeds three, similar in shape and resin-pits to those of *J. formosana*. This species is closely allied to *J. formosana*, mainly differing in the blunt and not spine-tipped leaves.

² Specimens kindly sent me from Formosa by Mr. T. Kawakami are identical with specimens which I collected in central China in the mountains of Hupeh. Elwes gathered it in February 1912, at about 8000 ft. on the ridges above Arisan; but saw it only in a bushy form.

in 1845. Another at Glasnevin, which bore fruit in 1911, was obtained some years ago from Messrs. Veitch, who have, however, no longer the plant for sale.

It has been much confused with *J. rigida*; and all the reputed trees¹ of *J. oblonga pendula* on the continent are referable to this Japanese species. (A. H.)

JUNIPERUS DRUPACEA

Juniperus drupacea, Labillardière, *Icon. Pl. Syr.* ii. 14, t. 8 (1791); Loudon, *Arb. et Frut. Brit.* iv. 2494 (1838); Lindley, in *Gard. Chron.* 1854, pp. 387, 455, fig.; Webster, in *Gard. Chron.* xix. 519, fig. 80 (1896); Kent, *Veitch's Man. Conif.* 173 (1900).
Arceuthos drupacea, Antoine and Kotschy, in *Oester. Bot. Wochblatt.* iv. 249 (1854).

A dioecious tree, attaining about 60 feet in height, usually in cultivation columnar in habit, but in the wild state broadly pyramidal.² Young branchlets triangular, with three prominent linear ridges and three grooves, due to the decurrent bases of the leaves. Older branchlets, from which the leaves have fallen, terete and smooth, with a brown scaly bark. Buds, one terminal and usually two or three in the axils of the leaves on the branchlet of the first year, about $\frac{1}{8}$ inch long, surrounded by minute sharp-pointed lanceolate scales, the outermost of which persist on the apex of the second and third year's branchlets.

Leaves, all acicular, spreading in whorls of threes, about $\frac{1}{2}$ to $\frac{7}{8}$ in. long, $\frac{1}{10}$ to $\frac{1}{8}$ in. broad, jointed at the base, decurrent on the branchlet to the next whorl, linear-lanceolate, widest near the base, gradually tapering to the apex, which ends in a sharp cartilaginous point; lower surface green, convex, with a linear prominent keel; upper surface concave, with a broad green midrib deeply furrowed near the base, and two white stomatic bands, not extending to the margin, which is entire.

Staminate flowers, five or six in a head, on a short scaly stalk, arising in the axil of a leaf on the second year's branchlet; stamens nine to twelve in each flower.

Fruit ripening in the second year, larger than in any other species, $\frac{3}{4}$ to 1 in. in diameter, on a short scaly stalk, ovoid or nearly spherical, brown or bluish with a glaucous bloom, usually composed of nine fleshy scales, in whorls of threes, united together, ovate, thickened and often mucronate at the apex; enclosing a large globose hard bony stone,³ with three small cells, each containing a minute oblong kernel, one of which is often aborted.

This remarkable species is a native of the mountains of Asia Minor, Syria, and Greece. It is found throughout the Taurus range in Asia Minor, several localities being mentioned by Boissier,⁴ between Karaman and Ermenek, in the Bulgardagh, and in the Akkerdagh, close to Marasch. It grows at elevations of 1600 to 5600 feet, and either forms small pure woods or is scattered amidst the forests of cedar and

¹ Specimens sent by Späth from Berlin, and by Pardé from Nancy and Les Barres.

² Walter Siehe, in *Gartenflora*, xlvi. 207 (1897), states that this tree in the Cilician Taurus never assumes the narrow columnar form which is so common in cultivation. Young trees in the wild state are pyramidal in habit; whilst older trees, which are mainly females preserved by the peasants on account of their fruit, have a rounded head of foliage.

³ Antoine and Kotschy, *loc. cit.* consider the bony stone to arise from the union of the testa of the seeds with the inner part of the three upper scales.

⁴ *Flora Orientalis*, v. 706 (1881).

Abies cilicica. Siehe mentions¹ enormous trees between Namrun and Güllek in Cilicia, which are over 3 ft. in diameter. It also occurs in Syria, on Mount Cassio, and on the Lebanon and Anti-Lebanon ranges. In Greece it appears to be confined to Mount Malevo, in the southern part of the Morea, where, according to Halacsy,² it forms a small wood at 3700 to 4000 feet altitude. According to Boissier,³ the reported occurrence of this species in Crete is erroneous.

It is known to the Turks as *Andys* or *Habel*, and is called *Duffran* by the natives of Syria, who collect and eat the fruits, which have a pleasant though resinous flavour.

This species is said by Loudon⁴ to have been introduced in 1820, but he acknowledges that he had only seen young plants, and these were probably incorrectly named, as Lindley⁵ in 1854 speaks of *J. drupacea* as a new plant. It is generally believed to have been for the first time introduced into western Europe in that year by Kotschy, who collected it in Asia Minor in 1853.

So far as we know it has never produced fruit in England, where all the trees in cultivation are supposed to be males. It is normally dioecious, but M. Allard⁶ states that a tree in his arboretum at Angers, which bore staminate flowers for a long time, ultimately produced fruit, and afterwards remained monoecious. A female plant at Angers has, however, never produced staminate flowers. M. Mottet⁶ states that a small tree at Verrières, only 6 ft. high, has produced fruit, though no other tree of the same species is near it, and he supposes that it must have been fertilised by the pollen of another species. (A. H.)

This species usually forms a narrow column and is one of the most beautiful of the junipers, yet is rarely seen in collections. It is perfectly hardy, and, judging from the way it grows at Colesborne, thrives in a limestone soil. The best specimen which I have seen is at Eastnor Castle, where there is a well-shaped tree, 31 ft. by 3½ ft. in 1908. This produced staminate flowers in May 1899, of which there are specimens in the British Museum. At Scorrier, in Cornwall, a fine specimen was 36 ft. by 1 ft. 9 in. in 1911. There are two good trees at Kew about 30 ft. high. Henry saw at Holkham in 1911 two very narrow columnar trees, about 40 ft. high by 3 ft. in girth. At Brickendon Grange, Hertford, a fine specimen measured 36 ft. high in 1912. Smaller trees occur at Highnam, Tortworth, Chiltley Place near Liphook, Young's nursery at Milford near Godalming, and other places. In Ireland the best specimen that we have seen, a tree about 30 ft. high, is growing at Woodstock, Kilkenny.

In France it attains a larger size, and at Angers and Montpellier has produced fruit. A tree in M. Allard's arboretum at Angers, nearly 40 ft. high, is figured in *Bull. Soc. Dend. France*, 1908, p. 109. Another⁷ at Antibes, about 30 ft. high, has a leaning stem and wide-spreading branches, being very different in habit from the usual form of this species in cultivation. (H. J. E.)

¹ In *Mitt. Deut. Dend. Ges.* 1911, p. 305.

² *Comp. Fl. Græc.* iii. 455 (1904). There is a specimen in the Cambridge Herbarium collected by Orphanides on Mount Malevo.

³ *Flora Orientalis*, v. 706 (1881).

⁴ *Encycl. Trees*, 1084 (1842).

⁵ *Gard. Chron.* 1854, p. 455.

⁶ Cf. Mottet, in *Rev. Hort.* 1904, p. 356, figs. 147, 148, where a tree is figured in the park of Baron Mallet at Château des Côtes, near Versailles, which Elwes found to be 36 ft. high in 1909.

⁷ Erroneously labelled *J. Oxycedrus*, var. *macrocarpa*.

JUNIPERUS RECURVA

Juniperus recurva, Buchanan-Hamilton, ex Don, *Prod. Fl. Nepal.* 55 (1825); Loudon, *Arb. et Frut. Brit.* iv. 2504 (1838); Masters, in *Gard. Chron.* xix. 468 and 574, fig. 69 (1883), and in *Journ. Linn. Soc. (Bot.)* xxvi. 542 (1902); J. D. Hooker, *Fl. Brit. India*, v. 647 (1888); Kent, Veitch's *Man. Conif.* 185 (1900); Gamble, *Indian Timbers*, 698 (1902); Brandis, *Indian Trees*, 694 (1906).

Sabina recurva, Antoine, *Cupress. Gatt.* 67, tt. 88, 90, 91 (1857).

A tree, attaining in the Himalayas 30 ft. or more in height. Bark brown, thin, peeling off in long fibrous strips. Branches curved, more or less pendulous. Young branchlets marked between the whorls by the decurrent bases of the leaves, which are separated by three grooves. Older branchlets from which the leaves have fallen smooth, with a light reddish-brown scaly epidermis.

Leaves all acicular, densely imbricated in whorls of threes, their basal part being decurrent on the branchlet, loosely appressed, directed forwards, scarcely spreading; linear-lanceolate, ½ to ¾ in. long, ⅓ to ⅔ in. broad, ending in a sharp cartilaginous point; outer surface convex, channelled longitudinally from the insertion to about the middle, greyish green; inner surface concave, whitened throughout. The leaves persist for several years, becoming brown in the third and fourth years, the mixture of green and brown leaves giving the foliage a peculiar appearance.

Flowers monoecious.¹ Staminate flowers, terminal or solitary in the axils of one or two of the leaves on the ultimate branchlets, oblong, about ⅓ in. long, with twelve to sixteen stamens. Fruit axillary, ripening in the second year, sessile, bracteate at the base, dark purplish brown, ovoid, about ⅔ in. long, composed of three or six united scales, each bearing a triangular spreading mucro, prominent near the umbilicate apex of the fruit. Seed solitary, occupying the greater part of the berry, ovoid, with a thin narrowed apex, marked on the surface with two or three large depressions for resin-glands.

This species is a native of the eastern Himalayas, occurring in Sikkim and Bhutan, between 9000 and 12,000 feet. It is represented in the north-western Himalayas, China, and Japan by the closely allied species or variety, *J. squamata*.

(A. H.)

In the very moist climate of the interior of Sikkim, where it is common in the Lachen and Lachoong valleys, from about 10,000 to above 13,000 feet, Sir Joseph Hooker, whose sketch² of it has been reproduced in Veitch's *Coniferae*, fig. 58, gives 30 ft. as its height; but if my recollection is correct, I saw much larger trees above Lachoong; and G. A. Gammie, in his account of a botanical tour in Sikkim,³ says that in the Sebu valley he saw large trees at 11,000 feet; and at 13,000 feet in the same valley it was the only arborescent vegetation.

¹ This species appears to be always monoecious. Kent, Veitch's *Man. Conif.* 187 (1900), states that a tree at Fota is a male. We have specimens of this bearing both staminate and pistillate flowers on different branchlets of the same branch.

² *Himalayan Journals*, ii. 45, fig. (1854).

³ Published as a Government paper, No. 41 B.S.I., dated Calcutta, 26th July 1893, reprinted in *Kew Bulletin*, October-November 1893, p. 311.

According to Gamble its growth is slow, about twenty-two rings per inch of radius for the Sikkim tree; and the wood is very good, equal to the best pencil cedar, but is not used except to burn as incense in the Buddhist temples.

This is the most ornamental of the junipers on account of its graceful drooping habit; and though introduced¹ in 1830, and hardy enough to grow well and ripen its berries in Scotland, it is not common in cultivation, and is seldom found in nurseries.² Its success in cultivation seems to depend principally on sufficient moisture in summer, all the best specimens that I have seen being in districts where the rainfall is heavy.

The largest I know in England is at Bicton, where there are two trees about 40 and 35 ft. high by 3 ft. 4 in. in girth, which bear abundance of berries. At Hafodunos in Denbighshire I saw in 1911 a very fine tree with three stems from the ground, almost equal in height, 40 ft. to 41 ft., and each about 2 ft. in girth. At Bodorgan in Anglesea there is a good-sized tree. Even in the drier climate of Gloucestershire there is a thriving tree at Highgrove, near Tetbury, the seat of Arthur Mitchell, Esq., from the berries of which I have raised plants; and another occurs at Highnam. There are also good specimens at Pencarrow and Menabilly in Cornwall, Mamhead in Devon, Bayfordbury and High Canons, Herts, Rotherfield Park, Hants, and Holkham, Norfolk.

In Scotland there is a small tree at Murthly, from which I have raised seedlings; and a thriving shrub at Drumtochty Castle. Another at Dalkeith was 14 ft. high in 1907.

In Ireland there is a large bushy tree³ with nine main stems, 40 ft. high and thirty-seven paces round at Castlewellan (Plate 349). At Salterbridge, Co. Waterford, the seat of Major Chearnley, I saw in 1910 another of the same type and almost as large; and at Fota I measured a tree 38 ft. high in 1910. (H. J. E.)

JUNIPERUS SQUAMATA

- Juniperus squamata*, Buchanan-Hamilton, in Lambert, *Genus Pinus*, ii. 17 (1824); Don, *Prod. Fl. Nepal*, 55 (1825); Loudon, *Arb. et Frut. Brit.* iv. 2504 (1838); Endlicher, *Syn. Conif.* 18 (1847); Koch, *Dendrologie*, ii. pt. ii. 121 (1873).
Juniperus religiosa,⁴ Royle, *Illust. Him. Plants*, i. 351 (1839) (name only).
Juniperus densa,⁵ Gordon, *Pinet. Suppl.* 32 (1862).
Juniperus recurva, Don, var. *squamata*, Parlato, in De Candolle, *Prod.* xvi. 2, p. 482 (1868); Brandis, *Forest Flora N.W. India*, 536 (1874), and *Indian Trees*, 694 (1906); Hooker, *Fl. Brit. India*, v. 647 (1888); Masters, in *Journ. Linn. Soc. (Bot.)* xxvi. 543 (1902).
Juniperus morrisonicola, Hayata, in *Gard. Chron.* xliii. 194 (1908), in *Journ. Coll. Sci. Tokyo*, xxv. art. 19, p. 211, fig. 7 (1908), and xxx. art. i. p. 307 (1911), and in *Journ. Linn. Soc. (Bot.)* xxxviii. 298 (1908).
Sabina squamata, Antoine, *Cupress. Gatt.* tt. 89, 90 (1860).

A shrub, with long decumbent stems, running over and under the surface of the ground, from which arise numerous short erect branches. Young branchlets green,

¹ According to Loudon, *Trees and Shrubs*, 1089 (1842). Seeds were subsequently sent home to Kew by Hooker in 1850.

² It is known in some nurseries as *J. repanda*, Hort. ex Carrière, *Conif.* 27 (1867).

³ Figured by Earl Annesley, *Beautiful and Rare Trees*, 54 (1903).

⁴ This is identified with *J. squamata* by Hooker, *Fl. Brit. India*, v. 647 (1888).

⁵ Gordon's account is confused, as he states that the berries are three-seeded; otherwise his description applies to

J. squamata.

with three grooves separating the decurrent pulvini of the leaves. Leaves all acicular, densely imbricated in whorls of threes, appressed or slightly spreading, decurrent on the branchlets, broader and shorter than in *J. recurva*, the free part $\frac{1}{8}$ in. long and $\frac{1}{4}$ in. wide, curved, gradually tapering to an acute apex, which is tipped with a sharp cartilaginous point; ventral surface concave, whitened, usually with a faint or obsolete midrib; dorsal surface convex, green, with a median furrow extending from the base to near the apex. Older branchlets stout, reddish brown, covered with persistent reddish brown acicular leaves.

Fruit ellipsoid, reddish brown at first, turning black when ripe in the second year, smaller and of a different shape from that of *J. recurva*, about $\frac{1}{4}$ to $\frac{1}{3}$ in. long, somewhat less in diameter, composed of three or six scales, each with a triangular mucro, umbilicate at the apex. Seed solitary, ovoid, broadest above the base, and tapering to an apiculate apex, nearly filling the cavity of the fruit, with about four ridges running from base to apex, and three or four depressions below the middle for resin-glands.

J. squamata, differs mainly from *J. recurva* in habit and in having stouter broader needles; but it is readily distinguishable, and has a much wider distribution. It varies considerably in the colour of the leaves, and appears occasionally to become an erect instead of a prostrate shrub.

It occurs in Afghanistan, the Himalayas, and the mountains of China and Formosa. It grows at a high elevation in the Himalayas, being most common in the north-west; but is also found in Sikkim, where Gammie states that it attains 15,000 ft. altitude. Brandis describes it as a gregarious shrub, often covering large areas, either pure or mixed with *J. communis*, with decumbent stems, at times six inches in diameter, running over the ground and giving off numerous short branches, which make it very difficult to traverse such thickets.

It is also found at high elevations in China, in the provinces of Hupeh, Szechwan, and Yunnan. In Hupeh, where I saw it in 1888, it is a shrub about a foot high, usually growing on rocky ground, and spreading over the surface to a radius of six feet or more. It resembles in habit the dwarf form of *J. communis*, but is readily distinguished by its broader shorter leaves and one-seeded berries. *J. squamata* grows in Formosa on Mt. Morrison, near the summit at 13,200 ft. altitude.

J. squamata was introduced¹ into England about 1836, and is occasionally cultivated in rockeries, being known occasionally as *J. pseudosabina*,² *J. densa*, etc.

In its typical form, it has leaves of a pure green tint, which are occasionally nearly as long as those of *J. procumbens*, Siebold. There are specimens at Kew, Bicton, Bayfordbury, and Glasnevin.

The following is probably a variety of *J. squamata*; but in the absence of fruit I hesitate to assign it to that species:—

¹ Gordon, in Loudon, *Gard. Mag.* xvi. 10 (1840), states that it was raised in the Chiswick Garden from Indian seed sent three or four years previous to 1840.

² *J. pseudosabina*, Fischer and Meyer, is a Turkestan shrub. Cf. p. 1423, note 1.

Juniperus procumbens, Siebold, in *Ann. Soc. Hort. Pays-Bas*, 1844, p. 31, and in Siebold and Zuccarini, *Fl. Jap.* ii. 59, t. 127, fig. iii. (1870) (not Sargent¹).

Juniperus chinensis, var. *procumbens*, Endlicher, *Syn. Conif.* 21 (1847).

A prostrate shrub similar to *J. squamata* in habit, but differing in the branchlets being glaucous-white on the edges of the pulvini: leaves longer, their free part $\frac{1}{3}$ in. long, gradually tapering to an acuminate spine-like apex; upper surface concave and covered except along the margins with a white stomatic band, divided except near the apex by an elevated and usually green midrib; lower surface convex, bluish, spotted with white, and with a median furrow which is variable in length. Fruit not seen.

This beautiful shrub was first described by Siebold,² who stated that it was wild in the mountains of Japan, and was cultivated in gardens and temple woods at Nagasaki. It has been collected since only by Faurie,³ who found it at high elevations in Hondo.

Siebold considered it to be perhaps *J. nipponica*, Maximowicz,⁴ a species with which it has no affinity; and subsequent botanists confused it with *J. chinensis*,⁵ a totally different species. It resembles *J. squamata* very closely, differing only in the glaucous tint of the leaves and branchlets; but in the absence of fruit cannot be safely united with that species.

J. procumbens is said⁶ to have been introduced, by living plants, into the Botanic Garden at St. Petersburg in 1864; but does not appear to have been known in England until of late years.⁷ It is now imported largely from Japan, and was a striking feature in the exhibit of Japanese plants at the Anglo-Japanese Exhibition of 1909. It is the most ornamental of the creeping junipers, and is occasionally sold under the erroneous name of *J. litoralis*,⁸ a totally distinct species. So far as I know it has not yet produced fruit in England. (A. H.)

¹ *J. procumbens*, Sargent, *Forest Flora of Japan*, 78 (1894), and in *Garden and Forest*, x. 421 (1897), is a variety of *J. chinensis*, described on p. 1432.

² One of Siebold's original specimens, a branch without fruit, of *J. procumbens* is in the Kew herbarium, where it was sent from the Leyden Museum.

³ Masters, in *Bull. Herb. Boissier*, vi. 274 (1898), refers two specimens collected by Faurie, "No. 47, summit of Sennintoge, and No. 3409, summit of Ckokkai," to *J. recurva*, var. *squamata*. No. 3409 is in the Kew herbarium, and is identical with *J. procumbens*, Siebold.

⁴ *J. nipponica*, Maximowicz, in *Mél. Biol.* vi. 374 (1867), is a remarkably distinct species, of which little is known, except the original specimen described by Maximowicz. This species has not been introduced into Europe.

⁵ Siebold's plant has been much confused with *J. chinensis*, var. *japonica*, which is also cultivated in Japan. Gordon's specimen of *J. japonica procumbens* in the Kew herbarium is *J. chinensis*.

⁶ Bretschneider, *Hist. Europ. Bot. Disc. China*, 610 (1898).

⁷ The plant at Kew was introduced from Japan in 1893.

⁸ *J. litoralis*, Maximowicz, in *Mél. Biol.* vi. 375 (1867), is a sea-shore plant, which grows abundantly on the shore of Hakodate Bay in Yezo, and near Honjo on the west side of Hondo, where it was found by J. Veitch in 1892. It also grows in Kiusiu and the Liu Kiu Islands. It has three-seeded berries, and has some affinity with *J. rigida*. It has never been introduced into England so far as we are aware. Bretschneider, *op. cit.* 610, referring to it as *J. conferta*, Parlatores, says that it was introduced into St. Petersburg in 1864, along with *J. procumbens*, Siebold.

JUNIPERUS WALLICHIANA

Juniperus Wallichiana, J. D. Hooker, ex Parlatores, in De Candolle, *Prod.* xvi. 2, p. 482 (1868);

Brandis, *Forest Flora N.-W. India*, 537 (1874), and *Indian Trees*, 695 (1906).

Juniperus pseudosabina, J. D. Hooker, *Fl. Brit. India*, v. 646 (1888) (not Fischer and Meyer¹);

Kent, Veitch's *Man. Conif.* 184 (1900); Gamble, *Indian Timbers*, 698 (1907).

A tree, attaining in the Himalayas 60 ft. in height. Leaves dimorphic. Adult foliage with tetragonal ultimate branchlets, about $\frac{1}{2}$ in. in diameter, densely covered with scale-like leaves, which are arranged in four ranks in decussately opposite pairs, closely appressed, narrowly ovate, about $\frac{1}{16}$ in. long, tapering to an acute apex, bright green with a whitish margin, marked on the back with a linear glandular furrow extending from the base to near the apex. Leaves on the main axes, larger, up to $\frac{1}{4}$ in. long, tipped with acuminate points. Juvenile foliage, often preponderant on adult trees; leaves acicular, in threes, decurrent, densely clothing the branchlet in successive whorls, slightly spreading, about $\frac{1}{8}$ in. long, sharply mucronate, whitened on the inner (upper) surface, usually marked on the back with a longitudinal furrow.

Flowers dioecious. Fruit, ripening in the second year, on the ends of short curved branchlets, ovoid, $\frac{2}{3}$ in. long, $\frac{1}{3}$ in. broad near the base, dark purplish brown, becoming quite blue when ripe; smooth on the surface except for the minute mucros which indicate the three to five component scales; depressed at the summit with a minute transverse rhomboidal apiculate umbo. Seed, one in each fruit, large for the genus, $\frac{1}{4}$ in. long, ovoid, compressed, with a narrow thin pointed apex, and two or three depressions for resin-glands about the middle of each surface.

This species is a native of the Himalayas from the Indus to Bhutan, occurring between 9000 and 15,000 ft. elevation. In the western part of its range, it is a large gregarious shrub; but in Sikkim, it becomes a large tree, sometimes 60 ft. in height, with a stout trunk and dark branches and foliage. An illustration of it is given by Hooker,² who calls it the "Black Juniper." Mr. J. Claude White³ saw a large "weeping cypress," at Chalimaphe in Bhutan, which was 50 ft. round the trunk at five feet from the ground; and this remarkable tree in all probability was *J. Wallichiana*.

J. Wallichiana was introduced in 1849, when Sir J. D. Hooker sent seeds from India to Kew.⁴ It is very rare in cultivation, the only specimens which we have seen being one in the Juniper collection at Kew, about 20 ft. high; and another of the same size at Leonardslee, which bore fruit in 1911. (A. H.)

¹ *J. pseudosabina*, Fischer and Meyer, in *Index Sem. Hort. Petrop.* 65 (1841), and *Plant. Schrenk.* ii. 13 (1842), differs in appearance from the Himalayan tree, the scale-like leaves being less acute, and the fruits smaller and often globose. It was described from specimens gathered in the Altai and the Tarbagatai mountains in Turkestan. It appears to be a low shrub, like *J. Sabina* in habit, and has not apparently been introduced.

² *Him. Journ.* ii. 55, fig. (1854).

³ *Sikkim and Bhutan*, 131 (1909). No specimens of this enormous tree appear to have been collected.

⁴ See Kew archives, "List of Seeds received from Dr. Hooker during his Travels in India," where "No. 78, 1849 (No. 152), *Juniperus*, large tree," is evidently *J. Wallichiana*.

JUNIPERUS PHAENICEA

Juniperus phænicea, Linnæus, *Sp. Pl.* 1040 (1753); Loudon, *Arb. et Frut. Brit.* iv. 2501 (1838); Parlato, in De Candolle, *Prod.* xvi. 2, p. 486 (1868); Vallot, in *Journ. de Bot.* ii. 329 (1883); Mathieu, *Flore Forestière*, 517 (1897); Ascherson and Graebner, *Syn. Mitteleurop. Fl.* i. 250 (1898); De Coincy, in *Bull. Soc. Bot. France*, xlv. 432 (1898); Kent, *Veitch's Man. Conif.* 182 (1900); Kirchner and Schröter, *Lebenges. Blütenpfl. Mitteleuropas*, i. 316 (1906); Albert and Jahandiez, *Pl. Vasc. du Var*, 451 (1908).

Juniperus Lycia, Linnæus, *Sp. Pl.* 1039 (1753); Loudon, *Arb. et Frut. Brit.* iv. 2502 (1838).
Sabina phænicea and *Lycia*, Antoine, *Cupress. Gattung.* tt. 42, 44 (1860).

A shrub or tree, attaining usually about 20 ft. in height. Foliage dimorphic. Leaves on young plants, and very rarely on isolated branches of adult trees, acicular, spreading in whorls of threes, not jointed at the base, decurrent on the branchlet, about $\frac{1}{4}$ in. long, with two stomatic lines on both the upper and lower surfaces. On adult trees, branchlet systems two- to three-pinnate; ultimate branchlets terete, about $\frac{1}{25}$ in. in diameter; leaves scale-like, either in four ranks in opposite decussate pairs, or in six ranks in alternating whorls of threes, closely appressed, ovate-rhombic, about $\frac{1}{25}$ in. long, blunt at the apex, serrulate in margin, rounded on the back, which is often marked with a longitudinal or oval furrow.

Flowers usually monœcious, rarely diœcious.¹ Fruit very variable in size and shape, ripening in the second year, on short scaly stalks, shining yellow or reddish brown, with remarkably fibrous yellowish flesh; composed of six to eight scales, with no distinct lines of separation between them, each marked by a minute or obsolete mucro; in the typical form, globose or sub-globose, $\frac{1}{4}$ in. to $\frac{1}{2}$ in. in diameter. Seeds variable in number, three to nine, shining brown, separable with great difficulty from the adherent yellow flesh, triquetrous, furrowed longitudinally with two or three depressions for the closely adherent glands.

This species is remarkably variable in the size, shape, and colour of the fruits. Five or six varieties can be distinguished in specimens gathered by Jahandiez² near Hyères, which were sent to me by Lord Walsingham. The typical form of the species has globose berries; but these vary in size from $\frac{1}{4}$ in. to $\frac{1}{2}$ in. in diameter, and in colour from dark reddish brown to yellow or orange brown.

1. Var. *turbinata*, Parlato, in *Fl. Ital.* iv. 91 (1867).

Juniperus turbinata, Gussone, *Fl. Sic. Syn.* ii. 634 (1844).

Juniperus oophora, Kunze, in *Flora*, xxix. 637 (1846).

Fruit ovoid or shortly conical. Seeds deeply furrowed from base to apex, and compressed at the summit into a sharp transverse edge. This variety is met with in

¹ This is De Coincy's opinion. Most authors say that it is usually dioecious and occasionally monoecious. Some of the trees we have seen in cultivation are certainly monoecious.

² Albert and Jahandiez, *Pl. Vasc. du Var*, 451 (1908), state that shrubs with large globose berries grow on the maritime sands, whilst those with small berries occur in rocky situations. De Coincy, in *Bull. Soc. Bot. France*, xlv. 432 (1898), refers the form with large globose berries to *J. Lycia*, Linnæus, which may be named, if considered worth distinguishing, as *J. phænicea*, var. *Lycia*, Loiseleur, *Nouv. Duham.* vi. 47, t. 17 (1812).

nearly all the localities where the typical form occurs, and, like it, is variable in the size, shape, and colour of the berries.

2. Var. *filicaulis*, Carrière, *Conif.* 51 (1855) and *Conif.* 52 (1867).

Juniperus myosuros, Sénéclauze, *Catalogue*, 1854, p. 35.

A shrub with elongated twisted branches and slender pendulous branchlets. Leaves scale-like, as in the type; but occasional branchlets bear acicular juvenile foliage. The parent plant, which was 3 ft. high in 1867, is said by Carrière to have originated from a seed of *J. phænicea*, which was sown by Sénéclauze in his nursery at Bourg-Argental (Loire), sometime before 1854. Sénéclauze, however, in his *Catalogue*, 1867, p. 11, calls this plant *J. thurifera hybrida myosuros*; and its origin must be considered doubtful. We have seen no specimens.

J. phænicea is widely spread throughout the Mediterranean region, occurring in Spain and Portugal, south-eastern France, Corsica, Sardinia, Italy, Sicily, Dalmatia, Greece, Rhodes, Cyprus, Crete, and the Crimea; but appears to be unknown in Asia Minor. It is also common in Algeria, Morocco, the Canary and Madeira Islands. It usually grows in arid situations on rocky hills, and often forms extensive and impenetrable thickets, as in La Camargue at the mouth of the Rhone. It ascends in the Riviera to 4500 feet. In Algeria¹ it is common on the coast, and on the southern slopes of the mountains of the interior, where it is often the only arborescent vegetation, ascending to 6000 feet.

In the Canary Isles, *J. phænicea* was formerly one of the characteristic trees of the coast-region between 600 and 2000 ft. elevation; but has been much destroyed on account of its use for firewood. Dr. Burchard² states that it is still plentiful on the north side of Gomera and Hierro; but is nearly extinct on Grand Canary and Teneriffe, where only a few specimens remain in the south. On Gomera, it is usually seen as a globose bush on the cliffs, but becomes a tree when old. On the west point of Hierro, there are specimens supposed to be 1000 years old. Dr. Burchard² reproduces photographs of two of these remarkable trees, which have short stems, 4 to 5 ft. in diameter, with enormous crowns, spreading for an immense distance on one side of the trunk, as the result of the continuous influence for centuries of the north-east trade-wind.

Dr. Grabham tells us that in Madeira, *J. phænicea* was formerly widely distributed from sea-level to the highest summits of the mountains, but is now nearly extinct. The wood of this species is still to be seen in enormous beams and slabs in old buildings, and its fragrant roots of great size are often found underground.

According to Aiton, *J. phænicea* was first cultivated in Britain in 1683 by James Sutherland, curator of the Edinburgh Botanic Garden. It usually forms a pyramidal shrub or low tree, dense in habit; but is now rare in cultivation in this country. There are specimens at Highnam, Bicton, and Rostrevor. These bear small globose orange-coloured fruits.

It loves a warm climate, and is scarcely hardy in Germany; but a specimen,³

¹ Lefebvre, *Les Forêts de l'Algérie*, 431 (1900).

² In *Mitt. Dent. Dend. Ges.* 1911, pp. 286, 287.

³ Kirchner and Schröter, *op. cit.* 316 (1906).

sheltered by other trees and 6 ft. high, at Tübingen, bore, without any injury but a slight browning of the leaves, a minimum temperature in winter of $-29\frac{1}{2}^{\circ}$ Cent.

(A. H.)

JUNIPERUS FLACCIDA

Juniperus flaccida, Schlechtendal, in *Linnaea*, xii. 495 (1838); Sargent, *Silva N. Amer.* x. 83, t. 519 (1896), and *Trees N. Amer.* 89 (1905); Kent, *Veitch's Man. Conif.* 177 (1900).

Juniperus fetida, var. *flaccida*, Spach, in *Ann. Sc. Nat.* xvi. 300 (1841).

Juniperus gracilis, Koch, *Berl. Allg. Gartenzeit.* 1858, p. 341 (not Endlicher).

Sabina flaccida, Antoine, *Cup. Gatt.* 37, tt. 49, 50 (1857).

A tree, attaining 30 to 40 ft. in height, with brown bark separating into thin scales; branches widely spreading, with long pendulous branchlets. Leaves dimorphic. Adult foliage: leaves in opposite decussate pairs, slightly spreading, ovate-lanceolate, about $\frac{1}{2}$ in. long, decurrent, ending in a sharp cartilaginous point, rounded on the back, which is marked with a linear sunken gland, often exuding resin. Juvenile foliage, usually on the ends of some branchlets of adult trees, acicular-subulate, spreading, usually in whorls of threes, rarely in pairs, decurrent, about $\frac{1}{4}$ in. long, gradually tapering from the base to the very sharp cartilaginous apex; upper surface concave, with inflexed margins, and with two narrow stomatic lines; lower surface marked near the base with a linear gland, often exuding resin. Similar spreading acicular leaves, in pairs or in threes, are borne on the main axes of the branchlet-systems, and like these turn reddish brown in the third and fourth year, and fall in succeeding years, leaving the branchlets smooth with a scaly bark.

Flowers monœcious. Fruit, ripening in the second year, on a short ($\frac{1}{16}$ in. long) scaly stalk, four- to six-bracteate at the base, sub-globose, about $\frac{1}{2}$ in. in diameter, reddish brown with a glaucous bloom, and marked on the surface with a few minute tubercles; composed of six to eight opposite scales, each indicated by a reflexed triangular mucro. Seeds, six to twelve, several often aborted, embedded in a resinous pulp; cotyledons two.

(A. H.)

This species is a native of Texas and Mexico. It is limited in Texas to the Chisos Mountains, where it was discovered in 1888 by Dr. V. Harvard. It is common in north-eastern Mexico, at elevations of 6000 ft. to 8000 ft., on the hills to the east of the tablelands, ranging from Coahuila to Oaxaca, and extending eastward to about a hundred miles from the coast.

It was introduced¹ in 1838 from Mexico by Hartweg, but is probably too tender for our climate in most parts, as the only specimen which we know of in Britain is a fine tree at Bicton, which I found to be about 40 ft. by 3 ft. 10 in. in 1906. It grows in a sheltered hollow, and bears fruit regularly, which is smaller in size than in native specimens, and contains only imperfect seed.

Carrière states² that it is not hardy at Paris, but he mentions a tree at Angers

¹ Loudon, *Gard. Mag.* xv. 241 (1839), and xvi. 10 (1840).

² *Conif.* 49 (1867).

10 in. in diameter. It is said¹ to be occasionally cultivated in the south of France and in Algeria; but we have seen no specimens. There is a small tree in the Botanic Garden at Genoa, and a larger one in the Botanic Garden at Naples, which was bearing ripe fruit in March 1910.

(H. J. E.)

JUNIPERUS THURIFERA

Juniperus thurifera, Linnæus, *Sp. Pl.* 1039 (1753); Loudon, *Arb. et Frut. Brit.* iv. 2503 (1838); Parlatores, in De Candolle, *Prod.* xvi. 2, p. 487 (1868); Laguna, *Fl. Forest. Hispan.*, i. 103 (1883); De Coincy, in *Bull. Soc. Bot. France*, xlv. 430 (1898); Kent, *Veitch's Man. Conif.* 191 (1900).

Juniperus hispanica, Miller, *Gard. Dict.* ed. 7, No. 13 (1757), and ed. 8, No. 13 (1768).

Juniperus sabinoides, Endlicher, *Syn. Conif.* 23 (1847) (in part).

Juniperus cinerea, Carrière, *Conif.* 35 (1867).

A tree, attaining in Spain a height of 30 ft. to 40 ft. Leaves dimorphic. Adult foliage, with flattened branchlet-systems, pinnately divided mostly in one plane. Young branchlets tetragonal, slender, $\frac{1}{20}$ in. in diameter; leaves in opposite pairs in four ranks, appressed but free at their acuminate apices, ovate, about $\frac{1}{16}$ in. long, adnate to the branchlet in their basal half, marked on the back with an oblong glandular depression, minutely denticulate in margin. Juvenile foliage often present on adult trees; leaves in opposite pairs in four ranks, spreading, acicular, decurrent, $\frac{1}{2}$ to $\frac{1}{4}$ in. long, whitened on the upper surface.

Flowers diœcious. Fruit on short scaly stalks, ripening in the second year, sub-globose, $\frac{1}{3}$ in. or a little more in diameter, dark blue with a slight glaucous bloom when mature; composed of six scales in opposite decussate pairs, two at the base, the upper four scales meeting at the apex, which is marked with their lines of separation; each scale with a minute mucro. Seeds, two, three, or four, immersed in a granular sweet fragrant flesh, ovate, triquetrous, $\frac{1}{3}$ in. long, shining brown, smooth, narrowed at the apex to a curved point, with two or three oblong resin-pits at the base.

1. Var. *gallica*, De Coincy, in *Bull. Soc. Bot. France*, xlv. 232 (1897), and xlv. 430 (1898); Holmes, *Pharmac. Soc. Museum (London) Report*, 1907, p. 26.

A small tree, apparently differing only from the type, in the one to three seeds, being striate and not smooth on the surface, more prominent at the apex, and less angular.

This variety, which is the French form of the species, was first noticed in 1830 by Mutel, who gave it the name of *J. Sabina*, var. *arborea*.²

It appears to be confined to the Dauphiné, where it occurs at a few stations in the valley of the Isère, in the immediate neighbourhood of Grenoble; and in the valley of the Durance, chiefly near Embrun. Near Grenoble it is found on the

¹ Sargent, *Silva N. Amer.* x. 83 (1896).

² Mathieu, *Flore Forestière*, 519 (1897) refers the trees at Saint Crépin to *J. Sabina*. Cf. also Vidal, in *Bull. Soc. Bot. France*, xlv. 51 (1897).

mountains of Comboire, Néron, and Saint Eynard. In the valley of the Durance it is more abundant, and grows at Guillestre, Saint Clément, Saint Crépin, in the valley of Ubaye, near Gap, and at Remollon. M. Ph. Guinier informs us that in all these localities it grows on dry limestone soil, and usually as isolated trees. At Saint Crépin, however, it forms a small wood above the village, at 3500 ft. to 4000 ft. altitude. It is usually a small tree, 20 ft. to 25 ft. high, but in rare cases attains 40 ft. in height. The trunk is short, irregular, and deeply furrowed; and is frequently 6 ft. to 10 ft. in girth—one tree at Saint Crépin being as much as 17 ft. in girth. It attains a great age, a section in the Museum of the Forestry School at Nancy, 0.94 metres in girth, showing 175 annual rings, and another 1.48 metres in circumference showing 169 annual rings.

J. thurifera is a native of south-eastern France, Spain, Portugal, Sardinia,¹ Morocco, and Algeria. It is common in the mountains of central and southern Spain, occasionally forming pure open woods, one of which in the Sierra de Albarracin is figured by Willkomm;² or growing mixed with other conifers, as in the fine forests of *Pinus Laricio* in the Serrania de Cuença. Here,² on the Muela de S. Juan, near Tragacete, it attains 25 ft. to 35 ft. high, and 10 ft. to 13 ft. girth.³ Laguna, who gives many localities for this species in Spain, states that it never ascends to the high altitudes occupied by *J. Sabina*, nor descends to the hot and sandy plains, where *J. phoenicea* is often seen. It inhabits the zone between 2500 and 3500 ft. altitude, where there are abrupt changes of temperature, which it supports well. It is always met with on soils which are either pure limestone, or contain lime in considerable quantity.

In Algeria,⁴ *J. thurifera* grows mainly in the cedar forests at high elevations, where it is usually a small tree, not exceeding 20 ft. in height. It was collected in southern Morocco by Sir J. D. Hooker. (A. H.)

Although this species was cultivated by Miller in 1752, it has never become common, and according to Kent only thrives in warm and sheltered situations. Loudon records a tree at Boyton 28 ft. high in 1837, and another at Croome, forty years planted, which was 30 ft. high in 1838, but we have not found these specimens now living. The largest tree in England is one at Bicton, about 40 ft. high, 4 ft. 4 in. in girth, conical in shape, and bearing male flowers in April 1911.

There are two trees at Kew, about 30 ft. high, which were planted in 1870. Another at Bayfordbury, 30 ft. high, was planted in 1841. Smaller trees exist at Highnam and Leonardslee. I saw a tree bearing ripe fruit at Simon-Louis's nursery, Metz, which was about 40 ft. by 3 ft. in 1908. (H. J. E.)

¹ Grisebach, *Veg. der Erde*, i. 572 (1872), states that it occurs in Sardinia. Cf. Nyman, *Consp. Fl. Eur.* iii. 676 (1881).

² Willkomm, *Pflanzenverb. Iber. Halbinsel*, 160, 185, fig. 11 (1896).

³ Dillwyn, *Hort. Collinson*. 27 (1843), quotes a letter written to Collinson in 1766 by Bowles, an engineer in Spain, who states that large trees, girthing 14 ft., with wide-spreading branches like a beech, grew in the mountains near the source of the Tagus. Willkomm confirms this.

⁴ Lefebvre, *Forêts de l'Algérie*, 431 (1900).

JUNIPERUS PACHYPHLÆA

Juniperus pachyphlæa, Torrey, *Pacific R. R. Rep.* iv. pt. v. 142 (1858); Sargent, *Silva N. Amer.* x. 85, t. 520 (1896), and *Trees N. Amer.* 90 (1905); Kent, Veitch's *Man. Conif.* 181 (1900); Britton and Shafer, *North American Trees*, 113 (1908).

Juniperus plochyderma, Parlatores, in De Candolle, *Prod.* xvi. 2, p. 492 (1868).

Sabina pachyphlæa and *plochyderma*, Antoine, *Cupress. Gatt.* 39, 40, t. 52 (1857).

A tree, attaining in America 60 ft. in height and 15 ft. in girth. Bark, different from that of all the other junipers, $\frac{3}{4}$ to 4 inches thick, deeply divided into small square scaly plates. Branchlets slender, angled, becoming light brown, terete, and scaly after the fall of the leaves. Leaves dimorphic: on vigorous branchlets, acicular, spreading, in threes and in opposite pairs, $\frac{1}{8}$ to $\frac{1}{4}$ in. long, tipped with slender elongated cartilaginous points; upper surface concave and whitened, lower surface greyish green and keeled. The juvenile foliage gradually passes into the adult foliage; ultimate branchlets tetragonal, $\frac{1}{25}$ in. in diameter, with scale-like leaves in opposite pairs, imbricated, closely appressed, about $\frac{1}{16}$ in. long, ovate-rhombic, rounded at the narrowed apex, minutely toothed in margin, convex on the back, which is marked with a depressed oval gland, often exuding resin; leaves on the older branchlets tipped with a sharp point.

Flowers diœcious. Fruit ripening in the second year, sub-globose, nearly $\frac{1}{2}$ in. in diameter, sub-sessile, ebracteate, reddish brown covered with a glaucous bloom, tuberculate on the surface, with six to eight scales each marked by a slightly reflexed mucro. Seeds four, nearly filling up the cavity of the fruit, ovoid, angled, shining brown; flesh scanty, fibrous, yellow.

Reputed juvenile forms of this species, vars. *conspicua*, *elegantissima*, and *ericoides*, differing in habit and with blue or whitish-blue foliage, have lately been obtained by Barbier¹ at Orleans; and are now in cultivation at Kew² and Glasnevin.

This species grows on dry arid mountain slopes, at 4000 to 6000 feet elevation, from the Eagle and Limpio Mountains in south-western Texas, westward along the desert ranges of New Mexico and Arizona, and southwards into Mexico, where it occurs along the Sierra Madre to the state of Jalisco and over the mountains of northern Sonora and Chihuahua.

It was discovered in 1851 by Dr. S. W. Woodhouse in eastern New Mexico, and is considered by Sargent to be the most beautiful of all the west American Junipers, its thick checkered bark being unlike that of any other species.

It is uncertain when it was introduced into England. It is extremely rare, the only specimen which we have seen being a tree in Kew Gardens, about 20 ft. high, showing the peculiar bark, and producing on its stem several epicormic branches. This has not as yet produced flowers. (A. H.)

JUNIPERUS CHINENSIS

Juniperus chinensis, Linnæus, *Mantissa*, i. 127 (1767); Loudon, *Arb. et Frut. Brit.* iv. 2505 (1838); Siebold et Zuccarini, *Fl. Jap.* 58, tt. 126, 127, (1844); Parlato, in De Candolle, *Prod.* xvi. 2, p. 487 (1868); Franchet et Savatier, *Enum. Pl. Jap.* i. 472 (1875); Masters, in *Journ. Linn. Soc. (Bot.)* xviii. 497 (1881), and xxvi. 541 (1902), and in *Journ. Bot.* xli. 268 (1903); Beissner, in *Mitt. Deut. Dend. Ges.* 1896, p. 69, and 1898, p. 32, and in *Bull. Soc. Bot. Ital. Firenze*, 1898, p. 167; Kent, *Veitch's Man. Conif.* 169 (1900); Shirasawa, *Icon. Ess. Forest. Japon.* i. text 29, t. 12, figs. 14-27 (1899); Diels, in Engler, *Bot. Jahrb.* xxix. 220 (1901).
Juniperus cernua and *dimorpha*, Roxburgh, *Fl. Ind.* iii. 839 (1832).
Sabina chinensis, Antoine, *Cupress. Gattung.* 54, t. 75 (1857).
Sabina Cabianca, Antoine, *Cupress. Gattung.* 41, t. 54 (1857).

A tree, attaining in China and Japan a height of 60 ft. Leaves of two kinds: on adult trees scale-like; ultimate branchlets $\frac{1}{2}$ in. in diameter, clothed with four ranks of leaves in opposite pairs, which are imbricated, closely appressed, narrowly rhombic, $\frac{1}{10}$ in. long, tapering to rather an obtuse apex, adnate to the stem, entire in margin; outer surface convex, green with a pale margin, and marked with a depressed oval or oblong gland; interiorly concave, with a raised narrow midrib, glaucous. On older branchlets the scale leaves are larger, about $\frac{1}{10}$ in. long, conspicuously glandular on the back, persistent four or five years. On young trees and on occasional branches of old trees, the juvenile foliage is linear-acicular, $\frac{1}{3}$ in. long, spreading, either in whorls of threes or in opposite pairs, tipped with a rigid spine-like point, adnate to the branchlets, swollen on the upper surface near the base, but not jointed; concave above, with a green midrib and two glaucous bands; green and convex beneath.

Flowers dioecious. Staminate flowers bright yellow, very numerous.¹ Fruit ripening in the second year, borne on the ends of short branchlets, which are covered with ordinary scale-leaves; brown covered with a thick white mealy bloom; variable in shape, commonly sub-globose, but widest and usually depressed at the summit, averaging $\frac{1}{3}$ in. in diameter, composed of four to eight scales. Seeds two or three, rarely four or five, immersed in a resinous pulp, shining deep chestnut brown, smooth, broadly ovoid, with a wide base, gradually tapering to a sharp thin-edged apiculate apex, compressed from before backwards, each surface convex, with a longitudinal groove near the thinner outer edges.

This species is readily distinguishable by the pale margins of the scale-like leaves, which mark the ultimate branchlets with a series of white crosses. In nearly all adult trees, acicular foliage with the leaves either ternate or in opposite pairs can be found on some of the branches.

VARIETIES

I. This species is very variable in habit in the wild state; and, as Beissner² points out, in the mountains of Shensi in China, both male and female trees exist,

¹ On certain trees at Kew, and in wild specimens of Shensi (*vide* Beissner) staminate flowers are borne on branchlets with acicular as well as with scale-like foliage; and this seems peculiar to *J. chinensis*.

² In *Mitt. Deut. Dend. Ges.* 1896, p. 69, and 1898, p. 32.

which bear exclusively acicular foliage; whilst others occur in both sexes with the leaves mostly scale-like. There are no grounds for supposing that the sexes are distinguished in nature by any peculiar habit; but in cultivation, owing to long-continued propagation by cuttings from trees of different habit, many female trees differ in appearance from that commonly met with in male trees. This is by no means universal, as there are two trees of the same habit, but of different sexes, in the Cambridge Botanic Garden. A common staminate form, with preponderating acicular foliage, and dense branches, forming a conical pyramid, was formerly distinguished as *J. struthiacea*, Knight, *Syn. Conif.* 12 (1850). A pistillate form, known at first as *J. flagelliformis*, Loudon, *Trees and Shrubs*, 1090 (1842), was introduced from Canton in 1839 by J. Russell Reeves, and was subsequently named *J. Reevesiana*, Knight, *Syn. Conif.* 12 (1850).

II. The following are either closely allied species or varieties of *J. chinensis*:—

1. *Juniperus sphaerica*, Lindley, in Lindley and Paxton, *Flower Garden*, i. 58, fig. 35 (1850).

Juniperus chinensis, Linnæus, var. *Smithii*, Gordon, *Pinetum*, 119 (1858) (not Loudon¹).

Juniperus Fortunei, Van Houtte, *ex* Gordon, *Pinetum*, 119 (1858).

A tree, 30 to 40 ft. high, discovered by Fortune² in the hills north-west of Ningpo and near Shanghai, where it is frequently planted around graves. The type specimen, preserved in the British Museum, does not differ from *J. chinensis* in the foliage, which is all scale-like, no acicular leaves being present; but is monœcious, and bears fruit, quite spherical in shape and larger than that of *J. chinensis*, $\frac{7}{10}$ in. in diameter, smooth, dark purple, scarcely glaucous, containing five seeds, which are larger than, but similar in shape and colour to those of *J. chinensis*.

This is kept separate from *J. chinensis*, but with some doubt, by Parlato,³ Kent,⁴ and Masters;⁵ and is probably only a variety of that species, differing mainly in the larger spherical fruit, not covered with a whitish bloom, and containing numerous seeds. The branch collected by Fortune is monœcious; but this is perhaps an abnormality.

A specimen (No. 6576) which I collected in Fang district in the province of Hupeh, with large spherical glaucous berries, resembles Fortune's plant, but is dioecious and with only three seeds in each fruit. Wilson found in the same province another specimen with smaller four-seeded fruits.⁶

Fortune sent seeds in 1850 to Standish and Noble, who probably raised *J. sphaerica* in their nursery; but I have found no living specimens, either monœcious or with the large spherical berries of Fortune's plant. The trees now known in cultivation either as *J. sphaerica* or *J. sphaerica Sheppardii*, Veitch, *Man. Conif.* 290 (1881), usually prove to be female trees of *J. chinensis*, with a rather spreading habit.

¹ *J. chinensis Smithii*, Loudon, *Arb. et Frut. Brit.* iv. 2505 (1838), described (long before Fortune's discovery of *J. sphaerica*) as monœcious with angular fruits, was supposed to be of Nepalese origin, and may have been *J. religiosa*.

² *Residence amongst the Chinese*, 63, 140 (1857).

³ In De Candolle, *Prod.* xvi. 2, p. 488 (1868).

⁴ *Veitch's Man. Conif.* 190 (1900).

⁵ In *Journ. Linn. Soc. (Bot.)* xxvi. 543 (1902).

⁶ The fruits of cultivated trees of *J. chinensis* are usually three-seeded; but occasionally four or five seeds are present, the fruits in this case being small, covered with whitish bloom, and depressed at the apex, and not in the least like the large spherical bluish fruits of *J. sphaerica*.

2. Var. *Sargentii*, Henry (var. *nova*).

Juniperus procumbens, Sargent, *Forest Flora Japan*, 78 (1894), and in *Garden and Forest*, x. 421 (1897) (not Siebold).

A sea-shore plant,¹ forming dense mats, and sending out for long distances prostrate creeping stems, which bear foliage similar to that of *J. chinensis*: branchlets tetragonal, covered with minute scale-like appressed leaves, furrowed on the back; no acicular leaves being present on adult plants. Berries bluish, covered with a slight glaucous bloom; seeds three, like those of *J. chinensis*.

This is said by Sargent, who has kindly sent a dried specimen, to grow on the coasts of Korea and Japan, on low grassy bluffs freely exposed to the ocean gales. A few plants were raised in the Arnold Arboretum from seeds gathered in 1892 near the Aino village of Horobetsu on the coast of Yezo. I have seen no living specimens.

III. The following varieties are of horticultural origin:—

3. Var. *albo-variegata*, Veitch, *Man. Conif.* 288 (1881).

A compact shrub, differing from the type in many of the branchlets being creamy white at the tips. It usually bears adult scale-like foliage; but a form with acicular foliage is also in cultivation. It is said to have been first introduced from Japan by Fortune, and subsequently by J. Gould Veitch. It is known by several names, as var. *variegata*, Fortune; var. *argentea*, Gordon; and var. *argenteo-variegata*, Rehder.

4. Var. *aurea*, Young, *ex Gard. Chron.* 1872, pp. 8, 1193.

An upright form, with adult scale-like foliage, having the whole of the young growth suffused with a deep golden yellow, which gradually turns green in the summer. The colour is heightened by exposure to the sun. This originated in Maurice Young's nursery at Milford, Godalming, where the original plant was 12 ft. high in 1872, and when Elwes saw it in 1909 was still a small tree. The best specimens we know of this are at Burnham Park, the residence of Sir Harry J. Veitch, and are about 18 ft. high.

5. Var. *japonica aurea*, Masters, in *Journ. R. Hort. Soc.* xiv. 211 (1892).

Juniperus japonica aurea, Carrière, *Conif.* 32 (1867).

A straggling shrub, with long decumbent branches; branchlets tinged with golden yellow. This is said to have been first introduced by Fortune from Japan, and subsequently by J. Gould Veitch.

6. Var. *japonica aureo-variegata*, Masters, in *Journ. R. Hort. Soc.* xiv. 211 (1892).

Juniperus japonica variegata, Carrière, *Conif.* 31 (1867).

A dense dwarf shrub, with many of the branchlets of a deep golden yellow. Also of Japanese origin.

7. Var. *Pfitzeriana*, Späth, *Catalogue*, No. 104, p. 142 (1899).

A broad pyramidal shrub, with dense horizontal branches, and long and slightly pendulous branchlets, clothed with glaucous foliage. This originated in Späth's nursery at Berlin, where the original plant was 10 ft. high in 1901.

8. Var. *japonica*, Vilmorin, in *Hortus Vilmorin.* 58 (1906).

Juniperus japonica, Carrière, *Conif.* 31 (1855).

¹ *J. Thunbergii*, Hooker and Arnott, *Bot. Beechey's Voyage*, 271 (1841), gathered in the Liu Kiu Islands, is represented at Kew by a specimen with acicular leaves, which bears no fruit. It cannot be identified with certainty; but may be a form of *J. chinensis*.

A diffuse bushy plant, with mostly juvenile acicular foliage in threes; some of the terminal branchlets being covered with adult scale-like leaves, and occasionally bearing fruit.¹

This is a juvenile form of *J. chinensis*, of which the Japanese make dwarf plants, that are frequently imported into Europe. It was erroneously identified by Carrière with *J. procumbens*,² Siebold; and this mistake has been copied by Kent and other writers. Sargent describes,³ as *J. japonica*, a plant of compact habit, with many erect branches and acicular bluish-green needles, which is often cultivated in Japanese gardens, and is very hardy and distinct in appearance. It retains its peculiar compact juvenile habit for several years, but often becomes thin and ragged before it is 12 ft. high, and loses its value as an ornamental plant. Sargent adds that this is one of the most difficult conifers to transplant. Judging from the description, the variety alluded to by Sargent is *J. japonica pyramidalis*, Carrière, *Conif.* 32 (1867), but I have seen no specimen. (A. H.)

DISTRIBUTION

J. chinensis is a native of China, Mongolia, and Japan. In China, it is frequently cultivated in temple grounds; but appears to be truly wild in the mountains of Hupeh, Shensi, and Szechwan, where it is usually found growing solitary on cliffs, but occasionally as underwood⁴ in the forests. Père David⁵ found it abundant on the Moni-ula range of the Ourato territory in south-western Mongolia.

This is a favourite tree in the parks and temples of Peking, where it attains a great age. The largest I saw were at the temple of Confucius, and were said to be over 700 years old. In a double avenue here, one tree on the left-hand side was about 40 ft. by 17 ft.; and another whose trunk was covered with burrs was 14 ft. in girth. At the Ming Tombs there are many very old junipers and fine specimens of arbor vitæ, together with numerous pine trees (*Pinus Bungeana* and *P. funebris*).

In Japan, it is also common in cultivation; but is recognised as a native tree by Japanese botanists⁶ and foresters. Shirasawa states that it is wild in the mountains of the Shinano province in central Hondo, mixed with *Pinus densiflora* and *Quercus serrata*, and forming a tree 30 to 40 ft. in height, with straggling contorted branches and greyish green foliage. It occasionally attains a large size, as Sargent⁷ mentions two venerable trees at the temple of Zenkogi in Nagano,⁸ which are 70 to 80 ft. high with hollow trunks about 6 ft. in diameter. I never saw it wild; but I saw several handsome trees in the ancient temple of Tennoji at Osaka, with fine large round heads, the best with a trunk 10 ft. high and 10 ft. in girth, and with a spread of branches of about 14 yards. One had a very twisted and fluted stem. This species is known to the Japanese as *Bya Kushin*.

¹ This is *J. japonica*, Carrière, and what is cultivated under that name in Veitch's nursery at Coombe Wood.

² *J. procumbens*, Siebold, is a very distinct species. Cf. p. 1422.

³ In *Garden and Forest*, x. 421 (1897).

⁴ Diels, in Engler, *Bot. Jahrb.* xxix. 220 (1901).

⁵ Franchet, *Pl. David.* i. 291 (1884), describes, as var. *pendula*, a form with elongated pendulous branches, found by Père David in Shensi.

⁶ Matsumura, *Index Pl. Jap.* 10 (1905), gives as localities, Kunasiri in the Kuriles, Rebunsiri in Yezo, Hakoda in Nippon, and the Liu Kiu Islands.

⁷ *Forest Flora of Japan*, 78 (1894).

⁸ Shirasawa states "the temple of Keuchoji in the province of Sagami."

This tree was first described in 1767 by Linnæus, who states that it was then cultivated at Upsala. It appears, however, to have been first introduced into England by William Kerr, who sent plants from Canton to Kew in 1804. Next to the Virginian juniper, it is the species now most commonly cultivated in nurseries and private gardens. It is absolutely hardy everywhere, seems quite indifferent to soil, and in many places is a very ornamental shrub or small tree. It ripens seed, which, so far as my observations go, germinate the year after they are sown. The finest trees we have seen are:—At Arley Castle, several old specimens, the largest of which was 48 ft. by 5 ft. 3 in. in 1907; at Eastnor Castle, a well-shaped tree, 48 ft. by 3 ft. which was bearing fruit in 1908; at Hardwicke, near Bury St. Edmunds, a fine tree, 38 ft. by 3 ft. 10 in., with abundant ripe berries in 1905; at Redleaf in Kent, a tree about 35 ft. high in 1907; at Westonbirt, a tree 32 ft. high and growing fast, which in 1909 was covered with fruit. A tree growing at Rood Ashton, Wilts, about 25 ft. high, wide-spreading in habit, was figured in *Gardeners' Chronicle*, xlii. 163, fig. 63 (1907). (H. J. E.)

JUNIPERUS BERMUDIANA

Juniperus bermudiana, Linnæus, *Sp. Pl.* 1039 (1753); Loudon, *Arb. et Frut. Brit.* iv. 2498 (1838); W. J. Hooker, in *London Journ. Bot.* ii. 141, t. 1 (1843); Endlicher, *Syn. Conif.* 29 (1847); Parlato, in De Candolle, *Prod.* xvi. 2, p. 490 (1868) (in part); J. M. Jones, *Botany of Bermuda*, 272 (1873); Hemsley, in *Gard. Chron.* xix. 656, figs. 105, 106 (1883), in *Journ. Bot.* xxi. 259 (1883), and in *Voy. Challenger, Bot.* i. 81, t. 5 (1885); Sargent, in *Garden and Forest*, iv. 289, figs. 51, 52 (1891); Masters, in *Journ. Bot.* xxxvii. 1-11 (1899); Kent, Veitch's *Man. Conif.* 166 (1900).

Juniperus oppositifolia, Moench, *Meth.* 698 (1794).

Juniperus pyramidalis, Salisbury, *Prod.* 397 (1796).

A tree, attaining 50 ft. in height in the Bermudas, with dark red bark and spreading branches. Foliage of two kinds: on adult trees scale-like; ultimate branchlets tetragonal, about $\frac{1}{10}$ in. in diameter, densely covered with imbricated leaves, which are usually in four ranks, about $\frac{1}{2}$ in. long, ovate, obtuse at the narrow incurved apex, greyish green or glaucous on the back, which is usually marked with a longitudinal furrow, entire in margin; on older branchlets, in four ranks or ternate in six ranks, those on the main axes always ternate, up to $\frac{1}{4}$ in. long, and becoming acuminate at the apex. Juvenile foliage, occasionally present on some branches on old trees, in alternate whorls of threes, about $\frac{1}{3}$ in. long, acicular, slightly spreading; upper surface whitened with a raised midrib; lower surface greyish green, very convex, and marked with a longitudinal furrow.

Flowers dioecious.¹ Fruit ripening in the first year, sub-globose, about $\frac{1}{4}$ in. in diameter, dark brown, covered more or less with a bluish bloom, with six to eight scales, each marked by a depression with a minute mucro. Seeds, two to three, immersed in fleshy pulp, shining chestnut brown, ovoid, oblique at the broad base, tapering to the thin-edged apex, with two furrows on the outer surface.

¹ Stewardson Brown, in *Proc. Acad. Nat. Sc. Philadelphia*, lxi. 488 (1909), says that the tree is dioecious: "At the time of flowering in March and April the staminate trees are a golden colour, presenting a strong contrast with the rich blue-green of the pistillate tree." Most authorities say it is monoecious, but specimens with fruit in the British Museum bear no male flowers.

This species is confined¹ to the Bermuda Islands, where it is the only indigenous exogenous tree. It was formerly abundant² on the islands, thriving both on the dry limestone hills and in the brackish swamps. The trees grow to a large size in the salt-water marshes, and have much darker heartwood than those on the hills, but not nearly so durable.³ Large trees are no longer common. Sargent⁴ gives an illustration of one in the churchyard of Devonshire parish, which was about 50 ft. high and 15 ft. in girth, and states that only two larger trees were known to exist. Another illustration shows the habit of this species in the Devonshire marshes. The wood was formerly much used in shipbuilding and in making beautiful furniture. "Cedar" chests and cabinets over two hundred years old are preserved as heirlooms by the descendants of the old Bermuda families, who live in houses finished with this wood, which becomes with age a rich dark colour like mahogany.

The Bermuda juniper was cultivated⁵ in England as early as 1684, but it is not hardy in the climate of London. Knight and Perry⁶ state that it was hardy in their day in Devonshire, and that plants remained uninjured in the open air during the winter of 1849 in Oxfordshire. We have seen, however, no living specimens in England except a shrub at Bicton, about 2 ft. high, which is not thriving, and small plants which were received at Kew⁷ in 1910. Reputed specimens of this species at Castlewellan,⁸ as well as some plants that were formerly cultivated at Kew under the name *J. bermudiana*, turned out to be *Cupressus funebris*.

This species is cultivated in the south of France, Italy, and the Canary Isles. There is a good specimen, which bears fruit regularly, in Dr. Perez' garden at Orotava. Dr. Perez,⁹ as the result of numerous experiments, finds that seeds of this species germinate speedily when immersed in boiling water for three, six, or ten seconds, and at the end of the time are plunged into water at 65° to cool. Longer exposure to boiling water destroys the embryos. (A. H.)

JUNIPERUS VIRGINIANA, PENCIL CEDAR

Juniperus virginiana, Linnæus, *Sp. Pl.* 1039 (1753); Loudon, *Arb. et Frut. Brit.* iv. 2495 (1838); Parlato, in De Candolle, *Prod.* xvi. 2, p. 488 (1868); Sargent, *Silva N. Amer.* x. 93 (in part), t. 524 (1896), and *Trees N. Amer.* 94 (1905); Kent, Veitch's *Man. Conif.* 192 (1900); Mohr, *U.S. Forestry Bull.* No. 31 (1901); Pinchot, *U.S. Forestry Circ.* No. 73 (1907); White, *U.S. Forestry Circ.* No. 102 (1907); Clinton-Baker, *Illust. Conif.* ii. t. 74, fig. 4 (1909).

Juniperus caroliniana, Miller, *Dict.* ed. 8, No. 4 (1768).

Juniperus arborescens, Moench, *Meth.* 699 (1794).

Juniperus fragrans, Salisbury, *Prod.* 397 (1796).

Sabina virginiana, Antoine, *Cupress. Gattung.* 61, tt. 83, 84 (1857).

A tree, attaining in North America 100 ft. in height and 12 ft. in girth, often

¹ Kent states that pieces of its wood were found 50 ft. below low-water mark, during dredging operations undertaken for the construction of a dock.

² J. M. Jones, *Botany of Bermuda*, 272 (1873), states that the trees are becoming extinct, no longer growing in the salt-marshes; but Sargent's later account does not confirm this.

³ A. Haycock, in *Gard. Chron.* xxv. 176 (1899). Capt. L. Clinton-Baker informs us that the best trees in 1911 averaged 40 to 50 ft. in height and 9 ft. in girth.

⁴ *Garden and Forest*, iv. 289, figs. 51, 52 (1891).

⁶ For the early history of this species, see Hemsley's account, cited at the head of this article. ⁶ *Syn. Conif.* 11 (1850).

⁷ A tree in the Temperate House at Kew, which was about thirty years old, was cut down in 1905.

⁸ *List of Plants Hardy at Castlewellan*, 65 (1897). ⁹ In *Gard. Chron.* l. 127 (1911).

with the trunk fluted at the base. Bark, $\frac{1}{4}$ in. thick, reddish brown, shredding off in long strips. Leaves of two kinds: on adult trees scale-like; ultimate branchlets very slender, $\frac{1}{30}$ in. in diameter, clothed with four ranks of leaves in opposite pairs, which are imbricated, appressed but free towards the apex, ovate, acute or acuminate with a short point, $\frac{1}{16}$ in. long, adnate, entire in margin; green and glabrous on the back, which is often marked with a small oval glandular depression. On older branchlets the scale-leaves are broadly ovate, acute, larger, about $\frac{1}{2}$ in. long, and become brown and withered, ultimately disappearing in the fifth or sixth year. Acicular leaves often present on occasional branches of adult trees, spreading in pairs, $\frac{1}{5}$ to $\frac{1}{4}$ in. long, ending in a spine-tipped apex, adnate, swollen at the base, but not jointed; concave and glaucous above; green and convex beneath. The acicular leaves on seedlings and young plants are arranged in alternate whorls of threes.

Flowers usually diœcious, rarely monœcious. Fruit ripening in one year, borne at the ends of short branchlets, which are furnished with ordinary adult scale-leaves; sub-globose, but usually longer than broad, about $\frac{1}{4}$ in. long, bluish, covered with a glaucous bloom, composed of four or six scales. Seeds, one or two, immersed in a resinous flesh, ovoid, broad at the base, tapering towards the apex, smooth, shining chestnut brown, with two indistinct longitudinal furrows, and with or without resin-pits at the base. Seedling¹ with two ligulate cotyledons, which have no resin-canals; primary needles with one resin-canal immediately below the dorsal ridge.

ALLIED SPECIES AND VARIETIES

This species was formerly supposed to spread over the greater part of the North American continent; but the geographical forms of the west and south are now considered by American botanists to be two distinct species.

I. *Juniperus scopulorum*, Sargent, in *Garden and Forest*, x. 420, fig. 54 (1897), *Silva N. Amer.* xiv. 93, t. 739 (1902), and *Trees N. Amer.* 96 (1905).

Juniperus excelsa, Pursh, *Fl. Amer. Sept.* ii. 647 (1814) (not Bieberstein).

Juniperus dealbata, Loudon, in *Gard. Mag.* xvi. 639 (1840), and *Trees and Shrubs*, 1090 (1842) (not Douglas²).

(?) *Juniperus fragrans*, Knight and Perry, *Syn. Conif.* 13 (1850); Carrière, *Conif.* 57 (1855).

Juniperus bacciformis, Carrière, *Conif.* 56 (1855).

Juniperus Henryana, Brown (Camptst.), in *Trans. Bot. Soc. Edin.* ix. 377 (1868), and in *Gard. Chron.* 1873, p. 8.

Juniperus virginiana, Linnæus, var. *scopulorum*, M. E. Jones, in *Bull. Univ. Montana, Biol. Ser.* No. 13, p. 12 (1910).

Sabina scopulorum, Rydberg, *Flora of Colorado*, 10 (1906).

A tree about 40 ft. high and 9 ft. in girth, often divided near the base into several stems. Adult foliage like that of *J. virginiana*, but with a disagreeable pungent smell, and with stouter branchlets and leaves marked on the back by a conspicuous glandular pit. Fruit ripening in the second year, globose, $\frac{1}{4}$ in. in diameter, bright blue covered with a glaucous bloom. Seeds, two, triquetrous, reddish brown, prominently angled, and with one longitudinal groove.

This tree grows on dry rocky ridges and, except near the coast, usually at over

¹ Hill and De Fraine, in *Ann. Bot.* xlii. 696 (1908).

² Gordon, in *Gard. Chron.* 1842, p. 562, states that *J. dealbata*, Douglas, is the same as *J. nana*, Willdenow. Cf. p. 1401, note 1.

5000 feet elevation, from the eastern foothills of the Rocky Mountains from Alberta to Texas, westward to the coast of British Columbia and Washington, and to eastern Oregon, Nevada, and northern Arizona. This species was introduced into England from north-western America in 1839, under the name *J. dealbata*, Loudon; and was erroneously identified with *J. occidentalis*, Hooker, a species that has apparently never been in cultivation in this country. Soon after its introduction, *J. scopulorum* seems to have been known as *J. fragrans*, a name which still exists in nursery catalogues. It is a rare tree; but there is a specimen at Kew, not very thriving and about 15 ft. high, which is labelled *J. occidentalis fragrans*. We obtained in 1911 a fruiting branch from a small plant, named *J. fragrans*, in Dicksons' nursery, Chester. It is cultivated in Germany,¹ at Darmstadt and at Tübingen, where it has borne a temperature of -24° Cent.

II. *Juniperus barbadensis*, Linnæus, *Sp. Pl.* 1039 (1753); Loudon, *Arb. et Frut. Brit.* 2504 (1838); Mohr, *U.S. Forestry Bull.* No. 31, p. 37, plate ii. (1901); Sargent, *Silva N. Amer.* xiv. 89, t. 738 (1902), and *Trees N. Amer.* 95 (1905).

Juniperus virginiana, Linnæus, var. *australis*, Endlicher, *Syn. Conif.* 28 (1847).

Juniperus virginiana barbadensis, Gordon, *Pinetum*, 114 (1858) (in part).

Juniperus bermudiana, Lunan, *Hort. Jamaic.* i. 84 (1814) (not Linnæus).

Sabina barbadensis, Small, *Flora S.E. United States*, 33 (1903).

A tree, attaining 50 ft. in height and 6 ft. in girth; branches and branchlets pendulous. Adult foliage similar to that of *J. virginiana*, but branchlets more slender, and leaves smaller, acuminate, and conspicuously marked on the back by an oblong or linear oil-gland. Flowers diœcious. Fruit ripening in the first year, sub-globose, $\frac{1}{8}$ to $\frac{1}{6}$ in. in diameter, bluish with a glaucous bloom; seeds, one or two, ovoid, pointed, ridged.

This species occurs in inundated coastal river swamps from southern Georgia southward to the Indian River, Florida; and on the west coast of Florida from Charlotte Harbour to the Appalachicola River, often forming thickets under the shade of larger trees. It is often planted in the cities and towns near the coast from Florida to western Louisiana, and is now said to be naturalised on the Gulf Coast. This species also occurs in the West Indies, in San Domingo, the Bahamas, Antigua, St. Lucia,² and the mountains of Jamaica. It appears to be now extinct in Barbadoes.²

The "red cedar" which grows on the northern Bahama Islands is usually referred to this species, but it has lately been separated³ as *Juniperus lucayana*, Britton, on account of its depressed globose and somewhat laterally flattened fruit. Little is left of it on account of its use formerly for construction and in more recent times for making pencils. The juniper of eastern Cuba is closely related to, if not identical with, that of the Bahamas.³

III. *Juniperus Bedfordiana*, Loudon, *Trees and Shrubs*, 1090 (1842).

Juniperus gracilis, Endlicher, *Syn. Conif.* 31 (1847).

Juniperus virginiana, Linnæus, var. *Bedfordiana*, Knight, *Syn. Conif.* 12 (1850); Parlatores, in De Candolle, *Prod.* xvi. 2, p. 489 (1868); Veitch, *Man. Conif.* 284 (1881); Kent, Veitch's *Man. Conif.* 193 (1900).

Juniperus virginiana, Linnæus, var. *gracilis*, Sargent, in *Silva N. Amer.* x. 96, note 1 (1896).

¹ *Mitt. Dent. Dend. Ges.* 1906, p. 37, and 1908, p. 144.

² Cf. Stapf, in *Kew Bull.* 1911, p. 377.

³ Britton and Shafer, *North American Trees*, 121 (1908).

A dense low tree, columnar in habit, with slender elongated pendulous branchlets; leaves bright green, acicular, like the juvenile foliage of *J. virginiana*. This handsome tree was first mentioned by Loudon, who merely states that it closely resembles *J. virginiana*. Its origin is unknown,¹ but it is usually considered to be identical with *J. barbadensis*, and the fact that it is rather tender in England supports this view. As it has only juvenile foliage, and apparently never bears fruit, the question cannot be decided.

IV. Many varieties of *J. virginiana*, which are always propagated by cuttings, have arisen in nurseries, no less than twenty-one varieties being enumerated in the Kew Hand-List. According to Loudon, it varies much when raised from seed, as at White Knights, where there were hundreds of trees in 1838, differing much in appearance. Some were low and spreading, others were tall and fastigate, and some had pendulous branches. The foliage varied much in colour, being light green, dark green, or glaucous. The fruit also differed in size. The most important varieties are:—

1. Var. *pendula*, Knight, *Syn. Conif.* 12 (1850).

This exists in at least three forms:—

(a) Branches spreading, branchlets pendulous, leaves scale-like, bearing staminate flowers.

(b) Var. *pendula viridis*. Branches and branchlets pendulous; leaves scale-like, bright green.

(c) Var. *Chamberlainii*, Knight, *loc. cit.* Branches spreading and reflexed; branchlets pendulous; leaves mostly acicular, of a greyish tint.

2. Var. *pyramidalis*, Carrière, *Conif.* 47 (1867).

Columnar in habit, with either glaucous or bright green foliage.

3. Var. *dumosa*, Carrière, *Conif.* 45 (1855).

A dense rounded shrub, with both acicular and scale-like leaves.

4. Var. *Schottii*, Gordon, *Pinetum*, 157 (1875).

A narrow pyramidal tree, dense in habit, with bright green scale-like leaves.

5. Var. *tripartita*, R. Smith, *ex Gordon*, *Pinetum*, 157 (1875).

A low spreading bush with dense branches, and bright green, usually acicular foliage.

6. Var. *glauca*, Knight, *Syn. Conif.* 12 (1850).

Differs from the type in its beautiful glaucous silvery foliage, which is most pronounced in spring.

7. Var. *Triomphe d'Angers*, Beissner, *Nadelholzkunde*, 127 (1891).

Young branchlets creamy white, contrasting well with the dark bluish-green of the older foliage.

8. There are several variegated varieties, as *alba variegata* and *aurea variegata*, Gordon, *Pinetum*, 157 (1875), which are usually poor in colour.

9. Var. *elegantissima*, Beissner, *Nadelholzkunde*, 128 (1891).

A pyramidal tree, with the tips of the young branchlets golden yellow.

¹ There appears to be no ground for Loudon's statement, *Trees and Shrubs*, 1118 (1842), that it is identical with *J. gossainthana*, Loddiges, as the latter and *J. Bedfordiana* are kept distinct by Knight and Perry, *Syn. Conif.* 11, 12, 13 (1850). Endlicher states that *J. Bedfordiana* is a native of Mexico.

10. The dwarf forms are often like *J. Sabina*, and are hard to distinguish in the absence of fruits, except by the much stronger disagreeable odour of the bruised branchlets of the latter species. (A. H.)

DISTRIBUTION

The distribution of this species, as now limited by Sargent,¹ is as follows:— From southern Nova Scotia and New Brunswick southward, often close to the sea-coast, to Georgia, southern Alabama and Mississippi, westward to the valley of the lower Ottawa river, eastern Dakota, eastern Nebraska, Kansas, Indian Territory, and eastern Texas; not ascending the mountains of New England and New York, nor the high southern Alleghanies; in middle Kentucky and Tennessee and northern Alabama and Mississippi, covering great areas of low rolling limestone hills with nearly pure forests of small bushy trees.

In New England it is very common in the south, rarer in Maine, New Hampshire, and Vermont; but nowhere, so far as I saw, attains the size of old trees in England. Dame and Brooks² give 25 to 40 ft. with a trunk diameter of 8 to 20 in. as the average size, and I saw none larger. It grows here on principally dry, rocky, and exposed hills, but also sometimes in wet ground; and on the abandoned cultivated fields which are so numerous in the hilly and poorer parts of Massachusetts is taking possession of the soil in many places. At Boston I noticed that both in Prof. Sargent's own grounds and in the Arboretum, pencil cedar was coming up freely from seed; and I have no doubt it will be planted largely in suitable localities farther south. The rapidly increasing demand for its useful wood has cleared out the accessible timber already in many districts.

In Canada, it is a comparatively rare tree, and is confined³ to the limestone districts in the St. Lawrence valley and along Lake Ontario to the Niagara peninsula, where considerable areas were covered with it in 1888. All the timber of any value has now been cut here, as it has been in New England generally.

Mohr says that there is hardly any tree in the Eastern States which is so indifferent to soil and climate as the juniper. It thrives in the valley of the St. Lawrence and in New England, often growing on barren hillsides where few trees succeed; on the exposed arid regions of Kansas and Nebraska, in air and climate with great extremes of heat and cold; on the limestone plateaux and hills of the south-western States, and on the deep soil of the coast of Georgia, but not ascending the mountains or descending to the alluvial river bottoms. It attains its maximum development south of lat. 36°, where in Alabama it is sometimes as much as 100 ft. in height, but is much oftener 60 to 70 ft. high, and in the north rarely exceeds 40 to 50 ft. and is often a mere shrub. As a rule it is scattered among other trees and forms a small proportion of the forest; but in the so-called "Cedar Barrens" of Tennessee, it formerly formed an almost pure forest extending over large areas;

¹ Sargent, in *Garden and Forest*, viii. 61, fig. 9 (1895), gives an excellent illustration of a mature tree near Wawa Station, Delaware County, Pennsylvania.

² *Trees of New England*, 27 (1902).

³ Britton and Shafer, *North American Trees*, 117 (1908), state that it also occurs in poor and rocky soil in Nova Scotia and New Brunswick; and there is a specimen in the Kew herbarium from Newfoundland.

and in the rocky hills of the Tennessee valley grows in mixture with ash, maple, and oak, and in the prairies of Alabama, with magnolia, lime, and hickory.

It grows best on a light loamy soil containing lime, and does not come to perfection on clay or sand. It reproduces itself freely from seed, which it bears every year, the berries being a favourite food of many birds, which scatter it widely. The seedlings endure shade, and spread over abandoned farms in New England and in the south; but Mohr says that its habit of reproducing itself from suckers seems to have weakened the vitality of the seed, and that under the best conditions only 15 to 25 per cent of the seed will germinate.

Excellent illustrations are given in Mohr's paper showing the botanical details and the structure of the wood, with a map giving the distribution of both this species and *J. barbadensis*.

CULTIVATION

Though described by Parkinson in 1640, and introduced to England before 1664 by Evelyn,¹ it has never become an abundant tree in England; and was much more generally planted a century ago than it is now. In most old places it may be found in a more or less damaged condition, for though a long-lived tree it is often broken by wind and snow; and it varies so much from seed that it is often mistaken for other species. As, however, it is very hardy, and will grow in almost any kind of dry and well-drained soil, but only to a large size where this is also deep and fertile, it should be planted more generally, and in some parts of the south of England might be tried for the sake of its very valuable timber. It is easily raised from seed,² and grows faster than the common juniper, but it does not produce seed freely in most places; and I am unable to say what part of America seed suitable for English planting is most likely to come from. Though in the northern United States and Canada it is usually a small and scrubby tree as compared with the large size it attains in the south, I can find no evidence that under cultivation this difference is reproduced. Prof. N. E. Hansen of the South Dakota Agricultural College, however, states, in a paper³ on the "Breeding of Cold-Resistant Fruits," that "The red cedar was formerly brought in large quantities from Tennessee, which is well to the south; northern nurserymen have learned that they must cultivate only the northern form of the red cedar to avoid total failure."

It seems to require fairly close planting, as well as pruning, in order to get a clean trunk; but I do not know to what extent it is capable of bearing shade in this climate. Under favourable conditions in America the growth at first is very rapid, trees only twelve years old having attained in Alabama 25 ft. high and 1 ft. in diameter. Up to from seventy to one hundred and twenty years the increase continues good, but after that age the trees often begin to decay, though they may live for several centuries, and attain a diameter at the butt of 2 to 4 ft.

¹ Aiton, *Hort. Kew.* v. 414 (1813).

² Sargent, in *Garden and Forest*, viii. 61 (1895) says that the seeds should be gathered in autumn and then moistened and mixed with sand, and kept in a pit till the following autumn, or the second spring, when they will produce strong plants, 6 to 8 in. high at the end of their second season and ready for transplanting.

³ *Report of Conference on Genetics (Roy. Hort. Soc.)*, 1906, p. 402.

Sargent says¹ that it bears pruning well, and is suitable for formal gardening; but is not good as a hedge plant, as its branches die when they come in contact with those of a neighbouring tree. There is, however, a thick hedge of this species in Barbier's nursery at Orleans, which is said to grow at the rate of a foot per year.

Trees in the American forest are often attacked by two species of *Polyporus*, which cause white rot and red rot of the timber, spoiling it for commercial purposes. These diseases have been described by Schrenk.²

As a rule, this species, like other junipers, is seen in a bushy form, but on good soil it is capable of producing a clean trunk of considerable length, and this would no doubt be more often the case if planted closer and pruned when young. Mr. A. D. Webster assures me that a tree which grew on sandy loam at Esher, had a trunk with a clean and well-rounded stem free from branches, for 33 ft. in length, and when measured by him contained fully 51 cubic ft. of timber.

REMARKABLE TREES

Among the finest specimens I have seen in England the largest is an immense old tree at Pains Hill, close to the cedar figured on Plate 128. It measures 13 ft. 9 in. in girth, with a bole about 5 ft. high, dividing into several stems, more or less broken, but one attains 68 ft. in height. At Woolbeding, in Col. Lascelles' grounds, there is a fine tree 65 ft. by 6 ft. 8 in. in 1906. At Bagshot Park a tree with a clean trunk measured 64 ft. by 7 ft. in 1907. At Sherborne, Dorsetshire, a clean-stemmed tree on the ruins of the old castle, 60 ft. by 7 ft. 3 in., is long past its prime. At Coolhurst, Sussex, there is a symmetrical tree 62 ft. by 7 ft. 3 in., and another, 56 ft. by 4½ ft. with a clean trunk of 25 ft. At Arley Castle,³ a tree in 1910 measured 68 ft. by 4 ft. 10 in. It is supported by a wire, as it was blown over and pulled upright again several years ago. At Raglan Castle, Monmouthshire, inside the ruins there is a fine old tree 53 ft. by 4 ft. 10 in. in 1906. At Wimpole, Cambridgeshire, a very handsome tree with pendulous branchlets was 50 ft. high in 1908.

In Scotland, the tree does not seem to attain so large a size, the best I have seen being one at Moncrieffe, Perthshire, which⁴ was 47 ft. by 6 ft. 10 in. in 1907. Another, at Murthly, in the Tayside walk, which in 1906 was bearing many berries, measured 40 ft. by 3½ ft.

We have seen no large trees in Ireland; but there is a good specimen of var. *glauca* at Hamwood.

The most remarkable trees that I have seen in Europe are two in the grounds of the Trianon, at Versailles, one of which, not more than about 30 ft. high, has immense spreading branches, which cover an area 57 paces round. The other, close to the château, I could not measure, but estimated it to be 75 ft. high. At Colombe, near Metz, there is an avenue of about fifty old trees, 40 to 50 ft. high, with trunks 4 to 5 ft. in girth, growing in an exposed situation.

¹ *Garden and Forest*, x. 142 (1897).

² *U.S. Dept. Agric. Bull.* No. 21 (1900).

³ Woodward, *Hortus Arleyensis*, No. 4 (1907).

⁴ Mentioned by Hunter, *Woods, Forests, and Estates of Perthshire*, 136 (1883), as *Cupressus thyoides viridis*.

In some parts of Germany the tree grows very well, but does not seem to have any economic value, and in Dr. Mayr's¹ opinion is only likely to be useful in the south of Europe.

TIMBER

The timber of the common and of the southern species present no essential difference and are not distinguished in commerce, though at the present time the greater part of that imported to Europe comes from the Southern States, that from Florida produced by *J. barbadensis* being considered the best.

Its great resistance to decay makes it very valuable, and formerly, when commoner, it was largely used in America for fencing, telegraph poles, boat- and house-building. Now, however, trees large enough for such purposes can hardly be found in the north, and the principal use for which it serves is to make the casing of lead-pencils. Mohr states that for this purpose alone 500,000 cubic feet are annually used in the United States, and 75,000 more exported, most of this going to Germany.

At Greenville, Alabama, the logs are cut into pieces of five standard sizes, varying from $\frac{3}{4}$ to $2\frac{1}{4}$ in. thick, which are packed for shipment in square wooden cases. The waste and sawdust from the mills is made into fine shavings, used for protecting furs and woollen goods against moths, and into paper for underlaying carpets.

Cigar-boxes are also made from this wood in Germany; but most of the so-called cedar in which Havana cigars are packed is the wood of *Cedrela odorata*, a very different tree of the West Indies.

Though in former times the wood was commonly used in this country for the finer kinds of joiner's work and interior decoration, under the name of cedar, red cedar, or pencil cedar, yet it has, during the last generation, become so scarce and dear, that its use is almost confined to the making of pencils. The greater part of the logs imported at present are from Jamaica, Alabama, and Georgia; and are usually small and faulty. The few large and clean ones which arrive are worth from 6s. to 8s. per cubic foot, whilst small logs and billets are sold at 2s. to 6s. per cubic foot in London.

The heart-wood is of a pinkish brown, becoming darker with age, and fading on exposure to the sun, and the sap-wood is whitish. It is distinguished by its fragrance, which, however, is fainter than that of Lebanon cedar, Lawson cypress, or camphor wood; and not too strong to use for the panelling or ceilings of living rooms. No wood is better adapted for delicate mouldings or carvings, though it is too soft to be used in any positions exposed to friction or contact with furniture. In some cases the heart-wood of old trees is beautifully variegated and twisted, and such pieces would be of the highest value for cabinetmaking, if procurable; but I have hardly ever seen the waved or curly grain, which is so ornamental in some other conifers, as pitch pine, redwood, or American cypress.

One of the best examples of the use of this wood for ornamental work is in the

¹ *Fremdländ. Wald- u. Parkbäume*, 292 (1906). Cf. Schwappach, in *Zeitschr. Forst- u. Jagdwesen*, xliii. 602 (1911), and in *Mitt. Deut. Dend. Ges.* 1911, p. 11.

library of Lord Llangattock's house, The Hendre, near Monmouth, which was panelled and ceiled by Messrs. Norman and Burt, from the design of Sir Aston Webb. Overmantels of this wood have been taken out of old London houses, where they have been for probably two centuries, and have realised very high prices; and on account of its scent, it was a favourite wood in early Victorian times for lining wardrobes, or for matchboarding bathrooms in country mansions. The roof of the fine old church at Bitton, near Bath, is entirely lined with pencil cedar, which was executed under Canon Ellacombe's direction, with wood purchased from a ship wrecked in the Bristol Channel; and though the odour is not strong enough to be very noticeable, except in damp weather, the effect is very good.

Oil of cedar, for which there is a large demand in the United States, is distilled from sawdust and other refuse of the wood, at Cedar Keys in Florida.¹ The wood contains as much as 4 or 5 per cent of this oil, which is used as a taenifuge. The shoots of *J. virginiana* are sometimes used medicinally in the United States, as a substitute for the true savin, but contain considerably less essential oil.²

(H. J. E.)

JUNIPERUS SABINA, SAVIN

Juniperus Sabina, Linnæus, *Sp. Pl.* 1039 (1753); Loudon, *Arb. et Frut. Brit.* iv. 2499 (1838); Parlatore, in De Candolle, *Prod.* xvi. 2, p. 483 (1868); Bentley and Trimen, *Medicinal Plants*, iv. t. 254 (1880); Mathieu, *Flore Forestière*, 518 (1897); Ascherson and Graebner, *Syn. Mitteleurop. Flora*, i. 251 (1898); Kent, *Veitch's Man. Conif.* 189 (1900); Kirchner and Schröter, *Lebengesch. Blütenfl. Mitteleuropas*, i. 320 (1906).
Sabina officinalis, Garcke, *Fl. Nord- u. Mitteleuropas*, 387 (1858).

A shrub, attaining about 15 ft. in height, with foliage of a strong and disagreeable odour, and bitter to the taste. Leaves of two kinds; on adult shrubs scale-like; ultimate branchlets very slender, tetragonal, $\frac{1}{30}$ in. in diameter, clothed with 4 ranks of leaves in opposite pairs, which are imbricated, appressed, ovate, acute or blunt at the apex, about $\frac{1}{20}$ in. long, adnate in their lower half, entire in margin, rounded on the back, which usually bears an elliptic depressed resin-gland. On older branchlets, the leaves are more elongated, about $\frac{1}{8}$ in. long, acuminate, becoming brown and withered in the third and fourth years. On young plants, and on isolated branches of adult shrubs, the juvenile foliage is acicular, slightly spreading, in opposite pairs, about $\frac{1}{8}$ in. long, acuminate at the apex, adnate and not jointed at the base; upper surface concave, glaucous, and with a prominent midrib; lower surface, green, convex, marked with a longitudinal depressed gland.

Flowers monœcious or diœcious. Fruit ripening in the autumn of the first year or in the following spring, borne on the ends of short scaly recurved branchlets; irregularly globose or ovoid, about $\frac{1}{8}$ in. in diameter, brownish blue, covered with a glaucous bloom, composed of four to six scales, each marked with an obsolete

¹ *Garden and Forest*, ii. 301 (1889).

² Flückiger and Hanbury, *Pharmacographia*, 628 (1879).

micro.¹ Seeds usually two, rarely one or three, immersed in a resinous flesh, ovoid-triquetrous, compressed, narrowed towards the apex, shining brown, with two or three longitudinal furrows, and verrucose on both surfaces towards the summit.

VARIETIES

The Savin, like most species of juniper, is variable in habit in the wild state in Europe, either occurring as a low prostrate shrub with the branches widely extended and lying on the ground, or as a tall upright dense pyramidal shrub, with horizontal or ascending branches. A fastigiate form has also been observed, similar in appearance to the Swedish variety of the common juniper.

The leaves on the adult plant are usually small, scale-like, blunt at the apex, and closely appressed, acicular leaves being not very common in the typical form. The following varieties, differing in foliage, have been described:—

1. Var. *lusitanica*, Ascherson and Graebner, *Syn. Mitteleurop. Flora*, i. 253 (1898).

Juniperus lusitanica, Miller, *Gard. Dict.* ed. 8, No. 111 (1768).

Juniperus sabinoïdes, Grisebach, *Spicil. Fl. Rum.* ii. 352 (1848) (not Nees²).

An upright shrub, with scale-like leaves, which are sharply acuminate at the apex. This variety is common in southern Europe.

2. Var. *tamariscifolia*, Solander, in Aiton, *Hort. Kew.* iii. 414 (1789).

A low spreading shrub, with mostly persistent juvenile acicular foliage; leaves on the ultimate branchlets in opposite pairs, slightly spreading, glandular on the dorsal surface, bright green in tint, about $\frac{1}{8}$ in. long; on the older branchlets, occasionally in whorls of threes. This variety, which has been known in cultivation for at least 200 years, is occasionally met with in the wild state in Europe.

3. Var. *variegata*, Carrière, *Conif.* 36 (1855).

A dwarf shrub, with adult scale-like foliage, the tips of some of the young branchlets being creamy white. This is mentioned by Loudon, and was known over a century ago in gardens. It is often planted in rockeries.

4. Var. *prostrata*, Loudon, *Arb. et Frut. Brit.* iv. 2499 (1838).

Juniperus prostrata, Persoon, *Syn. Pl.* ii. 632 (1807); Kent, Veitch's *Man. Conif.* 183 (1900); Britton and Shafer, *N. Amer. Trees*, 120 (1908).

Juniperus Sabina, var. *procumbens*, Pursh, *Fl. Amer. Sept.* 647 (1814); Jack, in *Bot. Gaz.* xviii. 372 (1893).

Juniperus repens, Nuttall, *Gen. Amer.* ii. 245 (1818).

A depressed, usually procumbent shrub, seldom more than 3 ft. high. Leaves usually of two kinds; the scale-like leaves appressed in four ranks, mucronate at the apex, with a well-marked depressed resin-gland, and similar to those of the type;

¹ The berries are in rare cases open and not coalesced at the summit, the tips of the seeds protruding. This sport is known as var. *gymnosperma*, Schröter, *op. cit.* 333, fig. 176 (1906).

² *J. sabinoïdes*, Nees, in *Linnaea*, xix. 706 (1847), is better known as *J. mexicana*, Sprengel, *Syst.* iii. 909 (1826), and is a native of Texas and Mexico.

the acicular leaves on a few of the branchlets, in opposite pairs, slightly spreading, with a longitudinal depressed gland on the back, about $\frac{1}{6}$ in. long. Fruit, on recurved stalks, light blue and scarcely glaucous, $\frac{1}{4}$ in. in diameter, with one to four seeds.

This, which is the American form¹ of the Savin, is considered by some botanists to be a distinct species. It is distributed from southern Maine to the shores of Hudson Bay, and westward from Newfoundland and northern New England through New York along the shores of the Great Lakes and through northern Minnesota and south Dakota to the eastern slopes of the Rocky Mountains in Alberta, Montana, and Wyoming. The American Savin grows mainly on sandy soil, as on the seashore of the Atlantic coast and on inland dunes and barrens, and thus differs remarkably from the lime-loving savin of Europe.

The American Savin is said to have been first introduced by Loddiges, who called it *J. hudsonica* in his catalogue of 1836. The shrub cultivated as var. *prostrata* is low and prostrate, bearing only acicular very glaucous foliage; leaves in their free part $\frac{1}{6}$ in. long, spreading, the glaucous bloom appearing on the dorsal surface near the base; ventral surface whitened; branchlets of the second and third year bright reddish brown, with persistent needles of the same colour. I have not seen this cultivated shrub in fruit or bearing scale-like leaves; but it has the disagreeable odour of the savin, and in all probability is, as reputed, of American origin. Sargent states² that it is the hardiest and most beautiful of all the prostrate junipers that can be grown in New England gardens.

DISTRIBUTION

The Savin is widely distributed, occurring in central and southern Europe, the Caucasus, and North America. It occurs mainly in Europe in extensive thickets on dry rocky sunny mountain slopes; but is also met with as undergrowth in many pine forests, as those of *Pinus sylvestris* in the Sierra Nevada in Spain, and of *P. leucodermis* in Herzegovina. It grows usually on limestone; but is occasionally seen on other formations. In Europe it is most common in Spain and Portugal, and in the Balkan peninsula. It is widely spread throughout the whole Alpine mountain system, but is rare towards the north, though it is met with in the Bavarian Alps and in a few stations in Switzerland. Its distribution in Russia is remarkable, as it occurs in isolated spots throughout the great plain, reaching as far north as the Baltic coast; but is a mountain plant, as usual elsewhere, in the Crimea and in the southern part of the Ural range. It also occurs in the Caucasus and the mountains of northern Persia; but is not met with in Asia Minor, and is totally absent from northern Africa. Its occurrence in Siberia is attested by Russian botanists; but we have seen no specimens. (A. H.)

The Savin was early introduced into England, as it is mentioned in Turner's *Names of Herbes*, published in 1548.

¹ Rehder, in Bailey, *Cycl. Amer. Hort.* 850 (1900), says that it is sometimes called in America the Waukegan juniper.

² In *Garden and Forest*, x. 421 (1897). Sargent adds that the European savin, if it has ever been tried in gardens in Massachusetts, has probably not proved hardy.

The finest specimen in Britain is probably one growing in the garden of Stourton Court, Stourbridge, the residence of R. Matthews, Esq. This is well figured in *Journ. R. Hort. Soc.* xxxiii. 327 (1908), where it is stated to measure 6 ft. high and $57\frac{1}{2}$ ft. in circumference. The soil is Old Red Sandstone.

The young green shoots of the Savin are used in medicine, and yield a volatile oil, which is officinal and possesses extremely active properties.¹ (H. J. E.)

JUNIPERUS EXCELSA

Juniperus excelsa,² Bieberstein, *Beschr. Länd. Casp.* 204, App. No. 72 (1800), and *Fl. Taur. Cauc.* ii. 425 (1808); Parlatores, in De Candolle, *Prod.* xvi. 2, p. 484 (1868); Boissier, *Fl. Orient.* v. 708 (1881); Siehe, in *Gartenflora*, xlv. 208, t. 26 (1897); Kent, *Veitch's Man. Conif.* 174 (1900).

Juniperus Sabina, Linnæus, var. *taurica*, Pallas, *Fl. Ross.* ii. 15 (1788).

Juniperus Sabina, Linnæus, var. *excelsa*, Georgi, *Besch. Russ. Reichs*, iii. 1358 (1802).

Juniperus foetida, var. *excelsa*, Spach (excl. syn. Amer.), in *Ann. Sc. Nat.* xvi. 297 (1841).

Juniperus polycarpus and *isophyllos*, Koch, in *Linnaea*, xxii. 303, 304 (1849).

Juniperus Olivierii, Carrière, *Conif.* 57 (1855).

Juniperus aegæa, Grisebach, *Veg. der Erde*, 378, 572 (1872).

Sabina excelsa, *polycarpus*, and *isophyllos*, Antoine, *Cupress. Gatt.* 45, 47, 48 (1857).

A tree, occasionally attaining in Asia Minor a height of 70 to 100 ft. Leaves dimorphic in wild specimens; but juvenile foliage is rarely seen on cultivated adult trees of the typical form. Adult foliage; ultimate branchlets very slender, $\frac{1}{30}$ in. or less in diameter; leaves scale-like, closely appressed, in four ranks in opposite decussate pairs, ovate-rhombic, about $\frac{1}{4}$ in. long, acute or obtuse, marked in the middle on the back with a depressed oval or linear gland; leaves on older branchlets, in pairs or in threes, spreading, mucronate, glandular on the back. Juvenile foliage, when present³; leaves acicular, spreading, in opposite pairs, $\frac{1}{8}$ to $\frac{1}{4}$ in. long, concave above with two stomatic bands, marked on the lower surface with a linear gland at the base.

Flowers monœcious or diœcious. Fruit, ripening in the second year, on short scaly stalks, globose, $\frac{1}{8}$ to $\frac{1}{2}$ in. in diameter, smooth, dark purplish brown, covered with a bluish bloom when ripe, composed of four or six scales, each marked by a minute mucro. Seeds, about six in each fruit, oblong, more or less triquetrous, apiculate at the apex.

1. Var. *stricta*, Rollisson, *ex Gordon, Pinetum*, 144 (1875).

A tree, narrowly pyramidal in habit, with glaucous juvenile foliage; leaves acicular, slightly spreading, about $\frac{1}{8}$ in. long including the basal decurrent part, whitened with a stomatic band above, marked with a minute gland near the base on the lower surface.

This originated in Messrs. Rollisson's nursery at Tooting, and appears to be

¹ Cf. Flückiger and Hanbury, *Pharmacographia*, 628 (1879).

² *J. excelsa*, Loudon, *Arb. et Frut. Brit.* iv. 2503 (1838), includes a mixture of junipers from Siberia, the Himalayas, and North America, and does not appear to refer to the true plant from Asia Minor.

³ Described from a native specimen collected by Haussknecht.

perfectly hardy, retaining its characters in old age. There are three trees at Kew, 25 to 30 ft. high, which were obtained from Rollisson in 1868.

Var. *Perkinsii* and var. *venusta*, Gordon, *Pinetum*, 144 (1875), are similar to var. *stricta*, only differing in the more glaucous leaves. A specimen of var. *Perkinsii* at Kew is almost columnar in habit.

J. excelsa is a native of the Balkan States, Island of Thasos,¹ Crimea, Asia Minor, Syria, Armenia, and the Caucasus. In Thrace, Macedonia, and the Rhodope mountains of Rumelia it is, according to Adamovic,² a shrub rather than a tree, ascending occasionally to 4000 ft. It is recorded for one station in Bulgaria, near the village of Beli Iskar. Köppen³ states that in the Crimea it is common on the coast side of the mountains, forming pure woods of considerable extent; but never attaining a large size, the tallest tree noted being about 30 ft.

J. excelsa appears to attain its greatest development in Asia Minor, where it forms extensive woods in the mountains, either pure or mixed with Lebanon Cedar and *Abies cilicica*. Siehe⁴ gives an illustration of a tree in the Cilician Taurus, nearly 100 ft. high, and states that it assumes two forms, being either a tall narrow pyramidal tree, or a shorter tree with wide-spreading branches; occasionally with a trunk $4\frac{1}{2}$ ft. in diameter. There are very fine woods at Namrun, Efrenk, and Güllek in Cilicia, where the trees are tall, slender, and dense upon the ground. Siehe considers that the timber will prove of great value for railway sleepers. The Turkish name of the tree is *arytsch*.

The date of introduction is uncertain, as Loudon's account of *J. excelsa* does not relate to this species; but it was probably brought into England about 1836. It usually forms a narrow columnar or pyramidal tree. A tree at Arley Castle, said to have been planted in 1877, measured⁵ 32 ft. by 3 ft. 1 in. in 1904. Another at High Canons, Herts, was 32 ft. by $2\frac{1}{2}$ ft. in 1908. There are trees of similar size in the botanic gardens at Kew and Cambridge. We have also seen good specimens at Hardwicke, Tortworth, Westonbirt, Highnam, and Eastnor. In Ireland there are trees at Glasnevin and Powerscourt.

J. excelsa has been much confused with the two following species, which are not apparently in cultivation. These are remarkably distinct from *J. excelsa* both in foliage and fruit.

1. *Juniperus macropoda*, Boissier, *Flora Orientalis*, v. 709 (1881).

A tree, occasionally attaining 70 ft. in height, but often shrub-like, which is a native of Persia, Afghanistan, and Baluchistan, where it forms extensive open forests, east of Quetta.⁶

This has much coarser foliage than *J. excelsa*, resembling that of *J. chinensis*. Fruit globose, $\frac{1}{8}$ in. in diameter, brownish purple, tinged with a glaucous bloom, each of the four to six scales with a prominent mucro. Seeds, two to four, ovoid.

¹ It is not recorded for any of the islands in the Ægean Archipelago except Thasos, where it grows in the pine woods on the coast. Cf. Grisebach, *Veg. der Erde*, 378, 572 (1872).

² *Veget. Balkanländer*, 152 (1909).

³ *Holzgewächse Europ. Russlands*, ii. 423 (1889).

⁴ In *Gartenflora*, xlv. 208, t. 26 (1897), and in *Mitt. Dent. Dent. Ges.* 1911, p. 306.

⁵ Woodward, *Hortus Arleyensis*, 19 (1907).

⁶ Cf. Lace, in *Journ. Linn. Soc. (Bot.)* xxviii. 307 (1891). Gamble, *Indian Timbers*, 698 (1902), gives also some particulars concerning this tree, which he considers to be identical with the Himalayan *J. religiosa*.

1448 The Trees of Great Britain and Ireland

II. *Juniperus religiosa*, Carrière, *Conif.* 41 (1855) (not Royle¹).

Juniperus gossainthanea,² Loddiges, *Catalogue*, 48 (1836); Loudon, *Trees and Shrubs*, 1090 (1842).

Juniperus chinensis, Parlatore, in De Candolle, *Prod.* xvi. 2, p. 488 (1868 (in part) (not Linnaeus)).

Juniperus excelsa, Brandis, *Forest Flora, N.W. India*, 538, t. 68 (1874) (not Bieberstein).

Juniperus macropoda, Hooker, *Fl. Brit. India*, v. 647 (1888) (not Boissier).

A tree, occurring in the inner dry ranges of the north-western Himalayas from Chitral and Kashmir to Nepal, at 5000 to 10,000 ft. altitude. It often attains 50 ft. in height, with a girth of 6 or 7 ft.; but occasionally trees of enormous girth are met with, one at Lahoul measuring $33\frac{1}{2}$ ft. in circumference.

This species has foliage similar to that of *J. macropoda* and *J. chinensis*. Fruit obovoid, widest at the apex, which is depressed, $\frac{1}{4}$ in. in diameter, bluish black with a soft juicy pulp. Seeds, one to three, ovoid, sharp-pointed, with large resin-glands.

(A. H.)

¹ *J. religiosa*, Carrière, the first published name with a description, should be adopted for this species. *J. religiosa*, Royle, *Illustr. Himal.* i. 351 (1839), without any description, is possibly *J. squamata*. Cf. p. 1420, note 4.

² This name was published without any description, and, moreover, is somewhat doubtful. Cf. p. 1438, note 1.

ATHROTAXIS

Athrotaxis,¹ Don, in *Trans. Linn. Soc.* xviii. 172, tt. 13, 14 (1839); Bentham et Hooker, *Gen. Pl.* iii. 430 (1880); Masters, in *Journ. Linn. Soc. (Bot.)* xxx. 21 (1893).

EVERGREEN trees belonging to the division Taxodineæ of the order Coniferae. Leaves persistent for several years, spirally arranged, homomorphic, crowded, imbricate, spreading or closely appressed, adnate at the base, free at the apex; without scaly buds.

Flowers monœcious, solitary at the apices of the branchlets. Staminate flowers catkin-like, with crowded stamens spirally arranged on an axis; each stamen with a slender stalk and a sagittate connective, which bears two pollen sacs dehiscing longitudinally. Ovuliferous flowers, of ten to twenty-five spirally arranged scales; each scale with an adnate fleshy disc, bearing three to six ovules. Cones ripening in one year; scales, ten to twenty-five, woody, spirally arranged, cuneate and narrow at the base, horizontally spreading, dilated into a clavate or peltate lamina, which bears on the back or at the apex a triangular cuspidate process.² Seeds, three to six, pendulous from the thickened part of the scale below the apex; oblong, compressed, with a transverse hilum and two lateral wings. Cotyledons two, longer than the primary leaves.³

Athrotaxis is closely related to *Cryptomeria*; and Kent states that rooted cuttings of *Cryptomeria elegans* are used as stocks for grafting scions taken from the different species of Athrotaxis.

Fossil remains found in various deposits in Europe have been identified, but perhaps erroneously, with Athrotaxis. C. Reid⁴ has lately shown that the remains in the Bovey Tracey lignites belong to *Sequoia Couttsiae*, Heer, and not to Athrotaxis, as had been supposed by Starkie Gardner.

This genus is confined in the living state to Tasmania, where there are three species⁵ distinguishable as follows:—

¹ Derived from ἀθρός, crowded, and τάξις, arrangement. Endlicher, *Gen. Suppl.* i. 1372 (1841), and *Syn. Conif.* 193 (1847), gives the erroneous spelling *Arthrotaxis*, which has been followed by several writers.

² This process is the extremity of the scale in the flowering stage, which has coalesced almost completely with the ovuliferous disc, the latter having increased much in size during the ripening of the ovules into seed.

³ Masters, in *Journ. Linn. Soc. (Bot.)* xxvii. 235, 237 (1890).

⁴ In *Phil. Trans.* series B, vol. 201, p. 171, pl. 15, figs. 40, 41 (1910), where the distinctive characters of the epidermis of the leaves of *Sequoia* and *Athrotaxis* are made plain.

⁵ *Athrotaxis* (?) *tetragona*, W. J. Hooker, *Icon. Plant.* t. 560 (1843) belongs to a distinct genus, and is *Microcachrys tetragona*, J. D. Hooker, in *London Journ. Bot.* iv. 149 (1845). This is a low rambling shrub, also a native of Tasmania. It is occasionally cultivated in conservatories.

I. Leaves spreading, entire in margin, with two continuous white stomatic bands on the ventral surface, and two lateral stomatic depressions confined to near the base on the dorsal surface.

1. *Athrotaxis selaginoides*, Don.

Leaves very spreading, $\frac{1}{2}$ in. long, with a rigid spine-like acuminate apex, and an opaque margin.

2. *Athrotaxis laxifolia*, W. J. Hooker.

Leaves slightly spreading, $\frac{1}{4}$ in. long, obtuse or acute at the apex, and with a translucent margin.

II. Leaves closely appressed, scale-like and apparently in four ranks like Cupressus, but really spirally arranged; margin translucent and denticulate; ventral surface concealed; dorsal surface with indistinct stomatic lines.

3. *Athrotaxis cupressoides*, Don.

Leaves rhombic-ovate, obtuse at the apex, $\frac{1}{8}$ in. long. (A. H.)

ATHROTAXIS SELAGINOIDES

Athrotaxis selaginoides, Don, in *Trans. Linn. Soc.* xviii. 172, t. 14 (1839); W. J. Hooker, *Icon. Plant.* t. 574 (1843); J. D. Hooker, in *Lond. Journ. Bot.* iv. 148 (1845), and *Fl. Tasman.* i. 354 (1860); Masters, in *Gard. Chron.* ii. 724, figs. 140, 141 (1887), and iv. 544, fig. 79 (1888); Kent, Veitch's *Man. Conif.* 262 (1900); Rodway, *Tasmanian Flora*, 277 (1903); Baker and Smith, *Pines of Australia*, 303, plates on pp. 304, 305, figs. 217-228 (1910).

Athrotaxis Gunneana, Carrière, *Conif.* 207 (1867).

Athrotaxis Gunniana, Gordon, *Pinetum*, 47 (1875).

Cunninghamia selaginoides, Zuccarini, in Siebold, *Fl. Jap.* ii. 9, note (1844).

A tree, attaining a larger size than the other two species, up to 100 feet in height and 10 feet in girth. Bark described by Baker and Smith, as slightly furrowed and fibrous, but not very rough. Branchlets stout, entirely covered by the decurrent bases of the leaves. Leaves spirally arranged, loosely imbricated, widely spreading but incurved at the apex, rigid, coriaceous, about $\frac{1}{2}$ in. long, subulate, adnate but not jointed at the base, tapering to an acuminate spine-like apex; dorsal surface keeled with two lateral depressions near the base, which are whitened by stomatic lines; ventral surface concave, with two longitudinal white stomatic bands from the apex to the base separated by a green midrib; margin entire, opaque.

Cones ovoid or globose, about 1 in. in diameter, composed of 20 to 24 brown woody scales, which are about $\frac{1}{2}$ in. long, with a narrow cuneate base, and an oval or ovate expanded inflexed lamina, which terminates in a triangular thin process.

The species, which is known in Tasmania as King William Pine, is said by Rodway to occur in the western mountains, extending from Mount Field, Mount Hartz, Adamson Peak, and Mount La Perouse to the west coast. Baker and Smith state that it is common in the immediate neighbourhood of Williamsford,

at about 1000 ft. above sea-level. It is a prominent tree in the dense scrub which covers this locality, being associated with *Phyllocladus rhomboidalis*, *Nothofagus Cunninghami*, &c. These authors figure an old tree, said to be typical in habit, which shows a twisted stem, free of branches for three quarters of its height, and surmounted by a small irregular dense crown of foliage. *A. selaginoides* ascends to 3000 ft. or more, as it occurs on the summit of Mt. Reed and other mountains, usually in a much dwarfed and stunted form.

Baker and Smith, who give excellent figures of the structure of the leaves and wood, state that the wood is not unlike that of *Sequoia sempervirens*, both in general characters and in texture, being open and straight in the grain, easy to work, and very light in weight. It is pale reddish when freshly cut, but becomes lighter in colour on exposure. Possessing great durability, and considerable toughness and strength, it is used in Tasmania for cabinet-work, coach-building, and for making oars. Penny¹ states that it occurs in limited quantities; and is apparently never exported.

This species was introduced about the year 1857 by Mr. W. Archer of Cheshunt; but appears to be less common in cultivation than *A. laxifolia*. A thriving specimen at Osborne, Isle of Wight, planted in 1879, was 17 $\frac{1}{2}$ feet high in January 1912, when it bore both young and old cones. A tree at Lamellen, St. Tudy, Cornwall, which was 26 ft. high, died in 1909. From it Mr. Magor raised a few seedlings, which are still small plants. A specimen at Abbotsbury was killed by drought in the summer of 1911. The finest specimen is at Kilmacurragh, in Ireland, and measured 32 ft. high in March 1912, when it was bearing numerous old cones. A smaller tree is thriving at Rostrevor. (A. H.)

ATHROTAXIS LAXIFOLIA

Athrotaxis laxifolia, W. J. Hooker, *Icon. Plant.* t. 573 (1843); J. D. Hooker, in *Lond. Journ. Bot.* iv. 149 (1845), and *Fl. Tasman.* i. 354 (1860); Masters, in *Gard. Chron.* xxiv. 584, fig. 134 (1885), ii. 724, figs. 142, 143 (1887), and ix. 144, 147, figs. 37, 38 (1891), and in *Journ. Linn. Soc. (Bot.)* xxii. 201, fig. 26 (1886); Kent, Veitch's *Man. Conif.* 261 (1900); Rodway, *Tasmanian Flora*, 277 (1903); Baker and Smith, *Pines of Australia*, 313 (1910).
Athrotaxis Doniana, Maule, ex Gordon, *Pinet. Suppl.* 16 (1862).

A tree, attaining about 40 ft. in height. Bark reddish, fibrous, peeling off in long vertical ribbons. Branchlets slender, covered by the decurrent bases of the leaves. Leaves spirally arranged, closely imbricated, slightly spreading, about $\frac{1}{4}$ in. long; incurved at the acute or obtuse, rarely mucronate, apex; dorsal surface keeled, with two lateral depressions near the base, which are whitened by stomatic lines; ventral surface concave, with two longitudinal white stomatic bands; margin entire, thin and translucent towards the apex.

Cones sub-globose, $\frac{3}{4}$ in. in diameter, composed of 15 to 20 brown woody scales,

¹ *Tasmanian Forestry*, xi. 42 (1905). Penny quotes A. O. Green's tests of various Tasmanian timbers. This species is one of the lightest, a cubic foot weighing only 22 lbs.

which are about $\frac{3}{8}$ in. long, with a slender cuneate claw, and a thickened oval expanded lamina, bearing on the back a large ovate acute process.

This species was found by Gunn and Archer at the falls of the Meander river, and along rivulets near the summit of the western mountains in Tasmania; and is said by Rodway to occur on Field Range and near Mount La Perouse. It appears to occur at higher altitudes than the other species, reaching 4000 ft.

A. laxifolia was also introduced by Archer in 1857, and appears to be the most successful of the three species in cultivation in this country. The largest specimens are in Cornwall, where Elwes measured in 1911 a fine tree at Scorrier, 38 ft. high and 3 ft. 9 in. in girth; from it three seedlings were raised about twenty years ago, which are now 15 to 20 ft. high. Another fine specimen at Penjerrick was 32 ft. by 2 ft. 8 in. in the same year. One in Mr. R. Gill's nursery at Tremough near Penryn, measured 27 ft. high, and was bearing fruit in January 1912. Another, 17 ft. high, occurs at Trewidden near Penzance.

There is also a good tree at Menabilly, growing at 100 feet above sea-level in an exposed position, which was planted in 1880, and reported to be a perfect pyramid, 12 ft. high in 1891; it was 27 ft. high and 3 ft. in girth in January 1912. A branch of this tree with cones was figured¹ by Dr. Masters.

This species appears to be very hardy, and succeeds as far north as Durris in Kincardineshire, where a tree about 10 ft. high produced cones in 1909, from which numerous seedlings were raised; some of these have been planted out at Bayfordbury and in the Cambridge Botanic Garden.

In Ireland, there is a fine specimen at Kilmacurragh, 28 ft. high in 1912; and a smaller one at Castlewellan. (A. H.)

ATHROTAXIS CUPRESSOIDES

Athrotaxis cupressoides, Don, in *Trans. Linn. Soc.* xviii. 173, t. 13, fig. 2 (1839); W. J. Hooker, *Icon. Plant.* t. 559 (1843); J. D. Hooker in *Lond. Journ. Bot.* iv. 148 (1845), and *Fl. Tasman.* i. 354 (1860); Masters, in *Gard. Chron.* xxiv. 270, fig. 60 (1885), and ii. 725, figs. 144, 145 (1887); Kent, Veitch's *Man. Conif.* 261 (1900); Rodway, *Tasmanian Flora*, 277 (1903); Baker and Smith, *Pines of Australia*, 313 (1910).
Cunninghamia cupressoides, Zuccarini, in Siebold, *Fl. Jap.* ii. 9, note (1844).

A tree, attaining 40 ft. in height and 6 feet in girth, with ascending branches. Branchlets pseudo-opposite or alternate, densely covered with scale-like leaves, which appear to be in opposite decussate pairs, but in reality are in a spiral arrangement. Leaves on the ultimate branchlets, similar to those in *Cupressus*, homomorphic, densely appressed, closely imbricated, rhombic-ovate, about $\frac{1}{8}$ in. long, obtuse at the apex; ventral surface entirely concealed; dorsal surface keeled and marked with white stomatic dots in lines on the two sides; margin denticulate

¹ *Gard. Chron.* xxiv. 584, fig. 134 (1885) and *Journ. Linn. Soc. (Bot.)* xxii. 201, fig. 26 (1886). In *Gard. Chron.* xxiv. 660 (1885), it is stated that a tree produced cones in 1875 in Mr. Robert Loder's garden at Whittlebury, Towcester; but this cannot now be found and was probably cut down some years ago.

and translucent. Leaves on the older branchlets increasing in size, becoming dark brown and about $\frac{1}{2}$ in. long in the fifth or sixth year.

Cones, nodding on curved branchlets, $\frac{2}{3}$ in. in diameter; scales 10 or 12, much smaller than in the other species, less than $\frac{1}{4}$ in. long, with a triangular recurved process on the middle of the expanded lamina.

This species is said by Rodway to be a small erect tree, about 40 ft. high, found in the western mountains of Tasmania, near St. Clair and to the west and south-west of Field Range. It rarely exceeds 5 or 6 feet in girth; but Sir J. Hooker mentions one very old and hollow tree, which was 15 ft. in girth at $3\frac{1}{2}$ feet from the ground. Baker and Smith state that the timber resembles in all respects that of *A. selaginoides*.

It was introduced in 1857 by Mr. Archer at the same time as the other species, and resembles them in cultivation; but it is rare and has not attained in this country as great a height as *A. laxifolia*. In Cornwall, a tree 20 ft. high was bearing cones in Gill's nursery, near Penryn, in January 1912; and a smaller specimen, also bearing fruit, occurs at Trewidden. Kent mentioned in 1900 a fine specimen at Upcott, near Barnstaple; which, Mr. W. Harris informs us, has lately lost its leader and is now only 13 ft. high. In Hillier's nursery at Shroner, near Winchester, a tree, planted in 1887, was 12 ft. high in 1910, and had commenced to bear cones in small quantity. There is also a small specimen at Brickendon Grange, Hertford, which was 5 ft. high in 1911.

In Ireland, a fine specimen bearing fruit at Kilmacurragh was 21 ft. high in March 1912; while another at Powerscourt¹ was 22 ft. high. A thriving tree at Castlewellan, 15 ft. high, bore 18° of frost without injury in February 1912. (A. H.)

¹ Erroneously called *A. Doniana* in *Gard. Chron.* xlix. 219 (1911).

FITZROYA

Fitzroya, J. D. Hooker, ex Lindley, in *Journ. Hort. Soc. Lond.*, vi. 264 (1851), and ex W. J. Hooker, *Bot. Mag.* t. 4616 (1851); Bentham et Hooker, *Gen. Pl.* iii. 425 (excl. *Diselma*) (1880); Masters, in *Journ. Linn. Soc. (Bot.)* xxx. 17 (1893).

A GENUS belonging to the division Cupressineæ of the order Coniferæ, characterised by the cones, composed of nine scales, in three alternating whorls, the three lowermost scales minute and sterile; those of the intermediate whorl larger, and either empty or each bearing a single two-winged seed; the three upper scales largest and fertile, each bearing two to six seeds, which are partly three- and partly two-winged. The apex of the axis of the cone terminates in three peculiar processes,¹ the precise morphological nature of which is unknown, but possibly they may represent an aborted whorl of scales. Only one species is known, in the description of which below, the vegetative and other characters of the genus are given in detail.

Diselma, a genus founded by Sir J. D. Hooker,² was united by Bentham and Hooker³ with *Fitzroya*, but appears to be sufficiently distinct. In *Diselma*, the cones are composed of two pairs of opposite scales, the outer pair small and empty, the inner two scales larger and fertile, each with two seeds, which are three-winged. *Diselma Archeri*, J. D. Hooker, *Fl. Tasman.* i. 353, t. 98 (1860), the only known species, differs greatly from *Fitzroya* in habit, having minute scale-like appressed leaves, like those of a *Cupressus*, in opposite decussate pairs; and is a shrub⁴ about 6 ft. high, growing between 3000 and 4500 feet elevation in the western mountains of Tasmania. *D. Archeri* was formerly represented in the Temperate House at Kew by a single specimen, which is no longer living. At present it is apparently not in cultivation in England. (A. H.)

FITZROYA PATAGONICA

Fitzroya patagonica, J. D. Hooker, ex Lindley in *Journ. Hort. Soc. Lond.* vi. 264 (1851), and ex W. J. Hooker, *Bot. Mag.* t. 4616 (1851); Lindley, in Paxton, *Flower Garden*, ii. 115 (1852); Kent, Veitch's *Man. Conif.* 198 (1900); Castillo and Dey, *Jeog. Vej. Rio. Valdivia*, 27, fig. 8 (1908).

An evergreen tree, attaining in Chile 100 to 160 ft. in height, and 10 to 16 ft. in girth; but dwarfed to a low shrub at high elevations. Bark reddish, longitudinally fissured, and peeling off in narrow ribbons. Young branchlets green,

¹ These gland-like processes secrete resin and exhale a slight fragrant odour.

² *Fl. Tasman.* i. 353, t. 98 (1860).

³ *Gen. Plant.* iii. 425 (1880).

⁴ Cf. Baker and Smith, *Pines of Australia*, 300 (1910).

glabrous, flexile, slender, covered by the decurrent bases of the leaves, which are separated between the whorls by three linear grooves. Older branchlets until the seventh year, stouter, reddish, marked by withered leaves and their remains. Buds ovoid or globose, composed of green scales, which are slightly modified and shortened ordinary leaves. Leaves persistent for several years, in alternating whorls of threes, decurrent by their bases on the branchlets; their free part spreading, spatulate, incurved at the rounded apiculate apex, about $\frac{1}{8}$ in. long; upper surface concave, with two narrow white stomatic depressions extending from the apex to the middle of the leaf or beyond, and separated by a raised green midrib; lower surface convex, with a broad green raised midrib, on each side of which is a narrow white stomatic depression often extending from near the apex to the adnate base of the leaf. On the main axes, the leaves are often $\frac{1}{2}$ in. long, adnate in greater part to the branchlet, and becoming reddish brown in the third and fourth years.

Flowers¹ usually dioecious; sometimes monoecious or hermaphrodite. Staminate flowers solitary in the axils of the leaves towards the apex of the branchlet, cylindrical, subtended at the base by a few scales, composed of 15 to 24 stamens in ternate whorls; anthers 4-celled. Ovuliferous flowers, solitary and sessile on the ends of short leafy branchlets near the apex of a branch, composed of nine scales, in three alternating whorls; the three lowermost scales minute and sterile; the three scales of the intermediate whorl either empty or each bearing a single two-winged ovule; the uppermost three scales always fertile, each bearing a central three-winged ovule and one to five lateral two-winged ovules; oblong tubercles at the summit of the axis of the cone, three, yellowish, translucent, about $\frac{1}{8}$ in. long. Cones, scarcely larger when mature than in the flowering stage, sub-globose when closed and about $\frac{1}{3}$ in. in diameter, ripening in one year, with three minute scales at the base of the six large woody scales, each of the latter with a dorsal process, spreading widely to let loose the seeds, which are variable (nine to sixteen) in number (equalling the number of ovules in the flower). Seed with an oblong compressed body and two or three broad lateral membranous wings; the seed with the wings nearly orbicular and about $\frac{1}{6}$ to $\frac{1}{5}$ in. in diameter. Cotyledons two.

This species is a native of South America, occurring in Chile and northern Patagonia. It extends from the coast range immediately north of Valdivia southward to the island of Chiloe and the mainland opposite in about lat. 42° 40', and reaches inland to the central cordillera of the Andes. It is known to the inhabitants as *alerce*,² and covers immense tracts of marshy and peaty ground with extensive woods, which are called *alerzales*. These woods are widely distributed, the best known being in the coast range of Valdivia, around Lakes Llanquihue and Nahuelhuapi, in the neighbourhood of Puerto Montt, and in the valley of the river Maullin.³

¹ The flowers of *Fitzroya*, which are complicated and variable, are being investigated at Cambridge by Mr. R. C. Maclean. Monoecious flowers occur in Chilean specimens, as well as on the tree at Hewell Grange. The hermaphrodite flowers of the latter have several whorls of scales; the scales in the three lowermost whorls bear anthers, those in the upper two whorls bear ovules; the axis ends in the normal three gland-like processes.

² *Alerce* is used in Spain as the name of the larch; and is derived from the Arabic, *al-arzah*, signifying cedar.

³ Cf. Reiche, *Verbreit. Chilen. Conif.* 5 (1900), and *Pflanzenverb. Chile*, 63, 238 (1907).

Castillo and Dey¹ state that enormous trees still occur, up to 160 ft. in height and 16 ft. in girth; and mention veterans, which are said when felled to have shown 4000 annual rings; but this seems scarcely credible. Captain Fitzroy² in whose honour the genus was named, and who commanded the "Beagle" between 1828 and 1836, states on good authority, that a tree in the cordillera on the mainland opposite Chiloe had a stem measuring 76 ft. in length to the first branch, and 30 ft. in girth at five feet from the ground. It yielded 1500 planks. W. Lobb saw on the precipices around Valdivia trees 100 ft. in height and 8 ft. in diameter; and states³ that it ascends the mountains to the limit of perpetual snow, where it is occasionally only a few inches high.

Fitzroya patagonica was first introduced⁴ in 1849 by W. Lobb, who sent home seeds from Valdivia; and again by R. Pearce, who collected in Chile for Messrs. Veitch in 1859-1862. It is perfectly hardy in this country, and at Kew⁵ bore without injury the severe frost of 1908-1909, when the temperature fell to 10° Fahr.; nevertheless, it is slow in growth, and seems to develop oftener into a bushy shrub than a tree, but this may be due to most of the specimens in cultivation being derived from cuttings.

The finest trees are in Cornwall and Devon. One at Killerton, planted in 1864, was 34½ ft. by 3 ft. 2 in. in 1911. Another at Bicton was 35 ft. high in the same year. An ill-shaped tree at Penjerrick, dividing into several stems at the base, was about 35 ft. high in 1910. At Coldrenick a similar tree with several stems was 25 ft. high in 1911. Masters figured⁶ a tree at Pencarrow, planted in 1852 by Sir W. Molesworth, which was reported in 1902 to have been 21 ft. in height, with a spread of branches of 46 ft. At Abbotsbury, a tree was killed by drought in the summer of 1911. At Upcott, Barnstaple, a well-grown and healthy specimen was 28½ ft. high in January 1912. There are smaller trees at Highnam near Gloucester, and at Leaton Knolls, Shrewsbury. In the pinetum at Uplyme, Dorset, there is a fine tree, 30 ft. by 3 ft. 3 in. in 1912.

At Belsay Castle, Newcastle-on-Tyne, there is a fine specimen, which was planted about 1856, and measured 28½ ft. high in January 1912. Sir Arthur E. Middleton, Bart., informs me that it is growing in a sheltered place in an old sandstone quarry, where the soil contains a considerable admixture of clay. This tree has been kept from an early date to one leader; otherwise it would have spread in an irregular way. There are also several bushy specimens at Belsay Castle, where this species has never been touched in the slightest degree by frost.

Nearly all the cultivated trees which we have seen bear only female flowers, and in consequence the seed, which is freely produced, is infertile. A tree, however, at Hewell Grange, Redditch, which is about 28 ft. high, is monœcious, and bore in May 1912 both male and female flowers in profusion, as well as a few which were hermaphrodite.

¹ *Jesq. Veg. Rio Valdivia*, 28 (Santiago, 1908). Reiche gives the maximum as 180 ft. high, 16 ft. in diameter, and 2500 years old.

² *Narrative of Voyages of the Beagle*, i. 275, 282, and ii. 391 (1839). Cf. also Cook, in Loudon, *Gard. Mag.* xv. 694 (1839).

⁴ *Hortus Veitchii*, 38, 46, 340 (1906).

⁶ *Gard. Chron.* xxxi. 392, Supply. Illust. (1902).

³ *Journ. Hort. Soc.* vi. 262 (1851).

⁵ *Kew Bull.* 1909, p. 235.

The only specimen that we know of in Scotland is one at Ardgowan, which was about 25 ft. high in 1909. A tree at Murthly, recorded at the Conifer Conference as 16 ft. high and 30 years old in 1891, was killed in the severe winter of 1893-1894, when the thermometer registered at Murthly 11° Fahr. below zero.

In Ireland a tree at Powerscourt was 30 ft. high in 1910; and another at Fota was 25 ft. high in 1912. There are also good specimens at Kilmacurragh, Rostrevor, and Castlewellan.¹ (A. H.)

TIMBER

The wood is very valuable; and is remarkable for the extraordinary straightness of the grain, which makes it very easy to rend into thin boards. These are used as shingles for roofing, which after exposure to the weather turn blue and resemble slates; and also for floors and partitions. Castillo and Dey state that it is very durable in contact with water, is unaffected by heat or humidity, and has lasted in roofs without alteration for over 100 years. Captain Fitzroy² says that "it does not shrink or warp; and, though brittle, is of very close grain and well adapted for furniture. Of this wood, the country people make staves for casks; and the bark of the tree is used for caulking the seams of vessels, being extremely durable when constantly wet, though it soon decays when exposed to the sun and air." Spars of alerce, which proved to be very strong, were obtainable 80 or 90 ft. in length. I saw mule-loads of these shingles 8 ft. long and very thin, on my journey from Nahuelhuapi to Puerto Montt, and very large stumps of trees in the country near that port; but I was unable to visit the forest where it grows. The wood is apparently still unknown in Europe; but I bought three boards in London imported from Chile, which are of a rich reddish colour with very fine and close grain. (H. J. E.)

¹ Figured by Earl Annesley, *Beautiful and Rare Trees*, t. 68 (1903), who states that this species should be planted in deep loam and peat, as it is a deep-rooting tree which grows slowly till it is well established.

² *Narrative of Voyages of the Beagle*, i. 275, 282, and ii. 391 (1839). Cf. also Cook, in Loudon, *Gard. Mag.* xv. 694 (1839).

SAXEGOTHÆA

Saxegothæa, Lindley, in *Journ. Hort. Soc. Lond.* vi. 258 (1851); Bentham et Hooker, *Gen. Pl.* iii. 434 (1880); Masters, in *Journ. Linn. Soc. (Bot.)* xxvii. 299 (1889), and xxx. 10 (1893); Pilger, in Engler, *Pflanzenreich*, iv. 5, *Taxaceæ*, 42 (1903); Stiles, in *New Phytologist*, vii. 209-222, figs. 28-34 (1908), and *Ann. Bot.* xxvi. 446, 463 (1912); R. B. Thomson, in *Bot. Gaz.* xlvii. 344-354, pl. 22-24 (1909).

A GENUS belonging to the division Podocarpeæ of the order Taxaceæ, mainly characterised by the yew-like foliage with true scaly buds, and by the female cones composed of spirally and loosely imbricated carpellary scales, the uppermost of which are fertile, each bearing internally near the base a cavity from which hangs a single free minute ovule; scales ultimately becoming fleshy, coalescing to form an irregular globose head, only a few of the ovules ripening into seeds, which when mature are set free by the gaping apart of the fertile scales. The genus, which has been studied by W. Stiles at Cambridge, is a remarkable one, all parts of the plant having a simple structure, suggesting that it is a primitive type. *Saxegothæa* is allied to *Araucaria* as well as to *Podocarpus*, resembling the latter in leaf, but the former in the female flowers and in the wingless pollen grains. Only one species is known, in the following description of which the other characters of the genus are given in detail.

(A. H.)

SAXEGOTHÆA CONSPICUA

Saxegothæa conspicua, Lindley, in *Journ. Hort. Soc. Lond.* vi. 258, figs. A and B (1851), and in Paxton, *Flower Garden*, ii. 111, fig. 190 (1852); Masters, in *Gard. Chron.* ii. 684, figs. 130, 131 (1887), and v. 782, fig. 125 (1889); Kent, Veitch's *Man. Conif.* 158 (1900); Pilger, in Engler, *Pflanzenreich*, iv. 5, *Taxaceæ*, 42 (1903); Castillo and Dey, *Jeog. Vej. Rio Valdivia*, 31, fig. 12 (1908).

An evergreen tree, attaining in South America 30 to 40 ft. in height, becoming at high elevations a low dense shrub. Bark greyish brown, scaling off like that of a plane tree, leaving the reddish brown cortex beneath exposed in patches. Branches widely spreading, pendulous at the ends, giving off the branchlets in opposite pairs or in whorls of three or four; young branchlets slender, glabrous, marked by the decurrent bases of the leaves, green with inconspicuous white dots on the lower side. Buds minute, globose, surrounded by three to seven ovate greenish scales, which persist brown and withered at the apex of the branchlet of the second year. Leaves, persistent about five years, arising in spiral order, spreading radially on

leading shoots, but thrown into a pectinate arrangement on lateral branches; linear, straight or curved, $\frac{1}{2}$ to $\frac{3}{4}$ in. long, narrowed into a petiolate base, decurrent on the branchlet, tapering at the apex, which ends in a sharp cartilaginous point; upper surface dark green with a raised narrow midrib; lower surface with a narrow green midrib, on each side of which is a broad stomatic band, composed of about twelve close lines of dots, and wider than the green margins.

Flowers monœcious. Staminate flowers cylindrical, solitary or two or three in the axils of the leaves near the end of the branchlet, shortly stalked, subtended by four to six scales; composed of numerous spirally arranged anthers, each with two cells, dehiscing longitudinally. Ovuliferous flowers solitary on the ends of the branchlets, on short peduncles bearing a few modified leaves; succeeded by numerous, spirally arranged, densely imbricated, triangular-ovate, pointed carpellary scales, the lower sterile, the upper fertile, each with a depression on the upper surface near the base, in which is borne an inverted ovule. Fruiting head, ripening in the first year, irregularly globose, $\frac{1}{3}$ to $\frac{1}{2}$ in. in diameter, with fleshy scales coalescent at the base and free at the apex, containing six to twelve ripened seeds, which are set free by the separating of the fertile scales. Seed, about $\frac{1}{8}$ in. in width and length, smooth, shining brown, ovoid, compressed from back to front, with two sharp lateral edges; base broad, marked by the rough surface of the hilum. Cotyledons two.

This species is a native of Chile and western Patagonia,¹ where it grows in the lower regions of the mountains in the dense forests, composed mainly of evergreen bush and conifers, like *Fitzroya patagonica*, *Libocedrus tetragona*, *Podocarpus chilina*, and *Podocarpus nubigena*. Castillo and Dey say that these two species of Podocarpus and Saxegothæa are known in Chile as *mañiu*, and yield a fine homogeneous wood, yellow in tint, and admirably suited for joiner's work.²

Saxegothæa conspicua was discovered³ by W. Lobb in southern Chile in 1846, and introduced in 1847. It does not appear to have succeeded in our climate, and is now very rare. At Kew, it is perfectly hardy, but grows slowly, and has a stunted appearance.

There are two specimens at Strete Raleigh, near Exeter, the seat of Mr. Imbert Terry, both probably original introductions, and about 30 ft. high in 1909, when the larger was 4 ft. 3 in. in girth at two feet from the ground.⁴

There is a fine specimen at Coldrenick, about 35 ft. high, with a short bole, only a foot long, dividing into about nine stems, 4 to 6 in. in diameter, with wide-spreading branches, which I saw in 1911. Both this tree, and those at Strete

¹ Dusen, in Scott, *Princetown Univ. Exped. Patagonia*, viii. 20 (1903), says it grows in the forests of the middle and lower Aysen valley in Patagonia. Reiche, *Verbreit. Chilen. Conif.* 5 (1900), gives the Aysen valley, lat. 45° 10', as its known southerly limit, while it extends northwards to the Rio Maule in lat. 35° 20'. It occurs on Chiloe, but not in the Guaytecas and Chonos islands.

² Capt. Fitzroy, *Narrative of Voyages of the Beagle*, i. 280 (1839), says:—"Mañiu, a tree of great dimensions, tall and straight, the leaf is like that of a yew: it is a very useful wood for shipbuilding, for planks, and next to *alerce*, is the best for spars that the island of Chiloe produces; but the large trees have a great tendency to become rotten at the heart owing possibly to the humidity of the climate, and to the very wet soil. Of twenty trees that were cut down, not one was sound at the heart. The wood is heavy, with large knots, which penetrate into the trunk to a great depth. A great deal of this timber grows in the Gulf of Peñas." It is doubtful what species is here referred to; but Saxegothæa does not now occur so far south as the Gulf of Peñas.

⁴ Cf. Dallimore, in *Kew Bull.* 1909, p. 336.

1460 The Trees of Great Britain and Ireland

Ralegh, produce flowers and fruit abundantly; but I am not aware that seedlings have been raised. In the pinetum at Uplyme, Dorset, there is a remarkably fine specimen with a single stem, which was 40 ft. high and 3 ft. 4 in. in girth, when I saw it in July 1912. At Abbotsbury this species is represented by a shrubby plant, 4 ft. high and 4 ft. across. At Bury Hill near Dorking there is a tree about 20 ft. high.

Bean¹ saw in 1907 a specimen, about 12 ft. high, at Ochertyre in Perthshire.

The only specimens that we know of in Ireland are a spreading bush at Rostrevor, where, Sir John Ross-of-Bladensburg informs us, it was planted in 1891; and two bushy trees, about 20 ft. high, which Elwes saw at Kilmacurragh in 1908.

(A. H.)

TORREYA

Torreya,¹ Arnott, in *Ann. Nat. Hist.* i. 130 (1838); Bentham et Hooker, *Gen. Pl.* iii. 431 (1880); Eichler, in Engler and Prantl, *Pflanzenfam.* ii. 1, p. 111 (1889); Masters, in *Journ. Linn. Soc. (Bot.)* xxx. 5 (1893); Pilger, in Engler, *Pflanzenreich*, iv. 5, *Taxaceae*, 105 (1903); Sargent, in *Bot. Gaz.* xlv. 226 (1907).
Tumion, Rafinesque, *Amenities of Nature*, 63 (1840); Sargent, *Silva N. Amer.* x. 55 (1896).
Caryotaxus, Zuccarini, ex Endlicher, *Syn. Conif.* 241 (1847).

EVERGREEN trees belonging to the order Taxaceæ, with fissured bark and opposite or whorled branches. Young branchlets green, with linear pulvini, separated by slight grooves. Buds, one terminal, and occasionally two to four lateral, clustered at the end of the branchlet, composed of a few decussately opposite scales. Base of the branchlet marked with scars, left by the fall of the bud-scales of the previous season; occasionally two or three of these persisting brown, unenlarged, and inconspicuous. Leaves spirally arranged, but thrown, by twisting and turning of their bases, into a pectinate arrangement on lateral branches, as in the yew; persistent three or four years; stalked, linear, tipped with a bristle-like cartilaginous point; upper surface green, convex; lower surface with a raised green midrib, and two white stomatic bands, sunk in longitudinal depressions; fibro-vascular bundle undivided, with a solitary resin-canal beneath it.

Flowers diœcious, or monœcious² with the sexes on different branches. Staminate flowers solitary in the axils of the leaves of the current year's branchlet, surrounded at the base by several pairs of decussate scales, composed of numerous stamens, in whorls of fours, on a stipitate slender axis; filament expanded into four pollen-sacs; connective truncate or crest-like and dentate.

Pistillate flowers in pairs on rudimentary branchlets,³ which are solitary in the axils of a few leaves towards the base of the current year's shoot; each flower subtended by four decussate scales and a bract, and consisting of a solitary terminal ovule, surrounded at the base by a small disc, the aril, which grows upwards and ultimately becomes confluent with the succulent testa of the seed. Seed, as only one flower of each pair develops, solitary; ripening in the second year, drupe-like, with an outer succulent resinous coat and an inner woody shell, within which is the ruminant albumen and a minute embryo with two cotyledons. The shell bears a slightly projecting point at the apex, around which there is a dark-coloured oval,

¹ According to the Vienna rules of nomenclature, the name *Torreya* is to be retained for this genus. It had previously been applied to a species of *Clerodendron* by Sprengel, *Neue Entd.* ii. 121 (1821).

² The flowers are usually said to be diœcious, but the trees in cultivation are monœcious.

³ This occasionally terminates in a third ovule, or produces an extra bract. Cf. Miss Robertson, in *New Phytologist*, iii. 142 (1904).

circular, or saddle-shaped area, representing the outer surface of the integument where it is free from the aril; and below this are two opposite minute shield-like prominences, each with a minute aperture. The seed is sessile or short-stalked, and subtended at the base by six decussate scales,¹ from which it separates, when it falls after ripening.

Seedling: see under *T. californica*.

All species of *Torreya* sprout freely from the stump and roots when cut; and bear pruning freely. They are propagated by cuttings² or by grafting on the common yew or on species of *Cephalotaxus*.

During the tertiary period the genus inhabited the Arctic region, and spreading southward existed in Europe. All the living species produce handsome, close-grained, pale yellow wood,³ useful for cabinet-making, and durable when placed in contact with the soil as posts for fencing.

The species of *Torreya* superficially resemble those of *Cephalotaxus*; but the two genera are readily distinguishable.

Torreya.—Leaves with long spines at the apex, and narrow stomatic bands beneath. Buds with few decussate scales, all deciduous or two to four persisting minute and inconspicuous at the base of the branchlet.

Cephalotaxus.—Leaves with short-pointed apices; under surface with broad stomatic bands extending from the midrib almost to the outer margin. Buds with numerous imbricated scales, which persist at the base of the branchlet.

The four living species of *Torreya* are distinguishable as follows:—

I. *Leaves and branchlets foetid.*

1. *Torreya taxifolia*, Arnott. Florida. See p. 1466.

Leaves linear, $\frac{3}{4}$ to $1\frac{1}{2}$ in. long, $\frac{1}{8}$ in. broad, pale green beneath, with a broad midrib and narrow scarcely depressed stomatic bands; petiole, $\frac{1}{25}$ in.

II. *Leaves and branchlets pungent-aromatic.*

2. *Torreya californica*, Torrey. California. See p. 1465.

Leaves linear, $1\frac{1}{4}$ to 3 in. long, $\frac{1}{8}$ in. broad; glaucous beneath with a broad midrib and slightly depressed narrow stomatic bands; petiole, $\frac{1}{12}$ in.

3. *Torreya nucifera*, Siebold and Zuccarini. Japan. See p. 1463.

Leaves lanceolate-linear, $\frac{3}{4}$ to $1\frac{1}{4}$ in. long, $\frac{1}{8}$ to $\frac{1}{6}$ in. wide; green beneath with deeply depressed broad stomatic bands, about as wide as the midrib.

III. *Leaves and branchlets devoid of any peculiar odour or taste.*

4. *Torreya grandis*, Fortune. China. See p. 1464.

Leaves lanceolate-linear, $\frac{1}{2}$ to 1 in. long, $\frac{1}{8}$ in. wide; thinner in texture than those of *T. nucifera*, but with similar stomatic bands. (A. H.)

¹ These are the four decussate scales and bract of the flower which develops—the sixth scale being the bract and remains of the other flower which does not develop.

² Rehder states, in Bailey, *Cycl. Am. Hort.* iv. 1822 (1902), that plants raised from cuttings grow slowly and remain bushy. This may account for the few good specimens of *Torreya* which exist in cultivation. The seeds are difficult to transport, as they soon become rancid.

³ Figured by Mayr, *Fremdländ. Wald- u. Parkbäume*, 423, pl. x. 23 (1906).

TORREYA NUCIFERA

Torreya nucifera, Siebold and Zuccarini, in *Abh. Akad. München*, iv. 3, p. 234 (1846); Franchet et Savatier, *Enum. Pl. Jap.* i. 475 (1875); Masters, in *Journ. Linn. Soc. (Bot.)* xviii. 500 (1881), and xxvi. 546 (1902); Shirasawa, *Icon. Ess. Forest. Japon.* i. text 32, t. 15, figs. 19-34 (1900); Kent, Veitch's *Man. Conif.* 119 (1900); F. W. Oliver, in *New Phytologist*, i. 151, fig. 6 (1902); Pilger, in Engler, *Pflanzenreich*, iv. 5, *Taxaceae*, 105 (1903).

Taxus nucifera, Linnæus, *Sp. Pl.* 1040 (1753); Thunberg, *Fl. Jap.* 275 (1784).

Podocarpus nucifera, Persoon, *Syn.* ii. 633 (1807); Loudon, *Arb. et Frut. Brit.* iv. 2100 (1838).

Caryotaxus nucifera, Zuccarini, ex Endlicher, *Syn. Conif.* 241 (1847); Henkel and Hochstetter, *Syn. Nadelholz.* 366 (1865).

Tumion nuciferum, Greene, in *Pittonia*, ii. 194 (1891).

A tree, attaining in Japan 80 ft. in height, with bright red bark, and pungent aromatic branchlets and leaves. Young branchlets green, glabrous, becoming reddish in the second year. Buds prismatic, about $\frac{1}{8}$ in. long, with six to eight decussate external scales. Leaves, $\frac{3}{4}$ to $1\frac{1}{4}$ in. long, $\frac{1}{8}$ to $\frac{1}{6}$ in. wide, lanceolate-linear, tapering from near the base to the narrow acuminate spine-tipped apex; shining dark or yellowish green above; lower surface with two deeply depressed white stomatic bands, about as wide as the midrib, but not so wide as the marginal green bands; petiole about $\frac{1}{16}$ in. long.

Staminate flowers, $\frac{1}{3}$ in. long; connective crest-like, denticulate. Fruit narrowly obovoid, $\frac{3}{4}$ to 1 in. long, green tinged with purple; flesh thin, resinous; shell light brown, with irregular longitudinal depressions; inner coat dark red, folded for a short distance into the albumen. (A. H.)

This species is a native of Japan, occurring as a rare tree in the southern islands and in the forests of southern and central Hondo, where, according to Sargent, it reaches a height of 80 ft., and is remarkable for the beauty of its bright red bark and lustrous dark green foliage. The only place where I saw the tree wild was in virgin forest on the slopes of the Kiresima volcano in southern Kiusiu. Here there were trees up to about 10 in. in diameter, scattered in a dense forest of *Abies firma* and *Tsuga*, mixed with oaks, chestnut, and other broad-leaved trees. Seedlings were found in dense shade and could be distinguished by the sharp points of their leaves. I was told by the foresters that much larger trees existed, but only in remote and inaccessible places. Where it was planted in Kisogawa and below Koyasan at 1500 ft. elevation, it attained a height of 40 to 50 ft. with a girth of 8 ft. or more; and had very much the habit of a yew, but made a cleaner trunk with less tendency to branch. It is known in Japan as *Kaya*; and an oil is extracted from the seeds, which is used in cooking. The wood, according to Rein, is light yellowish in colour, and is used for making chests and boxes. The wood is also used for making Japanese chess-men.

The Japanese *Torreya* was described and figured by Kaempfer, *Amœn. Exot.* 815 (1712); and seems to have been introduced¹ into England in 1764 under the

¹ Aiton, *Hort. Kew.* v. 416 (1813).

name *Taxus nucifera*. Loudon gives the date of introduction as 1820, and states that a tree at White Knights was 13 ft. high in 1834. Siebold sent it to Holland about 1840. It is rare in cultivation, and is never seen except as a shrub.

(H. J. E.)

TORREYA GRANDIS

Torreya grandis, Fortune, in *Gard. Chron.* 1857, p. 788, and 1860, p. 170, and in Gordon, *Pinetum*, 326 (1858); Masters, in *Journ. Linn. Soc. (Bot.)* xviii. 500 (1881), xxvii. 323, fig. 28 (1890), and xxvi. 546 (1902), and in *Gard. Chron.* ii. 681, fig. 117 (1884); Franchet, *Pl. David.* i. 292 (1884).

Torreya Fargesii, Franchet, in *Journ. de Bot.* xiii. 264 (1899); Pilger, in Engler, *Pflanzenreich*, iv. 5, *Taxaceae*, 108 (1903).

Torreya nucifera, Siebold and Zuccarini, var. *grandis*, Pilger, *op. cit.* 107 (1903).

Caryotaxus grandis, Henkel and Hochstetter, *Syn. Nadelholz.* 366 (1865).

Tunion grande, Greene, in *Pittonia*, ii. 194 (1891).

A tree, attaining 80 ft. in height in China, with leaves and branchlets devoid of a disagreeable or pungent odour. Young branchlets green, glabrous, becoming yellowish brown in the second year. Leaves, $\frac{1}{2}$ to 1 in. long, $\frac{1}{8}$ in. broad, linear-lanceolate, similar to those of *T. nucifera* in shape, but thinner in texture, with similar deeply depressed stomatic bands, nearly as wide as the midrib, but narrower than the marginal green bands.

Fruit broadly ellipsoid, $\frac{3}{4}$ to 1 in. long; flesh not disagreeable in odour; shell reddish brown, with irregular shallow depressions over the surface; inner coat only slightly folded into the albumen.

Torreya grandis was discovered by Fortune in 1855 in the coast province of Chekiang in China, in the mountains south-west of Ningpo, at 4000 ft. elevation. Here numerous fine trees were seen, many of which were 60 to 80 ft. in height. It was subsequently collected in the adjoining province of Fukien by Père David. The same tree¹ also exists in the central provinces of Hupeh and Szechwan, in the mountains between 4000 and 6000 ft. elevation; where it occasionally attains a height of 50 ft., but it is more commonly shrubby, bearing fruit when only 8 ft. high.

This tree is known to the Chinese as *fei*; and the kernels, called *fei-shih*,² are sold in the drug-shops of most Chinese towns, being considered a valuable remedy in cases of cough, asthma, etc. They are occasionally eaten like hazel nuts, and though reputed laxative, are considered wholesome.

Torreya grandis was introduced by Fortune, who sent seeds in 1855 to Glendinning's nursery at Chiswick, where they germinated freely. This species is not common in collections, the only specimen which we have seen being a small shrub in the Cambridge Botanic Garden, which was obtained from Veitch in 1894.

(A. H.)

¹ The *Torreya* of Central China is considered by Franchet and Pilger to be a distinct species, *T. Fargesii*; but I can see no characters by which it can be separated from the Chekiang species.

² Cf. Hanbury, *Sc. Papers*, 233 (1876).

TORREYA CALIFORNICA

Torreya californica, Torrey, in *New York Journ. Pharm.* iii. 49 (1854); J. D. Hooker, in *Gard. Chron.* xxiv. 553 (1885); Masters, in *Gard. Chron.* v. 800, figs. 126, 127 (1889); Kent, Veitch's *Man. Conif.* 117 (1900); Pilger, in Engler, *Pflanzenreich*, iv. 5, *Taxaceae*, 109 (1903); Jepson, *Silva of California*, 167 (1910).

Torreya Myristica, J. D. Hooker, in *Bot. Mag.* t. 4780 (1854); Murray, in *Trans. Bot. Soc. Edin.* vi. 217, pl. iii. (1860); Masters, in *Gard. Chron.* xxii. 681, fig. 116 (1884).

Caryotaxus Myristica, Henkel and Hochstetter, *Syn. Nadelh.* 368 (1865).

Tunion californicum, Greene, in *Pittonia*, ii. 195 (1891); Sargent, *Silva N. Amer.* x. 59, t. 513 (1896), and *Trees N. Amer.* 98 (1905).

A tree, attaining in California 100 ft. in height, and 12 ft. in girth, usually considerably smaller. Leaves, branches, and wood pungent-aromatic. Young branchlets glabrous, green, becoming brown in the second year. Buds, up to $\frac{1}{4}$ in. long, prismatic, with eight to ten decussate outer scales, those towards the apex elongated. Leaves, $1\frac{1}{4}$ to 3 in. long, $\frac{1}{8}$ in. wide; linear, tapering in the anterior third to an acuminate spine-tipped apex; dark shining green above; lower surface flat, glaucous, with two slightly depressed white stomatic bands (about 0.3 mm. wide), much narrower than the broad midrib (about 1 mm. wide), and the two outer glaucous bands (each about 0.7 mm. wide); petiole stout, $\frac{1}{2}$ in. long.

Staminate flowers $\frac{1}{3}$ in. long; connective truncate, not dentate. Fruit¹ ellipsoid or obovoid, 1 to $1\frac{1}{2}$ in. long; light green streaked with purple; flesh thin, resinous; shell fawn-coloured, smooth or with irregular slight longitudinal ridges; inner coat reddish, deeply folded into the white albumen.

Seedling² similar to that of *Ginkgo biloba*, with two thick and fleshy cotyledons, remaining underground; the stem bearing below a few scales, which are succeeded by ordinary leaves, the transition between the scales and the leaves being gradual.

(A. H.)

This species is a native of California, growing on the borders of mountain streams, nowhere common, but widely distributed from Mendocino County to the Santa Cruz mountains in the coast region, and along the western slopes of the Sierra Nevada from Eldorado to Tulare County, at 3000 to 5000 ft. elevation. It is most abundant and of its largest size in the northern coast ranges. Hough, in *American Woods*, pt. vi. p. 50, describes a fine tree overthrown by a flood near the coast in Mendocino County, from which the specimens of wood in his book were cut. It was 85 ft. long to the point, 5 in. in diameter, where its dead top was broken off. Its straight columnar trunk was 12 ft. in girth at eighteen inches, and 8 ft. at thirty-five feet from the ground. Assuming that the growth of this tree had been as uniform as in the section, which shows ten rings to the inch, it would have been from 250 to 300 years old, and the contents of the log about 300 cubic feet.

¹ Described from specimens grown at Orton. Cf. F. W. Oliver, in *Ann. Bot.* xvii. 466, pl. xxiv. (1903), for a detailed description of the remarkable structure of the seed of this species.

² Miss Chick (Mrs. Tansley) describes seedlings grown from seed produced at Orton, in *New Phytologist*, ii. 83, plates vii. viii. (1903).

Hough states that it is an excellent, light, and durable wood, well suited for boat-building and cabinetmaking, but too rare to be generally known or used. Jepson adds that the wood is strongly odorous, with white sapwood and clear light yellow heartwood, susceptible of a fine polish.

This tree was discovered in 1851 by William Lobb, who sent specimens and seeds in that year to Messrs. Veitch, which were described as *T. Myristica* in 1854 by J. D. Hooker, a short time after it had been published as *T. californica* by Dr. Torrey, who had received specimens from Mr. Shelton.

Though hardy in most parts of Great Britain, this species requires a heavy rainfall together with rich deep soil to grow to any size; and owing to its being usually planted in open situations, instead of in the densely wooded ravines which it likes, it has a tendency to spread and form branches rather than make a trunk.

By far the largest specimen that I know is at Tregothnan, which, when I first saw it in 1905, was 35 ft. by 6 ft.; and in 1911 had increased to 45 ft. high. Its shape is spoilt by three large lower branches; its trunk shows some large nipple-like protuberances resembling those often seen on the deodar.

Another tree at Orton Hall, Peterborough, has produced fruit regularly for the last twenty years, from which numerous seedlings¹ have been raised. It measured about 25 ft. by 4 ft. in 1905. At Poles, near Ware (Herts), a tree, which has never flowered, measured 40 ft. by 4 ft. in 1910. It was planted in 1858.

At Tortworth,² there is a handsome specimen, 25 ft. by 4 ft. in 1904, with branches spreading to a diameter of 36 ft.; and at Westonbirt, there is a tree in a shaded position, 29 ft. by 2 ft. 9 in. in 1907. At Chipping Campden, there is a tree about 30 ft. high, which bore staminate flowers in profusion in May 1911.

In Scotland it succeeds as far north as Durris in Kincardineshire, where a healthy specimen is about 20 feet high.

In Ireland, the best example is at Verner's Bridge, near Lough Neagh, where a tree measured 40 ft. by 4 ft. 7 in. in 1904. There are also specimens at Fota and Castlemartyr; the latter, forking near the ground, was 30 ft. high when I saw it in 1908.

(H. J. E.)

TORREYA TAXIFOLIA

Torreya taxifolia, Arnott, in *Ann. Nat. Hist.* i. 130 (1838); W. J. Hooker, *Icon. Plant.* tt. 232, 233 (1840); Kent, *Veitch's Man. Conif.* 119 (1900); Pilger, in Engler, *Pflanzenreich*, iv. 5, *Taxaceae*, 108 (1903).

Taxus montana, Nuttall, in *Journ. Acad. Sc. Phil.* vii. 96 (1834) (not Willdenow).

Caryotaxus taxifolia, Henkel and Hochstetter, *Syn. Nadelh.* 367 (1865).

Tumion taxifolium, Greene, in *Pittonia*, ii. 194 (1891); Sargent, *Silva N. Amer.* x. 57, t. 512 (1896), and *Trees N. Amer.* 98 (1905).

A tree, attaining in Florida 40 ft. in height and 6 ft. in girth, with foetid leaves, branches, and wood. Young branchlets green, with occasional minute hairs; older

¹ These grow very slowly at Colesborne and are now at eleven years old under two feet high.

² A section from another tree which died at Tortworth was sent by the Earl of Ducie to the Cambridge Forestry Museum.

branchlets yellowish red. Buds as in *T. californica*. Leaves $\frac{3}{4}$ to $1\frac{1}{2}$ in. long, $\frac{1}{8}$ in. wide; linear, tapering in the anterior third to an acuminate spine-tipped apex; shining green above; lower surface pale green, with two stomatic bands, scarcely depressed, and narrower than the midrib and the external bands; rounded at the base, with a short petiole, about $\frac{1}{5}$ in. long.

Staminate flowers, $\frac{1}{4}$ in. long; connective minute, rounded, not dentate. Fruit obovoid, 1 to $1\frac{1}{2}$ in. long, dark purple; flesh foetid, coriaceous; shell smooth, light brown; inner coat brownish and not so deeply folded into the albumen as in *T. californica*.

This species, of which I have seen no living specimen, appears to be very similar to *T. californica*, but has smaller leaves, with very short petioles, and, according to Sargent, is different in odour.

T. taxifolia is restricted to north-western Florida, where it grows on limestone cliffs and in swamps¹ along the banks of the Appalachicola River, from River Junction to near Bristol in Gadsden County. The wood, according to Sargent, is hard, strong, clear bright yellow, with thin lighter-coloured sapwood, and is used locally for fence-posts. Owing to the peculiar odour of the whole tree, noticeable also in the wood when burnt, it is known as "stinking cedar." Dr. Torrey informed Arnott that a blood-red turpentine, of a pasty consistence, flows sparingly from the bark, and is soluble in alcohol.

This species was discovered in 1833 by H. C. Croom, and was introduced² into England, in 1840, by A. J. Downing, who sent a living plant to London, which was propagated³ by Masters of the Canterbury Nursery. It probably proved unsuitable to our climate; and I have seen no specimen which could be identified with this species.

According to Sargent⁴ it can be kept alive in eastern Massachusetts in sheltered, well-shaded situations; and occasional individuals have survived a number of years near New York and Philadelphia.

(A. H.)

² Loudon, *Gard. Mag.* xvi. 658 (1840).

³ Loudon, *Trees and Shrubs*, 944 (1842), states that it was propagated by grafting on the yew.

⁴ Sargent, in *Garden and Forest*, x. 400 (1897).

CEPHALOTAXUS

Cephalotaxus, Siebold and Zuccarini, *ex* Endlicher, *Gen. Suppl.* ii. 27 (1842); Bentham et Hooker, *Gen. Pl.* iii. 430 (1880); Masters, in *Journ. Linn. Soc. (Bot.)* xxx. 4 (1893), and in *Gard. Chron.* xxxiii. 227 (1903); Worsdell, in *Ann. Bot.* xv. 637 (1901); Pilger, in Engler, *Pflanzenreich*, iv. 5, *Taxaceae*, 99 (1903).

EVERGREEN shrubs or small trees, belonging to the order Taxaceae, with opposite or whorled branches. Young branchlets green, marked by white stomatic dots, and with linear pulvini, separated by slight grooves. Buds, with numerous imbricated scales, which persist as a conspicuous sheath at the apex of the branchlet of the second year. Leaves spirally arranged, radially spreading on vertical shoots, but on lateral branches thrown by twisting of their bases into a pectinate arrangement; persistent three or four years, very shortly stalked, linear, acute at the apex; upper surface green with a prominent midrib in a depression; lower surface with two whitish broad bands, composed of numerous stomatic lines, separated by a narrow raised green midrib, and bounded on each outer side by a very narrow marginal green band; fibro-vascular bundle undivided, with a single resin-canal beneath it.

Flowers dioecious.¹ Staminate flowers in globose heads, which are solitary in the axils of the leaves of the branchlets of the previous year; each head with six to eleven flowers, each of which is subtended by a bract and has seven to twelve stamens; pollen-sacs two or three, dehiscing longitudinally.² Pistillate heads few, each solitary in the axil of a scale-leaf near the base of the branchlet of the current year, and composed of a stipitate axis, towards the end of which are three or four decussate pairs of opposite bracts; each bract is cup-shaped at the base and bears two erect ovules side by side. Usually only one or two of the ovules in a head develops, forming a drupe-like seed, with a fleshy outer covering, and an inner hard woody shell, which encloses the albumen and embryo. The seedling³ has two long linear cotyledons, immediately above which and decussate with them on the stem is a pair of primary leaves, which are followed at intervals by either whorls or pairs of larger leaves.

Six species⁴ of *Cephalotaxus* are known, one of which is possibly a hybrid,

¹ In rare cases, the flowers are monoecious, as in a shrub of *C. Fortunei*, described by Carrière in *Rev. Hort.* 1878, p. 116, fig. 24.

² Kerner, *Nat. Hist. Plants*, Eng. Trans. ii. 124 (1898), states that the anthers open and shut periodically.

³ Cf. Masters, in *Journ. Linn. Soc. (Bot.)* xxvii. 241 (1889).

⁴ *C. Mannii*, Hooker, native of the Khasi Mountains; *C. Griffithii*, Hooker, of Assam and Manipur; and *C. Oliveri*, Masters, of Central China, are not now in cultivation. The plants of *C. Griffithii*, formerly in the temperate house at Kew, mentioned by Hooker, *Fl. Brit. India*, v. 648 (1890), died many years ago. The young plants at Coombe Wood, referred to *C. Oliveri* in *Gard. Chron.* xxxiii. 227 (1903), and *Hortus Veitchii*, 338 (1906), are *C. drupacea*.

Podocarpus argotania, Hance, a peculiar conifer in southern China, is referred to *Cephalotaxus* by Pilger; but is distinct.

natives of China, Japan, Khasi Mountains, Assam and Manipur. As none of the three species in cultivation forms a tree in this country, they do not properly come within the scope of our work; but are now briefly described, owing to their interest as conifers, which are frequently seen in gardens. All the three species are perfectly hardy; but succeed best in shady situations, sheltered from the wind. When propagated by scions or cuttings, terminal shoots should be selected, as these form regular plants with whorled branches like seedlings; whereas cuttings from lateral branches grow into irregular low spreading shrubs.¹ (A. H.)

CEPHALOTAXUS DRUPACEA

Cephalotaxus drupacea, Siebold et Zuccarini, *Fl. Jap. Fam. Nat.* ii. 108 (1846), and *Fl. Jap.* ii. 66, tt. 130 and 131 (1870); Franchet et Savatier, *Enum. Fl. Jap.* i. 473 (1875); Masters, in *Gard. Chron.* xxi. 113 (1884), and xxxiii. 228, fig. 94 (1903), and *Journ. Linn. Soc. (Bot.)* xxii. 201 (1886) and xxvi. 544 (1902); Kent, Veitch's *Man. Conif.* 112 (1900); Shirasawa, *Icon. Ess. Forest. Japon.* i. text 31, t. xiv. figs. 1-12 (1900); Pilger, *Taxaceae*, 100, figs. 19, 20 (1903); Hemsley, in *Bot. Mag.* 8285 (1909).
Taxus baccata, Thunberg, *Fl. Jap.* 275 (1784) (not Linnæus).

A large shrub or small tree, occasionally attaining in Japan 40 ft. in height. Leaves on lateral branches pectinate, but spreading outwards usually in a V-shaped arrangement and not remaining in one plane, linear, $\frac{3}{4}$ to $1\frac{1}{2}$ in. long, straight or falcate, tapering towards the triangular acute apex, which is often tipped with a short spine-like point; stomatic bands beneath, each composed of about thirteen to fifteen lines. Staminate heads $\frac{1}{3}$ in. in diameter, on very short scaly stalks. Fruit brown, $\frac{3}{4}$ to 1 in. long, pyriform, broadest at the rounded apex, which has a circular depression bearing a minute mucro, and narrowed towards the base; kernel light brown, smooth, ellipsoid, $\frac{3}{8}$ in. long, $\frac{2}{8}$ in. wide, rounded at the base, the two sharp lateral edges in the upper half uniting into a slight apiculus at the apex.

This species is a native of Japan and central China. In Japan,² it is generally scattered through the mountain forests, extending northward to central Hokkaido, where it grows on low hills as an undershrub, 2 or 3 ft. high, of the deciduous forest; while in Hondo, where it ranges between 2000 and 3000 ft. altitude, it becomes a bushy tree, averaging 25 ft. high, and occasionally attaining 40 ft.³ It is known to the Japanese as *Inu-gaya*. In China, it has been found in the mountains of Hupeh and Chekiang and in the Chusan Archipelago.

C. drupacea was introduced by Siebold into the Botanic Garden at Leyden in 1829; but does not appear to have been known⁴ in English gardens till 1844. It

¹ Cf. Rehder, in Bailey, *Cycl. Amer. Hort.* 276 (1900).

² A species of *Cephalotaxus*, not yet determined, occurs in the mountains of Formosa at about 8000 feet altitude. Cf. Hayata, in *Journ. Coll. Sci. Tokyo*, xxv. 215 (1908). Elwes saw this as a bush without flowers or fruit on Arisan in 1912.

³ Mayr, *Fremdländ. Wald- u. Parkbäume*, 269 (1906), says that in the warmer parts of Japan it becomes a tree, rarely attaining 60 ft. in height.

⁴ Nicholson, *Gard. Dict.* i. 294 (1884), gives 1844 as the date of introduction into England. It was mentioned as a cultivated plant by Knight and Perry, *Syn. Conif.* 51 (1850), who gave for it the synonyms *Taxus coriacea* and *Cephalotaxus coriacea*.

always remains a spreading bush in this country, an old specimen at Kew being about 10 ft. high and 15 ft. through, and clothed to the ground with luxuriant dark green foliage.
(A. H.)

CEPHALOTAXUS FORTUNI

Cephalotaxus Fortunei, W. J. Hooker, in *Bot. Mag.* t. 4499 (1850); Masters, in *Gard. Chron.* xxi. 114, fig. 21 (1884), and xxxiii. 228 (1903), and *Journ. Linn. Soc. (Bot.)* xxvi. 545 (1902); Franchet, *Pl. David.* i. 292 (1884), and in *Journ. de Bot.* 1899, p. 265; Kent, Veitch's *Man. Conif.* 113 (1900); Pilger, *Taxaceae*, 103 (1903).

A small tree or large shrub, attaining the same dimensions as *C. drupacea*. Leaves on lateral branches pectinate and spreading in one plane, falcate, $1\frac{1}{2}$ to 3 in. long, tapering gradually in the anterior third to an acuminate, usually spine-tipped apex; stomatic bands beneath conspicuously white, each of eighteen to twenty-one lines, covering nearly the whole surface, the midrib and green margins being narrower than in *C. drupacea*. Staminate heads, less than $\frac{1}{4}$ in. in diameter, on scaly stalks, which are $\frac{1}{6}$ in. long. Fruit olive-green, about $1\frac{1}{4}$ in. long and $\frac{5}{8}$ in. in diameter, elongated ovoid, contracted towards the base, and broadest at the rounded apex, which is tipped with a short elevated point, arising from a circular depression; kernel elongated ellipsoid, about 1 in. long and $\frac{2}{8}$ in. wide, light mottled brown, minutely tuberculate on the surface, rounded at the base; upper half with two sharp lateral edges which unite at the apex to form an apiculus.

This species is occasionally monœcious.¹ In the Cheshunt Nurseries,² there was a female plant, which bore fruit in 1862 and 1863, though no flowers were borne on a staminate plant close by; and it was supposed to have been pollinated by a yew; but the seeds were not sown, and may have been infertile.

C. Fortunei is a native of China, occurring in the mountain woods of Szechwan, Hupeh, Yunnan, Kiangsu, and Chekiang, where it usually grows as a large bush in the shade of broad-leaved trees. It was discovered in the mountains south-west of Ningpo,³ in 1848, by Fortune, who sent seeds to the Bagshot Nursery in that year, which germinated freely. It is perfectly hardy in this country, and may be seen in many collections of conifers, forming a spreading shrub, with handsome foliage. The largest that we have seen is about 25 ft. high at Coldrenick. It appears to be little known in America.⁴
(A. H.)

¹ Cf. Carrière, in *Rev. Hort.* 1878, p. 116, fig. 24, where a branch, bearing both male and female flowers, is depicted.

² Cf. *Gard. Chron.* 1863, p. 1062.

³ Bretschneider, *Hist. Europ. Bot. Disc. China*, 502 (1908), points out that the statement usually made, that Fortune found it in North China, is erroneous.

⁴ Sargent, in *Garden and Forest*, x. 391 (1897).

CEPHALOTAXUS PEDUNCULATA

Cephalotaxus pedunculata, Siebold and Zuccarini, *Fl. Jap. Fam. Nat.* ii. 108 (1846), and *Fl. Jap.* ii. 67, t. 132 (1870); Franchet et Savatier, *Enum. Pl. Jap.* i. 473 (1875); Franchet, *Pl. David.* i. 292 (1884); Masters, in *Gard. Chron.* xxi. 113, fig. 22 (1884), and xxxiii. 228 (1903), and *Journ. Linn. Soc. (Bot.)* xxii. 201 (1886), and xxvi. 545 (1902); Kent, Veitch's *Man. Conif.* 114 (1900); Diels, *Flora von Central China*, 214 (1901).
Taxus Harringtonia, Knight, *ex Forbes, Pin. Woburn.* 217, t. 66 (1839); Loudon, *Gard. Mag.* xv. 273 (1839), and *Trees and Shrubs*, 942 (1842).
Cephalotaxus Harringtonia, Koch, *Dendrologie*, ii. 2, p. 102 (1873).
Cephalotaxus drupacea, Siebold and Zuccarini, var. *pedunculata*, Miquel, *Procl. Fl. Jap.* 333 (1867).
Cephalotaxus drupacea, Siebold and Zuccarini, var. *Harringtonia*, Pilger, *Taxaceae*, 102 (1903).

A large shrub or small tree. Leaves on lateral branches, pectinate, spreading either in one plane or in a V-shaped arrangement, straight or falcate, $1\frac{1}{2}$ to $2\frac{1}{2}$ in. long, tapering in the anterior third to an acute apex, which is often tipped with a spine; stomatic bands beneath each of sixteen to twenty-one lines, not so white as in *C. Fortunei*. Staminate heads in clusters of two to five, or occasionally solitary, on scaly peduncles, which are $\frac{1}{4}$ to 1 in. in length. Fruit olive-green, $\frac{3}{4}$ to 1 in. long, ellipsoid, not contracted at the basal end, with a circular depression at the apex from which arises a short mucro; kernel similar in size and shape to that of *C. drupacea*, but mottled light brown and slightly tuberculate on the surface.

The following varieties have been described:—

1. Var. *sphaeralis*, Masters, in *Gard. Chron.* xxi. 113, fig. 23 (1884), and in *Journ. Linn. Soc. (Bot.)* xxii. 203, plate vii. (1886).

Fruit smaller, globose, not depressed at the apex, which bears a long mucro. This was described by Masters from a specimen growing in the Rev. J. Goring's garden at Steyning; and a shrub at Kew has also borne similar fruit.

2. Var. *fastigiata*, Carrière, *Prod. et Fix. Var.* 44, fig. 1 (1865), and *Conif.* 717 (1867); Masters, in *Gard. Chron.* xxi. 113, fig. 20 (1884).

Cephalotaxus Buergeri, Miquel, *Procl. Fl. Jap.* 333 (1867).

Podocarpus koraiana, Siebold, in *Ann. Soc. Hort. Pays-Bas*, 1844, p. 34; Carrière, in *Rev. Hort.* 1863, p. 349, fig. 36; Maximowicz, *Mé. Biol.* vii. 563 (1870).

A fastigiate form, similar to the Irish yew in habit; branches and branchlets directed vertically upwards; leaves spreading radially on the branchlets.

This handsome shrub appears to have originated in Japan, whence it was introduced in 1861 into England, where it is perfectly hardy.¹ It has never, so far as is known, borne flowers either in Japan or in Europe; and is always propagated by cuttings. It frequently produces near the base lateral branches² with normal foliage; and grafts, that are taken from these branches, reproduce the ordinary form of the species.

¹ Sargent, in *Garden and Forest*, x. 391 (1897), states that it is not hardy in eastern New England, but there are good plants near New York and Philadelphia.

² Figured by Masters, in *Journ. Linn. Soc. (Bot.)* xxvii. 245, fig. 5 (1889), and *Gard. Chron.* xxxiii. 227, fig. 96 (1903). Cf. De Vries, *Mutation Theory*, 110, fig. 16 (1911), who instances these reverted branches as showing the phenomenon of atavism by bud-variation.

C. pedunculata has been long in cultivation in Japan, where it is known as *Chosen-gaya* or *To-gaya*, meaning Korean or Chinese Cephalotaxus; and was introduced there in ancient times from Korea or China by the Buddhist monks. It is unknown in the wild state, and in all probability is a hybrid between *C. Fortunei* and *C. drupacea*, which originated in China, where these two species are both native. It usually resembles more the former species in foliage, and the latter species in fruit; but differs from both in the clustered staminate heads, which is possibly an abnormal condition. There are plants in gardens reputed to be, but not exactly matching *C. Fortunei*, which may be seedlings of *C. pedunculata*. The latter species has leaves of a darker hue than *C. Fortunei* and *C. drupacea*; and is equally hardy, but is scarcely so ornamental as the true *C. Fortunei*, which has the leaves much whiter beneath.

The original *C. pedunculata*, long cultivated in Japan, was always a male plant, no doubt propagated by grafts and cuttings; and it was introduced¹ into England in 1837. So far as can be ascertained, the history of the female plant is as follows:—The seeds of *C. Fortunei*, which were sent by Fortune² from China in 1848 to the Bagshot Nursery, produced two kinds of plants; one kind with long leaves, identical with the true wild plant of *C. Fortunei*; and the other kind with shorter leaves, identical with *C. pedunculata*, and comprising individuals which bore fruit.³

(A. H.)

¹ Cf. Loudon, *Trees and Shrubs*, 943 (1842). It appears to have been introduced by Siebold into Holland in 1829.

² Cf. Fortune, in *Gard. Chron.* 1863, p. 1134.

³ W. Gorrie, in *Gard. Chron.* 1861, p. 51, points out that the shorter-leaved plants bearing fruit were certainly not *C. drupacea*. Fortune, believing that these plants constituted a new species, sent specimens from Chekiang in 1858, which are now preserved in the Lindley herbarium at Cambridge. These specimens, however, are simply a ♀ branch of *C. Fortunei*, and a ♂ branch of *C. drupacea*; and only show, that as both these species occur in Chekiang, the seed which he sent in 1848 may have been in part of hybrid origin.

KETELEERIA

Keteleeria, Carrière, in *Rev. Hort.* 449 (1866); Pirota, in *Ann. R. Ist. Roma*, iv. 200 (1889);

Masters, in *Journ. Linn. Soc. (Bot.)* xxx. 33 (1893).

Abies, Bentham et Hooker, *Gen. Pl.* iii. 442 (in part) (1880) (not Linnæus).

EVERGREEN trees belonging to the division Abietinæ of the order Coniferae, and closely allied to *Abies*, from which they differ mainly in the persistent scales of the cones, in the fascicled staminate flowers, and in the leaves with the midrib prominent on both surfaces and ending in a spine on young plants. Branchlets smooth, with circular depressions, from which the leaves arise. Buds, of numerous imbricated scales, persisting after the branch has developed as a conspicuous sheath at its base. Leaves solitary, spiral on the branchlets, but thrown usually into a pectinate arrangement on lateral branches; linear, with the narrow stalk-like base expanded into a circular disc; acute or retuse at the apex (spine-tipped in young plants); upper surface with the midrib prominent in a longitudinal depression; lower surface with a raised midrib, two longitudinal sets of white stomatic lines, and two green marginal bands; fibro-vascular bundle undivided, with two resin-canals close to the epidermis of the lower surface near the outer angles.

Staminate flowers, in umbel-like clusters, each cluster of five to ten flowers either terminal or in the axil of a leaf on the current year's branchlet, arising on a short stalk covered with imbricated scales; each flower with a stipitate axis bearing numerous anthers, each with two pollen sacs; pollen grains with air-vesicles.

Cones erect on the branches, ripening in one year, and very similar to those of *Abies*, but differing in the persistent bracts and scales, the latter gaping apart to shed the seeds. Seed as in *Abies*, with resin-vesicles, and a hatchet-shaped wing, but detachable from the latter, which envelops it on one surface and two edges.

About five species of *Keteleeria* are known in the living state, natives of China, Formosa, and Tonking. They are closely related¹ to the silver firs, but exist in a warmer and drier climate, to which their varnished coriaceous needles are adapted. The leaves resemble superficially those of *Cephalotaxus*, but are readily distinguishable by the circular disc at the base.

Two species have been introduced into Europe.

¹ They have been erroneously supposed by various authors to be allied to *Pseudotsuga* and *Torreya*.

KETELEERIA FORTUNEI

- Pseudotsuga jezoensis*, Bertrand, in *Ann. Sc. Nat.* xx. 87 (1874).
- Abictia Fortunei*, Kent, Veitch's *Man. Conif.* 485 (1900).

A tree, attaining in China 80 ft. in height, with thick whitish bark, divided into irregular plates, and somewhat like that of the cork oak. Young branchlets¹ slender, with a scattered short wavy soft pubescence. Buds ovoid, rounded at the apex, with numerous scales. Leaves on adult trees $\frac{1}{2}$ to $1\frac{1}{4}$ in. long, $\frac{1}{8}$ in. wide, linear; rounded, retuse or acute at the apex; midrib prominent in a longitudinal depression on the upper surface; lower surface with twelve to sixteen lines of stomata on each side, extending from the raised midrib nearly to the margin, which shows a very narrow green depressed border.

Leaves on young plants 1 in. long, $\frac{1}{8}$ in. broad, ending in an acuminate apex, tipped by a spine-like point; upper surface as in adult leaves; lower surface with a very narrow raised midrib, and two wide bands, each of sixteen stomatic lines, extending to a linear groove just inside the margin.

Cones on pubescent scaly stalks, nearly cylindrical, 4 to 5 in. long, $2\frac{1}{4}$ in. wide, bluish before ripening, brown tinged with purple when mature; scales about $1\frac{1}{4}$ in. wide, broadly oval with a short claw, concave internally from side to side, with the upper part inflexed, and the margin slightly denticulate; externally covered with slight pubescence towards the base; bract $\frac{5}{8}$ in. long, with a linear claw, expanded above into a denticulate lamina, ending in a sharp mucro. Seeds covering the whole of the scale, except its lateral borders.

This species is a native of the coast range of the province of Fukien in eastern China, where it was seen by Maries² in 1878, growing wild in quantity and associated with *Pinus Massoniana*. It was discovered in 1844 by Fortune, who found a single tree near the Kushan temple, which is situated in the mountains a few miles to the eastward of Foochow at about 2000 ft. elevation. Fortune sent specimens and seed to Messrs. Standish and Noble, who raised young plants, most of which appear to have been distributed on the continent by Van Houtte. None of the original

¹ On the tree at Pallanza the branchlets in November are dark red, with merely traces of pubescence.

² *Hortus Veitchii*, 341 (1906).

plants survived in England, but a fine specimen¹ is growing in Rovelli's nursery at Pallanza, which measured 55 ft. by 8 ft. in 1909. This tree produces seed freely, from which numerous plants have been raised since 1884. Mr. Rovelli states that they are very difficult to transplant; and we know of none which have as yet attained any size in England. (A. H.)

KETELEERIA DAVIDIANA

- Abies sacra*, Franchet, *Pl. David.* i. 290, t. 14 (1884).
- Pseudotsuga Davidiana*, Bertrand, in *Ann. Sc. Nat.* xx. 86 (1874).
- Podocarpus sutchuenensis*, Franchet, in *Journ. de Bot.* 1899, p. 265, ex Diels in Engler, *Jahrb.* xxxvi. No. 5, p. 3 (1905).

A tree, attaining² in China 100 ft. in height and 16 ft. in girth. Young branchlets slender, with short stiff erect hairs. Buds as in *K. Fortunei*, but with scales not keeled on the back. Leaves on adult trees similar to those of that species, but slightly larger, with a wider prominent midrib beneath, on each side of which are nine lines of stomata.

Leaves on young plants $1\frac{1}{4}$ in. long, $\frac{1}{7}$ in. broad, tapering to an acuminate spine-tipped apex; lower surface with a broad green midrib, elevated in the central line as a narrow ridge, two stomatic bands, each of eight to nine lines, and two marginal green bands, near the edge of each of which is a linear longitudinal groove.

Cones sub-sessile or stalked, nearly cylindrical, 6 to 8 in. long, 2 in. in diameter, brown when ripe: scales about 1 in. long and $\frac{3}{4}$ in. wide, ovate, with a rounded or slightly contracted truncate apex, which is inflexed; concave internally from side to side; outer surface minutely pubescent towards the base: bract $\frac{1}{2}$ in. long, with an oblong claw ending in a denticulate lamina, scarcely broader than the claw, and tipped with an acuminate point. Seeds not extending quite to the apex or lateral margins of the scale.

This species, which was discovered by Père David in 1869, is widely distributed throughout the interior of China, occurring in the provinces of Shensi, Hupeh, Szechwan, and Yunnan; and has recently been found in the mountains of Formosa. In China it is a tree of lower elevations than *Abies* or *Picea*, and forms woods in a warm climate on dry hills at about 2000 to 4000 ft. altitude in western Hupeh, and

¹ Figured in *Gard. Chron.* xxv. 428, fig. 83 (1886). According to Carrière, *Rev. Hort.* 1887, p. 211, it was planted in 1859. Carrière adds some interesting details of this species, which he states can be multiplied, but with difficulty, by cuttings and layers.

² I measured a tree of this size in the Wushan district, north of the Yangtse in eastern Szechwan, in 1888.

1476 The Trees of Great Britain and Ireland

at 4000 to 5000 ft. in southern Yunnan. It shows a considerable amount of variation in the wild state; and Franchet described as a distinct species (*Abies sacra*) a form with glabrous branchlets in Shensi. The Formosan tree¹ is distinguished by Hayata² as var. *formosana*.

I sent seed from Hupeh in 1888, which was raised at Kew, where there is a specimen in the Temperate House about 4 ft. high. Wilson³ sent to Coombe Wood in 1901 seeds from western China, which germinated freely, producing hardy plants which are now about 4 ft. high. These appear to constitute two varieties, differing slightly in the length of the foliage.

A log of this species, about 10 in. in diameter, which is now in the Cambridge Forestry Exhibition, was obtained in the mountains of Hupeh by Mr. E. H. Wilson in 1910, during his last voyage in Central China. This was quickly grown, averaging 12 rings to an inch of radius. The wood strongly resembles in appearance that of the common silver fir, and is soft, light, and easily worked. It differs from *Abies* slightly in structure, having resin-canals. (A. H.)

¹ I saw this fine tree in North Formosa in March 1912, at about 2000 ft. above sea-level, in a thick virgin forest at Kinkaryo on the Hokusii river, about 6 miles from Heirimbi. It attains a very large size; but I was unable to measure any old trees on account of the difficulty of reaching them. When the Japanese occupied Formosa it was abundant in this district; but most of the large trees were cut down and used in building houses at Taihoku. I saw in the house of S. Nanasumi, chief of police at Heirimbi, very wide boards, cut from this tree, of a rich purplish brown colour, unlike that of any conifer known to me. A specimen of this wood is now in the Cambridge Forestry Museum. *Keteleeria* is known to the Chinese as *Yu-san*, and to the Japanese as *Shima-momi*. The only other part of Formosa where it is known to occur is near Bosan in the south-west.—H. J. E.

Larix Kaempferi, Carrière, in *Flore des Serres*, xi. 97 (1856); Masters, in *Journ. Linn. Soc. (Bot.)* xviii. 523 (1881); Franchet, *Pl. David.* i. 286 (1884).
Pinus Kaempferi, Parlatore, in De Candolle, *Prod.* xvi. 2, p. 412 (not² Lambert).
Laricopsis Kaempferi, Kent, Veitch's *Man. Conif.* 404 (1900).

A tree, attaining in China 120 or 130 feet in height. Bark reddish brown, fissured into small narrow scaly plates. Branchlets of two kinds, long shoots and short shoots or spurs, as in the larches (cf. Vol. II. p. 345). Long shoots in the first year glabrous, glaucous, with linear pulvini, separated by slight grooves; in the second year reddish brown with broad white corky fissures between the pulvini.

¹ Bentham and Hooker mention *Pseudolarix*, in a note under *Larix*, as probably a distinct genus.

² *Pinus Kaempferi*, Lambert, *Genus Pinus*, ii. preface, p. v (1824), and the original *Abies Kaempferi*, Lindley, *Penny Cycl.* i. 34 (1833), were names applied to the true larch of Japan, *Larix leptolepis*, which was first mentioned as "*Larix conifera, nucleis pyramidalis foliis deciduis*," by Kaempfer, *Amen. Exot.* 833 (1712). The name *Abies Kaempferi* was subsequently applied by Lindley in error to the Chinese *Pseudolarix*, which was quite unknown to Kaempfer or to Lambert; and Gordon's name, *Pseudolarix Kaempferi*, founded on Lindley's erroneous application, was rightly changed by Mayr to *Pseudolarix Fortunei*.

Short shoots with annual zones of growth, each zone marked by a depression and a ring of subulate scales. Buds of three kinds, as in the larches; those terminating (*a*) the long shoots and (*b*) the short shoots, conic, surrounded by acuminate scales, ending in long subulate points; and (*c*) lateral buds, solitary in the axils of a few leaves of the long shoots, globose, with rounded or short-pointed scales.

Leaves deciduous, solitary and spirally arranged on the long shoots, and in clusters of fifteen to thirty at the apices of the short shoots; jointed at the base with the tip of a pulvinus, linear, straight or falcate, $1\frac{1}{2}$ to 2 in. long, $\frac{1}{12}$ in. broad, acute or acuminate, green and slightly convex above; under surface with a raised green midrib, two longitudinal channels covered with white stomatic lines, and a narrow thin outer margin. Fibro-vascular bundle undivided; resin-canals three, all close to the epidermis, one in the median line near the upper surface, and two lateral, near the outer edges of the lower surface.

Flowers monœcious. Staminate flowers, pendulous, twenty-five to thirty in a cluster, at the apex of a leafless short shoot, each subtended by loose scarious scales, and including the slender stalk about $\frac{3}{8}$ in. long; anthers twenty, two-celled, opening transversely; pollen grains winged as in *Pinus*, and different from the simple pollen of *Larix*. Pistillate flowers globose, $\frac{3}{4}$ in. in diameter, terminating a short leafy branch, which arises from the apex of a short shoot; ovules, two on each scale, reversed. Cones, erect on the branches, ripening in the autumn of the first year, ovoid, $1\frac{1}{2}$ to 2 in. long; scales numerous, imbricated, coriaceous, reddish brown when ripe, $\frac{3}{4}$ to $1\frac{1}{4}$ in. long, ovate, tapering to a blunt, acute, or notched apex, sagittate at the base, with a claw bent upwards at a right angle, which arises by a narrow linear attachment from the axis of the cone: bract, ovate-lanceolate, $\frac{1}{5}$ to $\frac{1}{3}$ in. long, acuminate, denticulate, adnate to the base of the scale, and deciduous with it. Seeds, two on each scale, which they completely cover with their short body and long wing; wing oval-lanceolate on the outer edge, straight on the inner edge, pale brown, translucent, enclosing the body of the seed on the front and sides in a cavity; body detachable from the wing, white, obovate, with two large resin-vesicles; cotyledons five to seven. As the cone ripens the scales gape apart, showing the wings of the seeds projecting beyond them, and giving them the appearance of a whitish margin. Soon afterwards the scales, bracts, and seeds fall together to the ground, the central axis of the cone being the only part of it left on the branch, as is the case in *Cedrus* and *Abies*.

This remarkable conifer is a native of the provinces of Chekiang and Kiangsu in eastern China, where it is known from two localities, both in about lat. $29^{\circ} 30'$. Fortune discovered it in 1853, in the mountains south-west of Ningpo, where there were some fine trees growing near the Tsan-tsin monastery¹ at 1000 to 1500 ft. elevation; and in 1854 he found a plantation, about twenty miles westward, in the vicinity of the Quan-ting monastery, on a mountain slope at about 4000 ft. altitude, one of the trees, standing alone and clothed with branches to near the ground, being 130 ft. in height and 8 ft. in girth. The Rev. G. E. Moule also found

¹ This monastery is about a day's journey from Ningpo. Cf. Bretschneider, *Hist. Europ. Bot. Disc. China*, 416 (1898).

some trees¹ in the hills west of Ningpo in 1874. The only other locality where this species has been seen is the Lüshan mountains, south of Kiukiang in Kiangsu, where it was discovered by Abbé David in 1868, and afterwards by Maries,² who mentions immense trees; but Wilson³ only succeeded in finding in these mountains, some wild, and half a dozen planted trees, none of considerable size.

Fortune had been acquainted with this tree for some years previously as a dwarf plant⁴ in pots, contrived, though only $1\frac{1}{2}$ to 2 ft. high, to look like an aged Cedar of Lebanon. It appears to be known to the Chinese, as either *chin-sung*, "golden pine," or *chin-lo-sung*, "golden deciduous pine," names applied on account of the beautiful yellow colour of the foliage for a short time before it falls in autumn.

Fortune sent seeds from Chekiang in 1853, and again in 1855 to Glendinning's nursery, Chiswick; but he states⁵ that of all the packages of seed, which he sent for several years in succession, only one batch ever germinated; and that the only plants living in England in 1860 were natural seedlings which had been dug up in the woods of China and sent⁶ home in Wardian cases in 1854.

The tree is perfectly hardy, as it withstood the severe winter of 1859-1860 at Ambleside⁷ and at Hafodunos⁷; and possibly its rarity in collections is due to the small number of plants actually introduced; but it appears to be extremely slow in growth in England. It will not endure lime in the soil, as the seedlings raised and planted at Colesborne soon die. (A. H.)

REMARKABLE TREES

The finest tree that we know of is in a sheltered situation at Carclew, which, when I saw it in 1902, was 35 ft. by 5 ft. In 1910 it was 40 ft. by 5 ft. 2 in. I am told by Mr. Simmons, the head-gardener at Carclew, that he has never found fertile seed on it. There is a healthy tree in the grounds at Hutley Towers near Ryde, which in 1906 was 30 ft. by 2 ft., but it produced no cones either in 1905 or 1906. At Joldwynds, near Dorking, the seat of Sir W. Paget Bowman, Bt., there is a tree, planted about 1879, which is now $27\frac{1}{2}$ ft. by $2\frac{1}{2}$ ft. Though perfectly healthy and branching to the ground it has never produced any seed.

There are several trees at Kew, the largest of which near the main gate is probably one of the original seedlings.⁸ It flowered profusely in June 1907, producing fully developed cones with imperfect seed, no embryo being formed.⁹ It bore cones freely again in 1910; and measured 31 ft. by 2 ft. 4 in. in 1912.

At Tortworth, a tree measured in 1910, 37 ft. by 4 ft. 1 in. Lord Ducie informs me that it was planted on 3rd November 1858, in a bed of sand overlying carboniferous limestone, deep enough, however, to sustain a heavy growth of

¹ Referred by Hance to *Larix dahurica*, but evidently, from the Chinese name "*chin-sung*," used by Moule, he was speaking of *Pseudolarix*.

² Cf. Bretschneider, *op. cit.* 741 (1898).

³ *Var. nana*, Masters, in *Journ. Linn. Soc. (Bot.)* xviii. 523 (1881).

⁴ Fortune, in *Gard. Chron.* 1855, p. 644. Kent says that until the tree coned at Pallanza, plants were obtained by layering.

⁵ In *Gard. Chron.* xlii. 344 (1907).

⁶ In *Gard. Chron.* 1860, p. 170.

⁷ *Gard. Chron.* 1860, pp. 74 and 386.

⁸ It is apparently the tree mentioned by J. Smith, *Records of Kew Gardens*, 290 (1888), as 5 ft. high in 1864.

⁹ According to Masters, in *Gard. Chron.* ii. 440 (1887) and *Journ. Roy. Hort. Soc.* xiv. 68 (1892), this species first produced fruit in England in 1887 at Lucombe and Pince's nursery, Exeter, but this tree is no longer living.

1480 The Trees of Great Britain and Ireland

Rhododendron. The tree is very brittle, and has lost many branches, and is somewhat ragged in look although it is in a very sheltered position. It produced cones on four or five occasions; but in no case did they contain fertile seed.

The Rev. Hon. W. Ellis informs me that at Bothelhaugh, near Morpeth, Northumberland, a tree planted over thirty years ago is under 6 ft. high. At Coombe Wood, the largest specimen measured 35 ft. by 3 ft. 8 in. in 1910. At Scorrier, near Truro, a healthy tree was 30 ft. by 3 ft. in 1911.

We have seen no trees in either Scotland or Ireland.

The finest specimen in Europe is growing in Rovelli's nursery at Pallanza; and measured 64 ft. by 6 ft. 10 in. in 1909. This tree produced staminate flowers in 1884; and since then has coned regularly every two or three years. Large numbers of natural seedlings appear in prepared soil under the tree; and the seed is said to germinate better where it falls, than when collected and sown in pans under glass. As the seeds and scales fall together and close to the parent tree, young seedlings probably succeed best with considerable shade.

In Belgium it is said¹ to have attained no less than 46 ft. in height by 3 ft. in girth at the nursery of the Horticultural Society of Calmpthout, near Antwerp, where seedlings grew as fast as those of the common larch; and Dr. Masters mentioned,² in 1883, a fine tree in Linden's nursery at Ghent.

At Verrières, near Paris, one of the original trees³ is about 35 ft. high and 3 ft. in girth. It produces fruit and fertile seed, but in no great quantity. There is a good specimen⁴ at Karlsruhe, about 35 ft. high, which bore cones for the first time in 1896; the seed, however, was unfertile.

In the United States this tree thrives well, as it delights in hot summers; and Sargent states that he never saw a plant which appeared to suffer from heat or cold, fungoid diseases, or the attacks of insects. The largest specimen⁵ is growing in Parson's nursery at Flushing, Long Island, which was imported from London in 1859 when it was 3 ft. high. It measured in 1895 55 ft. high, with a stem 2 ft. in diameter, and branches 50 ft. across, and has borne seed frequently. Another specimen in Mr. Hunnewell's pinetum at Wellesley, Mass., measured⁶ in 1905 35 ft. in height and 4 ft. in girth, with a spread of branches of 37 ft. This tree has borne seed since 1887, and many seedlings have been raised from it. Sargent reports⁶ another large specimen on Mr. Probasco's estate at Cincinnati. (H. J. E.)

CATALPA

Catalpa,¹ Scopoli, *Introd. Hist. Nat.* 170 (1777); Bentham et Hooker, *Gen. Pl.* ii. 1041 (1876); Bureau, in *Nouv. Arch. Mus. Hist. Nat.* vi. 169 (1894); Dode, in *Bull. Soc. Dendr. France*, i. 194 (1907).

DECIDUOUS trees, belonging to the order Bignoniaceæ. Branchlets stout, with thick pith; leaf-scars elevated, orbicular, marked with a circle of dots, which are the tiny scars left by the fibro-vascular bundles of the fallen petiole. Buds minute, globose, immersed in the bark, with two to four external scales; all axillary, no true terminal bud being formed, the top of the branchlet dying in summer, and leaving an elevated circular scar close to the upper axillary bud. Leaves simple, opposite or in whorls of threes, entire or lobed, long-stalked, pinnately-nerved, without stipules.

Flowers perfect, in terminal panicles or corymbs.² Calyx gamosepalous, membranous, splitting when the flower opens into two broad ovate entire lobes. Corolla gamopetalous, inserted on a nearly obsolete disc; tube broad, campanulate, oblique, enlarged above into a spreading bilabiate limb, the posterior lip two-partite, the anterior three-lobed. Stamens inserted near the base of the corolla, two, anterior, filaments flattened, anthers bilocular and opening longitudinally. Staminodes similarly inserted, three, posterior, filiform, minute or rudimentary. Ovary sessile, two-celled; style elongated, divided at the apex into two stigmatic lobes³; ovules numerous in several series on a central placenta. Fruit, a long nearly cylindrical capsule, tapering from the middle to each end, persistent on the branches during winter, and ultimately splitting into two valves. Seeds numerous, small, oblong, compressed, inserted in two or four ranks near the margin of the woody septum, with broad lateral wings, notched at the base of the seed, and ending in tufts of long coarse hairs.

The leaves of *Catalpa* show on their lower surface in the axils of the nerves clusters of circular glands which secrete nectar, and are visited by numerous insects, especially ants and bees, the latter getting honey from them as well as from the

¹ *Catalpa* is a corruption of *Catawba*, the name of an Indian tribe that formerly occupied Georgia and the Carolinas.

² Bureau divides the temperate species into two sections:—

(a) *Thyrsoideæ*, comprising *C. bignonioides*, *C. speciosa*, and *C. Kaempferi*; inflorescence a narrow panicle, the secondary axes being branched.

(b) *Corymbosæ*, including *C. Bungei* and *C. Fargesii*; inflorescence a corymb, with simple secondary axes.

³ The stigmatic lobes exhibit sensitive movements, opening and shutting like the leaves of a book, with the visits of bees and other insects. Cf. Masters in *Gard. Chron.* xiii. 651 (1880), and Kerner, *Nat. Hist. Plants*, Eng. Trans. ii. 281 (1898). This phenomenon in *C. bignonioides* has been studied by Meehan, in *Proc. Amer. Assoc. Adv. Sc.* 1873, pp. 72, 73, and in *Bot. Gaz.* viii. 191 (1883); and in the case of *C. speciosa* by Antisdale, in *Bot. Gaz.* viii. 171 (1883).

flowers. These glandular areas, which are large and conspicuous near the base of the leaf, bear no pubescence.¹

The seedlings² of *Catalpa* have stalked deeply bifid obovate cotyledons raised above ground, and followed on the stem by opposite decussate or ternately verticillate ovate leaves.

Catalpas may be propagated³ by both stem and root cuttings.

Eight species of *Catalpa* are known, of which three are natives of the West Indies and not hardy. The West Indian species constitute a distinct section, characterised by lanceolate or elliptic leaves. The remaining five species, with ovate leaves, inhabit the United States and China; and have all been introduced into cultivation in Europe. They may be arranged as follows:—

I. *Leaves glabrous.*

1. *Catalpa Bungei*, Meyer. China. See p. 1489.

Leaves, with a disagreeable peculiar odour, entire with a long slender acuminate apex, or with one or two long-pointed lateral lobes, or coarsely serrate in margin.

II. *Leaves pubescent with simple hairs.*

* *Branchlets glabrous.*

2. *Catalpa bignonioides*, Walter. United States. See p. 1485.

Leaves, with a disagreeable peculiar odour, usually entire with a short apex, glabrous above, pubescent beneath, the pubescence not covering the whole surface of the midrib.

3. *Catalpa speciosa*, Warder. United States. See p. 1483.

Leaves inodorous, usually entire with a long acuminate apex, glabrous above, pubescent beneath, the pubescence covering the midrib entirely.

** *Branchlets with stiff glandular hairs.*

4. *Catalpa Kaempferi*, Siebold and Zuccarini. Wild in Central China, long cultivated in Japan. See p. 1487.

Leaves inodorous, usually three-lobed; pubescent on the upper surface throughout, and on the lower surface on the midrib and nerves.

III. *Leaves tomentose with branched hairs.*

5. *Catalpa Fargesii*, Bureau. Central China. See p. 1490.

Leaves entire or with one or two acute lateral lobes; tomentose on the lower surface throughout, and on the upper surface mainly on the nerves.

(A. H.)

¹ Cf. Ryder in *Proc. Philad. Acad.* 1879, p. 161, and *Amer. Nat.* xiii. 648 (1879). The glandular areas are greenish in the two species from the United States, and purplish in the three Chinese species. They are almost entirely confined to the base of the leaf in *C. Fargesii* and *C. Bungei*; but are also present in the upper axils of the leaf in *C. Kaempferi*, *C. speciosa*, and *C. bignonioides*.

² Described by Lubbock, *Seedlings*, ii. 335, 339, fig. 571 (1892).

³ Cf. J. Clarke in *Gard. Chron.* xlvii. 100 (1910).

CATALPA SPECIOSA, WESTERN CATALPA

Catalpa speciosa,¹ Warder, *ex Engelmann*, in *Bot. Gaz.* v. 1 (1880); Sargent, *Silva N. Amer.* vi. 89, tt. 290, 291 (1894), and *Trees N. Amer.* 795 (1905); Bureau, in *Novv. Arch. Mus. Hist. Nat.* vi. 184 (1894); André, in *Rev. Hort.* lxxvii. 136, fig. (1895); Hall and Schrenk, *U.S. Dep. Agric. Bur. Forestry, Bull.* No. 37 (1902); Roberts and Dickens, *Kansas State Agric. College, Bull.* No. 108 (1902); Dode, in *Bull. Soc. Dendr. France*, i. 195 (1907).
Catalpa cordifolia, Jaume, in Duhamel, *Traité des Arb.* ii. t. 5 (1802) (excl. text) (not Moench).

A tree, rarely attaining in America 120 feet in height and 14 feet in girth, usually smaller. Bark thick, deeply furrowed, and roughened with scales. Young branchlets glabrous. Leaves similar to those of *C. bignonioides*, but without their peculiar odour, often larger, up to 10 in. long and 7 in. wide, with longer acuminate points; glabrescent above; lower surface with the pubescence of simple hairs more marked than in *C. bignonioides*, spreading over the whole of the midrib and extending to the petioles.

Flowers appearing two weeks earlier than those of *C. bignonioides*, few in open panicles, which are about 6 in. long and broad; calyx purplish, glandular-pubescent; corolla white, 2 in. long, 2½ in. wide, often spotted externally with purple near the base; marked internally on the lower side with two bands of yellow blotches following two lateral ridges, and a few purple spots on the lobes of the lower lip of the limb. Fruit, 8 in. to 20 in. long, ½ in. to ¾ in. in diameter in the middle, with a thick wall, splitting into two concave valves. Seeds 1 in. long, ½ in. wide, light brown, with wings rounded at the ends and ending in a fringe of short hairs.

C. speciosa under favourable conditions differs from *C. bignonioides* in habit, forming a narrow tree with ascending branches; but in the arboretum at Segrez, where there are old trees of both species, they are nearly alike in appearance. They are readily distinguished by their flowers, fruits, and seeds; but when these are absent, the main distinctive character is the odour of the leaves.²

This species in its natural range is confined to a limited region, extending from the valley of the Vermilion river, Illinois, through southern Illinois and Indiana, western Kentucky and Tennessee, south-eastern Missouri, and north-eastern Arkansas. It comes in contact with *C. bignonioides* in south-eastern Missouri; and is abundant and of its largest size in southern Illinois and Indiana. It has become naturalised through cultivation in southern Arkansas, western Louisiana, and eastern Texas.

It has been planted in the United States as far north as South Dakota, southern Michigan, and Minnesota, and southern Massachusetts; and westward to eastern

¹ Warder, in *Western Hort. Review*, iii. 533 (1853), was the first to distinguish *C. speciosa*, but did not then publish this specific name. It appears to have been first used by Sargent, who, in *Gard. Chron.* xii. 784 (1879), points out that the western *Catalpa* differs from *C. bignonioides*; and says that if distinct, it should be known as *C. speciosa*.

² W. H. Lamb, in *Proc. Soc. Amer. Foresters*, vii. 80, figs. 1, 2 (1912), points out that the septum of the pod (the long wrinkled partition along which the seeds are arranged) is nearly circular in section in *C. speciosa*, and lenticular or narrowly elliptic in *C. bignonioides*.

Nebraska, Kansas, and Oklahoma. It has succeeded on irrigated lands in New Mexico, Utah, and Colorado, at low altitudes and where the soil is free from alkali. The range for economic planting appears to be on the fertile alluvial lands of the middle west, south of lat. 41° .

This species, though only distinguished by Warder as late as 1853, appears to have been introduced early into France, as it was figured in *Nouveau Duhamel* in 1802; but no trees so old as this are now known in Europe. Prof. Sargent sent seeds to Kew in 1880, and probably about the same time to Segrez and Les Barres in France. At Kew *C. speciosa*, though forming a better tree than *C. bignonioides*, is very slow in growth, the tallest example, now thirty years old, from seed, being about 25 feet high. It is perfectly hardy, as it has borne at Kew 0° Fahr. without injury, and does not suffer in the severe winters of New England. Bureau states that on M. André's property in Touraine it did not suffer from a temperature of -26° Cent.

It came into vogue in America as a tree for planting to produce timber quickly about 1879 to 1883, when large plantations were made by R. Douglas, near Farlington in Kansas, which are now owned by the railway company. One forty-acre tract of these plantations is, however, *C. bignonioides*. (A. H.)

CULTIVATION

An immense quantity of literature on this species has appeared in America, mainly by Mr. John P. Brown of Connersville, Indiana, who devoted a great part of his magazine, *Arboriculture*, to advocating the economic value of this tree. Though this publication contains many illustrations and details on the growth of the Catalpa in many localities and under varied conditions, it has more interest for American than for British readers, and our space will not allow me to refer to them in detail. There seems to be little doubt that in the rich alluvial valleys of the Ohio, Tennessee, Arkansas, and other tributaries of the Mississippi, its growth is very rapid when young, and it is one of the most valuable trees for fencing, lumber, railway sleepers, and other purposes,¹ on account of the durability of its timber; but it requires a much longer and hotter summer than any part of our islands afford. The latest account of this species is by Oman,² who studied the results obtained by four plantations in Kansas, which were cut in 1902-1906. He gives valuable hints regarding the proper mode of planting, and states that the financial returns on deep fertile porous soil are remarkable. This tree endures inundation, one plantation having been completely submerged for a week without injury. It coppices freely, and can even be propagated by cuttings; but suckers from the roots have not been observed.

Large quantities of seedlings have been raised and distributed in this country on several occasions,³ but we cannot hear of a single place in which they show any

¹ It is also a suitable timber for furniture, as shown by an arm-chair given me by Mr. Brown at Louis in 1904, which has handsome grain, takes a good polish, and has worn well.

² *Proc. Soc. Amer. Foresters*, vi. 42-52 (1911).

³ About 150 trees of this species, which were raised from seed in the Royal Horticultural Society's garden at Chiswick in 1880, were distributed widely to the members; but we have not seen any of these (*Gard. Chron.* xlvii. 245 (1910)).

signs of becoming a timber tree. I agree entirely with the opinion that Mr. Bean has expressed in *Kew Bulletin*, 1907, p. 43, that it is improbable that this tree can be grown anywhere in England with any hope of profit, though as an ornamental tree of small size it may have considerable value in favourable situations.

A plantation of it was made near Tottenham House, Marlborough, by the Marquess of Ailesbury, where the young trees in 1907 were 3 to 6 ft. high, but so far as we can learn they grow slowly and do not ripen their wood in autumn, which is the case with those I have raised myself. (H. J. E.)

CATALPA BIGNONIOIDES, COMMON CATALPA

Catalpa bignonioides, Walter, *Fl. Car.* 64 (1788); Bureau, in *Nouv. Archiv. Mus. Hist. Nat.* vi. 175 (1894); Dode, in *Bull. Soc. Dendr. France*, i. 194 (1907); Sargent, in *Bot. Gaz.* xlv. 226 (1907).

Catalpa cordifolia, Moench, *Meth.* 464 (1794); Nuttall, *Gen. N. Amer. Pl.* i. 10 (1818).

Catalpa communis, Dumont de Courset, *Bot. Cult.* ii. 189 (1802).

Catalpa syringifolia, Sims, in *Bot. Mag.*¹ t. 1094 (1808); Loudon, *Arb. et Frut. Brit.* iii. 1261 (1838).

Catalpa Catalpa, Karsten, *Pharm. Med. Bot.* 927 (1882); Sargent, *Silva N. Amer.* vi. 86, tt. 288, 289 (1894), and *Trees N. Amer.* 793 (1905).

Bignonia Catalpa, Linnæus, *Sp. Pl.* 622 (1753) (in part).

A tree, rarely attaining in America 60 ft. in height and 10 ft. in girth, usually smaller. Bark separating on the surface into large thin irregular scales. Young branchlets glabrous. Leaves (Vol. III., Plate 204, Fig. 5) emitting when bruised a disagreeable odour, ovate, about 5 to 6 in. long, and 4 to 5 in. wide; cordate, truncate, or cuneate at the base, contracted into a slender acuminate point or rounded at the apex, usually entire or occasionally with one or two slight lateral lobes, glabrous above, pubescent with simple hairs on the nerves and veinlets beneath, the pubescence on the midrib being confined to its edges close to the surface of the blade; glandular areas pale; petioles glabrous.

Flowers numerous in a compact panicle, about 8 to 10 in. long and broad; calyx glabrous, green or light purple; corolla white, $1\frac{1}{2}$ in. long and wide, marked on the inner surface on the lower side by two rows of yellow blotches along two parallel ridges or folds, and on the throat and lower lobes of the limb by numerous conspicuous purple spots. Fruit, 6 to 20 in. long, $\frac{1}{4}$ to $\frac{1}{3}$ in. thick in the middle, with a thin wall, splitting into two flat valves. Seeds about 1 in. long, $\frac{1}{4}$ in. wide, silvery grey, with pointed wings, ending in long pencil-like tufts of white hairs.

The following varieties have arisen in cultivation:—

1. Var. *aurea*, Lavallée, *Arbor. Segrez.* 175 (1877).

Leaves pale yellow, retaining their colour throughout the season. One of the best golden-leaved small trees² in cultivation. Its origin is unknown to me.

2. Var. *purpurea*, Rehder, in Bailey, *Cycl. Amer. Hort.* i. 258 (1900).

Leaves purplish, with dark purple glandular spots. It is said by Nicholson to

¹ The plate was drawn from a branch of a tree growing in Mr. Granger's garden at Exeter in 1808.

² A specimen at Kew is figured in *Gard. Mag.* 1910, p. 709.

have originated in the United States, and is possibly a hybrid. It is cultivated by Simon-Louis at Metz.

3. Var. *variegata*, Bureau, *op. cit.* 183.

Variiegated with white or yellow. In var. *Koehnei*, Dode, *op. cit.* 206, the leaves are pale yellow, with irregular angular green patches. Cultivated by Simon-Louis.

4. Var. *erubescens*, Nicholson, in *Woods and Forests*, 1885, p. 52.

Catalpa erubescens, Carrière, in *Rev. Hort.* l. 460 (1869).

This form, which I have not seen, is said to have purplish petioles and glandular spots, with a more compact inflorescence, and a more highly coloured corolla with a less deeply divided limb than the type. It is possibly, as Dode suggests, a hybrid.

5. Var. *nana*, Bureau, *op. cit.* 183.

A low spreading bush, with crowded branches, occasionally grafted high. The leaves are identical in odour and in all other respects with *C. bignonioides*; and there are no grounds for supposing it to be a form of *C. Bungei*, under which name it is commonly known in nurseries and gardens. It has not yet flowered anywhere, and appears to have been first cultivated at Segrez¹ in 1877, where it may possibly have arisen as a sport.

C. bignonioides is a native of the eastern part of the United States; but the exact localities where it is truly native cannot be determined with certainty. It is usually supposed to be indigenous on the banks of rivers in south-western Georgia, western Florida, and central Albania and Mississippi, and to be naturalised throughout the south Atlantic States. On account of its handsome flowers it was extensively planted for ornament; and its dissemination has been aided by its winged seeds, which are borne to a considerable distance by the wind and float on water without injury for a long period. As it bears moderately severe winters it may possibly have been a native of the more northern parts of the Alleghany range, where it is not now met with in the existing forests. It thrives as far north as Philadelphia, but is killed during the winter at Rochester on Lake Ontario, and often succumbs at St. Louis.²

(A. H.)

The first account of this species was published in *The Natural History of Carolina* by Catesby, who introduced³ it into England in 1726.

The largest tree mentioned by Loudon was one at Syon, 52 ft. high and 3 ft. in diameter, of which only the dead stump remains, but there is a spreading tree grown from one of its layered branches on the north side of the lake which was in flower in July 1912 when I saw it last. A tree at Kew, which died in 1907, when it was about sixty years old, was 30 ft. high and 6 ft. 1 in. in girth. A tree in the Terrace Gardens, Richmond, was 35 ft. by 8 ft. 1 in. in 1912. A fine specimen⁴ in Mr. Denne Dunn's garden at Canterbury was 32 ft. high in 1876. At Caldrees, Ickleton, near Cambridge, there is a fine tree, which flowers freely every year; it is about 35 ft. high and 7 ft. in girth.

¹ Lavallée, *Arb. Segrez.* 176 (1877), where it is named *C. Bungei*, var. *nana (pumila)*. Cf. also Lavallée, *Icon. Arb. Segrez.* ii. 35 (1880).

² R. Douglas, in *Woods and Forests*, 1884, p. 566.

³ Aiton, *Hort. Kew.* ii. 346 (1789).

⁴ Figured in *Gard. Chron.* v. 13, fig. 2 (1876). In *Gard. Chron.* xxvi. 257 (1897) mention is made of a large tree at Rosslyn, Stamford Hill.

There are many trees of considerable age, but of no great height, in parks and places¹ in and around London, the best known of which was one at Gray's Inn, which died a few years ago. This *Catalpa* was reported by tradition to have been brought from America by Sir W. Raleigh, and to have been planted by Bacon; but there is no good authority for this, and the tree is not long-lived in England.

At Ham Manor, near Arundel, I saw a very well-shaped tree (Plate 350) in 1907 which measured 52 ft. by 7 ft. with a clean bole 15 ft. high. There is a tree at Heywood, Wilts, which, in 1906, was about 30 ft. high and 15 ft. in girth below the branches. A photograph sent me by the then gardener, Mr. Robinson, showed it in full flower as a very beautiful tree. Another at Elbridge, as measured by Mr. Furze in 1904, was 41 ft. high, 14 ft. in girth, and had a spread of 61 ft. A fine old tree at Wilton House, Wilts, was, when I saw it in 1906, showing signs of decay, but measured 53 ft. by 6½ ft. (H. J. E.)

CATALPA KAEMPFERI

Catalpa Kaempferi, Siebold and Zuccarini, in *Abhand. Akad. München*, iv. pt. ii. p. 142 (1846); J. D. Hooker, *Bot. Mag.* t. 6611 (1882); Lavallée, *Icon. Arb. Hort. Segrez.* 33, t. 10 (1885); Hemsley, in *Journ. Linn. Soc. (Bot.)* xxvi. 235 (1890); Bureau, in *Nouv. Arch. Mus. Nat. Hist.* vi. 190 (1894).

Catalpa ovata,² G. Don, *Gen. Syst.* iv. 230 (1837); Sargent, *Silva N. Amer.* vi. 84, note (1894).

Catalpa Bungei, Decaisne, in *Rev. Hort.* v. 406 (1851) (not C. A. Meyer); Carrière, in *Flore des Serres*, viii. 8 (1852); Jacques, in *Flore des Serres*, x. 188 (1855).

Catalpa Henryi, Dode, in *Bull. Soc. Dend. France*, i. 199 (1907).

Bignonia Catalpa, Thunberg, *Fl. Jap.* 251 (1784) (not Linnæus).

A tree, attaining 70 ft. in height; bark brown, slightly fissured. Young branchlets with numerous sessile glands and scattered stiff glandular hairs.³ Leaves (Vol. III. Plate 204, Fig. 6) without a disagreeable or peculiar odour, ovate, variable in size, averaging 5 to 6 in. in width and length, cordate at the base, shortly acuminate at the apex; rarely entire, usually with one or two (occasionally three or four) triangular sharp-pointed lateral lobes; upper surface covered with a minute pubescence, the nerves often purple and with scattered long hairs; lower surface pubescent on the nerves and veinlets; petiole with glands and glandular hairs, as on the branchlets.

Flowers numerous in much-branched panicles, which are 4 to 9 in. long; calyx glabrous; corolla pale yellow, about ¾ in. long and broad, marked externally with two orange bands and numerous purple spots. Fruit, 7 to 12 in. long, cylindrical, ½ in. in diameter, with a thin wall, splitting into two concave valves. Seeds, ⅓ in.

¹ Mr. Hugh Boyd Watt, in an article on *Catalpas* in London and neighbourhood, which appeared in *The Field*, Feb. 17, 1912, states that there was abundance of fruit in the autumn of 1911 on the trees in Victoria Embankment gardens, Brunswick Square, Hampstead, Richmond, Kew, and Syon House. Six large trees in Palace Yard, Westminster, bore no fruit, though they flowered in the preceding summer. There was no fruit formed in 1909 and 1910; but there was a good crop in 1906.

² This is the oldest name of the species; but it has never been in use.

³ These peculiar hairs, which are characteristic of this species, are deciduous in the course of the season.

long, $\frac{1}{8}$ in. wide, greyish brown, with pointed wings ending in long pencil-like tufts of white hairs.

This species is much planted in gardens and around temples in Japan; but is not a native of that country, according to the Japanese botanists, who state that it was introduced at an early period by the Buddhist monks. It was found wild¹ in central China by myself and by Wilson in western Hupeh, and by Giraldi² in Shensi.

It was first made known to Europeans by Kaempfer, who visited Japan in 1690, and published³ in 1712 a good description and figure of the tree. It is usually known in Japan as the *Ki-sasage*, or "bean-tree" on account of its peculiar pods. Dupont, in a letter to Lavallée, mentions that he never saw this tree in the forest in Japan, but always planted, and records one 75 ft. in height and 5 ft. in girth growing near a temple.

It was introduced into Europe from Japan by Siebold in 1849, and has probably thriven best at Segrez, where Lavallée mentions a tree, which covered an area over 40 yards in circumference. It appears to be much hardier both in France and at Boston⁴ (U.S.) than *C. bignonioides*.

Plants raised from seed⁵ sent from central China by Wilson to Coombe Wood, and by Père Farges to Les Barres, appear to be identical in all respects⁶ with trees of Japanese origin.

The finest specimen of *C. Kaempferi* known to us in England is a tree at Syon, which measured, when Elwes saw it in July 1912, 62 ft. by 5 ft. 1 in. It was then in full flower, with capsules of the previous year containing ripe seeds. The oldest tree at Kew, about 20 ft. high, was procured from Volxem in 1879.

A remarkable hybrid has arisen between *C. Kaempferi* and *C. bignonioides*:—*Catalpa hybrida*,⁷ Späth, in *Gartenflora*, lvii. 481, t. 1454 (1898).

Catalpa × J. C. Teas, Sargent, in *Garden and Forest*, ii. 303, fig. (1889); *Catalpa Teasiana*, Dode, in *Bull. Soc. Dend. France*, i. 205 (1907).

A tree, said to be of remarkably vigorous growth, resembling *C. Kaempferi* in foliage, but intermediate in flowers and fruit between that species and *C. bignonioides*. It produces extremely large panicles, 18 to 20 in. long and 10 in. wide, of 200 to 300 fragrant flowers, about 1 in. long; corolla tinged with yellow in the throat and marked with broad purple stripes. Fruit 12 to 15 in. long, $\frac{1}{4}$ in. wide.

This hybrid was raised about 1880 in J. C. Teas' nursery at Baysville, Indiana, from seed out of a peculiar single pod which was observed on a tree of *C. Kaempferi*. The latter grew near trees of both *C. bignonioides* and *C. speciosa*, but the pollen

¹ It is figured in the *Chih Wu Ming*, xxxiii. pl. 48 (1848).

² Cf. Diels, in Engler, *Jahrb.* xxxvi. heft 4, p. 98 (1905).

³ *Aman. Exot.* 842 (1712).

⁴ Sargent, in *Gard. Chron.* xii. 784 (1879).

⁵ Sargent, in a letter to Kew, dated 2nd February 1900, states that seeds received from Shanghai in 1892 of reputed *C. Bungei*, produced plants of *C. Kaempferi*.

⁶ A young tree at Kew, 10 ft. high, of Chinese origin, bears leaves identical in odour, shape, pubescence, and colour, with an older tree of Japanese origin. Specimens sent from Les Barres show no differences.

⁷ Dode, *op. cit.* 204, identifies *C. hybrida*, Späth, with *C. erubescens*, Carrière, described above, p. 1486. Rehder, however, in Bailey, *Cycl. Am. Hort.* i. 258 (1900), considers Späth's description to refer to Teas' hybrid; and this appears to be correct. Späth does not say, as Dode asserts, that the hybrid originated in his nursery.

appears to have come from the former. As Sargent points out, *C. bignonioides* and *C. Kaempferi* flower at the same time, whereas *C. speciosa* is two to three weeks earlier than *C. Kaempferi*. Moreover, Penhallow,¹ by an examination of the wood of the different species of *Catalpa* and of the hybrid, has shown conclusively that the latter is a cross between *C. bignonioides* and *C. Kaempferi*, in which the characters of the latter are dominant; and that *C. speciosa* was in no way concerned in its production. Penhallow adds, that some of the seedlings of the hybrid, but not all, revert to *C. Kaempferi*.

"Teas' Japan hybrid," as it is commonly called, was introduced into Kew gardens in 1891, and flowered in 1900 and succeeding years, but has not produced fruit. At Kew it shows no excessive vigour.

C. japonica, Dode, in *Bull. Soc. Dend. France*, i. 200 (1907), said to have been introduced from Japan in 1886 by Simon-Louis, is unknown to me; but from the description appears to be another hybrid between *C. bignonioides* and *C. Kaempferi*. (A. H.)

CATALPA BUNGEI

Catalpa Bungei, C. A. Meyer, in *Bull. Acad. Sc. St. Pétersb.* ii. 51 (1837); Maximowicz, *Prim. Fl. Amur.* 475 (1859); Kurz, in *Journ. Bot.* ii. 193 (1873); Lavallée, *Arbor. Segrez.* 176 (1877); Hance, in *Journ. Bot.* xi. 37 (1882); Franchet, *Pl. David.* i. 229 (1884); Hemsley, in *Journ. Linn. Soc. (Bot.)* xxvi. 234 (1890); Bureau, in *Nouv. Arch. Mus. Hist. Nat.* vi. 197, pl. 4 (1894); Bean, in *Kew Bull.* 1907, p. 102.

Catalpa syringifolia, Bunge, *Enum. Pl. China Bor.* 45 (1835) (not Sims).

Catalpa heterophylla, Dode, in *Bull. Soc. Dend. France*, i. 203 (1907).

Catalpa Duclouxii, Dode, in *Bull. Soc. Dend. France*, 1907, p. 201, and 1909, p. 154.

A tree, attaining in China 40 feet in height. Young branchlets glabrous, covered with minute glands. Leaves with a disagreeable odour, variable in size and shape, about 5 in. long and 4 in. wide, ovate or deltoid, cuneate or truncate at the base, ending in a long slender acuminate apex; entire, or with two lateral long-pointed lobes, or with several irregular acute teeth on each side; upper surface dark green, shining, glabrous; lower surface pale green, glabrous; petiole glabrous.

Flowers, three to nine, in a loose corymb; axis and pedicels glabrous or with a few simple hairs; calyx glabrous, green below, pink above; corolla, $1\frac{1}{4}$ in. long, with a wide campanulate tube, which is tinged with yellow along two projecting ridges and is elsewhere spotted purple, and a white five-lobed limb, with numerous purple dots, which give the whole flower a decidedly pinkish tint. Fruit, described as very long and slender, 25 to 40 in. in length and $\frac{1}{8}$ in. in diameter. Seeds greyish brown, $\frac{3}{8}$ in. long, with narrow pointed wings, ending in pencil-like tufts of pale yellow hairs.

The foliage of this tree is very variable—entire or two- to three-lobed leaves occurring on old trees; whilst those with a dentate margin are characteristic of

¹ In *Amer. Naturalist*, xxxix. 113, figs. 1-8 (1905).

branches ending in an inflorescence, and are normally developed on the ordinary branches of young trees. As both forms occur on the same individual, var. *heterophylla*, Meyer, cannot be maintained as a distinct variety.¹ In northern China, the leaves are quite glabrous; but in the mountains of central China, there are traces of pubescence (simple hairs) on the upper surface of the leaves and on the petioles. Specimens with more numerous flowers in the corymb, which has one or two of the lateral axes branched, have been considered to be a distinct species, *C. Duclouxii*, Dode; but these are probably trees of greater vigour and not even a distinct variety.

C. Bungei is readily distinguishable by its glabrous shining leaves, with longer and more slender points to the lobes than is the case in the other species.

This tree is widely spread throughout the mountains of China, from Peking in the north to Yunnan in the south-west, and is also recorded from the coast provinces of Shantung and Chekiang. Wilson found it in Szechwan at 8850 feet altitude, as a "tree 40 ft. in height, with white flowers suffused and spotted with pink." In Hupeh, it grows at about 4000 to 5000 feet elevation in the mixed forests of deciduous trees, and, my notes state, "40 feet high, 4 feet in girth, with pinkish flowers, which, together with the leaves, are of a disagreeable odour." It is much planted in temple grounds, at Peking, Shanghai, and elsewhere, and is usually known as the *chiu* tree.² It flowers at Peking in May.

This species is very rare in cultivation, the plants generally sold under this name by nurserymen being either the dwarf form of *C. bignonioides* or *C. Kaempferi*. Bureau knew of only one living specimen in France, a small tree at Segrez, which had not produced flowers.

It was introduced³ about 1904 into the Arnold Arboretum by seed procured from Peking; and a tree sent by Sargent to Kew in 1905 is now about 8 feet high.

(A. H.)

CATALPA FARGESI

Catalpa Fargesii, Bureau, in *Novv. Archiv. Mus. Hist. Nat.* vi. 195, pl. 3 (1894); Dode, in *Bull. Soc. Dend. France*, i. 204 (1907).

Catalpa vestita, Diels, in *Engler, Jahrb.* xxix. 577 (1900).

A small tree, distinct from the other species, in the presence of stellate tomentum or branched hairs on the young branchlets, leaves, axes of the inflorescence, pedicels, bracts, and calyx. Leaves about 5 in. long and 4 in. broad, entire or with one or two acute lateral lobes, subcordate at the base, acuminate at the apex; tomentose on the lower surface throughout, on the upper surface mainly on the nerves.

¹ Cf. Bretschneider, *Bot. Sincium*, in *Journ. N. China Branch, R. Asiat. Soc.* xvi. 112 (1882), who states that "the leaves on the same tree are very variable, cordate, entire, lobed, lacinate, triangular, sinuate, etc."

² Bretschneider gives an account of the Chinese literature of this tree in *Bot. Sin.* ii. 339 (1882) and iii. 478 (1895). The classical name *tze*, with which he identifies the *Catalpa*, possibly indicated *Sassafras Tsumu*. Cf. vol. iii. p. 515.

³ Cf. Rehder, in *Mitt. Deut. Dend. Ges.* 1907, p. 76.

Flowers few, seven to ten in a compact corymb; calyx covered externally with stellate tomentum; corolla, similar in size to that of *C. Bungei*, white, spotted with reddish brown dots. Fruit 18 to 20 in. long, $\frac{1}{5}$ in. in diameter. Seeds yellowish grey, about $\frac{2}{5}$ in. long, with sharp-pointed wings, ending in long silky hairs.

C. Fargesii is a native of western China, where it has been found in the mountains of Szechwan and Shensi by Farges, Giraldi, and Wilson. The latter introduced¹ it in 1901. Young plants show merely slight traces of the branched hairs on the branchlets and leaves, which are so characteristic of wild specimens; but as they grow older this peculiar pubescence may increase in quantity. Plants of this species, raised from seed sent by Wilson (Nos. 636 and 640) in 1905, are growing freely at Colesborne, where they have endured 30° of frost without injury, though the wood does not ripen well in autumn. These are now 4 to 6 ft. high. There are also young plants at Kew and Aldenham. (A. H.)

¹ *Journ. Roy. Hort. Soc.* xxviii. 50 (1902).

PAULOWNIA

Paulownia,¹ Siebold and Zuccarini, *Fl. Jap.* i. 25 (1835); Bentham et Hooker, *Gen. Pl.* ii. 939 (1876); Dode, in *Bull. Soc. Dend. France*, 1908, p. 159; Schneider, *Laubholzkunde*, ii. 618 (1911).

DECIDUOUS trees belonging to the order Scrophulariaceæ. Branchlets with chambered pith, showing in winter large oval raised opposite leaf-scars. Buds axillary, no true terminal bud being formed, minute, covered with two or four pubescent scales. Leaves simple, opposite in decussate pairs, stalked, ovate, cordate.

Flowers in large terminal erect panicles, opening in spring before the leaves; calyx five-cleft, campanulate, persistent at the base of the fruit; corolla gamopetalous, inserted on the base of the calyx, with a long slightly curved tube, and five spreading lobes, the three lower lobes longer than the two upper lobes; stamens four, affixed to the tube of the corolla, didynamous, included, with divaricate anthers; ovary superior, two-celled, with numerous ovules; style one, slender, slightly thickened towards the summit, stigmatic on the inner side. Fruit, ripening in one year, a two-celled woody or coriaceous capsule, ovoid, loculicidally dehiscent by two valves; placentæ two, ovate, compressed; seeds numerous, minute, oblong, surrounded by a broad translucent striated wing.

Two species of *Paulownia*² have been clearly distinguished, one of which, little known and not in cultivation in England, may be here briefly described.

I. *Paulownia Fortunei*, Hemsley, in *Journ. Linn. Soc. (Bot.)* xxvi. 180 (1890).

Leaves narrowly oval, longer and more acuminate than in *P. tomentosa*, covered beneath with a dense whitish tomentum. Flowers longer and relatively narrower than in *P. tomentosa*; calyx-lobes deltoid, obtuse, usually brown tomentose throughout, occasionally glabrescent except on the borders. Fruit, 3 to 3½ in. long, narrowly ovoid; seeds ¼ in. long, much larger than those of *P. tomentosa*.

¹ Named after Anna Paulowna, Queen of the Netherlands.

² Hayata, in *Bull. Congrès Internat. Bot. Bruxelles*, 41, pl. 24 (1910), and in *Journ. Coll. Sci. Tokyo*, xxx. 209 (1911), mentions a possible new species in Formosa. Elwes saw this in 1912 at a village near Horisha in Central Formosa; but it was not in leaf. There is also a supposed new species from Western China, raised at the Arnold Arboretum from seed sent by E. H. Wilson. It is in cultivation at Kew and Aldenham; but the young plants cannot at present be distinguished from *P. tomentosa*. Cf. *Gard. Chron.* xlvi. 275, fig. 116 (1910).—A. H.

I raised seedlings from Mr. Wilson's seeds, No. 769, collected in his journey of 1908 in Western China, which appear at three years old to be hardier and more rapid in growth than those which I have raised from the common species. The seedlings of the latter were killed to the ground for three years after planting out; whilst the West China form is now, at three years old, 14 ft. high, of which 10 ft. is the growth of 1911. This form seems likely to be a most ornamental tree even in cold parts of England; but must be planted in warm sheltered places where its immense juvenile leaves, measuring 21 in. by 23 in., will not be torn by wind.—H. J. E.

This species, which is probably smaller in size than *P. tomentosa*, occurs both in the north of China, where it has been collected at Chefoo, and in the south, where it has been found in the province of Kwangtung.

P. Duclouxii,¹ Dode, in *Bull. Soc. Dend. France*, 1908, p. 162, is apparently a variety with white flowers, tinged with pink, and not spotted as in the type. This is said to have been raised by C. Sprenger² of Corfu from seed, which he received from Dr. Dode.

PAULOWNIA TOMENTOSA

Paulownia tomentosa, Koch, *Dendrologie*, ii. pt. 1, p. 299 (1872); Shirasawa, *Icon. Ess. Forest. Japon*, i. text 129, t. 85 (1900).

Paulownia imperialis, Siebold and Zuccarini, *Fl. Jap.* i. 27 (1835); Loudon, *Trees and Shrubs*, 671 (1842); W. J. Hooker, *Bot. Mag.*³ t. 4666 (1852); Hemsley, in *Journ. Linn. Soc. (Bot.)* xxvi. 180 (1890).

Bignonia tomentosa, Thunberg, *Fl. Jap.* 252 (1784).

A tree, attaining 80 ft. in height and 12 ft. in girth. Young branchlets green, glandular, and pubescent. Leaves broadly ovate, about 7 to 8 in. long, and 6 to 7 in. wide, cordate at the base, shortly acuminate at the apex, undivided or with one or two short lateral deltoid lobes, entire in margin; upper surface dark green, pubescent with short erect hairs; lower surface greyish green, covered with a thin tomentum; petiole 3 to 5 in. long, glandular, pubescent.

Flowers violet, the lower lip marked with dark coloured spots and two yellow bands; calyx with five ovate erect lobes, covered with a dense rusty brown tomentum. Capsules ovoid, about 1½ in. long, and 1 in. broad; seeds minute, about ⅓ in. long.

1. Var. *Fargesii*, Henry (var. *nova*).

Paulownia Fargesii, Franchet, in *Bull. Mus. Hist. Nat. Paris*, 1896, p. 280.

Flowers paler in colour. Adult leaves more glabrous than in the type. This was described by Franchet from a specimen sent by Père Farges from the mountains of north-eastern Szechwan; and appears to be identical with a tree found by me growing on cliffs in the mountains of Hupeh (No. 5346 A). The pentagonal ribbed calyx, noticed by Franchet, appears to be due to drying of the specimen, and not to be specially characteristic of this form, as a similar calyx occurs in some specimens of typical *P. tomentosa*. Var. *Fargesii* was introduced into cultivation in France by M. M. de Vilmorin, who raised it from seed received from Père Farges; and it flowered⁴ in M. Boucher's nursery at Paris in 1905.

P. tomentosa is a native of the mountains of central and western China, where it has been found growing wild at altitudes of about 4000 feet by Père Farges in Szechwan, and by myself in Hupeh and Yunnan. It is the *fung* tree of the Chinese

¹ *P. meridionalis*, Dode, *loc. cit.*, described from a tree growing in Laos in Indo-China, is allied to or perhaps a form of *P. Fortunei*. ² Cf. *Mitt. Deut. Dend. Ges.* 1910, p. 246.

³ Figured from a tree in the garden at Bishopstowe, near Torquay, the first which flowered in the open air in England.

⁴ Cf. *Journ. Soc. Nat. Hort.* vi. 324 (1905). C. Sprenger of Corfu, states in *Mitt. Deut. Dend. Ges.* 1910, p. 247, that he has raised *P. Fargesii* from seeds received from the mountains of north-west Hupeh in central China.

classics,¹ the wood of which was used in ancient times for making lutes. It is largely planted as an ornamental tree throughout China, Korea, and Japan; and was probably introduced into the latter country at an early period by the Buddhist monks.²

This species often produces root-suckers at a considerable distance from the parent tree; and when cut down, sprouts vigorously from the stool. The seedling, which has an herbaceous stem, usually dies down at the end of the first year; but in the following spring a permanent and more woody stem arises from a bud close to the ground. The leaves on young plants (which are very large), on root-suckers, and on coppice shoots differ from the foliage of the adult tree, their margin being furnished with numerous short teeth, while their upper surface is velvety to the touch and very viscid, owing to the presence of numerous glandular hairs and sessile glands.

The Paulownia may be raised from seed sown in spring, or from root-cuttings; and may also be propagated by stem-cuttings under glass, or even from leaf-cuttings. At Kew this species is very effective as a foliage plant in beds out of doors. The plants, when about three years old, are cut down in early spring to within 6 inches of the ground; and when they start to grow, all the buds except one on each stem are removed. Watered in dry weather and mulched with manure, stems are produced about 6 ft. high, which bear enormous leaves, 12 to 18 in. in diameter.

This tree was introduced³ into Europe in 1834, by seeds sent from Japan to Paris by M. de Cussy; and one of the original trees in the Jardin des Plantes measured in 1904 about 60 ft. in height, and 12 ft. in girth. It succeeds well in France and Italy, where it attains a considerable size, and regularly produces flowers and fruit.

It was introduced⁴ into England by seeds from Japan in 1838, and was cultivated in the Horticultural Society's garden at Chiswick; but it has never attained large dimensions in this country, and probably many of the older trees were killed in the severe winters of 1860 and 1866. It flowers frequently in the south of England, but rarely produces fruit, and very seldom fertile seed. (A. H.)

The largest tree I know of in England is one standing near the entrance lodge at Westonbirt, Gloucestershire, which as measured in August 1911, by Mr. A. Chapman, was 56 ft. by 7 ft. at 3 ft. from the ground.

The next is at Wilton House, which in 1906 measured 53 ft. by 6 ft. 8 in., but being in a damp situation it has only flowered twice in fifty years, and Mr. Challis informed me that it suffered much in the hard winters of 1860-61, and 1879-80. A fine tree at Linton Park, Maidstone, in 1911 measured 45 ft. high and 9 ft. in girth at 6 ft. from the ground. At Caldrees, Ickleton, Cambridgeshire, there is a tree about 25 ft. high and 3½ ft. in girth, which produces flowers and fruit nearly every year. From its seeds, plants were raised in 1902, one of which was planted at Ickleton Grange, and is now 12 ft. high.

¹ Cf. Bretschneider, *Bot. Sinic.* ii. 348 (1892). It is colloquially known in China as the *pao-t'ung*, in order to distinguish it from the *wu-t'ung* (*Sterculia platanifolia*), and the *t'ung-yu* (*Alcurites cordata*).

² It is figured by Kaempfer, *Amen. Exot.* 860 (1712).

³ *Actes Premier Congrès Internat. Bot., Paris*, 536 (1900). Cf. also *Gard. Chron.* 1841, pp. 349, 701, where it is stated that a single plant was raised in the Royal Garden in Paris, from Japanese seed, in 1834.

⁴ Loudon, *Gard. Mag.* xvi. 635 (1840). It flowered in a greenhouse at Oakfield near Cheltenham in 1843, according to Loudon, *Gard. Mag.* 1843, p. 649.

At Swanmore Cottage, Hants, Mr. Molyneux showed me a well-shaped tree, 35 ft. by 7½ ft., in 1906, which flowers occasionally but never ripens seed. At Ashstead Park, Surrey, the seat of Mr. P. Ralli, there was in 1892 a fine tree, 45 ft. by 7½ ft., which flowers freely in warm seasons.¹ At Whitbourn Court, near Worcester, Sir R. Harrington has a tree which he raised from seed gathered in the Vatican gardens at Rome in 1888, which in 1905 was 23 ft. by 4 ft., and with a head 25 ft. in diameter. In Cornwall, where the climate does not suit it so well, the largest I have seen, at Scorrier, was about 25 ft. high in 1911.

There are specimens 20 to 30 ft. high in the Kew and Cambridge Botanic Gardens; at Grayswood, Haslemere; in several gardens in Kent; at East Cowes Castle in the Isle of Wight; at Hursley Park, Winchester; at Abbotsbury²; at Bicton³; at Trevarno,⁴ Cornwall; and at Singleton Abbey, Swansea.

In Scotland, the only places where I have seen it are at Castle Kennedy, where in 1906 I saw a poor-looking tree about 25 ft. high, which evidently does not like the climate; and at Tynninghame, East Lothian, where Mr. Brotherston measured a tree 3 ft. 9 in. in girth at 3 ft. from the ground, which has been in bad health for years, so we may conclude that the summers of Scotland are too short and cold for it.

In Ireland, there are two old but not very thriving trees at Glasnevin; but at Mount Usher, there is a fine tree nearly 40 ft. high, and over 6 ft. in girth.

In America,⁵ it does not flower regularly north of New York; but is fairly hardy in sheltered positions as far north as Massachusetts, where the flower-buds are killed every winter; and it can be cultivated as a foliage plant even in Montreal.

TIMBER

In Japan, it is known as *kiri*; and produces a very light, dull white, shining wood, which is used for making boxes, musical instruments, linings of safes, clogs, doors, and in cabinet work. As large planks are not usually obtainable, Paulownia boards are made by joining small pieces together with paste and bamboo pegs, as shown at the Anglo-Japanese Exhibition at Shepherd's Bush, London. On my last visit to Japan I saw well-made wardrobes of this wood, which is preferred to all others for this purpose on account of its resistance to damp. Clothes kept in drawers of this wood are said to remain free from mould during the rainy season. These wardrobes are sometimes framed in the wood of *Diospyros Kaki*, the heart-wood of which is black mottled with grey, and very handsome. The large braziers, called *Hibashi* in Japan, are often made of sections of the trunk of Paulownia turned in such a way as to show its beautiful grain. (H. J. E.)

¹ *Gard. Chron.* xii. 440 (1892).

² Fruit was sent to Kew from Abbotsbury in January 1902.

³ *Quart. Journ. Forestry*, i. 54 (1907).

⁴ Cf. *Gard. Chron.* xxvi. 211 (1899). In *The Field*, 1908, p. 233, the tree at Trevarno, said to be twenty years old and 30 ft. high, is reported to have produced a few years previously a good crop of fruit.

⁵ Rehder, in Bailey, *Cycl. Amer. Hort.* 1223 (1901). Britton and Brown, *Illustrated Flora Northern U.S.* iii. 157 (1898), state that it has escaped from cultivation in southern New York, in New Jersey, and in the Southern States.

ROBINIA

Robinia, Linnæus, *Gen. Pl.* 220 (1737) and *Sp. Pl.* 722 (1753); Bentham et Hooker, *Gen. Pl.* i. 499 (1865); Schneider, *Laubholzkunde*, ii. 79 (1907).
Pseudacacia, Moench, *Meth.* 145 (1794).

DECIDUOUS trees and shrubs belonging to the division Papilionaceæ of the order Leguminosæ. Leaves unequally pinnate, alternate, stalked: leaflets opposite, rarely sub-opposite or alternate, stipellate, stalked, entire, penninerved. Stipules in pairs, at first setaceous, ultimately either deciduous or developing into persistent spines. No true terminal bud is formed, the tip of the branchlet falling off early in summer and leaving a scar at the apex of the twig. Buds minute, multiple, three to five superposed vertically, not apparent¹ in summer and autumn, being concealed by the enlarged base of the petiole; in winter, embedded in a projection on the branchlet between the stipules, and covered by three scales, which are united together and form the leaf-scar. Usually only the uppermost bud develops—the scales, which are very tomentose within, bursting open, and afterwards persisting at the base of the new branchlet during the following season.

Flowers in pendulous racemes, arising from the axils of the leaves, with long pedicels and caducous bracts and bracteoles. Calyx campanulate, unequally five-toothed. Corolla papilionaceous; petals with short claws, inserted on a tubular glandular disc, connate with the base of the calyx-tube; standard large, reflexed, obcordate; wings oblong, curved, free; keel-petals incurved, obtuse, united below. Stamens ten, inserted with the petals; nine inferior united into a tube; upper stamen free at the base. Ovary stalked; style subulate, inflexed, pubescent, ending in a small stigma; ovules numerous, hanging in two rows from the ventral suture. Pods in pendulous racemes, linear-oblong, compressed; valves two, thin, membranous; seed-bearing suture with a narrow wing. Seeds numerous, reniform, oblique, with a persistent incurved stalk.

About eight species of *Robinia* are known, confined to the United States and Mexico. Four, all natives of the United States, occur in cultivation:—

I. *Branchlets without glands.*

1. *Robinia Pseudacacia*, Linnæus. See p. 1497.

Branchlets at first slightly pubescent, soon becoming glabrous. Leaflets

¹ Occasionally a supra-axillary bud is formed, visible above the insertion of the leaf; it develops into a short-lived feeble branch.

Robinia

1497

pubescent, minutely apiculate. Stipules persisting as glabrous hard woody spines.

2. *Robinia neomexicana*, Gray. See p. 1506.

Branchlets densely pubescent. Leaflets pubescent, tipped at the acute apex with a long mucro; stipels mostly persistent. Stipules persistent as slightly pubescent hard woody spines.

II. *Branchlets glandular.*

3. *Robinia viscosa*, Ventenat. See p. 1507.

Branchlets with short-stalked glands, exuding a viscid matter. Leaflets pubescent, shortly apiculate. Stipules usually deciduous, occasionally persistent as slender short spines.

4. *Robinia hispida*, Linnæus. See p. 1508.

Branchlets with glandular bristles and dense pubescence. Leaflets glabrous, except for slight pubescence on the midrib beneath. Stipules usually deciduous, occasionally persistent as minute blunt spines. (A. H.)

ROBINIA PSEUDACACIA, FALSE ACACIA, LOCUST

Robinia Pseudacacia, Linnæus, *Sp. Pl.* 722 (1753); Cobbett, *Woodlands*, Nos. 322-398 (1825); Loudon, *Arb. et Frut. Brit.* ii. 609 (1838); Withers, *The Acacia Tree* (1842); Wilkomm, *Forstliche Flora*, 930 (1887); Sargent, *Silva N. Amer.* iii. 39, tt. 112, 113 (1892), and *Trees N. Amer.* 572 (1905); Mathieu, *Flore Forestière*, 119 (1897); Schneider, *Laubholzkunde*, ii. 82 (1907).

Robinia fragilis, Salisbury, *Prod.* 336 (1796).

Pseudacacia odorata, Moench, *Meth.* 145 (1794).

A tree, attaining about 80 feet in height and 15 feet in girth. Bark thick, brownish, with broad and deep longitudinal fissures, separated by scaly ridges. Young branchlets, at first slightly pubescent, soon becoming glabrous. Leaf-rachis slightly pubescent. Leaflets, nine to nineteen, elliptic or oval, rounded at the base; rounded, truncate or emarginate at the apex, which terminates in a minute mucro; upper surface covered with minute appressed pubescence, lower surface paler with scattered hairs; petiolule, $\frac{1}{8}$ in., slightly pubescent; stipels linear, $\frac{1}{16}$ in., early deciduous.

Flowers in loose pubescent non-glandular racemes; pedicels slender, $\frac{1}{2}$ in. long, pubescent; calyx gibbous, pubescent, the lowest lobe acuminate and longer than the others; petals white, with a greenish yellow patch on the middle of the inner surface of the standard. Pod, 2 to 4 in. long, glabrous, persistent on the leafless branches late in winter; seeds usually four to eight.

The stipules,¹ at first linear, subulate, membranous, pubescent, and about $\frac{1}{2}$ in. long, are either deciduous or develop into spines, which persist for several years and occasionally attain $\frac{3}{4}$ in. in length. These spines are glabrous, triangular, com-

¹ Cf. Colomb, in *Ann. Sc. Nat.* vi. 65 (1887).

pressed, straight or turned up at their sharp points; and in winter, together with the concealed buds and the stout glabrous angled twigs, serve to identify this species.

The flowers are fragrant,¹ and are visited by bees, as they contain much honey. In southern Italy,² the flowers are developed before the leaves; but north of the Alps the leaves unfold earlier or at the same time as the flowers. The leaves droop at night.

Seedling:³—The cotyledons, raised above ground on a glabrous caulicle, are oblong-oval, obtuse, entire, shortly stalked, light green, thick in texture, obscurely veined, and about $\frac{1}{2}$ in. long. The slightly pubescent stem bears alternate leaves; first leaf always unifoliolate, rounded, obtuse, and broader than long; second leaf with three leaflets, the terminal orbicular one larger than the two lateral elliptic leaflets; succeeding leaves with three to five leaflets.

This species produces numerous root-suckers,⁴ arising singly or in groups of two or three at a considerable distance from the tree. Leaves on root-suckers smaller than on adult trees, but with the usual number of leaflets, which are cordate at the base; stipules usually aborted or very short.

The tree, when cut down, produces coppice shoots freely; and on this account, and because of its facility of reproduction from root-suckers, it is much cultivated in the warmer parts of Europe as coppice with a short rotation.

VARIETIES

A large number of varieties have arisen in cultivation in Europe. Some have been successfully raised from cuttings; but they are usually propagated by grafting.

1. *Leaves as in the type; habit peculiar.*

1. Var. *pyramidalis*, Pépin, in *Rev. Hort.* iv. 240 (1845) (var. *fastigiata*, Nicholson).

Narrowly pyramidal, resembling the Lombardy Poplar in shape; branches directed vertically upwards. This was introduced by M. Leroy of Angers, and a fine specimen in the Jardin des Plantes at Paris was planted by Pépin in 1843. The best example of this we know is in the public gardens at Le Mans, in France, where Elwes measured one in 1908 nearly 60 ft. high. There are four specimens in the public garden at Genoa, one about 40 ft. in height, which are more broadly pyramidal in habit, the branches not being so upright. These correspond to the description of var. *stricta*, Link, *ex Loudon, Arb. et Frut. Brit.* ii. 610 (1838). Both these varieties are suitable for planting in streets; but seem to be scarcely known in England, except at Kew, where there is a good example of var. *pyramidalis* about 35 ft. high.

2. Var. *Ultriciana*, Reuter, *ex Dippel, Laubholzkunde*, iii. 702 (1893). Branches pendulous.

¹ Cf. Mesnard, in *Ann. Sc. Nat.* xviii. 341 (1893).

² Kerner, *Nat. Hist. Plants*, Eng. Transl. i. 562 (1898).

³ Cf. Lubbock, *Seedlings*, i. 422, fig. 275 (1892), and Ledoux, in *Ann. Sc. Nat.* xviii. 369, fig. 39 (1903).

⁴ Cf. Dubard, in *Ann. Sc. Nat.* xvii. 167 (1903).

A tree at Kew, called var. *pendula nova*, has slightly pendulous branches with small leaflets.

3. Var. *tortuosa*, De Candolle, *Cat. Pl. Monspel.* 136 (1813).

A tree, with wide-spreading twisted branches.¹ The habit is well figured by Schneider, *Dendrol. Winterstudien*, 89, fig. 90 (1903).

4. Var. *umbraculifera*, De Candolle, *Cat. Pl. Monspel.* 137 (1813).

A compact, rounded bush, giving dense shade; branches without spines; seldom if ever flowering.² Suitable for rock gardens, and often called Parasol Acacia. It is said³ to have originated from a burr on a tree of the typical form. There are two good specimens at Kew, about 15 ft. high, grafted at about 10 ft. from the ground.

5. Var. *Bessoniana*, Nicholson.

A compact, dense, round-headed tree, without spines. This resists wind, and is much used for avenues and street planting. It is readily propagated by cuttings.

6. Var. *inermis*, De Candolle, *Cat. Pl. Monspel.* 136 (1813).

Branches without spines; otherwise as in the type.

II. *Leaves different from those of the type.*

7. Numerous varieties with differently coloured foliage are known, the peculiarities of which are indicated by their names, as var. *aurea*, Kirchner; var. *aureo-variegata*, Schneider; var. *argenteo-variegata*, Kirchner; and var. *purpurea*, Dippel.

8. Var. *crispa*, De Candolle, *Prod.* ii. 261 (1825).

Leaflets curled; branches without spines. On a tree of this variety in the Jardin des Plantes at Paris, only the upper leaflets were abnormal, the lower three or four pairs of each leaf being of the ordinary form.

9. Var. *bullata*, Koch, *Dendrologie*, i. 56 (1869).

Leaflets crowded and puckered with swellings.

10. A series of forms, with remarkably small leaflets, have arisen in cultivation, as var. *amorphaeifolia*, Link; var. *myrtifolia*, Koch; var. *tragacanthoides*, Kirchner; var. *sophoraefolia*, Kirchner (*R. coluteoides*, Koch). In var. *linearis*, Kirchner, and var. *dissecta*, Koch, the leaves are remarkably narrow.

11. Var. *monophylla*, Kirchner, *Arb. Musc.* 377 (1864).

Leaves with only one leaflet, which is much enlarged, or with, in addition, three to five leaflets, all larger than in the type. This appeared in 1855 as a single plant in a bed of seedlings in M. Deniaux's nursery at Brain-sur-Authion (Maine-et-Loire). The original plant was transplanted into the Jardin des Plantes at Paris, where it flowered and gave seeds in 1865. The seeds when sown were said to have yielded about one-quarter of the variety, the remainder being normal. The one-leaved Robinia is also said to be liable to a petaloid alteration of the stamens, which impairs fertility.⁴

A tall, slender tree of var. *monophylla* at Brocklesby Park, 57 ft. high and

¹ This variety occasionally develops remarkably thick corky bark. Cf. *Mitt. Deut. Dend. Ges.* 1911, p. 404, fig.

² Koch, *Dendrologie*, i. 57 (1869) states that he saw a flowering branch, which had been produced by an unclipped bush of this variety. The flowers were white, and not yellow, as stated by Dumont de Courset, *Bot. Cult.* vi. 140 (1811).

³ Carrière, *Prod. et Fixat. Vars.* 54 (1865).

⁴ De Vries, *Plant Breeding*, 617, 664 (1906).

2 ft. 8 in. in girth in 1908, showed no sign of having been grafted, and had produced three suckers with normal leaves, one being 36 ft. distant from the parent tree and 8 ft. in height. There are two trees about 30 ft. high at Kew, differing in habit—one, narrow with ascending branches; the other wider, with pendulous branches.

III. Flowers differing from those of the type.

12. Var. *Decaisneana*, Carrière, in *Rev. Hort.* 1863, p. 151, with coloured plate.

Flowers pale pink, and larger than in the type; otherwise similar. This originated in the nursery of M. Villevielle at Manosque (Basses-Alpes), and flowered for the first time in 1862. This variety is said to come fairly true from seed. It is well known in English nurseries, and seems to be a very vigorous grower.

13. Var. *lutea*, Schneider, *Laubholzkunde*, ii. 83 (1907).

Flowers pale yellow. This variety is mentioned by Dumont de Courset, *Bot. Cult.* vi. 140 (1811) as var. *flore luteo*, but it is doubtful if it is now in cultivation.

14. Var. *semperflorens*, Carrière, in *Rev. Hort.* xlii. 502 (1871) and xlvii. 191, with coloured plate (1875).

A tree of great vigour, producing annual shoots of abnormal length (up to 6 ft. long), which bear flowers continually from June to September. This originated as a single seedling in M. Durousset's nursery at Genouilly (Seine et Loire), and has been in commerce since 1875. The original tree was transplanted in 1874 into the Jardin des Plantes at Paris, and was remarkable for its constant production of numerous flowers. Carrière counted on one branch no less than 145 racemes.

HYBRIDS

1. *Robinia dubia*, Foucault, in Desvaux, *Journ. de Bot.* ii. 204 (1813); Loudon, *Arb. et Frut. Brit.* ii. 627 (1838).

Robinia ambigua, Poiret, in Lamarck, *Encyc. Suppl.* iv. 690 (1816).

Robinia intermedia, Soulange-Bodin, in *Ann. Soc. Hort. Paris*, ii. 43 (1828).

This hybrid between *R. Pseudacacia* and *R. viscosa* is a small tree, differing mainly from the first named species in the young branchlets and flowering peduncles being slightly viscid-glandular and in the flowers being pale pink. It has been in cultivation about 150 years.¹

2. *Robinia bella-rosea*, Nicholson, *Dict. Garden.* iii. 310 (1887).

This is similar to the last, but the branchlets are more plainly viscid-glandular, whilst the flowers are larger and deep pink in colour.

3. *Robinia Holdtii*, Beissner, in *Mitt. Deut. Dend. Ges.* xi. 117 (1902); Koehne in *Gartenflora*, lii. 272 (1903).

A hybrid between *R. Pseudacacia* and *R. neomexicana*, which originated² about 1890 in Mr. Von Holdt's garden at Alcott in Colorado. Leaflets larger than those of *R. neomexicana*, darker green than those of *R. Pseudacacia*. Flowers varying in colour, white flushed with pink or deep pink. A few stalked glands occur on the flowering peduncle and on the pod.

¹ It is possibly *R. echinata*, Miller, *Dict.* ed. 8, No. 2 (1768).

² Beissner, *op. cit.* 118, states that a similar plant also originated in Späth's nursery.

4. *Robinia coloradensis*, Dode, in *Bull. Soc. Bot. France*, lv. 650 (1908).

A peculiar tree¹ raised at Les Barres from seed, sent by M. Berthoud from Golden in Colorado. It is probably a seedling of *R. Holdtii*.

5. *Robinia Holdtii britzensis*, Späth, in *Gartenflora*, lii. 557 (1903).

This is a vigorous plant which was raised in Späth's nursery from a seed produced by a tree of *R. neomexicana* in 1893. It, however, closely resembles *R. Pseudacacia*, only differing from this species in having traces of purple on the standard of the flower.

DISTRIBUTION

R. Pseudacacia is considered by American botanists to be indigenous in the Alleghany Mountains from Pennsylvania to Georgia, but it is now widely naturalised throughout most of the United States east of the Rocky Mountains and in Nova Scotia and Ontario. Dame and Brooks say² that it is thoroughly at home in Maine, forming wooded banks along streams, and fairly abundant in thickets and along roadsides and fences in the New England States generally. Plate 353, reproduced from a photograph sent by Miss Cummings, shows a tree at Boston (Mass.). A shrubby form, which occurs in Kansas, Arkansas, and Indian Territory, is perhaps a true native and not an escape from cultivation. The tree attains its largest size³ in West Virginia. It is found in the forest in mixture with other trees, growing on the slopes with oaks, chestnut, hickories, and maples, while along the streams it is associated with ash and black walnut. It often spreads by its root-suckers, forming thickets of small trees. In the mountains of Pennsylvania and West Virginia, burnt and cut-over forest lands are speedily covered with seedlings,⁴ which often grow up into pure stands of considerable extent.

On account of the excellence of its timber for fence posts and for all uses requiring contact with the soil, and also for fuel, the Robinia was much planted⁵ formerly throughout the United States, and succeeded well south of the 38th parallel; but at the present time planting is restricted or rendered useless on account of the ravages of the locust-borer⁶ (*Cyllene Robiniae*, Forster). The grubs of this beetle bore holes through the bark deep into the wood, which becomes completely honey-combed with galleries. Young plantations are often attacked, especially in the States east of the Rocky Mountains. The Robinia thrives in the dry prairie regions, and has been planted with success on alkaline soil in the San Joaquin valley in California.⁷

INTRODUCTION

This species was introduced into France by Jean Robin, who received seeds from America in 1601; and the oldest tree known was planted in 1636 by Vespasian

¹ Cf. Vilmorin, *Frut. Vilmor.* 54, fig. (1994), whose description does not agree with that of Dode. The individuals that were raised may have differed considerably.

² *Trees of New England*, 131 (1902).

³ Ridgway measured a cultivated tree in Illinois, 95 ft. high and 11½ ft. in girth.

⁴ The seed is retained in the pods on the trees till late in the year, and is distributed to great distances by the strong winter winds.

⁵ Directions for planting in the United States are given in the *United States Forest Circular*, No. 64 (1907).

⁶ Cf. *United States Entom. Comm., Fifth Report*, 355 (1890).

⁷ Hilyard, *Sails*, 480 (1906).

Robin in the Jardin des Plantes at Paris, where the stump, largely made up by cement, still remains, and produces a few shoots and flowering branches every year.¹

The date of introduction² into England is uncertain; but Parkinson, in his *Theatre of Plants*, published in 1640, mentions the tree as having been grown by Tradescant "to an exceeding height." During the seventeenth and eighteenth centuries the Robinia was occasionally planted; but it only came prominently into vogue by the vigorous advocacy of Cobbett, who began to write about it in 1823.

(A. H.)

CULTIVATION

No tree except the oak has probably been so much written on in England as the Robinia or Locust, as William Cobbett, its great advocate, always called it, though now it is more commonly, though incorrectly, called Acacia. That great Englishman was, during his exile in America, so much impressed with the valuable qualities of its wood, that, though suffering under a grievous and unjust political persecution, "nevertheless I did not forget my country and the duty I still owed to her"; and when he returned to England in 1819 brought with him a parcel of seed, which he had no means of sowing till 1823. He then began sowing it on a very small scale at first, but later he raised it in large quantities, and sold more than a million plants. In *Woodlands*, Cobbett devoted many pages to an account of this species, which he considered was going to supplant all other trees in England; but Cobbett's enthusiasm in arboriculture, as in politics, often outran his discretion, and though many of his trees still remain, mostly long past their prime and in a more or less decayed condition, the Robinia has never realised his predictions. It has always been obnoxious to the British woodman, partly on account of its thorns which tore his clothes and hands, partly on account of the hardness of its wood which blunted his tools, and partly because of its liability to be broken by the wind, and to reproduce from suckers when cut.

Cobbett had many admirers, one of whom, Lord Folkestone, afterwards Earl of Radnor, bought 13,600 locust trees, which were one-year seedlings one year transplanted; and carried them in a large waggon from Sussex to Coleshill, Berkshire, in the latter part of March 1824. These were planted in clumps of one to several hundreds in a large plantation in Coleshill Park; and when Cobbett saw them in 1826 they averaged more than 12 ft. high, and, as he says, "looked like clumps of trees which had been planted many years previous to the planting of the trees of the rest of the plantation." He calculated the cost of trees, trenching, and planting, at £134, and thought that, at six or seven years old, they would be fit to cut for hop-poles, and then be worth 1s. each, leaving a profit of £529 on the five acres which he supposed them to cover. Of course if this profit or anything like it had been realised here or elsewhere, the tree would not have been neglected as it has been

¹ Cf. *Actes Premier Congrès Internat. Bot. Paris*, 536 (1900). This old tree is figured by Sargent in *Garden and Forest*, iii. 305, fig. (1890). When Elwes saw it in 1905 it had a branch about 40 ft. high producing good foliage.

² Dr. Yule, in *Mem. Caled. Hort. Soc.* ii. 413 (1819), states that it was first planted in Scotland by Mr. Cockburn at Ormiston Hall, Haddingtonshire.

almost everywhere in England. When I visited Coleshill in June 1905, I could find no one who remembered them, and the late Mr. Pleydell-Bouverie, uncle of the present Lord Radnor, who then lived at Coleshill, thought that they had all disappeared with the exception of a few near the house, which measured 60 ft. by 8 ft. 3 in. and 65 ft. by 9 ft. 3 in., and two or three in the park.

Neither at Botley, where Cobbett lived for some years and planted American trees, nor in the surrounding district, where the soil and climate suit this tree as well as any in England, could I find any trace of locust plantations.

The only plantation which we have seen and of which any exact details are on record, is the Brickhills plantation on the estate of Sir Hugh Beevor at Hargham, Norfolk. This has been described¹ by its owner in the *Quarterly Journal of Forestry*, ii. 301-303 (1908), and the results are so favourable that they should be read by everyone. Sir Hugh sums up by saying, "For its own sake I shall continue to grow it for estate use, having always utilised and refused to sell any. The chief use I put it to now is as stakes for rabbit-proof fencing; and these when taken up at the end of ten years will be used again for a similar term. To supply stakes no tree is so well fitted, and it would be worth planting for this purpose only."

In 1842 W. Withers of Holt, Norfolk, compiled a work² of over 400 pages on this tree, in which he prints a great many communications, among which one written by F. Blaikie from Holkham in 1828 states, "I found great difficulty in protecting young locust trees from hares and rabbits. These animals prefer it to any forest tree. They could not have been so plentiful as they are now, at the time Mr. Coke reared the innumerable locust trees growing at this place. Those trees thrive on our most inferior sandy soils where other forest trees barely exist. We do not succeed in raising plants from home-grown seed, though it appears sound and well grown." Here also I failed to find any evidence that this species was now valued; and it may be said generally that though in almost every southern county large trees may be found, which are often decayed at the heart, yet Robinia is no longer looked on as useful for general planting; and that unless pruning of the branches is carefully attended to, this tree is more likely to suffer from wind when young than other trees.

All my observations go to show that Robinia is essentially a lover of a hot, dry, and sandy soil, though it only attains a large size and age on a good sandy loam; and while it tolerates lime, grows much better without it. It is easy to raise from seed and grows rapidly from the first; but the shoots often fail to ripen and are liable to freeze when young. It should be transplanted in the spring when a year old, as its root system is not naturally fibrous, and be planted out when two or three years old in a sunny position. Though Robinia trees may be seen drawn up to a great height in mixed plantations,³ where their rapid growth has given

¹ Sir Hugh Beevor gives me the following notes on this plantation, which was made in 1829 and measured in 1901:—"Where pure the trees cover not quite an acre; on the best half-acre there are 40 trees per acre with a volume of 1000 cubic ft.; canopy incomplete on account of windfalls; largest tree with a volume of 80 cubic ft."

² *The Acacia Tree* (1842).

³ Paeske of Brunswick, in *Mitt. Deut. Dend. Ges.* 1911, p. 77, recommends the planting of Robinia as scattered solitary trees in hirsch woods, which will provide shelter against the wind, and yet give enough sunlight for it to develop well. Amidst birch, the Robinia cleans its stem perfectly, being often free from branches up to 40 ft. in fairly good soil.

them the lead, this species will not bear much shade; and if grown for economic purposes it ought to be cut when twenty to thirty years old, or as soon as it is fit to make a good gate-post. On any suitable soil the wood is then at its best; whereas if left to grow into larger timber, the trunk becomes deeply furrowed or burry, and usually begins to decay inside at fifty to sixty years old. It would perhaps make a good mixture if planted in alternate lines five feet apart with sweet chestnut and cut out as soon as large enough; leaving the chestnuts to form a clean crop dense enough to suppress the stool shoots of the Robinia by its shade, and in their turn to be clean felled at fifty to sixty years old. This opinion is shared by Mr. Braid, forester to the Earl of Dudley, who finds Robinia a valuable tree when properly treated, on dry sandy land near Kidderminster.

REMARKABLE TREES

Perhaps the finest tree in England is the one growing in front of Frogmore House, near Windsor (Plate 351), which, when I measured it in 1908, was 88 ft. high by 14 ft. 7 in. in girth. President Roosevelt told me in 1904 that he hardly thought that such a tree could be now found in the United States. It is probably over a hundred years old, as I am told by Mr. Nutt, Clerk of Works at Windsor Castle, that Frogmore was bought in 1748 by Sir E. Walpole; and leased to Queen Charlotte in 1809. Another fine tree at The Mote, Maidstone (Plate 352), which I saw in 1902 measured about 80 ft. high.

At Kew a very old tree was probably planted by Aiton about 1760.

At Pains Hill there are some very large trees, one of which in 1904 was about 60 ft. high by 17 ft. 3 in. in girth; another was 70 ft. by 12½ ft. These were probably planted about 1750.

At Burwood House, Surrey, Col. Thynne in 1900 measured a tree 86 ft. by 13 ft. 3 in., which I have not seen. At Bowood, Wilts, I found, in 1908, a tree nearly 90 ft. high by 8½ ft. in girth. At Arley Castle there is a tree 85 ft. by 9 ft. in 1905 which was planted in 1820. At Stanway, Gloucestershire, there is a very old tree whose top is dying, and has been taller; in 1911 I made it 65 ft. by 11 ft. 10 in. At Audley End, in 1908, there was a healthy tree close to the house 80 ft. by 11 ft. 2 in. At Hatfield, Herts, there are several good trees, the largest, near the conservatory, measuring, in 1911, 67 ft. high by 12 ft. 8 in. in girth at three feet from the ground. In Tree Court of Caius College, Cambridge, there is an old tree about 60 ft. high, and 11 ft. 7 in. in girth, dividing at 10 ft. from the ground into two main stems. At Kenwood, near London, a very old tree, split nearly to the ground, with a decayed top, measured 45 ft. by 16 ft. in 1909. In an old gravel pit at Hitchin, Herts, drawn up in a thick wood among elms, I saw in 1905 a tall slender tree 80 to 90 ft. high, with a clean bole over 50 ft. high. At Holly Dale, near Keston, Kent, Mr. Webster records¹ a tree 78 ft. by 11 ft. 7 in., containing 110 ft. of timber and with a spread of 54 ft. At Chilham Castle, Kent, there is a fine tree, 75 to 80 ft. high and of moderate girth, on the lawn.

¹ *Trans. Roy. Scot. Arb. Soc.* xii. 312 (1890).

Sometimes the trunks of old trees are covered with burrs, the most remarkable that I have seen being a tree at Coolhurst, Sussex, which had a short trunk 14½ feet round; and another at Henley Park, Surrey, the seat of Sir J. Roberts, which was 65 ft. by 12½ ft.

In the north-west of England the tree rarely attains any great size; but Clark¹ records one at Dovenby Hall, Cumberland, 55 ft. by 9 ft. in 1887, which was planted in 1795.

In Wales the best I have seen is at Golden Grove, which in 1906 was 65 ft. by 8½ ft.

In Scotland it only thrives in the drier climate of the east, the best I know of being at Gordon Castle, a sound healthy tree which in 1904 was 56 ft. by 9 ft. At Murthly Castle a tree, forked near the ground, was in 1906 about 50 ft. by 6 ft. The largest trees measured by Mr. Renwick are two at Cordale House, Dumbartonshire, 64 ft. by 7 ft. and 53 ft. by 6 ft. 7 in., and one at Mauldslie Castle, 60 ft. by 6 ft. 1 in., all taken in 1911.

In Ireland, Henry has seen very few large trees, the finest being probably one at Doneraile, Co. Cork, which is about 12 ft. in girth, with a *Pyrus Aucuparia* arising from the stem at 9 ft. from the ground. At Glenomera, Co. Clare, a young healthy tree in a wood measured, in 1907, 59 ft. by 5 ft. 9 in. At Woodstock, Kilkenny, I saw in 1909 a tree near the Lodge, about 60 ft. by 6 ft. 9 in.

TIMBER

Such a mass of details are found in the writings of Loudon, Cobbett, and Withers as to the durable properties of this timber, that I need not repeat them at length; but I can say, from personal experience that for gate- and fencing-posts it is unrivalled for strength and durability by any native timber except that of the yew. Mr. H. Clinton-Baker² showed me the hanging-post of his lodge gate, which is now absolutely sound at the ground level, with the date 1849 cut on it. I was told that the spurs put up to support the oak posts of a fence at Pains Hill had remained sound for eighty years. I have myself proved that a tree planted on fair loam will in twenty-five years produce three good gate-posts, whilst oak at the same age would not make one.

On the Continent it is considered by wheelwrights to be superior to all other timber for spokes, and is now used extensively for wheel spokes of motor cars. For such purposes it must be cut before the wood has become old and lost its elasticity; and I believe that it is best when 9 to 12 inches in diameter. From one short log of this size, for which I paid 5s., the spokes of a heavy timber carriage wheel were made. Notwithstanding these good qualities the timber has no recognised value among English timber merchants, and "Acorn," in *English Timber*, says that it is so little known in home timber yards that there are no specific outlets for its disposal. Therefore I should advise that it be kept for home use only.

¹ *Trans. Eng. Arb. Soc.* 1887, p. 143.

² Two fencing stakes made of Robinia, which had been put down in 1848 in the pinetum at Bayfordbury, were perfectly sound in October 1911, when they were presented by Mr. H. Clinton-Baker to the Cambridge Forestry Museum.

The Robinia has proved very useful in the afforestation of the steppes of Russia and Hungary. The plantations in Hungary,¹ mostly pure and growing on light dry soil, covered an area of 70,000 hectares in 1899. These plantations are usually treated as coppice with a rotation of twenty years. Illes² states that in Hungary, a plantation, fifty years old, produced 8800 cubic feet of timber per acre, the trees averaging 90 ft. in height and 10 in. in diameter. In Roumania, the tree has been used with great success in fixing the moving sands on the Danube, and 5000 to 6000 hectares have been planted.

(H. J. E.)

ROBINIA NEOMEXICANA, WESTERN LOCUST

Robinia neomexicana, Gray, in *Mem. Amer. Acad.* v. 315 (1853); Sargent, *Silva N. Amer.* iii. 43, t. 114 (1892), and *Trees N. Amer.* 573 (1905); Wittmack and Bretschneider, in *Gartenflora*, li. 649, t. 1385 (1892); Robinson, *Flora and Sylva*, 1904, p. 57, with coloured plate.

A small tree, attaining 25 ft. in height and 2 ft. in girth, with thin scaly slightly furrowed bark. Young branchlets densely covered with appressed pubescence, some of which is retained in the second year. Leaflets nine to twenty-three, elliptical, rounded at the base, acute or rounded at the apex, which ends in a long slender mucro; pubescence as in *R. Pseudacacia*; stipels, $\frac{1}{10}$ in. long, often persistent; petiolules $\frac{1}{8}$ in. long, pubescent. The leaflets are somewhat smaller and bluer in tint than those of *R. Pseudacacia*.

Flowers³ in short compact glandular long-peduncled racemes; calyx-lobes all acuminate, appressed pubescent; corolla pink or white tinged with pink; standard narrow with a yellow blotch on the inner surface. Pod about 3 in. long, glandular pubescent.

This species differs little in appearance from the common Robinia, but is readily distinguished by the densely pubescent branchlets and the persistent stipels at the base of the leaflets. In winter the branchlets retain some of the pubescence, and are often covered with a glaucous bloom. The stipules become spinescent, as in *R. Pseudacacia*, but retain traces of pubescence, and are not quite glabrous as in that species.

This species forms hybrids with *R. Pseudacacia*, which are described on p. 1500.

R. neomexicana grows on the banks of mountain streams, and is distributed from the valley of the Purgatory river in southern Colorado through northern New Mexico to the Santa Catalina and Santa Rita Mountains in Arizona, whence it extends northward to southern Utah. It ascends to 7000 feet altitude.

It was introduced⁴ into cultivation in the Harvard Botanic Garden, U.S.A., in

¹ Cf. Booth, *Einführ. Ausländ. Holzarten*, 65 (1903).

² Quoted by Unwin, *Future Forest Trees*, 45 (1905). A plantation in France, fifty years old, yielded about 4300 cubic ft. per acre. Cf. *Bull. Soc. Forest. Franche-Comté*, x. 18 (1911).

³ A form with white flowers is said to have been found wild in Arizona. Cf. *Mitt. Deut. Dend. Ges.* 1911, p. 423.

⁴ Cf. W. J. Bean, in *Gard. Chron.* xxxv. 229 (1904). It appears to have been introduced on the Continent by Dieck, who states in his catalogue, *Neuheiten Offerte Nat. Arb. Zöschel*, 1889-1890, p. 13, that he received it from Prof. Sargent. It was soon afterwards obtained from the same source by Späth.

1882, and was sent from there to Kew in 1887. It is perfectly hardy at Kew, ripening seed, and has already attained a height of 25 feet. It is an ornamental small tree, producing beautiful pale pink flowers in June, and occasionally a second time in autumn. It flowers best in hot dry summers. (A. H.)

In my trial ground at Colesborne a seedling procured from Kew has endured winter frosts below zero without injury, and ripens its wood in a young state better than the common Robinia. At Aldenham House a young tree 15 ft. high bore fruit in 1911, and evidently liked the hot dry summer. Mr. Vicary Gibbs considers its flowers more ornamental than those of any variety, except *R. Pseudacacia* var. *Decaisneana*. (H. J. E.)

ROBINIA VISCOSA, CLAMMY LOCUST

Robinia viscosa, Ventenat, *Hort. Cels.* 4, t. 4 (1800); Loudon, *Arb. et Frut. Brit.* ii. 626 (1838); Sargent, *Silva N. Amer.* iii. 45, t. 115 (1892), and *Trees N. Amer.* 574 (1905).
Robinia glutinosa, Sims, in *Bot. Mag.* xvi. t. 560 (1803).

A tree, attaining 40 ft. in height and 3 ft. in girth, with thin smooth dark brown bark. Young branchlets covered with sessile and short-stalked glands, exuding a viscid matter. Leaflets nine to twenty-five, ovate or oval, rounded at the base, acute or rounded at the apex, which ends in a short mucro; pubescence similar to that of *R. Pseudacacia*; stipels slender, mostly deciduous; petiolules $\frac{1}{8}$ in. long, pubescent.

Flowers, about ten to fifteen, inodorous, in pubescent glandular short racemes; pedicels pubescent; calyx-lobes all subulately pointed, pubescent; corolla pale pink, with a narrow standard marked on the inner surface with a pale yellow blotch. Pod about 3 in. long, glandular-hispid.

This species is readily distinguished in winter by the viscid glandular twigs, which look as if oiled. The stipules are subulate, ultimately either deciduous or developing into slender short spines.

No varieties¹ of this species are known; but it forms hybrids with *R. Pseudacacia*, which are described on p. 1500.

The Clammy Locust, as it is called in America, is confined in the wild state to the mountains of North and South Carolina, where it occurs as a small tree or large shrub, often spreading by root-suckers and forming considerable thickets. It has been widely planted in the eastern United States, and is now naturalised in many places east of the Mississippi and as far north as the Canadian frontier.

It was introduced into England in 1797, and first flowered, according to Sims, in Mr. Whiteley's garden at Old Brompton in 1800. It is occasionally seen in botanic gardens, as at Kew, where there are several old specimens 25 to 35 ft. in height, which are probably the finest in Europe. This species is much slower in growth than *R. Pseudacacia*, but is ornamental on account of its pink flowers, which are produced in June and July. (A. H.)

¹ In Loudon, *Gard. Mag.* xvii. 391 (1841), it is stated that Vilmorin found at Verrières seedlings of this species with branchlets, which were not viscid.

ROBINIA HISPIDA, ROSE ACACIA

Robinia hispida, Linnæus, *Mantissa*, 101 (1767); Curtis, *Bot. Mag.* t. 311 (1795); Loudon, *Arb. et Frut. Brit.* ii. 627 (1838); Sargent, *Silva N. Amer.* iii. 37 (1892).
Robinia hispida-rosea, Loiseleur, in *Nouv. Duham.* ii. 64 (1804).
Robinia rosea, Loiseleur, *op. cit.* t. 18 (1804).
Pseudacacia hispida, Moench, *Meth.* 145 (1794).

A shrub, attaining about 10 ft. in height. Young branchlets covered with dense pubescence, interspersed with glandular bristles, which persist in the second year. Leaf-rachis with similar pubescence and bristles. Leaflets, seven to eleven, larger than in the other species, 1 to 2 in. long, oval, rounded at the base, rounded or occasionally slightly cuspidate at the apex, which is tipped with a long pubescent mucro; glabrous, except for slight pubescence on the midrib beneath; stipels persistent; petiolule, $\frac{1}{2}$ to $\frac{1}{4}$ in. long, pubescent and glandular-hispid.

Flowers few, five to nine, in loose pendulous racemes, pink, without odour; calyx-lobes all ending in long subulate teeth; peduncles, axis, pedicels, and calyx covered with white pubescence interspersed with glandular bristles. Fruit,¹ about 2 in. long, slightly constricted between the seeds, covered with glandular bristles. The stipules are usually deciduous, but occasionally develop on the older branchlets as minute blunt spines.

Two forms of this species and a probable hybrid are known:—

1. Var. *typica*, Schneider, *Laubholzkunde*, ii. 81 (1907), described above. This is characterised by numerous glandular bristles on the branchlets and leaf-rachis.

2. Var. *macrophylla*, De Candolle, *Prod.* ii. 262 (1825).

Var. *inermis*, Kirchner, *Arb. Musc.* 373 (1864).
Robinia macrophylla, Schrader, *ex De Candolle, loc. cit.*

Glandular bristles few or none on the branchlets and leaf-rachis, but present on the peduncles and calyx of the flower and on the pod. Leaves and flowers larger than in the typical form. Var. *macrophylla* appears to have arisen in cultivation in Europe.²

3. *Robinia Kelseyi*, Cowell, in Bailey, *Cycl. Amer. Hort.* 1538 (1902); Hutchinson and Bean, in *Bot. Mag.* t. 8213 (1908).

A small shrub, which originated³ in H. P. Kelsey's nursery at Boston, U.S.A.

¹ Mr. T. Meehan, who studied this plant in the wild state in Tennessee, says that it produces fruit very rarely, and is usually reproduced in the forests by root-suckers. He procured two pods in 1894, one of which he sent to the Kew herbarium. Cf. *Kew Bulletin*, 1893, p. 341, and Nicholson, in *Gardeners' Magazine*, 1894, p. 118. Carrière, in *Rev. Hort.* xxxix. 431, fig. 38 (1867), describes imperfect fruits which were produced on a tree at Paris.

² Cf. Carrière, *Prod. et Fixat. Vars.* 54 (1865), and in *Rev. Hort.* liv. 109 (1972).

³ Mr. Kelsey in a letter to Kew says that it came up spontaneously in his nursery; but supposes that it may have come into his collection with seed of other plants from the southern Alleghany Mountains.

With *R. Kelseyi* should be compared *R. Boyntoni*, Ashe, in *Journ. Elis. Mitch. Soc.* xiv. part ii. p. 53 (1897), which I have not seen. This is identified by Schneider, *Laubholzkunde*, ii. 82, note (1907) with *R. hispida*, var. *rosea*, Pursh, *Fl. Amer. Sept.* ii. 488 (1814); and is said to occur in North Carolina, Tennessee, Georgia, and Alabama. *R. Boyntoni*, according to Ashe's description, is very similar to *R. Kelseyi*, but with glabrous fruit. Small, *Flora South-eastern U.S.* 613 (1903), however, says that the pod is hispid.

It is probably a hybrid between *R. hispida* and *R. Pseudacacia*, resembling the latter in the slightly pubescent and usually non-glandular¹ branchlets, and in the small size of the leaflets, which are seven to eleven in number, $\frac{1}{2}$ to $1\frac{1}{2}$ in. long, glabrous, lanceolate, and tipped with a conspicuous mucro. The flowers are similar to those of *R. hispida*, but smaller; and are pink in colour, few (about five to eight) in the raceme,—with the peduncle, axis, pedicels, and calyx more or less covered with stalked glands, all the calyx-lobes being subulately pointed. Fruit reddish, $1\frac{1}{2}$ to 2 in. long, densely covered with glandular hairs; seeds three to four. Stipular spines are present on the branchlets, but are feebly developed.

This was introduced into commerce about 1901, and shrubs planted at Kew in 1903 have flowered and produced fruit.² It is not so rank in growth as *R. hispida*, and is less liable on this account to be injured by the wind. According to Mr. Bean, it can be readily propagated by grafting on the roots of *R. Pseudacacia*.

R. hispida, commonly known as the rose acacia, occurs in the mountains of Virginia, Kentucky, Tennessee, North and South Carolina, Alabama and Georgia.

It was introduced³ into cultivation in England by Sir John Colliton at Exmouth, in 1741. It is a handsome shrub with beautiful flowers, produced in June and July. It is usually grafted on the common Robinia; but Nicholson says that as it is readily propagated by root-cuttings, this mode of reproduction is preferable.

(A. H.)

¹ The branchlets bear occasionally one or two stalked glands.

² Cf. *Gard. Chron.* xlvii. 391, fig. 177 (1910), where the plant is figured. It obtained an award of merit at the Royal Horticultural Society on June 7, 1910.

³ Loudon, *Gard. Mag.* 1841, p. 637.

GLEDITSCHIA

Gleditschia, Clayton, ex Linnæus, *Gen. Pl.* 480 (1742); Willdenow, *Berl. Baumz.* 132 (1796); Spach, *Hist. Veg.* i. 90 (1834); Bentham et Hooker, *Gen. Pl.* i. 568 (1865); Maximowicz, *Mél. Biol.* xii. 450 (1886); Rehder, in Bailey, *Cycl. Amer. Hort.* 650 (1900).
Gleditsia, Linnæus, *Sp. Pl.* 1056 (1753); Schneider, *Laubholzkunde*, ii. 8 (1907).

DECIDUOUS trees belonging to the division Cæsalpinea of the order Leguminosæ. Stem and branches often armed with stout rigid sharp long-pointed spines, which are simple or branched. These spines are abortive branches, which arise above the axils of the leaves, being developed from buds embedded in the bark. Buds of the leafy branches, axillary, no true terminal bud being formed, concealed in the tissue of the twig, multiple, three or four superposed in a vertical line, the two or three lower without scales and covered by the base of the petiole in summer and by the leaf-scar in winter; the uppermost bud, larger than the others, covered with minute scales.

Leaves alternate or fascicled, long-stalked, equally pinnate or bipinnate, some of the pinnæ in the latter often reduced¹ to simple leaflets. Leaflets membranous, opposite or alternate, crenulate in margin, without stipels. Stipules leafy, early deciduous.

Flowers polygamous, dioecious, or perfect; regular, minute, greenish white, in axillary simple or spicate racemes, with scale-like caducous bracts. Calyx campanulate, lined with a disc, three- to five-lobed. Petals as many as the lobes of the calyx. Stamens, six to ten, inserted with the petals on the margin of the disc, exerted; filaments free, erect; anthers abortive in the pistillate flowers; ovary usually one-celled, rudimentary or absent in the staminate flowers; style short, with a dilated terminal stigma; ovules two or many.

Pod coriaceous, compressed; either elongated, containing pulp, many-seeded, and indehiscent; or short, without pulp, one- or two-seeded, and ultimately dehiscent. Seed oval or orbicular, more or less compressed, attached by a long slender funicle.

About a dozen species of *Gleditschia* are known, natives of North America, Caucasus, North Persia, Japan, China, Formosa, the Philippines, Celebes, Tropical Africa, and Argentina.

The following key comprises the species cultivated in Europe, which I have been able to identify. The leaflets described are those of the simply pinnate leaves on adult trees.

¹ Leavitt, in *Bot. Gaz.* xvii. 49, fig. 14 (1909), describes and figures these peculiar leaves, occurring in *G. triacanthos*.

Gleditschia

1511

I. Pods elongated, many-seeded, indehiscent.

* Leaflets, eight to twelve, prominently reticulate beneath.

(a) Branchlets pubescent.

1. *Gleditschia Delavayi*, Franchet. South-western China. See p. 1513.

Leaflets ovate-oblong, 2 to 2½ in. long, ¾ to 1½ in. wide, almost entire in margin. Pod, 16 to 20 in. long, flattened, twisted, not dotted with pits.

(b) Branchlets glabrous.

2. *Gleditschia sinensis*, Lamarck. North China. See p. 1513.

Leaflets ovate-lanceolate, 1¼ to 2½ in. long, ⅝ to 1 in. wide, crenulate. Pod, 6 to 10 in. long, convex on both surfaces, dotted with minute pits.

3. *Gleditschia macracantha*, Desfontaines. Central China. See p. 1514.

Leaflets ovate-oblong, 2 to 3 in. long, 1 to 1½ in. wide, crenulate. Pod, 6 to 12 in. long, slightly convex on both surfaces, dotted with minute pits.

** Leaflets twelve to twenty-eight, not prominently reticulate beneath. Branchlets glabrous.¹ Pods flattened, averaging 12 in. long, not dotted with pits.

4. *Gleditschia triacanthos*, Linnæus. North America. See p. 1517.

Leaf-rachis pubescent on all sides. Leaflets lanceolate, 1 to 1½ in. long, ⅜ to ⅝ in. wide, with dense conspicuous pubescence on the midrib beneath.

5. *Gleditschia caspica*, Desfontaines. South-west coast of the Caspian Sea. See p. 1512.

Leaf-rachis pubescent only on the outer edge of the groove. Leaflets narrowly elliptical or lanceolate, 1¼ to 1½ in. long, ⅝ to ¾ in. wide; glandular on the midrib above; shining and quite glabrous beneath. Young branchlets green.

6. *Gleditschia japonica*, Miquel. Japan, Manchuria, North China. See p. 1516.

Leaf-rachis as in *G. caspica*. Leaflets similar, but narrower and not glandular on the midrib above. Young branchlets purplish.

II. Pods short, one- to two-seeded, dehiscent.

7. *Gleditschia aquatica*, Marshall. North America. See p. 1520.

Leaf-rachis pubescent only on the outer edge of the groove. Leaflets, ten to twenty, lanceolate, about 1 in. long and ⅓ in. wide, distinguishable from the other species by their small size, and by being quite glabrous on both surfaces and only slightly ciliate on the margin. Young branchlets glabrous.

In addition to the species enumerated in the key, mention may be made here of a peculiar *Gleditschia*, growing in the nursery of Messrs. Simon-Louis at Plantières, which has been identified by Schneider, *Laubholzkunde*, ii. 10 (1907), with *Gleditschia ferox*, Desfontaines, *Hist. Arb.* ii. 247 (1809). This tree has remarkably stout, compressed, reddish brown spines, which attain on the trunk 10 in. in length, with branches 3 to 5 in. long; on the branchlets, the spines are about 1½ in. long, bearing two short lateral opposite smaller spines. The foliage on the specimen which I have seen, is mostly bipinnate, with six to ten pinnæ, each bearing twenty or more

¹ The branchlets of *G. triacanthos* are usually pubescent close to the base; but are glabrous elsewhere.

small leaflets. This tree has never borne fruit, and cannot be identified with any species known in the wild state. Whether it is a hybrid, which originated at an early period in France, or an unknown species, is uncertain.¹ A specimen is growing at Colesborne, where it is quite hardy, but does not seem likely to attain a tree-like habit.

(A. H.)

GLEDITSCHIA CASPICA

Gleditschia caspica, Desfontaines, *Hist. Arb.* ii. 247 (1809); Spach, *Hist. Vég.* i. 97 (1834); Loudon, *Arb. et Frut. Brit.* ii. 655 (1838); Boissier, *Fl. Orient.* ii. 631 (1872).
Gleditschia horrida, Makino, var. *caspica*, Schneider, *Laubholzkunde*, ii. 12 (1907).

A tree, attaining about 35 ft. in height. Young branchlets glabrous. Leaves simply pinnate or bipinnate with six to eight pairs of pinnæ; leaflets of the pinnate leaves, fourteen to twenty, narrowly elliptical or lanceolate, about $1\frac{1}{4}$ to $1\frac{1}{2}$ in. long, and $\frac{5}{8}$ to $\frac{3}{4}$ in. wide, rounded at the base, truncate or emarginate with a short mucro at the apex; upper surface with scattered short hairs on the midrib and nerves, and numerous minute glands on the midrib; lower surface glabrous, shining; margin crenulate, ciliate; stalklet very short, broad, pubescent above, glabrous beneath; rachis pubescent on the outer edge of the broad glandular often winged groove, elsewhere glabrous.

Flowers sub-sessile in slightly pubescent racemes or spikes; ovary glabrous. Pod thin and flattened, indehiscent, 9 to 12 in. long, 1 to $1\frac{1}{4}$ in. broad, with a sweet edible pulp,² straight or falcate, dark chestnut brown, smooth without dotted pits, slightly pubescent. Seeds numerous, close to the upper suture of the pod, oval, compressed, about $\frac{1}{2}$ in. long, shining, dark brown, marked on the surface with transverse raised lines.

The thorns on the branches in this species are chestnut brown, flattened or compressed in section, usually bipinnately branched, the primary branches coming off in different planes and bearing two or three lateral thorns. The thorns on the stem are much branched, and often very formidable.

G. caspica is limited to the wooded districts along the south-west coast of the Caspian Sea in Ghilan and Talysch. It is a rare tree, never attaining a large size, Medwedew³ giving its height as 30 to 35 ft. It ascends in the valleys to about 500 ft. altitude. The wood is used in the construction of mills, as it is durable under water. Cattle and wild pigs are fond of the sweetish pods.

G. caspica was introduced into England about 1822; and is usually seen as a small tree in botanic gardens,⁴ where its remarkable spiny trunk renders it an object of interest. It flowers, and occasionally produces fruit at Cambridge, where there are two trees of different sexes.

(A. H.)

¹ Rehder, in Bailey, *Cycl. Amer. Hort.* 650 (1900), states that *G. ferox* is often cultivated; but all the specimens which we have received from the Continent with this name, except the one from Simon-Louis, are referable to *G. caspica*.

² Cf. Hohenacker, in *Bull. Soc. Mosc.* iv. 351 (1838).

³ Cf. Köppen, *Holzgewächse Europ. Russlands*, i. 236 (1888), and Radde, *Pflanzenverb. Kaukasusländ.* 185, 189, 198 (1899).

⁴ Bean, in *Kew Bull.* 1908, p. 400, records a handsome tree, 40 ft. high, in the Schönbrunn Botanic Garden near Vienna.

GLEDITSCHIA DELAVAYI

Gleditschia Delavayi, Franchet, *Pl. Delav.* 189 (1889); Schneider, *Laubholzkunde*, ii. 11 (1907).

A tree, attaining in Yunnan 40 ft. in height. Young branchlets covered with a dense minute pubescence. Leaves on adult trees simply pinnate; leaflets ten to fourteen, oblong-ovate, 2 to $2\frac{1}{2}$ in. long, and $\frac{3}{4}$ to $1\frac{1}{2}$ in. broad; rounded or emarginate, and minutely apiculate at the apex; almost entire in margin, the crenations being few and indistinct; upper surface slightly pubescent on the midrib and veins; lower surface prominently reticulate, slightly pubescent on the midrib, elsewhere glabrous; stalklets short, stout, pubescent; rachis covered on all sides with a dense minute pubescence.

Flowers with short pedicels, perfect, in simple loose pubescent racemes; ovary glabrous. Pod indchiscent, 16 to 20 in. long, and 2 to $2\frac{1}{2}$ in. wide, flattened, twisted, glaucous, dark brown, slightly pubescent, not dotted with pits on the surface; seeds numerous, close to the upper suture.

The spines on the branchlets are terete, pubescent, simple or two- to three-forked.

G. Delavayi is readily distinguishable from all the other species by its pubescent branchlets and very large pods. It is a native of south-western China, where it was found in Yunnan by Delavay and myself at elevations of 4000 to 6000 ft. It was introduced into England by E. H. Wilson, who sent seeds in 1900 from Yunnan to Messrs. Veitch; but the plants raised from this consignment in the Coombe Wood nursery died in the winter of 1905-1906. Other plants raised two or three years afterwards from seed sent by Wilson from the Min valley in Szechwan still survive at Coombe Wood, as well as small plants at Kew and Cambridge.

This species is also in cultivation at Verrières near Paris. (A. H.)

GLEDITSCHIA SINENSIS

Gleditschia sinensis,¹ Lamarck, *Encycl.* ii. 465 (1786); Bunge, *Enum. Pl. Chin. Bor.* 21 (1831); Loudon, *Arb. et Frut. Brit.* ii. 654 (1838); Hemsley, in *Journ. Linn. Soc. (Bot.)* xxiii. 209 (1887); Schneider, *Laubholzkunde*, ii. 9 (1907).
Gleditschia horrida, Willdenow, *Sp. Pl.* iv. 2, p. 1098 (1806) (not Makino).
Gleditschia xylocarpa, Hance, in *Journ. Bot.* xxii. 366 (1884).
Gymnocladus Williamsii, Hance, *loc. cit.*

A tree, attaining in China 40 feet in height. Young branchlets glabrous. Leaves usually simply pinnate; leaflets eight to twelve, ovate-lanceolate, $1\frac{1}{4}$ to $2\frac{1}{2}$ in. long, $\frac{5}{8}$ to 1 in. broad; tapering to a rounded or truncate apiculate apex; upper surface minutely pubescent, but usually becoming glabrescent except on the midrib;

¹ *G. sinensis*, Bentham, *Fl. Hongk.* 100 (1861), and Maximowicz, in *Mé. Biol.* xii. 453 (1886), is not Lamarck's species; and is referable to *G. australis*, Hemsley.

lower surface, with scattered minute pubescence, which usually soon disappears, and with prominent reticulate venation; margin crenulate and ciliate; rachis pubescent on the edges of the groove; petiolule pubescent.

Flowers, on pedicels about $\frac{1}{8}$ in. long, in loose pubescent racemes; ovary pubescent on the borders. Pod indehiscent, 6 to 10 in. long, $\frac{3}{4}$ to $1\frac{1}{4}$ in. broad, swollen and convex on both surfaces, glaucous, glabrous, dark purplish brown, marked on the surface with dot-like pits. Seeds numerous, placed in the centre of the pod, oval, about $\frac{2}{5}$ in. long, convex on both surfaces, pointed at the apex, smooth, shining, brown, marked with transverse lines.

The spines on the branchlets are terete, usually with one or two lateral smaller spines. A variety¹ without spines is said to have arisen in Camuzet's nursery in 1823.

G. sinensis was described in 1786 by Lamarck from a tree, which had been cultivated for nine years in the Royal Garden at Versailles. It was said to have been raised from seed² received from China; and Lamarck adds that the pods were somewhat cylindrical and contained globose seeds. In Gay's herbarium at Kew, there is a specimen, labelled *G. sinensis*, Lamarck, which was gathered in 1822 from a tree, probably the original one, at the Trianon; and this specimen may be regarded as an undoubted type of Lamarck's species.³ It is identical with a species of *Gleditschia* which occurs wild on the mountains near Peking, and is cultivated farther south, as at Shanghai and Ningpo. The pods, which are called *tsao-chia*, are used as soap for washing clothes by the Chinese.

Loudon reported large trees of this species at Syon and the Mile End Nursery in 1838; but it is doubtful if these were accurately named; and they cannot now be found. We have not seen a single example in Britain. It is not common even in France, though there are large specimens at Verrières⁴ near Paris, and at Montpellier. (A. H.)

GLEDITSCHIA MACRACANTHA

Gleditschia macracantha, Desfontaines, *Hist. Arb.* ii. 246 (1809); Loudon, *Arb. et Frut. Brit.* ii. 654 (1838).

Gleditschia Fontanesii, Spach, *Hist. Vég. i.* 95 (1834).

Gleditschia officinalis,⁵ Hemsley, in *Kew Bulletin*, 1892, p. 82.

A tree, attaining in central China 50 ft. in height. Young branchlets glabrous. Leaves simply pinnate, with six to twelve leaflets, which are variable in size; those

¹ De Vries, *Plant Breeding*, 617 (1906).

² Bretschneider, *Hist. Europ. Bot. Disc. China*, 49, 52, 77 (1898), supposes that the seed was sent from Peking by Père D'Incarville; but the latter died in 1757, and Lamarck's account, though not quite clear, seems to indicate that the seeds were received about 1777.

³ *G. sinensis* has been much confused with other Chinese species by various authors. There are good specimens in the British Museum, gathered by Bretschneider and Williams near Peking.

⁴ Cf. *Hortus Vilmorinianus*, 19 (1906), where a tree of this species, wrongly identified as *G. caspica*, is reported to be 50 ft. high and 5 ft. in girth. It was probably planted in 1825.

⁵ This species was founded on specimens, bearing unripe and aborted pods, which were gathered on 26th July 1888.

towards the base of the shoot, very large, ovate-oblong,¹ 2 to 3 in. long, and 1 to $1\frac{1}{2}$ in. broad; those towards the apex of the shoot, smaller, ovate-lanceolate, $1\frac{1}{2}$ in. long and $\frac{3}{4}$ in. broad; glabrous, except on the midrib above, which is pubescent throughout, and on the midrib beneath, which bears a few scattered hairs; margin crenulate; lower surface prominently reticulate; rachis pubescent on the edges of the groove; petiolules pubescent.

Flowers in loose pubescent simple racemes; pedicels slender, pubescent, $\frac{1}{4}$ to $\frac{1}{2}$ in. long; ovary pubescent. Pod indehiscent, 6 to 12 in. long, 1 to $1\frac{1}{2}$ in. broad, straight or curved, not twisted, slightly convex on both surfaces, not so swollen as in *G. sinensis*, and not so flattened as in *G. triacanthos*, dark purplish brown, glabrous, shining, often glaucous, dotted with minute pits. Seeds numerous, placed towards the centre of the pod, oval, about $\frac{1}{2}$ in. long, convex on both surfaces, shining brown, marked with transverse raised lines, becoming deeply pitted when dried in the immature state.

The spines on the branchlets are terete, conical, reddish brown, simple or with one or two small lateral thorns.

This species is closely allied to *G. sinensis*, but appears to differ in the shape of the leaflets, which are larger, broader, and more prominently reticulate; and has pods, which can be readily distinguished. In the Kew herbarium, there is a branch with a pod, gathered by Gay in 1814 from a tree in M. Morel's garden near Paris. This tree is stated by Gay to have been identical with a tree of *G. macracantha* in the Jardin des Plantes, doubtless the one on which Desfontaines founded this species. Gay's specimen may then be accepted with certainty as a type of *G. macracantha*.

G. macracantha occurs in the wild state in the mountains of central China,² where it was found by Dr. Faber and myself in the provinces of Hupeh and Szechwan. Young unripe and aborted pods are gathered by the Chinese, and used as a drug, known as *ya-tsao*.³

G. macracantha was probably introduced into France by seed sent from China by the missionaries towards the end of the 18th century. A large tree of this species is said by Loudon to have been growing at Syon in 1838; but little reliance can be placed on his identification. It is apparently now unknown in cultivation in England; but it thrives well in the south of France and in Italy, whence we have obtained specimens from Montpellier and La Mortola. (A. H.)

¹ On one of the trees at Montpellier, the large leaflets are occasionally obovate, a shape not seen in any other species.

² A specimen gathered by Ford's collector in 1888 on Lantao Island, near Hong-Kong, is probably this species.

³ Cf. Hanbury, *Science Papers*, 248, 1876. These pods, of which there are specimens from China in the London Pharmaceutical Museum, appear to be aborted and contain no seeds. Similar pods have been produced on a solitary tree at La Mortola, which bears only pistillate flowers, the anthers being absent or sterile.

GLEDITSCHIA JAPONICA

Gleditschia japonica, Miquel, in *Ann. Mus. Bot. Ludg. Bat.* iii. 54 (1867); Franchet et Savatier, *Enum. Pl. Jap.* i. 114 (1875) and ii. 327 (1879); Maximowicz, *Mél. Biol.* xii. 452 (1886); Sargent, in *Garden and Forest*, vi. 163, t. 27 (1893), and *Forest Flora Japan*, 35, t. 11 (1894); Shirasawa, *Icon. Ess. Forest. Japon.* i. text, 87, t. 51, figs. 15 to 30 (1900).
Gleditschia horrida,¹ Makino, in *Tokyo Bot. Mag.* xvii. 12 (1903); Schneider, *Laubholzkunde*, ii. 11 (1907).
Fagara horrida, Thunberg, in *Trans. Linn. Soc.* ii. 329 (1794).

A tree, attaining in Japan 60 to 70 ft. in height, with a trunk occasionally 3 ft. in diameter. Young branchlets glabrous, purplish. Leaves similar to those of *G. caspica*, but with the leaflets apparently narrower, always lanceolate, tapering to a rounded or acute (not emarginate) apiculate apex, and without glands on the midrib of the upper surface; lower surface slightly pubescent on the midrib.

Pods thin, flattened, about 10 to 14 in. long, falcate, often twisted, shining or glaucous, brown, glabrescent, without dot-like pits on the surface. Seeds numerous, situated towards the upper suture of the pod, oval, flattened, about $\frac{1}{3}$ in. long, marked with transverse lines.

This species is closely allied to, if not really identical with *G. caspica*; but the material examined has been insufficient for determination. The purplish colour of the young branchlets in cultivated specimens of *G. japonica* may not be a constant character.

This species is a native of Japan, Manchuria,² and north China. In Japan, it is rare towards the north, where it is occasionally seen on the banks of rivers at no great altitude. It is more abundant and attains its largest size on the banks of the Kisogawa and other streams in the centre of the main island at elevations of about 2000 ft., where it thrives best in rich alluvial soil, though it is often seen on gravelly slopes. The pulp of the pods is much used for washing cloth by the Japanese, who call the tree *Saikachi*.

In Manchuria, it is said by Komarov³ to be wild in the neighbourhood of Mukden; and there are specimens in the Kew herbarium collected by Ross and Webster in other districts. Bretschneider also sent this species to Kew from the neighbourhood of Peking.

The only specimen which we have seen in England is a tree at Kew, about 15 ft. high, obtained from Yokohama in 1894. A young tree at Verrières, raised from Chinese seed, appears to belong to this species. (A. H.)

¹ This name is inadvisable, as *G. horrida*, Willdenow, *Sp. Pl.* iv. 2. p. 1098 (1806), is a synonym of *G. sinensis*, Lamarck.

² Cf. T. Nakai, in *Journ. Sci. Coll. Tokyo*, xxvi. 142 (1910), who records a variety of this species without spines from Korea. His *G. caspica* from the same region is doubtless *G. japonica*.

³ In *Act. Hort. Petrop.* xxii. 566 (1904).

GLEDITSCHIA TRIACANTHOS, HONEY LOCUST

Gleditschia triacanthos, Linnæus, *Sp. Pl.* 1056 (excl. β) (1753); Loudon, *Arb. et Frut. Brit.* ii. 650 (1838); Sargent, *Silva N. Amer.* iii. 75, tt. 125, 126 (1882), and *Trees N. Amer.* 556 (1905); Schneider, *Laubholzkunde*, 12 (1907).
Gleditschia spinosa, Marshall, *Arb. Amer.* 54 (1785).
Gleditschia meliloba, Walter, *Fl. Carol.* 254 (1788).
Gleditschia elegans, Salisbury, *Prod.* 323 (1796).
Gleditschia brachycarpa,¹ Pursh, *Fl. Amer. Sept.* i. 221 (1814).
Gleditschia heterophylla, Rafinesque, *Fl. Ludovic.* 99 (1817).

A tree, attaining in America 70 to 140 ft. in height and 10 to 20 ft. in girth. Bark divided by deep fissures into narrow longitudinal scaly ridges. Young branchlets green, slightly pubescent at the base below the insertions of the lower leaves, elsewhere glabrous; shining brown and glabrous in the second year. Leaves simply pinnate or bipinnate, with four to seven pairs of pinnæ; leaflets of the pinnate leaves, 14 to 28, lanceolate, averaging 1 to $1\frac{1}{2}$ in. long, and $\frac{3}{8}$ to $\frac{5}{8}$ in. wide, minutely apiculate at the rounded or acute apex; margin crenulate and ciliate; both surfaces pubescent with scattered curved hairs, which are dense and conspicuous on the yellowish green midrib beneath, and on the short stout stalklets; rachis with a narrow groove, and densely pubescent on all sides; venation inconspicuous and not prominent on the lower surface.

Flowers with short pedicels; staminate flowers numerous in usually clustered pubescent racemes; pistillate flowers few in solitary racemes. Pod, 12 to 16 in. long, 1 to $1\frac{1}{2}$ in. broad, indehiscent, thin and flattened; straight or falcate, often twisted; shining dark brown without dot-like pits, pubescent; inner coat thin and papery. Seeds numerous, placed close to the upper suture of the pod, separated by a succulent pulp, oval, about $\frac{1}{3}$ in. long, compressed, marked with a few transverse lines, and becoming pitted on drying.

The spines on the branchlets are conical, terete, unbranched or three-forked, the branching being simply pinnate in one plane; their colour is reddish at first, becoming ultimately shining dark brown.

The seedling² has oval-oblong sessile cotyledons, and bears in the first year pinnate leaves with about 20 very small leaflets.

VARIETIES AND HYBRID

1. Var. *inermis*, Pursh, *Fl. Amer. Sept.* i. 221 (1814).

Spines entirely absent or feebly developed.³ According to Loudon, abundance

¹ Said to differ from the type in bearing short pods. The pods, however, are variable in size on individual trees; and this cannot be maintained even as a distinct variety.

² Cf. Tübenf, *Samen, Früchte u. Keimlinge*, 127 (1891).

³ Sargent, *Silva N. Amer.* iii. 75, note 3 (1882), states that trees growing under conditions where they have been freely exposed to light most frequently develop spines; while those growing in the forest, shaded by other trees, are often unarmed.

of plants without spines may be selected from beds of seedlings of the ordinary form.

2. Var. *Bujoti*, Rehder, in Bailey, *Cycl. Amer. Hort.* 650 (1900).

Gleditsia Bujoti, Neumann, in *Rev. Hort.* iv. 205 (1845).

Branches pendulous; leaflets narrower than in the typical form.

3. Var. *nana*, Hort. Kew. A small round-headed tree of compact habit, with dark green foliage, and leaflets shorter and broader than in the type. This, of which there is a living example at Kew, appears to be identical with *G. ferox*, var. *nana*, Rehder, in Bailey, *Cycl. Amer. Hort.* 650 (1900); and is possibly *G. sinensis*, var. *nana*, Loudon, *Arb. et Frut. Brit.* ii. 654 (1838).

4. This species probably hybridizes with *G. aquatica*. Schneck, in *Plant World*, vii. 252 (1904), states that he found several trees of evidently hybrid origin growing on the edge of a swamp on Mt. Carmel, Illinois. These bore pods about 5 in. long and 1½ in. broad which were entirely destitute of pulp.

G. texana, Sargent, in *Bot. Gaz.* xxxi. 1 (1901), *Silva N. Amer.* xiii. 13, t. 627 (1902), and *Trees N. Amer.* 557 (1905), bears similar pods, and is said to be only found as a single grove of large trees, growing in alluvial soil along the Brazos river, near Brazoria in Texas. As both *G. triacanthos* and *G. aquatica* are found in the valley of the Brazos river, it is probable that *G. texana* is a hybrid between these two species. There are similar pods, without foliage, in the Kew Herbarium, which are labelled "*Gleditschia brachyloba*,¹ Mississippi Banks, Nuttall."

A small plant of *G. texana*, obtained from the Arnold Arboretum in 1900, is now growing at Kew. It differs from native specimens in having spines on the branchlets. (A. H.)

DISTRIBUTION AND CULTIVATION

G. triacanthos is a native of North America, extending from the western slope of the Alleghany Mountains in Pennsylvania westward through Ontario and Michigan to Minnesota, Nebraska, Kansas, and Indian Territory, and southward to Alabama, Mississippi, and the valley of the Brazos river in Texas. It usually grows on the borders of streams or in valleys in moist fertile land, either singly or in rare cases covering considerable areas almost exclusively, and occasionally occurs on dry gravelly hills. Sargent states that it is now often found naturalised in the region east of the Alleghany Mountains. It attains its largest size in Indiana and Illinois, where Ridgway² states that it was formerly one of the most majestic trees of the forest. Many were 120 to 140 ft. high, with straight trunks clear of branches to 50 or 70 ft., and 4 to 6 ft. in diameter. No trees except the Cypress and Catalpa had a more characteristic appearance, its tall straight but usually inclined trunk, of a dark grey or nearly black colour, being conspicuous at a distance, while the delicate foliage made its top contrast with other species. He³ gives 156 ft. as its maximum height, on the authority of Dr. Schneck, who showed me the remains of

these wonderful woods in 1904, when I could find no tree of this species larger than about 110 ft. by 9 ft.

G. triacanthos is a very ornamental tree, with fine foliage, which turns a bright golden yellow colour in autumn. It was first cultivated in England at Fulham, where a tree planted by Bishop Compton about 1700 bore fruit¹ in 1729. Though the seeds rarely if ever ripen in England, I have easily raised seedlings from French seed by soaking them in water before sowing. The seedlings do not ripen their wood in the open, and should be kept in a frame for two or three years. This species does not appear to be long lived in our climate, as most of the old trees mentioned by Loudon in 1838 cannot now be found. He figures one at Syon 57 ft. high, with a trunk 3 ft. in diameter; but the largest tree² there now was only 46 ft. by 2 ft. in girth in 1910.

In England one of the finest trees is growing near the Palm House at Kew. It measures 54 ft. by 6 ft. 10 in., and bears fruit occasionally. At Fawley Court a fine tree with flaky bark, like that of a tree at Verrières, and with very few spines, was 74 ft. by 5 ft. 10 in. in 1905. An old tree at Arley Castle³ measured 51 ft. by 5 ft. 5 in. in 1904. At Belton, Grantham, Miss Woolward reports a tree 47 ft. by 4 ft. in 1907.

Other large trees measured by me are at Bisterne Park, Hants, 62 ft. by 8 ft., with a bole of 30 ft., decaying in 1906; at Ham Manor, Sussex, 60 ft. by 4 ft. 7 in. in 1907; at Stowe, Bucks, 53 ft. by 4 ft. 10 in. in 1905; in the grounds of Wadham College, Oxford, 53 ft. by 4½ ft. in 1907; and one of the same size at Bibury Rectory, Gloucestershire, in 1908.

In Wales the only large tree I have seen is a very fine one at Golden Grove, 65 ft. by 4½ ft., a healthy tree with very few spines.

In Scotland and Ireland we have not seen any trees of note.

This species attains a large size, and produces fruit with good seed regularly in the south of France and in Italy. In the neighbourhood of Parma it is used for making formidable hedges. At Montpellier there is a fine specimen, narrowly pyramidal in habit, very different in aspect from the usual form seen in cultivation. In the Bishop's garden at Beauvais I measured in 1908 a tree 80 ft. by 7 ft.; and at the Château de Geneste, near Bordeaux, in 1909, one 80 ft. by 8 ft. At Schloss Dyck, in Germany, an even larger tree is reported,⁴ measuring about 90 ft. by 7 ft.

TIMBER

The wood is heavy, hard, and strong, with a coarse open grain, reddish brown at the heart with yellowish white sapwood. Being durable in the soil, it is used in the United States for posts and rails and to a small extent for wheel hubs; but I have never seen or heard of it in the English timber market, and it is not likely to have

1520 The Trees of Great Britain and Ireland

any special commercial value. The best specimen of it which I have seen was cut down at Wretham Rectory, Norfolk, in 1884, when it produced a log 30 ft. long, containing 69 cubic feet of timber. From it a bookcase of very nice appearance was made.
(H. J. E.)

GLEDITSCHIA AQUATICA

Gleditschia aquatica, Marshall, *Arb. Amer.* 95 (1785); Sargent, *Silva N. Amer.* iii. 79, t. 127 (1892), and *Trees N. Amer.* 558 (1905).
Gleditschia inermis, Miller, *Dict.* ed. 8, No. 2 (1768); Schneider, *Laubholzkunde*, ii. 13 (1907).
Gleditschia caroliniensis, Lamarck, *Encyc.* ii. 465 (1786).
Gleditschia monosperma, Walter, *Fl. Carol.* 254 (1788); Loudon, *Arb. et Frut. Brit.* ii. 653 (1838).

A tree, attaining in America 50 to 60 ft. in height, with a short trunk occasionally 8 ft. in girth. Young branchlets glabrous. Leaves simply pinnate, or bipinnate with three or four pairs of pinnæ; leaflets of the simple pinnate leaves, ten to twenty, lanceolate, about 1 in. long and $\frac{1}{3}$ in. wide, gradually narrowing to an obtuse apex, which is usually without any distinct mucro; margin crenulate, slightly ciliate; both surfaces shining, glabrous; stalklet slender, slightly pubescent; rachis pubescent on the edge of the narrow groove, elsewhere glabrous.

Pod thin and flattened, without pulp, dehiscent; either one-seeded, rhomboid, 1 to $1\frac{1}{2}$ in. long, or two-seeded, with the edges nearly parallel, about $2\frac{1}{4}$ in. long; reddish brown, glabrous, and without dotted pits on the surface. Seed orbicular, flattened, about $\frac{1}{3}$ in. in diameter, orange-brown, marked on the surface with transverse wavy lines.

The spines in this species are shining dark reddish brown, compressed and not terete in section, usually unbranched, or rarely with short branches arising pinnately in one plane.

G. aquatica is a native of the coast region of the United States from South Carolina, Georgia, and Florida westward through the Gulf States to the Brazos river in Texas; and extends northward in the Mississippi basin, through Louisiana, Arkansas, Kentucky, and Tennessee to southern Illinois and Indiana. East of the Mississippi river, it is rare and only found in river swamps; but westward it is very abundant on rich alluvial land, occupying in Louisiana and Arkansas extensive tracts, which are inundated for a considerable period every year.

It is said by Loudon to have been introduced into England in 1723 by Catesby; but it is extremely doubtful if the large trees considered to be this species by Loudon were correctly named, as in all probability they were simply *G. triacanthos*.

The only specimen which we have seen in this country, is a small tree at Kew, about 10 ft. high.
(A. H.)

LABURNUM

Laburnum, Linnæus, *Syst. Nat.* 4 (1735); Medicus in *Vorl. Churfürstl. Ges.* ii. 363 (1787); Grisebach, *Spicil. Fl. Rum.* i. 7 (1843); Bentham et Hooker, *Gen. Pl.* i. 481 (1865); Schneider, *Laubholzkunde*, ii. 37 (1907).
Cytisus, Linnæus, section *Laburnum*, Wettstein, in *Oesterr. Bot. Zeitschr.* xl. 435, t. iv. (1890), and xli. 127, 261 (1891).

DECIDUOUS small trees or shrubs, belonging to the division Papilionaceæ of the order Leguminosæ. Leaves alternate, compound, with three stalked leaflets, and more or less persistent stipules. Flowers yellow, in terminal racemes; calyx campanulate, two-lipped, the upper lip with two short teeth, the lower lip with three short teeth; standard ovate or orbicular, erect; wings obovate; keel incurved, shorter than the wings; stamens monadelphous, five short versatile anthers alternating with five basifixed anthers; ovary stalked, ovules numerous; style glabrous, incurved, with a terminal stigma. Pod linear, flattened, stalked. Seeds without an excrescence at the hilum.

This genus comprises three species, one of which *L. caramanicum*, Bentham and Hooker, a native of Greece and Asia Minor, is a low shrub, which need not be further alluded to.
(A. H.)

LABURNUM ALPINUM, ALPINE LABURNUM

Laburnum alpinum, Berchtold and Presl, *Opir. Rost.* iii. 99 (1830-1835); Grisebach, *Spicil. Fl. Rum.* i. 7 (1843); Schneider, *Laubholzkunde*, ii. 39 (1907).
Cytisus alpinus, Miller, *Dict.* ed. 8, No. 2 (1768); Loudon, *Arb. et Frut. Brit.* ii. 591 (1838).
Cytisus angustifolius, Moench, *Meth.* 145 (1794).

A tree similar in size, bark, and mode of branching, to *L. vulgare*. Young branchlets glabrous. Leaves similar to those of *L. vulgare*, but with glabrous petioles; leaflets more variable in shape, oval, oblong, or even obovate, acute and mucronate at the apex, entire in margin; dark green and glabrous above; light green and glabrous beneath, except for a few long hairs on the base of the midrib.

Flowers in long and slender racemes,—smaller, paler yellow, and opening later than those of *L. vulgare*; calyx and pedicels glabrous. Pod, about $1\frac{1}{2}$ to 2 in. long, glabrous, with the upper suture winged; seeds brown.

This species is variable in the wild state:—

1. Var. *pilosum*, Koehne, *Deut. Dendr.* 326 (1893), has leaflets with a few scattered hairs on the under surface.

2. Var. *microstachys*, Koehne, *loc. cit.* Racemes shorter and less pendulous than in the type. This occurs in sunny arid localities.

3. Loudon mentions a pendulous form in Loddiges' nursery, which, from the description, appears to have been a hybrid between this species and *L. vulgare*.

This species has much the same distribution as *L. vulgare*, but is found at a higher elevation in the mountains of central Europe, being common in the Jura, the Alps, and the Carpathians.

The two species were confused; but *L. alpinum*¹ appears to have been as early introduced as the other. It is more hardy, and is cultivated 5° of latitude farther north in Norway and Sweden. It thrives in the Highlands of Scotland,² and hence is often, but erroneously, called Scotch Laburnum. The largest specimens, which we have seen of this species in Britain, are the fine old trees in the Edinburgh Botanic Garden, which were planted about 1820 and are now showing signs of old age. One of these in 1911 was over 40 ft. high and nearly 5 ft. in girth.

(A. H.)

LABURNUM VULGARE, LABURNUM

Laburnum vulgare, Berchtold and Presl, *Opir. Rost.* iii. 99 (1830-1835); Grisebach, *Spicil. Fl. Rum.* i. 7 (1843).

Laburnum anagyroides, Medicus, in *Vorl. Churfürstl. Ges.* ii. 363 (1787); Schneider, *Laubholzkunde*, ii. 37 (1907).

Cytisus Laburnum, Linnæus, *Sp. Pl.* 739 (1753); Loudon, *Arb. et Frut. Brit.* ii. 590 (1838).

A small tree, seldom exceeding 30 ft. in height, with smooth greenish bark, and few long shoots, most of the lateral buds developing only short shoots, on which the leaves are borne in fascicles. Young branchlets covered with appressed silky pubescence. Leaves on long pubescent stalks. Leaflets three, elliptic, the terminal one larger than the two lateral; tapering at both ends, mucronate at the apex; upper surface dark green, glabrous; lower surface pale, more or less covered with appressed silky pubescence; margin entire; venation pinnate; stalklets silky pubescent. Buds with two to three silky external scales, a true terminal bud being present, which is surrounded in winter by acuminate silky stipular leaf bases.

Flowers in long pendulous racemes; the axis, long slender pedicels, and calyx being covered with silky appressed hairs. Corolla large, yellow; standard veined with dark purple lines. Pods about 2 in. long, often contracted in the middle, at first silky, then becoming glabrescent, thickened on both sutures, dehiscent. Seeds reniform-orbicular, depressed, black.

¹ Loudon, *Arb. et Frut. Brit.* ii. 917 (1838) says that the Alpine Laburnum, though actually a much lower tree than the mountain ash, will, when drawn up in woods, attain twice the height of the latter tree. This species was called Tree Laburnum by Sang, Nicol's *Planter's Kalendar*, 91 (1812) to distinguish it from the common Laburnum, which was said to be more shrubby in growth in Scotland.

² See Plate 370, where in the accompanying letterpress are given further particulars.

This species is variable in the wild state, three sub-species having been established by Wettstein; but Schneider only recognises the typical form and the following variety:—

1. Var. *Alschingeri*, Reichenbach, *Icon. Flor. Germ.* xxii. 30 (1869).

Cytisus Alschingeri, Visiani, *Fl. Dalmat.* iii. 262 (1852).

Lower lip of the calyx much longer than the upper lip, not approximately equal in length as in the type. Leaflets greyer and more pubescent beneath.

A considerable number of varieties have arisen in cultivation, the most important of which are:—

2. Var. *quercifolium*, Loudon. Leaflets, three or five, deeply lobed.

3. Var. *bullatum*, Koch, *Dendrologie*, i. 17 (1869). Leaflets curled, and puckered with swellings.

4. Var. *sessilifolium*, Kirchner, *Arb. Musc.* 399 (1864). Leaflets crowded, sessile.

5. Var. *aureum*, Simon-Louis, *Cat.* 1880, p. 51; Van Houtte, *Flore des Serres*, xxi. 2242, 2243 (1875). Foliage yellow.

6. Var. *pendulum*, Koch, *loc. cit.* Branchlets pendulous.

7. Var. *Carlievi*,¹ Kirchner, *Arb. Musc.* 398 (1864). Leaflets smaller than in the type. Flowers small, in short, more or less erect racemes.

HYBRIDS

L. vulgare is one of the parents in each of the following hybrids:—

I. *Laburnum Watereri*, Dippel, *Laubholzkunde*, iii. 673 (1893).

Laburnum vulgare, vars. *Watereri*, *intermedium*, and *Parksii*, Kirchner, *Arb. Musc.* 399, 400 (1864). *Cytisus Watereri*, Wettstein, in *Oesterr. Bot. Zeitschr.* xli. 129 (1891).

This is intermediate between *L. vulgare* and *L. alpinum* in the characters of the branchlets, foliage, and pods, and in the time of flowering; but it approaches the former species in the colour of the flowers, and exceeds it in the length of the racemes, which bear numerous flowers on long pedicels. The young branchlets, petiole, and under surface of the leaflets, have a few scattered appressed hairs.

This hybrid has been noticed in the wild state,² as at Bozen in the Tyrol, where Hausmann gathered it in 1856. It appears to have originated several times in cultivation; and was first noticed in 1842, when it was offered for sale by T. D. Parkes,³ a nurseryman at Dartford. He states that it was raised from seed, and had flowers of a deeper colour than *L. vulgare*, borne in racemes 15 in. long.

It afterwards appeared in a bed of seedlings in Waterer's nursery. Darwin⁴ found that 20 per cent of the pollen grains were ill-formed and useless, and that in most seasons it yielded no fruit.⁵ In 1865 his tree produced a few pods, some of

¹ Several plants appear to be known under this name, and possibly may be different forms, arising from the hybrid in the second generation.

² Wettstein, in *Oesterr. Bot. Zeitschr.* xli. 170 (1891).

³ Cf. *Gard. Chron.* 1842, pp. 365 and 705.

⁴ *Variation of Animals and Plants*, i. 416 (1890). A shrub at Aldenham, named *L. Alschingeri*, agrees in foliage and long racemes with *L. Watereri*; but produces every year abundance of pods, which apparently contain good seed. Mr. Vicary Gibbs raised seedlings from it some years ago.

⁵ Wettstein states that 42 per cent of the pollen grains are useless; and in 1890 made the following observations on three trees of similar age in the Vienna Botanic Garden:—*L. vulgare* bore 654 pods, with about 3000 seeds; *L. alpinum* produced 562 pods, with about 2500 seeds; while *L. Watereri* bore only 7 pods, with 21 seeds, of which only 5 were fertile.

which contained one or two apparently good seeds. Some of these germinated; and he raised two trees, one of which resembled the parent, but the other was remarkably dwarf in habit with small leaves.

This hybrid, which is usually sold as *L. Watereri* or *L. Parksii*, is very ornamental, occasionally bearing racemes 16 or 18 in. long, and is said to be very rapid in growth.¹

II. *Laburnum Adami*, Kirchner, *Arb. Musc.* 397 (1864).

Cytisus Adami, Poiteau, in *Ann. Soc. Hort. Paris*, vii. 501 (1830), and in Loudon, *Gard. Mag.* xvii. 59 (1841).

Cytisus Laburnum, Linnæus, var. *coccineum*, Lindley, in *Bot. Reg.* xxxiii. t. 1965 (1837).

Cytisus Laburnum, Linnæus, var. *purpurascens*, Loudon, *Arb. et Frut. Brit.* ii. 590 (1838).

This remarkable hybrid, between *Laburnum vulgare* and *Cytisus purpureus*, Scopoli, has normally glabrous branchlets, petioles, and leaves, with leaflets smaller than those of *L. vulgare*; and bears dingy red small flowers, in short pendulous racemes, which never set seed. It is usually reproduced by grafting on the common Laburnum, and is remarkable in often producing stray branches which revert back to one or both of the parents. A single tree is thus often seen bearing three kinds of foliage and flowers: (a) the hybrid foliage and flowers; (b) branches with the yellow flowers and leaves of *L. vulgare*; and (c) branches with the leaves and small purple flowers of *Cytisus purpureus*.² The yellow flowers produce pods which yield fertile seed, from which Darwin³ raised seedlings resembling in most respects the common Laburnum. The branches with purple flowers are said by Darwin to be not quite the same as those of *Cytisus purpureus*, and are not perfectly fertile; but he raised seedlings from their seed which differed in no respect from pure *Cytisus purpureus*.

This hybrid is said to have originated in 1825 in the nursery of M. Adam at Vitry, near Paris. He inserted on a stock of *L. vulgare* a shield of the bark of *Cytisus purpureus*, which produced in the following year several shoots, one of which was more vigorous and had larger leaves than the others. This shoot was propagated, and as soon as it bore the peculiar flowers intermediate between the two species, was recognised as a hybrid which had been produced by grafting. This account has been disputed by some botanists; and De Vries,⁴ who has made a study of the plant, states that Camuzet, a contemporary of M. Adam, maintained that he had seen the tree from which the latter had taken his graft, and that it was not *Cytisus purpureus*, but *L. Adami* itself, so that the latter must have originated earlier and been an ordinary chance hybrid from seed. Camuzet's statement seems very improbable; and against this view may be stated the fact that Reisseck, Caspary, and Darwin tried in vain to cross the flowers of *C. purpureus* with those of *L. vulgare*.

¹ Cf. Harrison Weir, in *Gard. Chron.* xxvi. 83 (1899).

² Mixed flowers also occur. Braun, *Rejuvenescence* (Ray Soc.), 317, plate v. (1853), gives an instance of a raceme which bore 21 flowers of *L. Adami*, 3 flowers of *L. vulgare*, and 8 mixed flowers. In the latter, half of the corolla was reddish like *L. Adami*, the other half yellow like *L. vulgare*; similarly, half of the calyx was reddish brown and glabrous, as in *L. Adami*, the other half green and pubescent, as in *L. vulgare*.

³ *Variation of Animals and Plants*, i. 414 (1890).

⁴ *Mutation Theory*, ii. 622, figs. 139, 140 (1911). Cf. also Bateson, in *Nature*, lxxxviii. 37 (1912).

The literature concerning *L. Adami* is very extensive, and need not be cited¹ here; but the reader may refer to an article by R. P. Gregory in *Gard. Chron.* l. 162, 185 (1911) on graft-hybrids, in which is given the anatomical evidence that *L. Adami* resembles *Cytisus purpureus* in the structure of the epidermis, whilst its internal structure is that of *L. vulgare*.

There are good specimens² at Kew, and in several private gardens.

DISTRIBUTION

L. vulgare is a native of Central Europe, occurring in the east of France from Lorraine, through the Jura to the Dauphiné, where it is common in woods on calcareous soil. It is rare in Switzerland, but is widely spread through Lower Austria, Styria, Carinthia, Carniola, and Hungary south of the Danube, attaining its southerly limit in northern Italy, Dalmatia, Servia, and Bulgaria.

All parts of the plant are said to be poisonous; but this is doubtful, as we have heard no case of animals³ being affected from browsing on the leaves alone. The seeds, however, contain a highly poisonous alkaloid,⁴ *cytisine*, discovered by Husemann and Marmé in 1865; and ten seeds have proved fatal to a child.

The flowers are produced regularly in May; but in some seasons, as in 1908, a few trees flower a second time⁵ in October.

In old trees of Laburnum, decayed at the base, adventitious roots are occasionally thrown out at some distance above the ground, and act as props to the stem. An instance of this in the Edinburgh Botanic Garden was described and photographed by Dr. Borthwick.⁶ (A. H.)

CULTIVATION

It was cultivated⁷ by Tradescant in England in 1596, and is largely planted everywhere as a small ornamental tree.

The common Laburnum is very hardy. It was not hurt in Suffolk by the severe winter of 1860-1861, and flowered well in the following May. The blossoms,

¹ The early history is given by Loudon, *Gard. Mag.* xii. 225 (1836), and xv. 122 (1839); and by Dillwyn, in *Gard. Chron.* 1841, pp. 325, 366, and 1842, p. 397. Cf. also Kerner, *Nat. Hist. Plants*, Eng. Trans. ii. 570 (1898).

² Cf. Bean, in *Gard. Chron.* xxxv. 371 (1904). Cf. also *The Garden*, lxxix. 333 (1906), and *Gard. Chron.* xxxvi. 217 (1904), where an illustration is given of a tree of *L. Adami* in Pennick's nursery at Delgany, Co. Wicklow.

³ In the case reported by Dr. Stark in *Gard. Chron.* xvi. 666 (1881), where cattle died at Huntfield, Lanarkshire, after browsing on Laburnum, the pods were eaten as well as the leaves and branches. In *Gard. Chron.* l. 310 (1911) a case is recorded of two cows which died after eating the tops of a felled Laburnum tree; but these bore seed-pods as well as foliage. The flowers are poisonous, according to Taylor, *Med. Jurisp.* 730-733 (1905), who considers a recorded case of poisoning by the bark at Inverness to be doubtful.

⁴ Flückiger and Hanbury, *Pharmacographia*, 172 (1879). The alkaloid *laburnine* here mentioned proved to be only impure *cytisine*. Cf. Kunkel, *Toxicologie*, ii. 847 (1901).

⁵ Cf. *Gard. Chron.* xxxii. 253, 271, 290 (1902), and xlii. 313, 363 (1908). Autumnal flowers, seen in October at Kingston-on-Thames, and on 1st November at Antwerp, were noticed as borne in short racemes.

⁶ *Notes R. Bot. Garden, Edinburgh*, xviii. 121, plate 24 (1907).

⁷ By Act V, Ed. IV. cap. 4 (Ireland), every Englishman was required to have a bow of his own height made of yew, wych hazel, ash, or awburne. The *awburne* was possibly the Laburnum, as it is identical with the Scottish name for this tree, *hoburn saugh*, which is given in Jamieson's *Dictionary*. Cotgrave's *Dictionary* (1611) gives the French word, "*Aubourt*, a kind of tree, Latin *alburnus*; it bears long yellow blossoms which no bee will touch." The flowers of the Laburnum are visited by bees; but Cotgrave here repeats an erroneous statement of Pliny. Cf. the correspondence on this subject in *The Phytologist*, iv. 191, 255 (1860). Matthiolus mentions that in his time the wood of the Laburnum was considered to make the best bows.

however, are sometimes completely killed by late frosts in April, as in 1859 at Mildenhall.¹ It is planted in Norway as far north as Trondhjem, and in Sweden as far as Stockholm.²

No tree is more easily raised from seed, or more easily transplanted than the Laburnum; and its rapid growth when young, and ability to thrive on the poorest, driest, and most chalky soils, makes it a valuable addition not only to pleasure grounds, where it is most generally seen, but also for plantations.

Boutcher³ recommends planting it in plantations where hares are numerous, because as long as they can get Laburnum they will touch no other tree, and though eaten to the ground every winter they will spring up again every summer. I have proved the truth of this to some extent at Colesborne, and planted Laburnums in quantity on the edge of plantations. But as the tree has a tendency to branch freely, and the branches are easily broken by the wind, pruning must be done for some years if a clean bole is desired. There is much variation in the habit; some, having a weeping tendency, should be selected for ornament; whilst for timber, clean stems of 10 to 12 ft. should be aimed at; and on good soils I believe that, though the wood is hardly known to modern cabinetmakers, it will have a considerable value at an age when few other hardwoods have any.

REMARKABLE TREES

One of the finest I have seen in the south, is near the East Lodge at The Mote, near Maidstone, in a sheltered dell. This in 1911 was 38 ft. high, with a bole 8½ ft. in girth and 8 ft. high, but the stem was partly decayed and patched with lead and plaster.

At Ickleton Grange, near Cambridge, Mr. G. W. H. Bowen showed Henry, in June 1912, a remarkable plantation of Laburnum (*L. vulgare*), which is said to have been made about 1790 by Mr. Percy Wyndham. It is four acres in extent, and is situated on the south slope of a hill, the soil being very thin and resting on impermeable chalk. The plantation was coppiced at an early period, most of the trees being bushy, with several wide-spreading limbs, arising from stools of considerable size. The largest specimen has eight great stems, 3 to 5 ft. in girth, and about 30 ft. high. Though close together and almost forming pure canopy, the trees are thinly clad with foliage; and the soil beneath is covered with thick grass. Seedlings, as soon as they appear, are eaten by rabbits; but in the same soil in a garden at some distance, which is surrounded by a Laburnum hedge, seedlings are very numerous. Mr. Bowen has also some thriving Laburnums, which were originally put down as stakes for fencing, but speedily developed roots and grew in this chalky soil.

At Coolhurst, near Horsham, there is a very old tree which leans over the road and has been propped up to keep it from falling. In 1906 it was about 35 ft. high by 3 to 4 ft. in girth. At "The Laburnums," near Stroud, there is a group of three trees, the stems of which are close together at the base, girthing respectively

¹ Bunbury, *Arb. Notes*, 6 (1889).

² Willkomm, *Forstl. Flora*, 918 (1887).

³ *Forest Trees*, 109 (1775).

8 ft. 3 in., 7 ft. 5 in., and 6 ft. near the ground, with a height of about 30 ft., and a spread of foliage of about 18 yards.

In the laundry yard at Alnwick Castle there is an immense spreading tree, dividing at the ground into two main trunks about 43 ft. high and 11 ft. 2 in. round at the ground. This is probably one of three trees mentioned by Loudon,¹ the largest of which in 1835 measured 6 ft. 11 in. in girth, and contained 46 ft. of timber. Mr. Gillanders believes it to be over one hundred years old, and says that it shows signs of decay.

At Inveraray it also grows to a large size, as I saw a log lying in the Duke of Argyll's yard in 1905 which was about 8 ft. in girth, and from which some very handsome furniture was afterwards made. At Dalkeith Palace² there is a remarkable Laburnum, low and spreading in habit, but covering a piece of ground 60 ft. across.

TIMBER

The wood of Laburnum is hard and heavy, weighing about 53 lbs. to the cubic foot when dry, according to Loudon, and is very durable when exposed to wet; and Mr. Vicary Gibbs tells me that a clothes-line prop of laburnum outlasted one of yew.

In colour the heartwood is dark when old, but the wood varies in colour with age, and rapidly becomes darker when exposed to light, becoming dark olive or red brown, and showing small medullary rays. When thoroughly dry it makes remarkably good joints, and is a first-class cabinetmakers' wood, taking a fine surface and good polish. Sang says³ that in his time (1812) it was the most valuable timber grown in Scotland, and that a quantity of it was sold in 1809 at Brechin Castle and Panmure at 10s. 6d. per foot. It was then used for cabinetmaking, musical instruments, handles, and chairs;⁴ and I can say from personal experience that it is a most excellent wood for furniture. I have seen old cabinets made in Scotland in which this wood was used in transverse sections, like the so-called oyster-shell cabinets made from slices of walnut wood. I believe it would also be well adapted for parquet.

(H. J. E.)

CASTANOPSIS

Castanopsis, Spach, *Hist. Vég.* xi. 185 (1842); Bentham et Hooker, *Gen. Pl.* iii. 409 (1880).

Castanea, Endlicher, *Gen. Pl.* 275 (in part) (1836); Prantl, in Engler and Prantl, *Nat. Pflanzenfam.* iii. pt. 1, p. 55 (1894).

Callaeocarpus, Miquel, *Pl. Jungh.* i. 13 (1851).

TREES or shrubs belonging to the order Fagaceæ, differing mainly from *Castanea* in the leaves being evergreen, and the buds covered with numerous imbricated scales; moreover, a true terminal bud is formed. Leaves coriaceous, five-ranked, entire or dentate. Catkins erect. Staminate flowers usually in clusters of threes, in simple or branched catkins; calyx, five- or six-partite; stamens six to twenty. Pistillate flowers, one to three, in an involucre, in simple or branched catkins or scattered at the base of the staminate catkin; calyx six-cleft, with abortive stamens; ovary three-celled, with two ovules in each cell; styles three, each ending in a minute stigma. Fruit, ripening in the second year, the spiny involucre enclosing one to three nuts. Nuts ovoid or globose, angled, usually containing one seed, which bears at its apex the aborted ovules.

About thirty species of *Castanopsis* have been described, one of which is a native of California and is the only species in cultivation. The others occur in south-eastern Asia and the Malay Archipelago, extending as far north as the eastern Himalayas, southern China, and Formosa.

CASTANOPSIS CHRYSOPHYLLA

Castanopsis chrysophylla, A. de Candolle, in *Journ. Bot.* i. 182 (1862), and *Prod.* xvi. 2, p. 109 (1864); Sargent, *Silva N. Amer.* ix. 3, t. 439 (1896), and *Trees N. Amer.* 223 (1905); Earl of Ducie, in *Gard. Chron.* xxii. 411, fig. 120 (1897); Masters, in *Gard. Chron.* xxxvi. 152, fig. 59 (1904); Jepson, *Silva of California*, 239, plate 74 (1910).

Castanea chrysophylla, Douglas, ex W. J. Hooker, *Comp. Bot. Mag.* ii. 127 (1836), *Fl. Bor. Amer.* ii. 159 (1839), *London Journ. Bot.* ii. 496, t. 16 (1843), and *Bot. Mag.* t. 4953 (1856); Jepson, *Fl. W. Mid. Calif.* 145 (1901).

A tree, rarely attaining in America 120 ft. in height and 20 ft. in girth, but usually smaller. Bark, 1 to 3 in. thick, and deeply divided by longitudinal fissures into rounded scaly ridges. Young branchlets covered with yellow scurfy scales. Leaves (Vol. III, Plate 202, Fig. 10), persistent two or three years, oblong, averaging 3 to 4 in. in length, and 1 to 1½ in. in breadth, tapering at the base and

apex, often contracted at the apex into a short broad point; thick, coriaceous, entire in margin; dark green, shining and glabrous above; under surface bright yellow, coated with minute scales; lateral nerves pinnate, twelve to sixteen pairs, looping just before they reach the margin; petiole ¼ to ½ in. long.

Staminate catkins simple or branched; stamens six to ten. Pistillate flowers borne on short separate catkins or scattered at the base of the staminate catkin. Fruit-involucre spiny, like that of the common chestnut, irregularly four-valved, containing one or occasionally two nuts; nuts ½ in. long, angled, with a hard shell and a sweet kernel.

The typical form described above is a tree, with large leaves, which gradually passes at high elevations into a shrub, distinguished as follows:—

1. Var. *minor*, A. de Candolle, *Prod.* xvi. 2, p. 110 (1864).

Var. *pumila*, Vasey, in *Rept. Comm. Agric.* 1875, p. 176 (1876).

Castanea chrysophylla, var. *minor*, Bentham, *Pl. Hartweg.* 337 (1857).

A shrub 2 to 15 ft. high. Leaves similar to those of the type in shape, but smaller, 1 to 2 in. long, very golden beneath.

This variety occurs in the Santa Cruz mountains and northwards as far as the south fork of the Salmon river. It is often gregarious on chaparral slopes and on the pine barrens of the Mendocino coast.

2. Var. *sempervirens*, Henry.

Castanopsis sempervirens, Dudley, in Merriam, *Biol. Survey Mt. Shasta*, 142 (1899).

Castanea sempervirens, Kellogg, in *Proc. Calif. Acad.* i. 71 (1855).

A shrub, 1 to 8 ft. high. Leaves elliptical, 1 to 2½ in. long, variable at the base, rounded or obtuse at the apex, pale yellow beneath. This is retained by Jepson, *Silva of California*, 241 (1910), as a distinct species, on account of the usually more numerous (ten to seventeen) stamens; but he acknowledges that there is no difference in the fruits. It grows on arid mountain slopes from Mt. Jacinto northwards through the Sierra Nevada and coast ranges to Mt. Shasta at 3000 to 8000 ft. elevation.

This species, in its typical form as a large tree, occurs in the Redwood belt of Mendocino and Humboldt counties of California, and northwards in the Siskiyou, Coast Range and Cascades of Oregon, as far as the valley of the Columbia river. Southward and eastward in California, only the shrubby forms occur. As a tree it appears to be rare, fruiting very sparingly, so that good seed can scarcely ever be procured. Jepson states that the largest trees now existing scarcely exceed 115 ft. in height; but are occasionally 4 to 6 ft. in diameter.

C. chrysophylla was discovered in 1830 by David Douglas on the Grand Rapids of the river Columbia in Oregon, at Cape Orford, and near Mt. Hood. Seeds were sent to Kew, by the collector Burke,¹ in 1845, from which a solitary plant was raised, which produced fruit when only 5 ft. high in 1856. It was reintroduced by William Lobb, who² sent seeds to Messrs. Veitch in 1853; but, so far as I can judge, the

¹ Cf. *Bot. Mag.* t. 4953. A MS. note at Kew states that Burke collected in North America in 1845.

² *Hortus Veitchii*, 393 (1906).

typical form has never been introduced, all the specimens which I have seen being var. *minor*. (A. H.)

The finest specimen in England is probably that at Tortworth,¹ which was procured from Messrs. Veitch about 1854-1856, and had attained 20 ft. by 1 ft. 5 in. in 1879, and 27 ft. by 3 ft. in 1897; and on 1st August 1911 measured 29 ft. by 3 ft. 5 in., with a circumference of branches as much as 75 ft. This tree is growing in a sheltered position on the side of a hill in a sandy loam, resting on the Old Red Sandstone formation. Up to 1882 it bore sterile fruits; but since that date has produced fertile seed, from which many seedlings have been raised. One of these in the late Sir J. D. Hooker's garden at Sunningdale was 10 ft. high in 1897. I have several times endeavoured to grow seedlings from this tree at Colesborne, but in every case they have died before or after turning out of their pots. I attribute this to excess of lime, and it is clear that *Castanopsis* is intolerant of lime in the soil.

At the Heatherside Nursery, Farnborough, there is a fine specimen with a single stem, but with very wide-spreading branches, which was 35 ft. high and bearing fruit in July 1910. There is said to be a good specimen at Pencarrow in Cornwall.

A shrub² only 2 ft. high produced fruit in 1904 at Kaimes Lodge, Murrayfield, Midlothian.

In Ireland the finest specimen, about 30 ft. high, was at Old Connaught House, Bray; but it died a short time before 1905, when Henry saw the dead stump still remaining. (H. J. E.)

UMBELLULARIA

Umbellularia, Nuttall, *Sylva*, i. 87 (1842); Bentham et Hooker, *Gen. Pl.* iii. 162 (1880).

Oreodaphne, sub-genus *Umbellularia*, Nees ab Esenbeck, *Syst. Laurin.* 462 (1836).

Drimophyllum, Nuttall, *Sylva*, i. 85 (1842).

A GENUS belonging to the order Lauraceæ, the characters of which are given in the following description of the only¹ species known.

UMBELLULARIA CALIFORNICA, CALIFORNIAN LAUREL

Umbellularia californica, Nuttall, *Sylva*, i. 87 (1842); Sargent, *Silva N. Amer.* vii. 21, t. 306 (1895), and *Trees N. Amer.* 334 (1905); Jepson, *Flora W. Mid. Calif.* 191 (1901), and *Silva Calif.* 242, plates 10 and 76 (1910); Chesnut, in *Contrib. U.S. Nat. Herb.* vii. 349 (1902); Eastwood, *Trees of California*, 53 (1905); Power and Lees, in *Trans. Chem. Soc. London*, 1904, p. 629.

Tetranthera (?) *californica*, Hooker and Arnott, *Bot. Voy. Beechey*, 159 (1833).

Oreodaphne californica, Nees ab Esenbeck, *Syst. Laurin.* 463 (1836); Hooker, *Bot. Mag.* t. 5320 (1862).

Drimophyllum pauciflorum, Nuttall, *Sylva*, i. 85, t. 22 (1842).

Laurus regalis, Standish and Noble, *Pract. Hints on Planting*, 160 (1852).

An evergreen tree, variable in habit, occasionally attaining 120 ft. in height and 10 to 15 ft. in girth; but oftener a smaller tree or large bush, rarely reduced to a prostrate shrub. Young branchlets green, glabrous. Leaves persistent two to six years, coriaceous, very aromatic, alternate, simple, lanceolate or narrowly elliptical, averaging 3 to 4 in. long and 1 to 1½ in. broad, cuneate or rounded at the base, tapering to an acute or rounded apex, entire in margin; main veins pinnate, eight to twelve pairs, curved, looping before they reach the margin, connected by reticulate veinlets; dark green and shining above, duller and paler beneath, with a minute scattered pubescence when young, ultimately glabrous; petiole ½ to ⅓ in.

Flowers minute in stalked simple umbels, which are solitary and axillary or crowded near the apex of the branchlet; each umbel with four to nine flowers on slender pedicels arising in the axils of deciduous bracts; calyx with six pale yellow obovate lobes; petals absent; perfect stamens nine, in three series, the inner three with a stalked orange gland on each side of the base of the filament, and alternating with three scale-like staminodia; anthers four-celled, four-valved, the three inner

¹ *Umbellularia parvifolia*, Hemsley, *Biol. Centr. Amer.* iii. 77 (1882), a native of Mexico, belongs to another genus, and is correctly named *Litsea parvifolia*, Mez, in *Jahrb. Königl. Bot. Gart. Berlin*, v. 481 (1889).

extrorse, the outer two series introrse; ovary sessile, with a solitary ovule, and one style, crowned by a capitate stigma.

Fruit, an ovoid berry, about 1 in. long, surrounded at the base by the enlarged calyx, greenish or purplish, containing a large seed, with a hard woody outer shell, and a thin papery inner coat, destitute of albumen; embryo with two large thick cotyledons.

The Californian Laurel is a native of California and south-western Oregon, occurring mainly in the coast ranges from the Umpqua river southward. It is less abundant on the high western slopes of the Sierra Nevada, where it ascends to 4000 ft. in the Yosemite Valley and to 5000 ft. in the Kaweah basin. It is also found on the southern slopes of the San Bernardino mountains at 2000 to 2500 ft., and on the west slope of San Jacinto below 5000 ft.; and reaches its most southerly point in the Oriflamme Cañon near Julian.

Prof. Jepson gives a detailed account of the remarkable variation in the habit of this species. As a tree of considerable or very large size, it is found on the banks of streams, usually in rich alluvial soil. It forms tall bushy thickets on the northern walls of cañons; and becomes a low shrub, 3 to 4 ft. high, in the chaparral of the higher parts of the coast range. A curious prostrate form grows here and there on the bluffs facing the ocean in Mendocino county.

The finest trees in California, 70 to 120 ft. in height, and 9 to 20 ft. in girth, occur in groves, unmixed with other species, on the Eel river and other streams to the northward.

I saw this tree in Oregon, where it grows on the alluvial flats of the Coquille¹ river, in mixture with *Acer macrophyllum*, and attains a large size, trees 70 to 80 ft. high and 10 to 14 ft. in girth being common. The tallest which I measured was 121 ft. high and 11 ft. in girth. The tree is most remarkable for the extraordinary density of its foliage, through which rain penetrates with difficulty and sunshine never. It sprouts freely from the stump when cut down; and when isolated, is prone to produce abundant epicormic branches on the stem.

All parts of the tree contain a volatile oil, which is most abundant in the leaves, amounting to 7½ per cent. This oil resembles menthol and camphor in its effects on the tongue and skin; and when inhaled produces dizziness and headache. The dried leaves spread about drive away fleas; and when used as a decoction are a powerful insecticide. The seeds are roasted and eaten by the Indians.

This species was discovered in 1792 by Archibald Menzies, on the shores of San Francisco Bay; and was introduced² into England from Oregon by David Douglas in 1826. One of his original plants, which was living at Kew in 1862, cannot now be found.³ (A. H.)

We have seen no large trees in England, where it apparently only forms a bush. There is a specimen, with fruit, in the Kew herbarium, sent by Canon Ellacombe from Bitton in 1876. At Grayswood, Haslemere, a large bush

bore flowers in May 1907. At Tortworth, a large bush bore ripe fruit on 15th October 1911, the seed of which germinated this spring in my garden at Colesborne. At Kew there is a young tree, 15 ft. high, near the Temperate House; and an older shrub on the wall near the Forestry Museum. The latter flowers sparingly in most years, but has never produced fruit.

I saw a large bushy specimen about 20 ft. high at Drove House, Thornham, Norfolk, which was bearing ripe fruit in November 1910. Major the Hon. G. Legh informed me that this tree might have been much taller, but that it had been topped by a previous tenant several years before. Considering the exposed situation close to the North Sea, it seems probable that if seedlings from the best form of this species were planted in deep shady valleys in the south-west of England, they might attain a considerable size.

The wood is hard, strong, and close-grained, taking a fine polish. It contains numerous small equal pores and many thin medullary rays. The sapwood is whitish; but the heartwood is of a rich yellow or brown colour, often with peculiar black streaks. The wood is used for making furniture, panelling, staves, shoe-lasts, etc., and is suitable for turnery. At North Bend and Myrtle Point, in south-western Oregon, there are factories where this wood is made into furniture and veneers. A figured board of this wood, which I obtained, under the name of myrtle, from the Californian State Exhibit at St. Louis in 1904, is in the collection of timbers at Cambridge University. (H. J. E.)

¹ It is reported to be abundant and of large size also on the Coos and Rogue rivers in Oregon.

² W. J. Hooker, *Comp. Bot. Mag.* ii. 127 (1836), where the tree is referred to as *Laurus regia*, Douglas.

³ *Cf. Bot. Mag.* t. 5320 (1862), where the plant figured was received from Berlin.

PRUNUS

Prunus, Linnæus, *Sp. Pl.* 473 (1753), and *Gen. Pl.* 212 (1754); Bentham et Hooker, *Gen. Pl.* i. 609 (1865).

TREES or shrubs, belonging to the order Rosaceæ. Leaves alternate, simple; usually serrate with or without glandular points to the serrations, rarely entire; petiole often with one or more glands.

Flowers perfect; solitary, or in fascicles, corymbs, or racemes; calyx-tube cup-shaped or tubular; sepals five, imbricated in the bud; petals five, white or pink; stamens ten to thirty, perigynous, inserted with the petals on the mouth of the calyx-tube; ovary one-celled, with a terminal style, and containing two pendulous ovules. Fruit, a fleshy drupe, with an indehiscent, one-seeded, smooth or rugged stone.

This genus comprises over one hundred species, mostly natives of the temperate regions of the northern hemisphere, a few being indigenous in tropical Asia and tropical America.

In the following article, only a few species, mainly of interest to foresters, are dealt with. These may be arranged as follows:—

SECTION I. *Cerasus*. Cherries.

Leaves rolled up in the bud. Flowers large, long-stalked, usually fascicled or in corymbs.

1. *Prunus Avium*, Linnæus. Europe, Asia Minor, Caucasus. See p. 1535.

Large tree. Leaves variable in shape, cuspidate-acuminate, with scattered long hairs on the midrib and nerves beneath. Branchlets glabrous. Inflorescence not leafy at the base.

2. *Prunus Cerasus*, Linnæus. Europe, Asia Minor, Caucasus. See p. 1541.

Small tree or shrub. Leaves smaller than, but similar in shape to *P. Avium*, nearly glabrous beneath. Branchlets glabrous. Inflorescence with leaves at the base.

3. *Prunus Mahaleb*, Linnæus. Europe, Asia Minor, Caucasus, Armenia, Turkestan. See p. 1542.

Small tree. Leaves broadly ovate, pubescent on each side of the midrib beneath. Branchlets densely pubescent.

SECTION II. *Padus*. Bird Cherries.

Deciduous trees or shrubs. Leaves rolled up in the bud. Flowers small in long racemes, which are leafy at the base.

Prunus

4. *Prunus Padus*, Linnæus. Europe, Temperate Asia. See p. 1543.

Small tree or shrub. Leaves slightly cordate at the base; pale beneath with axil-tufts of pubescence.

5. *Prunus serotina*, Ehrhart. North America. See p. 1546.

Large tree. Leaves tapering at the base; pale beneath with a dense band of rusty pubescence on each side of the midrib.

SECTION III. *Laurocerasus*. Cherry Laurels.

Evergreen trees or shrubs. Leaves rolled up in the bud. Flowers small in long leafless racemes.

6. *Prunus Laurocerasus*, Linnæus. Balkan Peninsula, Asia Minor, Caucasus, North Persia. See p. 1551.

Leaves with a few remote serrations on the margin, and with one or two glands on each side of the midrib beneath.

7. *Prunus lusitanica*, Linnæus. Spain, Portugal, Azores, Madeira, and Canary Isles. See p. 1553.

Leaves regularly serrate, without glands beneath. (A. H.)

PRUNUS AVIUM, WILD CHERRY, GEAN

Prunus Avium, Linnæus, *Fl. Suec.* 165 (1755); Willkomm, *Forstliche Flora*, 898 (1887); Ascherson and Graebner, *Syn. Mitteleurop. Flora*, vi. pt. ii. 151 (1906).
Cerasus Avium, Moench, *Meth.* 672 (1794); Mathieu, *Flore Forestière*, 137 (1897).
Cerasus sylvestris, Loudon, *Arb. et Frut. Brit.* ii. 693 (1838).
Prunus Cerasus, var. *Avium*, Linnæus, *Sp. Pl.* 474 (1753).

A tree, attaining 80 to 100 ft. in height. Bark smooth, shining grey, often peeling off on the surface in transverse annular strips; becoming deeply fissured and thick at the base of old trunks. Young branchlets glabrous. Leaves alternate on the long shoots, clustered at the apices of the short shoots or spurs, variable in shape and size, up to 5 in. long and 2 in. broad, ovate or obovate, elliptic or oblong, cuspidate-acuminate at the apex, cuneate or rounded at the base, biserrate or unequally serrate, the serrations tipped with a gland; upper surface dull, glabrescent; lower surface pale green, with scattered long hairs, mainly on the midrib and nerves; lateral nerves, twelve to sixteen pairs, looping before reaching the margin; petiole with a few scattered hairs, and usually with a pair of red prominent glands near its distal end.

Flowers, two to six in a cluster, appearing with the leaves, and usually situated on the short shoots, arising out of a bud, with no internal leafy scales; calyx-tube constricted near the apex, glabrous, with five entire reflexed lobes: petals five, white, obovate-rounded, emarginate. Fruit globose, smooth, reddish, shining; stone light brown, oval, compressed, furrowed on one edge.

This species suckers from the roots, but not so freely as *P. Cerasus*; and when cut down, produces coppice shoots.

VARIETIES AND HYBRID

I. In the wild and typical form of the species, the fruit is small, with little edible flesh. The cultivated cherries¹ with larger and more edible fruit derived from *P. Avium* comprise two main varieties:—

1. Var. *Juliana*. Heart or Gean Cherries. Fruit mostly black, with soft flesh.
2. Var. *duracina*. Bigarreau Cherries. Fruit mostly yellow or red, with firm flesh.

The Duke Cherries, with acid flesh, are referred to *P. Avium* as var. *regalis* by Bailey.²

II. The following varieties, cultivated for ornament, are peculiar in leaves, flowers, or habit.

3. Var. *decumana*, Koch, *Dendrologie*, i. 106 (1869). Leaves very large, occasionally as much as 10 to 12 in. in length, and 4 to 6 in. in breadth.
4. Var. *asplenifolia*, Kirchner, *Arb. Musc.* 254 (1864). Leaves with deeply incised teeth.
5. Var. *salicifolia*, Dippel, *Laubholzkunde*, iii. 615 (1893). Leaves very narrow.
6. Var. *flore pleno*, Kirchner, *loc. cit.* Flowers partially or completely double.
7. Pendulous and pyramidal forms are also known.

III. The following, which is in all probability a hybrid between *P. Avium* and *P. Mahaleb* is occasionally cultivated:—

8. *Prunus Fontanesiana*, Schneider, *Laubholzkunde*, i. 617 (1906).

Prunus græca, Desfontaines, *ex Koch*, *Dendrologie*, i. 109 (1869).

Cerasus Fontanesiana, Spach, *Hist. Vég.* i. 410 (1834).

A tree, resembling *P. Avium* in habit. Young branchlets covered with dense whitish erect pubescence. Leaves about 4 in. long, 2 in. broad, similar in shape and size to those of *P. Avium*, but differing in the more crenate serrations, which are tipped with sharp minute glands, as in *P. Mahaleb*; glabrous above; pale green beneath with long pubescence on each side of the midrib; petiole pubescent, with one or two large glands. Flowers about $\frac{4}{5}$ in. across.

This tree, the origin of which is unknown, is remarkable for never producing fruit. A specimen at Kew is about 25 ft. high.

DISTRIBUTION

P. Avium is widely distributed throughout nearly the whole of Europe, but appears to be rare in Spain and Italy as a wild tree; and in Russia,³ is confined to the south-western provinces and the Crimea. It also occurs in Asia Minor and the Caucasus. It extends as far north as the province of Bergen in Norway, where Schübeler mentions a pure wood of considerable extent at Urnäs; and its remains have been found in peat-mosses in Sweden.⁴

¹ An excellent account of the cultivated cherries was given by R. Thompson in *Trans. Hort. Soc.*, Second Series, i. 248-294 (1835).

² *Cycl. Amer. Hort.* 1453 (1901).

³ Köppen, *Holzgewächse Eur. Russlands*, i. 280 (1888).

⁴ Willkomm, *Forstliche Flora*, 899, note (1887).

It is difficult to state in what parts of the British Isles it is truly wild; but it is certainly a native of the southern counties of England, occurring in many woods as a rare tree; while in beech woods, as in the Chiltern Hills, it is rather common, and attains a great height.

P. Avium has been found¹ in the fossil state in neolithic beds at Crossness, Essex, and at Gayfield, Edinburgh; and in interglacial deposits at West Wittering and Selsey, Sussex. (A. H.)

CULTIVATION

Though much neglected of late years by planters, the cherry is perhaps our most beautiful native tree when in full flower; and as it grows well and to a large size, on soils of only moderate quality, and suffers less than most trees from spring frosts, it should be planted for ornament as well as for timber in all suitable places.

It seems to grow best among beech, and in woods where the stem is drawn up to a good height before its crown expands, though even in exposed situations it makes a fair-sized trunk. It is indifferent to the geological nature of the soil, growing equally well on calcareous, gravelly, or sandy soils, but not on wet or heavy clays.

It is easy to raise from seed, though as a rule the fruit is eaten by birds before it ripens, and the majority of the young trees that one sees in woods are grown from suckers which spring up at a considerable distance from the trunk. I have seen a colony of young cherries, thirty paces across, all of which had sprung from the roots of one tree after felling. When it has attained a few inches in diameter it is rarely attacked by rabbits. The seed, if put in a rot-heap when ripe, will germinate the following spring, though when kept dry for long, a large proportion will lie dormant for a year before coming up. The seedlings transplant without difficulty, and may be planted out with little or no risk of loss when 3 to 4 ft. high.

For an avenue of moderate size, planted about five yards apart, I can think of no more beautiful tree than the cherry. Mr. Foljambe of Osberton told me that his father was so fond of this tree, that after he became blind he used to ask to be led out into the place where they grew at the time when they were in flower, in order that their scent might recall their beauty the better.

REMARKABLE TREES

The largest cherry tree that I have seen in England was pointed out to me by the late Prof. Fisher in Windsor Park, near the Bishopgate, and not far from the house occupied by Lady Southampton. It has probably been drawn up by beech trees round it, and measured in 1904, 93 to 95 ft. high by 9 ft. 3 in. in girth, with a trunk free from branches for nearly forty feet. It is probably past its best, for the cherry is not a long-lived tree and generally begins to decay before reaching 100 years. In Gatton Park, Surrey, on a flinty chalk hill in a wood of beech, there are

¹ Cf. C. Reid, *Origin British Flora*, 114 (1899).

some fine cherries, and the best of those now standing is about 90 ft. by 7 ft. 6 in.¹ A tree cut here contained 78 cubic feet of sound timber, some of the boards being fully 2 ft. across and quite sound. At Walcot, Shropshire, there are some splendid vigorous young cherry trees, one of which that I measured recently being about 90 ft. high and only 4 ft. 9 in. in girth. These may attain 100 ft. in height as they are still growing. Plate 354 shows a wild cherry in Savernake Forest, with a burry trunk, 12 ft. 7 in. in girth at four feet, and 10 ft. 9 in. at five feet from the ground.

In Gloucestershire there was a tree on the Earl of Harrowby's estate near Campden, which, according to Loudon, measured 85 ft. by over 9 ft. I could not find this tree when I visited Norton Court in 1906, but can well believe the correctness of this measurement after seeing the fine development of ash, oak, and chestnut at this place. On my own land, however, though the tree grows well up to fifty or sixty years old, it does not attain these dimensions, one of 8 ft. in girth being the largest I have.

Probably one of the finest in the Chiltern Hills is a tree growing in Burke's Grove, Butler's Court, Beaconsfield, which was accurately measured in 1909 by Lord Grenfell and B. L. Majendie, Esq., R.N., as follows:—total height, 97 ft.; height to the first branch, 67 ft.; girth at five feet from the ground, 4 ft. 10 in. Mr. Leslie Wood has seen a tree in a beech wood near High Wycombe, 95 ft. in height.

At Camp Wood, The Coppice, Henley, where the beautiful whitebeam grows that was figured in Vol. I. Plate 51, there is a fine tree, which measured in 1905, 74 ft. in height, by 9 ft. 10 in. in girth, at two feet from the ground, above which it divides into two stems. In the adjoining Bolney Wood, two trees measured 79 ft. by 5 ft. 2 in., and 76 ft. by 4 ft. with stems clear of branches to forty feet, and rivalling in height the beeches amidst which they are growing.

In a wood near Riverhill, Kent, Mr. A. B. Jackson measured a tree, 70 ft. by 8½ ft. in 1908. At Sidmouth, Devonshire, Miss Woolward measured a tree, 62 ft. by 10 ft. in 1906. At Henham, Suffolk, there is a tree about 50 ft. high and 10½ ft. in girth, with branches which spread over an area eighty-two paces round.

On Ashampstead Common, Berks, Dr. Watney showed me a very fine tree which was in 1901 about 75 ft. by 8 ft., and was surrounded by quite a grove of suckers from the roots.

At Russells, near Watford, there is, in a thick plantation near the house, a tree about 90 ft. by 9 ft. 8 in., of which the bark, standing up in high ridges, makes the girth seem larger than it really is. The bole of this tree is clean for about 20 ft.

At Appleby Hall, the seat of Lady St. Oswald, in north Lincolnshire, there is a tree in the shrubbery which divides into three large stems at about seven feet and measures about 65 ft. by 11 ft. 9 in.

At Alnwick Castle, Northumberland, a very fine cherry growing in a wood in 1907 measured 80 ft. by 6 ft. 10 in. with a bole about 50 ft. high, but judging from the number of dead branches it is near its end.

¹ Mr. J. S. Elliott of Cranleigh informs me that he bought twenty cherry trees out of this wood containing 807 cubic ft.; the best ten of these averaged 57 cubic ft. each.

At Dynevor Castle there are many fine cherry trees in the slopes round the ruins, and I was told by the late Lord Dynevor that one was blown down in 1889 which at three feet from the ground was no less than 12 ft. 9 in. in girth. At Duffryn, near Cardiff, Mr. Coomber¹ measured in 1896 a tree 82 ft. high by 8 ft. 3 in. at five feet from the ground, with a bole 35 ft. high.

In Scotland the cherry is always called gean. The largest that I have seen is on the flat near the Tay at Murthly Castle, a tree 65 ft. by 11 ft. 5 in., with a bole of 9 ft. The main limb of this tree has decayed, and, in 1908, had a mountain ash about 15 ft. high growing out of the decayed stump. At Duns Castle, Berwickshire, there is a remarkably large tree which I am informed by Mr. J. Ferguson measures 42 ft. by 13 ft. 6 in. and still bears fruit, though not so much as it did 60 or 70 years ago, when the fruit of these trees was more valued in Scotland than it is now. At Gribton, near Dumfries, the seat of H. Lamont, Esq., Henry measured a tree, 56 ft. high by no less than 12 ft. 8 in. in girth, whose branches spread to a diameter of 70 ft.

At Gordon Castle there is a very fine old tree near the house 50 to 60 ft. high, which girths at two feet from the ground, where there is a large swelling, 14 ft. 2 in., and 10 ft. 5 in. at five feet. At Ardkinglas I have seen a fine old cherry by the garden wall which had a very large burr on the trunk.

At Mauldslie Castle, Lanarkshire, Mr. Renwick in 1899 measured a tree 52 ft. high and 13 ft. 2 in. in girth. In 1903, it was reported² to be in a state of decay, the trunk splitting, but supported by an iron band.

In Ireland, a most remarkable grove of cherry trees exists at Clonmannon, Co. Wicklow, though only ten survive out of the fifty which originally grew here on about an acre of lawn. The largest measured, in 1907, 70 ft. high by 10 ft. 10 in. in girth. Another was 55 ft. high and 12 ft. in girth at three feet from the ground, above which it divides into five great stems. Hayes³ records at the same place in 1794, a cherry tree of the Upton-mazard kind, no less than 15 ft. in girth at five feet from the ground, being the largest cultivated cherry tree that I have ever heard of. At Mount Usher, a tree dividing into two stems near the ground, 5 ft. 10 in., and 7 ft. 2 in. in girth respectively, was 62 ft. high in 1903. The girth of the main stem at the base was 11 ft. 3 in. in 1908.

At Glenstal, Co. Limerick, a tree in a wood, clear of branches to thirty feet, was 69 ft. by 6 ft. 3 in. in 1903. At Bunratty, Co. Clare, Mr. R. A. Phillips measured a tree on 14th May 1905, when it was in full flower, 70 ft. in height and 11½ ft. in girth, with a spread of branches fifty-seven feet in diameter.

Though the cultivated varieties of cherry never, in England at least, seem to attain the size of the wild cherry, yet in some districts they become very large. In Nash's orchard at George's Green near Slough I saw, on 23rd July 1908, a tree (Plate 355) at least 60 ft. high by 9 ft. 4 in. in girth. The fruit was being gathered with the help of a ladder with 77 rungs, and the men informed me that in this orchard no less than 101 sieves (25 pounds to the sieve) had been gathered

¹ *Gard. Chron.* xx, 664 (1896).

² *Trans. Nat. Hist. Soc. Glasgow*, vii, 83 (1903).

³ *Treatise on Planting*, 127 (1794).

from one tree. This was a late black cherry of moderate size known in the district as "Black bud" or "Croon's" cherry. W. Dumbarton, a resident of the place, further told me that in an orchard belonging to Sir R. Harvey at Iver, he had gathered thirty-five years ago 165½ sieves of cherries from one tree of the Bigarreau variety, which is still alive. This seemed to me incredible, but I was assured by Mr. Ford, steward to Sir R. Harvey, that he had heard this as a fact from natives of the place.

I saw at Golden Grove in Wales a cultivated cherry no less than 50 ft. by 9 ft. with a bole more than 20 feet high. But as a rule the trees in orchards are cut down or decay before they arrive at anything like the size mentioned above.

I have found no account of cherry trees of great size in Europe, except one by the Rev. R. Walsh,¹ who wrote as follows:—"The second variety is an amber-coloured transparent cherry, of a delicious flavour. It grows in the woods in the interior of Asia Minor, particularly on the banks of the Sakari, the ancient Sangarius. The trees attain a gigantic size, they are ascended by perpendicular ladders, suspended from the lowest branches. I measured the trunk of that from which the seeds I send were taken; the circumference was 5 ft., and the height where the first branches issued 40 ft.; from the summit of the highest branches was from 90 to 100 ft., and this immense tree was loaded with fruit."

TIMBER

The wood of this tree, though now little valued in the trade, is one of the best native woods for inside work, being easier to season and less liable to warp than most timbers. It has a fine even grain which takes a good surface and polishes well. Its colour is pale pinkish when fresh, but when oiled or waxed it becomes with age a dark pinkish or brown, and is highly ornamental when cut so as to show the fine medullary rays.

I have used it with very good effect for panelling a small room at Rapsgate Park, near Colesborne. I am informed by Mr. A. C. Forbes that the pews in the church at Gibside, Northumberland, which were made in 1812 of cherry wood, have not warped or shrunk in the least, the joints being as good as when made. Though the sapwood in some places is worm-eaten, the heartwood is almost free from this defect.

As far as my experience goes the wood is best when the trees are felled at about 4 to 5 feet in girth, older trees being often more or less decayed at the heart. It is sold standing at 6d. a foot or less, and may be bought in the form of board at a very reasonable price, and used for furniture and chair-making, as well as for all work where toughness and strength are not specially required. It may be made richer in colour by soaking it in lime water, and when treated in this way is very similar to pale-coloured mahogany. (H. J. E.)

¹ *Trans. Hort. Soc.* vi. 44 (1826).

PRUNUS CERASUS, DWARF CHERRY

Prunus Cerasus, Linnæus, *Sp. Pl.* 474 (1753); Willkomm, *Forstliche Flora*, 897 (1887); Schneider, *Laubholzkunde*, i. 614 (1906); Ascherson and Graebner, *Syn. Mitteleurop. Flora*, vi. pt. ii. 147 (1906).

Prunus acida,¹ Koch, *Dendrologie*, i. 112 (1869).

Cerasus vulgaris, Miller, *Gard. Dict.* ed. 8, No. 1 (1768); Loudon, *Arb. et Frut. Brit.* ii. 693 (1838).

Cerasus acida, Gaertner, *Fl. Wettar.* ii. 185 (1800); Mathieu, *Flore Forestière*, 139 (1897).

A shrub or rarely a small tree, sending up numerous suckers from the root, and distinguishable from *P. Avium* as follows:—Leaves smaller, almost but not quite glabrous on the shining under surface; glands often absent on the petiole. Flowers, two to five in a cluster, generally on the long shoots, and not on short spurs, as in *P. Avium*; arising out of a bud, the inner scales of which are accrescent and leafy; calyx-tube glabrous, scarcely constricted at the apex, with obtuse deflexed crenate lobes. Fruit globose, shining red, smooth; stone smooth, brown.

A considerable number of the orchard cherries have been derived from this species. These constitute two well-marked groups; those with colourless juice, like the Kentish cherry, and those with coloured juice, like the Morellos. Var. *acida* (*Prunus acida*, Koch) is a shrubby form, with small leaves, and dark red sour fruit, with an ovoid stone.

The following varieties² are cultivated for ornament, being peculiar in leaves, flowers, or habit.

1. Var. *semperflorens*, Loudon, *Arb. et Frut. Brit.* ii. 701 (1838).

Prunus semperflorens, Ehrhart, *Beit.* vii. 132 (1792).

Cerasus semperflorens, De Candolle, *Fl. Franc.* iv. 481 (1805).

Flowering and fruiting throughout the whole summer. This, which is usually grafted high, is known as "All Saints' Cherry." Its origin is uncertain. Koch states³ that it comes true from seed. There is a good specimen at Kew; and it is cultivated by Messrs. Veitch.

2. Var. *persiciflora*, Koch, *Dendrologie*, i. 111 (1869). Flowers double, rose-coloured.

3. Var. *Rhexii*, Kirchner, *Arb. Musc.* 252 (1864). Flowers double, white. This is figured as var. *ranunculiflora*, in *Flore des Serres*, xvii. t. 1805 (1867-1868).

4. Var. *cucullata*, Kirchner, *loc. cit.* Leaves puckered with swellings.

5. Var. *aucubæfolia*, Dippel, *Laubholzkunde*, iii. 613 (1893). Leaves spotted with yellow.

6. Var. *globosa*, Späth, *Cat.* 1887-1888, p. 101. A low globose shrub, with small leaves.

P. Cerasus is usually considered to be a true native of south-eastern Europe, Asia Minor, and the Caucasus; but it has escaped from cultivation in many districts

¹ The name *P. acida* has been used by various authors for different forms of the cherry. *P. acida*, Ehrhart, *Beit.* vii. 130 (1792), was applied to the cultivated sour cherries with colourless sap.

² Carrière, *Prod. et Fix. Vars.* 37 (1865), mentions several curious varieties which I have not seen.

³ *Dendrologie*, i. 113 (1869).

of central Europe, and is now found apparently wild in various localities in England, Scotland, and Ireland. There are many records¹ of *P. Cerasus* in the county floras; but in most cases its occurrence is so rare and local, as to suggest that it is possibly only a recent escape² from some neighbouring orchard, from which the fruit has been carried by birds. It is said, however, to be well established in some woods on the Pennine range in Cumberland, and in others in Surrey and Kent. Mr. R. A. Phillips tells me that it is plentiful in old hedgerows in many parts of Ireland; and he has seen it in a wild glen near Lehinch in County Clare. (A. H.)

PRUNUS MAHALEB, ST. LUCIE CHERRY

Prunus Mahaleb, Linnæus, *Sp. Pl.* 472 (1753); Ascherson and Graebner, *Syn. Mitteleurop. Flora*, vi., pt. ii. 156 (1906).

Prunus odorata, Lamarck, *Fl. Franc.* iii. 108 (1778).

Cerasus Mahaleb, Miller, *Gard. Dict.* ed. 8, No. 4 (1768); Loudon, *Arb. et Frut. Brit.* ii. 707 (1838); Mathieu, *Flore Forestière*, 140 (1897).

Padus Mahaleb, Borkhausen, *Handb. Forstbot.* ii. 1434 (1803).

A deciduous shrub or small tree, occasionally attaining 40 ft. in height. Young branchlets pubescent with dense erect short hairs. Leaves broadly ovate, 1½ to 2 in. long, 1 to 1½ in. broad; shortly acuminate at the apex, rounded at the base; dark shining green and glabrous above; lighter green beneath, with dense long pubescence on each side of the midrib; crenately serrate, each serration with a minute sharp gland; petiole slender, glabrous, with one or two large glands.

Flowers, appearing with the leaves, in short simple corymbs, each with two small leaves at the base, and four to eight flowers above; axis, slender pedicels, and wide-mouthed calyx glabrous; sepals ovate, obtuse, entire. Fruit ovoid, ⅓ in. long, blackish when ripe.

I. The following varieties are known in the wild state:—

1. Var. *transilvanica*, Schur, *Enum. Pl. Trans.* 180 (1866). Flowers small, numerous in the corymb; sepals reflexed. This occurs in Transylvania.

2. Var. *Cupaniana*, Fiori and Paoletti, *Fl. Anal. Ital.* i. 561 (1896) (*Prunus Cupaniana*, Gussone, *Flor. Sic. Syn.* i. 553 (1842)). A low shrub, with small coriaceous leaves; flowers few in the corymb. This occurs in mountain woods in Sicily; and a similar, if not identical form, has been found in Dalmatia.

II. Several varieties have arisen in cultivation:—

3. Var. *chrysoarpa*, Nicholson, in *Kew Hand-List Trees*, i. 143 (1894). Fruit yellow.

4. Var. *globosa*, Dieck, ex Dippel, *Laubholzkunde*, iii. 621 (1893). A globose compact bush.

¹ Mr. W. B. Crump has sent me specimens from Elland Park Wood, near Halifax, taken from small trees and bushes which resemble *P. Cerasus* in habit and are apparently wild. The flowers, however, have a calyx with the constricted tube and entire lobes of *P. Avium*; and in all probability these trees are hybrids between the two species.

² Mr. M. R. Pryor sent me a specimen from a shrub about 14 ft. high, growing in a wood at Weston Park, Stevcnage. This shrub, the only one we know of apparently wild in Herts, has not increased appreciably in size during the last twenty years.

5. Var. *monstrosa*, Kirchner, *Arb. Musc.* 258 (1864). Branches and branchlets very short and thick.

6. Var. *variegata*, Nicholson, *loc. cit.* Leaves variegated with white.

7. Var. *albomarginata*, Dippel, *loc. cit.* Leaves with a white edge.

P. Mahaleb is widely distributed in central and southern Europe, the Crimea, Asia Minor, the Caucasus, Armenia, and Turkestan. In France it grows mainly on rocky ground on the limestone formation, and occurs as far north as the departments of Seine Inférieure, where it is rare, and Pas-de-Calais; but in the west is not known wild north of La Rochelle. In Germany, it occurs in Alsace, Baden, and Bavaria; and, further east, is met with in lower Austria, Hungary, and Transylvania; but is more common southwards in the Tyrol, Carniola, Dalmatia, the Balkan States, and Greece. It also occurs in northern Spain, and in a few localities in Switzerland.

The scented kernels are sold in the bazaars of North-western India, and the tree is cultivated in Baluchistan.¹ The young branches are utilised for pipe-stems; and the tree is cultivated in Austria for this purpose.² (A. H.)

This can hardly be considered as a timber tree, as it rarely, if ever, exceeds 40 ft. high, but it produces, under favourable conditions, a trunk of considerable thickness, which produces a wood known in France under the name of *Bois de St. Lucie*,³ formerly much sought after by turners and cabinetmakers. It was introduced into England in 1764. Its principal use in England is as a stock on which to graft cultivated cherries, but it is also sometimes planted as underwood for game covert; and Loudon says, that when grafted on the wild cherry stock it makes a much larger tree than on its own roots. Whether this had been the cause of the large size attained by a tree at Devonhurst, Chiswick,⁴ or not, I cannot say, but I measured this shortly before it was cut down to clear the site, and found it 30 ft. high by 8 ft. 5 in. in girth, the spread of the foliage being 55 ft. in diameter. In the public gardens at Bury St. Edmunds there is a large old tree about 40 ft. by 5 ft. 9 in.

A tree in the Botanic Garden of Trinity College, Dublin, measured 40 ft. by 6 ft. in 1908. (H. J. E.)

PRUNUS PADUS, BIRD CHERRY

Prunus Padus, Linnæus, *Sp. Pl.* 473 (1753); Willkomm, *Forstl. Flora*, 901 (1887); Ascherson and Graebner, *Syn. Mitteleurop. Flora*, vi. pt. ii. 159 (1906).

Prunus racemosa, Lamarck, *Fl. Franc.* iii. 107 (1778).

Cerasus Padus, De Candolle, *Fl. Franc.* iv. 480 (1805); Loudon, *Arb. et Frut. Brit.* ii. 709 (1838); Mathieu, *Flore Forestière*, 141 (1897).

Padus vulgaris, Borkhausen, *Handb. Forstbot.* ii. 1426 (1803).

Padus racemosa, Schneider, *Laubholzkunde*, i. 639 (1906).

A deciduous shrub or small tree, attaining about 30 ft. in height. Young branchlets glabrous. Leaves, disagreeable in odour, averaging 4 in. long and 2 in.

¹ Hooker, *Fl. Brit. India*, ii. 312 (1878).

² Mathieu, *Flore Forestière*, 141 (1897).

³ Named after the monastery of Sainte-Lucie in the Vosges.

⁴ Devonhurst was a house, with pleasure grounds, built on the site of part of the Horticultural Society's Garden at Chiswick, where a considerable number of interesting trees remained till 1904. Cf. *Gard. Chron.* iv. 726 (1888).

broad, obovate-oblong or elliptic, acuminate at the apex, slightly cordate at the base; glabrous above, paler beneath with brown axil-tufts of pubescence; lateral nerves, 10 to 14 pairs, dividing and looping before reaching the margin, which is finely serrate, with close serrations, each ending in a sharp cartilaginous point; petiole glabrous, slender, with 1 to 4 glands near the insertion of the blade.

Flowers, appearing after the leaves, in racemes about 5 in. long, which have usually one or two small leaves near the base; axis, slender pedicels, and calyx glabrous; sepals glandular-fimbriate; petals white. Fruit globose, about $\frac{1}{3}$ in. in diameter, without a persistent calyx, shining, blackish; stone irregularly pitted.

VARIETIES

I. Besides the typical form described above, which has finely serrate leaves and pendulous racemes, and is prevalent in the plains of central Europe, the following geographical varieties are known:—

1. Var. *borealis*, Schneider, *Laubholzkunde*, i. 640 (1906).

Var. *petraea*, Fiek, *Fl. Schles.* 119 (1881).

Prunus borealis, Salisbury, *Prod.* 356 (1796); Schübeler, *Pflanzen-Welt Norw.* 369 (1873).

Prunus petraea, Tausch, in *Flora*, xxi. 719 (1831).

Leaves with coarser serrations. Racemes erect. This is prevalent in the mountains of Silesia, Bohemia, and Transylvania, and in the Alps; and is also the wild form, which occurs in Scandinavia and the British Isles.

2. Var. *pubescens*, Regel, *Fl. Ussur*, No. 149, ex Maximowicz, in *Mel. Biol.* xi. 706 (1883). Young branchlets, under surface of the leaves, and racemes, more or less covered with reddish brown pubescence. This occurs, but mixed with the typical form, in Manchuria, Saghalien, and north China.

3. Var. *cornuta*, Henry.

Prunus cornuta, Steudel, *Nomencl.* ii. 403 (1841).

Padus cornuta, Carrière, in *Rev. Hort.* 1869, p. 275, fig. 64.

Cerasus cornuta, Royle, *Illust. Bot. Himal.* 207 (1839).

Branchlets glabrous. Leaves rounded at the base, bluish green beneath with reddish brown axil-tufts. Racemes long and, like the pedicels, pubescent. Fruit large, $\frac{1}{3}$ to $\frac{1}{2}$ inch in diameter, with a smooth stone. This occurs in the Himalayas, at 6000 to 12,000 feet, and is considered by Hooker¹ to be a form of *P. Padus*; but by Koehne and Schneider to be a distinct species. It is represented at Kew by a tree 15 feet high.

II. The following have appeared in cultivation²:—

4. Var. *leucocarpa*, Koch, *Dendrologie*, i. 120 (1869). Fruit white to yellowish.

5. Var. *commutata*, Dippel, *Laubholzkunde*, iii. 647 (1893). Flowers and leaves appearing very early in the season. Said by Schneider to be from eastern Asia, and to be commonly cultivated under the name of *P. Grayana*.³

¹ *Fl. Brit. India*, ii. 315 (1878).

² *P. Laucheana*, Bolle, in Lauche, *Deut. Dend.* 652 (1882) is said to be a hybrid between *P. Padus* and *P. Virginiana*; and, according to Schneider, is sometimes known in cultivation as *P. Patus*, var. *rotundifolia*.

³ Cf. *Garden and Forest*, i. 295 (1888). *P. Grayana*, Maximowicz, in *Bull. Acad. St. Petersb.* xxix. 107 (1883), is a distinct Japanese species.

6. Var. *bracteosa*, Seringe, in De Candolle, *Prod.* ii. 539 (1825). Leaves at the base of the raceme very large.

7. Var. *aucubæfolia*, Kirchner, *Arb. Musc.* 259 (1864). Leaves spotted with yellow.

8. Var. *aurea*, Nicholson, *Kew Hand-List Trees*, i. 229 (1902). Leaves yellow.

9. Forms, pyramidal and pendulous in habit, are also in cultivation; and a variety with double flowers is mentioned by Schneider, and is in cultivation at Kew.

DISTRIBUTION

P. Padus is the most widely distributed of all the species of *Prunus*, occurring throughout nearly all Europe, in Siberia, Manchuria, Japan, north China, the Caucasus, Persia, and the Himalayas.

In Europe, it is more common in the north, as in Scandinavia, Denmark, and northern Russia; but is also widely spread in central Europe, and extends in the south to the mountains of northern Portugal, the Sierra Nevada in Spain, Pyrenees, Apennines, and the mountainous regions of the northern Balkan States. In Russia, it extends as far north as the Kola peninsula; but is rare in the southern provinces, and does not occur on the mountains of the Crimea. Bode¹ saw a tree in Courland, 40 feet in height and 4 feet in girth.

In the British Isles, it is most common in the Highlands; but occurs in many woods in northern England, ascending to 1500 feet in Yorkshire. In Radnorshire and other parts of Wales it is in waste places more often a shrub than a tree. It has been found² in the fossil state in neolithic beds at Northampton, Hornsea and Sand le Meer in Yorkshire, and at Hailes near Edinburgh, and in interglacial deposits at Selsey, Sussex, and at Airdrie, Lanarkshire. In Ireland, it is widely distributed,³ occurring in old woods and in river glens; but is absent from the southern uplands and rare on the central plain. (A. H.)

Dr. Walker⁴ states that at Drumlanrig there were in 1773 two trees about 40 feet high, one being no less than 8 feet in girth. In 1834, however, they had quite disappeared. We have seen none approaching these in size.

Schübeler says that in Norway where the tree is called "Hegg," from which the Scotch name hagberry is no doubt derived, he saw a tree at Mollenhof near Drammen, which was 58 ft. high, by 5 ft. 5 in. in girth; and in Sweden he mentions one which at 1 foot from the ground was 9 ft. in girth.

Though now seldom planted in England, the bird cherry is very ornamental when in flower, easily raised from seed, and flourishes on poor dry soil. Loudon strongly recommends the variety *bracteosa*, on account of its large pendulous racemes of flowers and fruit.

I have not heard of any use being made of its hard yellowish wood in England, but in France it was formerly used by country cabinetmakers. (H. J. E.)

PRUNUS SEROTINA, AMERICAN BLACK CHERRY

Prunus serotina, Ehrhart, *Beit.* iii. 20 (1788); Bentley and Trimen, *Medicinal Plants*, ii. t. 97 (1880); Sargent, *Silva N. Amer.* iv. 45, t. 159 (1902), and *Trees N. Amer.* 524 (1905); Von Schwerin, in *Mitt. Deut. Dend. Ges.* 1906, p. 1.

Prunus virginiana, Miller, *Gard. Dict.* ed. 8, No. 3 (1768) (not Linnæus).

Cerasus serotina, Loiseleur, *Nouv. Duham.* v. 3 (1812); Loudon,¹ *Arb. et Frut. Brit.* ii. 712 (1838).

Cerasus virginiana, Michaux, *Fl. Bor. Amer.* i. 285 (1803) (not Loiseleur); Loudon,¹ *Arb. et Frut. Brit.* ii. 710 (1838).

Padus serotina, Agardh, *Theor. Syst.* t. 14, f. 8 (1858); Schneider, *Laubholzkunde*, i. 643 (1906).

A deciduous tree, attaining in America 100 ft. in height and 15 ft. in girth. Bark, $\frac{1}{2}$ to $\frac{3}{4}$ in. thick, broken on the surface into small irregular scaly plates. Young branchlets glabrous. Leaves slightly coriaceous, about 3 to 4 in. long, and $1\frac{1}{4}$ to 2 in. broad, obovate-oblong or elliptic, acuminate at the apex, tapering at the base; shining and glabrous above; lower surface light green, with a dense band of rusty pubescence on each side of the midrib, elsewhere glabrous; regularly and sharply glandular-serrate; with one or two glands at the base of the leaf, or on the summit of the glabrous petiole.

Flowers in racemes, terminating short leafy branchlets; axis and slender pedicels glabrous; calyx cup-shaped, with short ovate sepals, which persist on the ripe fruit; petals obovate, white. Fruit globose, slightly lobed, $\frac{1}{3}$ to $\frac{1}{2}$ in. in diameter, red before ripening, almost black when ripe; flesh dark purple, juicy; stone obovate, compressed, smooth, broadly ridged on the ventral suture.

This species is often confused with *P. virginiana*, Linnæus, a North American shrub. The leaves of the latter are oval, cuspidate-acuminate, usually glabrous beneath, with long pointed serrations; and the inner bark of the branchlets has a strong disagreeable odour, that of *P. serotina* being aromatic and agreeable. In the former species the calyx is deciduous; in the latter it is persistent on the fruit.

VARIETIES

I. This species is very variable in the wild state: and several geographical forms have been distinguished, and ranked by American botanists as either varieties or distinct species:²—

1. Var. *neomontana*, Small, *Fl. S.E. United States*, 574 (1903). Leaves coriaceous, very large, coarsely toothed, whitish beneath; sepals pubescent. Occurs on the higher summits of the Alleghany Mountains.

2. *Prunus Cuthbertii*, Small, in *Bull. Torrey Bot. Club*, xxviii. 290 (1901). Branchlets, axis of the inflorescence, and pedicels pubescent. Leaves coriaceous. A shrubby form, growing in rich sandy soil in Georgia.

¹ Loudon describes *P. serotina* under both *C. virginiana* and *C. serotina*; and seems to have been unacquainted with the true *P. virginiana*, Linnæus.

² *Padus eximia*, Small, *Fl. S.E. United States*, 573 (1903), a glabrous form with leaves delicately reticulate-veined beneath, occurring in river valleys in southern Texas, can scarcely be distinguished from the type.

3. *Prunus australis*, Beadle, in *Biltm. Bot. Studies*, i. 162 (1902). Branchlets, axis of the inflorescence, and pedicels pubescent. Leaves covered beneath with reddish brown pubescence. Fruit dark purple. Occurs only in one locality, on clay soil at Evergreen in Alabama, where it is a tree about 60 ft. high.

4. *Prunus alabamensis*, Mohr, in *Bull. Torrey Bot. Club*, 1899, p. 118. Branchlets, axis of the inflorescence, and pedicels pubescent. Leaves slightly pubescent beneath. Fruit purple. A tree about 30 ft. high, occurring in the mountains of Alabama and Georgia.

5. *Prunus Capuli*, Cavanilles, ex Sprengel, *Syst.* ii. 477 (1825); Hemsley, in *Biol. Cent. Amer. Bot.* i. 367 (1879); Bolle, in *Mitt. Deut. Dend. Ges.* 1898, p. 56.

Cerasus Capollin, De Candolle, *Prod.* ii. 539 (1825); Loudon, *Arb. et Frut. Brit.* ii. 713 (1838).

Cerasus Capuli, Lavallée, *Arb. Segrez.* 115, t. 34 (1885).

Leaves lanceolate, long acuminate at the apex; underneath without bands of pubescence along the midrib. Inflorescence long and slender, fruit larger than in *P. serotina*. This occurs in the mountains of New Mexico, Arizona, Mexico, and Guatemala. It is said by Loudon to have been introduced in 1820; and in 1838 a vigorous tree, trained against a wall in the Horticultural Society's Garden, retained its leaves nearly all the winter. It is cultivated in France,¹ where, according to Lavallée, it was introduced in 1867, and endured the severe winter of 1879-1880; and in Algeria attains about 30 ft. in height.

6. *Prunus salicifolia*, Humboldt, Bonpland, and Kunth, *Nov. Gen. et Spec.* vi. 190, t. 563 (1825). An evergreen tree, occurring in Colombia, Ecuador, Peru, and Bolivia. It differs little in botanical characters from *P. Capuli*. Not introduced.

II. A number of varieties have appeared in cultivation in Europe:—

7. Var. *variegata*, Zabel, *Laubholz-Benennung*, 244 (1903). Leaves variegated with white.

8. Var. *pendula*, Dippel, *Laubholzkunde*, iii. 645 (1893). Branches pendulous.

9. Var. *salicifolia*,² Nicholson, *Kew Hand-List Trees*, i. 144 (1894).

Var. *phelloides*, Schwerin, in *Mitt. Deut. Dend. Ges.* 1906, p. 3.

Leaves lanceolate, long acuminate at the apex.

This variety, which has been confused with *P. Capuli*, is represented at Kew by a tree, about 30 ft. high, which flowers and fruits at the same season as the type, and is equally hardy. It may possibly have come from the United States, where narrow-leaved forms are said to occur.

10. Var. *aspleniifolia*, Kirchner, *Arb. Musc.* 260 (1864). Leaves irregularly dentate.

11. Var. *cartilaginea*, Kirchner, *Arb. Musc.* 260 (1864). Leaves very shining on both surfaces. (A. H.)

¹ Cf. Hamelin, in *Rev. Hort.* lvi. 111 (1884), and Carrière, in *Rev. Hort.* lxxiii. 62, 196, figs. 19, 20 (1891). Sargent states that plants of reputed *P. Capuli*, from France, proved hardy in the Arnold Arboretum; and he doubts their Mexican origin. I saw a tree about 40 ft. high under this name at Segrez in 1907, and raised seedlings from its fruit, which are alive at Colesborne, but do not grow as vigorously as the northern form.—H. J. E.

² This variety must not be confused with *Prunus salicifolia*, H.B.K., mentioned above.

DISTRIBUTION

The typical form of *P. serotina* is widely distributed in North America, occurring in Canada from Nova Scotia westwards to the northern shores of Lake Superior; and in the United States southwards to Florida, and westwards to Dakota, eastern Nebraska, Kansas, Indian Territory, and eastern Texas. Further west in southern Arizona and New Mexico, it is replaced by *P. Capuli*. Sargent states that it was once very abundant in the Alleghany Mountains, reaching its largest size from West Virginia to Georgia and Alabama. In the United States it usually grows in rich moist soil, but sometimes occurs on low sandy soil and on rocky cliffs by the sea-shore in New England. Pinchot¹ states that it grows fairly well in dry situations; but it is only in moist well-drained rich soils of mild climates that the maximum development is reached, as in the southern Alleghanies, where trees 90 ft. high and 4 ft. in diameter are not uncommon. In plantations in America it grows rapidly in youth; but is looked upon as a short-lived tree. Owing to the great value of its timber it has now become scarce in all accessible regions, and large trees are hardly to be found, the largest of which I have any record being a tree measured by Dr. Schneck in Wabash Co., Illinois, which was 135 ft. high by 10½ ft. in girth.²

I saw no such trees, however, in the Wabash valley; and in Canada in 1904, near Ottawa, where I found it scattered in the forest, it is a comparatively small tree. In southern Ontario, however, there are still, according to Macoun, many fine trees standing which are largely used for furniture making.

In Massachusetts, Emerson says³ that it rarely exceeds 40 to 50 ft. in height; but on the Ohio river, Michaux measured trees from 80 to 100 ft. high, with trunks 12 to 16 ft. in girth and clear of branches to 25 or 30 ft. He recommended its culture in the Rhine valley, which, he says, has most resemblance to its native regions.

CULTIVATION

It is difficult to say when this species was introduced, as it was formerly confused with *P. virginiana*, which Loudon says was introduced in 1724. It has never become a common tree, and was hardly known to nurserymen until recently, when it has been planted largely as a forest tree in some places in Europe.

The only place where I have seen this tree fairly at home in England is in Sherwood Forest, where several trees have been planted on Lord Manvers' property. The first of these I found quite unexpectedly myself, and recognised it by its shining foliage; the others were pointed out to me by Mr. Foljambe, who said he had known them as American cherries for many years, though I could obtain no information as to how or when they were introduced. One of these trees was about 50 ft. by 4½ ft., and bore a few ripe fruits in October 1905, from which I raised a plant the

² Ridgway, in *Proc. U.S. Nat. Mus.* xvii. 411 (1894).

³ *Trees and Shrubs of Massachusetts*, ii. 516 (1875).

following spring. Another not far from the Buck Gate was 46 ft. by 6½ ft., and had a large limb broken off, from which I got a small board which shows nice colour and well-marked medullary rays.

There was a large but decayed tree at Chiswick House near Kew, which in 1904 was about 50 ft. by 7 ft., probably the same as the tree mentioned by Loudon in 1838 as being 25 ft. high, eight years after planting.

At Arley Castle a tree, probably planted about 1820, was, in 1904, 53 ft. high and 7½ ft. in girth near the ground, below the point where it gives off a large limb.

Judging from these, and from what I know of its native habitat, this species might be tried with a fair chance of becoming a small timber tree, in rich sandy soil and sheltered woods in the warmest parts of England; but the tree has such a strong tendency to become bushy, that unless carefully pruned and closely crowded it will form a large shrub rather than a tree.

Seedlings raised at Colesborne from seed which I collected near Ottawa grow slowly and seem to want more heat than they get here, but my soil probably contains more lime than this tree likes.

It is rare in Scotland, but Renwick¹ measured in 1907 a tree at Auchendrane, Ayrshire, 42 ft. high with a short bole 5 ft. 8 in. in girth, and dividing into two stems at three feet from the ground. It was planted in 1818. Walker² mentions a tree at Hopetoun House, which was planted in 1747, and cut down in 1788, when it was 3 ft. 10 in. in girth. It yielded a plank, a foot broad, of red wood, which was finely veined and took a good polish, equalling mahogany in appearance.

In an article on this species by Graf von Schwerin³ a tree is mentioned as growing in the Palace garden at Rastede, Oldenburg, which at seventy-six years old is 15 metres high and 2.35 metres in girth at one metre from the ground. The photograph of this tree shows it to be a very well-shaped one with a fine head 12 metres in diameter; and a coloured plate of the leaves, flowers, and fruit is given. It is said to succeed best in dry sandy ground, and to be well worth cultivating as a forest tree on account of its beauty and the value of its wood.

This species has been tried as a forest tree in Germany. Schwappach lately reports⁴ that it thrives well on fresh loamy sand, attaining about 50 ft. in height and 10 in. in diameter at twenty years old. It grows remarkably fast in youth, and is very suitable for filling up gaps in broad-leaved woods or in pine plantations. It succeeds best when mixed singly with beech, as it then forms a clean stem. When planted in groups, it is apt to become very branching. It has been tried⁵ in Belgium for planting along roads, and has been successful between Curange and Zolder in Campine.

Mayr however considered that it will only be a success as a timber tree in those localities which have a warm summer, and rich light soil, for though it exists as far north as Canada, it only attains large size where the summers are longer and hotter than in any part of England, and where the soil is unusually fertile.

TIMBER, BARK

Next to black walnut, this was considered in the United States as the finest native hardwood in general use, but has now become so scarce, that it is hardly procurable for export and has been generally superseded as a furniture wood by imported mahogany. It is pale red, and when figured is extremely handsome, but such specimens are rare. A large board of it, which was given me from the State Exhibit of St. Louis at the Exhibition in 1904, was cut from a tree which grew in Cape Girardeau, County Missouri, and produced 2000 ft. of good lumber, of which more than a quarter was 2 ft. wide and over. From this a handsome table top has been made, the legs of which were cut from a tree of the same species grown at Arley Castle, of which a plank was kindly given me by Mr. R. Woodward.

Defebaugh¹ quotes the reminiscences of E. N. Mead of Buffalo, an early lumberman in M'Kean County, Pennsylvania, as to the abundance and size of the cherry which existed there sixty years or more ago, very little of which is now left, as follows:—"The operation with which I was connected, was a small one, only about 300 acres, but it was considered the best cherry grove in the county. We turned out a little over 3 million ft., or an average of 10,000 ft. per acre. We cut nothing under 12 in. at top, and not so small as 12 in. unless very smooth and straight. It would, I suppose, be impossible to find any stock to-day which would approach this in quality. It was pronounced the finest ever sent to the Albany market. We cut it all with a circular saw. With a modern bandsaw we could have produced lots of stock 36 inches wide. I will relate one circumstance that occurred. Two of my log-cutters sawed down most of their trees. In this case they cut entirely through the tree, driving wedges behind the saw, and the tree stood on the stump 24 hours, until a breeze toppled it over. It was over 3 ft. in diameter at the butt, made four 16 ft. logs, and stood straight as a gun barrel."

The bark² of *P. serotina* has long been used medicinally, and is recognised both by the United States and British Pharmacopœias.

The fruit is small and black, like that of the Portugal laurel, and was used in America to flavour brandy, the flavour being superior to that of the common cherry. (H. J. E.)

¹ *Lumber Industry of America*, ii. 618 (Chicago, 1907).

² Cf. Power and Moore, in *Trans. Chem. Soc.* xcv. 243-261 (1909), who have analysed the bark, which yields prussic acid and many other constituents. The same authorities, in *Trans. Chem. Soc.* xcvi. 1009 (1910), give an account of the chemical properties of the leaves. The barks of other species of *Prunus* are frequently used as adulterants. Cf. F. M. Holmes, in *Pharm. Journ.* 1909, p. 192.

PRUNUS LAUROCERASUS, COMMON LAUREL

Prunus Laurocerasus, Linnæus, *Sp. Pl.* 474 (1753); Bentley and Trimen, *Medicinal Plants*, ii. t. 98 (1880).

Padus Laurocerasus, Miller, *Gard. Dict.* ed. 8, No. 4 (1768).

Cerasus Laurocerasus, Loiseleur, *Nouv. Duhamel*, v. 6 (1812); Loudon, *Arb. et Frut. Brit.* ii. 716 (1838); Boissier, *Fl. Orient.* ii. 650 (1872).

Laurocerasus officinalis, Roemer, *Fam. Nat. Syn.* iii. 91 (1847); Schneider, *Laubholzkunde*, i. 646 (1906).

An evergreen large shrub, occasionally arborescent. Young branchlets glabrous. Leaves coriaceous, persistent two years, 5 to 6 in. long, 2 to 3 in. broad, obovate-oblong or narrowly elliptic, acuminate at the apex, tapering at the base, with a few remote minute serrations; glabrous; shining above; duller and lighter green beneath, and marked on each side of the midrib near the base with one or two circular glands; lateral nerves pinnate, about 8 to 10 pairs, dividing and looping before reaching the margin; petiole short, stout, without glands.

Flowers, in erect leafless racemes, about 4 in. long, arising in an axil of a leaf on the preceding year's shoot; axis and pedicels glabrous; calyx-tube wide at the mouth; sepals minute, triangular, often with peculiar teeth; petals small, wrinkled; ovary superior, glabrous, green, with a short glabrous style, and a capitate stigma. Fruit ellipsoid, $\frac{1}{2}$ in. long, plum-coloured when ripe, depressed at the base; flesh scanty; stone ovoid, pointed at the apex, smooth, with a prominent ridge on one side.

VARIETIES

I. The common laurel varies in the wild state, the typical large-leaved form being common at low altitudes in the Caucasus; while at high elevations, between 6000 and 7000 feet on limestone formation, there occurs a form with shorter racemes and smaller leaves, var. *brachystachius*, Albow, *Fl. Colchica*, 68 (1895). Another form with longer narrower leaves, var. *laurifolius*, Albow, is met with in the valleys of Guria. The following appears to be the European variety of the species:

1. Var. *shipkaensis*, Späth, ex Dippel, *Laubholzkunde*, iii. 649 (1893). Leaves, lanceolate or narrowly elliptic, about 3 in. long, and 1 in. broad, entire in margin; glands on the back inconspicuous or absent. Racemes, $1\frac{1}{2}$ in. long; calyx green; sepals broad, triangular, each with two minute reddish glands on the margin; petals white, orbicular, not wrinkled.

This is a small shrub, about 3 ft. high, which has been found wild on the Balkan range, near the Shipka Pass, and in other localities. It was introduced into cultivation by Späth, and has proved much hardier¹ than the type in Switzerland and Germany, and thrives in the United States as far north as central New York.² It is in cultivation at Kew and Cambridge.

¹ *Mitt. Deut. Dend. Ges.* 1898, p. 96.

² Rehder, in Bailey, *Cyc. Amer. Hort.* 1455 (1901).

Var. *serbica*, Pančić, from Servia, is similar, but not exactly identical, having a more upright growth, with obovate wrinkled leaves. It is not in cultivation in England; but has proved very hardy¹ in Germany, where it bore -20° Cent. at Bergsdorf.

II. A large number of varieties² have appeared in cultivation, of which the more important are:—

2. Var. *angustifolia*, Nicholson, *Kew Hand-List Trees*, i. 145 (1894). Leaves long and narrow, scarcely an inch in breadth.

3. Var. *rotundifolia*, Nicholson, *loc. cit.* Leaves rounded at the apex. This is said³ to be more suitable for making hedges than the type, and succeeds better than it in towns.

4. Var. *parvifolia*, Nicholson, *loc. cit.* Leaves, $1\frac{1}{2}$ in. long, $\frac{1}{2}$ in. broad, with a few coarse serrations. A low shrub, in cultivation at Kew.

5. Var. *camelliæfolia*, Nicholson, *loc. cit.* Leaves bent back, and twisted on their base. A curious form, not common in cultivation. The best specimen that we have seen is at Poles Park, Herts.

6. Var. *variegata*, Nicholson, *loc. cit.* Leaves blotched with white.

DISTRIBUTION AND CULTIVATION

The common laurel is a native of the Balkan Peninsula, Asia Minor, the Caucasus, and North Persia. It is most common in the Caucasus, where, however, it is not known in Georgia or Talysch, being confined to the west, in Abchasia, Mingrelia, and Imeritia, where the typical broad-leaved form occurs at all elevations between sea-level and 4000 ft., being replaced higher up by peculiar shrubby forms.⁴ Boissier records it in Asia Minor from near Trebizond, and at the base of Mount Olympus in Bithynia. In Europe, it is recorded by Adamovic⁵ for south-eastern Servia, the Balkan range between Rumelia and Bulgaria, Thrace, and Laconia in Greece.⁶

(A. H.)

The laurel was introduced to Vienna in 1576 by Ugnad from Constantinople, at the same time as the horse chestnut; and soon spread over Europe. According to Evelyn, it was first brought into England, in 1614, by the Countess of Arundel, at Wardour Castle, where, Loudon says, there were in his time a great number of very old laurels. Parkinson in 1629 says that he had seen it in fruit at Highgate; and it became very common at an early period in English gardens, and in many parts of Ireland, where old houses are often surrounded by a dense thicket of laurels, which grow in that country, as in all the moister parts of England, with great luxuriance. It is now by no means so popular as formerly, but on account of the facility with which it can be reproduced from cuttings and layers, and its persistence in coming up from the stool when cut to the ground, it is likely to remain one of our commonest garden shrubs.

¹ *Mitt. Dent. Dend. Ges.* 1897, p. 68.

³ *Cf. Gard. Chron.* viii. 572 (1890).

⁶ *Veg.-verhalt. Balkanländer*, 132, 464, 489 (1909).

² *Cf. Gard. Chron.* v. 620, figs. 105, 106 (1889).

⁴ Radde, *Pflanzenverbr. Kaukasus*, 178, 347 (1899).

⁵ *Cf. Halacsy, Consp. Fl. Græcæ*, i. 498 (1901).

By far the largest on record in England, is mentioned by Mr. E. C. Batten,¹ who quotes Dr. Prior for the fact that a common laurel at Fyne Court, Somersetshire, grew to the height of 72 ft. before it was cut. At Powis Castle I have seen a bush over 40 ft. high with five stems over 4 ft. in girth. It was cultivated at Mill Hill by Collinson about 1750, and I have seen at that place what is supposed to be part of the original plant.

At Shelton Abbey, Wicklow, there was a magnificent specimen in Loudon's time, which was 45 ft. in height and 6 ft. in girth, at 90 years old.

The laurel is not hardy in most parts of Germany, and at Karlsruhe suffers much in severe winters; but at Baden-Baden and Mainau, where the humidity of the air is greater, it succeeds fairly well.² In the United States, it is hardy as far north as Washington, D.C.³

The leaves are used in medicine; and when distilled with water, yield bitter almond oil and prussic acid.⁴ The fresh leaves are sometimes used for flavouring sweetmeats, custards, creams, etc.; but should be used with caution, as, on account of their poisonous qualities, they may produce injurious or even fatal effects.

The wood is, so far as I know, of no value except for firewood.

(H. J. E.)

PRUNUS LUSITANICA, PORTUGAL LAUREL

Prunus lusitanica, Linnaeus, *Sp. Pl.* 473 (1753).

Padus lusitanica, Miller, *Gard. Dict.* ed. 8, No. 5 (1768).

Padus eglandulosa, Moench, *Meth.* 672 (1794).

Cerasus lusitanica, Loiseleur, *Novv. Duham.* v. 5 (1812); Loudon, *Arb. et Frut. Brit.* ii. 714 (1838).

Laurocerasus lusitanica, Roemer, *Fam. Nat. Syn.* iii. 92 (1847).

An evergreen tree, attaining occasionally 50 or 60 feet in height, and 6 feet in girth; often shrubby. Young branchlets glabrous. Leaves persistent two years, coriaceous, but thinner in texture than those of *P. Laurocerasus*, ovate-oblong, 3 to 4 in. long, $1\frac{1}{2}$ to 2 in. broad, acuminate at the apex, rounded at the base; glabrous; above shining, beneath lighter green and without glands; lateral nerves 8 to 10 pairs, dividing and looping before reaching the margin; regularly serrate, the serrations ending in glandular points; petiole about $\frac{3}{4}$ in. long, usually without glands.

Flowers in racemes, about 4 in. long, arising in the axils of the leaves on the preceding year's shoot; axis and pedicels glabrous; calyx wide at the mouth; sepals irregular, dentate; petals white. Fruit ovoid, with scanty flesh, about $\frac{3}{8}$ in. long.

¹ *Trans. Eng. Arb. Soc.* ii. 221 (1895).

² *Mitt. Dent. Dend. Ges.* 1908, p. 150.

³ Rehder, in Bailey, *Cycl. Amer. Hort.* 1455 (1901).

⁴ *Cf. Flückiger and Hanbury, Pharmacographia*, 255 (1879).

VARIETIES

I. In addition to the typical form, which occurs in Spain and Portugal, the following geographical varieties are known:—

1. Var. *Hixa*, De Candolle, *Prod.* ii. 540 (1825); Lowe, *Flora Madeira*, i. 236 (1836). Leaves narrower, more oblong, about 5 in. long and $1\frac{1}{2}$ in. broad. Racemes, 6 to 8 in. long, with flowers less crowded than in the type.

Indigenous in the Madeira and Canary Islands. Lowe states that in 1836, it was nearly extinct in Madeira; but a few trees remained, 40 to 60 ft. in height, and occasionally 6 ft. in girth. According to Webb and Berthelot,¹ it grows on the north-east of Teneriffe in woods, at about 2000 feet, attaining in the wood of Las Mercedes 30 ft. in height. Webb, however, informed Loudon that on Teneriffe, Grand Canary, and Palma, it occasionally reached a height of 60 or 70 ft.

2. Var. *azorica*, Nicholson, in *Kew Hand-List Trees*, i. 147 (1894). Leaves more coriaceous, and more coarsely serrate than in the type. Racemes short, densely flowered. Indigenous in St. Miguel in the Azores, where it was collected by Hunt in 1845, and later by Godman.² This variety, which is in cultivation at Kew, is shrubby.

II. Several varieties have arisen in cultivation as seedlings:—

3. Var. *myrtifolia*, Nicholson, *loc. cit.* A shrub of compact habit, with small leaves, $1\frac{1}{2}$ to 2 in. long.

4. Var. *variegata*, Nicholson, *loc. cit.* Leaves variegated with white. This is said by Koch, *Dendrologie*, i. 125 (1869), to be cultivated in France.

DISTRIBUTION AND CULTIVATION

P. lusitanica is a native of Spain and Portugal, and of the Azores, Canary, and Madeira Islands. In Portugal, where it is called *azareiro*,³ it is apparently not a common tree, as the only localities mentioned by Willkomm,⁴ where it is indigenous, are the Serras of Bussaco, Estrella, and Gerez.⁵ It is abundant in the woods of Bussaco, where Elwes⁶ saw it in 1909 attaining a height of 50 to 60 feet and 5 to 6 ft. in girth.⁷ On the Serra de Gerez, it grows up to 3000 ft. elevation as a scattered tree in woods composed mainly of *Quercus pedunculata*, *Arbutus*, holly, and sycamore. Webb informed Loudon that it formed here a small tree 20 ft. high; but growing with it was a taller tree, 60 to 70 ft. high, which he supposed to be var. *Hixa*, but which was undoubtedly the same.⁸ In Spain this species is rare and

¹ *Hist. Nat. Isles Canar.* iii., *Phyt.* ii. 19, t. 38 (1836). The leaves figured scarcely differ from those of the Portuguese tree; but the flowers are in longer racemes.

² Watson, in Godman, *Nat. Hist. Azores*, 158 (1870).

³ Broteiro, *Fl. Lusit.* ii. 252 (1804).

⁴ *Pflanzenverb. Iber. Halbinsel*, 112, 312, 318, 321 (1896).

⁵ It was collected also at Cintra by Welwitsch.

⁶ In the forest of Bussaco the Portugal laurel attained a height of 50 to 60 ft., with trunks 5 to 6 ft. in girth, but it did not form an important element in the forest, either here or in the Serra de Gerez, where it was smaller. I did not see in the Serra de Gerez any tree so large as the ones mentioned by Webb.—H. J. E.

⁷ Cf. J. de Vilmorin, in *Bull. Soc. Dend. France*, 1907, p. 49.

⁸ Webb, *Iter. Hisp.* 48 (1838), mentions only one form of *P. lusitanica*, as occurring in the Serra de Gerez.

local, occurring according to Willkomm on the north slope of Montseny, near Barcelona, and in a few woods in Navarre. (A. H.)

The Portugal laurel is stated by Aiton to have been introduced into the Oxford Botanic Garden in 1648; and Loudon says that this tree survived until 1828, when it was cut down, the trunk being nearly 2 ft. in diameter; but Collinson¹ states that it was first brought to England in 1719 by Fairchild, the famous nurseryman at Hoxton.

Though the Portugal laurel is hardy in the greater part of England, it is liable to be severely injured, and sometimes killed to the ground in very severe winters, and grows best in the south and west of England, especially near the sea. It ripens fruit in most seasons, and is easy to raise from seed; and though an ornamental tree of some merit, is not so popular now as it formerly was.

The oldest living tree that I know of is one at Mill Hill, where it was probably planted by Peter Collinson about 160 years ago, and is now decaying. It had five stems over 4 ft. in girth. At Fyne Court, Somersetshire, Mr. Batten,² quoting Dr. Prior, says that Portugal laurels of enormous size were formerly seen with their boughs bending to the ground and rooting, and an upright trunk grew from the arch thus formed. Henry saw at Belvoir Castle, in 1907, a well-shaped tree, 40 ft. in height, and 6 ft. in girth; and another at Leonardslee in 1910, 45 ft. by 4 ft. 3 in.

In Scotland it is hardy as far north as Banffshire, and grows to a very large size at Gordon Castle. At Moncrieffe, Hunter³ mentions a specimen which in 1883 covered an area 186 ft. round, though cut back on one side, but I did not see this when I visited the place in 1907. At Biel, the seat of Mrs. Hamilton Ogilvy in East Lothian, I saw a very fine tree in 1911, with a clean trunk, 4 ft. 8 in. in girth. Bean⁴ saw a specimen at Ochertyre in 1907, which was 30 ft. high, with a spread of foliage 50 ft. in diameter; and there are two trees at Raith, with short stems, nearly 2 ft. in diameter.

In Ireland we have not noted any remarkable for their size, but, as a rule, it grows luxuriantly.

The Portugal laurel, though rarely planted in Germany, where it is supposed not to be hardy, has borne at Karlsruhe — 16° C. of frost in winter; and produces flowers and fruit every year at Mainau.⁵

The wood, as shown by a fine specimen in the Earl of Yarborough's exhibit at Lincoln in 1907, resembles that of the cherry in colour, and shows well-marked medullary rays which make it very ornamental. It seems well fitted for small cabinet work. (H. J. E.)

PYRUS (*continued*)

IN our Article in Vol. I. pp. 141-170, the genus *Pyrus* has been defined, and some of the sections have been fully described. In this concluding part, an account will be given of the apples, pears, and mountain ashes, which constitute three sections of the genus.

SECTION PYROPHORUM

This section of the genus *Pyrus* comprises the true pears, which are deciduous trees or shrubs, with branchlets of two kinds, long shoots and short shoots, the latter spur-like and often ending in thorny points. Leaves simple, stalked, scattered on the long shoots, clustered on the spurs; in the bud rolled inwards towards the midrib. Flowers perfect, in corymbs on the short shoots; sepals five, usually persistent on the apex of the fruit, occasionally deciduous; ovary usually five-celled, rarely two- or three-celled; styles five, rarely two or three; fruit turbinate or sub-globose, with granular flesh.

The true pears comprise about sixteen species, natives of Europe, northern Africa, and extra-tropical Asia. The following synopsis gives a brief account of the wild species which are in cultivation:—

I. *Leaves deeply cut into small segments.*

1. *Pyrus heterophylla*, Regel and Schmalhausen, in *Act. Hort. Petropol.* v. pt. ii. 581 (1878).

A small thorny tree, with glabrous branchlets. Leaves very remarkable, about 2 in. long, glabrous, deeply and pinnately cut to near the midrib into about five variously lobed and serrate narrow segments. Fruit depressed-globose, about 1 in. in diameter.

This occurs in mountain valleys at high elevations in Turkestan. It is represented at Kew by a straggling bush about 3 ft. high.

II. *Leaves sharply serrate, the serrations ending in long slender points.*

2. *Pyrus sinensis*, Lindley, in *Trans. Hort. Soc.* vi. 397 (1826), and *Bot. Reg. Bot.* 1248 (1829).

Pyrus ussuriensis,¹ Maximowicz, *Prim. Fl. Amur.* 102 (1859).

Pyrus Simonii,² Carrière, in *Rev. Hort.* 1872, p. 28.

¹ This is the Manchurian pear, which is said by Ascherson and Graebner, *op. cit.* 60, to be the earliest of all pears to flower in the Berlin Botanic Garden, where it was raised from seed sent by Maximowicz.

² Sent to the Jardin des Plantes at Paris by Simon in 1861. This is considered by Bretschneider, *Hist. Europ. Bot. Disc. China*, 830 (1898), to be a cultivated variety, the *Pai-li* of north China, which bears delicious apple-shaped fruit of a pale yellow colour.

A tree without thorns, attaining 60 ft. in height. Branchlets and buds glabrous. Leaves, 3 to 4 in. long, ovate, acuminate, glabrous, glandular on the midrib above, distinct from all the other species in the fine serrations with long slender points. Fruit globose, about 1 in. in diameter.

A native of China, Manchuria, Korea, and Japan. Introduced in 1820. It is the *Sha-li* or "sand pear" of the Chinese. Many cultivated varieties are known, some of which have proved useful in the United States, where this species is an excellent ornamental tree, very vigorous in growth.¹ Trees at Kew about 25 ft. high are very thriving.²

III. *Leaves sharply serrate, the serrations without long points.*

3. *Pyrus betulifolia*, Bunge, *Enum. Pl. Chin. Bor.* 27 (1834).

A small tree without thorns. Branchlets and buds grey tomentose. Leaves, 1½ to 2½ in. long, ovate to ovate-rhombic, acuminate; dark green and shining above with glands on the midrib, lighter green beneath, both surfaces retaining in summer traces of the tomentum with which they were covered in spring; petiole long, tomentose. Flowers with a two-celled ovary and two styles. Fruit depressed-globose, about ¾ in. in diameter.

A native of north China, where it is called *tu-li*. Introduced first in 1863 by Simon³ into the Jardin des Plantes at Paris; and subsequently by Bretschneider,⁴ who sent seeds to Kew and the Arnold Arboretum⁵ in 1882. A tree at Kew of this origin, about 30 ft. high with pendent branches, is very thriving.

4. *Pyrus syriaca*, Boissier, *Diag. Nov. Pl. Orient.* x. 1 (1849).

A shrub or small tree, usually thorny. Branchlets and buds glabrous. Leaves, 1½ to 2 in. long, lanceolate or obovate; acute, rounded, or mucronate at the apex; variable at the base, often very tapering, and decurrent on the petiole; glabrous; sharply and finely serrate. Fruit turbinate, 1½ in. in diameter, with a thickened stalk.

A native of Cyprus, Syria, Asia Minor, and Kurdistan. A small tree at Kew,⁶ about 15 ft. high, was obtained from Decaisne in 1874.

IV. *Leaves crenate in margin.*

* *Leaves coriaceous in texture.*

5. *Pyrus Korshinskyi*, Litwinow, in *Trav. Mus. Bot. Acad. Imp. Sc. St. Petersb.* i. 17 (1902).

A tree, height not stated. Branchlets and buds grey tomentose. Leaves coriaceous, about 3 in. long and ½ to 1½ in. broad, lanceolate or ovate-oblong, more or less grey tomentose on both surfaces; with coarse crenate or bi-crenate

¹ Cf. Bailey, *Cyc. Am. Hort.* 1470, 1471 (1901).

² A tree at Kew labelled *P. sinensis*, with coarse sharp-pointed serrations to the leaves, is perhaps *P. Balansa*, Decaisne, *op. cit.* t. 6 (1871), raised from seed brought from Laristan in Persia. It is intermediate in foliage between *P. sinensis* and *P. communis*.

³ Cf. Carrière, *Rev. Hort.* 1879, pp. 318, 319, where the plant is figured from specimens cultivated at Paris.

⁴ *Hist. Europ. Bot. Disc. China*, 1053 (1898).

⁵ Cf. *Garden and Forest*, vii. 224 (1894), where a figure is given.

⁶ This species has been confused with *P. glabra*, Boissier, *Diag. Nov. Pl. Orient.* vi. 53 (1845), which is not in cultivation. The latter, a native of Persia, differs from all the species, in having glabrous entire lanceolate leaves.

serrations, tipped with peculiar minute sharp incurved glands; petiole long, grey tomentose. Fruit sub-globose, $\frac{7}{8}$ in. in diameter, on stout peduncles, crowned by the persistent calyx.

This very distinct species¹ occurs in the mountains of Bokhara, Fergana, and Turkestan, at 4000 to 7000 ft. elevation. It is represented at Kew by a tree² about 20 ft. high, obtained from Dieck in 1891, and by a shrub obtained from Späth in 1900.

** *Leaves not coriaceous.*

(a) *Midrib glandular above (in some of the leaves at least).*

6. *Pyrus Pashia*, Buchanan-Hamilton, *ex Don, Prod. Fl. Nepal.* 236 (1825).

A variable species in the Himalayas, of which the following form is in cultivation:—

Var. *Kumaoni*, Stapf, in *Bot. Mag.* t. 8256 (1906).

A tree without thorns, attaining about 50 ft. in height. Branchlets and buds glabrous. Leaves narrowly ovate, 2 to $3\frac{1}{2}$ in. long, $1\frac{1}{4}$ to 2 in. broad, glabrous, subcordate at the broad rounded base, contracted into a long acuminate apex, frequently glandular on the midrib above; petiole long, glabrous. Fruit globose, 1 in. in diameter, from the apex of which the sepals fall off early.

This is represented at Kew by a grafted tree, about 25 ft. high, which has been growing in the collection of Rosaceæ for many years.³ The flowers are handsome, at first suffused with pink, ultimately becoming white.

(b) *Midrib without glands.*

7. *Pyrus communis*, Linnæus. See p. 1560.

V. *Leaves entire in margin, or partly indistinctly crenulate.*

* *Midrib glandular above.*

8. *Pyrus eleagrifolia*, Pallas, in *Nov. Act. Petrop.* vii. 355, t. 10 (1793).

A spiny tree or shrub. Branchlets and buds grey tomentose. Leaves about 2 in. long and $\frac{3}{4}$ in. broad, obovate or obovate-lanceolate, usually tapering in the basal half, acute or rounded and mucronate at the apex, entire in margin; upper surface with scattered tomentum throughout, and peculiar dark glands on the midrib; lower surface densely covered with grey tomentum, obscuring the venation; stalks short, tomentose. Fruit pyriform, 1 in. long, with the upper part of the peduncle much thickened.

A native of the Crimea, Caucasus, and Asia Minor. Introduced in 1800.

There is a good specimen at Arley Castle, which Elwes found to be 44 ft. by 4 ft. in 1911. It is forked at two feet from the ground, and bears fruit regularly in some quantity. There is a tree of this species at Glasnevin, which has long been labelled *P. sinaica*.⁴ Elwes measured it, in 1908, as 40 ft. by 5 ft. 7 in.,

¹ *P. bucharica*, Litwinow, *op. cit.* i. 18 (1902), described from a sterile branch and said occasionally to have lobed and pinnatifid leaves, appears to be the same species.

² Both the specimens at Kew were obtained under the name *P. heterophylla*, which is a totally distinct species. Cf. p. 1556.

³ The history of this tree is unknown. *P. Pashia* is said by Loudon, *Arb. et Frut. Brit.* ii. 891 (1838), to have been introduced in 1825; but we have seen no specimens except the tree at Kew.

⁴ Cf. p. 1559, note 1.

with a bole 10 ft. long; and it appears to be one of the earliest trees planted in this garden, which was founded in 1798. A tree at Beauport, Sussex, 32 ft. by 5 ft., was bearing fruit in November 1911.

** *Midrib without glands.*

(a) *Under surface of the leaves with only traces of tomentum in summer.*

9. *Pyrus amygdaliformis*, Villar, *Cat. Meth. Jardin Strasbourg*, 323 (1807).

A spiny shrub or small tree. Branchlets and buds slightly tomentose. Leaves, 1 to 2 in. long, coriaceous; variable in shape, lanceolate to narrowly elliptical, acuminate or rounded with a mucro at the apex; covered in spring on both surfaces with grey tomentum, which disappears in greater part during summer, usually entire in margin; petiole short, slightly tomentose. Fruit sub-globose, $\frac{3}{4}$ in. in diameter, with the stalk scarcely thickened.

A native¹ of southern Europe, occurring in France on dry arid soil in the region of the olive, and spread through Spain, Italy, Istria, Dalmatia, Balkan States, Greece, and Asia Minor. In March 1910 Elwes saw a fine tree in flower on the Plan d'Aups near St. Baume, in the department of Var, at about 3000 ft. altitude. It was about 25 ft. by 6 ft.

Introduced in 1810, and occasionally seen in botanic gardens; it attains at Cambridge 30 ft. in height.

(b) *Leaves densely tomentose beneath in summer.*

10. *Pyrus nivalis*, Jacquin, *Fl. Austr.* ii. 4, t. 107 (1774).

A tree without thorns. Young branchlets and buds more or less tomentose. Leaves $2\frac{1}{2}$ to 3 in. long, $1\frac{1}{4}$ to $1\frac{1}{2}$ in. broad, elliptic to obovate-oblong, usually cuneate at the base, abruptly contracted into an acuminate apex; covered at first with a grey tomentum, persisting in summer on the under surface, and to a less extent on the shining green upper surface; margin entire or irregularly and minutely crenulate towards the apex; petiole tomentose, about 1 in. long. Fruit pyriform, about $1\frac{1}{2}$ in. in diameter.

This tree, which is known in Austria as the *schnee birn* or "snow pear," is doubtfully wild in Croatia, Hungary, and Transylvania. Schneider regards it as a cultivated form of *P. eleagrifolia*; but Focke² with more probability considers it to be a cross between *P. amygdaliformis* and *P. communis* which has escaped from cultivation. It appears to be closely allied to, if not identical with *P. salvifolia*,³ De Candolle, *Prod.* ii. 634 (1825), which is naturalised in woods and hedges in central France, and often cultivated for making perry.

P. nivalis was introduced in 1826, and is represented at Kew by a tree about 25 ft. high.

¹ *P. persica*, Persoon, *Syn. Pl.* ii. 40 (1807) is probably a hybrid, arising from *P. amygdaliformis*, as there are no grounds for supposing it to be a native of Persia or Mount Sinai, as was formerly supposed. It has obovate-oblong or elliptic leaves, 2 to $2\frac{1}{2}$ in. long, 1 in. broad, entire in margin, mucronate at the rounded apex, dark shining green and slightly tomentose above, pale and with scattered tomentum beneath; buds glabrous. This is represented at Kew by a tree 20 ft. high obtained in 1875 from Decaisne, as *P. sinaica*, Thouin, in *Mém. Mus. Hist. Nat.* i. 170 (1815); and by an older tree, 30 ft. high, similarly labelled, at Cambridge. Decaisne, *Jardin Fruitier*, t. 15 (1871), however, gives a figure of *P. sinaica*, which does not agree in foliage with the tree which he sent to Kew.

² *Ex Ascherson and Graebner, op. cit.* 65 (1906).

³ Cf. Mathieu, *Fl. Forest.* 170 (1897).

11. *Pyrus salicifolia*, Pallas, *Itin.* iii. 734 (1736).

A tree, often spiny, about 30 ft. high. Branchlets grey tomentose. Buds with brown ciliate scales, usually glabrous on the surface. Leaves, 2 to 3 in. long, averaging $\frac{1}{2}$ in. broad, linear-lanceolate, very tapering at both ends, and often prolonged at the apex into a sharp point; entire in margin; covered slightly on the upper surface and densely on the lower surface with a white silky appressed tomentum; petioles short, tomentose. Fruit turbinate, about $\frac{3}{4}$ inch in diameter, with a persistent calyx.

A native of the Crimea, Caucasus, and Armenia. Introduced in 1780, and often planted as an ornamental tree, on account of its whitish foliage, which at a distance resembles that of *Salix alba*.

P. canescens,¹ Spach, *Hist. Veg.* ii. 129 (1834), judging from a tree at Kew, about 30 ft. high, obtained from Decaisne in 1875, is possibly a hybrid of *P. salicifolia*. It has lanceolate or narrowly elliptic leaves, about $2\frac{1}{2}$ in. long, acute or mucronate at the apex, minutely crenulate, often twisted, and resembling in tomentum those of *P. salicifolia*. The buds are also like those of the latter species. (A. H.)

PYRUS COMMUNIS, COMMON PEAR

Pyrus communis, Linnæus, *Sp. Pl.* 459 (1753); Loudon, *Arb. et Frut. Brit.* ii. 880 (1838); Willkomm, *Forstliche Flora*, 843 (1887); Mathieu, *Flore Forestière*, 167 (1897); Schneider, *Laubholzkunde*, i. 661 (1906); Ascherson and Graebner, *Syn. Mitteleurop. Flora*, vi. pt. 2, p. 60 (1906).

A tree or shrub, with numerous short shoots or spurs, which often end in thorny points. Bark smooth at first, ultimately broken on the surface into small scales. Young branchlets glabrous. Leaves, scattered on the long shoots, clustered on the short shoots, variable in size and shape, usually ovate or oval, rounded or subcordate at the base, acute or shortly acuminate at the apex; minutely crenate in margin except occasionally near the base; slightly tomentose when young, nearly quite glabrous in summer, dark green and shining above, paler beneath; petiole slender, nearly as long as or even exceeding the blade in length. In winter the buds are ovoid, pointed, shining brown, with a few glabrous ciliate scales; lateral buds, nearly as large as the terminal bud, either appressed or slightly diverging from the twig; leaf-scars crescentic, three-dotted.

Flowers, six to twelve in a leafy corymb, the axis of which, together with the pedicels, and external surface of the calyx-tube and sepals, is more or less covered with greyish tomentum; inner surface of the sepals with a dense rusty tomentum; petals white, with a short claw; styles five, free, almost as long as the fifteen to twenty stamens. Fruit turbinate, narrowing gradually towards the thickened stalk, crowned by the persistent calyx.

¹ *P. canescens*, Decaisne, *Jardin Fruitier*, t. 19 (1871) does not appear to agree with Spach's description.

VARIETIES AND HYBRID

1. Var. *Pyraster*, Linnæus, *Sp. Pl.* 479 (1753), is similar to the type in foliage and thorns; but has globose fruit. It is of uncertain origin, and is seldom found in woods, being probably in most cases an escape from an adjoining orchard.

2. Var. *sativa*, De Candolle, *Prod.* ii. 634 (1825). This name is applied to the cultivated varieties¹ of the pear, which are usually large trees without thorns. They also differ from the wild type, in having larger foliage, and larger and more edible fruit. Many forms of cultivated pears are probably, however, of hybrid origin; and can scarcely be assigned to var. *sativa*.

The following, which have been described as three distinct species, are probably geographical races of *P. communis*.

3. Var. *cordata*, J. D. Hooker, *Student's Flora*, 131 (1878).

Var. *azarolifera*, Durieu de Massoneuve, in *Bull. Soc. Bot. France*, v. 726 (1858).

Var. *Briggsii*, Boswell-Syme, in *Journ. Bot.* ix. 182 (1871).

Pyrus cordata, Desvieux, *Obs. Pl. Anjou*, 152 (1818); Decaisne, *Jardin Fruitier*, i. 330 (1871); Masters, in *Journ. Bot.* xiv. 225, t. 180 (1876); Hy, in *Bull. Herb. Boissier*, 1895, App. 1, p. 9.

Fliche, in *Bull. Soc. Bot. France*, xlvii. 108 (1900).

A spiny shrub, said by Fliche to propagate itself freely by root-suckers. Leaves smaller than in the type, sub-orbicular to ovate, about 1 in. in width, subcordate at the base. Flowers smaller than in the type. Fruit, globose on the French shrub, slightly turbinate on the English plant, very small, not exceeding $\frac{1}{2}$ in. in diameter; calyx persistent.

This remarkable pear is wild in the west of France, in Brittany, Anjou, and the Landes. The English form, which differs only in the shape of the fruit, was first found in a hedge between Thornbury and Wood Common in Devon, and later in two hedgerows in Cornwall²; but is now known to be undoubtedly wild³ in the valley of the Wye, at Symonds Yat, on Dorward, and in Dixton parish. There is a specimen at Kew about 12 ft. high, which was obtained from Veitch in 1898.

A similar plant, *P. Boissieriana*, Buhse, *Aufzähl. Pfl.* 87 (1860), found on Mt. Elburz, in Persia, was identified by Boissier⁴ with *P. cordata*; and, as no similar pear has been found in the vast region intervening between western France and northern Persia, this disjointed distribution has given rise to much speculation.⁵

4. Var. *longipes*, Henry (var. *nova*).

Pyrus longipes, Cosson and Durieu, in *Bull. Soc. Bot. France*, ii. 310 (1855).

A small tree, with a few spines. Leaves, about 2 in. long and 1 in. broad, ovate, acuminate, sub-cordate, glabrous, finely and crenately serrate, on long slender petioles. This, which differs little in foliage from *P. cordata*, has also

¹ These are described by Decaisne, *Jardin Fruitier du Muséum* (1871-1872).

² Davey, *Flora of Cornwall*, 183 (1909).

³ Riddelsdell, in *Journ. Bot.* xlix. 170 (1911). A small tree about 10 ft. high, which produces flowers very sparingly, on the cliff at Pen Moel, Chepstow, is probably wild.

⁴ *Fl. Orient.* ii. 653 (1872).

⁵ Dr. Phené associates *P. cordata* with the island of Avalon (which means "apples"), now Glastonbury, where King Arthur is said to have been buried. Cf. *Gard. Chron.* iv. 684 (1875).

small globose fruit, about $\frac{1}{2}$ in. in diameter, from the summit of which the calyx ultimately falls off completely. It is a native of the borders of mountain streams in Algeria. A tree at Kew, about 25 ft. high, was obtained from Decaisne in 1875.

5. Var. *Mariana*, Willkomm, in *Linnaea*, xxv. 25 (1852).

Pyrus Bourgeana, Decaisne, *Jardin Fruitier*, i. t. 2 (1871).

A small tree. Leaves ovate, about an inch in length, rounded at the base, on very long slender petioles. Fruit globose, about $\frac{1}{2}$ in. in diameter, with a persistent calyx. This is a little-known variety, which occurs in the Sierra Morena in Spain.

6. *Pyrus auricularis*, Knoop, *Pomol.* ii. 38 (1763).

Pyrus irregularis, Muenchhausen, *Hausvater*, v. 246 (1770).

Pyrus Polloeria, Linnæus, *Mant.* ii. 244 (1771).

Pyrus Bollwyleriana, De Candolle, *Fl. France, Suppl.* v. 530 (1815); Loudon, *Arb. et Frut. Brit.* ii. 890 (1838).

A tree, attaining about 50 ft. in height. Branchlets and buds tomentose. Leaves, 3 to 4 in. long, 1 to 2 in. broad, elliptic, rounded, and unequal at the base, shortly acuminate at the apex; margin irregularly, coarsely, and sharply serrate or biserrate; upper surface shining green, glabrescent, with glands on the midrib; lower surface more or less covered with greyish tomentum; petiole $\frac{3}{4}$ to $1\frac{1}{2}$ in. long, grey tomentose. Flowers five to twenty, in tomentose corymbs: sepals tomentose on both surfaces; styles two to five, united and tomentose at the base. Fruit pyriform, 1 in. in diameter, reddish yellow, sweet to the taste.

This tree, which is a hybrid between *P. communis* and *P. Aria*, was first noticed at Bollweiler in Alsace, about 1650, when it was described by Bauhin.¹ It apparently does not come true from seed; and one of the seedlings, which is nearer to *P. communis*, has been named var. *bulbiformis*, Tartar.² *P. auricularis* was introduced in 1786, and is occasionally seen in botanic gardens. A large tree of it was cut down in Kew Gardens some years ago, of which a board a foot wide is now in the Cambridge Forestry Museum. There is a fine specimen at Arley Castle, which measured 59 ft. by 4 ft. 5 in. in 1904. Elwes saw an old tree, 43 ft. high, with a short bole, near the house at Beauport, Sussex, in 1911. It bears fruit very sparingly, scarcely any being produced in some seasons.

DISTRIBUTION

There is no agreement amongst botanists as to the distribution of the common pear, which has long been in cultivation in Europe. In many places, where it is now apparently wild, it is probably only an escape from orchards. It occurs either wild or naturalised throughout the greater part of Europe, northern Africa, Asia Minor, the Caucasus, and north Persia. According to Willkomm, it is not met with in the greater part of Scandinavia, in Finland, northern Russia, Esthonia, Livland, and the provinces east of the Volga; but it is wild in the ash forests of the Ukraine, and in the mountains of the Crimea. In Germany, it is rare and only naturalised

¹ *Hist. Plant.* i. 59 (1650).

² *Wien. Obst. u. Gartens.*, 1878, p. 26, fig. 8.

in the north-western plain; and elsewhere is seen in hedges, copses, and the edges of the broad-leaved forests. In the Swiss Alps and the Jura,¹ it ascends to 2700 ft. and in the Tyrol to 4800 ft. In France, it is found as a scattered tree in most of the broad-leaved forests of the plains and low hills; but is absent in the region of the olive. In England, it occurs as a rare tree in woods, thickets, and hedgerows from Yorkshire southwards, but it is a doubtful native, except in the form var. *cordata*. *P. communis* has been found² in the fossil state in neolithic peat at Crossness, Essex, determined from wood examined by the late Professor Marshall Ward.

(A. H.)

REMARKABLE TREES

It is not our intention to deal here with the cultivated varieties of pear, which are very numerous; and with regard to those used for making perry, we refer our readers to the *Herefordshire Pomona* as the most comprehensive recent work on the subject.

The largest pear tree which I have ever seen or heard of stands alone on the north side of a hill on Church Farm in the parish of Lassington, about two miles from Gloucester, in a grass field of rather strong land on the Old Red Sandstone. Whether it is, as I believe a wild pear, or not, it is on its own roots, and bears small fruit which ripen earlier than any of the perry pears of the district. It is described in Witchell's *Fauna and Flora of Gloucestershire*, 264 (1892), as being 18 feet in girth, but I measured it, in January 1909, as $16\frac{1}{2}$ ft. in girth and about 50 ft. high. The trunk is about 15 ft. high, and, though hollow at the base, with a large limb broken off, seems healthy, and the branches are full of young wood. By a rough estimate it must contain at least 200 cubic feet in the trunk, and another 100 feet or more in the larger limbs, and is the oldest-looking pear tree that I ever saw (Plate 356).

Another very large pear tree grows at Hardwicke Court near Gloucester, and measures $13\frac{1}{2}$ ft. in girth at a foot from the ground, dividing above this point into three main trunks.

One of the most remarkable trees in Great Britain is the pear at Holme Lacy Rectory. This is described in Littlebury's *Herefordshire Gazetteer* as having been a very old tree in 1776, when it yielded 15 to 16 hogsheads of perry in one year. At that time it covered half an acre of ground. It was described by a correspondent of Loudon in 1836 as at this time much smaller, but still healthy and vigorous.³ Its peculiar feature is the way in which its branches after extending laterally to a considerable distance, fall to the ground and take root, giving rise to a new tree which again extends in the same way, so that it is a remarkable instance of layering. It is now impossible to say where the original trunk first stood, as it is divided into three parts, of which the principal trunk measures 59 ft. by 8 ft. 8 in., and spreads a long way into a shrubbery; another in the meadow outside the

¹ Lord Ducie has a thriving tree at Tortworth raised from seed sent from the Jura by Mr. G. H. Wollaston.

² Cf. C. Reid, *Origin British Flora*, 119 (1899).

³ Edwin Lees figures in *Gard. Chron.* ix. 268, fig. 45 (1878), a part of this tree, which he said measured 80 feet from the base of the principal fallen trunk to the end of the branches; but I cannot recognise the part of the tree which he sketched.

garden has several stems, which spread a long way; and the fallen stems seem sound. Perhaps the most striking part of this tree, which has probably been separately planted, is now in a meadow 200 yards off on the banks of the Wye. This has eight different stems whose various branches measured, in July 1908, 126 paces in circumference. The older trunks have very rugged bark, and twist from left to right. The late Rev. A. Ley informed me that the fruit was small; and the local blacksmith, who makes perry from it which I found to be very fair, said that it most resembled a variety locally called "Taunton Squash."

The cultivated pear seems to attain its greatest size on rather heavy Red Sandstone soils in the neighbourhood of Worcester. One of the largest I have seen is in an orchard at Eardiston, $15\frac{1}{2}$ miles from Worcester, on the road to Ludlow, and $3\frac{1}{2}$ miles from Newnham Bridge Station. This pear tree is mentioned by Rider Haggard in *Rural England*, i. 340 (1902), as being 17 ft. in girth, but when I visited it in March 1907, I made it 62 ft. by $13\frac{1}{2}$ ft. It grows on a steep bank sheltered from the north, on which side it is hollow at the butt. (Plate 357.)

There is an orchard of very fine old pears, many of which are now decaying and others gone, since they were described in *Herefordshire Pomona* (vol. i. p. 20) as "an orchard of Barland pears, perhaps unequalled in the world." They grow on Monkland farm between Worcester and Malvern, and, according to tradition, were planted by the Monks of Malvern, in which case they must be 300 years old. Mr. E. Lees, in *Botany of the Malvern Hills*, 62 (1843), writes of them:—"There are more than seventy lofty trees, and in a 'hit,' as it is called, the produce has amounted to 200 hogsheads. The orchard in question occupies five or six acres, and the price of perry varies from 6d. to 1s. 6d. per gallon. Supposing the average price to be £3 per hogshead, the perry produced would be worth £600, but a 'hit' must not be expected every year, and the trees are now becoming very old."

There is another orchard not far off on Lower Woodfield Farm which Mr. Slater, forester to Earl Beauchamp, showed me in 1908, and which are also called Barland pears.¹ The best of these are about 60 ft. high, and two which I measured were 11 ft. and $8\frac{1}{2}$ ft. in girth.

At Forthampton Vicarage near Tewkesbury there is another magnificent orchard of so-called "Hufcap" pears,² which strongly resemble the Barland in bark and habit, and like them are all grafted at about 6 ft. from the ground. These are said to have been planted in the reign of Charles II., and are growing on a strong red marl. They are in three lines, and though several of them are partially decayed,

¹ The Barland pear is figured by Hogg and Bull, *Herefordshire Pomona*, vol. i. plate xviii. (1876-1885), and is said to have originally grown in a field called Bare Lands, near Ledbury. Evelyn says of it in his *Pomona*:—"The horse pear and Barland pear are reputed of the best as bearing almost their weight of spritful and vinous liquor. They will grow in common fields of gravelly and stony ground to that largeness, as only one tree has been usually known to make three or four hogsheads." The fruit he describes as "of such insufferable taste that hungry swine will not smell to it, or if hunger tempt them to taste, at first crush they shake it out of their mouth." The authors of *Pomona*, however, say that Barland perry does not bottle well. It curdles in the bottles, and in Herefordshire is usually drunk as soon as made, when it is considered very wholesome, and singularly beneficial in nephritic complaints.

² The Black Hufcap pear is figured by Knight, *Pomona Herefordiensis*, plate xxiv. (1811), and is said to have been known from the seventeenth century and to be best of all the varieties. The fruit is very harsh and austere, but becomes very sweet during the process of grinding. Its perry possesses much strength and richness, and has the credit of intoxicating more rapidly than that made from any other pear. The Yellow Hufcap is a very favourite pear near Ledbury, earlier than the Black Hufcap, and bears freely, though usually in great abundance every second year. Its perry is excellent.

flower profusely, and in some years produce abundance of fruit. The largest sound tree that I measured here was over 50 ft. high and 10 ft. in girth.

In Scotland the pear rarely attains a great size; and I have seen none which were very noteworthy; but in the *Old and Remarkable Trees of Scotland* (p. 244), the Rev. R. Bremner describes a Chaumontel pear tree in the minister's garden at Banff, which was reported to be one hundred and fifty years old, and was 42 ft. by 9 ft. and 150 ft. round the branches.

Walker¹ measured in 1799 a tree at Restalrig, near Edinburgh, which was 12 ft. in girth at $2\frac{1}{2}$ ft. from the ground, above which point it began to branch. This was a sort of early pear, called the "Golden Knap," which he considered to be the largest and most durable of any of the kinds of pear; and recommended it to be raised from seeds and planted out without being grafted, as these wildings, as they are called, form the most vigorous and largest trees, and should be chosen as stocks for grafting. The fruit, though often scarcely edible, is useful in making perry.

Hunter² mentions an orchard pear tree at Gourdie Hill near Perth, which was no less than 65 ft. by 10 ft., but we do not know if either of these is still living.

TIMBER

It seems strange that a wood, having such valuable qualities as the pear, should be practically neglected in this country. It is so hard, fine-grained, and compact that it is one of the very best woods for cogs, wood-screws, and tool-handles. It takes dye so well that when stained black it is difficult to distinguish from ebony, and for carving it is one of the finest hardwoods known.³ At Windsor Castle there is a very beautiful panel carved in high relief from pear wood.

Like many hardwoods it is slow and difficult to season, and unless thoroughly dry is liable to warp and crack badly. When trees of sufficient size can be procured, it is better, in order to avoid warping, to cut the boards on the quarter; and as it takes a fine polish and has a rich pinkish brown colour, it might be used for chair and cabinet-making with good effect. But the greater part of the old pear trees which are grown in the Severn valley are only used for firewood, and are said to burn with a very hot and slow flame. (H. J. E.)

¹ *Essays on Nat. Hist.* 84 (1812).

² *Woods and Forests of Perthshire*, 503 (1883).

³ Drawing squares and curves are often made of pear wood.

SECTION MALUS

This section of the genus *Pyrus* comprises the apples, which are deciduous trees or shrubs, resembling the true pears in the occurrence of long and short shoots and in the arrangement of the leaves. Leaves simple, often lobed, stalked. Flowers in cymes, terminal on the short shoots; sepals 5, acuminate, either persistent and erect on the fruit or deciduous; ovary usually 5-celled, rarely 3-celled; styles united at the base. Fruit with homogenous flesh, hollowed out or rounded at the base; with papery carpels joined at the apex, free in the middle.

There are about ten species of apples, distributed in Europe, extra-tropical Asia, and North America. The following synopsis gives a brief account of the wild species, and of some of the more important hybrids, which are met with in cultivation.

I. EUMALUS, Zabel, *Laubholz-Benennung*, 185 (1903).

Leaves rolled inwards in the bud; on adult trees, serrate, without lobes or irregular teeth.

* *Calyx persistent on the fruit.*

† *Fruit depressed at both the base and apex.*

1. *Pyrus Malus*, Linnæus. See p. 1570.

†† *Fruit not depressed at the apex.*

2. *Pyrus Ringo*, Koch, *Dendrologie*, i. 213 (1869); Wenzig, in *Linnaea*, xxxviii. 37 (1874); Stapf, in *Bot. Mag.* t. 8265 (1909).

Branchlets more or less tomentose. Leaves elliptic-ovate, 2 to 3 in. long, shortly acuminate, more or less tomentose beneath, finely and sharply serrate. Fruit ovoid, about $1\frac{1}{4}$ in. long and 1 in. in diameter, yellow, hollowed at the base, crowned by the persistent sepals, which are united together at their base.

A small tree introduced by Siebold from Japan in 1856. It is supposed to be a hybrid between *P. Malus* and *P. spectabilis*. At Kew, it is very ornamental, when covered with its beautiful fruits; and is represented by two trees, one with densely tomentose leaves, the other with slightly tomentose leaves. A pyramidal variety, var. *fastigiata bifera*, Dieck, is also known, which is said to flower usually twice in the season.

3. *Pyrus spectabilis*, Aiton, *Hort. Kew.* ii. 175 (1780).

Branchlets slightly pubescent. Leaves oblong-elliptic, 2 to 3 in. long, 1 to $1\frac{1}{4}$ in. broad, acute at the apex, pubescent on the midrib beneath and on the petiole; margin with minute close serrations, which are callous and mostly incurved at their tips. Fruit globose, yellow, about 1 in. in diameter, not hollowed out at the base, crowned by the persistent sepals, which are united together at their base.

A native of north China and Japan. Introduced in 1780, and often cultivated

on account of its large pink flowers, about 2 in. across, which appear early in the season. Forms with double flowers occur, one of which with very large flowers is known as var. *Riversii*.

4. *Pyrus prunifolia*, Willdenow, *Phytog.* i. 8 (1794); J. D. Hooker, in *Bot. Mag.* t. 6158 (1875).

Young branchlets tomentose. Leaves usually elliptic, about 3 in. long and 2 in. broad (occasionally a few are sub-orbicular and smaller), contracted above into a cuspidate acuminate apex, tomentose on the midrib and nerves beneath and on the petiole, conspicuously glandular on the midrib above; margin with irregular serrations, which are crenate or bluntly triangular. Fruit globose or ovoid, about an inch in diameter, yellow on one side, bright red on the other, depressed at the base, crowned by the persistent sepals, which are united together at their base.

P. prunifolia has never been found in the wild state, and is of uncertain origin. It was reputed, when introduced in 1753, to have come from Siberia. It closely resembles *P. baccata*, differing mainly in the persistent calyx of the fruit; and is supposed by Bailey¹ to be a hybrid between that species and *P. Malus*. It is cultivated at Kew; and at Bayfordbury there is a fine specimen, 35 ft. by 5 ft. 7 in., with the stem forked a few feet from the ground.

5. *Pyrus Scheideckeri*, Späth, in *Gartenflora*, liii. 417, t. 1529 (1904).

Young branchlets slightly pubescent. Leaves ovate, acuminate, about 3 in. long, with scattered pubescence on the under surface and hairy petioles; margin coarsely and sharply serrate and biserrate. Fruit, $\frac{3}{4}$ in. in diameter, globose, usually crowned by the persistent calyx, occasionally some of the sepals being deciduous.

This originated in Scheidecker's nursery at Munich, as a seedling of *P. floribunda*, but is evidently a hybrid, the other parent being probably *P. prunifolia*. It is a small tree, producing large flowers, white tinged with pink, in great abundance; and is in cultivation at Kew.

** *Calyx not persistent on the fruit.*

6. *Pyrus baccata*, Linnæus, *Mant.* 75 (1767).

Branchlets glabrous. Leaves ovate-oblong, $2\frac{1}{2}$ to $3\frac{1}{2}$ in. long, $1\frac{1}{4}$ to 2 in. wide, contracted above into a cuspidate acuminate apex; glabrous beneath, except for slight pubescence on the midrib; glandular on the midrib above; margin with shallow usually crenate serrations. Fruit globose, $\frac{3}{4}$ in. in diameter, hollowed at the base and apex, the apex being marked with a circular brown scar, no trace of the calyx remaining.

This species,² which is usually known as the Siberian crab, is widely distributed in eastern Siberia, Manchuria, central and northern China, and throughout the Himalayas at 6000 to 10,000 ft. altitude. It was introduced in 1784.

¹ *Cycl. Amer. Hort.* 1472 (1901).

² Figured by Sir J. D. Hooker in *Bot. Mag.* t. 6112 (1874), who states that, in the western parts of the Himalayas, this species becomes more pubescent in all its parts.

It is one of the most beautiful and generally cultivated of its genus, both for its flowers, and its fruit,¹ which makes a delicious jelly. It grows on good soil to a considerable size. Elwes saw at Patshull, Staffordshire, the seat of the Earl of Dartmouth, a tree, measuring 40 ft. by 7 ft., with a burry trunk.

7. *Pyrus sikkimensis*, J. D. Hooker, *Flora Brit. India*, ii. 373 (1878), and in *Bot. Mag.* t. 7430 (1895).

Branchlets tomentose. Leaves ovate to ovate-oblong, 2 to 3 in. long, ending in a long caudate-acuminate apex; tomentose beneath; margin with fine close sharp-pointed serrations. Fruit, $\frac{2}{3}$ in. in diameter, turbinate, not depressed at the base, marked at the apex with a brown circular depressed scar, no trace of the calyx remaining.

A small tree, native of Sikkim and Bhutan between 7000 and 10,000 ft. altitude. It is in cultivation at Kew, where a tree about 25 ft. high has spiny branches on the trunk.

8. *Pyrus Halleana*, Sargent, in *Garden and Forest*, i. 152 (1888).

Branchlets slightly pubescent. Leaves coriaceous, lanceolate to ovate, 2 to 3 in. long, usually tapering gradually to an acuminate apex; quite glabrous on both surfaces and on the petiole, glandular on the midrib above; margin undulate, finely serrate. Fruit globose, $\frac{1}{4}$ in. in diameter, not hollowed at the base, marked at the apex by a depressed circular scar, no trace of the calyx remaining; and containing very large seeds.

This small tree was introduced in 1863 into the United States from Japan, where, however, it is not known in the wild state. It bears beautiful pink flowers, which are usually double. The original tree in Mr. Parkman's garden in Jamaica Plain, Massachusetts, was 18 ft. high in 1888. There is a small specimen at Kew.

- II. SORBOMALUS, Zabel, *Laubholz-Benennung*, 189 (1903). Leaves folded in the bud; on adult trees irregular in outline, some being lobed or dentate.

* *Calyx persistent on the fruit.*

† *Leaves covered beneath with dense grey tomentum.*

9. *Pyrus ioensis*, Bailey, in *Amer. Gard.* xii. 473 (1889).

Branchlets densely grey tomentose. Leaves ovate, acute, about 3 in. long, often with two or four lateral lobes, crenately serrate, covered beneath with a dense grey tomentum; petioles tomentose. Fruit sub-globose, $1\frac{1}{4}$ in. in diameter, depressed at the base, on a stout tomentose stalk.

This is the common crab-apple of the Mississippi basin in the United States. It was introduced at Kew in 1906. Bechtel's crab, a form with large pink double flowers, is often cultivated in the United States. *P. Soulardi*,² Bailey, which is wild here and there in the Mississippi valley, is supposed to be a natural hybrid between *P. Malus* and *P. ioensis*.

¹ The fruit which I bought at several railway stations in Siberia in May 1912 was juicy and well-flavoured.—H. J. E.

² Britton and Shafer, *N. Amer. Trees*, 434 (1908), say that this hybrid is cultivated in the north central States for its fruits, which are highly prized for cider and jellies, and used as a substitute for the quince where that fruit will not thrive.

†† *Leaves not covered beneath with dense grey tomentum.*

10. *Pyrus coronaria*, Linnæus, *Sp. Pl.* 480 (1753).

Young branchlets slightly tomentose. Leaves variable in shape, ovate or triangular, about 3 in. long, acute at the apex; margin irregular with large serrated teeth; lower surface green, pubescent on the nerves. Fruit 1 to $1\frac{1}{2}$ in. in diameter, globose, depressed at the base, fragrant, covered with a waxy exudation.

A native of the eastern parts of Canada and the United States. Introduced in 1824, and said by Loudon¹ to have become naturalised near White Knights and Godalming, where it attained 30 ft. in height.

11. *Pyrus angustifolia*, Solander, in Aiton, *Hort. Kew.* ii. 176 (1789).

Branchlets glabrous. Leaves oblong-lanceolate, $1\frac{1}{2}$ to 3 in. long, acute or rounded and apiculate at the apex, tapering at the base; margin with irregular teeth and crenate serrations; under surface glabrous except for slight pubescence on the midrib. Fruit sub-globose, 1 in. in diameter, very fragrant.

A native of the United States from Pennsylvania to Florida and Louisiana. Introduced in 1750.

** *Calyx not persistent on the fruit.*

12. *Pyrus rivularis*,² Douglas, *ex Hooker, Fl. Bor. Amer.* i. 203 (1833).

Branchlets slightly tomentose. Leaves ovate, about 3 in. long, acute or acuminate, slightly tomentose beneath; margin sharply serrate, with often two to four small lateral lobes or large teeth. Fruit ellipsoid, $\frac{1}{2}$ to $\frac{3}{4}$ in. long.

A tree, 40 ft. high, occurring in western North America from Alaska to California. Introduced in 1836.

13. *Pyrus Toringo*, Siebold, in *Ann. Mus. Lugd. Bot.* iii. 41 (1856).

Malus Toringo, Siebold, *Cat. Rais.* 4 (1856); Carrière, in *Rev. Hort.* 1870-1871, p. 451, coloured plate.

Branchlets tomentose. Leaves on the short shoots, ovate, $1\frac{1}{2}$ to 2 in. long, more or less tomentose beneath, sharply serrate; on the long shoots, 2 to $2\frac{1}{2}$ in. long, trilobed, with a large ovate acuminate irregularly serrated terminal lobe, and two smaller triangular lateral lobes. Fruit globose, about $\frac{1}{4}$ in. in diameter.

A native of Japan,³ introduced by Siebold in 1856.

14. *Pyrus floribunda*, Nicholson, in *Kew Hand-List Trees*, 181 (1894) (not Lindley).

Malus floribunda, Siebold, *Cat. Rais.* 5 (1859), *ex Van Houtte, Flore des Serres*, xv. t. 1585 (1865); Carrière, in *Rev. Hort.* 1870-1871, p. 591, coloured plate.

Branchlets slightly pubescent. Leaves ovate to elliptic, 2 to $2\frac{3}{4}$ in. long, 1 to $1\frac{1}{2}$ in. broad; petiole and under surface pubescent, the pubescence dense on

¹ *Arb. et Frut. Brit.* ii. 908 (1838).

² Britton and Shafer, *N. Amer. Trees*, 435 (1908), adopt for this species the name *Pyrus diversifolia*, Bongard, in *Mem. Acad. Petersb.* ii. 133 (1833), which is strictly applicable to a pubescent variety.

³ *Malus Sargentii*, Rehder, in Sargent, *Trees and Shrubs*, i. 71 (1903), is a very tomentose variety of *P. Toringo*, which was found by Sargent in a brackish marsh near Moronan in Japan.

the midrib and scattered elsewhere; margin sharply serrate, some of the leaves having one or two large teeth on each side. Fruit globose, $\frac{1}{4}$ to $\frac{1}{3}$ in. in diameter, with a depressed circular scar at the apex, no trace of the calyx remaining.

This was introduced in 1856 by Siebold from Japan, where it is not known in the wild state; and is supposed by Schneider to be a cross between *P. baccata* and *P. Toringo*. It is a shrub, producing an abundance of beautiful pink flowers, which appear with the leaves. (A. H.)

PYRUS MALUS, COMMON APPLE

Pyrus Malus, Linnæus, *Sp. Pl.* 479 (1753); Loudon, *Arb. et Frut. Brit.* ii. 891 (1838); Wilkomm, *Forstl. Flora*, 847 (1887); Ascherson and Graebner, *Syn. Mitteleurop. Flora*, vi. pt. 2, p. 74 (1906).

A tree or large shrub with scaly fissured bark. Leaves scattered on the long shoots, clustered on the short spurs, usually oval, rounded at the base, shortly acuminate at the apex, crenate in margin. Flowers, 5 or 6 in an umbellate cyme, at the apex of a short shoot; sepals 5, triangular, acuminate; petals 5, pink externally, white internally; stamens about 20, with white filaments and yellow anthers; styles 5, united at the base. Fruit sub-globose, about an inch in diameter, depressed both at the base and apex, crowned by the calyx-segments, which are not united at the base.

The wild apple, described above, is often considered to constitute two species, which, as intermediate forms are common, are best treated as two varieties:—

1. Var. *sylvestris*, Linnæus, *Sp. Pl.* 479 (1753).

Malus sylvestris, Miller, *Gard. Dict.*, ed. 8, No. 1 (1768).

Malus acerba, Méral, *Pl. Env. Paris*, 187 (1812); Mathieu, *Fl. Forest.*, 171 (1897).

Pyrus acerba, De Candolle, *Prod.* ii. 635 (1825).

Young branchlets slightly pubescent, soon becoming glabrous. Leaves glabrous above, shining and scattered pubescent beneath; petiole slightly pubescent. Axis of inflorescence and pedicels slightly pubescent; calyx-tube glabrous; sepals glabrous externally, pubescent internally. This is generally supposed to be the variety indigenous in western and central Europe.

2. Var. *pumila*, Henry.

Var. *mitis*, Wallroth, *Sched. Crit.* 215 (1822).

Pyrus pumila, Koch, *Dendrologie*, i. 203 (1869).

Malus pumila, Miller, *Gard. Dict.*, ed. 8, No. 3 (1768); Schneider, *Laubholzkunde*, i. 715 (1906).

Malus paradisiaca, Medicus, *Gesch. Bot.* 78 (1793).

Young branchlets tomentose. Leaves ovate or oval, often cuneate at the base, crenately or sharply serrate, dull and more or less tomentose beneath. Axis of the inflorescence, pedicels, calyx, and both surfaces of the sepals, tomentose.

This variety, though often found naturalised in western Europe, is considered by Ascherson and Graebner and by Schneider to be only truly wild in south-eastern Europe, southern Russia, Siberia, Turkestan, Caucasus, and Asia Minor. It is the

source of most of the cultivated apples, though some of these have arisen from var. *sylvestris*, and others from crosses of the two forms.

It is impossible here to enter into any account of the apples cultivated for their fruits; but the following peculiar varieties may be briefly noticed.

3. Var. *astracanica*, Loudon, *Arb. et Frut. Brit.* ii. 893 (1838).

Malus astracanica, Dumont de Courset, *Bot.* v. 426 (1811).

Pyrus astracanica, De Candolle, *Prod.* ii. 635 (1825).

Leaves large, coarsely serrate and in part bi-serrate, tomentose beneath. Flowers and fruits on long stalks. On account of the length of the peduncles, this is considered by Schneider and by Ascherson and Graebner, to be a hybrid between *P. Malus*, var. *pumila*, and *P. baccata*; but this is very doubtful. A tree cultivated at Kew under this name agrees with a herbarium specimen, which was collected by Schrenk in Songaria. Loudon states that this variety is "a native of about Astrachan, on the testimony of gardeners," and mentions two kinds, one with red fruit, the other with wax-coloured fruit.

4. Var. *Niedzwetzkyana*, Ascherson and Graebner, *op. cit.* 78 (1906).

Pyrus Niedzwetzkyana, Hemsley, in *Bot. Mag.* t. 7975 (1904).

Adult leaves tinged with red on the midrib and nerves. Flowers deep pink. Fruit with a crimson skin and pale purple flesh. Nearly all the other parts of the tree, as the wood and bark, are also coloured red.

This remarkable variety was obtained by Dieck,¹ who introduced it in 1891, from Kashgar and the plateau of Talgar, near Vernoie, in south-west Siberia. Goeze² states that a similar tree is cultivated in the Caucasus. This variety is hardy at Kew, where it flowers and produces fruit.

5. Var. *apetala*, Ascherson and Graebner, *op. cit.* 78 (1906).

Pyrus apetala, Muenchhausen, *Hausv.* v. 247 (1770).

Pyrus dioica, Moench, *Verz. Weissenst.* 87 (1785); Loudon, *Arb. et Frut. Brit.* ii. 892 (1838).

Flowers with two rows of sepals and 10 to 15 styles; without petals or stamens. Fruit seedless.

The origin of this is unknown. It was said by Loudon to have been in continental gardens in his time; but was not introduced in 1838. There is a specimen at Kew, but I have seen no flowers or fruit.³

6. Schneider mentions var. *pendula*, a tree with pendulous branches and branchlets; and var. *aucubæfolia*, in which the leaves are spotted with yellow.

DISTRIBUTION

The common apple is widely distributed throughout nearly all Europe, Asia Minor, the Caucasus, north Persia, south-western Siberia, Turkestan, and the

¹ *Neuh. Offer. Nat. Arb. Zöschchen*, 1891, p. 16, where the name is given as *Malus Medwitskyana*, which was afterwards changed by Dieck to the spelling given above.

² *Gard. Chron.* ix. 461 (1891). Cf. also Graebner, in *Mitt. Deut. Dend. Ges.* 1911, p. 254, who mentions a fine specimen at Karlsruhe. Young plants vary much in the colour of the leaves.

³ Bailey, *Cycl. Amer. Hort.* 1473 (1901), states that it is figured and described in *American Gardening*, x. 244, 279, and xi. 6 (figs.), 624.

north-western Himalayas. In many places it is undoubtedly an escape from cultivation; and its exact distribution as a wild tree cannot be defined with accuracy.

It is apparently indigenous in Europe as far north as lat. $63^{\circ} 49'$ in Norway, and lat. 61° in Sweden. In Russia its northern limit passes through Åbo in Finland, Lake Ladoga, Tver, Jaroslav, and Kazan; and it is said to be common in the forests of the plain in the southern provinces and in the mountains of the Crimea. It reaches in the Caucasus an elevation of 5000 ft., becoming a tree 30 to 40 ft. in height; and extends from there into the Persian province of Ghilan. It appears to be undoubtedly wild in the mountains of Turkestan, where it has been collected by various Russian travellers. Aitchison found the apple only as a cultivated tree in Afghanistan; but, according to Hooker, it is apparently wild in the north-western Himalayas, where it ascends to 9000 ft., and in western Tibet, where it reaches an altitude of 11,400 ft.

In central Europe, according to Ascherson and Graebner, the glabrous variety is scattered throughout the forests, being more common in those composed of conifers and broad-leaved species, and is usually seen in glades and on the margin of woods. In the north-western German plain, the apple is often met with remote from orchards, and is considered to be truly wild. It ascends in the Alps to about 5500 ft. elevation.

In France, Mathieu also is of opinion that the indigenous apple is the glabrous variety, occurring as a scattered tree in the forests of the plains and low hills, except in the Mediterranean region. It ascends in the Jura to about 3000 ft. altitude.

In Britain, the apple¹ is found apparently wild in copses and hedges from the Forth and Clyde southwards; and is undoubtedly wild in many parts of Ireland.

In the eastern United States, it has escaped from cultivation, and is common in woods, thickets, and road-sides, especially in southern New York, New Jersey, and Pennsylvania.²

(A. H.)

We must refer our readers to Loudon and to the *Herefordshire Pomona* for a full account of the cultivated apples, which we have no space to describe in this work. So far as I know, no variety of apple approaches the pear in size or age. Loudon stated that near Hereford some attained 40 ft. in height. The largest cultivated tree that I have seen is a tree in Lady Jenkins's garden at Botley Hill, Hants, adjoining the house where Cobbett once lived. This is of the variety called "Hambledon Deux ans," and in 1906 measured 47 ft. by 7 ft. and appeared sound. I was told that it had borne as much as forty bushels of fruit in one year, and often as much as twelve or fifteen bushels. Some of the last year's fruit was still edible on 21st June though shrivelled and partly rotten.

The wild crab tree seems to attain as great a size as the cultivated apples, though rarely seen under conditions where it has a chance to show its best growth. In an album of sketches by Jukes of trees at Studley Royal, which I have seen

¹ Leighton, *Flora of Shropshire*, 527 (1841), states that the glabrous and pubescent varieties are both equally wild and common. Bromfield, *Flora Vectensis*, 165 (1856), states that the pubescent form is extremely common and truly wild over most parts of the Isle of Wight, in woods, thickets, copses, hedgerows, and rough bushy places.

² Britton and Brown, *Illust. Flora N. United States*, ii. 236 (1897).

in the library there, is an excellent drawing of a crab which grew in the valley known as Mackershaw Trough, and in 1837 was 45 ft. high by 3 feet in girth at three feet from the ground. But this tree was no longer alive when I visited the place in 1905. In the hedgerows of the Cotswold hills it sometimes attains 30 ft. by 5 ft. Near the water tower at Barnsley Park, Cirencester, there is a tree, which in 1911 was about 45 ft. in height by 10 ft. in girth at 3 ft. from the ground, above which it divides into three stems.

Sir R. Christison¹ measured in 1876, at Kelloe, near Duns, Berwickshire, a perfectly healthy crab tree, 50 ft. high and 8 ft. in girth. It produced flowers abundantly and fruit in considerable quantity.

The crab tree comes up from seed pretty freely, but cannot be recommended for cultivation, as both its fruit and flowers are inferior to many of the exotic apples. It is not particular about soil, but seems to grow most freely on soils containing lime.

Though inferior to that of the pear tree, which it resembles in colour, hardness, and size, yet the wood of both wild and cultivated apples has some value for turnery, and was used for cog wheels and country furniture until driven out by wholesale manufacturers who use foreign wood only. I have used it for flooring blocks, for which its hardness and colour makes it very suitable, but the majority of the apple trees are usually decayed at heart before they cease to bear, and when worn out are used, like the pears, for firewood.

(H. J. E.)

¹ *Trans. Bot. Soc. Edinburgh*, xii. 186 (1876).

SECTION AUCUPARIA

Small trees or shrubs, defined in Vol. I. p. 142, as constituting one group of the section Sorbus¹ of the genus Pyrus. They are characterised as follows:—Leaves deciduous, alternate, unequally pinnate, with serrate leaflets and foliaceous stipules. Flowers perfect, in terminal compound corymbose cymes; calyx urn-shaped, with five persistent lobes; petals five, suborbicular, white; stamens about twenty; ovary usually three-celled, and surmounted by three styles, occasionally two- to four-celled, with two to four styles; ovules two in each cell. Fruit a small sub-globose pome, with acid flesh and papery carpels, which are free at the apex; seeds two, or one by abortion, in each cell.

About twenty species of the section Aucuparia are known, widely distributed over the extra-tropical regions of the northern hemisphere. Of these *P. Aucuparia*, which is a native tree, will be described in detail. About six exotic species have been introduced.

I. Buds very glutinous, showing no white tomentum at the tip.

* *Stipules early deciduous.*

1. *Pyrus americana*, De Candolle, *Prod.* ii. 637 (1825).

Leaflets, thirteen to seventeen, 2 to 2½ in. long, ¾ in. broad; under surface pale with scattered pubescence. Fruit, ¼ in. in diameter, said by Sargent² to be bright red, but purplish or bronze-coloured in England. A small tree, widely spread in North America. Introduced in 1782, and said by Loudon to be more tender than the native species; but it appears to thrive at Kew and at Tortworth.

Var. *decora*, Sargent, *Silva N. Amer.* xiv. 101 (1902).

This differs from the type in bearing large scarlet fruit, ½ in. in diameter. It is apparently the tree often known in cultivation as *P. sambucifolia*.³

2. *Pyrus commixta*,⁴ Ascherson and Graebner, *Syn. Mitteleurop. Flora*, vi. pt. 2, p. 90 (1906).

Leaflets, nine to thirteen, 2 in. long, ⅝ in. broad, tapering to a long caudate-acuminate apex, glabrous beneath. Fruit red, ¼ in. in diameter. A small tree, native of Japan.⁵ A specimen at Kew, obtained from Späth in 1900, is about 15 ft. high and very thriving.

¹ *Sorbus* is regarded by many botanists as a distinct genus; but there is no agreement amongst the various authorities as to its limits. Koehne, *Deutsche Dendrologie*, 246 (1893), includes in *Sorbus* only the mountain ashes. Schneider, *Laubholzkunde*, i. 667 (1906), gives it a much wider scope. Ascherson and Graebner, *Syn. Mitteleurop. Flora*, vi. pt. 2, p. 85 (1906), takes another view, which agrees practically with the arrangement given in our Vol. I. pp. 141-142.

² *Silva N. Amer.* iv. 79, tt. 171, 172 (1892). It is described by Sargent, *Trees N. Amer.* 356 (1905), as *Sorbus americana*, Marshall, *Arb. Amer.* 145 (1785).

³ The true *P. sambucifolia*, Chamisso and Schlechtendal, in *Linnaea*, ii. 36 (1827), is a native of eastern Siberia, Saghalien, and Yezo; and has not yet been introduced.

⁴ This was first described as *Sorbus Aucuparia*, var. *japonica*, Maximowicz, in *Mit. Biol.* ix. 160 (1873). It is *Sorbus japonica*, Koehne, in *Gartenflora*, l. 408 (1901) (not Siebold); and is also named *Sorbus commixta*, Hedlund, in *Kgl. Svensk. Vet. Akad. Handl.* xxxv. 38 (1901).

⁵ Var. *rufo-ferruginea*, Shirai, ex Schneider, *Laubholzkunde*, i. 678 (1906), has rusty red pubescence on the rachis and under surface of the leaflets. This was collected by Elwes at Chuzengi at 4000 ft. altitude, and is possibly a distinct species. It has not been introduced.

* *Stipules persistent till the time of fruiting.*

3. *Pyrus discolor*, Maximowicz, *Prim. Fl. Amur.* 103, note (1859).

Leaflets fifteen to seventeen, remotely placed on the rachis, 1½ to 2 in. long, ending in a long acuminate point, pale and glabrous beneath. Fruit pale pink. Readily distinguishable by its palmately cleft or lobed persistent stipules.

A small tree, wild in the neighbourhood of Peking. *Sorbus pekinensis*, Koehne,¹ in *Gartenflora*, L., 406 (1901), which was described from plants raised in Germany, is identified with this species by Schneider.² Small trees at Kew, obtained from Späth and Lemoine, agree with a native specimen in the British Museum, except that the buds are pubescent at the tip and not completely viscid.

II. Buds more or less covered with dense white tomentum.

* *Stipules early deciduous.*

4. *Pyrus tianshanica*, Franchet, in *Ann. Sc. Nat.* xvi. 267 (1883).

Branchlets glabrous. Leaflets eleven to thirteen, 1 to 1½ in. long, ⅔ in. broad, green and glabrous on both surfaces. Fruit ⅔ in. in diameter, bright red.

A shrub, about 10 ft. high, occurring in Turkestan, Afghanistan, and western Kashmir. Introduced³ into Kew in 1896, and described by Sir J. D. Hooker, in *Bot. Mag.* t. 7755 (1901). This does not seem to thrive in England, as the specimens which I have seen are stunted in growth and bear small leaflets.⁴

5. *Pyrus Aucuparia*, Gaertner. See p. 1576.

Branchlets pubescent. Leaflets eleven to fifteen, about 2 in. long, pale and pubescent beneath.

** *Stipules persistent till the time of fruiting.*

6. *Pyrus pohuashanensis*, Hance, in *Journ. Bot.* xiii. 132 (1875).

Leaflets thirteen to fifteen, 2½ to 3 in. long, ¾ in. broad, pale and pubescent beneath. Fruit ⅔ in. in diameter, orange-coloured. The persistent stipules are obovate and shortly toothed.

A small tree, discovered in 1874 on the Po-hua mountain, west of Peking, by Bretschneider, who sent seed to the Arnold Arboretum. The trees which were raised produced flowers and fruit⁵ for several years previous to 1893; and a seedling sent in that year to Kew is now about 20 ft. high and very thriving, producing abundance of handsome fruit.

III. Buds tipped at the apex with reddish hairs; scales glabrous, ciliate in margin.

7. *Pyrus Vilmorini*, Ascherson and Graebner, *Syn. Mitteleurop. Flora*, vi. pt. 2, p. 90 (1906).

¹ Cf. also Koehne, in *Mitt. D. Dend. Ges.* 1906, p. 56.

² *Laubholzkunde*, i. 669 (1906).

³ It appears to have been introduced into the St. Petersburg Botanic Garden in 1889. Cf. *Gard. Chron.* xxv. 389 (1899).

⁴ Schneider, *Laubholzkunde*, i. 668 (1906), describes this species under the name *Sorbus tianshanica*, Ruprecht, in *Mem. Acad. St. Petersburg*, xiv. 46 (1869), and states that the leaflets are 2 in. long and over ½ in. broad.

⁵ Cf. Bretschneider, *Hist. Europ. Bot. Disc.* 1054 (1898). The trees in the Arnold Arboretum were considered for many years to be *P. discolor*, Maximowicz; but Rehder, in *Mitt. Deut. Dend. Ges.* 1901, p. 117, showed that they were the same as Hance's species, and named them *Sorbus pohuashanensis*.

Leaflets, on a winged rachis, nineteen to twenty-nine, very small, scarcely exceeding $\frac{1}{2}$ in. in length, serrate only near the apex. Fruit $\frac{1}{3}$ in. in diameter bright red.

This pretty shrub,¹ which is a native of Yunnan in China, was introduced at Kew from Les Barres² in 1905. (A. H.)

PYRUS AUCUPARIA, MOUNTAIN ASH, ROWAN

Pyrus Aucuparia, Gaertner, *De Fruct.* ii. 45, t. 87 (1791); Loudon, *Arb. et Frut. Brit.* ii. 916 (1838); Ascherson and Graebner, *Syn. Mitteleurop. Flora*, vi. pt. 2, p. 86 (1906).
Sorbus Aucuparia, Linnæus, *Sp. Pl.* 477 (1753); Willkomm, *Förstliche Flora*, 862 (1887); Mathieu, *Flore Forestière*, 181 (1897); Schneider, *Laubholzkunde*, i. 672 (1906).
Aucuparia silvestris, Medicus, *Gesch. Bot.* 86 (1793).

A tree, occasionally attaining 50 ft. in height. Bark thin, smooth, greyish, becoming thicker, darker in colour, and fissured at the base of old trunks. Young branchlets more or less tomentose at first, ultimately glabrescent. Leaves, about 6 in. long, unequally pinnate, with a grooved rachis, tufted with long hairs and glandular at the insertion of the leaflets, elsewhere slightly pubescent; leaflets eleven to fifteen, opposite, subsessile, about 2 in. long, lanceolate-oblong, unequal at the base, acute at the apex, sharply serrate except near the base; upper surface dull green, glabrous; lower surface pale, more or less pubescent.

Flowers in large corymbose cymes, the axis and branches of which are more or less tomentose; calyx and pedicels pubescent; petals white, equal in length or shorter than the stamens; styles usually three, tomentose at the base. Fruit spherical or ellipsoid, $\frac{2}{3}$ in. in diameter, smooth, usually red.

The terminal buds³ are large, ovoid-conic, and covered in greater part with dense white tomentum; the lateral buds are smaller, slightly flattened, and appressed. The leaf-scars, visible in winter, are crescentic, five-dotted, and situated on prominent pulvini.

VARIETIES

I. This species varies in the wild state, as regards the amount of pubescence; and two distinct varieties are recognised:—

1. Var. *glabrata*, Wimmer and Grabowski, *Fl. Schles.* ii. 1, p. 21 (1821).

Buds, branchlets, and leaves glabrous; leaflets smaller than in the type. This is the common form at high elevations in the mountains of central and south-eastern Europe.

¹ Cf. Hutchinson, in *Bot. Mag.* t. 8241 (1909), where it is figured under the name *Sorbus Vilmorini*, Schneider, in *Bull. Herb. Boissier*, vi. 317 (1906).

² This was raised at Les Barres from seeds received from Père Delavay in 1889, and was described as *Cornus foliolosa*, Franchet, in *Vilmorin, Fruct. Vilmorinianum*, 103 (1904); but is not, as was supposed, identical with *Pyrus foliolosa*, Wallich. The latter does not appear to be in cultivation.

³ The stipules are described by Lubbock, in *Journ. Linn. Soc. (Bot.)* xxx. 492, 493 (1895).

2. Var. *lanuginosa*, Ascherson and Graebner, *op. cit.* 88 (1906).

Sorbus lanuginosa, Kitaibel, *Schult. Oest. Fl.* ii. 50 (1814).

Pyrus lanuginosa, De Candolle, *Prod.* ii. 637 (1827).

Buds, branchlets, and leaves very tomentose, the pubescence remaining on the leaflets till autumn, and on the branchlets till the second year. This is prevalent in the plains and on the low hills of south-eastern Europe.

II. Several varieties with peculiar fruit are known:—

3. Var. *dulcis*, Krätzl, in *Wiener Illust. Gartenzeit.* 1885, p. 65.

Var. *moravica*, Zengerling, *ex Dippel, Laubholzkunde*, iii. 367 (1893).

Fruit sweet, larger than in the type. The leaflets are remarkable, being long and narrow, with the serrations confined to near the apex.

This tree was found wild about the year 1800, in a mountain forest of the Spornhau parish in northern Moravia,¹ and was subsequently propagated by grafting. It was introduced² in 1885 in Sweden, where it has proved very hardy, ripening its fruit as far north as lat. 66°, where no other fruit tree can be cultivated. A tree at Kew, about 15 ft. high, was obtained from Späth in 1900.

4. Var. *rossica*, Späth, in *Mitt. Deut. Dend. Ges.*, 1896, p. 196; Koehne, in *Gartenflora*, L., 412 (1901).

Fruit sweet, leaflets as in the type. This is said to be planted in southern Russia, where at Kiev the berries, powdered with sugar and packed in little boxes, are sold and exported. This variety, which I have not seen, was introduced by Späth in 1896.

5. Var. *Fifeana*, Dippel, *Laubholzkunde*, iii. 367 (1893). Fruit yellow. The origin of this tree, which was called var. *fructu luteo* by Loudon, is unknown. There is a handsome specimen at Kew.

III. The following varieties are peculiar in habit or foliage:—

6. Var. *fastigiata*, Loudon, *loc. cit.* Branches upright. This originated in Hodgins's nursery at Dunganstown in Co. Wicklow.

7. Var. *pendula*, Kirchner, *Arb. Musc.* 293 (1864). Branches very pendulous. This when grafted six or eight feet high, makes a graceful tree. Beissner³ describes and figures a remarkable weeping tree in the churchyard of Wiesbaden; the branches are interlaced and twisted to an extraordinary degree.

8. Var. *integerrima*, Koehne, in *Gartenflora*, L., 411 (1901), and *Mitt. D. Dend. Ges.* 1906, p. 55. Leaflets entire in margin, the upper three occasionally united together. This was found⁴ in the Jena Botanic Garden, and is possibly a hybrid, though the flowers differ in no respect from those of *P. Aucuparia*.

9. Var. *asplenifolia*, Koch, *Dendrologie*, i. 189 (1869). Leaflets irregularly and deeply toothed. This is represented at Kew by a tree obtained from Dale in 1899; and appears to differ slightly from var. *laciniata*, Beissner, in *Gartenwelt*, iii.

¹ Cf. Willkomm, *Forstl. Flora*, 863 (1887).

² Cf. Hartman, in *Garden and Forest*, 1895, p. 162.

³ In *Mitt. Deut. Dend. Ges.* 1911, pp. 246 and 247.

⁴ Lange, *Danske Flora*, iii. 370 (1864), describes a similar plant, found wild in the island of Bornholm.

267 (1899). The latter is said to have been found wild in the Erz Mountains; and in a specimen at Kew, obtained from Späth in 1906, the irregular tothing is almost confined to the leaflets on the barren branches.

10. A variety with variegated leaves is mentioned by Loudon; and another with yellowish foliage is occasionally seen, which is named var. *Dirkenii* or var. *Dirkenii aurea*.

HYBRIDS

The following, which were formerly considered to be varieties of *P. Aucuparia*, are of undoubted hybrid origin.¹ They differ from this species, in having the uppermost three or five leaflets united together into one segment:—

1. *Pyrus satureiifolia*, Ascherson and Graebner, *op. cit.* 106 (1906).

Sorbus satureiifolia, Koehne, *Deut. Dendrologie*, 248 (1893).

A small tree. Leaflets nearly glabrous beneath, not decurrent on the rachis; the uppermost three united into one segment.

This appears to be identical with *Sorbus neuillyensis*, Dippel, *Laubholzkunde*, iii. 370 (1893), of which there is a tree at Kew, about 20 ft. high, obtained from Simon-Louis in 1900.

Sorbus saturejæfolia, Koch, *Dendrologie*, i. 189 (1869), is similar in the shape of the foliage, but the leaflets are described as being tomentose on both surfaces. This appears to be identical with *Sorbus subserrata*, Opiz, in *Flora*, vii. suppl. 13 (1824): and is said by Ascherson and Graebner to be inconstant as regards the union of the upper leaflets.

2. *Pyrus decurrens*, Ascherson and Graebner, *op. cit.* 106 (1906).

Pyrus lanuginosa, Hort. (not De Candolle²).

Sorbus decurrens, Hedlund, *op. cit.* 49 (1901).

A small tree. Leaflets tomentose beneath, more or less decurrent on the rachis; the upper three, five, or seven leaflets united into one segment.

This is represented at Kew by a tree about 25 ft. high, which is of considerable age, and apparently less vigorous in growth than *P. Aucuparia*.

DISTRIBUTION

P. Aucuparia is widely distributed throughout almost all Europe;³ but does not occur in Portugal, southern Spain, southern Italy,⁴ Dalmatia, and Greece. It is most common in northern regions, extending as far north as Iceland, the North Cape, and the Kola Peninsula; but is reduced to a low shrub beyond lat. 67° in

¹ *Pyrus pinnatifida*, Ehrhart, described in Vol. I. p. 163, is usually considered to be a hybrid between *P. Aucuparia* and *P. intermedia*; but Schneider, *Laubholzkunde*, i. 691 (1906), who describes it under the name *Sorbus hybrida*, Linnæus, believes it to be a true species, as it comes true from seed.

² Cf. var. *lanuginosa*, p. 1577.

³ The mountain ashes resembling *P. Aucuparia* in the Caucasus, Siberia, and western Himalayas, are considered to be three distinct species by Schneider and by Hedlund.

⁴ *P. pramorsa*, Gussone, *Fl. Sicul. Syn.* i. 561 (1842), is considered by Schneider to be a distinct species, inhabiting Sicily and the Madeira Islands.

Scandinavia and Russia. In Russia, it is widely spread in the forests of the plains, but does not occur south of a line passing through Orenburg, Tambof, Voronej, Kursk, and Podolia. In Germany, it grows on all soils, forming part of both the broad-leaved and coniferous forests, and often ascends to timber line, attaining an altitude of 4000 to 5000 feet. It reaches still higher elevations in the Carpathians and the mountainous districts of the Balkan states. In France it is more common in hilly and mountainous regions, often becoming a bush on elevated precipices; but occurs in a few forests in the plains of the north. In the British Isles it is probably indigenous only in mountainous and hilly districts, though it is seen as a rare tree in woods as far south as the Isle of Wight. It ascends in the Highlands to about 2600 feet. This species has been found in the fossil state,¹ in neolithic deposits at Caerwys, Flintshire. (A. H.)

CULTIVATION

Though the mountain ash in England is usually not over thirty or forty feet high, yet it has a tree-like rather than a bushy habit, and is so beautiful for its fruit and for the elegance and autumnal colours of its foliage, that it should be planted on the edges of all copses, and in hedges and pleasure grounds. No native tree surpasses it in the autumn when laden with its red berries, and though birds are so fond of these that they are mostly eaten before winter, yet where the tree is abundant, it is one of the most beautiful features of the scenery. To see its foliage at its best, one must however, go to more northern regions such as Norway, where I have seen the hillsides absolutely scarlet with it in the first week of October, mixed with the silver bark and golden leaves of the birch and aspen.

It is so easy to raise from seed, which should be sown when ripe, or treated like haws, and so indifferent as to soil and situation that it may be planted almost anywhere, but usually grows best in mountainous and northern regions.

The finest trees which I have seen are at Walcot, Shropshire, where in 1905 I measured a well-shaped specimen 56 ft. by 6½ ft. with a clean bole 20 ft. long, and at Stratton Strawless, Norfolk, where in 1907 I saw a tree 56 ft. by 5 ft., the trunk of which was covered by large burrs. Though Loudon says that the largest trees of this species are in the West Highlands, yet I have never seen or heard of any equal to those mentioned above.

In Norway where it is almost everywhere a common tree, and is called *Rogn*, the bark is the favourite winter food of the elk, and the fruits are very much liked by bears, so that in districts where these animals are found the tree becomes comparatively scarce. The largest that I have seen were rarely 30 to 40 ft., though Schübeler mentions one near Christiania 48 ft. high. He illustrates² a good wild tree at Akureyri, in Iceland, which shows that even in this inhospitable and treeless land the species thrives well.

No tree is more commonly seen as an epiphyte in this country than the mountain ash, whose berries are often dropped by birds on the decaying branches

¹ Cf. C. Reid, *Origin British Flora*, 119 (1899).

² *Vaestlivet i Norge*, 92, fig. 42 (1879).

1580 The Trees of Great Britain and Ireland

or crowns of other trees, where they grow and flourish; sometimes attaining a considerable size and age, and sending their roots down to the ground. The best example I have seen of this is in Glenaffric, Inverness-shire, where an immense old alder tree about 19½ ft. in girth had been split to the ground by a rowan (known in Gaelic as *cuern*), which had commenced life in its head and was 4½ ft. in girth in 1910. Mr. Stephenson Clarke, the lessee of Glenaffric forest, told me of this tree, which he has photographed.

A good many superstitious ideas as to the value of this tree as an antidote to witchcraft are said by Loudon and others to have been formerly prevalent; but these are now dying out except in remote districts.

The wood is hard, heavy, and close-grained, of a grey or whitish colour, and so tough and strong that it was formerly used for bows¹; but though well suited for tool-handles, hoops, and even for chair-making, it is rarely used in this country.

(H. J. E.)

¹ Evelyn, *Sylva*, 68 (1679), who calls it quickbeam or witchin.

MAGNOLIA

Magnolia, Linnæus, *Sp. Pl.* 535 (1735); Bentham et Hooker, *Gen. Pl.* i. 18 (1862); Nicholson, in *Gard. Chron.* xvii. 515 (1895); Rehder, in Bailey, *Cycl. Amer. Hort.* 964 (1900); Schneider, *Laubholzkunde*, i. 328 (1905).

DECIDUOUS or evergreen trees and shrubs, belonging to the order Magnoliaceæ. Leaves alternate, simple, stalked, entire, with pinnate lateral nerves, which unite and loop before reaching the margin; in most species punctate with translucent dots; petiole channelled at the base, marked with two linear scars, continuous with an annular scar around the branchlet, due to the early fall of the two connate stipules,¹ which, adnate to the petiole, formed a cylindrical sheath in the bud.

Flowers perfect, large, solitary, terminal; sepals and petals imbricate in the bud, inserted under the ovary; sepals three, often similar to the petals in size and colour, occasionally smaller and greenish; petals six, nine, or twelve, in two, three, or four rows; stamens and pistils numerous, imbricated, the stamens below the pistils on an elongated receptacle; ovary sessile, one-celled; style short, recurved, stigmatic on the inner surface; ovules, two. Fruit cone-like, composed of numerous coalesced two-seeded follicles, dehiscent on the back; seeds on long stalks, with a red or scarlet outer coat, and a minute embryo, situated at the base of the fleshy albumen.

About twenty-five species of *Magnolia* are known, natives of North America, China, Japan, Assam, and the Himalayas. The following key comprises the species, which are cultivated in the open air in this country:—

I. *Leaves evergreen, coriaceous.*

1. *Magnolia grandiflora*, Linnæus. United States. See p. 1583.

Branchlets rusty tomentose. Leaves obovate-oblong, acuminate at the apex, more or less covered beneath with brownish tomentum.

2. *Magnolia Delavayi*, Franchet. China. See p. 1592.

Branchlets glaucous, minutely pubescent. Leaves ovate-oblong or elliptic, mucronate at the apex, glaucous with scattered pubescence beneath.

II. *Leaves sub-evergreen, falling before the young leaves appear in the following spring, bluish white and pubescent beneath.*

3. *Magnolia glauca*, Linnæus. United States. See p. 1585.

Branchlets glabrous. Leaves elliptic or oblong-lanceolate, rounded or acute at the apex.

¹ Cf. Lubbock, in *Journ. Linn. Soc. (Bot.)* xxx. 466 (1895).

4. *Magnolia Thompsoniana*, Koch. A hybrid. See p. 1585.

Branchlets glaucous, with a few hairs at the insertion of the leaves. Leaves obovate-elliptic, acute at the apex.

III. *Leaves deciduous in autumn.*

* *Leaves cordate at the base.*

5. *Magnolia Fraseri*, Walter. United States. See p. 1590.

Branchlets glabrous. Leaves obovate, deeply cordate and auricled at the base, pale or light green beneath.

6. *Magnolia macrophylla*, Michaux. United States. See p. 1589.

Branchlets densely pubescent. Leaves obovate-oblong, cordate or subcordate at the broad truncate base, bluish white beneath.

** *Leaves not cordate at the base.*

(a) *Leaves large, with more than twenty pairs of lateral nerves.*

7. *Magnolia tripetala*, Linnæus. United States. See p. 1588.

Branchlets glabrous. Leaves membranous, obovate-oblong, tapering towards the base and apex, pale with a scattered minute pubescence beneath.

8. *Magnolia hypoleuca*, Siebold and Zuccarini. China and Japan. See p. 1592.

Branchlets glabrous. Leaves coriaceous, obovate, acute or cuspidate at the apex, bluish grey with scattered white hairs beneath.

- (b) *Leaves moderate or small in size, with less than twenty pairs of lateral nerves.*

† *Leaves pale beneath.*

9, 10. *Branchlets pubescent.*

9. *Magnolia acuminata*, Linnæus. Ontario, United States. See p. 1586.

Large tree. Leaves oval, acuminate at the apex, pubescent on both surfaces; lateral nerves, twelve to fifteen pairs.

10. *Magnolia parviflora*, Siebold and Zuccarini. Japan. See p. 1598.

Shrub. Leaves obovate, acuminate at the apex, glabrous above, minutely pubescent beneath; lateral nerves about nine pairs.

11-13. *Branchlets glabrous.*

11. *Magnolia Campbelli*, Hooker and Thomson. Eastern Himalayas. See p. 1590.

Branchlets glaucous. Leaves narrowly elliptic, acuminate, pale with a bluish tint and glabrous beneath.

12. *Magnolia Watsoni*, Hooker. Japan (?). See p. 1598.

Leaves obovate, acute at the apex, greyish beneath, with scattered appressed hairs.

13. *Magnolia salicifolia*, Maximowicz. Japan. See p. 1595.

Leaves lanceolate, tapering to an acuminate and often curved apex; pale with a bluish tint and minutely pubescent beneath.

†† *Leaves green beneath.*

14. *Branchlets glabrous.*

14. *Magnolia Kobus*, De Candolle. Japan. See p. 1594.

Leaves obovate, cuspidate at the apex, tapering at the base, with axil-tufts of pubescence beneath.

15-17. *Branchlets pubescent.*

15. *Magnolia denudata*, Thunberg. China. See p. 1597.

Branchlets with silvery appressed pubescence at the tip, elsewhere glabrous. Leaves obovate or oval, and broadest at the middle, acute or shortly acuminate at the apex, tapering at the base.

16. *Magnolia conspicua*, Salisbury. China. See p. 1596.

Branchlets more or less covered with appressed pubescence. Leaves obovate, cuspidate at the apex, usually rounded at the base.

17. *Magnolia stellata*, Maximowicz. Japan. See p. 1599.

Branchlets more or less covered with appressed pubescence. Leaves obovate-oblong or oblanceolate, gradually tapering to the base, variable at the apex.

(A. H.)

MAGNOLIA GRANDIFLORA

Magnolia grandiflora, Linnæus, *Syst.* ii. 1082 (1759); Loudon, *Arb. et Frut. Brit.* i. 261 (1838); Sargent, in *Bot. Gaz.* xlv. 226 (1907).

Magnolia foetida, Sargent, in *Garden and Forest*, ii. 615 (1889), *Silva N. Amer.* i. 3, tt. 1, 2 (1890), and *Trees N. Amer.* 316 (1905).

An evergreen tree, attaining in America 60 to 80 ft. high, with a straight trunk occasionally 12 ft. in girth. Bark with thin appressed scales. Young branchlets covered with rusty red tomentum. Leaves coriaceous, persistent two years, 6 to 8 in. long, 2 to 3 in. wide, obovate-oblong or narrowly elliptic, with a short acuminate apex; upper surface dark green, shining, glabrous; lower surface covered more or less with a rusty brown tomentum, or occasionally glabrescent.

Flowers, on stout tomentose stalks, fragrant, 7 to 8 in. across; the three petaloid sepals and six (rarely nine to twelve) petals creamy white, ovate or oval, narrowed at the base. Fruit rusty tomentose.

Several varieties¹ have originated in European nurseries:—

1. Var. *exoniensis*, Loudon. Rather fastigiate in habit, with broadly elliptical leaves, rusty tomentose beneath. It begins to flower when only a few feet high. This variety appears to differ scarcely from var. *lanceolata*, Aiton,² *ex* Sims, *Bot. Mag.* t. 1952 (1818), though Loudon kept it distinct.

2. Var. *angustifolia*, Loudon. Leaves lanceolate, undulate in margin. Introduced from Paris in 1825.

3. Var. *Gallissoniensis*, Simon-Louis, *Cat.* 59 (1869). According to Rehder,³ this variety has proved the hardiest in Europe; and Mouillefert⁴ says that it makes the finest standard tree.

4. A variety with double flowers is known; and this peculiarity has been observed as a sport on a tree of the ordinary kind in England.⁵

M. grandiflora is a native of the south-eastern United States, extending from North Carolina along the coast to Florida, and westward through the Gulf States to

¹ Dr. J. Bedelian of Nikita, in the Crimea, writes concerning the great variability of this species in *Gard. Chron.* xlii. 390 (1907). Cf. also *ibid.* xliii. 83 (1908).

² In Bailey, *Cycl. Amer. Hort.* 968 (1900).

³ *Traité des Arbres*, i. 112 (1892).

⁴ Cf. *Gard. Chron.* viii. 223 (1890).

⁵ Cf. *Gard. Chron.* viii. 223 (1890).

the Brazos river in Texas, ascending in the Mississippi valley to southern Arkansas and the mouth of the Yazoo river. It is best developed in the forests of western Louisiana, where it is one of the most characteristic trees. It usually grows in rich moist soil on the borders of river swamps and of the ponds in the pine-barrens. Plate 353, reproduced from a photograph kindly sent by Miss Cummings, shows the habit of the evergreen *Magnolia* in North Carolina. (A. H.)

The date of introduction is somewhat uncertain, but it is supposed on good authority to have been grown at Exmouth by Sir John Colliton before 1737, and a tree there, of which a long account is given in *Gardener's Magazine*, xi. 70 (1835), was for many years the parent by layering of great numbers of plants, and was cut down by mistake in 1794.

This tree surpasses all others in the temperate zone except perhaps the Himalayan *M. Campbelli*, in the beauty, size, and fragrance of its flowers; but being a native of more southern climates, it only succeeds without protection in the warmest parts of Great Britain, and even then is but a poor and stunted tree compared to what it is in south-western France, Portugal, and Italy.

Though rarely planted as a standard tree we have seen it up to 20 to 30 ft. high in a few places, the best perhaps being at Powderham Castle. It was, however, reported¹ in 1894 to be 36 ft. high by 4 ft. 8 in. in girth at East Cowes Castle, and 50 ft. by 5 ft. at Rozel Bay, Jersey. A tree at Gunnersbury House measured 31 ft. by 2 ft. 8 in. in 1911. There are two trees in the Azalea garden at Kew, about 23 ft. high; and a fine specimen trained against the Museum, which is about 35 ft. high.

On a wall even in cold parts of England it has survived a temperature below zero, though it only flowers after two good seasons, and then often so late that the flowers are cut off by early frosts. Though it sets seeds in hot summers, I am not aware that they ever ripen here; and plants which I have raised from foreign seed grow slowly and want greenhouse treatment for some years.

The largest trees that I have seen in Europe of this species are in the garden of Baron Soutelinho (Mr. A. Tait) at Oporto, one of which, now nearly dead, was 11½ ft. in girth, and another, also showing signs of decay, was 62 ft. by 11 ft. A third with a fine stem clean of branches to 35 ft. was in perfect vigour and 60 ft. by 7 ft. in 1909. In France the largest that I know are in the public gardens of Bordeaux, one of which, that had been transplanted when already an old tree, was 59 ft. by 6 ft. 3 in. in 1909.

On the Isola Madre in Lake Maggiore, I measured a tree in 1906 which was 70 ft. by 6 ft. 9 in. and ripened seed freely.

Sargent says that this species has the hardest, heaviest, and best wood of the American *Magnolias*, but it is little used, even in the United States, and hardly known in commerce. I believe, however, that some of it is mixed with the so-called canary or white wood (*Liriodendron*), and is not easy to distinguish without careful examination. It is a close-grained wood of pale creamy yellow, or brownish yellow colour, showing a minute silver grain, and looks as if it would take a fine polish.

(H. J. E.)

¹ *Gard. Chron.* xvi. 286, 375 (1894).

MAGNOLIA GLAUCA

Magnolia glauca, Linnæus, *Syst.* ii. 1082 (1759); Loudon, *Arb. et Frut. Brit.* i. 267 (1838); Sargent, *Silva N. Amer.* i. 5, t. 3 (1890), and *Trees N. Amer.* 317 (1905).

A tree, occasionally attaining in America 50 to 70 ft. in height and 10 ft. in girth, but usually much smaller. Branchlets slender, glabrous. Leaves remaining on the branches usually throughout the winter till the young leaves appear in spring, but in England some fall earlier; elliptical or oblong-lanceolate, about 4 inches long and 2 in. broad, rounded or acute at the apex; thin in texture; upper surface bright green, shining, glabrous; lower surface bluish white and covered more or less with fine white pubescence.

Flowers, on slender glabrous stalks, creamy white, fragrant, globose, 2 to 3 in. across; sepals membranous and shorter than the nine or twelve obovate petals. Fruit pink, 2 in. long, glabrous.

1. Var. *longifolia*, Loudon. This variety, which I have not seen, is said by Sargent to have lanceolate leaves, and to continue flowering for a period of two or three months. According to Loudon, it originated in Belgium, and was considered to be of hybrid origin.

2. The following is usually considered to be a hybrid, between *M. glauca* and *M. tripetala*:—

Magnolia Thompsoniana, Koch, *Dendrologie*, i. 369 (1869); Sargent, in *Garden and Forest*, i. 269, fig. 43 (1888).

Magnolia glauca, var. *major*, Sims, *Bot. Mag.* t. 2164 (1820).

Magnolia glauca, var. *Thompsoniana*, Loudon, *Arb. et Frut. Brit.* i. 267 (1838).

Magnolia major, Schneider, *Laubholzkunde*, i. 334 (1905).

A small tree. Young branchlets glaucous, glabrous except for a few hairs at the insertions of the leaves. Leaves obovate-elliptic, 6 to 8 in. long, 1½ to 3 in. wide, acute at the apex; upper surface light green, glabrous except for pubescence on the midrib; lower surface whitish, with a greyer tint than *M. glauca*, covered more or less with a fine pubescence. Flowers white, fragrant, 5 to 6 in. across; sepals shorter than the petals, greenish, reflexed as in *M. tripetala* when the flower opens, and not so early deciduous as in *M. glauca*; petals nine, obovate-oblong, contracted into a narrow claw.

According to Sabine,¹ this was raised in Thompson's nursery at Mile End in 1808, in which year the *Magnolias* fruited freely. A tree of *M. tripetala* was growing close to the tree of *M. glauca*, from which the seed was obtained that gave rise to the new plant. The latter has much larger flowers than those of *M. glauca* and in some respects shows the influence of *M. tripetala*.

M. Thompsoniana, like some hybrids, is hardier than either of the parents, being much less liable to injury from spring frosts, and is commoner in cultivation than *M. glauca*. (A. H.)

¹ In *Trans. Hort. Soc.* iii. 205 (1823).

M. glauca is a native of the eastern parts of the United States, where it is known as Sweet or Swamp Bay, being an evergreen tree in the south, and becoming deciduous in the north. It occurs in one or two stations in Massachusetts and Long Island, and is distributed along the coast from New Jersey to Florida, ranging inland to Franklin County in Pennsylvania; and extending through the Gulf States to south-western Arkansas and Trinity River in Texas. It usually grows in swamps and along the borders of the ponds in the pine barrens; and attains its largest size in Florida.

This species was introduced by Banister, who sent it to Bishop Compton, at Fulham, in 1688. Loudon mentions several places in England where it was cultivated in 1838, and states that it frequently ripened seed. It is now a rare tree, seldom seen¹ except in botanic gardens. The finest specimen that we know is at White Knights, an old tree about 30 feet high in 1905. It is said by Sargent to grow better when grafted on stocks of *M. acuminata* than on its own roots. (H. J. E.)

MAGNOLIA ACUMINATA, CUCUMBER TREE

Magnolia acuminata, Linnæus, *Syst.* ii. 1082 (1759); Sims, *Bot. Mag.* t. 2427 (1823); Loudon, *Arb. et Frut. Brit.* i. 273 (1838); Sargent, *Silva N. Amer.* i. 7, tt. 4, 5 (1890), and *Trees N. Amer.* 319 (1905).

A deciduous tree, attaining in America 60 to 90 ft. in height, and 10 to 12 ft. in girth. Bark $\frac{1}{2}$ in. thick, furrowed, scaly. Young branchlets, with dense appressed whitish pubescence towards the base, elsewhere with scattered long hairs. Leaves oval, 6 to 9 in. long, 4 to 5 in. broad, acuminate at the apex, broad and rounded or cuneate at the base; upper surface dark green, dull, with a scattered minute pubescence on the surface, denser on the midrib; lower surface pale, with scattered wavy white hairs; petiole pubescent.

Flowers on pubescent stalks, campanulate, greenish yellow or glaucous green, about 2 to $3\frac{1}{2}$ in. long; sepals membranous, soon reflexed; petals six, ovate or obovate, pointed, upright, those of the outer row much broader than those of the inner row. Fruit glabrous, dark red, 3 in. long.

In winter the branchlets are reddish, glabrous; marked with V-shaped six-dotted leaf-scars, the two apices of which are continuous with a linear scar encircling the stem and indicating the fall of the stipule. Buds surrounded by a single scale, pubescent with silky hairs, the terminal bud much larger than the lateral buds.

1. Var. *cordata*, Sargent, in *Amer. Journ. Science*, xxxii. 473 (1886), *Silva N. Amer.* i. 8, t. 6 (1890), and *Trees N. Amer.* 320 (1905).

Magnolia cordata, Michaux, *Fl. Bor. Amer.* i. 328 (1803); Loudon, *Arb. et Frut. Brit.* i. 275 (1838).

A small tree, with leaves more greyish pubescent beneath than in the type, and rarely cordate at the base. Flowers smaller, bright canary yellow.

¹ Bunbury, *Arb. Notes*, 55 (1889), states that two trees planted at Barton, Suffolk, in 1861, died in a few years.

This variety is said by Loudon to have been brought from America¹ by Lyon in 1801, the original tree in Loddiges' nursery being about 15 ft. high in 1838. No wild tree exactly similar to this variety has been discovered; but forms approaching it in the pubescence and shape of the leaves and in the small size and colour of the flowers have been found on the Blue Ridge in South Carolina, and in central Alabama. We have seen no large specimens in England. Bean² saw at Herrenhausen, Hanover, a tree 35 ft. high by 3 ft. 1 in. in 1908. (A. H.)

DISTRIBUTION AND CULTIVATION

M. acuminata extends from western New York and southern Ontario, where Macoun gives the Niagara Falls as its only natural station, southward along the Alleghany Mountains, to southern Alabama, Kentucky, Tennessee, Arkansas, and Mississippi. It seems to be rare in the north, and attains its greatest size and abundance only in the rich woods of the lower valleys of east Kentucky and Tennessee.

It was introduced into cultivation in England by Bartram, who sent plants to Peter Collinson in 1736.

It is the only Magnolia which as yet has grown to be a large tree in this country, and seems to require less summer heat, and to endure more severe frost than any of the other American species; but it only becomes a fine tree in warm rich soils in the southern half of England. I am not aware that it has ever ripened seed³ in this country; but Loudon says that seedlings are preferable to plants raised from layers, and that they were used as stocks on which to graft other species of Magnolia. Masters says⁴ that it is one of the very best of trees for towns.

Loudon mentions as the largest specimen known to him, one recently cut down at Thorndon Hall, the seat of Lord Petre in Essex, which was nearly 7 ft. in girth; and there was another in the same park 37 ft. by 7 ft., which survived until 1903. He figures one at Syon 49 ft. high in 1838, which may not be the same as one now growing in the Church Walk there, and recorded by Jackson as 51 ft. 5 in. by 3 ft. 7 in. in girth.

The finest tree known to us (Plate 358) grows at West Dean Park, and when I saw it in 1906 was 60 ft. by 7 ft., with a clean trunk about 25 ft. high. There is a much taller but ill-shaped tree branching near the ground at Albury, which was about 75 ft. high in 1905. At Claremont in 1903 I saw a tree about 55 ft. by $6\frac{1}{2}$ ft., which in 1883 was 40 ft. high. In 1910 Mr. Bean⁵ found it to be 60 ft. high. At The Mote, Maidstone, I measured a handsome tree 68 ft. by 4 ft. 9 in. in 1911. Another standing close to it was 56 ft. by 6 ft.

At Heanton Satchville, in North Devon, in 1905 I saw a straight well-shaped pyramidal tree 57 ft. by 5 ft. 3 in. At Arley Castle there are two fine trees 65 ft.

¹ Sargent, in *Garden and Forest*, 1889, p. 338, states that two specimens in the Harvard Botanic Garden are known to have been fully grown trees in 1842.

² *Kew Bull.* 1908, p. 392.

³ Bunbury, *Arb. Notes*, 55 (1889), says that the fruit always dropped off from the tree at Barton, before it was half ripe.

⁴ *Gard. Chron.* vi. 474 (1889).

⁵ *Kew Bull.* 1910, p. 164.

and 62 ft. high by over 6 ft. girth, which were planted in 1820. At Barton, Suffolk, a tree over 70 ft. high in 1904, when it appeared to be dying at the top, was planted in 1826. This tree was not injured by the severe winter of 1860-1861.

At Westonbirt a tree, 62 ft. by 5 ft. 9 in. in 1906, had been split nearly to the ground, but had been so well repaired by hoops round the trunk, that the two parts were growing together. At Chatsworth, Mr. A. B. Jackson measured in 1908 a tree 50 ft. by 4 ft. 6 in. At Essendon Place, Herts, there is a very narrow slender tree, which Henry found to be 56 ft. high by 3 ft. 4 in. in girth in 1907. At Merton Hall, Norfolk, a tree, which was raised from seed in 1862, measured 50 ft. by 4 ft. 4 in. in 1908. At Nuneham Park, Oxon, there is a tree which was 40 ft. by 4 ft. in 1907. At Fawley Court, Henley, a fine specimen was 40 ft. by 5½ ft. in the same year.

In Scotland, the finest tree we have heard of is one recorded by Hunter¹ as growing in the American garden at Dunkeld, which measured 40 ft. by 3 ft. 4 in. in 1883; but I did not see it when I visited this place in 1906. At Biel, East Lothian, I saw a healthy tree about 30 ft. by 5 ft. in 1911.

In Ireland probably the tallest tree is one at Curraghmore, which Henry found to be 60 ft. by 4 ft. 6 in. in 1907. At Narrow Water Castle, Co. Down, Captain Hall informed us in 1907, that there was a remarkable tree, 41 ft. by 5½ ft. This had not grown in height for some years past, owing to the top catching the wind, but it increased enormously below; and the branches, widely spreading and reaching the ground, now cover an area 192 ft. in circumference.

The tallest tree in Europe, if correctly measured, is probably one at Schloss Dyck, near Dusseldorf, in Germany, which was reported² in 1904 to be 30 metres in height and 2.12 metres in girth.

The wood of this tree resembles that of *M. grandiflora*; but, judging from Hough's specimen, is rather darker in colour, and even more like the wood of *Liriodendron*. Hough says that it is largely used for doors and wainscots, and for bowls, troughs, and wooden ware; but I have never seen this wood in England, or heard of its being imported under its own name. (H. J. E.)

MAGNOLIA TRIPETALA, UMBRELLA TREE

Magnolia tripetala, Linnæus, *Syst.* ii. 1082 (1759); Loudon, *Arb. et Frut. Brit.* i. 269 (1838); Sargent, *Silva N. Amer.* i. 13, tt. 9, 10 (1890), and *Trees N. Amer.* 321 (1905).
Magnolia umbrellata, Lamarck, *Encycl.* iii. 673 (1789).
Magnolia frondosa, Salisbury, *Prod.* 379 (1796).

A deciduous tree, attaining in America 30 to 40 ft. in height and 5 ft. in girth. Young branchlets glabrous. Leaves, variable in size, usually 12 to 20 in. long and 6 to 8 in. broad, obovate-oblong, tapering towards the base and apex, the latter ending in an acuminate point; upper surface green, glabrous; lower surface pale, with a scattered minute pubescence, densest on the midrib and nerves. In winter,

¹ *Woods of Perthshire*, 52 (1883). An old tree at Blair, near Dalry, Ayrshire, is said by the gardener to flower annually and to have been 45 ft. high in July 1912.

² *Mitt. Dent. Dend. Ges.* 1904, p. 19.

the glabrous branchlets¹ have broad oval leaf-scars, with numerous dots arranged in two or three series. The buds are glabrous, glaucous.

Flowers on slender glaucous glabrous stalks, cup-shaped, eight to nine inches across, disagreeable in odour; sepals light green, becoming reflexed; petals, six or nine, coriaceous, white, ovate, pointed, those of the outer row much longer and broader than those of the inner rows. Fruit, 2½ to 4 in. long, glabrous, pink.

This species, which has the leaves crowded at the summits of the flowering branches, is widely distributed in the region of the Alleghany Mountains, from the valley of the Susquehanna River in Pennsylvania southwards to Kentucky, Alabama, Tennessee, north-eastern Mississippi, and Arkansas, and extending nearly to the coast in the south Atlantic States. It usually grows on the banks of mountain streams or on the edges of swamps. (A. H.)

This species was introduced into England in 1752, and seems to have been commoner in Loudon's time than it is now. He mentions trees at Cobham (Kent), Syon, Golden Grove, Croome, and Walton House, 30 to 36 ft. high, which cannot now be found; and states that at Deepdene self-sown seeds had produced plants. We have only seen a few small trees, none of which look very thriving, at Kew; Holkham; Stanage Park, Herefordshire; and Canford, Hants. (H. J. E.)

MAGNOLIA MACROPHYLLA

Magnolia macrophylla, Michaux, *Fl. Bor. Am.* i. 327 (1803); Loudon, *Arb. et Frut. Brit.* i. 271 (1838); Sargent, *Silva N. Amer.* i. 11 tt. 7, 8 (1890), and *Trees N. Amer.* 320 (1905).

A deciduous tree, attaining in America 30 to 50 ft. in height and 5 ft. in girth. Young branchlets covered with a dense short pubescence, retained in part in the second year. Leaves, the largest of any of the species in cultivation, 12 to 25 in. long, 6 to 10 in. broad, obovate-oblong, acute or acuminate at the apex, cordate or subcordate at the truncate base; upper surface bright green, glabrous; lower surface bluish white, with a scattered fine pubescence, which is denser on the midrib.

Flowers, on stout tomentose stalks, white, cup-shaped, fragrant, 10 to 12 in. across when expanded; sepals membranous, much narrower than the six ovate concave thick creamy white petals, which become reflexed above the middle. Fruit pubescent, pink, nearly 3 in. long. (A. H.)

This species is a rare tree in the south-eastern United States, occurring from North Carolina and south-eastern Kentucky, southwards to Florida, Alabama, Mississippi, Louisiana, and central Arkansas. It usually grows in sheltered valleys in deep rich soil.

It was introduced into England in 1800. None of the trees at Arley, Chiswick, and White Knights, mentioned by Loudon, can now be found; but there is a fine specimen at Claremont, which, in 1910, was 40 to 45 ft. in height, and 2 ft. 11 in. in girth.² (H. J. E.)

¹ Cf. Foerste, in *Bot. Gaz.* xx. 80, t. 8 (1895).

² Bean, in *Kew Bull.* 1910, p. 163.

MAGNOLIA FRASERI

Magnolia Fraseri, Walter, *Fl. Carol.* 159 (1788); Sargent, *Silva N. Amer.* i. 15, tt. 11, 12 (1890), and *Trees N. Amer.* 322 (1905).

Magnolia auriculata, Lamarck, *Ency.* iii. 645 (1789); Loudon, *Arb. et Frut. Brit.* i. 276 (1838).

Magnolia auricularis, Salisbury, *Parad. Lond.* i. t. 43 (1806).

A tree, attaining in America 40 ft. in height and 4 ft. in girth, often dividing near the base into diverging stems. Young branches glabrous. Leaves 8 to 12 in. long, 5 to 6 in. wide, obovate, acute at the apex, deeply cordate and auricled at the base; both surfaces and petiole glabrous; pale beneath.

Flowers on stout glabrous glaucous stalks, opening after the leaves, cream-white, sweet-scented, 6 to 9 in. across; sepals quickly deciduous; petals six or nine, obovate, acuminate, membranous, contracted below the middle. Fruit glabrous, pink, 4 to 5 in. long, the ripe carpels ending in long subulate persistent tips.

1. Var. *pyramidata*, Nuttall, *Gen. N. Amer. Plants*, ii. 18 (1818).

Magnolia pyramidata, Pursh, *Fl. Amer. Sept.* ii. 382 (1814); Edwards, in *Bot. Reg.* t. 407 (1819); Sargent, *Trees and Shrubs*, iii. 101 (1903), and *Trees N. Amer.* 323 (1905).

Flowers much smaller than in the type, 3 to 4 in. across. Fruit, 2 to 2½ in. long, the ripe carpels ending in short incurved persistent tips.

This variety occurs in rich alluvial soil in the coast region from southern Georgia through western Florida to southern Alabama. It was introduced into Loddiges' nursery by Lyon in 1818.

M. Fraseri is a native of the southern Alleghany Mountains, from southwestern Virginia to northern Georgia and Alabama, eastern Tennessee, and northern Mississippi; most abundant and of its largest size on the upper waters of the Savannah River in South Carolina. The typical form is a native of mountain valleys.

M. Fraseri was introduced into England in 1786; and seems to be very uncommon. A tree at Kew, which belongs to var. *pyramidata*, is about 20 feet high; and produces small flowers freely from the middle of May to the end of June, which are almost yellow at the time of opening, becoming a rich cream colour as they fade. At Leonardslee,¹ it succeeds in a sheltered position. (A. H.)

MAGNOLIA CAMPBELLI

Magnolia Campbelli, J. D. Hooker and Thomson, in J. D. Hooker, *Illustr. Him. Plants*, tt. 4, 5, (1855); J. D. Hooker, *Fl. Brit. India*, i. 41 (1872), and in *Bot. Mag.* t. 6793 (1885); King, in *Ann. Bot. Gard. Calcutta*, iii. pt. 2, p. 208, tt. 51, 52 (1891); Gamble, *Indian Timbers*, 9 (1902).

A large deciduous tree, attaining occasionally in the Himalayas 150 ft. in height, and 12 to 20 ft. in girth. Young branchlets glabrous, glaucous. Leaves

¹ *Gard. Chron.* xli. 223 (1907).

membranous, narrowly elliptic, 4 to 8 (rarely 12) in. long, 2 to 3 (rarely 4) in. broad, shortly acuminate at the apex, slightly pubescent when young, but glabrous on both surfaces when mature, light green above, pale beneath; petioles glabrous.

Flowers appearing before the leaves, globose, 6 to 10 in. across, delicately scented, deep rosy pink¹ externally, cream-white internally; sepals three, similar in shape and colour to the nine or twelve petals, all elliptic-oblong, and rounded at the apex. Fruit about six inches long, cylindrical, with red seeds. (A. H.)

This species is a native of Sikkim and Bhutan, occurring, according to Gamble and Hooker, at elevations of 8000 to 10,000 ft.; but I have seen it in the Rangirun forest, near Darjeeling, below the road leading to Pashok, which cannot be higher than 7000 ft. Hooker² describes it as a large forest tree with black bark, often 80 ft. high and 12 to 20 ft. in girth; and Gamble says that, according to King, specimens 150 ft. high were common in Sikkim in 1849, but that the demand for building timber and tea-box boards has made large trees scarce. Though the tree itself is not a handsome one, it is impossible to exaggerate its beauty when seen in April standing leafless, but covered with its immense rosy flowers among the chestnuts, oaks, and other trees, in one of the most beautiful forests in the world.

Repeated attempts were made to introduce this species by seed; but on arrival the fleshy albumen was always found decayed and the minute embryo killed. Ultimately, about 1880, living plants were sent to Kew from the Calcutta Botanic Gardens.

It is perfectly hardy at Kew, and has attained a considerable size in the milder parts of this country; but apparently requires a greater degree of heat and moisture in summer, and remains usually in a bushy state. It flowered for the first time in Europe in 1885 in Mr. Crawford's garden at Lakelands, Cork, and was then figured in the *Botanical Magazine*. It has since flowered at several places, as in 1898 at Veitch's nursery³ at Exeter, where it had been growing in the open for twelve years, and at Leonardslee⁴ in 1907, when it was about 20 ft. high. At Abbotsbury,⁵ where it was about 25 ft. high in 1903, it is the earliest of all the species in flower, being two or three weeks in advance of *M. stellata* and *M. conspicua*. A specimen at Belgrove,⁶ Cork, produced 147 flowers in 1903; but the late Mr. Gumbleton stated that in other years either no buds were set or the flowers never opened, having been killed by frosts and cold winds. Nicholson mentions⁷ a fine specimen at Fota, 25 ft. high in 1895, which produced beautiful flowers of a much richer tint than those at Lakelands. (H. J. E.)

¹ The flowers are variable in the depth of the pink hue; and are occasionally white.

² *Him. Journ.* i. 125 (1854), where he mentions that *Rhododendron Dalhousiae* often grows epiphytically upon its branches.

³ *Gard. Chron.* xxiii. 89, fig. 33 (1898).

⁴ *Ibid.* xlii. 3 (1907).

⁵ *Ibid.* xxxiii. 174, fig. 73 (1903). This tree was, when I saw it in July 1912, about 30 ft. high and 2½ ft. in girth.—A. H.

⁶ *Ibid.* xxxiii. 172 (1903) and xlii. 33 (1907).

⁷ *Ibid.* xvii. 515 (1895).

MAGNOLIA DELAVAYI

Magnolia Delavayi, Franchet, *Pl. Delav.* 33, tt. 9, 10 (1889); Sprague, in *Bot. Mag.* t. 8282 (1909).

An evergreen tree, about 30 ft. high. Young branchlets glaucous, minutely pubescent. Leaves coriaceous, persistent two years, ovate-oblong or elliptic, 7 to 12 in. long, and 4 to 7 in. wide, rounded and mucronate at the apex; dull green and glabrous above; lower surface glaucous, with scattered fine pubescence; midrib beneath very prominent and, like the petiole, very stout and more or less pubescent.

Flowers creamy white, fragrant, about 7 in. across; sepals three, oblong, reflexed; petals about seven, spatulate-obovate. Fruit about 5 in. long.

This is a native of Yunnan in south-western China, where I saw it growing in rocky situations and woods at 5500 to 7000 ft. above sea-level. It was introduced by Wilson in 1900; and flowered at Kew in 1908. It is scarcely hardy at Kew,¹ though it thrives against a wall; but it will probably succeed better in the milder parts of England, Wales, and Ireland. Both the foliage and flowers are very handsome. (A. H.)

MAGNOLIA HYPOLEUCA

Magnolia hypoleuca, Siebold and Zuccarini, in *Abh. Ak. München*, iv. pt. ii. 187 (1845); Sargent, in *Garden and Forest*, i. 304, fig. 49 (1888); Matsumura, in *Journ. Coll. Sc. Imp. Univ. Tokyo*,² xii. 284 (1899); Shirasawa, *Icon. Ess. Forest. Japon*, i. text 70, t. 39, figs. 13-29 (1900); Skan, in *Bot. Mag.* t. 8077 (1906); Mayr, *Fremdländ. Wald- u. Parkbäume*, 481 (1906).

A deciduous tree, attaining 100 ft. in height and 10 ft. in girth in Japan. Young branchlets glabrous. Leaves coriaceous, often crowded at the ends of the branches, obovate or obovate-elliptic, about 8 to 15 in. long and 6 to 8 in. broad, acute or cuspidate at the apex: upper surface light green, glabrous; lower surface bluish grey, with scattered curved white hairs, often with dense appressed pubescence on the midrib; petiole pubescent.

Flowers, opening when the leaves are nearly fully grown, very fragrant, 6 to 8 in. across, creamy white or white; sepals coriaceous, tinged with red: petals nine, coriaceous, obovate-spatulate, rounded or cuspidate at the apex. Fruit red, 5 to 8 in. long.

M. hypoleuca is a native of China and Japan. In central and western China it is commonly cultivated around dwellings in mountainous districts at elevations between 2500 and 4500 ft. It is known to the Chinese as *hou-p'o*, its bark³ being esteemed as a valuable drug, which is exported to all parts of China. Neither

¹ Cf. *Kew Bull.* 1909, p. 235. A tree in the Temperate House at Kew is about 20 ft. high.

² Recorded as doubtfully wild in the Liu Kiu Islands.

³ Cf. Hanbury, *Sc. Papers*, 266 (1876), and Bretschneider, *Bot. Sinic.* iii. 472 (1895). Père David, *Journ. Trois. Voy. Chine*, ii. 360 (1875), mentions a large plantation of this tree in the province of Kiangsi.

Wilson nor myself ever found the tree in a wild state in China; but it is probably indigenous in some of the unexplored districts. It is mentioned in the earliest Chinese Herbal, which was compiled about 200 B.C.; and it is extremely unlikely to have been introduced from Japan. (A. H.)

This beautiful tree is called *Honoki* in Japan, where it is most common and attains a large size in the forests of Hokkaido. It also occurs in the mountains of Hondo, at elevations of 2000 to 5500 ft. The largest that I saw were about 100 ft. high, usually with tall clean stems. This species requires a rich moist soil and a considerable rainfall in summer; and produces valuable timber. The wood¹ is firm and uniform in texture, and of a yellowish or greenish white colour, and is largely used for drawing-boards, musical instruments, lacquer work, and many other purposes. It seems very similar to the wood of *M. grandiflora*, and is said to be little subject to warping and splitting. Its charcoal is highly prized in Japan for polishing lacquer-ware and metallic mirrors, and for finishing cutlery.

Though introduced² as long ago as 1865 by Thomas Hogg into the United States, where it has proved hardy in the north, it does not seem to have attracted attention in this country till recently; but on account of its large beautiful leaves, sometimes 2 ft. long, and its fragrant flowers, it is well worth cultivation in the south and west of England. Plants which I raised from seed, grew slowly at first, and for the most part died when planted out, owing, I believe, to the presence of lime in the soil. The oldest tree appears to be one at Grayswood, Haslemere, which was obtained from Yokohama in 1884, and flowered in 1905. A tree at Kew, which flowered in the same year, when it was 14 ft. high, was obtained from Japan in 1890. One at Trewidden, Cornwall, which was planted about 1893, is 30 ft. high by 2½ ft. in girth at one foot from the ground; this produces flowers abundantly; and bore ripe fruit in September 1911. Another at Enys, was about 20 ft. high in 1911. Wilson sent seeds to Messrs. Veitch, who now have the Chinese plant growing in their nursery at Coombe Wood.

In Ireland I have seen it growing well at Baronscourt, Co. Tyrone, the seat of the Duke of Abercorn, where the soil and climate seem to be less favourable than in many parts of Ireland.

This species was raised³ in 1877 from seed in the botanic garden at Heidelberg, and flowered there when about 20 ft. high in 1898. Mayr who had a high opinion of it as a forest tree, suitable for producing good timber quickly in central Europe, introduced it in 1890 into the experimental garden at Grafrath near Munich, where a tree attained 20 ft. in height at ten years old. Schwappach⁴ states that the experimental plots of this species at Eberswalde are very thriving, the trees being 42 ft. high after seventeen years' growth. The growth is rapid in youth, like the ash, which it also resembles in its requirement for space. Schwappach recommends planting it, mixed with oak and beech, on soils suitable to these species. Count Von

² According to *Garden and Forest*, i. 304, fig. 49 (1888), where the figure is taken from a tree in New York, which was 28 ft. high in 1898.

³ *Semaine Horticole*, 1900, p. 199.

⁴ In *Zeitschr. Forst. u. Jagdwesen*. xliii. 604 (1911), and *Mitt. Deut. Dend. Ges.* 1911, p. 12.

Schwerin, who gives a good account¹ of *M. hypoleuca*, states that the seeds, when sent from Japan, dry up and lose their germinating power, unless they are packed in their fleshy covering in charcoal dust or peat powder. (H. J. E.)

MAGNOLIA KOBUS

Magnolia Kobus, De Candolle, *Syst.* i. 456 (1818); Maximowicz, in *Mél. Biol.* viii. 507 (1872); Shirasawa, *Icon. Ess. Forest. Japon.* i. text 71, t. 39, figs. 1-12 (1899); Matsumura in *Journ. Sc. Coll. Imp. Univ. Tokyo*,² xii. 284 (1899); Masters, in *Gard. Chron.* xxxvii. 265, *Supply. Illust.* (1905); Bean, in *Bot. Mag.* t. 8428 (1912).
Magnolia glauca, var. *a.*, Thunberg, *Flora Jap.* 236 (1784).
Magnolia tomentosa, Thunberg, in *Trans. Linn. Soc.* ii. 336 (1794) (in part).

A deciduous small tree. Young branchlets slender, glabrous. Buds pubescent. Leaves membranous, averaging 3 to 5 in. long, and 2 to 3 in. wide, occasionally up to 6 in. long and 4 in. wide; obovate, gradually tapering to the cuneate base, cuspidate-acuminate at the apex; upper surface green, glabrescent, often pubescent on the midrib; lower surface lighter green, with pubescence on the lateral nerves, forming axil-tufts at their junctions with the midrib; margin ciliate; lateral nerves eight to ten pairs; petiole with scattered long hairs.

Flowers, appearing before the leaves, 4 in. across; sepals very small, narrow, quickly deciduous; petals six, obovate, rounded or emarginate at the apex, white, with a purple median line externally. Fruit, dark brown, 4 in. long, often curved and contorted.

1. Var. *borealis*, Sargent, *Trees and Shrubs*, ii. 57 (1908).

Magnolia Kobus, Sargent, in *Garden and Forest*, vi. 64, fig. 11 (1893), and *Forest Flora of Japan*, 9, fig. 3 (1894) (not De Candolle).

A large tree, attaining in Japan 80 ft. in height and 6 ft. in girth, with a straight trunk, covered with dark slightly fissured bark; leaves larger than in the type; flowers with pure creamy white sepals.

This variety, according to Sargent, is a native of Yezo, where it grows plentifully in the forests of the hills around Sapporo. It also occurs in northern Hondo. So far as we know, it is not in cultivation in England.

The typical form of the species is a small tree, about 20 to 30 ft. high, which is occasionally seen at considerable elevations in the Hakkone and Nikko mountains, and is recorded for Fujiyama by Hayata.³ Shirasawa states that the wood is harder than that of *M. hypoleuca*; but owing to the rarity of trees of a large size, is little used. It is known in Japan as *Kobushi*.

M. Kobus was introduced into the United States by Thomas Hogg, and was distributed from Parsons' nurseries under the name *M. Thurberi*. Sargent states that in New England it is the hardiest, most vigorous, and fastest growing of all the Magnolias. Rehder, however, says that it flowers sparingly, and is not showy. A tree in the Arnold Arboretum flowered when fifteen years old.

¹ In *Mitt. Deut. Dend. Ges.* 1904, p. 1.

² Recorded as doubtfully wild in the Liu Kiu Islands.

³ *Vegetation of Mt. Fuji*, 56 (1911).

M. Kobus was introduced into England by Maries in 1879; and one of the original trees¹ at Coombe Wood, which died in 1906, was about 20 ft. high in 1902. Some of the specimens of *M. stellata* at Kew were grafted on stock of *M. Kobus*, obtained from this source. This species was again introduced² about 1887 by Messrs. R. Veitch and Sons, Exeter, who reported that it proved fast in growth, some of the plants, transplanted two or three times, having attained 12 to 14 ft. in height in seven or eight years.

We have seen no large specimens in England, except one at Abbotsbury, which has borne flowers for the past ten years, and was about 25 ft. high in July 1912. A tree at Kew, obtained from Harvard in 1889, is only 15 ft. high. One in Victoria Park, Bath, about 13 ft. high, produced flowers very freely in 1911, but set no fruit.³ In Mr. Thomas Irvine's garden at Newry, there is a fine specimen, planted about twenty-one years ago, which is 18 ft. high. It produces flowers in abundance every year, and is very thriving. (A. H.)

MAGNOLIA SALICIFOLIA

Magnolia salicifolia, Maximowicz, in *Bull. Acad. St. Petersb.* xvii. 418 (1872), and *Mél. Biol.* viii. 509 (1872); Shirasawa, *Icon. Ess. Forest. Japon.* i. text 72, t. 40, figs. 18-31 (1899); Sargent, in *Garden and Forest*, vi. 65, fig. 12 (1893), and *Forest Flora of Japan*, 10, fig. 4 (1894).
Buergeria (?) *salicifolia*, Siebold and Zuccarini, in *Abh. Akad. München*, iv. pt. ii. 187 (1845).

A small deciduous tree, attaining in Japan, about 30 ft. in height and 4 ft. in girth. Bark smooth. Young branchlets glabrous, slightly glaucous. Leaves membranous, lanceolate, 3 to 4 in. long, 1 to 1½ in. broad, gradually tapering to an acuminate and often curved apex, cuneate at the base; upper surface light green, glabrous; lower surface pale, more or less covered with a minute pubescence; punctate with numerous translucent dots; lateral nerves, about twelve pairs, yellowish, as is also the midrib; petiole glabrous.

Flowers campanulate, 3 to 4 in. across; sepals green, much smaller than the petals, spreading, early deciduous; petals six, white, oblong-spatulate, spreading, slightly reflexed at the apex, about 2½ in. long. Fruit narrowly cylindrical, 3 in. long, pale brown; seeds compressed, triangular, almost black.

This little-known species is a native of Japan, where it grows in mountain forests in Hondo, at 2000 to 5000 feet elevation. It was introduced⁴ in 1892 into the Arnold Arboretum by Professor Sargent, who collected seed on Mount Hakkoda; and is represented at Kew by a small specimen obtained from Yokohama in 1906. This, as well as a shrub at Arley, flowered⁵ for the first time in 1912. The flowers are handsome and fragrant. (A. H.)

¹ Note in Arboretum Herbarium, Kew. It is impossible to say whether Maries's introduction was typical *M. Kobus* or var. *borealis*; but all the specimens which we have seen in cultivation belong to the former.

² *Gard. Chron.* xxxvii. 265, *Supply. Illust.* (1905).

³ It was reported, in *Gard. Chron.* xxxvi. 322 (1904), to have produced fruit, when about 8 ft. high in 1904.

⁴ It is mentioned in Veitch's *Catalogue of Trees and Shrubs*, 1902, p. 45.

⁵ Cf. *Gard. Chron.* li. 222, 245, fig. 99 (1912).

MAGNOLIA CONSPICUA

Magnolia conspicua, Salisbury, *Parad. Lond.* t. 38 (1806); Sims, *Bot. Mag.* t. 1621 (1814); Loudon, *Arb. et Frut. Brit.* i. 278 (1838).

Magnolia precia,¹ Correa, in Ventenat, *Jard. Malm.* 24, note 2 (1803); Schneider, *Laubholzkunde*, i. 331 (1905).

Magnolia yulan, Desfontaines, *Hist. Arb.* ii. 6 (1809).

A deciduous tree, attaining in China 30 to 50 ft. in height. Young branchlets more or less covered with appressed white pubescence. Leaves obovate, or obovate-oblong, about 4 to 6 in. long and 2½ to 4 in. wide, cuspidate-acuminate at the apex, usually rounded and unequal at the base; upper surface light green, more or less covered with a minute pubescence, dense on the midrib and nerves; lower surface lighter green, similarly pubescent with longer white hairs; minutely punctate with translucent dots; network of veins beneath wrinkled and prominent; petiole pubescent.

Flowers, appearing in spring before the leaves, campanulate, sweet-scented, about six inches across, pure white; sepals resembling the petals; petals six, fleshy, concave, oblong-obovate or spatulate. Fruit brownish, 3 to 6 in. long.

Numerous varieties² of this species have arisen in cultivation in Europe, which are supposed to be of hybrid origin.

1. *Magnolia Soulangiana*, Soulange-Bodin, in *Ann. Soc. Hort. Paris*, 1826, p. 90.

Magnolia conspicua, var. *Soulangiana*, Lindley, in *Bot. Reg.* t. 1164 (1828); Loudon, *Arb. et Frut. Brit.* i. 278 (1838).

Leaves similar to those of *M. conspicua*; but usually narrower in proportion to their length, longer acuminate at the apex, and tapering at the base. Flowers, later in opening, fragrant, delicate green at first, the sepals and petals becoming white inside, and purplish outside.

This was raised about 1820 at Fromont, near Paris, from the seeds of a plant of *M. conspicua*, which stood near one of *M. denudata*, in front of the château of M. Soulange-Bodin; the flowers of the former, it was supposed, being fertilised by the pollen of the latter. It resembles *M. denudata* in the later opening and colour of the flowers.

2. *Magnolia Lennei*, Topf, ex Van Houtte, *Flore des Serres*, xvi. tt. 1693, 1694 (1867). Leaves similar to those of *M. conspicua*, broadly obovate-oval, but with a longer acuminate apex, and tapering at the base. Flowers, appearing with the leaves, deep crimson outside, very fragrant.³ This originated in the Salvi Garden at Vicenza in Italy; and was sent from there in 1850 to Topf, at Erfurt, who named it after Lenné, director of the Potsdam Garden. Whether it is a seedling of *M. conspicua* or of *M. Soulangiana* is unknown.

¹ This name was published without any description, and cannot therefore be used, although the earliest.

² Var. *purpurascens*, Maximowicz, in *Mit. Biol.* viii. 509 (1872), is a variety with purple flowers, cultivated in Japan.

³ According to *Gard. Chron.* xxvi. 379 (1899), it produced, in 1893 and 1899, pink fruit with orange seed at Straffan, Kildare. It ripened fruit in 1911 at Enys in Cornwall.

Var. *rosea grandiflora* was raised from a seed of *M. Lennei*, and is one of the most beautiful varieties.

3. Numerous other hybrids are in cultivation, which mainly differ in colour and time of flowering, as var. *Alexandrina*,¹ var. *Norbertiana*, and var. *nigra*.²

M. conspicua is a native of China, where it has been found wild in the mountainous districts of Hupeh and Szechwan. It is cultivated extensively by the Chinese, who call it *yü-lan*; and it is mentioned in their earliest literature. It is not considered to be a native of Japan, where it was probably introduced from China by the early Buddhist monks.

It was introduced into England by Sir Joseph Banks in 1789: and is commonly cultivated for its beautiful flowers, which appear in spring the earliest of all the species, except *M. stellata* and *M. Campbellei*. The flowers are liable to be injured by frosts and cold east winds. The finest specimen is probably one³ at Gunnersbury House, which was 31 ft. high by 2½ ft. in girth in 1911. A tree, said⁴ to be over seventy years old, and about 25 ft. high, was growing at Slocock's Nursery at Woking, in 1898, and bore flowers described as pure white suffused with purple. A fine specimen at La Fantaisie, Jersey, is figured in *Gard. Chron.* xxxvi. 59, fig. 25 (1904). One trained against the wall of Hornby Grange, Northallerton, and 30 ft. high, was reported⁵ to have borne 2000 flowers in 1896. (A. H.)

MAGNOLIA DENUDATA

Magnolia denudata,⁶ Lamarck, *Encycl.* iii. 675 (1789); Schneider, *Laubholzkunde*, i. 330 (1905).

Magnolia obovata, Thunberg, in *Trans. Linn. Soc.* ii. 336 (1794) (Excl. *Icon. Kaempf.* t. 43).

Magnolia purpurea, Curtis, *Bot. Mag.* t. 390 (1797); Loudon, *Arb. et Frut. Brit.* i. 282 (1838).

Magnolia discolor, Ventenat, *Jard. Malm.* t. 24 (1803).

A deciduous shrub, rarely exceeding 10 ft. in height. Young branchlets glabrous except near the tip, where they are covered with silvery appressed pubescences. Leaves membranous, about 4 to 5 in. long and 2 to 3 in. broad, obovate, or oval and broadest at the middle, acute or shortly acuminate at the apex, tapering at the base; upper surface dark green, with scattered appressed hairs, denser on the midrib and nerves; lower surface pale green, glaucescent, with similar pubescence, confined mainly to the midrib and nerves; punctate with minute translucent dots; margined with scattered cilia; lateral nerves eight to ten pairs; petiole with appressed pubescence.

Flowers, appearing before the leaves, without scent, campanulate; sepals small, ovate-lanceolate, greenish yellow, spreading, and slightly reflexed; petals six, purple outside, white inside, about 3½ in. long, broad, ovate, obtuse, slightly fleshy. Fruit brownish.

¹ Cf. Loudon, *Gard. Mag.* xix. 269 (1843), where this variety is said to flower later than *M. conspicua*, and earlier than *M. Soulangiana*.

² According to *Hortus Veitchii*, 370 (1906), var. *nigra* was introduced from Japan by J. Gould Veitch. Cf. Nicholson, in *The Garden*, xxv. 276, fig. 434 (1884). It has dark plum-coloured flowers.

³ Figured in *Gard. Chron.* ix. 591, fig. 5 (1891).

⁴ *Gard. Chron.* xxiii. 262 (1898).

⁵ *Ibid.* xix. 494 (1896).

⁶ This is the oldest name, and Lamarck's description is satisfactory.

1. Var. *gracilis*, Dippel, *Laubholzkunde*, iii. 151 (1893).

Magnolia gracilis, Salisbury, *Parad. Lond.* t. 87 (1806); Loudon, *Arb. et Frut. Brit.* i. 283 (1838).

Branchlets slender; leaves narrower; flowers smaller, dark purple. Introduced from Japan in 1804.

M. denudata is a native of China, where it has not, however, so far as I know, been collected in the wild state. It is mentioned in the earliest Chinese literature under the name *mu-lan*, which it still bears. It is cultivated throughout China and Japan, having been introduced into the latter country at an early period. It was brought to England from Japan by Thunberg in 1790; and is occasionally cultivated, though it is not so ornamental as the hybrids. It produces its flowers just after *M. conspicua*. (A. H.)

MAGNOLIA PARVIFLORA

Magnolia parviflora, Siebold and Zuccarini, in *Abh. Akad. München*, iv. pt. ii. 187 (1846); Maximowicz, in *Mél. Biol.* viii. 509 (1872); J. D. Hooker, in *Bot. Mag.* t. 7411 (1895); Shirasawa, *Icon. Ess. Forest. Japon*, ii. t. 17, figs. 1-5 (1908).

A deciduous shrub,¹ attaining about 10 ft. high in Japan. Young branchlets covered more or less with a minute pubescence. Leaves membranous, 4 to 5 in. long, 2½ to 3 in. wide, obovate or oval, shortly acuminate at the apex, rounded at the base; upper surface shining dark green, glabrous; lower surface bluish white, more or less covered with a scattered minute pubescence, denser and longer on the midrib and nerves; lateral nerves about nine pairs, greenish, as is also the margin; petiole pubescent.

Flowers appearing in June after the leaves, on long stalks; cup-shaped, fragrant, 3½ to 4 in. across; sepals pink, nearly as large as the petals, soon reflexed; petals six, obovate, very concave, white.

This handsome species is a native of Japan, where it occurs in mountain woods at high elevations on the main island and in Kiusiu. It was introduced into Kew from Yokohama in 1893, and flowered in the following year. It is said to be rather tender at Leonardslee²; but thrives at Westonbirt, where a small shrub was bearing flowers on 25th May 1912. (A. H.)

MAGNOLIA WATSONI

Magnolia Watsoni, J. D. Hooker, in *Bot. Mag.* t. 7157 (1891); Masters, in *Gard. Chron.* xvi. 188, fig. 29 (1894); Nicholson, in *Gard. Chron.* xvii. 516, fig. 72 (1895).

A deciduous shrub. Young branchlets glabrous. Leaves slightly coriaceous, about 5 to 6 in. long and 3 to 3½ in. broad, obovate to elliptical, acute at the apex, tapering at the base; upper surface light green, pubescent on the midrib,

¹ Maximowicz, *loc. cit.*, states that this is occasionally a large tree; but Shirasawa gives its height as about 10 feet.

² *Gard. Chron.* xli. 222 (1907).

glabrous elsewhere; lower surface greyish, thinly covered with scattered appressed hairs, dense on the midrib and nerves; lateral nerves about fifteen pairs, with the midrib and margin yellowish; petiole pubescent.

Flowers appearing at the same time as the leaves, shortly stalked, 5 to 6 in. across, highly fragrant, resembling in odour those of *Calycanthus*; sepals oblong, pink, ultimately deflexed; petals six to nine, obovate, concave, spreading, cream-coloured.

This species was described by Sir Joseph Hooker from a shrub, which was purchased in the Japanese Court of the Paris Exhibition in 1889, and which flowered at Kew in the following year. It is unknown in the wild state in Japan, and is possibly a hybrid between *M. hypoleuca* and *M. parviflora*. At Stevenstone, North Devon, there is a fine shrub,¹ 18 ft. high, with seven main branches, which bore about 100 flowers in June 1909. (A. H.)

MAGNOLIA STELLATA

Magnolia stellata, Maximowicz, in *Bull. Acad. Imp. Petersburg*, xvii. 418 (1872) and *Mél. Biol.* viii. 509 (1872); J. D. Hooker, in *Bot. Mag.* t. 6370 (1878); Masters, in *Gard. Chron.* vii. 618 fig. 102 (1890), and xxxix. 260, figs. 108, 109 (1906); Nicholson, in *Gard. Chron.* xvii. 516, fig. 73 (1895).

Magnolia Halleana, Parsons, in *The Garden*, xiii. 572, fig. 132 (1878).

Buergeria stellata, Siebold and Zuccarini, in *Abh. Akad. München*, iv. pt. ii. 186 (1846).

A deciduous shrub or small tree. Young branchlets more or less covered with appressed silvery long hairs. Leaves membranous, about 3 in. long and 1 in. broad, obovate-oblong or oblanceolate, gradually tapering to the base; rounded and emarginate, acute, or shortly acuminate at the apex; upper surface glabrous; lower surface green, glabrous between the nerves, which with the midrib and petiole are more or less covered with appressed pubescence or are glabrescent; lateral nerves about ten pairs; margin non-ciliate.

Flowers opening before the leaves, about 3 in. across, sweet-scented, short-stalked; sepals similar to the petals; petals nine to eighteen, narrow, linear-oblong, at first spreading, then reflexed, white, with a faint pink streak externally. Fruit, about 2 in. long; carpels cuspidate, only a few ripening.

This species is a native of Japan, where it is wild in woods in central Hondo, and is everywhere cultivated. It was introduced into cultivation in the United States by Dr. Hall² in 1862, and was put into commerce by S. B. Parsons of Flushing, New York, under the name *M. Halleana*. It was introduced³ from Japan into England by Messrs. Veitch, and flowered for the first time in this country in their nursery at Coombe Wood in 1878. It is very hardy and produces flowers most profusely, at an early age, when it is hardly 2 feet high; and is now seen in many gardens. (A. H.)

¹ *Kew Bull.* 1909, p. 337.

² An account of the plants introduced by Dr. Hall from Japan, is given in *The Garden*, xiii. 572 (1878), reproduced in *Gard. Chron.* xlv. 275 (1909).

³ Cf. *Hortus Veitchii*, 370 (1906). This form has the petals slightly suffused with pink, and has been named var. *rosea*.

HALESIA

Halesia, Ellis, in Linnæus, *Syst. Nat.* 1044 (1759), and in *Phil. Trans.* li. 931 (1761) (not Browne¹); Bentham et Hooker, *Gen. Pl.* ii. 669 (excl. *Pterostyrax*) (1876); Perkins, in Engler, *Pflanzenreich*, iv. 241, *Styracaceæ*, 94 (1907); Schneider, *Laubholzkunde*, ii. 582 (1911).

Mohria, Britton, in *Garden and Forest*, vi. 434 (1893) (not Swartz²).

Mohrodendron, Britton, in *Garden and Forest*, vi. 463 (1893); Sargent, *Silva N. Amer.* vi. 19 (1894), and *Trees N. Amer.* 754 (1905).

Carlomohria, Greene, in *Erythea*, i. 236 (1893).

DECIDUOUS trees or shrubs, belonging to the order Styracaceæ. Branchlets slender, with chambered pith; one large bundle-scar in the centre of each leaf-scar. Buds all axillary, no true terminal bud being formed, two or three superposed above each leaf-scar, with a few imbricated scales. Leaves simple, alternate, stalked, penninerved, without stipules, denticulate in margin, more or less stellate-pubescent.

Flowers regular, perfect, in fascicles or short racemes, arising from the axils of the leaf-scars of the previous year's branchlet; calyx-tube obpyramidate, four-ribbed, with a short four-toothed limb; corolla epigynous, campanulate, divided into four or five shallow or deep lobes. Stamens, eight to sixteen in one series, adnate to the tube of the corolla, included; filaments nearly free or more or less connate; ovary, two- to four-celled, inferior in greater part, gradually contracted into an elongated style, which is stigmatic at the apex; ovules, four in each cell, two ascending and two pendulous. Fruit, a drupe, crowned by the calyx-tube and the thickened persistent style, dry, indehiscent; with a thick exocarp, produced into two or four wings; containing a thick and bony obovate stone, gradually narrowed at the base into an elongated stipe, one- to four-celled. Seed solitary in each cell.

Halesia comprises three species, natives of the United States, one of which, *Halesia parviflora*³ is a small shrub, not known in cultivation in Europe.

Pterostyrax, Siebold and Zuccarini, *Fl. Jap.* 96 (1835), was included under *Halesia* by Bentham and Hooker, *Gen. Pl.* ii. 669 (1876); but is a distinct genus, comprising three species, shrubs or small trees, natives of China and Japan, with

¹ *Halesia*, Patrick Browne, *Hist. Jamaica*, 205 (1755), was applied to a West Indian tree, which is a species of *Guettarda*, a genus founded by Linnæus in 1753.

² *Mohria*, Swartz, *Syn. Fil.* 159 (1806), is a genus of ferns, with one species, in South Africa.

³ *H. parviflora*, Michaux, *Fl. Bor. Amer.* ii. 40 (1803), is a little-known shrub of southern Georgia and Florida, which has never been properly described. The plant described under this name by Lindley, *Bot. Reg.* t. 952 (1825), and Loudon, *Arb. et Frut. Brit.* ii. 1190 (1838), is *Styrax americana*, Lamarck. Cf. Perkins, *Styracaceæ*, 76 (1907), and also a note by Smith, in Rees' *Cyclopædia*, under the article on *Halesia*.

foliage and stellate pubescence similar to that of the species of *Halesia*. *Pterostyrax* differs from the latter as follows:—Branchlets with solid pith. Flowers numerous in axillary and terminal panicles, arising on the current year's branchlets; corolla five-partite; stamens ten, exerted, unequal. Fruit small, either obovate and five-winged, or cylindrical and ten-ribbed.

Of the three species, one appears to be in cultivation,¹ and deserves a brief mention:—

Pterostyrax hispida, Siebold and Zuccarini, in *Abh. Akad. München*, iv. 3, p. 132 (1846). A small tree, 20 to 30 ft. high, native of the main island of Japan and central China, which was introduced² about 1870. It is perfectly hardy at Kew, coming into flower late in June, and ripening occasionally its seed. It was lately figured in *Bot. Mag.* t. 8329 (1910) from a specimen in Canon Ellacombe's garden at Bitton. (A. H.)

HALESIA DIPTERA

Halesia diptera, Ellis, in *Phil. Trans.* li. 931, t. 22 B (1761); Linnæus, *Sp. Pl.* 636 (1762); Loudon, *Arb. et Frut. Brit.* ii. 1191 (1838); Perkins, *Styracaceæ*, 97 (1907); Schneider, *Laubholzkunde*, ii. 583 (1911).

Halesia reticulata, Buckley, in *Proc. Acad. Sci. Philad.* 1860, p. 444.

Mohria diptera, Britton, in *Garden and Forest*, vi. 434 (1893).

Mohrodendron dipterum, Britton, in *Garden and Forest*, vi. 463 (1893); Sargent, *Silva N. Amer.* vi. 23, t. 259 (1894), and *Trees N. Amer.* 756 (1905).

A large shrub or small tree, not exceeding 30 ft. in height. Young branchlets with a few very scattered stellate hairs. Leaves membranous, ovate, 4 to 5 in. long, 2½ to 3½ in. wide, acuminate at the apex, rounded or cuneate at the base; margin with remote serrations tipped with long cartilaginous points; glabrous on both surfaces, except for scattered stellate hairs on the midrib and nerves; green beneath; petiole about ½ in. long, with slight stellate pubescence.

Flowers on long slender pedicels, in fascicles of three or four; calyx pubescent externally, with four short distinct triangular teeth; corolla white, divided nearly to the base into four or five lobes; stamens usually eight, rarely ten to sixteen with pubescent filaments, which are united together in their lower half; ovary usually two-, occasionally three-celled, tomentose; style tomentose. Fruit oblong, compressed, 1½ to 2 in. long, with two large opposite wings, and two or three additional slight ridges; stone narrowly obovate, conspicuously furrowed; seeds acuminate at the ends.

This is a native of the coast region of the United States, from South Carolina to northern Florida, and westward to Texas, ascending in the Mississippi valley to

¹ The other species, not yet introduced are:—

(1) *Pterostyrax psilophylla*, Diels, ex Perkins, *Styracaceæ*, 103 (1907). A shrub found by Wilson in central China, closely allied to *P. hispida*.

(2) *Pterostyrax corymbosa*, Siebold and Zuccarini, *Fl. Jap.* 96, t. 47 (1835). A shrub, native of Japan.

² Cf. Koch, *Dendrologie*, ii. pt. i. 198 (1872).

central Arkansas. It is usually a large shrub, growing on the borders of swamps and in other wet situations. It is hardy in gardens as far north as Philadelphia.

H. diptera is said by Loudon to have been introduced into England in 1758; and a shrub trained against a wall produced flowers and fruit many years ago in Loddiges' nursery. It appears to be extremely rare in cultivation at the present time, the only specimen which I know being one at Kew, about 15 ft. high, obtained from Meehan in 1896. This has not yet produced flowers or fruit. (A. H.)

HALESIA CAROLINA, SNOWDROP TREE

Halesia carolina, Linnæus, *Syst. Nat.* 1044 (1759); Perkins, *Styracaceæ*, 94 (1907); Schneider, *Laubholzkunde*, ii. 583 (1911).

Halesia tetraptera, Ellis, in *Phil. Trans.* li. 932, t. 22 A (1761); Linnæus, *Sp. Pl.* 636 (1762); Loddiges, *Bot. Cat.* t. 1173 (1827); Loudon, *Arb. et Frut. Brit.* ii. 1190 (1838).

Mohria carolina, Britton, in *Garden and Forest*, vi. 434 (1893).

Mohrodendron carolinum, Britton, in *Garden and Forest*, vi. 463 (1893); Sargent, *Silva N. Amer.* vi. 21, tt. 257, 258 (1894), and *Trees N. Amer.* 755 (1905).

Carlomohria carolina, Greene, in *Erythea*, i. 246 (1893).

A tree, attaining occasionally in America 80 to 90 ft. in height and 9 ft. in girth, but usually much smaller, and often a large bush throwing up several stems from the ground. Bark divided into broad rounded scaly ridges. Young branchlets stellate-pubescent. Leaves oval, 4 to 6 in. long, 2 to 3 in. wide, thicker in texture than those of *H. diptera*, acuminate at the apex, rounded or cuneate at the base; margin minutely serrate, with very short callous points; glabrescent above; lower surface pale or whitish, more or less densely covered with stellate pubescence; petiole about $\frac{1}{2}$ in. long, covered with stellate hairs.

Flowers, opening in spring just after the leaves begin to unfold, on long slender pedicels, in fascicles of three or four; calyx glabrous, four-ribbed, with four minute deltoid ciliate teeth; corolla bronzy red before opening, white when open, with four short lobes, the division between the lobes not exceeding one-third the length of the corolla; stamens, ten to sixteen, with glabrous filaments, connate only at the base; ovary four-celled, glabrous; style glabrous. Fruit, ripening late in autumn, and persisting on the tree in winter; ellipsoid, $1\frac{1}{2}$ in. to 2 in. long, with four broad wings; stone obovate, obscurely ridged; seeds rounded at the narrow ends.

This species as seen in cultivation is very variable; and the following hybrids or varieties are known:—

1. *Halesia stenocarpa*, Koch, in *Wochenschr. Gärtn. u. Pflanzenk.* i. 190 (1858), and *Dendrologie*, ii. pt. i. 200 (1872).

Leaves similar to the type in shape, consistence, and pale colour beneath; but with more distinct serrations, and with sparser stellate pubescence on the lower surface. Flowers: corolla deeply divided to near the base into four lobes; filaments with scattered hairs, connate at the base or at some distance above it; ovary and style glabrous. Fruit with four narrow wings.

This is intermediate between *H. carolina* and *H. diptera*; and, as Koch points out, is probably a hybrid. It has the deeply partite corolla and hairy filaments of the latter species, but resembles the former in foliage. The wings of the fruit are four in number, as in *H. carolina*, but are much narrower than in that species.

This variety or hybrid occurs in the wild state, as shown by specimens from Carolina and Florida in the Kew Herbarium. It appears to be much commoner in cultivation¹ than the species. All the old trees in England, and one in the Botanic Garden at Berlin dating from the time of Willdenow, belong to *H. stenocarpa*.

2. Var. *mollis*, Lange, in *Bot. Tidsk.* xix. 1, p. 258, fig. 2, a-g (1894).

Leaves in shape, colour beneath, and minute serrations, similar to the type, but densely tomentose with stellate hairs on the lower surface. Corolla² deeply divided to near the base into four lobes; filaments pubescent. Fruit as in the type.

This, which mainly differs from the typical form in the deeply divided corolla, is of unknown origin. It is represented at Kew by a shrub about 5 ft. high, which was planted in 1887.

3. Var. *glabrescens*, Lange, in *Bot. Tidsk.* xix. 1, p. 257, fig. 1 (1894).

Leaves narrowly elliptic, up to 6 in. long and 2 in. broad, gradually tapering to a long acuminate apex, sparingly stellate-pubescent beneath. Corolla² with four shallow lobes. Fruit with four very narrow wings.

This, the origin of which is unknown, is represented at Kew by a dense shrub, about 12 ft. high, which suckers very freely, and produces flowers and fruit, as described above.

4. Var. *Meehani*, Sargent, in *Garden and Forest*, v. 611 (1892).

Halesia Meehani, Meehan, in *Garden and Forest*, v. 534, fig. 91 (1892).

A round bush, attaining about 12 ft. in height. Leaves thick, wrinkled, pale, and on young vigorous plants often conspicuously glandular-serrate. Flowers smaller than in the type, with a short calyx-tube, and a cup-shaped corolla not narrowed at the base; pedicels not exceeding $\frac{1}{2}$ in. in length.

This was found in Meehan's nursery at Germantown, Philadelphia, as a solitary plant in a bed of seedlings raised from the seed of a tree of *H. carolina*. It bore fruit abundantly, and one of the seedlings raised from it seemed exactly similar to *H. carolina*. According to Wyman,³ the flowers last longer than in the other kinds of *Halesia*. It is not in cultivation, so far as I know, in England. (A. H.)

DISTRIBUTION

H. Carolina was first described by Catesby in the *Natural History of Carolina*. It ranges from the mountains of West Virginia to southern Illinois, and south-

¹ *Halesia tetraptera*, var. *dialypetala*, Reuber, in *Mitt. Deut. Dend. Ges.* 1907, p. 75, described from a tree in the Arnold Arboretum, is probably *H. stenocarpa*.

² Lange describes the corolla in var. *mollis* as divided to the middle, and in var. *glabrescens* as deeply divided to the base; but in specimens at Kew identical in other respects with these varieties, the corolla is as stated above. It is possible that the flowers may vary in these varieties, when they are raised from seed.

³ In Bailey, *Cyc. Amer. Hort.* 710, fig. 1017 (1900).

ward to Florida, Alabama, and Mississippi. It grows on rich wooded slopes and river banks, attaining its largest size in the forests on the western slopes of the southern Alleghany Mountains, where it sends up tall straight trunks, sometimes 3 ft. in diameter and 50 to 60 ft. high.

Sargent says that the wood is light, soft, and close-grained, of a light-brown colour, but it does not seem to have any special use or value in America, and is not mentioned in Hough's *American Woods*.

This species, or the form *H. stenocarpa*, was introduced in 1756, when John Ellis raised plants from seeds sent from America by Dr. Alex. Graham. The plant figured as *H. tetraptera* by Sims, *Bot. Mag.* t. 910 (1805), shows the petals deeply divided to the base, and is *H. stenoptera*; and all the old trees that we have seen are of this form.

Though one of the most ornamental flowering deciduous trees that we have, the Snowdrop tree has never become common in cultivation, and like many old favourites has been neglected for the numerous new introductions from China and Japan. Though usually seen rather as a shrub than a tree, it has in a few places attained such large dimensions that it may rank with *Arbutus*, *Laburnum*, and *Magnolia* among trees of the third rank in size, but of the first in beauty. It seems to thrive best in a warm sandy loam, free from lime; to require a long and warm summer to ripen its wood properly; and to be proof against the most severe frosts when well established in the south and east of England. It ripens seeds in warm summers only, but I have not succeeded in raising plants from English-grown seeds.

Loudon records the finest trees known to him at Purser's Cross and Syon, 30 ft. high and 4 to 4½ ft. in girth, but these seem to be no longer living. The tallest that we have seen is in an outlying part of the woods at Pains Hill, where a tree, forked at the base and almost prostrate, is 48 ft. from the root to the top. The two stems were 3 ft. 6 in. and 3 ft. 2 in. in girth; and the tree was bearing fruit when I saw it in 1908.

Another very large tree grows in the grounds of Mr. Boardman, Town Close House, Norwich, and when figured by Grigor in 1841 was 29 ft. high and 4 ft. in girth, with a circumference of 33 yards. When I saw it in 1908 it was 32 ft. by 6 ft. 3 in., forking at about 4 ft. from the ground; and one of the limbs was 4½ ft. in girth. Its fruit was nearly ripe in October. There is a handsome tree at Leonardslee, about 25 ft. by 2 ft., with a clean stem 15 ft. long. There is a fine specimen in Colonel Duncombe's grounds at Waresley Park, Herts, which is about 35 ft. high by 4½ ft. in girth. Mr. Wyndham Fitzherbert reports¹ a tree in a garden at Kidderminster, 28 ft. in height and 5 ft. in girth, with a spread of branch of 48 ft. He states that some small trees planted in decomposed peat made astonishing growth, attaining 20 feet in height in twelve years. At Milford Lodge, Craven Arms, there is a fine tree about 30 ft. in height.

We have seen no specimens in Scotland or Ireland. (H. J. E.)

¹ *Gardening Illustrated*, 19th November 1910.

MORUS

Morus, Linnæus, *Gen. Pl.* 283 (1737); Bureau, in De Candolle, *Prod.* xvii. 237 (1873); Bentham et Hooker, *Gen. Pl.* iii. 364 (1880); Bailey, *Cycl. Amer. Hort.* 1033 (1901).
Morophorum, Necker, *Elem. Bot.* iii. 255 (1790).

DECIDUOUS trees and shrubs belonging to the order Moraceæ. Leaves alternate, distichous, simple, stalked, serrate, with or without lobes; palmately three- to five-nerved at the base, pinnately nerved above; stipules lateral, lanceolate, early deciduous.

Flowers monœcious or diœcious, in solitary spikes,¹ which arise on the base of the current year's shoot in the axil of a leaf or of a deciduous scale; calyx deeply divided into four lobes; corolla absent. Staminate spikes elongated, cylindric; stamens four, inserted opposite the rounded calyx-lobes, beneath the minute rudimentary ovary; filaments ultimately exerted, uncoiling like a spring at the moment of dehiscence of the two-celled anthers, and forcibly scattering the pollen. Pistillate spikes short, oblong; ovary sessile, one-celled, with a solitary pendulous ovule; style divided nearly to the base into two stigmatic lobes. Each ovary results in an achene, enclosed in the calyx, which becomes thickened and fleshy. The whole mass of achenes, closely packed together in one spike, forms a multiple fruit, the mulberry superficially resembling a blackberry (*Rubus*), but very different in structure.

In winter, the species of *Morus* show the following characters:—No terminal bud is formed, the tip of the branchlet dying off in early summer, and leaving a scar at the apex of the twig. Buds all axillary, arranged in two ranks, ovoid, acuminate; scales, five to seven, closely imbricated in two ranks, the inner accrescent and falling in spring, marking the base of the shoot with ring-like scars. Leaf-scars on prominent cushions, nearly circular, concave with a slight rim, marked on the surface by an irregular group of dots. Stipule-scars linear, one on each side of the leaf-scar.

About eight species of *Morus* are known, occurring in North America, Central America, Western South America, Western Asia, China, Japan, Indo-China, and the high mountains of the Indian Archipelago. Three species have been long in cultivation which are distinguishable as follows:—

1. *Morus nigra*, Linnæus. Native country uncertain, probably Western Asia.

See p. 1606.

¹ Androgynous spikes have often been observed on *M. alba* and *M. rubra*, growing in the Arnold Arboretum. Cf. *Garden and Forest*, viii. 223 (1895).

Leaves rarely lobed, deeply cordate at the base, shortly acuminate at the apex; margin ciliate; lower surface pubescent throughout.

2. *Morus rubra*, Linnæus. North America. See p. 1608.

Leaves rarely lobed, slightly cordate at the base, contracted above into a long acuminate apex; margin slightly ciliate; lower surface pubescent throughout.

3. *Morus alba*, Linnæus. China, Japan. See p. 1609.

Leaves often lobed, variable in size and shape, thinner in texture than those of the preceding species; margin non-ciliate; lower surface glabrous, except for pubescence on the midrib and nerves.

The following species, lately introduced, may be briefly noticed:—

4. *Morus cathayana*, Hemsley, in *Journ. Linn. Soc. (Bot.)* xxvi. 456 (1894).

A tree, about 20 to 30 ft. high. Young branchlets densely pubescent. Leaves large, 4 to 5 in. long, ovate, cordate, cuspidate-acuminate, usually without lobes, crenate in margin; very scabrous above with minute blackish tubercles; lower surface softly pubescent throughout. Fruit, cylindrical, 1 in. long; styles as long as the ovary.

This was discovered by me in 1888 in the mountain forests of western Hupeh in China. It has lately been introduced by Wilson; and a plant at Kew, obtained from the Arnold Arboretum in 1907, is about 4 ft. high. (A. H.)

MORUS NIGRA, BLACK MULBERRY

Morus nigra, Linnæus, *Sp. Pl.* 986 (1753); Loudon, *Arb. et Frut. Brit.* iii. 1343 (1838); Bentley and Trimen, *Medicinal Plants*, t. 229 (1880); Willkomm, *Forstl. Flora*, 541 (1887); Mathieu, *Fl. Forestière*, 292 (1897).

A tree, attaining about 50 ft. in height. Bark thick, fissured into broad scaly plates. Young branchlets with a scattered downy pubescence. Leaves (Vol. IV. Plate 267, Fig. 1), subcoriaceous, 4 to 6 in. long, 3 to 5 in. wide, broadly ovate, deeply cordate at the base, acuminate at the apex; upper surface dark green, shining, with scattered short pubescence; lower surface pale green, covered throughout with a short downy pubescence; margin ciliate, with coarse triangular serrations; petiole $\frac{3}{4}$ in. long, pubescent. Staminate spikes, $\frac{3}{4}$ to $1\frac{1}{2}$ in. long. Pistillate spikes, $\frac{1}{2}$ in. long, on a short pubescent peduncle; style and stigmas pubescent. Fruit, about 1 in. long, black, very shortly stalked.

Lobed leaves¹ are rarely seen on adult trees, but are usual on root-suckers.

The native country of the black mulberry cannot be ascertained with certainty.² It has been cultivated in southern Europe from a very early period, but there is no evidence that it is indigenous in Italy or Greece. Boissier³ and De Candolle⁴ suppose it to be truly wild in the districts in Persia, bordering on the Caspian Sea; but

¹ Var. *laciniata*, Loudon (*M. laciniata*, Miller, *Dict.* ed. 8, No. 2 (1768)). This is only an individual variation, and cannot be retained as a distinct variety.

² Hehn, *Wanderings of Plants and Animals*, 290 (1888), states, without giving any evidence, that the mulberry is a Medo-Persian tree.

³ *Fl. Orient.* iv. 1153 (1879).

⁴ *Origin of Cultivated Plants*, 152 (1886).

Koch¹ never found it in the wild state in all his travels in the Orient; and Radde² states that it is only naturalised in the Caucasus.

According to Loudon, it was first introduced³ into England in 1548, when a few trees were planted at Syon, one of which still survives. Canon Ellacombe,⁴ however, believes that its introduction was much earlier, and adduces in support of this, that *morat*, a favourite drink in Anglo-Saxon times was a kind of mead, flavoured with mulberries. *Morus*, however, signified blackberry as well as mulberry; and *morat* may have been flavoured with blackberries. (A. H.)

Though the mulberry was often planted in old gardens and the remains of some still exist which may be over 300 years old, we are unable to find a tree of great size or age which is not more or less decayed at present.

The oldest, supposed to have been planted in the sixteenth century at Syon House, by the botanist Turner, was in Loudon's time 22 ft. high, and still exists; and though a wreck is one of the largest we know. Loudon speaks of one at Wardour Castle 40 ft. high, but I could find no trace of it when I was there in 1904. Among the drawings of the late E. Lees, there is one made in 1858 of a tree at the White Ladies, Worcester, partly prostrate, which seemed of unusual size, but I cannot hear whether it still exists. At Wotton House, Gloucester, a fine tree, 11 ft. in girth at 3 ft. from the ground, is said to have been planted by Queen Elizabeth. At Stoke Edith, Herefordshire, I saw in 1905, a very old tree with a prostrate trunk which had thrown up several stems. In front of the headmaster's house at Eton, Henry measured, in 1907, a tree 30 ft. by 8 ft. 3 in. There are old trees at Christ's, Jesus, and Emmanuel Colleges at Cambridge, which may have been planted in obedience to the edict of James I. in 1605, recommending the cultivation of silkworms and offering mulberry seed to all who would sow them. Christ's College purchased 300 trees in 1608. There are old trees at Dunster Castle and at Pembroke College, Oxford. One at Abington Park, Northamptonshire, is said to have been planted in 1778, by David Garrick.

In Scotland it exists on walls, but rarely fruits. In Ireland we have seen no large specimens, but Loudon mentions one in the grounds at Terenure, near Dublin, which was 25 feet high with a head 130 ft. in circumference.

The mulberry is a tree which has lost its former popularity in this country, and is now seldom planted, but as it requires more heat and sun than it usually gets in England, it is better⁵ on a wall than as a standard, if grown for its fruit. It is perhaps best propagated by means of large cuttings, which soon take root, and its fruiting is improved by careful pruning. It ripens seed in hot seasons, but the seedlings are very slow in growth, some that I raised in 1901 from home-grown seeds being now only 2 to 3 ft. high, as their young wood ripens badly.

The wood of the mulberry is very like that of Robinia in texture, colour, and useful properties; but yellow when fresh, it acquires in the course of time a brownish

¹ *Dendrologie*, ii. pt. i. 444 (1872).

² *Pflanzenverb. Kaukasuslând.* 182 (1899).

³ In *Gard. Chron.* 1868, p. 79, it is said that title-deeds, in the possession of Sir Henry Austen, showed that a mulberry tree, which was formerly growing at Shelford, was planted as a sapling in 1537.

⁴ *Plant-lore of Shakespeare*, 176 (1896).

⁵ Cf. Williams, in *Trans. Hort. Soc.* ii. 91 (1817.)

red tint, while that of the Robinia becomes brownish yellow. On a transverse section the pores of the outer part of each annual ring are minute and occur in groups, while in Robinia they are considerably larger in size and scarcely grouped. The sapwood is narrow, only 3 to 5 annual rings, and is white in colour. The wood is used in France for cooperage, wheelwright's work, vine props, and trenails. It takes a good polish and is often used for making furniture. The bark yields a fibre, which is sometimes used for cordage. Mulberries are used medicinally for the preparation of a syrup.¹

(H. J. E.)

MORUS RUBRA, RED MULBERRY

Morus rubra, Linnæus, *Sp. Pl.* 986 (1753); Loudon, *Arb. et Frut. Brit.* iii. 1359 (1838); Sargent, *Silva N. Amer.* vii. 79, t. 320 (1895), and *Trees N. Amer.* 303 (1905).

Morus canadensis, Poirét, in Lamarck, *Encycl.* iv. 380 (1797).

Morus scabra, Willdenow, *Enum.* 967 (1809).

Morus tomentosa, Rafinesque, *Fl. Ludovic.* 113 (1817).

Morus riparia, Rafinesque, *New Fl.* iii. 46 (1836).

Morus reticulata, Rafinesque, *Am. Man. Mulberry Trees*, 28 (1839).

A tree, attaining in America 70 ft. in height, with a short trunk 10 to 12 ft. in girth. Bark dark brown, divided into irregular scaly plates. Young branchlets covered with a dense minute pubescence, glabrous in the second year. Leaves (Vol. IV. Plate 267, Fig. 3) 3 to 5 in. long, 2½ to 4 in. wide, broadly ovate or orbicular, usually abruptly contracted into a long acuminate apex; broad, rounded or slightly cordate at the base; coarsely serrate; dull green with a scattered pubescence above; light green beneath and covered with a soft downy pubescence; petiole ¾ in. long, pubescent. Staminate spikes pendulous, 2 in. long, on pubescent peduncles. Pistillate spikes, 1 in. long, on short pubescent peduncles, densely flowered; style glabrous, short, with long stigmatic lobes. Fruit, about 1 in. long, at first bright red, becoming dark purple or nearly black and sweet when ripe.

The leaves on ordinary branches are usually entire or with one or two lobes; but on vigorous young shoots are often deeply three-lobed with oblique and rounded sinuses.

1. Var. *tomentosa*, Bureau, in De Candolle, *Prod.* xvii. 246 (1873).

Leaves scabrous above, pale and tomentose beneath. Louisiana, Texas. A large-fruited form of this was introduced into cultivation in America by Munson in 1889, as the Lampsas mulberry.²

The Red Mulberry is widely distributed in North America,³ from southern Ontario and Massachusetts southwards to Florida, and westwards to Michigan, Nebraska, Kansas, and the Colorado river in Texas. It is most abundant and of its largest size in the basin of the lower Ohio river and on the foothills of the southern Alleghany Mountains. Sargent gives⁴ a good figure of a tree in Alabama, and

¹ Cf. Flückiger and Hanbury, *Pharmacographia*, 544 (1879).

² Bailey, *Cycl. Amer. Hort.* 1035 (1901).

³ A closely allied species, *M. tiliaefolia*, Makino, in *Tokyo Bot. Mag.* xxiii. 88 (1909) is found in Japan.

⁴ In *Garden and Forest*, vii. 24, fig. 3 (1894).

states that there was one at Augusta, Georgia, 20 ft. in girth at 3 ft. from the ground; but this large size is exceptional.

This species has been tried, but with indifferent success, for feeding silkworms in America. It is occasionally planted in the southern States for its fruit, which is mainly used for feeding pigs and poultry. Bailey,¹ however, states that three of the named varieties of fruit-bearing mulberries belong to this species, as well as a yellow-leaved variety which is cultivated for ornament.

M. rubra is said to have been introduced into England, early in the seventeenth century; but is now scarcely known in cultivation, the only specimen which we have seen being a small tree at Kew, which died two or three years ago.

The timber, according to Sargent, is orange-coloured, with a thick light-coloured sapwood, soft and coarse-grained; but tough and resisting decay in contact with the soil. It is occasionally used in the United States for fencing, cooperage, and boat-building. (A. H.)

MORUS ALBA, WHITE MULBERRY

Morus alba, Linnæus, *Sp. Pl.* 986 (1753); Loudon, *Arb. et Frut. Brit.* iii. 1348 (1838); Willkomm, *Forstliche Flora*, 540 (1887); Hooker, *Fl. Brit. India*, v. 492 (1888); Mathieu, *Flore Forestière*, 290 (1897); Gamble, *Indian Timbers*, 634 (1902).

A tree, usually 30 to 40 ft. in height, but attaining, according to Mayr, much larger dimensions in Japan. Bark thick, fissured into broad scaly plates. Young branchlets with scattered minute pubescence. Leaves (Vol. IV. Plate 267, Fig. 2), thin and membranous, very variable in size and shape, ovate or oval, often with deeply indented sinuses, forming irregular lobes; base rounded, truncate, or widely cordate; apex obtuse, acute, or shortly acuminate; margin non-ciliate, irregularly serrate; upper surface shining, usually glabrous; lower surface dull green, pubescent on the midrib and nerves, elsewhere glabrous; petiole ¾ to 1½ in. long, glabrescent. Pistillate spikes on long slender peduncles; style glabrous or papillose, divided or not divided to the base into stigmatic lobes. Fruit, variable in size, ½ to 1½ in. long, white or reddish.

The seedling² has two cotyledons, raised above the ground, dark green above, pale beneath, about ⅓ in. long, tapering gradually to a short petiole, and faintly veined with a midrib and a few lateral nerves; primary leaves irregularly dentate.

No plant is more variable than *M. alba*; and possibly under this name are included two or three distinct species, natives of China and Japan, where the tree has been so long in cultivation, that it is almost impossible at the present day to distinguish the cultivated and possibly the hybrid forms, from those which are truly indigenous. For a complete account, Bureau,³ who enumerates sixteen main varieties, may be consulted. The following are worthy of note:—

1. Var. *mongolica*, Bureau, in De Candolle, *Prod.* xvii. 241 (1873).

¹ *Cycl. Amer. Hort.* 1034 (1901).

² Tureau, *Samen, Früchte, u. Keimlinge*, 53, 114 (1891).

³ In De Candolle, *Prod.* xvii. 238-245 (1873). Several of these varieties are now considered to be distinct species, as *M. serrata*, Roxburgh, *M. indica*, Linnæus, and *M. laevigata*, Wallich, which are wild in the Himalayas.

Leaves large, with three to seven lobes, and a long acuminate apex; serrations large, triangular, bristle-pointed. Fruit reddish in colour and insipid in flavour. This is common in the mountains around Peking, and was found by David near Jehol.

2. Var. *stylosa*, Bureau, in De Candolle, *Prod.* xvii. 243 (1873); Shirasawa, *Icon. Ess. Forest. Japon.*, ii. t. 6, figs. 1-11 (1908).

Morus stylosa, Seringe, *Desc. Muriers*, 225, t. 22 (1855).

Morus japonica, Audibert, *ex Seringe, loc. cit.*

A shrub rarely exceeding 10 ft. high. Leaves small, about 3 in. long and 1½ in. broad, very polymorphic, on the same individual simple, variously lobed or lacinate; serrations usually ending in long points; upper surface scabrous with short hairs; lower surface pubescent on the midrib and veins. Spikes slender; style twice as long as the ovary, dividing above into two pubescent stigmas. Fruit small, ½ in. long, reddish, with few achenes.

This, which is probably a distinct species, is wild throughout the mountains of central and western China; and also occurs in Korea and Japan. According to Seringe, it is tender in France; and Bailey says that it suffers when young in the northern United States.

3. Var. *tatarica*, Loudon, *Arb. et Frut. Brit.* iii. 1358 (1838).

Morus tatarica, Linnæus, *Sp. Pl.* 986 (1753).

A shrub or small tree, with numerous slender branches; leaves usually without lobes, broadly elliptic, obtuse at the apex, with blunt serrations.

This has been found in Russia, growing on tracts inundated by the Volga and the Don, apparently wild, but probably only naturalised. It is much hardier than the type; and was introduced in 1784 into England, and in 1875 into the United States, where in the western prairie States it is used as a windbreak, and for producing fence-posts and fuel.¹

Numerous varieties have arisen in cultivation:—

4. Var. *latifolia*, Bureau, in De Candolle, *Prod.* xvii. 244 (1873).

Var. *multicaulis*, Loudon, *Arb. et Frut. Brit.* iii. 1348 (1838).

Morus latifolia, Poiret, in Lamarck, *Encyc.* iv. 381 (1797).

Morus multicaulis, Perrottet, in *Ann. Soc. Linn. Paris*, 1824, p. 129.

A shrub, dividing near the base into many stems, and suckering very freely. Leaves large, usually without lobes, minutely tuberculate on the upper surface, which also shows here and there peculiar swellings. This is cultivated for feeding silkworms in southern and central China; and was introduced into France in 1821.

5. Var. *macrophylla*, Loddiges, *ex Loudon, Arb. et Frut. Brit.* iii. 1349 (1838).

This differs little from the preceding, except in habit, having a single stem.

6. Var. *venosa*, Delile, in *Bull. Soc. Agric. Hérault*, 1826, p. 13.

Leaves marked beneath with white prominent veins. This is said to have originated in Europe.

¹ Cf. Pinchot, *U.S. Forest Circ.* No. 83 (1907).

7. Var. *colombassa*, Seringe, *Descrip. Muriers*, 206 (1855). Leaves distant on the branches, small, thin, lobed.

8. Var. *pyramidalis*, Seringe, *Descr. Muriers*, 212 (1855). Branches vertical, similar in habit to the Lombardy poplar.

9. Var. *pendula*, Dippel, *Laubholzkunde*, ii. 10 (1892). Branches pendulous.

10. Var. *constantinopolitana*, Loudon, *Arb. et Frut. Brit.* iii. 1358 (1838).

Morus constantinopolitana, Poiret, in Lamarck, *Encycl.* iv. 381 (1797).

A tree with thick and twisted branches, resembling in habit *Robinia Pseudacacia*, var. *tortuosa*; leaves thick in texture. The origin of this peculiar form is unknown. It is well figured by Seringe, *Desc. Muriers*, 210, t. v. (1855).

The White Mulberry is undoubtedly a native of China, where it is common wild in the mountainous districts of the northern and central provinces. The cultivation of this species and the rearing of silkworms can be traced back to the remotest times of Chinese civilisation.¹ In Japan, where it is called *Kuwa*, several varieties of this species appear to occur wild; but the broad-leaved form, used for rearing silkworms, was probably introduced, with the art of sericulture, from China in the third or fourth century of our era. Mayr² states that *M. alba* grows wild and attains a large size in the virgin forests of central Yezo; and he measured a mulberry tree in the Bonin Isles 100 ft. in height and 10 ft. in girth.³

Complete details of the introduction of this species and the silk-worm industry into the Levant and Europe are given by Loudon, and need not be repeated here. The tree has been widely naturalised in many countries, as in Persia, Armenia, the Caucasus, Asia Minor, and in south-eastern Russia. It is only known in the cultivated state in Greece, Italy, and France.

The White Mulberry was introduced into England in 1596, but has apparently never succeeded in attaining a great size or age, the largest mentioned by Loudon being one at Syon, 45 ft. high and 6 ft. in girth in 1838. This tree no longer exists; but there are two young trees about 20 ft. high. Most trees which I have seen in this country are of small size and growing in botanic gardens, as at Kew, where the varieties are well represented. Elwes found a tree at Henham Hall, which was, in 1909, 20 ft. high with a head twenty paces round. Another at Beauport, Sussex, was 25 ft. by 3 ft. 3 in., and was bearing fruit in October 1911. This species is said⁴ to have set fruit in the open garden at Dalkeith in July 1894.

The finest specimen that I have seen in Europe, was growing on the roadside near Zvornik in the Drina valley in Servia, and measured 65 ft. by 8 ft. in 1909.

(A. H.)

³ The mulberry of the Bonin Isles, which may be a distinct species (*M. indica*?), is known in Japan as *Shima-guwa*. It produces a rich yellow wood with beautiful markings, which is highly valued, and used for high-class cabinet-making. I purchased a board of this wood at a high price in Tokio, part of which is in the Cambridge Forestry Museum.—H. J. E.

EUCALYPTUS

Eucalyptus, L'Héritier, *Sertum Anglicum*, 18, t. 20 (1788); Bentham and Mueller, *Flora Australiensis*, iii. 185 (1866); Bentham et Hooker, *Gen. Pl.* ii. 707 (1876); F. von Mueller, *Eucalyptographia*, decades i-x. (1879-1884); Naudin, in *Ann. Sc. Nat.* xvi. 337-430 (1883), and *Descript. Emploi Eucalpt. Europe*, 1-72 (Antibes, 1891); Masters, in *Gard. Chron.* xxi. 148 (1884), and ix. 176 (1891); M'Clatchie, *U.S. Dept. Agric. Forestry Bulletin* No. 35, pp. 1-106 (1902); Maiden, *Revision Genus Eucalyptus*, i. 1-24 (1903); Ingham, *Agric. Exper. Station, Berkeley, California, Bulletin* No. 196, pp. 1-114 (1908).

EVERGREEN trees or shrubs, belonging to the order Myrtaceæ. Bark on young trees smooth and peeling off; on old trees variable—(a) remaining smooth; (b) persistent and rugged at the base, but smooth on the upper part of the trunk and on the branches; (c) persistent and fibrous; (d) persistent, very hard, and deeply furrowed; or (e) persistent and dividing into separate scales on the trunk.

Leaves on young plants beyond the seedling stage, and also on suckers, opposite, horizontal, sessile, cordate: variable on adult trees, (a) in some species, remaining always opposite, horizontal, sessile, and cordate; (b) in other species, becoming alternate and stalked, after the first six or eight leaves on the seedling; or (c) in most of the species, remaining opposite for several years, subsequently becoming alternate and stalked. Usually the alternate leaves are similar on both surfaces, with the stalk twisted, so that the blade is placed in a vertical or oblique plane; but in a few species the upper surface of the alternate leaves is darker in colour than the lower surface, the petiole not being twisted, and the blade remaining in the horizontal plane. Leaves nearly always glabrous,¹ odorous, with pellucid or concealed oil-dots; venation pinnate, the branches always converging to an intra-marginal vein, which is either close to or at some distance from the edge.

Flowers usually in pedunculate umbels, rarely reduced to a single sessile flower; peduncles in most species solitary and axillary, or occasionally lateral at the base of the current year's shoot below the leaves, or in some species, clustered in terminal paniced umbels. Calyx of two parts: (a) the tube persistent, adnate to the ovary, and truncate and entire (or rarely 4-toothed) after the fall of the (b) lid or operculum, which covers the stamens in the bud. Petals none, unless represented in a few species by a membrane under the operculum. Stamens numerous,² inserted close to the edge of the calyx in several rows, free or rarely united at the base into four clusters, always deciduous; all fertile or some of the outer without anthers; filaments thread-like, usually inflexed (rarely straight) in the bud; anthers dorsifixed,

¹ In the seedlings of a few species the leaves and branchlets are hairy. In a few species the stalk is inserted above the base of the leaf, so that the blade is peltate; but this condition only persists in the adult foliage of one species.

² Kerner, *Nat. Hist. Plants*, Eng. trans., ii. 107, 449, 782 (1898), points out that the walls of the capsules of the Eucalypti are remarkably thick and strong, to protect the seeds against desiccation during long periods of drought. As, however, no rain occurs when the trees of most species are in flower, the pollen is left quite unprotected. There is no corolla, and the top of the calyx falls off, so that the whole of the stamens, often a hundred or more in number, are completely exposed.

their two cells parallel and distinct or divergent and confluent at their apex, opening usually by longitudinal slits, rarely by terminal pores. Ovary, free at the apex, two to six-celled; style long; stigma convex or flat, undivided; ovules numerous in each cell, the majority remaining unfertilised. Fruit, consisting of the enlarged truncate calyx-tube, enclosing a hard woody resinous capsule, which is provided with three to five valves, which are either wholly or partially exerted or entirely enclosed. Seeds numerous, but very few fertile; minute, polygonal, winged in a few species.

In Tasmania all the species take at least twelve months for the flower-bud to reach maturity, and another year for the fruit to perfect.¹ None of the species at low altitudes have any constant flowering period, and may be found in flower in any month of the year, one tree flowering at midsummer, while another beside it will not flower till winter. The flowers are fertilised by honey-feeding birds.

The leaves of all the species, and often the young branchlets, flowers, and fruits contain numerous oil-vesicles. The leaves of many species are distilled to yield this oil, which is variable in composition, but is volatile and antiseptic and used for pharmaceutical purposes.² The bark of several species exudes a resin,³ called *kino*, which contains tannin in commercial quantities; and it is on account of this resin, that the name gum trees was applied to the genus.

In many species of Eucalyptus and other genera of Myrtaceæ and Proteaceæ, which are natives of Australia, the leaf-blades, as was pointed out by R. Brown,⁴ are not placed horizontally like those of European broad-leaved trees; but are, by the twisting of their stalks, set vertically. This is a provision to lessen evaporation in the dry climate of Australia, since the narrow edge and not the broad surface of the leaf is directed towards the sun. In the Australian species of Acacia, the same adaptation is effected by the non-development of the blade of the leaf, the stalk becoming expanded, simulating the blade and forming a so-called phyllode, which is also directed vertically. In the Australian forests of Eucalypti and Acacias, the linear edges of the leaves and phyllodes cast little shadow, and sunlight streams on the ground. Behr⁵ describes a typical forest in South Australia, as follows: "As a rule a dense meadow sward, in most cases accompanied by a light park-like forest of gigantic Eucalypti, whose crowns, however, never meet. The smooth stems, freed from their outer layers of cortex, stand apart at definite and often regular distances."

The currently accepted opinion that some species of Eucalyptus in Australia are the tallest and largest trees in the world is based on records for *Eucalyptus amygdalina*,

¹ Rodway, *Wild Flowers of Tasmania*, 49 (1910), states, however, that *E. globulus* and many other species take two years from the first appearance of the bud to the fall of the operculum, and another two years to mature fruit. *E. calophylla* of West Australia flowers in a few months, and takes a year to produce ripe fruit. The seeds are retained and remain quite fertile for several years in the capsules, which open their valves often only when exposed to forest fires. Seedlings usually spring up in consequence in burnt-over lands. Most of the species also when killed by fire, rapidly regenerate by suckers from the roots.

² Cf. R. T. Baker and H. G. Smith, *Researches on Eucalypts* (1902). A complete set of oils of 109 species, with herbarium specimens of the timber and bark, are preserved in the Pharmaceutical Museum, Bloomsbury Square, London. Cf. *Pharmac. Journ.* 1904, p. 187.

³ This is called Australian or Eucalyptus kino, and is different from the officinal kino, which is produced by *Pterocarpus Marsupium*, a large deciduous tree of central and southern India. Cf. Flückiger and Hanbury, *Pharmacographia*, 894 (1879).

⁴ *Botany of Terra Australia*, i. 62 (1814).

⁵ *Linnea*, xx. 546 (1847). Schimper, *Plant Geography*, 495, 528, figs. 260, 261, 262 (1903) gives a general account of these forests, with pictures of the various types.

which were accepted as correct by Baron von Mueller, who states in his *Eucalyptographia* that four trees of this species were 415, 471, 410, and 420 ft. in height respectively. Dr. A. S. Ewart of the Melbourne University considers¹ that these measurements were grossly exaggerated; and instances the fact that the tree which many years previously D. Boyle had measured on the Dandenong range as 420 ft., was found by Fuller in 1889 to be only 220 ft. in height, with a girth of 48 ft. at six feet from the ground. Dr. Ewart states that although *E. amygdalina* (including *E. regnans*), is the tallest species in Australia, it rarely exceeds 300 ft. He gives as the maximum heights accurately recorded the following: a tree growing on the edge of a ridge found by Professor Kernot to be 302 ft.; others growing in thick groves, which were found by Perrin, Davidson, and Fuller to be 271, 294, 296½, 297, and 303 ft. The tallest Australian tree that has been correctly measured² appears to be one of *E. regnans*, on Mt. Baw-Baw, Gippsland, 91 miles from Melbourne, which Maiden³ gives as 326 ft. in height, and 25 ft. 7 in. in girth.

About 150 species of Eucalyptus are known, the greater part of which are natives of Australia and Tasmania, only three or four species occurring in New Guinea, the Moluccas, and Timor, and one species⁴ in the Bismarck Archipelago (New Britain) and the Philippine Islands.

The following notes deal shortly with some of the tender species,⁵ which have seemed to succeed in the British Isles for a time; but which we do not consider worthy of a lengthened notice.

Eucalyptus alpina, Lindley, a shrub confined to the summit of Mt. William, 5000 ft. altitude, fifty miles north of Melbourne. Planted out in Arran⁶ in 1884, it attained 14 ft. in height in eleven years, and seemed to be very hardy, flowering in the spring of 1888. It was, however, ultimately killed in 1894. At Kinloch Hourn, the seedlings which were planted out did not long survive.

E. amygdalina,⁷ Labillardière, a large tree abundant in Tasmania, and occurring in many localities in Victoria and New South Wales. There are three trees 20 ft. high, probably of this species, at Menabilly. Seedlings raised at Kinloch Hourn in 1890 were all killed in the winter of 1894-95, except one in a sheltered valley, which was cut to the ground, and died subsequently. Another batch of seedlings raised in 1895 were killed in 1899-1900. Planted at Cromla in Arran⁸ in 1895, it grew rapidly, and was 20 ft. in 1905. Mr. John Paterson, who sent a specimen branch, states that this tree was 30 ft. high in June 1911. We have a specimen from Brodick of a young tree planted out in 1909. At Abbotsbury, it was killed in 1908, when 20 ft. high, by 16° of frost. Mueller says that near Lake Maggiore in

¹ In *Phil. Trans. Roy. Soc. Series B*, vol. 199, p. 367 (1908). Cf. Hemsley, in *Gard. Chron.* xlvii. 69 (1910).

² The tallest tree in the world, that has been accurately measured, was the Redwood on Eel River, California, which was found by Sargent in 1896 to be 340 feet in height. Cf. our Vol. III. p. 692, and also p. 690, note 3.

³ Maiden, *Forest Flora*, ii. 161-165 (1907), gives accurate measurements of several trees that Ewart does not mention.

⁴ *E. Naudiniana*, Mueller. Cf. Maiden, *Revis. Gen. Eucalypt.* ii. 79 (1910). The distribution of this species is remarkable.

⁵ Some of these may be hardy in Mr. Heard's garden at Rossdohan in Kerry, and also in the Scilly Isles; but the climate of these localities is exceptionally free from frost.

⁶ Landsborough, in *Trans. Bot. Soc. Edin.* xx. 522 (1896). In *ibid.* xxiii. 147 (1905), Landsborough mentions a tree at Cromla in Arran, planted in 1895, which was 20 ft. high in 1905.

⁷ The tree recorded in *Gard. Chron.* xxvi. 790 (1886) under this name, as 60 ft. high at Fota, is *E. pauciflora*. Cf. p. 1632. The tree at Dalkeith, mentioned under this name in *Journ. Roy. Hort. Soc.* xviii. 76 (1895) was probably incorrectly named.

⁸ Landsborough, in *Trans. Bot. Soc. Edin.* xxiii. 148 (1905).

Italy, it endured a temperature of 18° Fahr., proving hardier than *E. globulus* or *E. rostrata*; and grew astonishingly fast, attaining a height of 60 ft. in nine years.

E. regnans, Mueller, closely allied to, if not a variety of, *E. amygdalina*, did not prosper in Arran¹; and seedlings were speedily killed at Kinloch Hourn.

E. Beauchampiana, Treseder, ex Masters, in *Gardeners' Chronicle*, xxxviii. 3, fig. 3 (1905), and xxxix. 174 (1906). This species was raised at Truro by Messrs. Treseder and Co., who inform us that they obtained the seed direct from New South Wales. They consider it to be hardier than the other species in their nursery, having withstood 20° of frost without injury. Their largest specimen is 30 ft. high and 18 in. in diameter; but has not yet flowered. This species was identified by Maiden, to whom I sent specimens, with *E. Stuartiana*,² Mueller, the Apple Eucalyptus of the cool tablelands of Victoria and New South Wales. Coming from this region, it is unlikely to prove very hardy; and was killed³ in the severe winter of 1908-1909, both at Wisley, where the temperature fell to 7.5° Fahr., and at Myddelton House, Herts, where the thermometer placed on the grass registered -1° Fahr. There is, however, a tree at Tregothnan, planted eight years, which was bearing fruit and measured 25 ft. high in February 1911. Another at Mount Usher, which was raised from seed obtained from the Sydney Botanic Garden in 1904, was 20 ft. high and bearing flowers in October 1911. There are two small trees about 15 ft. high at Menabilly, which are labelled *E. Stuartiana*; but differ from *E. Beauchampiana* in having glaucous foliage.

E. botryoides, Smith, the Bastard Mahogany of Queensland, New South Wales, and Victoria. A specimen of this planted⁴ in Arran in 1896 grew well for several years, but was ultimately killed by drainage from a manure heap. According to Mr. Birkbeck, this species bears more frost in winter than *E. globulus*, but less in spring. It was, however, killed at Abbotsbury in 1908.

E. citriodora, Hooker, a native of Queensland. According to Mr. Birkbeck, this only survived a few years out of doors at Menabilly; and seedlings were soon killed at Kinloch Hourn. It attained 25 feet at Tregothnan; but was killed to the ground in a severe winter.

E. ficifolia,⁵ Mueller, a native of New South Wales. This was reported⁶ to have flowered in the open air at Cove House, Tiverton, Devon; but Mr. W. North-Row informs us that this was an error, as the plant is growing in the border of a cool greenhouse. At Monreith, where it was growing on a south-east wall, it was killed⁷ in the severe winter of 1908-1909.

¹ Landsborough, in *Trans. Bot. Soc. Edin.* xx. 522. In *ibid.* xxiii. 149 (1905), a tree planted in 1892 is reported to have been, though cut by frost, 13 ft. high in 1905. The Rev. Dr. Landsborough informed Mr. Birkbeck that the tree at Roseneath, referred to *E. regnans* in *Gard. Chron.* xxvi. 715 (1886), was *E. viminalis*.

² *E. Beauchampiana* is erroneously referred by Masters to *E. cinerea*, Mueller. It is doubtful if the name *E. Stuartiana*, Mueller, can be retained for the "Apple Eucalyptus," as it was first applied by Mueller to another species. Cf. p. 1645, note 2.

³ *Journ. Roy. Hort. Soc.* xxxvi. 374 (1910).

⁴ *Trans. Bot. Soc. Edin.* xxiii. 149 (1905).

⁵ Figured by J. D. Hooker in *Bot. Mag.* t. 7697 (1900), from a specimen which flowered in a cool greenhouse at Arbroath, Scotland. There are two good trees in the Temperate House at Kew.

⁶ *Gard. Chron.* xlii. pp. 376, *Suppl. Illust.* and 418 (1907).

⁷ *Journ. Roy. Hort. Soc.* xxxvi. 374 (1910).

E. hæmastoma, Smith, a large timber tree of New South Wales and Queensland. Seedlings planted at Kinloch Hourn and in the Isle of Arran¹ were soon killed.²

E. leucoxydon, Mueller, the Iron-Bark of New South Wales, Victoria, and South Australia. This was killed at Abbotsbury in the severe weather of 1908. A tree at Rosssdohan, Kerry, of this species, as well as it can be identified from a barren branch, was 33 ft. by 2 ft. 3 in. in 1910.

E. obliqua, L'Héritier, the Stringy Bark, an immense tree, abundant in Tasmania and forming the great part of the hill forests, ascending, according to Sir J. D. Hooker, to 4000 feet; also common in Victoria, New South Wales, and South Australia. We have specimens, without flowers or fruit, from two trees at Menabilly, which are probably this species. The largest is reported to have been 40 ft. by 2 ft. 8 in. in January 1911; the smaller one being 26 ft. by 1 ft. 11 in. A tree at Tregothnan, planted about five years and 20 ft. high in 1911, may also be referred to this species. Seedlings did not survive at Kinloch Hourn; but Mr. T. A. Dorrien-Smith informed Mr. Birkbeck in 1894 that he had a thriving tree at Tresco, Scilly Isles, which was 30 ft. high and twenty years old. This species was killed at Abbotsbury in the severe weather of 1908. As it ascends to a high elevation in Tasmania, seeds from there should produce hardy plants; but it appears to be rare in collections, and possibly only lowland forms have been tried.

E. resinifera, Smith, a tall tree, occurring in New South Wales and Queensland, where it is known as Red Gum. This was recorded³ as one of the plants uninjured at Ventnor, Isle of Wight, in the severe winter of 1879-1880; but it is very doubtful if the tree was correctly named; and we have not seen or heard of any specimens of this species in the open air in the British Isles.

E. rudis, Endlicher, a native of West Australia. Planted out in 1887 at Cromla in Arran,⁴ it had attained 15 ft. high in 1895, when it lost all its branches and leaves. Afterwards it sprouted from the root, and was 22 ft. high in 1905. Seedlings planted out at Kinloch Hourn were speedily killed. At Bradfield, Devon, it was reported⁵ to have been cut to the ground in 1885; but it afterwards sent up strong shoots. It was killed at Abbotsbury in the severe winter of 1908.

E. stellulata, Sieber, a small tree, occurring in Victoria and New South Wales. This has produced flowers and fruit at Rosssdohan, Kerry; but it is unlikely to prove hardy anywhere except in the extreme west of Kerry or in the Scilly Isles. It has not been tried, so far as we know, except at Rosssdohan.

The following key, based on the characters of the foliage, will serve to distinguish the species in cultivation in the open air in Great Britain and Ireland, and includes only those which have attained a considerable age, and have borne flowers and fruit:—

¹ Landsborough, in *Trans. Bot. Soc. Edin.* xx. 524 (1896).

² A tree cultivated under this name at Abbotsbury is *E. urnigera*; and another so-named at Leonardslee is apparently a form of *E. Gunnii*, which has survived 26° of frost. Sir E. G. Loder has tried *E. globulus*, *E. coccifera*, *E. urnigera*, *E. pulverulenta*, *E. amygdalina*, and *E. viminalis*: but these are always killed by 20° to 24° of frost.

³ By Ewbank, in *Journ. Roy. Hort. Soc.* viii. 10 (1887).

⁴ Landsborough, in *Trans. Bot. Soc. Edin.* xx. 520 (1896), and xxiii. 149 (1905).

⁵ J. W. in *Gard. Chron.* xxvi. 754 (1886).

I. *Leaves on adult trees, opposite, sessile, cordate at the base.*

1. *Eucalyptus cordata*, Labillardière, Tasmania. See p. 1620.

Young branchlets quadrangular, glaucous, roughened with oil-glands. Leaves suborbicular or broadly ovate, 2½ in. long, 2 in. broad; both surfaces glaucous and roughened with numerous raised oil-glands; crenate in margin.

2. *Eucalyptus pulverulenta*, Sims. New South Wales, Victoria, and Queensland.

See p. 1622.

Young branchlets terete or angled, smooth. Leaves ovate, 1½ in. long and broad; glaucous, smooth; entire or slightly undulate in margin.

II. *Leaves on adult trees, alternate, stalked.*

* *Leaves 5 in. or more in length.*

3. *Eucalyptus globulus*, Labillardière. Tasmania, Victoria, and New South Wales. See p. 1623.

Young branchlets green, quadrangular. Leaves thick, lanceolate, very falcate, 6 to 9 in. long, 1 to 1½ in. wide.

4. *Eucalyptus pauciflora*, Sieber. Tasmania, South Australia, Victoria, and New South Wales. See p. 1631.

Young branchlets usually more or less covered with a glaucous bloom. Leaves thick, lanceolate, about 5 in. long and ¾ in. broad, usually falcate; main lateral veins longitudinal.

5. *Eucalyptus viminalis*, Labillardière. Tasmania, Victoria, South Australia, and New South Wales. See p. 1633.

Young branchlets green, very slender, with four linear ridges. Leaves narrowly lanceolate, 5 to 6 in. long, ½ to ¾ in. broad, falcate, tipped at the apex with a long slender curved or twisted filamentous point.

** *Leaves less than 5 in. long.*

(a) *Leaves and branchlets glaucous.*¹

6. *Eucalyptus coccifera*, J. D. Hooker. Tasmania. See p. 1635.

Young branchlets covered with a thick whitish bloom. Leaves lanceolate, 2½ to 3 in. long, ⅔ to ¾ in. wide, thick in texture, green or glaucous, tipped with a long slender curved point.

7. *Eucalyptus Gunnii*, J. D. Hooker. High altitudes in Tasmania, Victoria, and New South Wales. See p. 1638.

Young branchlets more or less glaucous. Leaves ovate-lanceolate, 2 to 2½ in. long, ⅝ to ⅞ in. broad, thick in texture, shining green, tipped with a short point.

(b) *Leaves and branchlets not glaucous.*

† *Leaf margin entire.*

8. *Eucalyptus whittinghamensis*, Nicholson. A hybrid, probably originating in Tasmania. See p. 1642.

Young branchlets¹ usually green, terete. Leaves lanceolate, 3 to 3¾ in. long, ⅝ to ¾ in. wide, usually straight, greyish green, entire in margin.

¹ Some of the descendants of *E. whittinghamensis* have glaucous branchlets.

9. *Eucalyptus acervula*, Miquel. Tasmania, Victoria, New South Wales, South Australia, and Queensland. See p. 1645.

Young branchlets green, terete. Leaves lanceolate, or ovate-lanceolate, 4 in. long, $1\frac{1}{4}$ in. broad, usually straight, dull green, often undulate in margin.

10. *Eucalyptus vernicosa*, J. D. Hooker. Tasmania. See p. 1646.

Young branchlets green, angled. Leaves alternate or sub-opposite, narrowly ovate or elliptical, $\frac{1}{2}$ to 2 in. long, $\frac{1}{2}$ to 1 in. broad, very thick and coriaceous, shining as if varnished on both surfaces.

†† Leaf-margin distinctly crenate.

11. *Eucalyptus Muelleri*, T. B. Moore. Tasmania. See p. 1647.

Young branchlets reddish. Leaves usually straight, lanceolate, 3 to 4 in. long, $\frac{3}{4}$ to 1 in. wide, thick in texture, shining polished green on both surfaces.

12. *Eucalyptus urnigera*, J. D. Hooker. Tasmania. See p. 1649.

Young branchlets green, tinged with red. Leaves ovate-lanceolate, 3 to $3\frac{1}{2}$ in. long, 1 to $1\frac{1}{2}$ in. broad, often falcate, thick in texture, dull yellowish green.
(A. H.)

CULTIVATION

If one may judge from the numerous references in horticultural literature to this genus, none has been more persistently tried in various parts of the country; and yet when we come to record the small number of trees which have endured our climate for more than a few years, it must be acknowledged that none has proved more disappointing. Even in those parts of the south and west where the thermometer only falls to 15° or 20° Fahr. at long intervals, not more than a few species have long endured, and possibly the absence of summer heat is the cause, quite as much as the cold and damp of winter. Though the Eucalypti seem indifferent as regards soil, and grow for a few years with great rapidity, yet with some exceptions they are short-lived, and die off suddenly after an inclement season, or blow down, when they become tall enough to be exposed to gales.

No one in England seems to have tried to graft the more tender species on stocks of the hardier ones, though, judging from experience in other genera, it might be possible to do this successfully.¹ On account of their leaves, flowers, bark, scent, and habit, all so unlike those of any European trees, they form an attractive feature in gardens and pleasure grounds; and are so easy to raise from seed, that the certainty of their death after a few years will not deter gardeners from planting them.

A great many species have been tried at different times in the open in the British Isles; but only a few have proved hardy even in the mild climate of the south and west; and the only really large and old trees which have survived are those at Powderham, Penmere, Garron Tower, and Whittingehame. The Whittingehame hybrid is perhaps the hardiest of all, and is the only species which has succeeded out of doors at Kew.

¹ In *Gard. Chron.* xxv. 145 (1899) an interesting article on this question will be found, largely taken from a paper by M. Felix Sahut in the *Annales de la Société d'Horticulture de l'Herault*, which should be consulted by any one wishing to propagate Eucalypti by budding or grafting.

Mr. Robert Birkbeck, to whom we are much indebted for information concerning the cultivation of this genus, has tried forty or fifty species at Kinloch Hourn, on the west coast of Scotland, and sums up his experience as follows:—" *E. vernicosa* is the hardiest of all the species; *E. Gunnii*, *E. coccifera*, *E. cordata*, and *E. urnigera* may be considered quite hardy; *E. globulus* will stand 15° of frost only; and *E. amygdalina* about the same. Both *E. viminalis* and *E. pauciflora* are more tender than *E. globulus*. *E. alpina* is slightly hardier, but is killed by 20° of frost." Mr. Birkbeck gives a long list¹ of species which completely failed at Kinloch Hourn, and tells us that *E. alpina*, *E. amygdalina*, *E. viminalis*, and *E. globulus* were killed at Inveraray.

At no place have more species been tried in the open air than at Lady Ilchester's garden at Abbotsbury, in Dorsetshire; and Mr. Kempshall, head gardener there, sent us a list of forty species, all of which succumbed in the cold winters of 1907 and 1908, except the following:—*E. coccifera*, *E. cordata*, *E. Gunnii*, *E. Muelleri*, *E. vernicosa*, and *E. urnigera*, the last named being in his opinion the hardiest species.

Mr. Birkbeck gives the following rules for their propagation and planting:—Raise them from seed under glass; pot when 2 or 3 in. high; repot often as they never do well after their roots are pot-bound. Give them some bone-meal, keep under glass till 3 ft. high, and plant out in good soil in May or June, when they are about two years old. Keep them well staked, as they are easily blown down, but keep the fastenings loose, as they increase in girth quickly.

When planting has to be done on a large scale, seedlings should be treated exactly like pines and other conifers, *i.e.* they should, when about 6 in. high, be transplanted in the nursery to promote the formation of lateral rootlets, which will render easy their establishment in the ground where they are to remain permanently. Seedlings should not be dried up when being moved, and ought to be transplanted in cool cloudy weather, and watered for some days afterwards.

With regard to economic planting of the Eucalypti in warmer parts of the world than our own islands, we cannot enter into any details concerning the selection of the proper species; and must refer our readers to the excellent papers of Naudin,² which deal with their cultivation in the south of France, and to those of M'Clatchie² and Ingham,² which give a complete account of the results already obtained in California, where many species have been tried. The admirable report³ on Cyprus by Mr. D. E. Hutchins, whose long experience in South Africa enables him to speak with authority, may also be consulted. (H. J. E.)

¹ A list of thirty-five species tried at Kinloch Hourn is given in *Trans. Bot. Soc. Edin.* xx. 525 (1896). Mr. Birkbeck wrote a further account of his experience in *Gard. Chron.* xxv. 84 (1899).

² See the titles of these papers at the beginning of this article. Cf. also *U.S. Forest Service Bull.* No. 87, pp. 1-47 (1911), which gives an account by Zon and Briscoe of the species which are planted in Florida, with notes on their cultivation.

³ D. E. Hutchins, *Report on Cyprus Forestry*, pp. 64-67 (London, 1909); cf. also the same author, in Flint and Gilchrist, *Science in South Africa*, 395-396 (Cape Town, 1905).

EUCALYPTUS CORDATA, TASMANIAN HEART-LEAVED GUM

Eucalyptus cordata, Labillardière, *Pl. Nov. Holl.* ii. 13, t. 152 (1806); J. D. Hooker, *Fl. Tasm.* i. 132 (1860), and *Bot. Mag.* t. 7835 (1902); Bentham and Mueller, *Fl. Austral.* iii. 224 (1866); Mueller, *Eucalyptographia*, Dec. viii. (1882); Masters in *Gard. Chron.* iii. 798, fig. 111 (1888); Maiden, in *Rep. Austral. Assoc. Advance. Science, Hobart*, 1902, p. 374; R. T. Baker, in *ibid.* p. 344; Rodway, *Tasmanian Flora*, 58 (1903); Parsons, in *Gard. Chron.* xlvii. 168, *Suppl. Illust.* (1910).

A small tree, rarely exceeding 30 ft. high in Tasmania. Bark smooth, the older bark being shed in scales. Young branchlets quadrangular, glaucous, roughened with reddish oil-glands. Leaves (Plate 365, Fig. 1) on adult trees, opposite, in decussate pairs, sessile; suborbicular or broadly ovate, averaging $2\frac{1}{2}$ in. long and 2 in. broad; cordate and clasping at the base; rounded or acute, rarely emarginate, at the apex, which is usually tipped with a short triangular point; similar in colour on both surfaces, green, or more or less covered with a whitish bloom; margin reddish, revolute, distinctly crenulate; oil-glands very numerous, unequal, pellucid, the larger ones roughening the surface as minute protuberances; lateral nerves few, slender, spreading from the midrib at an angle of 80° .

Flowers in axillary umbels of threes, usually glaucous; peduncle stout, glaucous, $\frac{1}{4}$ in. long; calyx-tube campanulate, sessile, $\frac{1}{3}$ in. long, covered with oil-glands, usually with two lateral ridges; operculum cap-shaped, rounded, with a short conical umbo; stamens all perfect, inflexed in the bud; anthers ovate, with distinct parallel cells. Fruit hemispheric, but slightly contracted at the summit, where it is about $\frac{1}{2}$ in. in diameter; glaucous and slightly roughened with oil-glands; rim narrow, slightly elevated; capsule deeply enclosed, the four valves when open scarcely reaching the level of the rim.

Seedling,¹ with a terete tuberculate stem; cotyledons slightly emarginate, three-nerved, transversely oblong; primary leaves sub-sessile, opposite, acute, followed by crenate sessile leaves.

This species was discovered in 1792 by Labillardière near Recherche Bay in Tasmania, and appears to be confined² to this island, where it is rare and local, being recorded also for Mount Brown, Huon Road, Campania, and the Tasman Peninsula. It is without any economic value, and has no popular name in the colony; but Rodway calls it Heart-leaved Gum. It sometimes remains shrubby, and bears flowers and fruit when only 3 ft. high; but is usually a small erect tree, occasionally attaining 30 ft. in height, according to Mueller, who adds that Mr. Coombs found a tree 50 ft. high and 18 inches in diameter on the Sandfly river.

E. cordata appears to have been early introduced, as Sir J. D. Hooker knew

¹ Lubbock, *Seedlings*, i. 531 (1892).

² It is said by Deane and Maiden, in *Proc. Linn. Soc. N.S. Wales*, 1901, p. 126, to occur at Rockley Road, near Bathurst in N.S. Wales; but the specimen, which I have seen from that locality in the Cambridge Herbarium, is *E. pulverulenta*; and R. T. Baker, in *Rep. Austr. Assoc. Advance. Sc. Hobart*, 1902, p. 344, considers that the Bathurst tree is certainly the latter species.

about sixty years ago a plant trained on a wall at Kew, of which there is a specimen in the herbarium, gathered in 1851. This tree was eventually killed by frost. This species often flowers under glass at Kew, forming a pyramidal tree,¹ about 15 ft. high, and is much used in the young state for bedding out.²

At Menabilly there is a fine tree, which Mr. Bennett reported to be 50 ft. high by $2\frac{1}{2}$ ft. at three feet from the ground in 1909. Colonel Trefusis tells us that at Porthgwithen,³ in the same county, it produces flowers and is 28 ft. high and 1 ft. 2 in. in girth. A. B. Jackson saw a tree at Heligan 30 ft. high in 1909. It is also growing at Redruth and at Pencarrow in Cornwall, and at Exeter, where it has frequently flowered; but is ultimately killed by 20° of frost.⁴ At Abbotsbury this species is very thriving, surviving the severest winters and freely producing seed from which seedlings have been raised.

At Myddelton House,⁴ Waltham Cross, Herts, it produces flowers, and, though killed every ten years or so, is so beautiful that it is well worth growing. There is a specimen in the Arboretum Herbarium, Kew, sent some years ago from Vicar's Hill, Lymington, by Mr. E. H. Pember; but this does not appear to be now living, and was probably killed by frost.

On the west coast of Scotland this is one of the hardiest species. It has thriven at Kinloch Hourn,⁵ where, planted in 1894, a tree which had twice lost its top in a storm, was 34 ft. by 1 ft. 10 in. in 1905. At Cromla,⁵ in Arran, a tree planted in 1894, was 26 ft. by 13 in. in 1905. Here the flower buds form in August, and expand early in March of the following year, this tree being one of the first to flower in spring. At Inverewe on the west coast of Ross-shire this species is very thriving, and of all the species which flowered early in 1910, this was the only one which was in fruit in December of that year. The trees here were raised by Mr. Osgood H. Mackenzie from seed ripened at Abbotsbury; and one of them in 1911 was 33 ft. high by 18 in. in girth, at ten years old.

In Ireland, Elwes saw a tree in flower at Castlewellan,⁶ about 20 ft. high in 1908. At St. Anne's, near Dublin, a specimen,⁷ which was planted out in 1904, has passed through one or two severe winters, and was 20 feet high in 1909. There are trees at Rostrevor of the same size, which flower freely. (A. H.)

EUCALYPTUS PULVERULENTA, AUSTRALIAN HEART-LEAVED GUM

Eucalyptus pulverulenta, Sims, *Bot. Mag.* t. 2087 (1819); Bentham and Mueller, *Flora Austral.* iii. 224 (1866); Mueller, *Eucalyptographia*, Dec. viii. (1882); Howitt, in *Rep. Aust. Assoc. Advance. Sci.*, Sydney, 1898, p. 517, pl. xxvi.-xxix.; Deane and Maiden, in *Proc. Linn. Soc. N.S. Wales*, 1899, p. 465, and 1900, p. 110; Maiden, in *Proc. Linn. Soc. N.S. Wales*, 1901, p. 547; R. T. Baker, in *Rep. Aust. Assoc. Advance. Sci.*, Hobart, 1902, p. 345.

Eucalyptus cordata, Loddiges, *Bot. Cab.* t. 328 (1819) (not Labillardière).

Eucalyptus pulviger, A. Cunningham, in Field, *Geog. Mem. N.S. Wales*, 350 (1825).

A tree, attaining in Australia 50 ft. in height and 10 ft. in girth; but flowering when in a shrubby state. Bark light brown, persistent, somewhat fibrous. Young branchlets, terete or slightly angled towards the tip, covered with a white glaucous bloom. Leaves (Plate 365, Fig. 3) on adult trees, opposite, sessile, in decussate pairs, ovate, about $1\frac{1}{2}$ in. long and broad; cordate and clasping at the base; rounded or acute at the apex, which is tipped with a short triangular point; similar in colour on both surfaces, which are more or less covered with a whitish bloom; lateral veins slender, spreading from the midrib at an angle of 60° ; margin reddish, entire or slightly undulate; oil-glands numerous, mostly pellucid, not prominent or roughening the surface as in *E. cordata*.

Flowers glaucous, in axillary umbels of threes; peduncle stout, glaucous, $\frac{1}{8}$ in. long; calyx-tube sessile, turbinate, dotted with oil-glands, about $\frac{1}{8}$ in. long; operculum conic, tipped with an acuminate point; stamens all perfect, inflexed in the bud; anthers ovate, with distinct parallel cells. Fruit turbinate, about $\frac{1}{3}$ in. broad at the summit, glaucous, dotted with oil-glands; rim thick and convex; capsule slightly included, the three or four valves when open protruding beyond the orifice.

This species has thinner and smoother leaves than *E. cordata*, with their margin not crenate; the operculum of the flower bud is conical and long, while that of *E. cordata* is shorter and slightly convex; the fruits are smaller with more protruding valves than in the last-named species. The bark of the two trees is quite different, that of *E. pulverulenta* persistent and fibrous, while that of *E. cordata* is deciduous, smooth, and peeling off in ribbons.

1. Var. *lanceolata*, Howitt, in *Austr. Assoc. Advance. Sci.*, Sydney, 1898, p. 518.

Eucalyptus cinerea,¹ Mueller, in Bentham, *Fl. Austral.* iii. 239 (1866).

Eucalyptus nova-anglica, Deane and Maiden, in *Proc. Linn. Soc. N.S. Wales*, 1899, p. 616.

Eucalyptus Stuartiana, Mueller, var. *cordata*, Baker and Smith, *Researches on Eucalypts*, 105 (1902).

Leaves on old trees, lanceolate, 4 in. long, usually opposite, occasionally alternate.

E. pulverulenta is a native of Australia, where it was discovered by A. Cunningham on the Lachlan and Cox's rivers in New South Wales. The typical form of the species is widely diffused in the southern mountainous part of this colony from

¹ The type of *E. cinerea* comprises Cunningham's specimen from Lachlan river near Bathurst, and Mueller's specimen from Lake George, both localities in New South Wales. These specimens are, I think, intermediate between the typical form of *E. pulverulenta* and var. *lanceolata*.

Tumut to Berrima, and thence westerly to the Bathurst district. It also occurs near Lake George, and in Argyle and Camden counties; and is common in the Goulburn district. The lanceolate-leaved variety, which is known as Black Peppermint, is common over the greater portion of New England, and also occurs on the summit of Ben Lomond. Both the typical form and the variety occur in Gippsland in Victoria, at Buchan, near Walhalla, around Lake Omeo, and between the Avon and Mitchell's rivers.

Specimens of the lanceolate-leaved variety have been collected at Killarney and Stanthorpe in Queensland. This species appears to be always a small tree, of no economic value.

E. pulverulenta was introduced some years before 1819, when it was figured as *E. cordata* by Loddiges, who states that it only requires ordinary greenhouse protection in winter. It is, however, cultivated in the open air at Abbotsbury,¹ where it produces fruit freely, and is said to be hardy. It is also grown at Menabilly, where the best of five specimens is 32 ft. by 1 ft. 3 in.

E. pulverulenta has been much confused with *E. cordata*; and the trees recorded² at Braxted Park, Essex, which were said to have been 30 to 40 ft. high, and flowering freely in 1849-1851, were in all probability *E. cordata*.

E. pulverulenta did not succeed at Kinloch Hourn; and the tree³ planted in 1856 at Pirmill, Isle of Arran, must have died, as Dr. Landsborough does not mention it in his list of the Arran species in 1895.

Sir F. W. Moore tells us that a small plant at Kilmacurragh in Co. Wicklow appears to be perfectly hardy; and another at Mount Usher, about eight years old, was thriving and producing flowers in 1911. At Castlewellan,¹ Elwes collected a specimen from a tree 20 ft. high in 1908. (A. H.)

EUCALYPTUS GLOBULUS, BLUE GUM

Eucalyptus globulus, Labillardière, *Relation Voyage Recherche La Pérouse*, i. 153, *Atlas*, t. 13 (1799); J. D. Hooker, *Fl. Tasm.* i. 133 (1860); Bentham and Mueller, *Fl. Austral.* iii. 225 (1866); Mueller, *Eucalyptographia*, Dec. vi. with two plates (1880), and in *Gard. Chron.* xiv. 137, 213, 233 (1880); Bentley and Trimen, *Medic. Plants*, ii. t. 109 (1880); Hemsley, in *Gard. Chron.* ii. 784, *Supply. Illust.* (1887); Maiden, in *Austr. Assoc. Advance. Science*, Hobart, 1902, p. 372; Rodway, *Tasmanian Flora*, 58 (1903); Pinchot, *U.S. Dept. Agric. Forest Service*, *Circ.* No. 59 (1907).

Eucalyptus cordata, Miquel, in *Nederl. Kruidk. Arch.* iv. 140 (1859) (not Labillardière).

Eucalyptus diversifolia, Miquel, *loc. cit.*

Eucalyptus gigantea, Dehnhardt, *Cat. Pl. Hort. Camald.* 20 (1832) (not J. D. Hooker); Mueller, in *Nuovo Giorn. Bot. Ital.* xii. 47 (1880).

A tree, commonly attaining in Australia about 200 ft., rarely nearly 300 ft. in height. Bark smooth, greyish or bluish white, the outer layer peeling off in long ribbons. Young branchlets green, quadrangular, with four prominent ridges; older

¹ Both at Abbotsbury and Castlewellan, where both species occur, it was wrongly labelled *E. cordata*.

² *Gard. Chron.* xi. 469 (1892).

³ Landsborough, in *Trans. Bot. Soc. Edin.* xx. 524 (1896).

branchlets terete, reddish brown. Leaves (Plate 365, Fig. 10), on adult trees, alternate, lanceolate, about 6 to 9 in. long and 1 to 1½ in. broad, but often greater or less than these dimensions; falcate, thick and leathery, unequal and cuneate at the base, gradually tapering to an acuminate apex, which ends in a long curved slender point; margin revolute, whitish, undulate; both surfaces pale green and slightly shining; lateral veins numerous, arising at an angle of about 45°, with the circumferential vein regularly distant about $\frac{1}{16}$ in. from the margin; oil-dots scattered, unequal, mostly concealed; petiole twisted, flattened above, $\frac{3}{4}$ to 1½ in. long. Leaves on young plants and suckers, opposite, decussate, with a short and not twisted petiole; 2 to 5 in. long, 1 to 2½ in. broad; ovate, cordate at the base; acute or rounded at the apex, which is tipped with a cuspidate point; circumferential vein $\frac{1}{2}$ to $\frac{1}{8}$ in. distant from the white revolute crenate margin; both surfaces more or less covered with a glaucous bloom, which is also present on the slender four-angled branchlets.

Flowers¹ axillary, solitary or rarely two or three in an umbel, borne on a short laterally compressed stalk; flower-buds large and covered with a glaucous bloom; calyx-tube pyramidal, nearly $\frac{1}{2}$ in. long, $\frac{3}{4}$ in. wide at the distal end, with four longitudinal ridges, the lateral pair of which are very prominent; operculum hemispherical, exceeding the calyx-tube in breadth and length, very tuberculate on the surface, with a short triangular umbo; stamens all fertile; anthers ovate, with parallel cells; filaments inflexed in the bud. Fruit hemispheric or obpyramidal, glaucous, $\frac{3}{4}$ to 1 in. in diameter, with four longitudinal ridges, and an overhanging very broad rim, separated from the calyx by a furrow; capsule not sunk, the valves being nearly level with the rim.

The seedling² has a stem, terete at the base, and quadrangular towards the tip, warty on the surface and covered with a glaucous whitish bloom. Cotyledons deeply bifid, with obovate diverging lobes, about $\frac{1}{2}$ in. long and $\frac{2}{3}$ in. wide, three-nerved, the middle nerve ending in the sinus. Primary leaves, opposite, decussate, sessile, the first and second pairs linear-lanceolate and acute, tapering at both ends; third and fourth pairs lanceolate-oblong; fifth to eighth pairs oblong. Leaves on the subsequently developed branches, oblong, and subcordate at the base.

VARIETIES

According to Mueller,³ most of the Victoria specimens have smaller flowers and fruits, the latter more convex than those in Tasmania. According to Rodway,⁴ the common form in eastern Victoria bears three-flowered umbels; while in Tasmania the flowers are usually solitary. In cultivated specimens, however, the number of flowers in the umbel appears to be an inconstant character, though solitary flowers are usually borne in England. Rodway further states⁴ that in Tasmania, where this

¹ This species frequently flowers when very young. In *Gard. Chron.* xi. 180 (1892), a specimen three years old and 7 ft. high is said to have flowered in Thomson's nursery at Sparkhill, Birmingham.

² Lubbock, *Seedlings*, i. 530, fig. 339 (1892).

³ *Fl. Austr.* iii. 225 (1866).

⁴ In J. C. Penny, *Tasmanian Forestry*, 15 (905).

species and *E. viminalis* are mixed, a form is occasionally found, in which the flowers are in threes, with the operculum and fruit quite smooth, the latter only $\frac{1}{3}$ to $\frac{1}{2}$ in. in diameter, with the valves much protruding. This is possibly a hybrid.

DISTRIBUTION

The Blue Gum is a native of Tasmania, Victoria, and New South Wales. In Victoria, it occurs in valleys as well as on ridges and mountain slopes, chiefly in the humid southern and eastern districts from Cape Otway to Wilson's promontory, and extending northwards to the Hume and Tumut rivers in the southern part of New South Wales, where it is also met with between Braidwood and Araluen. It appears, however, to be very rare in New South Wales, as J. V. De Coque states¹ that he only knows of it in this colony in the Tumberumba district at 2500 to 3000 ft. elevation. There it is called *Eurabbie*, a purely local name, and is highly valued, and largely used for mining purposes, and for bridge-decking and girders. Except in the above district, it is little known in New South Wales, where it does not attain anything like the size and height that it does in Victoria or Tasmania; and recently fell into disrepute, owing to *E. amygdalina*,² which lacks strength and durability, having been mistaken for it. In Tasmania, it appears to be almost confined to the south-eastern part of the island near the coast, extending inland, according to Sir J. D. Hooker, from Hobart about forty miles. Rodway describes it as a tall erect tree, even in exposed situations, with few and acutely diverging branches. A tree of full growth will average 7 feet in diameter at the butt, 100 ft. to the lowest branch, and from 200 to 250 ft. in extreme height. In youth it grows rapidly; but when approaching maturity the growth is almost imperceptible; and Rodway supposes that the tree takes 300 to 400 years to attain its full dimensions. The Rev. J. E. Tenison-Woods says³ that in Tasmania the forests of blue gum are limited in extent, and are confined to a few localities, from sea-level to about 1000 ft. altitude. It is only on steep slopes in the deep mountain valleys and gorges that the trees attain a great height. He states that experiments have shown that the trees make two rings of growth each year; and that Mr. Hill, who cut up thousands of trees at his saw-mills at Honeywood, affirmed that he never found one over 75 years old; but this statement seems doubtful.

HISTORY

E. globulus was discovered in 1792 by Labillardière in Tasmania, and was described by him in 1799. It was introduced into continental conservatories early in the 19th century, where, on account of its different foliage in the young state it was known under several names.⁴ It appears to have been first cultivated out of

¹ In *Journ. Proc. Roy. Soc. N.S. Wales*, xxviii. 212 (1894).

² *E. Maidenii*, Mueller, another species also known as Blue Gum, has until recently been often confused with it.

³ In *Journ. Roy. Soc. N.S. Wales*, xii. 17-28 (1879). Cf. also *Gard. Chron.* xiv. 179 and 187 (1880).

⁴ *E. glauca*, De Candolle, *Prod.* iii. 221 (1828); *E. pulverulenta*, Link, *Enum. Pl. Berol.* ii. 31 (1822) (not Sims); *E. perfoliata*, Noisette, *ex Steudel, Nomencl.* 320 (1821); and possibly *E. perfoliata*, Desfontaines, *Cat. Hort. Paris*, 408 (1829).

doors in Europe at Camaldoli, near Naples, where the German gardener, Dehnhardt, employed at the Naples Botanic Garden, published it as *E. gigantea* in 1832. The tree, however, was only known as a curiosity, till Mueller sent large quantities of seed, gathered at the base of Mount Butler in 1853, to nearly all the botanic gardens of Europe. Probably from this seed, most of the earliest plants¹ were raised in Algeria, where the blue gum produced flowers for the first time in 1863. M. Prosper Ramel began in 1858 to extend the cultivation of this tree in the south of France, receiving large quantities of seed from Mueller.

The well-known plantations in the Campagna near Rome were commenced in 1879 by the Trappist monks of Tre Fontana, who received the first seed in that year from Mueller, through Dr. Goold, R.C. Archbishop of Melbourne. The blue gum was introduced in 1865 into Spain, where it became known as the fever tree, because it was believed in Spain, as in Italy, "to purify marshy regions that engender fever." The tree is also largely planted in the Nilgiri hills in India, where it is said to have been introduced as early as 1843. According to Mr. M'Clatchie, it was the first species of Eucalyptus planted in California, and the one that has been most successfully grown. The date of introduction there appears to have been 1856, when Mr. Walker planted fourteen species; but the cultivation of Eucalypti on a large scale in California is due to Mr. Nolan, a nurseryman of Oakland, who received a large supply of seed of several species from Australia in 1861. It is commonly planted in Chile, where in some parts of the country it has attained a great size, and is an important timber and shade tree.

With regard to the growth of the blue gum in foreign countries, Mueller states,² that a tree at Gaeta, planted in 1854, was 100 ft. high and 11 ft. in girth at the base in 1878. Dr. W. von Hamm of Vienna saw larger trees on Lake Maggiore, one³ of which, supposed to be twenty-eight years old, was 120 ft. high in 1878. At Hyères, a tree raised from seed in 1857, had attained in 1875 a height of 67 feet with a girth of 7 ft. near the base. Farther south, the growth is still more rapid, a tree at Malaga having attained 65 feet in six years. The greatest rapidity of growth occurs at considerable altitudes on the mountains of the tropics, where the climate is temperate and equable, combined with continuous humidity of the atmosphere. At Arambi, near Ootacamund in the Nilgiris in India, the blue gum attains a height of 107 ft. in nineteen years, and yields 8696 cubic feet per acre, equal to 457 cubic feet annually per acre at 7426 feet above sea-level in lat. 11° N.⁴ In California, according to M'Clatchie,⁵ trees about thirty years old have attained 150 ft. in height and 3 to 6 ft. in diameter. He gives a plate of an avenue at Santa Barbara, where the trees, planted thirty years ago, range from 3 to 5 ft. in diameter. M'Clatchie also says there are many instances of blue gums attaining 50 to 75 ft. in from five to ten years; and adds that it is without doubt the fastest-growing tree in the world.⁶

¹ Planchon, according to Mueller, states that the first plants in Algeria were raised in 1854, from seed sent by the Jardin des Plantes, Paris, which may have come from Hohart direct.

² *Eucalyptographia*, dec. vi. (1880).

³ Sir D. Brandis, quoted in *Kew Bull.* 1895, p. 3.

⁴ Ingham, in *Agric. Exp. Sta. Berkeley, Calif., Bull.* No. 196, p. 77 (1908), gives equally remarkable records; a plantation of 319 trees, set out 8 ft. apart on medium loam at Vacaville, averaged, at twenty-five years old, 125 ft. high and 14½ in. in diameter at breast height.

⁵ We are unaware of the existence of any such trees now.

⁶ *Eucalypts cultivated in the U.S.* p. 61, fig. 21 (1902).

The Eucalyptus was first planted in the Campagna and in other malarious districts on account of its supposed febrifuge action. At that time, it was not known that malaria is due to a parasite in the blood, which is carried to man by the bites of mosquitoes. The Eucalyptus plantations have indirectly, however, done good in two ways, by drying up the pools in which the mosquitoes breed, and by forming a screen, which hinders their flight.¹

Hutchins² says that it is not worth planting in Cyprus, as it will not succeed in the drier parts, and is second rate for its timber in wetter soils. Its wood burns badly in an open fireplace. (A. H.)

REMARKABLE TREES

E. globulus is perhaps not absolutely hardy in any part of Britain or Ireland; but it may survive many years and attain large dimensions in favourable localities.

The largest tree of which we have any record, grew at Rozel Bay, Jersey, about 200 yards from the sea on rock covered with little soil, but in a warm and dry situation. It was planted in 1862, and was reported³ by Mr. T. Sharman to have been 110 ft. high and 10 ft. 3 in. in girth in 1892. It produced flowers and fruit freely, from which seedlings were raised several times. It was killed⁴ by the severe frost of 1894-1895.

The oldest tree was one at Tresco, Scilly Isles, which was planted about 1850. It never reached more than 40 ft. in height, as the top was blown off from time to time, but it was 9 ft. in girth in 1891, when it was blown down.⁵ One of the best that I have seen in England is at Coombe Royal, Devonshire. Though only twelve years old in 1906, it was a tall straight tree, about 50 ft. by 2½ ft.⁶

At Menabilly, Mr. Bennett tells us of a tree, which was 75 ft. high by 3 ft. in girth in January 1911. There are two well-shaped trees in Sir Thomas Bazley's garden at Kilmorie, Torquay, which in October 1910 measured 58 ft. by 2 ft. 9 in. and 53 ft. by 4 ft. The latter is figured (Plate 359) from a photograph taken by Sir Thomas Bazley, who informed me that they were planted in 1897.

At Penmere, near Falmouth, the residence of Mr. Horton Bolitho, there is a remarkably fine tree⁷ (Plate 360) which I measured in 1911, as 95 ft. high by 7 ft. 9 in. in girth, with the bole clear of branches for about 40 ft. Mrs. W. L. Fox informs me that this tree was planted between 1864 and 1867.

At Trevarno, Cornwall, a tree about eight years old was 25 ft. high in 1890, and bore flowers for the first time, in great profusion.⁸ Trees flowered and produced

¹ Cf. Sir W. T. Thiselton-Dyer, in *Kew Bull.* 1903, pp. 1-10.

² *Report on Cyprus Forestry*, 65 (1909).

³ *Gard. Chron.* xi. 468, and xii. 408 (1892).

⁴ *Ibid.* xxxix. 281 (1906). In *Gard. Chron.* xxv. 145 (1899), it is stated that the genus Eucalyptus was practically exterminated from Jersey in the severe winter of 1894-1895.

⁵ T. A. Dorrien-Smith, in *Gard. Chron.* x. 737, fig. 107 (1891).

⁶ The statement in *Gard. Chron.* xxxiv. 292 (1903), that the blue gum flourishes at Powderham, and makes a growth of 60 ft. in ten years, is erroneous, as the only species cultivated there now is *E. coccifera* (cf. p. 1636). *E. globulus* was killed at Powderham in 1878-79, by 12° of frost, according to *Gard. Chron.* xii. 113 (1879).

⁷ In *Gard. Chron.* xiii. 268 (1893), Mr. Howard Fox reported several trees at Penmere, 50 to 70 ft. high and 7 ft. in girth in 1893, which were flourishing in exposed positions. Mr. Fox says that at his own garden at Rosehill, which is sheltered, the trees grow too fast for their roots, and are blown down by a strong gale.

⁸ *Gard. Chron.* viii. 138 (1890).

fruit in 1898 at Polgwin,¹ Cornwall, and at Huntly,² Bishops Teignton; and in 1888 at Beaconhill House, Exmouth.³

In the Isle of Wight, according to the Rev. H. Ewbank,⁴ the blue gum was very early planted, and had attained a large size at Ryde and elsewhere; but all these trees were killed in the severe winter of 1881. The same applies, he says, to Bournemouth, where the trees thrive for a time, but are ultimately killed by a severe frost. At Ventnor, however, there were said⁵ to be specimens 40 ft. high in 1890, which produced flowers and fruit regularly.

At Kew, seed was obtained⁶ from Tasmania in 1888, which had been gathered from a few trees⁷ growing in a sheltered gully near Tullochgorum, the only spot in Tasmania where this species occurs naturally in a cold climate. The seedlings which were raised did not prove as hardy as those from the ordinary form of the species; and all died in 1889, though they were protected by canvas screens.

At Tan-y-bwlch, North Wales, several trees⁸ had attained 50 feet in height at nine years from seed, and flowered freely, but were seriously injured in 1890-91. Seedlings were reported to have been raised from their seed, when they were only seven years old.⁹ At Colwyn Bay, a tree was reported¹⁰ to be 33 ft. high in 1894. Another, at Cefnamwich, Nevin, North Wales, sown in the spring of 1894 by Mr. Hugh G. Jones, was 59 ft. by 4 ft. 8 in. in December 1909.

At Belvoir Castle, this species¹¹ was killed when 12 ft. high on 8th February 1900, when the thermometer fell to 10° Fahr.

In Scotland, the tree only lives for a few years, even in the warmest places. The Rev. Dr. Landsborough, in his account¹² of the Eucalypti in Arran, says that the severe winter of 1880-1881 killed all the blue gums on the mainland of Scotland, including those at Stonefield, Loch Fyne, and all in Arran, except a tree at Lamlash, which, however, was blown down in 1892, when it was more than 40 ft. high. A tree,¹³ however, at Tighnabruaich, Kyles of Bute, which was cut to near the ground in 1894-95, when the temperature fell to 19° Fahr., made fresh growth, and was 54 ft. by 3 ft. 9 in. in 1905. At Logan House, near Stranraer, a tree¹⁴ planted against the south wall of the house, in 1884, had covered the whole wall in 1899; and produced flowers and fruit in 1894, from which numerous seedlings were raised. Two trees planted here in the woods in 1897 were reported to be thriving, although 17° of frost was registered in November 1898. At Castle Kennedy, I saw in 1906 a tree about

25 ft. by 2 ft., which had grown from the stump of one killed by frost in 1895-1896. At Kinloch Hourn, *E. globulus*, when planted out, speedily succumbs, as, according to Mr. Birkbeck, it is always killed by 15° of frost.

In Ireland, the tallest specimen is at Dinas Island, Muckcross, Killarney, and measured in 1909 about 77 ft. by 6½ ft. The gardener informed me that it was severely injured by cold in 1879; but it was, when I saw it, a healthy tree in full flower in August. A finer tree, planted about 1870, grows on the lawn of the Marquess of Lansdowne's house at Derreen, Co. Kerry, and measured about 60 ft. by 7¼ ft. in August 1910. At Rossdohan, Mr. S. T. Heard reports a tree, 50 ft. by 5 ft. 8 in. in 1910.

At Garron Tower, on the coast of Antrim, near Larne, at 250 ft. elevation above the sea, a tree,¹ planted in 1857, was 60 ft. high and 12 ft. in girth at a foot from the ground in 1897; and 75 ft. high by 13 ft. at four feet from the ground in 1911. It branches at five feet up into two main stems; and produces flowers and fruit regularly, and from its seed numerous seedlings have been raised.

Sir Jocelyn Coghill, Bart., sent to Kew a branch from a tree grown at Glen Barrahan, Castle Townsend, Co. Cork, which, at fifteen years old, was about 40 ft. high in 1889. In Co. Wicklow Henry found a tree at Clonmannon about fifteen years old, which was 53 ft. by 4 ft. in 1905; and another at Dunran, 49 ft. by 4 ft. 4 in., and in flower in August 1904.

The largest tree that I have seen in Europe is in a sheltered ravine in the forest of Bussaco, Portugal, a little below the hotel. It measured in 1909 about 140 ft. by 12 ft.

TIMBER

In an account² of the forests of Tasmania, compiled by Mr. J. C. Penny, it is stated that the blue gum is the most valuable timber tree of Tasmania, having wood of great durability, hardness, and weight. It is said to be superior to anything produced in the Australian States for wharf and bridge construction. A specimen of this timber 146 ft. long, 18 in. wide, and 6 in. thick, sawn clear of heart and sap, was sent to the Exhibition of 1851 from Long Bay, Tasmania.

Mr. Harold J. Shepstone, in an article in the *Scientific American*,³ says: The erection of the great national harbour at Dover has called attention to the wonderful properties of the Tasmanian blue gum. It is at once one of the strongest timbers in the world, as well as the densest and most durable. It is so heavy that it will sink like a piece of lead, whilst also practically immune from the attacks of the sea-worm (*Teredo navalis*). It has a specific gravity of 75 lbs. to the cubic foot, and being heavier than water, piles 100 ft. long and 18 to 20 in. square can be sunk in deep water, without weighting them at the bottom, which is necessary in the case of Oregon piles (Douglas fir) weighing only 48 lbs. to the cubic foot. Tests

¹ G. Porteous, in *Gardening*, 13th November 1897. In *Journ. Roy. Hort. Soc.* viii. 189 (1887), the tree was reported to have been about 50 ft. high and quite uninjured by the severe winter of 1879-1880.

² *Tasmanian Forestry*, 3 (Hobart, 1905).

³ *Scientific American*, Jan. 21, 1905, quoted by Penny, *Tasmanian Forestry*, 36 (1905).

¹ *Gard. Chron.* xxiv. 322 (1898).

² *Ibid.* xxiii. 346 (1898). The large trees at Huntly, being too near the house, have been cut down. Mrs. Carpenter tells us that they flowered three times.

³ *Ibid.* iv. 133 (1888).

⁴ *Ibid.* xxv. 19 (1899). In *Gard. Chron.* xi. 212 (1892), *E. globulus* is said to have flowered abundantly in the shrubberies at Bournemouth when only 12 to 15 ft. high. These were all destroyed, when six to ten years old, by the severe winter of 1890-91.

⁵ *Ibid.* viii. 694 (1890).

⁶ Cf. *Kew Bull.* 1889, p. 61, and *Gard. Chron.* xii. 728 (1892).

⁷ From a letter to Kew from the Botanic Garden, Hobart, which gives these particulars, it appears that the seed behaved differently in Tasmania, as seedlings planted at Tullochgorum grew into large trees, when native to the district; whilst those raised from seed from the warmer part of the island all died.

⁸ *Gard. Chron.* xi. 247 (1892).

⁹ *Ibid.* vii. 170 (1890).

¹³ *Ibid.* xxiii. 148 (1905).

¹⁴ *Gard. Chron.* xxv. 138 (1899).

carefully made have shown that it will bear about double the weight of English oak, and will remain sound under water for a very long period. These particulars have been confirmed; but I think the statement as to the comparative strength of English oak requires some explanation.

An instance is quoted of an old ferry-boat built of blue gum in 1818, that has been lying a wreck on the banks of the Derwent in Tasmania for more than fifty years, between high- and low-water mark, the timber of which is still quite sound.

For mining purposes, Mr. Griffen, Inspector of Mines at Launceston, Tasmania, says that it should occupy the first place; whilst Mr. Dudley of Hobart, who has forty years' experience of its use for bending and general wheelwrights' purposes, says that it is unsurpassed for felloes, spokes, shafts, and body-work. He prefers the timber of young trees, but states that it requires careful seasoning in closed sheds for two years after sawing, as it is very liable to crack and split if exposed to sun and wind when freshly cut. A diagram, showing the results of experiments made in 1899 for Messrs. Pearson by D. Kirkaldy and Son of London, is given by Penny in *Tasmanian Forestry*.

Experiments carried out¹ at Berkeley University, California, on the wood of the Eucalypti grown in that state, show that the fastest-growing species produce the strongest timber. Thirty-year-old blue gum proved stronger than hickory. In California the wood of *E. globulus* is hard, strong, and tough. It has competed with Robinia for insulator pins, and is used locally for waggon axles, spokes, hubs, and felloes.

With regard to the timber of trees grown in Europe, it is difficult to give a fair opinion, as reports of users vary extremely. Judging from what I saw in Portugal, however, the timber of *E. globulus*, in common with that of several other species, is extremely subject to split, warp, and twist, and requires a great deal of experience to season and convert it without great waste. None of the species² seem at present likely to produce timber of any commercial value in Great Britain, and it is therefore unnecessary to go into details.

(H. J. E.)

² *E. Muelleri*, T. B. Moore, is possibly an exception.

EUCALYPTUS PAUCIFLORA, WEEPING GUM

Eucalyptus pauciflora,¹ Sieber, in Sprengel, *Syst. IV. Cur. Post.* 195 (1827); Mueller, *Eucalyptographia*, Dec. iii. (1889); Rodway, *Tasmanian Flora*, 55 (1903).

Eucalyptus coriacea, A. Cunningham, ex Schauer in Walpers, *Rep.* ii. 925 (1843); J. D. Hooker, *Fl. Tasm.* i. 136 (1860); Bentham and Mueller, *Fl. Austral.* iii. 201 (1866); Maiden, in *Rep. Austr. Assoc. Advance. Science, Hobart*, 1902, p. 353, and *Revision Genus Eucalyptus*, i. 133, plates 26-28 (1904).

Eucalyptus submultiplinervis, Miquel, in *Nederl. Kruidk. Arch.* iv. 138 (1859).

Eucalyptus phlebophylla, Mueller, ex Miquel, in *Nederl. Kruidk. Arch.* iv. 140 (1859).

A tree, attaining in Australia and Tasmania, 100 ft. in height and 12 ft. in girth. Bark peeling off, smooth and white. Young branchlets green or more or less covered with a whitish bloom. Leaves (Plate 365, Fig. 7) on adult trees, alternate, lanceolate, about 5 in. long and $\frac{3}{4}$ in. wide, usually falcate, unequal and cuneate at the base, gradually tapering to an acuminate apex, which is tipped with a long slender hook-like curved point; green and shining on both surfaces, thick and firm in texture; margin entire or undulate; main lateral nerves apparently longitudinal, arising near the base, and running for a considerable distance parallel to the midrib; petiole twisted, about $\frac{1}{2}$ in. long.

Flowers in axillary umbels of five to fourteen; peduncles $\frac{1}{4}$ to $\frac{1}{3}$ in. long, slender; flower-bud with pedicel about $\frac{2}{3}$ in. long; calyx-tube obconic gradually passing into the terete or quadrangular pedicel; operculum hemispheric or shortly conic, and ending at the apex in a short point; stamens usually all perfect; anthers reniform, with short divergent cells confluent at the apex. Fruit, on short slender pedicels (less than $\frac{1}{2}$ in. long), pyriform, smooth, narrowed near the summit, $\frac{1}{8}$ to $\frac{5}{16}$ in. long and wide, with a broad rim and a narrow orifice; capsule included, with the valves when open extending nearly to the orifice.²

This species occurs in Tasmania, Victoria, New South Wales, and South Australia. In Tasmania, where it is known as weeping gum, on account of its pendulous branches and branchlets, it is a small tree, usually much branched, and attaining in favourable situations only 60 or 70 ft. in length. Mueller says that it grows both on the ridges of the lowlands and on the highlands.

In Australia it is known either as white gum from the colour of its bark, or cabbage gum on account of the softness of its timber. In Victoria, where it occurs in the south, north-east, and east, it appears to be essentially an alpine species, ascending in the Gippsland Alps, where it forms forests, to 5000 ft.; yet it is able to maintain itself to some extent in localities but little elevated above sea-level. In South Australia it only occurs in patches close to the sea-coast in the south-eastern district.

In New South Wales, it grows usually in the undulating grassy country in the

¹ Sieber's name, being the earliest and accompanied by a clear description, must be adopted, though it is not very appropriate, this species producing copious flowers.

² The cotyledons are figured by Kerner, *Nat. Hist. Plant.* Eng. Trans. i. 621, fig. 148 (1898).

mountains and high table-lands, frequently forming timber-line, which is about 6500 ft. on Mount Kosciusko. In the Braidwood district, however, it occurs at all levels up to the highest point, 5000 feet, and attains 80 ft. in height and 5 ft. in diameter; and Maiden states that all reports from this district agree in stating that the timber is soft, durable underground, but of no use above it. De Coque says¹ that the timber is inferior, being only used locally for fencing purposes; and recommends that it should be avoided by architects for use in work of any description. Cattle browse on the foliage in seasons of drought.

Mueller says that "the chief interest of this species concentrates in its quality to cope with rather severe frosts; indeed, together with *E. Gunnii*, it constitutes miniature forests up to 5500 feet in the mountains, growing close to glaciers, which on the shady sides of glens do not wholly melt in Victoria, wherever situated over 6000 ft. high,—though in the cooler latitudes of Tasmania, the limit of eternal snow descends 1000 ft. lower,—it being understood, only in the wide crevices of chasms of rock, or in other places where the sun cannot exercise any direct effect. Thus the bare crests may be free of snow in the height of summer even at nearly 7000 feet; and we have therefore nowhere in summer an absolute permanent snow-line in the strict sense of the word."

I am unaware of the date of the first introduction of this species, which has been tried only in a few places. It has very pendulous branches, and is an elegant tree producing abundance of flowers. At Abbotsbury, it was killed in 1908 when 16 ft. high. At Colwyn Bay, N. Wales, Mr. A. O. Walker says² that a tree about fifteen years old, had its leaves slightly injured by 19° of frost in January 1894.

The Rev. Dr. Landsborough states³ that in Arran the species has borne 21° of frost without injury, producing flowers every year, and equalling *E. coccifera* in hardiness. A tree at Craigard, Lamlash, sown in 1879, was 25 ft. high after being topped in 1895, when it produced seed, from which plants were raised in the Edinburgh Botanic Garden. It is one of the species that Mr. Osgood H. Mackenzie cultivates at Inverewe.

At Fota, in the south of Ireland, there is an old tree, about 50 ft. by 6 ft. 8 in., which was blown down in 1903, and then replaced in position. The stem is now partially decayed. At Rossdohan, Kerry, Mr. Heard has several trees, the largest about 31 ft. by 1 ft. 8 in. He says that all his species of *Eucalyptus* grow as well in peat as on gravel, being more easily blown down in the latter soil.

(A. H.)

¹ *Journ. Proc. Roy. Soc. N.S. Wales*, xxviii. 214 (1894).

² *Gard. Chron.* xvi. 74 (1894). According to *Journ. Roy. Hort. Soc.* viii. 120 (1887), and *Gard. Chron.* ii. 784 (1887), this tree was not injured in the severe winters of 1878-1879 and 1879-1880.

³ *Trans. Bot. Soc. Edin.* xx. 519 (1896), and xxiii. 147 (1905).

EUCALYPTUS VIMINALIS, MANNA GUM

Eucalyptus viminalis, Labillardière, *Pl. Nov. Holl.* ii. 12, t. 151 (1806); J. D. Hooker, *Fl. Tasm.* i. 134 (1860); Bentham and Mueller, *Fl. Austral.* iii. 239 (1866); Mueller, *Eucalyptographia*, Dec. x. (1884); Masters, in *Gard. Chron.* iv. 596, fig. 82 (1888); Deane and Maiden, in *Proc. Linn. Soc. N.S. Wales*, xxvi. 137 (1901); Deane, in *Rep. Austral. Assoc. Advance. Science, Hobart*, 1902, p. 378; Rodway, *Tasmanian Flora*, 57 (1903).

A tree, usually of moderate size, but occasionally attaining 200 ft. in height. Bark variable, sometimes peeling off in ribbons, and smooth and white from the base upwards, and sometimes persistent and scaly even to the upper branches. Young branchlets very slender, with four projecting ridges, green and not glaucous; older branchlets terete, reddish brown. Leaves (Plate 365, Fig. 8) on adult trees, alternate, narrowly lanceolate, averaging 5 to 6 in. long, and $\frac{1}{2}$ to $\frac{3}{4}$ in. wide; but often larger or smaller than these dimensions; falcate; unequal and cuneate at the base; gradually tapering to a long acuminate apex, prolonged into a long slender curved or twisted filament-like tip; margin whitish, undulate, revolute; equally light green and not glaucous on both surfaces; oil-dots numerous, unequal, pellucid on young leaves, not conspicuous on old leaves; lateral veins numerous, arising from the midrib at an angle of 45°, the circumferential vein being regularly distant $\frac{1}{2}$ in. from the margin; petiole slender, twisted, about $\frac{1}{2}$ in. long.

Flowers in axillary umbels, usually in threes, rarely six to eight; peduncle $\frac{1}{5}$ in. long; pedicels about $\frac{1}{2}$ in. long; calyx-tube hemispherical, about $\frac{1}{8}$ in. long, crowned by an operculum, equal in length, conical, and tipped with a short point; stamens all fertile, inflexed in the bud; anthers ovate, with parallel distinct cells. Fruit turbinate, about $\frac{1}{8}$ in. long, and $\frac{1}{8}$ in. in width at the distal end, on short pedicels; rim broad and convex; capsule not sunk, with usually four valves, protruding when open beyond the orifice.

This species is very variable; but typical Tasmanian specimens have three-flowered umbels, and very small fruits. Forms occur in which the flowers are more numerous, four to eight in the umbel, and with long pedicels; and such trees are said to have rough scaly bark. Forms also occur with three-flowered umbels and large fruits. The leaves are also sometimes very narrow, almost quite linear.

This species occurs in Tasmania, Victoria, South Australia, and New South Wales. In Tasmania, it is very abundant throughout the island, where it is known commonly as white gum, according to Rodway,¹ who states that it seldom exceeds the dimensions of a small tree, with a much-branched and spreading habit. In Australia, where it is widely distributed, it occasionally reaches a great height, being perhaps in rare cases as tall as any other species. It is usually known as manna gum, owing to its being the chief species which produces mellitose manna. This exudes from the bark in minute drops, and is supposed to be due to the punctures of species of cicada, though often no trace of insect attack can be found.

¹ In J. C. Penny, *Tasmanian Forestry*, 15, 18, 20 (1905).

This peculiar substance encrusts the bark like a coating of white sugar, and falls off in lumps. It is not known to possess any medicinal value; and is called "lerp" by the aborigines, who eat it as an article of food.

According to De Coque,¹ the timber possesses no durability, and is of no utility to architects; but is used extensively throughout New South Wales for cheap rough fencing. It is not mentioned amongst the species with useful timber enumerated by Mr. Penny in his account of the Tasmanian forests.

Manna gum appears to be rare in collections in the British Isles, the only large specimens being two trees at Rosdohan, Co. Kerry, the larger of which produced flowers and fruit in 1910. Mr. Heard informs us that it is now, after losing 15 ft. of the top, 37 ft. high by 4 ft. 3 in. in girth.

It is reported² to have stood the severe winter of 1885-1886 at Bradfield, Collumpton, Devon; but it was killed at Abbotsbury in 1905. Mr. G. F. Heath reports that at Silverton, Devon, a young plant now 10 ft. high bore in 1909-1910 over 12° of frost. At Menabilly, a tree of this species was 15 ft. high in 1910.

At Colwyn Bay,³ North Wales, it was 33 ft. high in January 1894, when it was killed back to the trunk by a severe frost, the temperature registered being 13° Fahr.; but it afterwards sent out shoots.

In Scotland this species did not succeed out of doors at Kinloch Hourn, as all the seedlings raised in 1894 and 1895 had perished in 1899. In Arran, a tree⁴ raised from seed in 1871, and planted at Cromla in 1874, flowered in 1886 and subsequent years, and had attained 40 ft. by 2 ft. 7 in. in 1895, when it was killed by severe frost, the temperature falling to 22° Fahr. on the 9th February. A tree⁵ at Roseneath, planted in 1876, suffered severely in 1880-1881, and was killed in 1894-1895. In Ireland, this species has grown very fast at Mount Usher, where a tree raised from seed in 1904, was 28 ft. in height and bearing fruit in October 1911.

At Pallanza in northern Italy, it is reputed to be the hardiest species; and I measured in 1909 a fine specimen in Rovelli's nursery as 70 ft. by 5 ft. Elwes saw a very large tree of *E. viminalis* in April 1909, growing on the west lawn at Monserrat in Portugal, which measured 100 ft. by 16½ ft. In California,⁶ this species nearly equals the blue gum in rapidity of growth, and has been extensively cut for fuel.

EUCALYPTUS COCCIFERA, MOUNTAIN PEPPERMINT

Eucalyptus coccifera,¹ J. D. Hooker, in *London Journ. Bot.* vi. 477 bis (1847), and *Fl. Tasm.* i. 133, t. 25 (1860); Lindley, in *Journ. Hort. Soc.* vi. 221 (1851); W. J. Hooker, *Bot. Mag.* t. 4637 (1852); Bentham and Mueller, *Fl. Austral.* iii. 204 (1866); Masters, in *Gard. Chron.* xiii. 395, fig. 69 (1880), ii. 784, fig. 151 (1887), and iii. 798, figs. 108, 109 (1888); Rodway, *Tasmanian Flora*, 56 (1903); Maiden, in *Rep. Aust. Assoc. Advance. Science, Hobart*, 1902 p. 365, and *Revis. Genus Eucalyptus*, i. 142, pl. 28 (1904).

A small tree, attaining in the high mountains of Tasmania 20 ft. in height. Bark smooth, white. Young branchlets terete, glabrous, glaucous, covered with a dense whitish bloom. Leaves (Plate 365, Fig. 9) on adult plants, alternate, lanceolate, about 2½ to 3 in. long, and ¾ to ¾ in. wide, unequal and tapering at the base, acuminate at the apex, which is tipped with a long slender curved hook; margin entire, whitish, revolute; equally green or glaucous on both surfaces; oil-dots numerous, pellucid, very unequal in size; thick in texture; lateral veins, arising at an acute angle (30°) from the midrib, not conspicuous; petiole twisted, ¾ to 1½ in. long. Leaves on young plants and on suckers, opposite, sessile, elliptical, about 1½ in. long and 1 in. broad, rounded at the base and apex, the latter tipped with a short sharp point; entire in margin; green or glaucous. Branchlets reddish, with numerous elevated globose oil-glands.

Flowers, in axillary umbels of three to seven; peduncles glaucous, thicker towards the distal end, ½ to ½ in. long; flower-buds sessile, glaucous, wrinkled, ½ in. long; calyx-tube turbinate, compressed on the back and front, with the two sides narrow and sharply winged; operculum short, nearly flat, depressed in the centre and with a warty margin; stamens all perfect, inflexed in the bud; anthers reniform with diverging cells. Fruit obconic, glaucous, about ½ in. long, and ¾ in. broad at the slightly contracted distal end; nearly smooth externally, the angles of the calyx having disappeared; rim ⅓ in. broad, flat or convex; valves slightly included, three to five.

The seedling² has a terete scabrous dark purple stem; cotyledons obcordate, cuneate at the base and retuse at the apex; leaves ovate-lanceolate, thin, entire.

Our cultivated trees of *E. coccifera* in England agree³ well with the type

¹ This species is named, not from the actual presence of insects on the tree, but because the branchlets have a conspicuous whitish bloom, like the waxy secretion of some species of *Coccus*.

² Lubbock, *Seedlings*, i. 532 (1892).

³ *E. coccifera* has been confused with the following forms in Tasmania, which have been studied by Maiden, who calls them "gum-top stringy barks," i.e. trees with smooth bark above and stringy bark near the base of the trunk; but very variable in the amount of each kind of bark on individual trees. I suspect that the following are natural hybrids; there is no reason to suppose that they are in cultivation in England.

A. *Eucalyptus Risdoni*, Hooker, var. *elata*, Bentham, *Fl. Austral.* iii. 203 (1866); Maiden, in *Rep. Aust. Assoc. Adv. Sc. Hobart*, 1902, p. 361, and *Rev. Genus Eucalyptus*, i. 69 (1903) and i. 144 (1904); Rodway, *Tasmanian Flora*, 56 (1903).

This name was given by Bentham to two specimens, both numbered 1095, which were collected by Gunn in 1847 on the west side of Lake St. Clair, where tall trees formed pure forest close to the water's edge. One specimen has glaucous branchlets, with alternate and very falcate leaves, unequal at the base, and ending at the apex in a hooked point; flower-buds, six to seven in an umbel, like those of *E. obliqua*, but glaucous and with conspicuous oil-dots. The other specimen has branchlets and flowers, which are not glaucous. These specimens which have leaves and flowers like *E. obliqua*, and glaucous branchlets

specimens of the species, which were collected in Tasmania on the summit of Mount Wellington by Gunn, and on the western mountains by Lawrence; but have larger leaves, and are usually more glaucous in all their parts.¹

E. coccifera is confined to Tasmania, where it is common on the summits of the mountains at 3000 to 4000 ft. elevation. Rodway describes it as a small erect tree, 8 to 12 ft. high; but it attains much larger dimensions in this country, and doubtless owes its small size in Tasmania to the exposed situations in which it is found. It is known as mountain peppermint, and has no economic value in its own country.

E. coccifera was discovered in 1840 by Gunn, and was probably introduced in the same year, as in 1851 there was a plant, said to be eleven years old, growing in Veitch's nursery at Exeter, which was then 20 ft. high and producing flowers. In the Chiswick Garden, according to Lindley, it lived for many years against a south wall, without being injured by frost; but plants growing in open borders dwindled away and died.

(A. H.)

REMARKABLE TREES

The finest Eucalyptus in Britain is the noble tree² of this species, which grows in the American garden at Powderham Castle, Devonshire (Plate 361). When I last measured it in 1907, it was 75 to 80 ft. high and 13 ft. in girth at 5 feet; but the gardener, Mr. Bolton, informs us that in January 1911 it was exactly 16 ft. in girth at 4 ft. from the ground; the spread of the horizontal branches being about 90 ft. It is perfectly sound and healthy, and regularly bears ripe fruit, from which seedlings have been raised. One of these, when planted out under a warm wall at Colesborne was almost killed in the winter of 1908-1909; and died in 1912. This tree probably dates from the original introduction of the species in 1840, as it produced flowers and fruit in 1852, from which the plate in the *Botanical Magazine*, t. 4637, was drawn. It grows in sandy loam on the Red Sandstone formation on a fairly high river bank, about ten yards from the water, and doubtless owes its vigour to this situation. It was not injured in 1878 or 1879, when the temperature fell to 16° and 9° Fahr. respectively. Masters³ states that this tree has changed its time of flowering, as it was reported to have produced flowers in December and January, 1880; while in 1883, it was in full flower in the month of June.

(H. J. E.)

and flower-buds like *E. Risdoni* and *E. coccifera* in all probability are hybrids. Rodway, *Notes on E. Risdoni* in *Proc. Roy. Soc. Tasman.* 367-369, plates 10-12 (1910), should be consulted on the varieties of this species.

B. *Eucalyptus radiata*, Sieber, var. 4, J. D. Hooker, *Fl. Tasman.* i. 137 (1860).

This name was given by Hooker to specimens 1100 and 1110, collected by Gunn in 1840 at Hobart and Grass Tree Hill. These two specimens are not identical, and are different from *E. Risdoni*, var. *elata*, from Lake St. Clair. They are close to *E. Risdoni*, and are probably hybrids of it with some other species.

Note.—*E. Risdoni*, Hooker, the "drooping gum," a small tree abundant in the dry hills of the southern parts of Tasmania, bears on the adult plant opposite sessile leaves; and seems to be entirely distinct from *E. Risdoni*, var. *elata*. *E. Risdoni* does not seem to have ever been tried in cultivation in England.

¹ Maiden, to whom I sent specimens of the Powderham and other trees, agrees with me that they are undoubtedly *E. coccifera*.

² Figured in *Gard. Chron.* xii. 113, fig. 18 (1879), and ii. 784, fig. 152 (1897). It was reported to be 58 ft. high and 7 ft. 4 in. in girth at 3½ ft. from the ground in 1879. Cf. also *Gard. Chron.* xxxiv. 291 (1903) and xxxix. 411 (1906).

³ *Gard. Chron.* xix. 730 (1883), and ii. 784 (1887).

At Tresco, Scilly Isles, this is reported to be the hardiest species, but dwarf in habit, a specimen, 35 years old, being only 12 ft. high in 1894.

At Menabilly the best specimen,¹ planted in 1884, was, according to Mr. Bennett, 65 ft. by 6 ft. 5 in. at 4 feet from the ground in 1911. This was 56 ft. by 5 ft. 8 in., when measured by Mr. A. B. Jackson in 1908. An older tree planted in 1879, was only 40 ft. by 4 ft. 8 in. At Coombe Royal, a tree thirty-five years old, was 30 ft. by 2½ ft. in 1904. Trees raised at Vicar's Hill, Lymington, from seed sent to Mr. E. H. Pember in 1896 by Sir Charles Barrington from trees grown by him near Limerick, were 31 ft. by 13 in. in girth in 1910. At Killerton, a tree, planted in 1891, was 33 ft. by 3 ft. 1 in. in 1911. At Osborne, a bushy specimen, in an exposed position, survived the winter of 1884, when 20° of frost were registered; but was only 10 ft. high in 1911, having lost its leader. At Tregothnan, there are trees about 20 to 25 ft. high, which were planted ten years ago. At Cuffnells, Lyndhurst, there is a tree about 35 ft. high, which bears fruit. At Abbotsbury, there are specimens, 20 to 30 ft. high, raised from an older tree, which are very hardy and thriving. At Bradfield, Devon, it² bore well the severe winter of 1885.

There is a tree, planted in 1896, which attained 16 ft. high in 1906, in a sheltered spot at The Holt, Harrow Weald, Hampshire. This tree is much frequented by blue tits; but Mr. A. Kingsmill could not find any insect on it to attract them.

It is said not to be quite hardy at Kew; but Nicholson says³ that young plants protected by a wall were not injured in the severe winter of 1879-1880. Seed was sent to Kew, which was gathered in 1888 from trees growing on the summit of Mount Wellington in Tasmania, where the branches were covered with icicles a foot long; but the seedlings raised succumbed in the winter of 1889, though they were protected by a canvas screen.⁴ It stood out of doors three years at Coombe Wood,⁵ but succumbed to the winter of 1909. *E. coccifera* is, in Mr. Birkbeck's opinion, one of the four hardy species; but we have not seen any trees of it in the eastern counties.

At Wimbledon, some plants⁶ endured without injury several cold winters, and attained 12 to 15 ft. in height; but becoming broken by a fall of snow, they were killed by a subsequent severe frost in 1893.

Mr. W. H. Divers, reports⁷ that at Belvoir Castle there are two trees, planted in 1899, which have proved quite hardy, and were 25 ft. high in 1909. This is the only one, of about eighteen species that were tried out-of-doors at Belvoir Castle, which has survived.

At Wansfell House, Windermere, a dozen trees⁸ had withstood the severe weather of the preceding five winters, and were 15 to 20 ft. high in 1893. Of these, three survive, and measured in February 1911, 38 to 45 ft. in height, and 19 to 22 in. in girth.

¹ This tree appears to have been incorrectly known at Menabilly as *E. Gunnii*, till 1900, when specimens were sent to Kew; and is probably the tree figured under that name in *Gard. Chron.* xi. 787, fig. 113 (1892) and xxxiii. 234, 97 (1903). ² *Gard. Chron.* xxvi. 754 (1886). ³ *Journ. Roy. Hort. Soc.* viii. 208 (1887).

⁴ *Kew Bulletin*, 1889, p. 61, and 1892, p. 309; and *Gard. Chron.* xii. 728 (1892).

⁵ It was stated in *Gard. Chron.* xxvi. 306 (1886) to be hardy at Coombe Wood. Mr. Harrow informs me that "none of the species prove in any degree hardy at Coombe Wood."

⁶ *Gard. Chron.* xiii. 237 (1893).

⁷ *Spring Flowers of Belvoir Castle*, 83 (1909).

⁸ *Gard. Chron.* xiii. 237 (1893).

At Nant-y-Glyn Hall, Colwyn Bay, North Wales, there is a tree about 20 ft. high. At Cefnamwich, Nevin, Mr. Hugh S. Jones informs us that he has a tree, 45 ft. high, which he raised from seed sixteen years ago.

On the west coast of Scotland this is one of the most successful species. A tree¹ at Stonefield, Loch Fyne, the residence of C. G. P. Campbell, Esq., was reported by the forester, Mr. R. Stewart, to be 47 ft. by 2 ft. 8 in. at 4 feet from the ground in 1910, and had never been injured by frost. At Castle Kennedy, there is a healthy young tree, which was raised from seed of a tree erroneously named *E. amygdalina*, which died some years ago. At Monreith, a young tree received from Mr. Birkbeck in 1899, is about 17 ft. high, and produces flowers and fruit regularly. At Dalkeith, this species,² growing in a sheltered spot, bore without injury the severe frost of 7th January 1894, when the thermometer fell to 4° Fahr.

At Kinloch Hourn,³ this species is very hardy, and there are several fine specimens, none of which were touched by the severe frost in 1893-1894. It was killed, however, in 1895 at Kilmarnock and at Whittingehame, where the tree was ten years old. At Roseneath,³ a tree planted in 1886, flowered in July 1891, when only 6½ ft. high, and was 19½ ft. high in 1905. In Arran,³ where it was planted in 1886 in a very exposed site at 250 feet above sea-level, it was 14 ft. in 1895, but succumbed in the following winter. At Gadgirth,³ Ayrshire, it also died, when about 5 ft. high. At Inverewe, this species is reported to be very successful.

In Ireland, this species has not been tried extensively; but it is perfectly hardy and thriving at Kilmacurragh and Mount Usher in Wicklow, and at Rossdohan in Kerry. At Coolfin, near Portlaw, Co. Waterford, the residence of Rev. W. W. Flemyng,⁴ there is a fine specimen, which was planted quite small in 1898, and measured no less than 35 ft. high in 1907.

(A. H.)

EUCALYPTUS GUNNII, CIDER GUM

Eucalyptus Gunnii, J. D. Hooker, in *Lond. Journ. Bot.* iii. 499 (1844), *Fl. Tasm.* i. 134, t. 27, (1860), and *Bot. Mag.* t. 7808 (1901); Bentham and Mueller, *Fl. Austral.* iii. 246 (1866); Mueller, *Eucalyptographia*, Dec. iv. (1879); Hemsley, in *Gard. Chron.* ii. 784, fig. 150 (1887); Deane and Maiden, in *Proc. Linn. Soc. N.S. Wales*, xxvi. 134 (1901); Maiden, in *Proc. Linn. Soc. N.S. Wales*, xxvi. 561 (1901), and in *Rep. Austr. Assoc. Advance. Sci., Hobart*, 1902, p. 377; Rodway, *Tasmanian Flora*, 57 (1903).

Eucalyptus Gunnii, var. *montana*,⁵ J. D. Hooker, *Bot. Mag.* t. 7808 (1901).

Eucalyptus Gunnii, var. *glauca*,⁶ Deane and Maiden, in *Proc. Linn. Soc. N.S. Wales*, xxiv. 464 (1899), and xxvi. 134 and 561 (1901).

¹ Dr. Landsborough, in *Trans. Bot. Soc. Edin.* xx. 518 (1896) and xxiii. 145 (1905), states that it was sown in 1881; flowered in 1895, when it was 21 ft. high; and was 27 ft. by 2 ft. 4 in. in 1905.

² *Journ. Roy. Hort. Soc.* xviii. 76 (1895).

³ Cf. Landsborough, in *Trans. Bot. Soc. Edin.* xx. 518 (1896), and xxxiii. 145 (1905).

⁴ Cf. *The Garden*, lxxi. 591, fig. (1907).

⁵ As Maiden points out, in *Proc. Linn. Soc. N.S. Wales*, xxvi. 588 (1901), this differs in no respect from the typical form of the species.

⁶ Maiden, in *Rep. Austr. Assoc. Advance. Sci., Hobart*, 1902, p. 377, suppresses var. *glauca*, which is only the typical form of the species.

A small tree, usually 20 to 30 ft. high in Tasmania, but occasionally attaining in sheltered places a height of 80 ft. Bark smooth and whitish, the outer layers peeling off in thin strips. Young branchlets slender, terete, more or less covered with a glaucous bloom. Leaves (Plate 365, Fig. 5) on adult trees, alternate, averaging 2 to 2½ in. long, and ⅕ to ⅔ in. broad, ovate-lanceolate, thick and firm in texture, rounded or cuneate and equal-sided at the base, usually straight and not falcate, gradually tapering to an acute apex, tipped with a short point; margin entire, revolute, whitish; equally greyish or glaucous green on both surfaces; oil-dots numerous, unequal, often concealed; lateral veins few, inconspicuous, arising at an angle of 70°; circumferential vein undulate, distant about ⅓ in. from the edge of the blade; petiole stout, twisted, about ⅓ in. long.

Young plants¹ have glaucous branchlets and foliage; leaves sessile, opposite in decussate pairs, oval or ovate, cordate at the base; rounded or acute at the apex, which is tipped with a short point; crenate in margin. As the plants grow older, and on suckers, the leaves become thicker in texture, and more ovate in outline.

Flowers in axillary umbels of threes; peduncle slender, ¼ in. long; pedicels distinct, about ⅓ in. long; flower-buds glaucous; calyx-tube campanulate, ⅓ in. long; operculum nearly hemispheric, much shorter than the calyx-tube, tipped with a short umbonate point; stamens all perfect, inflexed in the bud; anthers ovate, with parallel distinct cells. Fruit glaucous, pear-shaped, distinctly pedicellate, ⅓ in. long, ⅓ in. wide at the distal end, where it is contracted; rim narrow; capsule sunk, with three to four valves, which when open scarcely reach the orifice.

This species has scarcely any of the pungent odour, so common in many other species; and Mueller says that it is liable on this account to have the foliage browsed by cattle and sheep.

The typical form of *E. Gunnii* was discovered by Sir J. D. Hooker in 1840, "forming a forest of small trees in a swampy soil² at elevations of 3000 to 4000 ft. in the centre of Tasmania, where it is known to stock-keepers as yielding abundantly an agreeable sap; and hence is called cider tree or swamp gum." Rodway, who calls it cider gum, states that it is found in the midlands and lake country of Tasmania as a small tree seldom exceeding 20 ft.; but rarely in sheltered places attaining 80 ft. high.

It was subsequently found by Mueller on the summit of Mount Baw Baw in Victoria; and the same tree, according to Maiden, also grows in the Tingeringi and Snowy mountains of New South Wales at about 5000 ft. elevation.

This tree is considered by the colonists in Tasmania to be different from *E. acervula*, which is known as red gum, and only occurs at low levels. Both Sir J. D. Hooker and Rodway consider these two species to be quite distinct; and I see no reason for uniting them together under the same name (*E. Gunnii*), as has been done by Maiden and some other botanists. The transitional forms noticed by Maiden, of which I have seen no specimens, are more likely to be hybrids than varieties.

¹ Figured in *Gard. Chron.* xix. 437, fig. 65 (1883).

² Rodway, in a letter to Elwes, says *E. Gunnii* is almost entirely confined to exposed moorland at an altitude above 2000 ft., and will not live at low elevations.

This species was introduced, shortly after its discovery, into Kew Gardens, where a tree¹ lived for many years, being the first Australian tree that was cultivated in the open air in England. It was cut almost to the ground by cold in several severe winters; but as often, sent up from the base one or more stems, which grew to be 10 to 20 ft. in height. It died only three or four years ago. (A. H.)

REMARKABLE TREES

The most remarkable plantation of Eucalyptus that we know of in England, was made by the late John Bateman, Esq., of Brightlingsea Hall, Essex, who raised seeds of *E. Gunnii*, which² were sent to him from southern Argentina in 1887, by Mr. Shennan, who had naturalised there the Tasmanian *E. Gunnii*. Planted in an exposed situation in light sandy soil within a mile of the estuary of the Colne, some of the trees (Plate 362) have now attained a height of 40 to 50 ft. with a girth of 3 or 4 ft., and are quite uninjured by wind or frost, the lowest temperature recorded for the locality being 5° Fahr. When I saw them on 9th December 1906, some were in full flower, and many were covered with capsules of different ages. Mr. Bateman told me that they ripened seed every year, which he sowed in the open ground in April. The seedlings attain a height of about a foot in the first year, and 3 to 6 ft. in the second year. A self-sown seedling growing behind the coach-house was about 12 ft. high at three years old. Mr. Bateman found the tree somewhat difficult to transplant, and preferred to do this in September after a heavy rain. This species also seems to like a wet soil; and a great number of seeds had germinated in the gutter of the coach-house. Though the value of the timber³ is as yet unproved in England, this tree might be used for planting marsh land on the coast, where, owing to its evergreen character, it would afford excellent shelter to other trees. Seedlings from these trees, though showing no variation in their botanical characters, have varied considerably in their hardiness at Colesborne. Some were killed to the ground by a frost in December 1904, and grew again from the root; whilst others were little affected.

Mr. Bateman informed me that this species grows equally well on sandy upland, on loam, or on heavy marshy clay soil, if trenched. The trees do badly, if they have not moisture at the roots, at least till they are well established; or if they are planted in sheltered corners under the shade of other trees; or if planted close to a wall; or if nibbled by rabbits, hares, or stock. They can be safely planted up to the 1st May. At Brightlingsea, bees swarm on the flowers which are produced from May to January; but those opening after 15th September set no fruit.

¹ Cf. Hemsley, in *Gard. Chron.* ii. 784, fig. 150 (1887). Smith, *Records of Kew Gardens*, 265 (1880), states that it was 20 ft. high in 1863. Smith calls it *E. polyanthemos*, the erroneous name by which this specimen was known for many years at Kew.

² Cf. Bateman in *Gard. Chron.* xxv. 202 (1899). In an article, which he wrote in *The Garden*, lxi. 110 (1902), he states however that he received the seed from the extreme south of Tasmania in 1887, and planted out sixty seedlings in the autumn of the same year. These, when five years old, were 15 ft. high and produced flowers and seed.

³ The timber, according to Mr. Bateman, who used it for posts and rails, is very heavy. The wood of *E. Gunnii* is of no value in Tasmania, owing to its small size; and that of the allied species, *E. acervula*, seems to be little used except for firewood.

Mr. Llewellyn Lloyd tells us that numerous seedlings of the Brightlingsea trees have been planted in Essex,—as in his own garden at Kirby, and in that of Mr. J. B. Hawkins at Wyvenhoe. A tree at the Rectory, Frating, planted twenty-eight years ago in light sandy soil, is over 30 ft. high and about 2 ft. in girth. There are also some trees about eighteen years old and 30 ft. high at Birch Hall, Colchester, from which the Right Hon. James Round has lately raised seedlings. Messrs. Abbott, nurserymen at Ardleigh, near Colchester, are said to have a stock for sale.

At Menabilly, there was a tree of this species, from which the figure in *Bot. Mag.* t. 7808, was drawn¹ in 1901. It is doubtful if this is the same as a tree which was 38 ft. by 1 ft. 4 in. in January 1911.

At Borde Hill, Sussex, there is a tree in a sheltered corner close to the house, which flowered in July 1909, and bore fruit in the previous year. It measured 56 ft. by 3 ft. 9 in.; and Mr. Stephenson Clarke says that it has endured 22° of frost without injury. At Hemsted Park, Kent, a healthy tree was 33 ft. high in 1911. In Miss Breton's garden at Sandhurst, a tree eighteen years planted, was 48 ft. high by 2 ft. 5 in. in girth in 1911; and a seedling from this is 20 ft. high. At Colesborne I planted a tree which was raised by the late Sir Charles Strickland in 1903, under a high wall facing north, and here it grew to 15 feet high in four years. In the severe winter of 1908-1909, when the thermometer went below zero, the top of this tree was killed as far down as the sun struck it, but the remainder continued healthy, and flowered in August 1910. After its top was frozen it threw out many shoots at ground level. The buds on this tree are formed about August and remain unopened for about twelve months.

At Putley Court, Ledbury, there is a handsome tree, planted about 1887, which in 1910 measured 48 ft. by 2½ ft., and produced flowers and fruit.

Mr. J. P. Rogers sent us in 1910 a branch from a tree at Penrose, near Helston in Cornwall, which is about 45 ft. high, and 2 ft. 11 in. in girth at three feet from the ground. This was raised from seed about sixteen years ago; and about thirty seedlings from the same batch were planted out in the woods; but Mr. Rogers says that only two survived, and only one of these grew properly. This species is not rare in Cornwall, as it is growing also at Enys and Penjerrick.

This species is apparently quite hardy in the eastern counties, even at a considerable distance inland, where severe frost is not unusual. A tree in the Cambridge Botanic Garden, obtained from Dicksons of Chester in 1898, is very thriving and about 25 ft. high. Another, growing in a sheltered position in an old quarry at Furze Hill, North Walsham, which was planted, according to Mrs. Petre, in 1899, is now about 40 ft. by 2 ft. 9 in., and is thriving, though occasionally a few twigs are cut by severe frosts.

Mr. A. R. Wallace has written² an article on this species, which he cultivated in his garden at Parkstone, Dorset. Planted in 1889, it was 30 ft. high by 3½ ft. at a foot from the ground in 1902; but was cut down soon after.

¹ According to notes on a specimen in the Kew Herbarium, the tree mentioned in the text of the *Bot. Mag.* t. 7808, never existed. The tree, figured as *E. Gunnii* at Menabilly, in *Gard. Chron.* xi. 787, fig. 113 (1897), and xxxiii. 234, fig. 97 (1903), was not this species, but apparently *E. coccifera*. See p. 1637, note 1.

² *The Garden*, lxi. 57, and lxii. 47 (1902).

At Wisley, where several species, including *E. urnigera*, *coccifera*, *cordata*, and *Beauchampiana*, have lately been tried, Mr. Chittenden informs us that the only one which has survived is *E. Gunnii*, a small specimen of which is four years old. At Myddelton House, Herts, where the same species and some others were tried, *E. Gunnii* and *E. Whittingehamensis* were the only ones that bore without injury the winter of 1908-1909. The former was about 15 feet high in 1911.

In Scotland, this species has been considerably planted on the west coast, and thrives as far north as Inverewe, where there are several trees, 30 to 40 ft. high. At Kinloch Hourn, trees raised from Tasmanian seed are perfectly hardy, and did not suffer in the least in the severe winter of 1894-1895, when the temperature fell to 0° Fahr., and some of the branches of the Whittingehame seedlings were browned. In Arran, according to the Rev. Dr. Landsborough,¹ the species did not succeed very well, as one planted at Lamlash in 1884 was blown down in 1894, and another in an exposed situation at Whiting Bay had the twigs and leaves injured by frost. At Whitefarland, a tree was 19 ft. high in 1905.

Mr. R. Lindsay says² that in 1899 he raised at Kaimes Lodge, Midlothian, two trees from seed which he received from Mr. Bateman. These are now over 20 ft. high and have produced seed, from which he raised seedlings. In 1909-1910, these seedlings were completely killed, and the old trees were severely injured, but the latter have now recovered. At Dalkeith, it is reported³ to have borne without injury, growing in a sheltered place, the severe frost of 7th January 1894, when the temperature fell to 4° Fahr.

At Kilmacurragh, Co. Wicklow, this species is about 15 ft. high and perfectly hardy.
(H. J. E.)

EUCALYPTUS WHITTINGEHAMENSIS, WHITTINGEHAME GUM

Eucalyptus whittingehamensis, Nicholson, in *Kew Hand-List Trees*, 395 (1902).

Eucalyptus whittingehamei, Landsborough, in *Trans. Bot. Soc. Edin.* xx. 516 (1896).

Eucalyptus urnigera,⁴ Masters, in *Gard. Chron.* iii. 460, figs. 64, 65, and 798, fig. 110 (1888) (not J. D. Hooker).

A tree, raised at Whittingehame, Scotland, from seed, which was probably obtained in Tasmania. This differs usually from typical *E. Gunnii* in the absence of glaucous bloom on the branchlets and leaves of the adult plant. The leaves (Plate 365, Fig. 4) are lanceolate, longer in proportion to their width than those of *E. Gunnii*, and never ovate as in that species, about 3 to 3½ in. long and ½

¹ In *Trans. Bot. Soc. Edin.* xx. 517 (1896), and xxiii. 144 (1905). The tree, reported by Dr. Landsborough to be *E. Gunnii* at Stonefield, is *E. urnigera*.

² *The Garden*, lxxiv. 286 (1910).

³ *Journ. Roy. Hort. Soc.* xviii. 76 (1895).

⁴ The identification of the Whittingehame tree with *E. urnigera* is inexplicable, as the foliage and flowers of the latter are very different, and its fruits are much larger. Naudin, in *Desc. et Empl. Eucalpt.* 35 (1891), followed Masters; but he had not seen adequate material of the Whittingehame tree. According to Mr. Birkbeck, the cotyledons of the Whittingehame seedlings are quite different from those of *E. urnigera*; and he adds that no one who has seen both in the young state could possibly confuse them.

to ¾ in. wide, straight or occasionally slightly falcate, cuneate at the base, and gradually tapering to an acuminate apex, tipped with a short point; greyish green on both surfaces; thick and firm, with most of the oil-glands concealed; entire in margin; venation as in *E. Gunnii*; petiole twisted, ¼ to ½ in. long.

Flowers in umbels of threes, slightly glaucous, and with a more conical calyx-tube than in *E. Gunnii*. Fruit slightly larger than that of *E. Gunnii*, urn-shaped, with the rim overhanging the contracted part of the fruit just below it; capsule sunk, with three valves not extending when open to the orifice.

This tree is considered by Maiden,¹ who has seen branches both of the parent tree and of its seedlings, to be *E. Gunnii*; but it does not match any of the specimens in the Kew Herbarium, either of that species or of *E. acervula*, which is united with *E. Gunnii* by Maiden. It resembles *E. acervula* in the absence of glaucous bloom on the branchlets and in the size and shape of the leaves; but has only three flowers in each umbel and bears different fruit. It is certainly not *E. urnigera*. Seedlings of the parent tree show considerable variation in the foliage, which in some specimens, together with the branchlets and flowers, is glaucous; and this points to a hybrid origin. Moreover, some of the seedlings at least are considerably hardier than the parent. I have not been able to make a study of the seedling trees in a fruiting stage; but I suspect that the Whittingehame tree is a hybrid, with *E. Gunnii* as one of the parents. The peculiar urn-like shape of the fruit suggests the probability of *E. urnigera* being the other parent, though the tree at Whittingehame does not resemble the latter in foliage. (A. H.)

This remarkable tree is growing at Whittingehame,² the seat of the Right Hon. Arthur Balfour in East Lothian, where it was planted about sixty years ago, and is believed to have been raised from seeds brought by the late Marquess of Salisbury from Australia or Tasmania. Lady Gwendolen Cecil informs me that her father made his voyage round the world in 1851-1852³ and visited both Tasmania and New Zealand, as well as Australia, in which country she believes that his stay was very brief; so that there is little doubt that the tree is of Tasmanian origin. In February 1904, when I measured it, it was 60 to 63 ft. high and 13 ft. 5 in. in girth at two feet from the ground, where it divides into three stems, which afterwards divide into six main limbs of which the largest is over 5 feet in girth (Plate 363). I was informed by the late Mr. John Garrett, the gardener, that after the severe frost of 1861 it was killed down to 9 feet from the ground; but in 1894 it endured a temperature⁴ of -2° without serious injury. It ripens seed almost every year about September, and the seeds germinate and grow equally well if sown in autumn or spring. The bark of the old tree is more or less scaly and can be heard cracking in hot weather, and it remains green all the winter.

¹ In a note on a specimen at Kew, Maiden wrote in 1901: "*E. Gunnii*, varying a little from the type under cultivation." I sent in 1908 a number of specimens to Maiden, some of which he identified as *E. Gunnii*, whilst others he named *E. Whittingehamensis*.

² Whittingehame is three and a half miles from the sea, and 384 ft. altitude. The subsoil is gravel.

³ The Rev. Dr. Landsborough states that the seed was sown in 1845, but this is erroneous; 1852 is the probable date.

⁴ Dr Landsborough, in *Trans. Bot. Soc. Edin.* xxiii. 144 (1905) quotes a letter from Garrett, stating that "in the year 1894-1895, when on two nights the mercury sank at Whittingehame to zero, the young plants did not lose a leaf, while all those of the parent tree were destroyed."

Mr. Garrett informed me that of the numerous other species of *Eucalyptus* tried at Whittingehame, all perished in the severe winter of 1894-1895, with the exception of *E. vernicosa*, which was only damaged to a slight extent. None of the seedlings of *E. Whittingehamensis* were in the least injured. Of these he raised hundreds, which were distributed over the United Kingdom, the earliest dating from 1887, one of which at Whittingehame was 45 ft. high in 1903, while another raised from seed in 1886 was 29 ft. high and 14½ in. in girth in 1904. The true *E. Gunnii*, which he considered to be the species most like it, differed in producing seed freely, when only four years old, at Whittingehame. There is a thriving seedling raised in 1888 from seed of the Whittingehame tree, in the rose garden near the pagoda at Kew, which was planted in 1896, and is now about 40 ft. high. It has never suffered in the least from frost; and flowered for the first time in 1911. Two seedlings which were kindly sent me by Miss Balfour in 1905 were uninjured by the severe frost of that autumn, though one of them has died since, and the survivor does not seem to like the calcareous soil of Colesborne.

At Blackmoor, Liss, Hants, there are two trees, which were received from Whittingehame as one year seedlings in 1903. One is about 22 ft. high. The other, which was pollarded a year ago, is about 15 ft. high, and was bearing flower-buds in January 1911. At Leonardslee, Sussex, there is a tree which was 40 ft. by 3 ft. in January 1911, and was also bearing flower-buds. Sir E. G. Loder¹ received it from the Edinburgh Botanic Garden in 1889. At Terling Place, Essex, three seedlings were planted in 1895-1896, of which two were killed by a severe frost in 1909. The third was killed to within five feet of the ground, but is producing new shoots. At Hatfield House, Herts, four seedlings were planted in 1890, the best of which, growing in an open and exposed position, is now 40 ft. by 1 ft. 8 in., but has not yet flowered. A smaller one sheltered from the north was bearing flower-buds in January 1911. At Sandhurst, a Whittingehame seedling in Miss Breton's garden, planted thirteen years, was 35 ft. by 1 ft. 11 in. in 1911. At Abbotsbury, one four years old was 20 ft. high in 1911.

At Kinloch Hourn, Mr. Birkbeck planted the first seedlings of this in 1890 and 1891, and these had their leaves slightly browned in the severe winter of 1894-1895, when the temperature fell to 0° Fahr.; but have thriven since. In Kilmarnock² the Whittingehame seedlings were uninjured in the same winter, when *E. coccifera* was killed. A seedling at Monreith, planted when 2 ft. high in 1908, is now about 13 ft. high. Another at Inverewe, planted in 1896, was 45 ft. high by 2 ft. in girth in 1911.

(H. J. E.)

¹ Sir E. G. Loder says that his tree is much hardier and not the same as *E. urnigera*, several plants of which were killed at Leonardslee, although 20 ft. high, by a severe winter.

² Dr. Landsborough in a letter to Mr. Birkbeck.

EUCALYPTUS ACERVULA, SWAMP GUM

- Eucalyptus acervula*, Miquel, in *Nederl. Kruidk. Arch.* iv. 137 (1859) (not Sieber¹); J. D. Hooker, *Fl. Tasm.* i. 135 (1860); Rodway, *Tasm. Flora*, 57 (1903).
Eucalyptus Stuartiana, Mueller,² ex Miquel, in *Nederl. Kruidk. Arch.* iv. 131 (1859); Mueller, in Bentham, *Fl. Austral.* iii. 243 (1866) (in part).
Eucalyptus persicifolia,³ Miquel, in *Nederl. Kruidk. Arch.* iv. 137 (1859).
Eucalyptus Gunnii, J. D. Hooker, var. *acervula*, Deane and Maiden, in *Proc. Linn. Soc. N.S. Wales*, xxvi. 136 (1901).
Eucalyptus Gunnii, var. *elata*, J. D. Hooker, *Bot. Mag.* t. 7808 (1901).

A tree,⁴ attaining in Tasmania and Australia a height of 200 ft. in very favourable situations, but usually not more than 100 ft. Bark peeling off and smooth, except on old trunks, which are scaly near the base. This species differs from *E. Gunnii* in its larger size, and in the branchlets, leaves, flowers and fruit being never glaucous. Leaves larger than in that species, up to 4 in. long and 1¼ in. broad, lanceolate or ovate-lanceolate, dull green on both surfaces, often undulate in margin, usually straight, and not falcate, commonly equal but sometimes oblique at the cuneate base, tapering to the acuminate or cuspidate apex, which ends in a short point; thick and firm in texture; venation and oil-dots inconspicuous; petiole twisted, ½ to ¾ in. long.

Flowers, axillary or lateral, 4 to 8 in the umbel; peduncle ¼ to ⅝ in.; pedicels usually short and thick; calyx-tube conical, shining, ⅓ in. in diameter at the widest part; operculum shorter than or as long as the calyx-tube, conical, ending in a long point; stamens all perfect, inflexed in the bud; anthers ovate with parallel distinct cells. Fruit obconic, about ¼ in. long and ¼ in. broad at the distal end, with a narrow rim and a wide orifice; capsule scarcely sunk, with four valves protruding when open.

This is one of the most widely diffused species,⁴ occurring abundantly at low elevations in Tasmania, Victoria, and New South Wales; and by no means rare in South Australia and Queensland. It is known in Tasmania as red gum, in Victoria as swamp gum, and in New South Wales as white gum, swamp gum, or hickory. De Coque referring to it, under the name *E. Gunnii*, says⁵ that the swamp gum in New South Wales produces worthless timber, which is soft and spongy, open in the grain, and retentive of moisture. Totally unfit for any work whatever, it should never be used in any circumstances.

¹ *E. acervula*, Sieber, in De Candolle, *Prod.* iii. 217 (1828), is identified with *E. piperita*, Smith, by Bentham, *Fl. Austr.* iii. 207 (1866).

² *E. Stuartiana*, Mueller, was founded on a Tasmanian specimen collected by Stuart, which is *E. acervula*, Miquel. The name *E. Stuartiana*, Mueller, is now applied by Maiden to another species, the "Apple Eucalyptus" of Victoria and New South Wales. Cf. p. 1615.

³ *E. persicifolia*, Loddiges, *Bot. Cab.* vi. t. 501 (1821) is, I think, correctly referred to *E. viminalis*, Labill., by Bentham and Mueller, *Fl. Austral.* iii. 240 (1866); but Maiden, in *Proc. Linn. Soc. N.S. Wales*, xxvi. 556 (1901) considers it to be *E. acervula*, Miquel.

⁴ Maiden mentions several varieties, as *ovata* and *maculosa*, occurring in Australia, which it is not necessary further to allude to, as they would not be hardy in Britain.

⁵ *Journ. Proc. Roy. Soc. N.S. Wales*, xxviii. 213 (1894). Mueller, however, speaking of this species as a form of *E. Gunnii*, says that the wood is hard, good for many purposes, if straight stems are obtainable; as a rule not splitting well, but fair for fuel.

The only specimens which we know in England are three trees at Menabilly,¹ the largest of which was 29 ft. by 1 ft. 8 in. in January 1911; and another at Holkham, about nine years old, which was 30 ft. high in 1911. This species did not succeed at Kinloch Hourn, where all the seedlings were killed in 1894-1895.

(A. H.)

EUCALYPTUS VERNICOSA, DWARF GUM

Eucalyptus vernicosa,² J. D. Hooker, in *Lond. Journ. Bot.* vi. 478 bis (1847), and *Fl. Tasm.* i. 135 (1860); Bentham and Mueller, *Fl. Austral.* iii. 232 (1866); Rodway, in *Proc. Roy. Soc. Tasmania*, 1898-1899, p. 104, and *Tasmanian Flora*, 58 (1903); Maiden, in *Rep. Austr. Assoc. Advance. Sc., Hobart*, 1902, p. 376.

An erect shrub, with smooth bark, usually 4 to 6 ft., rarely 12 to 20 ft. in height in Tasmania. Young branchlets green and angled towards the top, reddish brown and terete elsewhere. Leaves (Plate 365, Fig. 2) on adult shrubs, alternate, opposite, or sub-opposite, narrowly ovate or elliptical, $\frac{1}{2}$ to 2 in. long, and $\frac{1}{2}$ to 1 in. wide, rounded or slightly tapering at the equal-sided base, rounded or acute at the apex, which is tipped with a short triangular sharp point; margin entire or faintly undulate; very thick and coriaceous in texture; equally green and shining as if varnished on both surfaces; oil-dots few, scattered, unequal, concealed in the thicker older leaves; lateral veins arising at an angle of 45° from the midrib; petiole $\frac{1}{8}$ to $\frac{1}{2}$ in. long.

Flowers in axillary umbels of three, two, or one; peduncle very short, not exceeding $\frac{1}{2}$ in. long; flower-buds sessile, $\frac{1}{4}$ to $\frac{1}{2}$ in. long, shining dark brown; calyx-tube turbinate, with two lateral ridges; operculum conical, shorter than the calyx-tube; stamens all perfect; anthers ovate, with closely contiguous but parallel and distinct cells. Fruit hemispheric, $\frac{1}{4}$ in. long, sub-sessile; rim narrow, flat or convex; capsule slightly sunk, with three to four valves protruding when open.

This species is confined to Tasmania, where it grows on the summits of the higher mountains, as on Mount Fatigue, where it was discovered by Gunn in 1842 at 4000 ft. altitude, on Mount La Perouse, Mount Sorell near Macquarie Harbour, Mount Geikie, and Mount Direction (2409 ft. altitude). It is called dwarf gum by Rodway, who says that it seems to occur only on the sub-alpine plains of the west and south-west of the island. He adds that on Mount La Perouse, where it attains 20 ft. in height, the leaves are all opposite and the flowers solitary; whereas on the west coast, where it remains bushy, the leaves are opposite and the flowers in threes; while taller plants on Mount Geikie bear large alternate leaves with flowers in threes. All these forms occur on the specimens raised from the same seed at Kinloch Hourn.

¹ A specimen branch of apparently another tree was sent from Menabilly to Kew in 1903, when it was reported to have been 33 ft. high. This tree cannot now be found.

² Apparently this is the *E. verrucosa*, mentioned by Landsborough in *Trans. Bot. Soc. Edin.* xx. 518 (1896). Mr. Birkbeck says in his notebook, that "they have two sorts at Edinburgh, one labelled *E. vernicosa*, the other *E. verrucosa*; except that the former has larger leaves, I see no difference." *E. verrucosa* is evidently a misprint, as no species has been described under that name.

We are unaware, when the species was first introduced.¹ Mr. Birkbeck considers it to be far the hardiest of the Eucalypts, forming a beautiful shrub, and not developing into a tree.

At Kinloch Hourn, it was planted in 1891, and had attained 13 ft. high in 1905, and has never been injured by frost. At Whittingehame, when about 5 ft. high it bore 26° of frost without injury, in February 1894; but it was killed to within three feet from the ground in the following severe winter.² It produced several shoots in the following year, one of which was preserved; Elwes found this 20 ft. high and very thriving in February 1905. It ripens seed freely at both Kinloch Hourn and Whittingehame. It is one of the species which is cultivated successfully at Inverewe on the west coast of Ross-shire. We have seen no specimens in England or Ireland, but, Mr. Kempshall states that at Abbotsbury it has passed through the last three severe winters without injury.

There is no specimen at Kew, a seedling, which was planted out in 1907, having died in 1910 without any apparent cause. (A. H.)

EUCALYPTUS MUELLERI, MUELLER'S RED GUM

Eucalyptus Muelleri, T. B. Moore, in *Proc. Roy. Soc. Tasm.* 1886, p. 208 (not Miquel,³ not Naudin⁴); Mueller in *Proc. Roy. Soc. Tasm.* 1886, p. 209; Maiden, in *Rep. Aust. Assoc. Advance. Sci., Hobart*, 1902, p. 376; Rodway, in *Proc. Roy. Soc. Tasm.* 1898-1899, p. 105, and *Tasm. Flora*, 58 (1903).

A tall erect tree, attaining in Tasmania in favourable situations a height of 200 ft.; but in some localities much smaller. Bark smooth from the base, greenish, blotched with reddish brown. Young branchlets glabrous, reddish, with prominent oil glands. Leaves (Plate 365, Fig. 6) alternate, thick and firm in texture, lanceolate, averaging 3 to 4 in. long and $\frac{3}{4}$ to 1 in. wide, straight or slightly falcate, unequal at the cuneate base, gradually tapering to an acuminate apex, ending in a short blunt point; margin white with remote and very shallow crenations; equally shining green on both surfaces; oil-dots numerous, irregular in size, mostly not pellucid; lateral nerves inconspicuous, arising from the midrib at an angle of 30°; petiole twisted, $\frac{1}{2}$ to $\frac{3}{4}$ in. long.

Flowers in umbels of threes; peduncle $\frac{3}{8}$ in. long; flower-buds sessile; calyx-tube angled; operculum cap-shaped, tuberculate, with an umbonate point; anther-cells parallel. Fruit-peduncle short, stout, $\frac{1}{4}$ to $\frac{1}{2}$ in. long, thickened at the distal

¹ Mr. Birkbeck received his first plant from the Edinburgh Botanic Garden in 1891.

² Landsborough, in *Trans. Bot. Soc. Edin.* xxiii. 145 (1905), who states that a seedling was planted at Cromla, Ayr, in 1906.

³ *E. Muelleri*, Miquel, in *Ned. Kruidk. Arch.* iv. 130 (1859), is a synonym of *E. incrassata*, Labillardière, a species occurring in Victoria.

⁴ *E. Muelleri*, Naudin, in *Rev. Hort.* lvii. 406 (1885), and in *Descrip. Eucalypt.* 45 (1821), described from a tree cultivated at Antibes, is unknown to me, and is a synonym of a previously described Australian species, possibly *E. salmonophloia*, Mueller. *E. Muelleriana*, A. W. Howitt, in *Trans. Roy. Soc. Victoria*, ii. pt. 1, p. 89 (1891) is a native of Gippsland in Victoria, and is possibly identical with *E. dextropinea*, R. T. Baker, in *Proc. Linn. Soc. N.S. Wales*, 1898, p. 417, t. 11.

end; fruit turbinate, $\frac{1}{3}$ in. long, about $\frac{5}{12}$ in. in diameter, reticulate-tuberculate on the surface, wide at the orifice with a convex rim; capsule slightly sunk, but with the three to four valves protruding when open.

This species¹ has been considered to be the lowland form of *E. vernicosa*; but it differs from that species in the shape and larger size of the leaves, which are not so thick or quite so shining as in that species, which has smaller fruit.

E. Muelleri is confined to Tasmania, where it was discovered by Mr. T. B. Moore in 1886, on the dividing range between the Huon and Derwent watersheds. Here on high bleak land, at 2000 feet elevation, there is a forest extending in a narrow strip for three miles along the southern side of the range, with trees averaging 100 ft. in height. Moore found trees 200 ft. in height in less exposed situations and at much lower elevations. Rodway,² who calls this tree mountain red gum, says that it is common on the mountains of south-western Tasmania at 2000 ft. elevation. Mueller states that this species is of great importance, as it is the only one of large size with good timber, which bears considerable frost. Both Mr. T. B. Moore and A. O. Green³ agree that the timber is valuable, being heavy, hard and strong; but the tree is not found in quantity near any shipping port.

This species is very rare in cultivation; and when found is generally labelled with an incorrect name. There are two trees at Abbotsbury, one about 40 ft. high, which were bearing fruit and flower buds in February 1911. These stand in an exposed position, and are considered to be very hardy. There is a young tree about 20 ft. high at Logan, Stranraer.

(A. H.)

There are two fine trees in a plantation near Derreen, Co. Kerry, one of which (Plate 364) the Marquess of Lansdowne showed me in August 1910. It was growing on wet peaty⁴ soil amongst poplars and *Thuya plicata*, which crowd it on both sides, and measured 63 ft. in height by 4 ft. 3 in. in girth at four feet above the ground. The other tree is about 100 yards distant, and measured, in 1911, 64 ft. by 5 ft. They are said to have been planted about 1880; and, as indicating their rapid growth, Lord Lansdowne says that close by there is a *Cupressus macrocarpa* of the same height, girthing 6 ft. 10 in., and a *Tsuga Albertiana*, also equal in height and 5 ft. 1 in. in girth. These two conifers were planted in 1878. A small specimen of *E. Muelleri* at Mount Usher is about 15 ft. high and very thriving. Seedlings of this valuable species, from seed kindly sent by Mr. Rodway, are now being raised at Holkham, Culford, Avondale, and other places.

(H. J. E.)

¹ There is no specimen of *E. Muelleri* in the Kew Herbarium, and my description is drawn up from fruiting specimens of the tree at Derreen, which were identified with this species by Maiden.

² In J. C. Penny, *Tasmanian Forestry*, 17, 19, 21 (Hobart, 1905).

³ In *Proc. Roy. Soc. Tasm.* 1902, p. 44.

⁴ Lord Lansdowne says the soil might be described as almost pure peat.

EUCALYPTUS URNIGERA, URN-BEARING GUM

Eucalyptus urnigera, J. D. Hooker, in *Lond. Journ. Bot.* vi. 477 bis (1847), and *Fl. Tasm.* i. 134, t. 26 (1860); Bentham and Mueller, *Fl. Austral.* iii. 227 (1866); Maiden, in *Rep. Aust. Assoc. Advance. Sci., Hobart*, 1902, p. 375; Rodway, *Tasmanian Flora*, 58 (1903).
Eucalyptus cornigera, Earl Annesley, *List of Plants hardy at Castlewellaan*, 88 (1903).

A tree, occasionally attaining 50 ft. in height in Tasmania. Bark peeling off, smooth, green blotched with reddish brown. Young branchlets terete, glabrous, green often tinged with red, dotted with oil-glands not raised above the surface. Leaves (Plate 365, Fig. 11) on adult trees, alternate, lanceolate or ovate-lanceolate, averaging 3 to $3\frac{1}{2}$ in. long and 1 to $1\frac{1}{2}$ in. broad, often falcate, equal or unequal at the short cuneate or rounded base, gradually tapering to the apex, which ends in a fine long straight point; margin whitish, revolute, with remote irregular shallow crenations; thick in texture, with numerous translucent unequal oil-dots; equally dull green on both surfaces; lateral veins numerous, arising from the midrib at an angle of 40° ; petiole twisted, $\frac{1}{2}$ to $\frac{3}{4}$ in. long.

Leaves on young trees and on suckers, opposite, sessile, orbicular or broadly ovate, $1\frac{1}{2}$ to 2 in. in diameter, deeply cordate at the base, emarginate at the apex, from which arises a short point; conspicuously crenulate in margin; green on both surfaces; lateral nerves 7 to 8 pairs, arising from the midrib at an angle of 70° . Branchlets reddish, covered with bright red raised oil-glands.

Flowers in axillary umbels of three; peduncle $\frac{3}{4}$ in. long, slender, slightly thickened at the distal end; pedicels $\frac{2}{5}$ to $\frac{1}{2}$ in. long; flower-buds, $\frac{1}{2}$ in. long; calyx-tube narrowly urn-shaped, swollen at the base, contracted in the middle, and expanded above; operculum wider than the calyx-tube, cap-shaped, with a projecting umbo in the centre; stamens all perfect, inflexed in the bud; anthers with distinct parallel cells. Fruit, on pedicels which are nearly $\frac{2}{5}$ in. long, urn-shaped, swollen below, narrowed in the upper third, with a projecting narrow rim; surface with raised oil-glands; valves deeply sunk. The fruit varies in size, long narrow and short broad forms occurring, varying from $\frac{1}{2}$ to $\frac{3}{4}$ in. long, and $\frac{3}{10}$ to $\frac{4}{10}$ across the distal end.

1. Var. *elongata*, Rodway, ex Maiden, in *Rep. Aust. Assoc. Advance. Sci., Hobart*, 1902, p. 376.

A taller tree than the type, attaining 200 ft. in height, with smooth ashy-white bark, and very long linear-lanceolate leaves (up to 6 to 9 in. in length). Flowers; operculum conical, umbonate, half the length of the calyx-tube. Fruit much shorter than in the type, pyriform-globose, slightly constricted. This occurs at 1000 to 2000 feet elevation in Tasmania, and, though I have seen no specimens, seems to me to be a distinct species, or possibly a hybrid of *E. urnigera* with *E. viminalis*. We have found nothing like this form in cultivation in England.

E. urnigera is confined to Tasmania, where it is common in the mountains,

especially in the south. Rodway,¹ who calls it urn-bearing gum, informs us that it has not been found at lower altitudes than 1000 feet, and extends up to 3000 feet. At 2000 feet it is very similar to *E. Muelleri* in general appearance, both of bark and habit; but below this altitude, it is said that the bark becomes ashy-white, and the leaves very long and narrow, constituting var. *elongata*. So far as we can ascertain this species has no economic value in Tasmania, the timber being considered, according to Rodway, brittle and worthless.

It was discovered² by R. Brown at the beginning of the nineteenth century; but was described by Hooker from specimens gathered by Gunn in 1842 on the summit of Mount Wellington and near Lake Echo. The exact date of its introduction is uncertain; but Hooker states that it was in cultivation in England in 1860.

This is one of the hardiest species, but is by no means a handsome tree, often being spare of branches. It is also devoid entirely of the glaucous bloom on the branchlets and leaves, which give a pleasing effect to *E. coccifera* and *E. Gunnii*. The late Earl Annesley considered it to be as hardy as the laurel; but it has suffered at several places from frost, especially when in a young stage.

The finest trees in England are two growing at Coombe Royal, Kingsbridge, Devon, the larger³ of which was 72 ft. by 9 ft., and the other 60 ft. by 6½ ft. in 1904.

At Menabilly, the finest Eucalyptus is a tree of this species, with a clean straight stem, which Mr. W. H. Bennett reported to be 80 ft. by 3 ft. 9 in. at three feet from the ground in 1909. It⁴ was raised from seed about twenty years ago, and is hardier at Menabilly than *E. coccifera* or *E. cordata*. Younger trees here, planted in 1901, were about 30 ft. high in 1911.

At Sidbury Manor, Sidmouth, there is a tree, of which Sir Charles Cave sent us a branch in 1910. Miss Woolward measured it in 1904, as 43 ft. high, with three stems springing from near the base, the main one being 3 ft. 8 in. in girth. It was then fifteen years old, and growing in a sheltered situation at 250 ft. above sea-level.

At Abbotsbury, this is considered to be one of the hardiest species. Young plants have passed through three severe winters without injury, and are now growing freely. There are several specimens, the largest of which is 50 ft. by 5 ft.⁵ At Leonardslee, Sussex, specimens of *E. urnigera*, though 20 ft. high, were killed in a severe winter. At Ponfield, Herts, a small tree, which was 15 ft. high in 1906, died in 1910. We have seen no specimens near London or in the eastern counties. At Cefnamwich, Nevin, N. Wales, a tree raised from seed in the spring of 1894, was 45 ft. high and 2 ft. 6 in. in girth in December 1910.

In Scotland, the finest specimens are at Stonefield, Loch Fyne, one of which measured in December 1910, 81 ft. high by 5 ft. in girth at four feet from the ground.

¹ In J. C. Penny, *Tasmanian Forestry*, 17, 19, 21 (1905).

² A specimen in the Kew Herbarium is labelled: "R. Brown, *Iter Australiense*, 1802-5, No. 4775."

³ From this tree, which was called *E. montana*, a specimen was sent to Kew, in 1874, when it was reported to be 50 ft. high. This tree is probably the oldest in England, and may date back earlier than 1860.

⁴ Mr. Rashleigh in a letter to Kew, reported it to be 60 ft. by 2½ ft. in 1903. It was 85 ft. by 4 ft. in January 1911.

⁵ *E. urnigera* has been grown at Abbotsbury under several names, as *E. hemastoma*, *E. rudis* × *E. rostrata*, and *E. Stuartiana*.

The forester, Mr. R. Stewart, says that it has never been injured by frost since it was planted out. It¹ had long been known erroneously both as *E. Gunnii* and *E. coccifera*.

This is one of the hardy species at Kinloch Hourn, where there are several good specimens. There are also many trees² on the hill-sides up to 600 ft. above sea-level, which were raised from Tasmanian seed in 1895, and were planted out in 1896 to 1898. They were about 24 to 28 ft. high in 1907. In Arran, a specimen³ planted in 1885 was killed in the winter of 1894-1895; but it was growing in a wood amidst higher trees, and never prospered. None of the Eucalyptus do well when shaded by other trees; and Mr. Bateman lays great stress on this fact, as borne out by his experiments in planting *E. Gunnii* at Brightlingsea. We have received a specimen from Whitefarland, Pirnmill, Arran, where there are several trees, the oldest of which, planted in 1895, is now 23 ft. by 3 ft. 4 in. at a foot from the ground. This species also thrives well at Inverewe, where a tree, twelve years old, was 35 ft. by 1 ft. 8 in. in 1912. It also succeeds at Logan, near Stranraer. A tree⁴ at Roseneath Manse, planted in 1883, was 12 ft. high in 1895, and had never been injured by frost; but it subsequently died in a mild winter without any apparent cause. At Dalkeith, it is reported⁵ to have borne without injury the severe frost of 7th January 1894, when the temperature fell to 4° Fahr.

In Ireland, this species proved very hardy at Castlewellan, where a tree⁶ attained 65 ft. in height; but it was blown down some years ago. There are two or three younger trees now living raised from its seed; but Eucalyptus trees are no longer planted at Castlewellan, as they are always blown down when they grow to a large size. We have not seen any specimens of *E. urnigera* elsewhere in Ireland except at Mount Usher, where there are small trees, raised from seed sown in 1904. These are very thriving, and bore fruit in 1911. (A. H.)

¹ This tree is erroneously called *E. Gunnii* by Dr. Landsborough, in *Trans. Bot. Soc. Edin.* xx. 517 (1896), and xxiii. 144 (1905). It was planted in 1881, had attained 38 ft. high in 1896, and measured 71 ft. by 4 ft. 4 in. in 1905.

² Erroneously called *E. acervula* by Dr. Landsborough, in *Trans. Bot. Soc. Edin.* xiii. 145 (1905).

³ Dr. Landsborough, in *Trans. Bot. Soc. Edin.* xx. 519 (1896), and xxiii. 146 (1905).

⁴ *Journ. Roy. Hort. Soc.* xviii. 76 (1895).

⁵ A tree formerly cultivated at Castlewellan as *E. cornigera* was undoubtedly *E. urnigera*; and specimens of it were so named by Naudin. It appears that the trees of this species at Castlewellan differed in habit. One with numerous spreading branches was called *E. cornigera*; others with few branches and ungainly in habit were named *E. urnigera*.

WALNUT AT CAM-YR-ALYN PARK

THE magnificent Walnut tree here represented was unknown to us when Vol. II. was published in 1907. We are indebted to Mr. F. R. S. Balfour for its discovery, and to Mr. G. Cromar for the following particulars:—The tree stands in Cam-yr-Alyn Park, Denbighshire, the property of Wilson Sweetenham, Esq., and in 1910, when the photograph was taken by Mr. W. P. Wilkes, was about 70 ft. high, and $32\frac{1}{2}$ ft. in girth. It has five main branches, which measure as follows: 9 ft. 4 in., 10 ft. 3 in., $12\frac{1}{2}$ ft., 9 ft., and $11\frac{1}{2}$ ft. respectively, and cover an area of 88 ft. by 80 ft. The tree is healthy, and grows on a light loam and gravelly soil, at an elevation of about 100 feet above sea-level. The water in this district is full of lime, and there is a stream about 15 yards from the tree.

WALNUT AT CAM-YR-ALYN PARK

PLATE 366.

ORIENTAL PLANE AT WESTON PARK

THE Plane tree here figured was referred to on page 622 in the third volume of our work, as having measured, in 1875, 80 ft. by 18½ ft. Until I saw it in 1909 I had not realised that though not quite so large as the tree at Ely, figured on Plate 174, it is in some respects a finer and better-shaped tree. Though it was seriously damaged in March 1894 by a gale, it is now in perfect health, and measured, in August 1909, about 80 ft. by 20 ft. in girth, and 120 paces round the branches. I am informed by the Earl of Bradford that he has no record as to the date when it was planted. The leaves of this tree are unusually large, and though not so deeply cut as usual in the Oriental Plane, were quite free from the fungus *Glæosporium* (cf. p. 618).

ORIENTAL PLANE AT WESTON PARK.

SCOTS PINE IN GLEN MAILLIE

THE remarkable tree which is here figured, though the size of the plate is insufficient to do it justice, is a larger one than any of those mentioned in Vol. III. of this work. I am not sure whether it is the same tree of which Capt. Ellice had sent me a sketch, and which is mentioned on p. 588. Though much injured by the breaking of two of the large limbs, it was still healthy when I saw it in 1910. The trunk in the smallest place near the ground measured 18 ft. 1 in., and at five feet from the ground, below the fork, 22 ft. in girth. Its height is about 75 ft. An unusual feature in this tree is a young pine about 25 ft. high and 2 ft. 9 in. in girth, which has grown from a seed dropped in the fork of the old tree; and which has now become as completely united with the sound wood of the trunk as if it was a true branch. A good-sized birch and a small rowan are also growing as epiphytes on the trunk.

The primæval forest, in which this tree is probably the largest, is in my judgment the finest in Scotland, and extends from a little above sea-level up to 700 or 800 feet. The largest trees in it are probably over 300 years old, and grow on dry ridges among patches of peat covered with long heather and intersected by small watercourses. A few hollies, rowans, and birches are scattered among the pines; but few seedlings of the latter are visible owing to the presence of deer. There are many fine timber trees, as well as trees attractive to the naturalist. Among them is one 74 ft. high and 13 ft. in girth, which has three tall clean stems of equal size, dividing at about 10 feet from the ground and remaining close together for a considerable height.

In Lochiel's house at Achnacarry there is a beautiful water-colour, painted in 1847 by I. Giles, of a pine called "The Fir of Gusach," which formerly grew on the shore of Loch Arkaig, but has long ago disappeared. It was remarkably similar in form and size to the tree now figured.

SCOTS PINE IN GLEN MAILLIE

LARCH AT POLTALLOCH

THE plate shows a remarkable instance of witches' broom, growing on a larch, which I first heard of from Col. Malcolm of Poltalloch, Argyllshire, to whom I am much indebted for the photograph. This tree grows in a wood called Bar-na-sluid, about two miles from Poltalloch, at perhaps 200 ft. above sea-level, and is believed to be 60 or 70 years old. When I saw it in September 1911, it appeared to be quite healthy, and was about 48 ft. by 5 ft. The dense mass of twigs forming the witches' broom was about 15 ft. wide and 10 ft. deep. A stunted spruce grew close to the base of the tree, which was cut away in order that the photograph might be taken.

LARCH AT POLTALLOCH.

PLATE 369.

LABURNUM ALPINUM

THE finest specimen, that I have seen or heard of, grows at Countesswells near Aberdeen, the seat of Sydney J. Gammell, Esq., to whom I am indebted for the photograph taken by him on 30th June 1912, when the flowers were a little past their prime. The age of this tree is uncertain, but probably coeval with the oldest part of the house, built about 1700. Though several large limbs have fallen outwards, and the main trunk, which is split into three portions at the base, has been cut off at about ten feet from the ground; yet the vitality of the tree is so great, and the old wood so resistant to decay, that the tree is covered with young branches; and in some seasons the racemes of flower are so thickly set that the leaves can hardly be seen. The height of the tree is about 30 ft.; the girth of the largest part of the trunk is 7 ft., and of the split trunk at the ground 10 ft. The spread of the branches covers an area 153 ft. round. The fertile granite soil of the district, where I saw many laburnums of large size, seems specially favourable to this species. A tree, self-sown, at the foot of a cherry at Balcraig farm, near Aboyne, was over 30 ft. high and almost without branches for 20 ft. Mr. H. B. Watt tells us of a fine tree in the grounds of Dr. R. Farquharson at Finzean, Aberdeenshire, which measured on 27th June 1912, when it was in full flower, about 25 ft. in height and 5 ft. 10 in. in girth at three feet from the ground. Here the altitude is 550 feet; but Mr. Watt sent us specimens in flower of both species from Braemar at 1100 to 1200 feet. The alpine laburnum seems to grow and flower in shade better than the common laburnum.

TILIA

Tilia, Linnæus, *Hort. Cliff.* 204 (1735), *Sp. Pl.* i. 514 (1753), and *Gen. Pl.* 267 (1767); Bentham et Hooker, *Gen. Pl.* i. 236, 986 (1862-7); V. Engler, *Monog. Gatt. Tilia*, pp. 1-159 (1909).

DECIDUOUS trees, belonging to the order Tiliaceæ, with tough fibrous inner bark. Leaves simple, long-stalked, alternate, arranged on the branchlets in two rows; unequal¹ and cordate or truncate at the base; acute or acuminate at the apex; serrate or toothed; venation pseudo-palmate, the midrib giving off secondary nerves pinnately on both sides, the lower two pairs of which arise together at the base, and give off tertiary nerves on the outer side only. Stipules ligulate, membranous, caducous.

Flowers white, fragrant, regular, perfect, in cymes; peduncle connate with the axis of a membranous elongated persistent bract, from the middle of which it apparently arises; inflorescence and bract springing from the axil of a leaf, alongside a bud, which develops into a branch in the following year.² Sepals five, distinct; petals five, imbricate in bud. Stamines either absent or present as petaloid scales, one opposite each petal, and united with the base of the stamens. Stamens numerous, free, or in five clusters united together at the base. Filaments unbranched, or forked at the apex, with each branch bearing an extrorse half-anther. Ovary sessile, five-celled; style erect, dilated at the apex into five spreading stigmatic lobes; ovules two in each cell. Fruit nut-like, dry, indehiscent, one-celled, and one- to two-seeded by abortion. Seeds obovate, with fleshy albumen. Cotyledons reniform or cordate, palmately five-lobed, raised above ground on germination.

In winter the twigs are zig-zag and bear lateral buds, disposed alternately in two ranks; each bud with two to three scales visible externally, ovoid, obliquely displaced to one side of the semicircular leaf-scar, which is set on a prominent pulvinus. Stipule-scars small, linear or oblong, one on each side of the leaf-scar. Terminal bud absent; a circular scar at the apex of the twig, opposite the uppermost leaf-scar, indicating where the tip of the branchlet fell off in early summer. Base of the branchlet girt with a ring of scars, due to the fall of the bud-scales in the previous spring.

About twenty species of *Tilia* can be distinguished. These are widely distributed in the temperate regions of the northern hemisphere, extending southward in North America as far as the highlands of Mexico; but in the old world, while common in Europe and in northern and eastern Asia, no species is known in

¹ Cf. Van Tieghem, in *Ann. Sci. Nat. (Bot.)* iii. 378 (1906), on the peculiar asymmetry in the leaves and stipules of the lime.

² The occurrence of an inflorescence and a normal bud in one and the same axil is unusual; and is explained by the fact that the former is the result of the very early development of a flower-bud under the first scale of the normal bud, the other scales of the latter remaining dormant until the following season.

northern Africa or in the Himalayas. A large number of hybrid forms have arisen, some of which are common in cultivation. The following key, based on the characters of the branchlets and leaves, will serve to distinguish the species and hybrids which are cultivated in this country.

I. LEAVES GREEN BENEATH, WITH AXIL-TUFTS OF PUBESCENCE, BUT WITHOUT ANY STELLATE TOMENTUM.

(a) *Axil-tufts*¹ present at the base of the leaf and elsewhere.

* *Branchlets glabrous, or nearly so. Leaves glabrous, except for axil-tufts beneath.*

1. *Tilia mongolica*, Maximowicz. North China and Mongolia. See p. 1679.

Branchlets quite glabrous, reddish. Leaves $2\frac{1}{2}$ in. wide, often trilobed, glaucous beneath with non-prominent tertiary veins, coarsely toothed.

2. *Tilia cordata*, Miller. Europe, Caucasus. See p. 1656.

Branchlets slightly pubescent at first, speedily becoming glabrous. Leaves 2 to $2\frac{1}{2}$ in. wide, bluish green beneath with non-prominent tertiary veins, finely serrate.

3. *Tilia vulgaris*, Hayne. A hybrid, occasionally wild in Europe. See p. 1664.

Branchlets quite glabrous. Leaves 3 in. wide, dull green above, pale green beneath and with prominent tertiary veins, finely serrate with short points to the teeth.

4. *Tilia euchlora*, Koch. A hybrid, occasionally wild in the Caucasus. See p. 1674.

Branchlets usually quite glabrous. Leaves $2\frac{1}{2}$ to 3 in. wide, dark shining green above, pale green beneath and with prominent tertiary veins, finely serrate with long points to the teeth.

** *Branchlets densely pubescent with long hairs.*

5. *Tilia platyphyllos*, Scopoli. Europe. See p. 1661.

Leaves 3 to 4 in. wide, upper surface with short scattered pubescence, lower surface covered with long hairs.

(b) *Axil-tufts absent at the base of the leaf, present elsewhere.*

6. *Tilia americana*, Linnæus. North America. See p. 1685.

Branchlets glabrous. Leaves 5 to 6 in. long and $3\frac{1}{2}$ to $4\frac{1}{2}$ in. wide, broadly ovate, cordate at the base, glabrous beneath and with numerous prominent parallel tertiary veins; margin with long-pointed coarse serrations.

7. *Tilia paucicostata*, Maximowicz. Western China. See p. 1680.

Branchlets glabrous. Leaves $2\frac{1}{2}$ in. long and 2 in. wide; ovate, usually truncate at the base, glabrous beneath with few prominent irregular tertiary veins; margin with long-pointed fine serrations.

II. LEAVES GREEN OR GREYISH BENEATH, WITH SCATTERED STELLATE TOMENTUM.

(a) *Under surface of the leaves without axil-tufts, but with long hairs on the midrib.*

8. *Tilia Moltkei*, Schneider. See p. 1686.

A hybrid, with large leaves similar to those of *T. americana* in shape and serrations. Buds and branchlets glabrous.

¹ These are tufts of hairs at the junctions of the midrib and lateral nerves on the under surface of the leaf, which are now often termed *domatia*; they are the abodes of mites, and serve a useful purpose in the economy of the tree. They were fully studied and described by Lundström, in *Nov. Act. Reg. Soc. Sci. Upsala*, xiii. pt. 2, pp. 3-10 (1887). Cf. Lord Avebury, *Brit. Flowering Plants*, 123 (1905).

9. *Tilia spectabilis*, Dippel. See p. 1686.

A hybrid similar to *T. Moltkei*, but with smaller leaves, which have long hairs on the principal nerves, as well as on the midrib. Buds pubescent in their upper half. Branchlets with traces of stellate pubescence.

(b) *Under surface of the leaves with axil-tufts.*

10. *Tilia Michauxii*, Nuttall. North America. See p. 1689.

Leaves usually large,¹ 5 to 7 in. in length and 4 to 6 in. wide; ovate-cordate, very oblique at the base, with long-pointed large triangular serrations. Buds and branchlets glabrous.

III. LEAVES WHITE OR GREY BENEATH, AND COVERED WITH A DENSE STELLATE TOMENTUM.

(a) *Branchlets glabrous.*

* *Axil-tufts present.*

- 10A. *Tilia Michauxii*, Nuttall. In some forms of this species the leaves are densely greyish tomentose beneath. See above, No. 10.

* *Axil-tufts absent.*

11. *Tilia heterophylla*, Ventenat. North America. See p. 1688.

Leaves ovate-cordate, very oblique at the base, 4 to 5 in. long, 3 to 4 in. wide, covered beneath with a silvery white tomentum; serrations coarse and short-pointed.

12. *Tilia Oliveri*, Szyszyłowicz. China. See p. 1681.

Leaves orbicular-ovate, 3 to 4 in. long, $2\frac{1}{2}$ to 3 in. wide, silvery white beneath; serrations minute, crenate.

(b) *Branchlets pubescent.*

* *Axil-tufts present.*

13. *Tilia Maximowicziana*, Shirasawa. Japan. See p. 1683.

Leaves orbicular-ovate, averaging 5 in. long and broad, covered beneath with a greyish tomentum; axil-tufts and tomentum on midrib and nerves brownish.

** *Axil-tufts absent.*

14. *Tilia tomentosa*, Moench. South-eastern Europe, Asia Minor. See p. 1675.

Leaves orbicular-ovate, 3 to 5 in. across, greyish or snowy white beneath, with stout or slender short petioles; serrations fine, regular, ending in short points. Buds, branchlets, and petioles grey tomentose.

15. *Tilia petiolaris*, Hooker. See p. 1677.

Possibly a sport of *T. tomentosa*, from which it differs in the pendulous habit of the tree, the long slender petioles, and the peculiar fruit.

16. *Tilia mandshurica*, Ruprecht and Maximowicz. Manchuria, North China, Korea. See p. 1682.

Leaves orbicular-ovate, 4 to 5 in. across, white beneath; margin often one- to two-lobed, with coarse serrations, ending in long awn-like points. Branchlets, buds, and stout petioles brown tomentose.

¹ In native specimens the leaves are smaller, averaging 4 to 5 in. long and 3 to 4 in. wide.

17. *Tilia Miqueliana*, Maximowicz. Cultivated in Japan. See p. 1684.

Leaves remarkably variable in shape, deltoid or ovate, usually much longer than broad, 3 to 4 in. long and 2 to 2½ in. wide, grey beneath; serrations irregular, ending in short points. (A. H.)

TILIA CORDATA, SMALL-LEAVED LIME

Tilia cordata, Miller,¹ *Gard. Did.* No. 1 (1768); Moench, *Verz. Ausl. Weissenst.* 135 (1785); Schneider, *Laubholzkunde*, ii. 372 (1909); V. Engler, *Monog. Gatt. Tilia*, 74 (1909).

Tilia europaea, Linnaeus, *Sp. Pl.* 514 (1753) (in part); Loudon, *Arb. et Frut. Brit.* i. 364 (1838).

Tilia ulmifolia, Scopoli, *Fl. Carn.* i. 374 (1772); Sargent, in *Garden and Forest*, ii. 256, f. 111 (1889).

Tilia parvifolia, Ehrhart, *Beitr. Naturk.* v. 159 (1790); Willkomm, *Forstliche Flora*, 729 (1887); Mathieu, *Flore Forestière*, 29 (1897).

Tilia microphylla, Ventenat, in *Mem. Acad. Sc. Paris*, iv. 5 (1803).

Tilia sylvestris, Desfontaines, *Table Éc. Bot. Mus. Paris*, 152 (1804).

A tree, attaining 100 ft. in height and 20 ft. in girth. Bark smooth and grey on young trees; ultimately on old trunks divided by narrow longitudinal fissures into scaly ridges. Young branchlets green, slightly pubescent at first, speedily becoming glabrous, the pubescence, however, being often retained on short shoots; older branchlets dark brown. Leaves² (Plate 407, Fig. 8), membranous, 2 to 2½ in. wide, usually broader than long, smooth and not wrinkled, cuspidate at the apex, cordate at the base; margin non-ciliate, regularly serrate, the teeth ending in short cartilaginous points; upper surface dark green, shining, glabrous except for occasional long hairs on the nerves; lower surface bluish or glaucous green, glabrous except for the conspicuous dense orange-brown axil-tufts at the base, and at the junctions of the midrib, primary, and secondary nerves; tertiary veins scarcely prominent on the under surface, and more irregular, and less straight and parallel than in *T. vulgaris* and *T. platyphyllos*; petiole about half as long as the blade, slender, glabrous, or with a few scattered hairs.

Cymes directed upwards, five- to seven-flowered; bract long-stalked, glabrous; pedicels glabrous or with a few scattered hairs; sepals pubescent; petals glabrous; stamens about thirty, longer than the petals; staminodes absent; ovary tomentose, style glabrous. Fruit globose, faintly ridged, apiculate at the apex, covered with long scattered tomentum; shell thin and fragile.

In winter the buds are more globose than those of *T. vulgaris* or *T. platyphyllos*, and appear to be composed of two external scales, though the

¹ E. G. Baker, in *Journ. Bot.* xxxvi. 318 (1898), states that Miller's specimen in the British Museum is *T. platyphyllos*; but there is no evidence that this is a type specimen. It is plain from Miller's statement that *T. cordata* "grows naturally in the woods in many parts of England," and from his identification of it with *Tilia foemina, folio minore*, C. Bauhin, *Pinax*, 426 (1671), that he meant the small-leaved lime.

² The leaves on coppice shoots in the first year are remarkably large. Mr. Riddelsdell sent us specimens from Glamorganshire, with leaves 5 to 7 in. long and nearly as broad, coarsely toothed, deeply and narrowly cordate at the base, ending at the apex in a long acuminate point, and on short petioles scarcely an inch in length. As the coppice shoots lengthen year by year, the leaves gradually assume their normal form, small in size, broader than long, and with long petioles. Lees, in *Bot. Worcestershire*, 16 (1867), argues from the variable appearance of the leaves of coppice shoots of *T. parvifolia*, that the common lime is only a variety of the latter. The coppice shoots of most broad-leaved trees have peculiar leaves, different from those in the adult state, and more alike in allied species, so that their discrimination is difficult.

pubescent tip of a third scale may be discerned at the apex of the bud; the first and second scales are shining, glabrous, ciliate.

This species is readily distinguished by the bluish tint of the under surface of the leaves, which are very different in their tertiary venation from the other common limes. The erect and not pendulous cymes of flowers are also a peculiar feature.

VARIETIES

This species, as limited here to the European and Caucasian small-leaved lime, displays little variation in the wild state, the varieties¹ established by Schneider on the shape and size of the leaf and the amount of the pubescence on the fruit, being probably due to soil conditions, and not worth enumerating. A few peculiar sports have been noticed, none of which appear to be known in England:—

1. Var. *vitifolia*, Schneider, *op. cit.* Leaves three-lobed. Wild in Hungary.

2. Var. *aureo-variegata*, Schneider,² *op. cit.* Leaves variegated with yellow.

3. Var. *cucullata*, Henry (*var. nova*). Similar to the variety so named of *T. platyphyllos*. De Vries, *Species and Varieties*, 355, 669 (1906) and *Mutation Theory*, 470, fig. 106 (1910), draws attention to a tree with peltate and pitcher-like leaves, which is growing at Lage Vuursche, near Amsterdam.

DISTRIBUTION

The small-leaved lime is a native of the greater part of Europe and of the Caucasus, the closely allied forms³ in Siberia, Manchuria, and Japan being now regarded as distinct species. In Europe, it extends from northern Spain to the Ural range, attaining its maximum development in Russia, where it occasionally forms pure woods, but more usually, as is always the case elsewhere, growing as isolated trees or in small groups with other deciduous trees. It occurs as far north as the province of Volgoda, where it disappears after becoming a small shrub at lat. 62°. In the Ural, it reaches as far north as lat. 58° 50'. The finest lime woods

¹ Var. *Blockiana*, Schneider (*T. Blockiana*, Borbas), and var. *ovalifolia*, Spach, with leaves larger and less cordate than usual, are possibly of hybrid origin.

² *Tilia ulmifolia*, Scopoli, var. *foliis variegatis*, Petzold and Kirchner, *Arb. Musc.* 156 (1864), is another name for this variety.

³ The Asiatic forms are distinguished as follows from the European *T. cordata*:—

A. *Tilia sibirica*, Bayer, in *Verh. Z. Bot. Ges. Wien*. xii. 23 (1862).

Tilia cordata, var. *sibirica*, Maximowicz, in *Bull. Ac. St. Petersb.* xxvi. 432 (1860). Indigenous in western Siberia. Not yet introduced. Differs mainly in the leaves, truncate or cuneate at the base, with sharper serrations, and long hairs on the nerves.

B. *Tilia amurensis*, Ruprecht, *Fl. Cauc.* 253 (1869).

Tilia Maximowiczii, Baker, in *Journ. Bot.* xxxvi. 319 (1898).

Tilia cordata, var. *mandshurica*, Maximowicz, in *Mé. Biol.* x. 584 (1880). Indigenous in Manchuria and Korea. Not yet introduced. Differs in the larger leaves, with fewer coarser serrations, which are tipped with long points.

C. *Tilia japonica*, Simonkai, in *Math. Term. Koesl.* xxii. 326 (1888).

Tilia cordata, var. *japonica*, Miquel, in *Ann. Mus. Lugd. Bat.* iii. 18 (1867); Sargent, in *Garden and Forest*, vi. 111 (1893), and *Forest Flora Japan*, 20 (1894); Shirasawa, *Icon. Ess. Forest. Japon.* i. text 115, t. 72, figs. 1-10 (1900). Indigenous in Japan, where it is a small tree, rarely higher than 60 ft. It was introduced into the Arnold Arboretum, U.S.A., in 1886, where it is hardy, producing flowers and fruit every year; but is said to be scarcely distinct from the European species. It appears to differ mainly in the flowers, which are 20 to 40 in each cyme, and possess staminodes. Specimens collected by Elwes at Asahigawa in Yezo show no difference in leaves and branchlets.

in Russia are in the region extending southwards from Kostroma to the edge of the steppe; and here both this species and *T. platyphyllos* grow together. In Norway it is found as a wild tree as far north as lat. $62^{\circ} 9'$ on the west coast, and in Sweden up to $63^{\circ} 10'$ in Angermanland; but according to Schübeler, it thrives when planted as far north as $67^{\circ} 56'$ in Norway, $65^{\circ} 50'$ in Sweden, and 63° in Finland.

It appears to be not a native tree in Belgium, Holland, Denmark, and north-western Germany; and is nowhere very common in central Europe at present, though it is supposed to have been more widely spread in ancient times, as the word linden is very prevalent in German and Slavonic names of places. It is rather a tree of the plains than of the mountains; but it ascends in Bohemia and Bavaria to 2000 ft., and in Switzerland and the Tyrol to 4000 ft. Bolle informed Sargent that very old and enormous trees¹ of this species, one being nearly 23 ft. in girth, exist at Paelitzaerder on the Paarestein lake near Eberswalde.

In France, it is met with in most of the forests of the plains and low hills, except in the departments bordering on the Mediterranean. It is occasionally treated as coppice, being used for firewood and making charcoal. Bast, which was formerly a product of some importance, is now only produced in the forest of Chantilly, nearly all the bast used being now imported from Russia. Mathieu mentions a tree, planted at Gerardmer in the Vosges, which measured 95 ft. in height and 19 ft. in girth, and was supposed to be at least 250 years old.

The small-leaved lime extends southwards to about lat. 41° , occurring in northern Spain, Italy, and the Balkan States; but is unknown in Greece and Sicily. Huffel² says that both it and *T. platyphyllos* are common in the forests of the hills of Dobrudja, Roumania, where they are the dominant trees.

The small-leaved lime is a native of England, ranging from Cumberland southward. It occurs in woods in rather inaccessible positions, where it is a rare tree, and more commonly in coppice, situations in which the indigenous vegetation has often been preserved. Ray³ considered this species to be a true native; and in his time it was frequent and wild in woods and coppices in Essex, Sussex, Lincolnshire, and especially in Bedfordshire, "where there were thousands of lime trees." He adds that it was less common in the Forest of Dean, and rare in Cranborne Chase in Dorset. Many of the local floras give instances of its occurrence, as J. G. Baker⁴ for Yorkshire, who states that it occurs "at Slip Gill near Rievaulx, where aboriginal woods composed principally of oak and hazel cover the steeply-sloping rocky banks of one of the loneliest and pleasantest glens in the eastern calcareous range." Ley⁵ records it for different parts of Herefordshire. Murray⁶ says it is abundant in the Leigh woods near Bristol. It is said⁷ to be wild in several localities in Glamorgan-shire. Bromfield⁸ mentions wild trees in one locality in the Isle of Wight, and in aboriginal woods on the chalk at Bordean Hill, near Petersfield, Hants.

Bromfield supposes that Lyndhurst, in the New Forest, owes its name to the

¹ Bean, in *Kew Bull.* 1908, p. 397, mentions a tree in the Grosse Garten, Dresden, branching close to the ground, where the trunk was about 8 ft. through.

³ *Syn. Meth.* 316 (1696) and *Philos. Letters*, 250 (1718).

⁶ *Flora Herefordshire*, 54 (1889).

prevalence of this species there in ancient times. Limehouse, in London, according to Stowe, was originally called Limehurst, meaning a grove of linden trees in Saxon times.

(A. H.)

Some doubt exists among botanists as to whether the small-leaved lime is truly native of England or not. It is not mentioned by Clement Reid as having been found in the fossil state in Britain; and by some it is supposed to have been introduced at an early epoch, perhaps by the Romans. But in some parts of the West Midlands it is found in woods remote from buildings, where one can hardly believe it was planted, so that it might fairly be considered a native but for one important fact. Notwithstanding many inquiries even in the districts where it now seems most at home, I have found no one who has seen a self-sown small-leaved lime. It seems hardly possible that a native tree should have lost its power of reproduction by seed, in a climate where it succeeds so well even as far north as Ross-shire; and in the north of France self-sown seedling limes are not uncommon, as I have myself observed in the Forêt de Retz. The tree has a remarkable power of persistence after repeated cutting, and of extending from stools to a considerable distance; so that in two old coppiced woods on my own property, it is now impossible to say where the stools originated. I have seen limes in remote rocky woods on the Wye valley near Moccas Court, whose stools had the appearance of very great age; and in the deep rocky gorge of Castle Eden Dene, on the coast of Durham, there are limes growing on such steep rocks that they could scarcely have been planted. But though rabbits will eat almost anything before they touch lime, I have searched in vain for seedlings in all these places. On the Carboniferous limestone rocks at Pen Moel near Chepstow, the residence of W. R. Price, Esq., I saw the tree growing in situations where it must have grown naturally from seed; and though Mr. Price has never found ripe fruit he has not the least doubt that it is indigenous here and elsewhere on the cliffs of the lower Wye valley.

E. Lees, in *Botany of Worcestershire*, 16 (1867) gives an excellent account of the occurrence of the lime in that county, where it is, in his opinion, "an undoubted native." He states that Shrawley wood, west of the Severn, which is about 500 acres in extent, is remarkable for a great part of it consisting of an undergrowth of lime, which is regularly cut as coppice-wood, and, therefore, is never in a flowering state.¹ On visiting this place, I agreed with Sir H. Vernon, of Hanbury Hall, near Droitwich, the owner of the wood, that the stools are in rows as though they had been planted; moreover there is not, so far as he knows, any lime in the adjoining woods. He says that this underwood used to be cut every seventeen years, and sent to the Potteries for making crates, but that this demand having ceased, it is now difficult to get rid of. It is now allowed to grow into poles, which are sometimes sold for copper-smelting in the Black Country, at about six or seven pounds per acre for twenty to twenty-five years' growth. In Sir H. Vernon's opinion, it would now pay better to grub the lime and plant larch in its place.

Lees² goes on to state that "Ockeridge wood, near Holt, though in a lesser

¹ Cf. p. 1656, note 2.

² Cf. also Lees' remarks in *Forest and Chase of Malvern*, abstracted in *Gard. Chron.* 1870, p. 1536.

degree, nourishes the same tree, as well as various coppices on the banks of the Severn between Ombersley and Hawford, where *T. grandifolia* exists in a naturalised state." He mentions "a very old and remarkable pollard tree of *T. parvifolia* at Hawford, on the ridge not far removed from the Severn. The base is more than 40 ft. round and six large boles arise from this in a semicircular manner. In fact, commencing with the border of Wyre forest and proceeding southward, the lime appears in numerous woods, coppices, and old hedgerows, to the very end of the Malvern range near Bromsberrow. The base of the round hills near Alberley, Ockeridge wood, the western base of the Berrow Hill near Martley, the banks of Leigh brook, Rosebury Rock on the Teme, the Old Storridge Hill, the country about Great Malvern, and ancient woods in the parishes of Castle Morton and the Berrow, may be particularly mentioned. Many of the old lime trees get pollarded, and then, in the course of years, put on a very grotesque appearance."

REMARKABLE TREES

The small-leaved lime apparently never attains so great a height in England as the common lime, but is occasionally of great girth and is certainly long-lived. A tree (Plate 372), remarkable for its spreading habit, at Sprowston Hall, Norwich, was figured by Grigor in *Eastern Arboretum*, 200 (1841), where it is stated that it measured 24 ft. 7 in. "near the ground" and was believed to have been planted on 30th January 1649. It still survives in a shattered condition.

There is a remarkably fine tree of this species at The Hall, Thirsk, the seat of Reginald Bell, Esq., who has kindly sent us photographs. In 1904 the trunk in its narrowest part was 20 ft. in girth, and the spread of the branches was about 250 ft. in circumference.

One of the finest small-leaved limes is growing on a flat by the River Teme, at Oakly Park, Ludlow, which, in 1908, as nearly as I could measure it, was about 110 ft. by 14½ ft.

A fine tree, of weeping habit, at Hursley Park, Hants, the seat of Sir G. A. Cooper, Bart., measures about 80 ft. by 15½ ft. Close to it stands the hollow trunk of a much larger tree of the same species, which was blown down some years ago, and measures 19½ ft. in girth. The spread of its branches is said to have exceeded 100 ft.

At Arley Castle, Bewdley, a good specimen measured, in 1903, 85 ft. by 9 ft. 9 in. At Woburn Abbey, the largest tree of this species measures 76 ft. by 7 ft. 4 in., but appears to be still young, as the bark is comparatively smooth.

In Lincolnshire, the tree is not uncommon in parks and hedgerows. In Burghley Park there are several old trees, one of which measured, in 1908, 80 ft. by 11 ft. 4 in. At Casewick House, another was 82 ft. by 9 ft. 6 in. in the same year. At Syston Park there is a fine specimen, which measured 97 ft. by 11 ft. in 1906.

(H. J. E.)

TILIA PLATYPHYLLOS, LARGE-LEAVED LIME

Tilia platyphyllos, Scopoli, *Fl. Carn.* i. 373 (1772); Sargent, in *Garden and Forest*, ii. 256, f. 109 (1889); Schneider, *Laubholzkunde*, ii. 376 (1909).

Tilia grandifolia, Ehrhart, *Beit.* v. 158 (1790); Willkomm, *Forstliche Flora*, 733 (1887); Mathieu, *Flore Forestière*, 33 (1897).

Tilia pauciflora, Hayne, *Arzn.* iii. 48 (1813).

Tilia corallina, Smith, in Rees, *Cycl.* xxxv. No. 2 (1819).

Tilia mollis, Spach, in *Ann. Sc. Nat.* ii. 336 (1834).

Tilia europæa, Linnæus, *Sp. Pl.* 514 (1753) (in part); Loudon, *Arb. et Frut. Brit.* i. 364 (1838).

A tree, attaining 130 ft. in height and upwards of 20 ft. in girth. Bark at first smooth and grey, ultimately on old stems with narrow shallow longitudinal fissures and ridges separating on the surface into small quadrangular scales. Young branchlets moderately covered with long white hairs; older branchlets glabrescent. Leaves (Plate 407, fig. 6) 3 to 4 in. in width and length, slightly uneven or wrinkled, ciliate in margin, regularly serrate, the serrations ending in short cartilaginous points; upper surface dull green, covered with short pubescence; lower surface lighter green, covered with long whitish pubescence, densest on the midrib, nerves, and veinlets, and forming dense axil-tufts at the base of the blade and at the junctions of the primary nerves with the midrib and with the secondary nerves; tertiary veinlets parallel and prominent on the under surface; petiole stout, shorter than the blade, whitish pubescent.

Flowers in pendulous, usually three-flowered cymes; about ½ in. in diameter, yellowish-white; sepals slightly pubescent externally, downy within; petals oblanceolate, longer than the sepals; stamens about thirty, longer than the petals; staminodes absent; ovary globose, tomentose; style glabrous. Fruit globose, pyriform, or ovoid, usually¹ with three to five prominent ribs, tomentose, apiculate at the apex; shell woody and hard.

In winter this species may be recognised by the twigs being slightly pubescent near the buds, which are minutely pubescent at the tip and show externally three glabrous ciliated scales.

VARIETIES

This species in the wild state varies considerably in the amount of pubescence on the leaves, branchlets, and petioles; and has been subdivided into five subspecies by Schneider, who acknowledges, however, the great difficulty of limiting them clearly. The most pubescent forms occur in northern Germany, northern France, and Scandinavia; while nearly glabrous forms are found in southern France, Austria, and the Balkan States. V. Engler disagrees with Schneider's classification; and considers that the limes occurring in southern France, the Pyrenees, Italy, etc., should be united with *T. caucasica*; but this view is hardly tenable. The bract is stalked in most cases, but is occasionally sessile; and abnormal forms occur

¹ A tree at Kew of undoubted *T. platyphyllos*, bore fruit in 1907, on which no trace of ribs was perceptible.

(var. *multibracteata*) in which two bracts are borne on one peduncle. The fruit is remarkably variable, both in shape and in the prominence of the ribs.

The southern more glabrous forms are rarely cultivated in England, the only specimen which I have seen being a tree at Kew about 25 ft. high, which is named var. *obliqua*.¹ The branchlets are nearly glabrous; leaves very oblique and truncate at the base, glabrous above, with scattered pubescence below. It bears flowers similar to those of the type.

A large number of sports have arisen both under cultivation and in the wild state, the most noteworthy of which are:—

1. Var. *pyramidalis*, Simonkai, in *Math. Term. Koezl.* 334 (1888). Pyramidal in habit; leaves usually more or less cordate at the base. According to Schneider this is occasionally wild in south-eastern Europe.

2. Var. *tortuosa*, Bean, in *Kew Hand-list Trees*, 71 (1902). A peculiar sport, with all the twigs and branches twisted and curved. This² originated in the Royal Horticultural Society's garden at Chiswick in 1888 as a single specimen out of a bed of 500 large red limes. Grafts were sent to Kew from Chiswick in 1890, and three trees about 18 ft. high survive, in the Lime collection.

3. Var. *aurea*, Loudon (var. *aurantia*). Twigs golden yellow.

4. Var. *corallina*, Solander, in Aiton, *Hort. Kew.* ii. 229 (1789). Twigs bright red. Both these varieties are conspicuous in winter, and have been known for more than a century. According to Koch they were probably introduced from England to the Continent. The latter is the red-twigged lime of some English nurseries.

5. Var. *laciniata*, Loudon (var. *asplenifolia*, var. *filicifolia*). Leaves smaller than in the type, deeply and irregularly cut and twisted. This never attains a large size,³ and is only suitable for planting as a curiosity in gardens. It commonly throws out branches on which the foliage is normal.

6. Var. *vitifolia*, Simonkai, *op. cit.* Leaves lobulate or weakly three-lobed.

7. Forms with variegated leaves are known, as var. *albo-marginata*, Van Houtte.

8. Var. *cucullata*, Schneider (*T. cucullata*, Jacquin,⁴ *Frag. Bot.* 19, t. 11, f. 3 (1800)). A form with small leaves, of which the edges of the two sides are joined together at the base, making the leaf pitcher-shaped. It is said to occur wild in southern Bohemia, where, according to Willkomm, there are some old trees, with all the leaves showing this peculiarity, at the monastery of Goldenkron, near Krumau.

DISTRIBUTION

This species is widely distributed throughout central and southern Europe, extending as far eastward as the Ural Mountains. Its northern limit as a wild tree is not known with certainty, and Willkomm considers it not to be indigenous in

¹ Probably identical with *T. obliqua*, Host, in Schmidt, *Oestr. Baumz.* iv. t. 224 (1822), and Host, *Fl. Austr.* ii. 62 (1831). The Kew tree agrees with a dried specimen collected in Host's garden in 1832.

² Cf. *Gard. Chron.* iv. 708 (1888).

³ A. B. Jackson saw a tree at Blenheim, 40 ft. by 3½ ft., in 1908.

⁴ Jacquin figures leaves from trees in a cemetery at Sedlitz, near Kuttendorf in Bohemia. Leneck, in *Mill. Nat. Ver. Univ. Wien*, 1893, pp. 19-29, figs. 1-11, gives an account of these abnormal leaves; and records a large-leaved lime growing at Leitmeritz in northern Bohemia, of which 20 to 30 per cent of the leaves were pitcher- or cowl-shaped. Cf. Just, *Bot. Jahresh.* xxii. pt. 2, p. 219 (1894).

northern Germany, Denmark, and the Baltic provinces of Russia. Bolle, however, states that it grows sparingly in these countries, and mentions small groups of wild trees growing in the islands on the west coast of Sweden, near Strömstad. It is most common in southern Russia, where in the provinces of Ukraine and Volhynia it often forms pure woods, though it is also seen in mixture with the small-leaved lime and *Quercus pedunculata*. It is also frequent in the southern states and Rhenish provinces of Germany, and ascends in the Bavarian Alps to 3300 ft. It is also widely spread in Austria, Hungary, and the Balkan States; and occurs in Italy and Spain, reaching its most westerly point in Asturias and New Castile. In France it is found scattered in the forests of the plain, except in the Mediterranean region, where, however, it has been observed as a rare tree in the Ravin des Arcs, 15 miles north of Montpellier.¹ More common in the hills and mountains, it attains its highest elevation, 4600 ft., in the Pyrénées-Orientales. It is replaced in Greece by the closely allied species *T. corinthiaca*, Bosc, and in the Caucasus, north Persia, and Armenia by *T. caucasica*, Ruprecht. Neither of these is in cultivation.

This species is a doubtful native of England, and was considered by Watson to be only a denizen. Bromfield² says that the broad-leaved lime, though partly naturalised in hedgerows, is nowhere indigenous in this country. Ley,³ in 1889, however, considered it to be truly wild in rocky woods in the lower valley of the Wye, where, on the Great Doward and at Symonds Yat, it grows on bare limestone rock in company with the small-leaved lime. The occurrence here of *Pyrus latifolia* as an indigenous tree supports Ley's opinion. Baker⁴ also considers it to be a native of Yorkshire, where it grows on the limestone scars of the lower part of Swaledale in a rocky wood, where no trees have ever been planted. Linton⁵ also records it as growing wild on limestone cliffs in Derbyshire. (A. H.)

REMARKABLE TREES

One of the oldest large-leaved limes in England is the famous tree⁶ planted by Queen Elizabeth during her visit to Burghley Park, Stamford. This is now only about 60 ft. high, having lost many limbs in recent years, but it is 20 ft. in girth, and still bears foliage freely.

The tallest trees of this species which I have seen are those on the hill in the park at Longleat, where there are many from 120 to 130 ft. high, and some probably

¹ Elwes found a lime wild in the Forêt de Sainte Baume, near Aubagne (Var), which was identified by M. Mader of Nice with *T. platyphyllos*. It is recorded for this station by Albert and Jahandiez, *Plant. Vasc. du Var*, 84 (1908). Enormous trees of this species are said to have existed in France, one at Château Chaillé near Melle (Poitou) having measured 50 ft. in girth in 1804, when it was 538 years old. T. Hartig alludes to another at Saint Bonnet which was 55 ft. in girth. Cf. Kanngieser, in *Flora*, xcix. 428 (1909). Willkomm, *Forstliche Flora*, 736, note (1887), mentions also large limes in Germany, one at Staffelstein in Bavaria being 57 ft. in girth at three feet from the ground. We have not been able to confirm these records.

² *Flora Vexl.* 83 (1856).

³ *Flora Herefordshire*, 54 (1889). The late Rev. Augustin Ley, who kindly sent me specimens for examination, informed me in a letter, that "it occurs sparingly in aboriginal woodland, through Herefordshire, where there are nine stations in which the tree is native. It extends northwards into Shropshire, westwards into Radnor and Brecon, and southwards along the Wye valley into west Gloucester and Monmouth. In many of its stations it occupies crannies of limestone cliff, where it is physically impossible that it should be planted."

⁴ *Flora North Yorkshire*, 274 (1906).

⁵ *Flora Derbyshire*, 91 (1903).

⁶ Figured in *Gard. Chron.* xvi. 400, fig. 78 (1881).

taller, all running up to a great height with clean straight stems. These are reputed to have been planted in 1690. At Revesby Abbey there is a fine old tree, about 100 ft. by 13 ft. 3 in., with the branches descending to the ground. The avenue at Poltimore, which is very fine, is composed of limes¹ of the species.

Mr. Renwick reports a large-leaved lime² at Ancrum, near Roxburgh, which in 1909 measured 26 ft. in girth at 6 ft. from the ground. (H. J. E.)

TILIA VULGARIS, COMMON LIME

Tilia vulgaris, Hayne, *Arzn.* iii. 47 (1813); Sargent, in *Garden and Forest*, ii. 256, fig. 110 (1889).

Tilia intermedia, De Candolle, *Prod.* i. 513 (1824); Mathieu, *Flore Forestière*, 32 (1897).

Tilia europæa, Linnæus, *Sp. Pl.* 514 (1753) (in part); Loudon, *Arb. et Frut. Brit.* i. 364 (1838).

Tilia cordata × *platyphyllos*, Schneider, *Laubholzkunde*, ii. 374 (1909); V. Engler, *Monog. Gatt. Tilia*, 144 (1909).

A tree, attaining 130 ft. in height and 15 ft. in girth. Bark similar to that of *T. platyphyllos*. Young branchlets green, glabrous, becoming dark-brown with age. Leaves (Plate 407, fig. 4) larger than those of *T. cordata*, averaging 4 in. in length and 3 in. in width, slightly wrinkled or uneven, cuspidate or acuminate at the apex, truncate or cordate at the base; margin slightly ciliate and regularly serrate, the teeth ending in short points; upper surface dark green, glabrous; lower surface pale green, with brown axil-tufts at the base and the junctions of the midrib, primary and secondary nerves, and a few scattered long hairs on the nerves, elsewhere usually glabrous; tertiary nerves on the lower surface prominent, mostly straight and parallel; petiole green, glabrous, about half the length of the blade.

Cymes pendulous, five- to ten-flowered, glabrous; bract slightly pubescent, sessile or stalked; sepals, petals, stamens, ovary, and style as in *T. platyphyllos*. Fruit ovoid or globose, apiculate at the apex, not ribbed when mature, covered with a dense tomentum; shell thick and tough.

The buds are similar to those of *T. platyphyllos*, showing three external scales, which are glabrous, shining, and ciliate; but the glabrous branchlets will readily distinguish the common lime in winter, those of *T. platyphyllos* always being more or less pubescent.

This species, though the most common lime in cultivation, both in Britain and on the Continent, is extremely rare in the wild state. Mathieu says that it is occasionally seen in woods³ in France; and Simonkai records reputed wild specimens from Upsala in Sweden and from Finland. Bolle informed Sargent that he had only once seen an indigenous specimen, a tree growing in the Tyrol.

¹ Cf. p. 1667, note 1, for other avenues of this species, and p. 1669.

² Cf. Christison, in *Trans. Bot. Soc. Edin.* xix. 494 (1893), who states that it was 20 ft. in girth at five feet up, the narrowest point, in 1877.

³ In the Cambridge herbarium there is a specimen gathered by Vincent in 1847 in the wood of Champigneulle, near Nancy; and another gathered in Switzerland by J. Stuart Mill, labelled "Mountain side, near Altdorf, Canton Uri, completely wild and native."

It is now universally admitted to be a hybrid between *T. cordata* and *T. platyphyllos*. The distinctive marks of these species and the hybrid are:—

T. platyphyllos. Branchlets and leaves very pubescent with long hairs. Buds with three external scales. Cymes pendulous, usually three-flowered. Fruit with prominent ribs; shell woody and hard.

T. cordata. Branchlets glabrous or nearly so. Leaves small, glabrous except for axil-tufts, bluish beneath with irregular and not prominent tertiary venation. Buds with two external scales. Cymes erect, five- to seven-flowered. Fruit faintly ridged; shell thin and fragile.

T. vulgaris. Branchlets quite glabrous. Leaves larger than those of *T. cordata*; under surface pale green, glabrous except for axil-tufts and a few hairs on the nerves, with parallel straight and prominent tertiary venation (as in *T. platyphyllos*). Buds with three external scales. Cymes pendulous, five- to ten-flowered. Fruit faintly ribbed; shell woody and hard.

There are at least two distinct forms of the common lime in cultivation in England and elsewhere which require further study, one with leaves light green beneath, longer than broad, the form described above and considered by botanists to be typical *T. vulgaris*, Hayne; and the following:—

1. *T. pallida*,¹ Wierzbicki, in Reichenbach, *Icon. Fl. Germ.* vi. 58, t. 315 (1844).

Leaves smaller, often not much larger than those of *T. cordata*, as broad as or broader than long, yellowish or bluish green beneath. It is readily distinguishable from *T. cordata* by its prominent tertiary venation, and has flowers and fruits like those of typical *T. vulgaris*. According to V. Engler, it is occasionally found in the wild state in Hungary.

Rarer hybrids also occur:—

2. *T. flavescens* and *T. floribunda*, A. Braun, in Doell, *Rhein Fl.* 672 (1843).

These peculiar trees, possibly hybrids of the same parentage as *T. vulgaris*, were noticed growing in an avenue at Karlsruhe in 1836. The leaves closely resemble those of *T. cordata*, but are larger and with paler axil-tufts. The cymes, with numerous flowers, in which staminodes² are developed, resemble in these respects those of *T. japonica*, the small-leaved lime of Japan. According to Koch,³ the seed was sown, and produced pure *T. cordata* seedlings; but two trees at Kew, labelled *T. flavescens*, presumably seedlings, have larger leaves than those of the common small-leaved lime, and are peculiar in their yellow branchlets and petioles. These, though young trees,⁴ bear flowers, few in the cyme, without staminodes, in partly erect and partly pendulous cymes. One obtained from Späth in 1900 is about 20 ft. high; the other, from Simon-Louis in 1902, is about 15 ft.

¹ Identified by Schneider, with *T. subparvifolia*, Borbas, in *Oest. Bot. Zeit.* xxxvii. 297 (1887). *T. vulgaris*, var. *pallida*, Sargent, *Bull. Pop. Inform.* No. 30 (1912), and in *Gard. Chron.* lii. 88 (1912), is the typical form of *T. vulgaris*, and not the tree described by Wierzbicki.

² On account of the staminodes, these trees are often supposed to be hybrids of *T. cordata* with *T. americana*, but they show no resemblance to the latter species in the shape, size, or serrations of the leaves.

³ *Dendrologie*, i. 481 (1869).

⁴ Sargent, *Bull. Pop. Inform.* No. 30, 1912, and in *Gard. Chron.* lii. 87 (1912), says that plants only a few feet high flower profusely.

3. *T. Beaumontia*,¹ which is sold in Späth's and Simon-Louis's nurseries, appears to be a form of the common lime, with pendulous branches.

The common lime is not indigenous in Britain, where it is never found except in plantations, avenues, and hedgerows, and rarely² produces natural seedlings. It comes into flower³ about ten days later than *T. platyphyllos*, and a fortnight earlier than *T. cordata*.

In the common lime and allied species, the upper surface of the leaves is frequently found in summer to be sprinkled over with a viscid saccharine fluid, which is popularly known as honey dew. There has been great diversity of opinion as to whether this honey dew is always an exudation from the leaves, or is in some cases voided by aphides on the leaves. Sorauer,⁴ the latest investigator of this subject, believes that the saccharine excretion originates without the assistance of aphides, and is the result of excessive transpiration, brought about usually by intense sunlight, a common occasion being when a cold night is followed by a hot morning sun. After the honey dew dries and thickens, it becomes the seat of growth of certain fungi, species of *Fumago*, which give the leaves a blackened appearance. Paths and garden seats situated under lime trees frequently show a disagreeable coating of this viscid exudation, which has fallen from the leaves.

The date of its introduction into England is uncertain, but this tree appears⁵ to have been first planted on a large scale by Le Notre,⁶ in the reign of Charles II., who used it for avenues, as was then the custom in France. The lime trees mentioned by Turner in 1562 as attaining a large size, and the old trees reported by Barrington⁷ to be growing in 1769 in Moor Park in Hertfordshire and on the river Neath in Glamorganshire, were probably *T. cordata*, and of indigenous origin.

(A. H.)

CULTIVATION

The lime seems to ripen its seed more often than is generally supposed in warm summers in the south of England, and I have raised seedlings⁸ from seeds gathered as far north as near Newark in 1904. In the same year Mr. A. C. Forbes sent me some of the common lime from Longleat, saying that very little, if any, of the seed of

¹ Cf. Schneider, *Laubholzkunde*, ii. 374 (1909), who considers it to be a hybrid between *T. euchlora* and *T. platyphyllos*.

² Mr. Anderson has found a few seedlings from trees planted on the edge of Lord Bathurst's deer park, just opposite the Royal Agricultural College at Cirencester.—H. J. E.

³ Cf. Dr. Moss, in *Bot. Exchg. Club Rep.* 1910, p. 550.

⁴ *Pflanzenkrankh.* i. 412-414 (1909). The literature about honey dew on the lime is extensive. Boussingault's article in *Comptes Rendus*, lxxiv. 87 (1872), and Rivière's and Roze's articles in *Bull. Soc. Bot. France*, xiv. 12, 15 (1867), are abstracted in *Gard. Chron.* 1872, pp. 509, 609. See also various letters in *Gard. Chron.* 1873, pp. 920, 952, 1308, 1340, 1372, 1404, 1501, 1602. Buckton, *British Aphides*, i. 39-47 (1876), may also be consulted.

⁵ Cf. Loudon, *Arb. et Frut. Brit.* i. 23, 24 (1838), who states, quoting Hasted, *Kent*, 562 (1769), that Sir John Speilman, in the reign of Elizabeth, brought over two lime trees from Germany, which were planted at Portbridge, near Dartford. These trees were cut down some time previous to 1769, and there is no means of determining what species of lime they belonged to.

⁶ According to Chalmers, *Biog. Dict.* xxiii. 251 (1815), Andrew Le Notre, who was born in 1613 and died in 1700, laid out St. James's and Greenwich Parks in the reign of Charles II.

⁷ In *Phil. Trans.* lix. 35 (1769).

⁸ In the west court of the University Library, Cambridge, which is laid out in grass, secluded, and surrounded by high buildings, there were in 1912 several natural seedlings, arising from seed brought by winds or birds. These included *Betula pubescens* and *B. verrucosa*, elder, *Salix Caprea*, *Crataegus monogyna*, sycamore, and a solitary seedling, three or four years old, which was apparently *T. vulgaris*. It differed slightly in having slight pubescence on the branchlets and under surface of the leaves, thus showing a reversion to *T. platyphyllos*.—A. H.

the small-leaved lime was fertile, possibly because it flowers later than the other. A small proportion of this seed germinated in the first spring, but most of it lay dormant till the following year, and this has been my experience with many sowings of seed from abroad of the various European forms, as well as of the American lime. After germination they grow slowly for the first two years, and the young wood is liable to be killed back in winter. For this reason layering is the method adopted by nurserymen, though the varieties are usually grafted. I cannot say that my experience is as yet long enough to justify me in preferring seedlings.¹

With regard to soil, the lime is not particular, but requires a good deep loam to bring it to perfection. It transplants very well, and may, if properly prepared by cutting round the roots two years previously, be safely moved when 20 to 30 ft. high.

Owing to the depreciated value of the timber, the lime cannot now be recommended except as an ornamental tree, the principal objection to it for this purpose being the early period at which its leaves wither and fall in autumn.

LIME AVENUES

The common lime is one of the most valuable avenue trees that we have; the fashion for planting them is, however, not very ancient, having apparently been introduced by Le Notre and other French landscape gardeners in the latter half of the seventeenth century, from which period most of our best avenues date.

Of these one of the finest is the avenue at Burghley Park, Stamford, the seat of the Marquess of Exeter. This is about 3000 yards long, with four rows of trees planted 6 yards apart in the row, 10 yards between the two outer rows and 20 yards between the inner ones. The trees are 100 ft. to 110 ft. in height on an average, and all appear to have been pollarded when young, though they have the upright habit which distinguishes most of the older lime avenues. I was informed by Mr. C. Richardson, of Stamford, that about fifty-five years ago—when lime wood was much more valuable than it now is, and made 5s. to 6s. per foot, single trees being sometimes sold at £40 to £50—an offer was made by a syndicate of London timber merchants to buy the whole of this avenue for £100,000. This story appears hardly credible, and I could obtain no verification; but, if made, the offer was refused, and there is no chance of such a price being paid for lime trees now.

Another beautiful avenue of fine tall limes is at Stratton Park, Hants, the seat of the Earl of Northbrook, whose late father informed me that it probably dates from about 1715. This avenue shows a common defect, which consists in the mass of spray that springs from some point usually near the root, though sometimes at 10 to 20 ft. up the trees, or even higher. I have searched in vain the works of Evelyn, Duhamel, Miller, Boutcher, and Loudon, for any reference to these abnormal growths,

¹ *T. platyphyllos* is usually imported from France as seedlings; and these appear to thrive in some cases better than plants of the common lime, which have been raised from layers. A young avenue of *T. platyphyllos* at Terling, Essex, with trees about 30 ft. high, is very thriving. The lime avenue at the back of Trinity College, Cambridge, which was celebrated by Tennyson, consists of two parts. That on the west side of the Cam now consists of 38 common limes, one half of which are very burry and much decayed, gaps showing where a few have died. These trees, which now average 6 ft. 9 in. in girth, were planted in 1671, at a cost of £10:6s., plus carriage from London amounting to £1:4s. On the east side of the Cam there are 20 trees, all but one of which are *T. platyphyllos*. These, which now average 6 ft. in girth, were planted in 1717, and look much healthier than the others. Cf. Willis and Clarke, *Archit. Hist. Univ. Camb.* ii. 641, 646 (1886).—A. H.

which, so far as I can learn, seldom appear on wild trees, or on any species but *T. vulgaris*. It is scarcely due to soil, since in some of the finest old lime avenues, as those at Cassiobury Park, Waldershare Park, and Newhouse Park, these growths appear in some trees only. They extend to a considerable height up some of the trees, which are much stunted, as it seems, from this cause. This may arise from the affected trees having been propagated by layers from inferior shoots, or having been planted later to fill gaps, and thus having to contend with trees already established.

It is, however, a point which deserves careful attention on the part of nursery-men; as, though these growths may be pruned off annually, they constantly reappear at the same spot, and not only take a great deal of trouble and time to remove, but eventually disfigure the trees; and limes which produce them rarely attain the same height or beauty as those which are free from them. The trees now sold by nursery-men, which are always propagated from layers, seem to be more subject to these growths than the limes planted two centuries ago; and I believe that limes raised from seed are rarely if ever affected.

The longest avenue of limes which I have seen is comparatively modern, and as I am informed by Mr. A. H. Elliott, agent for the Clumber estate, was planted by Henry, fourth Duke of Newcastle, about the year 1840. It is 1 mile and 1590 yards long, and consists of 1315 trees planted in a double row on each side of the drive at Clumber. The trees are 31 ft. apart each way, and the total width is 143 ft. The trees are fairly uniform in habit, but have spreading bushy tops, and when I saw them in 1906 did not exceed about 60 ft. in height by about 4½ ft. in girth. The soil is rather sandy, and the trees when planted were only 5 ft. high, and were not pruned sufficiently after planting to develop a good trunk, so that this avenue is never likely to rival those at Burghley, Ashridge, or Cassiobury. Mr. Elliott tells me that the trees have suffered considerably from the attacks of the following geometrid moths: *Cheimatobia brumata*, *C. boreata*, *Hybernia aurantiaria*, *H. defoliaria*, *H. progemmaria*, *Anisopteryx æscularia*; but this damage has been checked, if not entirely prevented, by putting grease bands on the trees, which arrest the female moths when they try to ascend the stems in the winter months, and by killing the pupæ in the soil in July with gas-lime. Besides this avenue there are at Clumber two much older ones, over 150 years old, running north and south on either side of the elm avenue leading to West Drayton. One of these is 385 yards long and 30 yards wide, the other 330 yards long and 55 ft. wide. The trees are planted 24 ft. apart. They were pollarded in 1888 in order to save their lives.

At Newhouse Park, near Mamhead, Devonshire, Sir Robert Newman showed me a fine avenue which seems to have been planted about 200 years ago in anticipation of a mansion which was never built. It is only 20 ft. wide and the trees 10 ft. apart; but favoured by a fine soil and climate, the trees, which seem to have been pollarded at 10 ft., have shot up to an immense height, averaging at least 120 ft., and several exceeding 130 ft. Two which I measured were 115 ft. by 5 ft. 9 in., and 135 ft. by 7 ft. 6 in. I have little doubt that they were seedlings. In a chestnut avenue at the same place the trees were much shorter and thicker, about 70 ft. to 80 ft. by 15 ft. to 18 ft. in girth.

At Cassiobury Park, Herts, there is a lime avenue supposed to have been planted by Le Notre, but some of the trees, which are very inferior to the rest in height and symmetry, are smothered in dense masses of small spray at 20 ft. to 30 ft. from the ground, and seem to have been planted later, possibly to replace dead trees in the original avenue. This avenue is 24 yards wide and the trees 8 yards apart. The best of the trees are 120 ft. to 130 ft. high, and one measures 13½ ft. in girth. There is a fine avenue, about half a mile long, at Denham Court, near Uxbridge.

At Braxted Park, Essex, the property of C. H. Du Cane, Esq., there is a lime avenue composed of three rows of trees on each side, which shows extraordinary variation in the growth of the trees, giving it a very irregular appearance. The tallest at the bottom of the hill are about 120 ft. high, and covered to an extent I have never seen elsewhere, with mistletoe growing in large bushes nearly up to their tops. At the top of the hill near the entrance gate, many of the trees are poor and stunted, with masses of spray at their root and higher up, and with gouty swellings on their branches which may be due to the mistletoe.

At Betchford Park, Surrey, there is a remarkable avenue of very old trees, some of which, when seen by Henry in 1906, were 130 ft. in height and 12 ft. to 13½ ft. in girth. This avenue was described as a very fine one by Dr. Aikin¹ in 1798.

At Doneraile Court, in Ireland, there is a fine avenue, one tree measuring 98 ft. by 10 ft. in 1907; most of the trees were covered with masses of spray.

An excellent article by Alfred Rehder of the Arnold Arboretum, on the lime as an avenue tree, in *Möller's Deutsche Gärtner Zeitung*, 1904, p. 188, should be consulted by those who think of planting. After giving the distinctive characters of the species, and describing their peculiarities of growth, he says that the choice must depend on the character of the soil and climate, and considers that the large-leaved lime, *T. platyphyllos*, is the best where the ground is deep and moist and where rapid growth and heavy shade are required. For drier soil he prefers *T. cordata*, which does not, however, make such a large or fine tree. *T. vulgaris* is in most of its characters intermediate, and this is the lime which is most generally used in England, though according to Rehder most, if not all, of the limes celebrated for their size and age in Germany are *T. platyphyllos*. He thinks that *T. euchlora*, Koch, is the best for town planting, because its smooth leaves do not hold the dust so much as those of other species, and because its leaves do not fall so early. He prefers *T. petiolaris*, the pendulous silver lime, for park avenues, and for single specimens where its branches can show their full beauty. Rehder does not give any observations as to the relative advantage of trees propagated from seed, from layers, or from grafts; but he rightly says that it is important that all the trees should be propagated from the same variety.

REMARKABLE TREES

Among the most remarkable limes that I have seen is a walk at Ashridge Park. These trees are individually much larger than those at Burghley or Stratton, and

¹ In *Monthly Magazine* for 1798, quoted in *Gard. Chron.* 1841, p. 4.

though planted only 4 to 5 yards apart, average 120 ft. high and about 10 ft. in girth. They have the amount of variation in their leaves that one would expect to find in seedlings, and though 250 years old¹ only one out of forty is decayed. The bark of these trees is more like that of an elm than the usual bark of a lime, but this is perhaps owing to some peculiarity in the soil. A great lime at the end of the pinetum at Ashridge is of a totally different character, having very drooping branches and an immense spread. It has a trunk about 30 ft. high, and does not exceed 80 ft. to 90 ft. in total height, but the branches cover a circumference of 110 paces.

In Windsor Park, near Cranbourne Tower, there are some extremely tall and graceful limes growing with beech in a circle which were planted² in 1697. The best of these that I measured was 130 ft. by 14 ft. in girth, a beech close by it being 125 ft. by 10 ft.

A remarkable case of the tendency of the lime to layer which occurs at Rothamsted, is figured in the *Gardeners' Chronicle*, June 5, 1875. Here a row of fine old limes have dropped their branches on each side to the ground, and these have grown up in a thick mass, forming a shady corridor on each side of the trunks. There is another good example at Enville Hall, Stourbridge, where hundreds of young stems have arisen from layers, the whole mass measuring 140 paces round in 1904.

A curious instance of natural inarching of the lime is described and figured in *Gard. Chron.* xi. 277 (1879).

The branches of the lime sometimes spread laterally to a great distance. One of the best instances I have seen was shown me by Mr. Tudway at the Coombe, near Wells in Somersetshire. The tree is a large-leaved lime growing in a sheltered dell, about 100 ft. by 14 ft., and has three immense horizontal limbs 8 to 9 ft. in girth, one of which extends for 64 ft. from the trunk. In Stoneleigh Park, Warwickshire, there are some fine limes remarkable for their wide-spreading branches. In the Thames valley there are many fine lime trees, one at Osterley Park being about 120 ft. in height; while at Crowsley Park, near Henley, there are several in a clump, one of which was 118 ft. by 12½ ft. in 1908.

E. Lees, in his account³ of the *Forest and Chase of Malvern*, speaking of the common lime, says:—"Some very fine trees now stand in a field about half a mile south of Bromsberrow Church, and by the side of the road leading from Ledbury towards Gloucester. Two of these, growing near each other, have become conjoined, both by the amalgamation of their arms, and by a lateral junction at the root.⁴ The largest of these trees is 27 ft. in circumference at three feet from the ground, and is 36 ft. round the base; the other is 11 ft. 3 in. in girth at a yard from the ground, and 19 ft. in circumference at the base. The whole mass, if measured as one tree (and the interval between the boles where the connecting root joins them is only 19 in.) is full 48 ft. in circumference. In a field on the Priory Farm, Little Malvern, are several large

¹ In a book called *Chiltern and Vale Farming*, p. 153, published in 1745, it is stated by the anonymous author, who lived close to Ashridge, that they were planted in 1660, and in 1745 or thereabouts were near 3 ft. in diameter at the bottom.

² W. Menzies, *History of Windsor Great Park*, 44 (1864).

³ Abstracted in *Gard. Chron.* 1870, p. 1536, figs. 264, 265, 266.

⁴ I visited these trees in 1905, and found the largest now standing to be about 80 ft. high and 20 ft. 9 in. in girth. The fruit was fully formed on 18th July.

trees of *Tilia platyphyllos*, but these do not belong exactly to forest trees, having certainly been planted either by one of the Priors of Little Malvern or some of his lay successors to the Priory lands."

A very large lime formerly grew in Hagley Park, Worcestershire, the seat of Lord Cobham, which, according to Lees,¹ in 1874 measured 27 ft. in girth at 3 ft. from the ground, but this I am told was blown down about twenty-five years ago. At Arley Castle there is a fine tree, about 120 ft. high by 12 ft. 8 in. in girth.

The most curious instance of artificial layering I have seen anywhere is at Knole Park, where a lime described by Loudon as having covered nearly a quarter of an acre in 1820 still grows. The central stem no doubt originally dropped its branches on the ground in a circle of about 8 yards in diameter. These have grown up into trees 80 ft. to 90 ft. high, some of which are thicker than their parent. These again have layered themselves in a second concentric circle 20 yards in diameter, the trees in which are 20 ft. to 40 ft. high, and these are now rooting their outer branches in a third circle more irregular than the others, and 8 yards distant from it, so that the total diameter of the group is 36 yards. All the stems are more or less covered with spray, and the central one seems to have long ceased to grow.

Strutt paid less attention to the lime than it deserves. He figures only two, one of which, at Cobham, is in the same plate with a sycamore; the other at Moor Park, near Rickmansworth, Herts. This stood at the end of a line of large limes, and was a very wide-spreading tree, with a trunk 17½ ft. at three ft. from the ground, and branches 120 yards in circumference. I am informed by Mr. Haynes, gardener at Moor Park, that this tree was blown down in 1860; but it is still alive, and some of the branches have taken root in the ground and have sent up stems about forty-five feet high. Within fifty yards of it another tree in the same row is now 21 ft. in girth.

A similar case of a lime having been blown down and the branches taking root occurs at Stratton Strawless. This tree, as Mr. Birkbeck tells me, was mentioned by Sir T. Browne in the reign of Charles I. It was blown down in 1895 and lay till 1900, when the roots were covered with a mound of sand. When I saw it in 1909, many branches were throwing up vigorous shoots, and the tree looked as if it might live for centuries. Its trunk was about 12 ft. in girth. A very fine tall red-twigged lime by the water at Gatton Park, in 1904, was 131 ft. by 12½ ft. A large spreading tree, at Osberton Grange, Notts, is about 80 ft. high by 19 ft. in girth.

At Dallam Tower, Westmoreland, there is an old lime in an exposed situation in the park which measures no less than 22 ft. 3 in. in girth, though not over 65 ft. in height; and, as showing the influence of situation on trees, I may say that, in a sheltered hollow close to the house at the same place, I measured a lime 128 ft. high, double the height of the first, but only 7 ft. 8 in. in girth.

There is a row of very large and apparently old limes at Hawsted, near Bury St. Edmunds, in the same field, and probably planted at the same time as the Oriental planes which we have described.² The largest is about 105 ft. by 20 ft. Another, whose trunk is covered with large burrs, is 16 ft. in girth. The leaves on the shoots from the base of these trees vary considerably in size and shape.

¹ *Gard. Chron.* i. 49 (1874).

² Cf. Vol. III. pp. 621, 622.

In the west garden at Hatfield House, Herts, there is a remarkable pergola of the common lime, about 280 yards long, and 10 ft. wide. The trees, which are pruned every year, stand 12 ft. apart in the row on each side, and are $7\frac{1}{2}$ ft. high.

In some parts of England, especially in Essex and Herts, the lime is infested by mistletoe, which often kills the branches and causes irregular excrescences, which sometimes have an elongated gourd-like shape. A remarkable specimen of this, taken from a tree in front of Spains Hall, the seat of A. W. Ruggles-Brise, Esq., in Essex, is now in the Forestry Museum at Cambridge. It was stated in the *Gardeners' Chronicle*,¹ in answer to an inquiry by me, that such swellings are abundant on the limes at Hampton Court and at Dropmore, where Mr. Page states that a large tree was cut down on account of it being in a dying condition.

In Scotland² the lime is at many places almost as fine as in England. An immense tree growing at Kinloch, Meigle, is, as I am told by Sir John Kinloch, about 90 ft. by 21 ft., and spreads over an area of a hundred yards in circumference. A wide-spreading lime at Gordon Castle, which is known as the Duchess' tree, measures about 89 ft. high and 17 ft. 4 in. in girth; its layered branches form a dense mass of shoots and have not been trained into trees like the lime at Knole. Their total circumference is not less than 126 paces, so that it covers as large an area of ground as the Newbattle beech.³ This tree is mentioned in *Old and Remarkable Trees* as having been, in 1867, 70 ft. by $16\frac{1}{2}$ ft. at 3 ft., the circumference of the branches being 310 ft. There is a wide-spreading common lime at Pitfirrane, near Dunfermline, of which the gardener, Mr. Percy Brown, has sent us a photograph. It was, in 1912, 74 ft. high, and 13 ft. 3 in. in girth, the circumference around the branches being 298 ft. At Leny there are some fine limes, one of which I found to be 105 ft. by 12 ft. 3 in., which, at such a high elevation above the sea, is remarkable. At Ancrum, near Roxburgh, Mr. Renwick saw a common lime 17 ft. 3 in. in girth in 1909.

At Roseneath, near the great silver firs (see p. 729), is an old avenue of large-leaved limes, covered with such a mass of small spray that it was impossible to see the bark near the ground, and one of these, measured over the spray with the tape as tight as I could make it, was no less than 24 ft. There are some fine lime trees of great size in the park at Taymouth Castle.

In Ireland we have seen no limes of remarkable size, and the tree never seems to have been so generally planted as in England. There is an avenue of fair-sized trees at Muckross Abbey; and Loudon mentions a tree in the park at Charleville forest, Co. Meath, which was reported at that time to be 110 ft. high and $5\frac{1}{2}$ ft. in diameter at 1 ft. from the ground. At Rossanagh a remarkable tree was growing in 1908 which, as I was informed by Mr. W. T. Tighe, was blown down about 1825. His grandfather had it pulled up into a leaning position, and placed a large boulder over the roots to keep it firm. It now leans at an angle of about 40° , and has grown into a flat trunk 6 ft. wide on the side but only 14 ft. 10 in. in girth. It is about 100 ft. in height and twice as large in girth as any other of the trees in the same line, which appear to have been planted at the same time.

³ Vol. I. p. 23, Plates 8, 9.

TIMBER

The wood of the lime is pale yellow or white, light, soft, and close-grained, and is not liable to become worm-eaten. It was formerly valued by pianoforte-makers for sounding-boards; and cutting boards used by shoemakers, glovers, and harness-makers, were made of it. I am informed by Mr. Anderson that twenty-five years ago he was sometimes able to sell the best part of large trees at as much as 5s. or 6s. per foot; and at Longleat a large lime tree blown down in the park realised 4s. 6d. per foot; but its use has now been superseded by foreign imports from America and elsewhere, and from one to two shillings per foot is its usual value. Owing to its softness, consistency, and non-liability to split, it was preferred for wood-carving; and all the finest carvings by Grinling Gibbons are said to be done in lime wood.¹

In northern Europe, especially in Russia, the inner bark of the small-leaved and large-leaved limes is largely used for making the bast mats which are used as dunnage in grain cargoes, and also imported for covering garden frames. The shoes worn by the Russian peasants are made from plaited lime bark, and Loudon says that ropes were made from it in his time in Devonshire and Cornwall; but this, like so many other rural industries, has now, I believe, quite died out.

I am indebted to Mr. J. Rose, of Messrs. Broadwood & Sons, for the following:—"Fine lime-tree was at one time very eagerly sought after in this country for the manufacture of pianoforte keys. When large and freely grown it is a beautifully straight and silky-grained wood, easily worked, not given to warping, very light in weight, and yet very tough. These qualities made it an admirable material for the purpose. But it became more and more difficult to obtain lime-tree of fine quality, and it was replaced by the importation of American basswood, a wood of similar character, easier to obtain in good sizes, free from knots, and straight in the grain, which is imported in the form of boards, or of glued-up and planed keyboards ready for the ivories. It has also been replaced, in part, for key-making by continental-grown pine, which has distinct advantages for the purpose."

A marked feature in the timber trade in recent years has been the importation of sawn timber, which has greatly affected the sale of home-grown timber. The manufacturer is now supplied with foreign timber ready sawn, seasoned to some extent, and often carefully graded; whereas home-grown timber has to be collected in comparatively small parcels, and its selection and handling require a great amount of knowledge and experience possessed by a very few persons. (H. J. E.)

¹ Evelyn (*Silva*, Hunter's ed. i. 205 (1801)), says: "Because of its colour and easy working, and that it is not subject to split, architects make with it models for their designed buildings; and the carvers in wood use it not only for small figures, but for large statues and entire histories in bass and high relieve; witness beside several more the festoons, fruitages, and other sculptures of admirable invention and performance, to be seen about the choir of St. Paul's and other churches, royal palaces, and noble houses in city and country; all of them the works and invention of our Lysippus, Mr. Gibbons, comparable, and for ought appears equal to anything of the antients. Having had the honour (for so I account it) to be the first who recommended this great artist to his Majesty Charles II., I mention it on this occasion with much satisfaction."

TILIA EUCHLORA

Tilia euchlora, Koch, in *Wochenschr. Gärtn. u. Pflanzenk.* ix. 284 (1866), and *Dendrologie*, i. 473 (1869); Schneider, *Laubholzkunde*, ii. 374 (1909); V. Engler, *Monog. Gatt. Tilia*, 149 (1909).
Tilia multiflora, Simonkai, in *Math. Term. Közl.* xxii. 328 (1888) (not Ledebour).
Tilia rubra, var. *euchlora*, Dippel, *Laubholzkunde*, iii. 63 (1893).
Tilia dasystyla, Jack, in *Garden and Forest*, i. 332 (1888); Nicholson, in *Kew Hand-list Trees*, 45 (1894) (not Steven).¹

A tree, attaining 50 ft. in height and 6 ft. in girth, but possibly larger in its native country. Bark grey and scaly. Young branchlets green, glabrous, the short shoots, however, being slightly pubescent. Leaves (Plate 407, Fig. 10) intermediate in size between those of *T. cordata* and *T. vulgaris*, averaging 2½ in. in width and length, orbicular-ovate, coriaceous, cuspidate at the apex, oblique and cordate at the base; upper surface dark shining green, glabrous; lower surface paler, almost glaucous, glabrous, except for brownish axil-tufts at the base and at the junctions of the midrib, primary and secondary nerves; margin regularly serrate, the teeth ending in long slender points; petiole glabrous, slender, more than half the length of the blade. Buds, with three external green glabrous ciliate scales.

Cymes glabrous, pendulous, exceeding the leaves in length, three- to seven-flowered; bract glabrous, tapering at both ends, shortly stalked; flowers similar to those of *T. platyphyllos*, but the ovary is tomentose with long hairs, which are continued on the base of the style, the upper ¾ of which is glabrous. Fruit ovoid, indistinctly five-ribbed, covered with dense short brownish grey tomentum, the base of the style persistent at the apex; shell thick and woody.

This species is remarkably distinct in appearance, owing to the dark green and remarkably glossy upper surface of the leaves. It comes into flower about the end of July at Kew, later in the season than most of the limes, and the flowers have a peculiar colour, owing to the distinctly yellow tinge of the petals and filaments.

It has been much confused with *T. dasystyla*,² Steven, a native of the Crimea, which has leaves quite different in colour and shape, and, as its name indicates, a densely tomentose long style.

Tilia euchlora is represented in the Kew herbarium by a wild specimen from Karabagh in Russian Armenia; but it is supposed by Schneider and V. Engler to be a hybrid; and, if this is the case, its parents are possibly *T. caucasica*,³ Ruprecht, the common large-leaved lime in the Caucasus, and *T. cordata*. It is always propagated in nurseries by budding on the common lime; and seedlings of it appear to be unknown.

¹ Loudon, *Arb. et Frut. Brit.* i. 366 (1838), refers to Steven's species from the Crimea, and not to the tree called by us *T. euchlora*, Koch.

² *T. dasystyla* is represented in the Kew herbarium by Steven's type specimen and two other specimens, all from the Crimea.

³ The Caucasian lime can scarcely be identified with *T. rubra*, De Candolle, in *Cat. Plant. Hort. Monsp.* 150 (1813), which is described as having leaves pubescent beneath as in *T. platyphyllos*, and evidently refers to the southern form of the latter species in Europe.

This species is perhaps the handsomest of all the limes, on account of its shining foliage, which is very late in falling in autumn, and seems to be free from insect and fungoid attacks and from honey dew. It is apparently quite as hardy as the common lime, and young trees at Kew are remarkably thriving and healthy. It was unknown in Loudon's time, and seems to have been introduced a short time before 1866, when it was first accurately distinguished by Koch. It is rather rare in cultivation in England, though it is planted in Berlin and other German cities,¹ and thrives² in the Arnold Arboretum in Massachusetts. (A. H.)

TILIA TOMENTOSA, WHITE LIME

Tilia tomentosa, Moench, *Verz. Ausl. Bäume Weissenst.* 136 (1785); V. Engler, *Monog. Gatt. Tilia*, 116 (1909); Schneider, *Laubholzkunde*, ii. 386 (1909).
Tilia alba, Aiton,³ *Hort. Kew.* ii. 230 (1789), and iii. 300 (1811); Waldstein and Kitaibel, *Icon. Pl. Hung.* i. 2, t. 3 (1802); Loudon, *Arb. et Frut. Brit.* i. 372 (1838).
Tilia pallida, Salisbury, *Prod.* 367 (1796).
Tilia rotundifolia, Ventenat, *Mém. Inst. Paris*, iv. 12, t. 4 (1803).
Tilia argentea, Desfontaines, in De Candolle, *Cat. Pl. Hort. Monsp.* 150 (1813).
Tilia petiolaris, De Candolle, *Prod.* i. 514 (1824) (not J. D. Hooker).

A tree, attaining 100 ft. in height and 15 ft. in girth, usually with markedly ascending branches. Young branchlets covered with white stellate tomentum, more or less retained in the second year. Leaves (Plate 407, Fig. 3), about 3 to 5 in. across, nearly orbicular, cuspidate at the apex, cordate or truncate at the base; margin often lobulate, serrate or biserrate, the serrations ending in short blunt cartilaginous points; upper surface green, with scattered stellate pubescence; lower surface covered with a dense whitish tomentum, without axil-tufts; petiole stout or slender, less than half the length of the blade, stellate-pubescent. Buds, with three external grey tomentose scales.

Flowers, in seven- to ten-flowered pendulous tomentose cymes, which are shorter than the leaves; bract tomentose, sub-sessile; sepals tomentose, clothed with long hairs at the base within; petals glabrous, longer than the sepals; staminodes slender, spatulate, shorter than the petals; stamens, shorter than the staminodes, numerous, with the halves of each anther on a distinct short stalk; ovary ovoid, tomentose; style glabrous. Fruit ovoid, elongated, apiculate, slightly five-angled, grey tomentose, smooth or only indistinctly warty; shell woody.

This species shows in the wild state considerable variation in the shape of the

¹ Mr. Bean, in *Kew Bull.* 1908, p. 390, says that this species, which is so promising a tree for street planting, is abundant in the Boskoop nurseries, near Gouda, in Holland.

² *Garden and Forest*, i. 332 (1888).

³ In Aiton, *Hort. Kew.* ii. 230 (1789), it is erroneously stated that the common white lime is a native of North America, an error which was rectified in the second edition of this work, iii. 300 (1811), where Hungary is correctly given. Some writers have supposed that *T. heterophylla* was the species referred to; but the type specimen in the British Museum, inscribed *Tilia alba* in Solander's handwriting, though bearing neither flowers nor fruit, is without doubt a branch of the common European lime, identical with var. *argentea*.

leaves—some specimens, distinguished by V. Engler, as var. *typica*, having suborbicular leaves, usually cordate at the base; whilst others, var. *petiolaris*,¹ V. Engler, have leaves usually broader than long, and more or less truncate or subcordate at the base. These are connected by numerous intermediate forms, and can scarcely be maintained as distinct varieties.

All the wild specimens which I have seen, are characterised by leaves, thin in texture, usually pale green above, greyish and not snowy-white beneath, and with slender petioles. Trees similar to the wild form are occasionally seen in cultivation; but the tree which is more commonly cultivated under the name *T. argentea*, and which possibly was the one described by Moench as *T. tomentosa*, and in that case technically the typical form of the species, differs considerably in having larger leaves, thick in texture, more or less orbicular, uneven on the surface, dark shining green above, snowy white beneath, margin often lobulate, petioles short and stout. It is convenient to distinguish this cultivated form, the origin of which is unknown to me, as var. *argentea*. It has always ascending branches, and is possibly a sport.

This species is a native of south-eastern Europe, and Asia Minor; but does not extend as far eastward as the Caucasus. Its northern limit is southern Hungary, where it is found in some parts of Banat, Slavonia, and Croatia. It is widely distributed throughout the Balkan peninsula, extending southwards as far as Laconia in Greece; and spreads eastward through Roumania and Moldavia to Bessarabia, Podolia, and the Crimea. In Asia Minor, it is limited to Bithynia and the island of Chios. It is usually a component of mixed deciduous woods, growing in valleys and mountain slopes at a low elevation, but occasionally forms pure woods of small extent.

(A. H.)

CULTIVATION

The white lime was introduced into England in 1767, and has been planted as an ornamental tree at many places; but I know no avenues of it in England.

This species should be multiplied either by seed, which here only ripens in hot seasons such as 1911, or by layering, as when grafted, as is often done, on the common lime, the scions grow thicker than the stock and produce an unsightly swelling at the point of junction. As an ornamental tree, and for use in towns, it is much superior to the common lime, on account of the freedom of the leaves from honey dew.

The only place where I have seen the silver lime growing wild in Europe is in the forests of Bosnia, near Maglai in the valley of the Bosna, at about 1000 ft. elevation. Here it was scattered in forests of oak, and other deciduous trees, and was so conspicuous when the silvery white undersides of the leaves were upturned by the wind, that at a distance of a mile or so I at first supposed it to be a tree covered with white flowers.² Probably some such experience must have induced a former owner of Highclere to plant it largely in that beautiful park, where, as Loudon

¹ To be carefully distinguished from *T. petiolaris*, Hooker (see p. 1677).

² In sunny weather, the leaves on the sunny side, especially at the ends of the branchlets, are reversed, turning their white sides to the light. This is a provision against excessive transpiration of water; and has been observed in the other silver limes and in *Quercus conferta*. See Kerner's remarks in his *Nat. Hist. Plants*, Eng. Trans. i. 338 (1898).—A. H.

remarks, its presence could be detected at some miles distance through the apparently dense forest by the white tops appearing at intervals among other trees.

The finest tree of this species that we have seen grows at Albury Park, Sussex, in front of the Duke of Northumberland's house, and measures 100 ft., or perhaps a little more, in height, by 13½ ft. in girth (Plate 373). The ascending branches seem characteristic of this species, in cultivation at least, but this tree has an unusually regular and perfect head. I was informed by the late Mr. Leach that at Albury the flowers of this tree are poisonous to bees,¹ whose dead or stupefied bodies are found lying on the grass below it in August, and this observation is confirmed by Mr. Comber at The Hendre and by other observers.

At Henham Hall, Suffolk, a tree measured 76 ft. by 8 ft. 10 in. in 1909. It is grafted on the common lime, and is of the typical upright habit. At Hewell Grange a large tree, with the bark decaying on one side, was 92 ft. by 9 ft. 8 in. in 1909. At Dropmore there are two trees in the avenue to the Taplow gate, the larger of which is about 70 ft. by 11 ft. 3 in. At Harpsden Rectory, Oxon., Henry saw two trees, the larger of which was 80 ft. by 6 ft. 8 in. in 1907. At Arley Castle, a round-headed tree of upright habit measured² 62 ft. by 6 ft. 9 in. in 1903. At Beauport, Sussex, there is a tall but slender tree in a rather crowded situation, which has been grafted at about 10 ft. from the ground. Dr. Masters reported³ a tree of fine proportions and symmetry at Strathfieldsaye, 70 ft. by 6 ft. 2 in., in 1899. Mr. Bean⁴ saw a tree 80 ft. high in the Royal Gardens at Sans Souci, Berlin. (H. J. E.)

TILIA PETIOLARIS, WEEPING WHITE LIME

Tilia petiolaris, J. D. Hooker, *Bot. Mag.* t. 6737 (1884) (not De Candolle); Boissier, *Fl. Orientalis*, *Suppl.* 136 (1888).

Tilia alba, Koch, *Dendrologie*, i. 478 (excl. syn.) (1869) (not Aiton).

Tilia tomentosa, Moench, var. *petiolaris*, Kirchner, in Petzold and Kirchner, *Arb. Musc.* 162 (1864); V. Engler, in *Mitt. Deut. Dend. Ges.*, 1907, pp. 218-221.

Tilia tomentosa, Moench, var. *sphaerobalana*, Borbas, in *Bot. Centralb.* xxxvii. 168 (1889); V. Engler, *Monog. Gatt. Tilia*, 121 (1909).

A tree, attaining 80 ft. in height, differing from the wild form of *T. tomentosa*, as follows: Branches and branchlets pendulous; leaves with long slender petioles, exceeding half the length of the blade; fruit globose, depressed at the summit, from which arises a short stout style, very warty on the greyish surface, and divided by five vertical furrows into as many lobes; seeds⁵ often imperfect.

The leaves (Plate 407, Fig. 2) average about 3 in. across, and are obliquely orbicular, cordate or truncate at the base, cuspidate at the apex, flat on the surface and not wrinkled; margin finely and regularly serrate, the teeth ending in short points; under surface covered with a dense white tomentum; upper surface dark

¹ The flowers of the large tree of *T. petiolaris* at Kew are equally poisonous to bees. Cf. p. 1679, note 1.

² R. Woodward, *Hortus Arleyensis*, 25 (1907).

³ In *Gard. Chron.* xxvi. 162 (1899).

⁴ *Kew Bull.* 1908, p. 395.

⁵ Engler, out of fifty fruits which he examined, found only three with good seed, 1 to 2 in each fruit.

green, with scattered stellate pubescence. The branchlets, buds, and flowers are identical with those of *T. tomentosa*.

This tree appears to be a sport of *T. tomentosa* of unknown origin. Schneider considers it to be a native of southern Hungary and the Balkan States; and no doubt, specimens of silver limes with longer petioles than usual occur in that region, but no one, so far as I am aware, has ever seen a tree in the wild state with the pendulous habit and the peculiar fruits of *T. petiolaris*, Hooker. V. Engler admits that it is only known in cultivation.

The history of this tree is obscure; but it seems to have been first accurately distinguished by Kirchner, who, in 1864, described it as *T. tomentosa*, var. *petiolaris*, and erroneously identified it with *T. petiolaris*, De Candolle.¹ Hooker, in *Bot. Mag.* t. 6737 (1884), following Kirchner, adopted De Candolle's name; but, though this was incorrect, it is convenient to retain the name as *T. petiolaris*, Hooker. This peculiar tree was not known in Loudon's time; but must have been introduced from the Continent soon afterwards, as the fine specimen in the Cambridge Botanic Garden was probably planted² in 1842. Before 1864 it was known in cultivation as *T. americana pendula*³; and Koch in 1869 considered it to be of American origin.

1. *Tilia orbicularis*, Carrière,⁴ which originated in Simon-Louis' nursery at Plantières, is evidently a seedling of *T. petiolaris*, from which it differs mainly in being less pubescent. The leaves, which are dark glossy green above and dull grey beneath, also differ from those of *T. petiolaris* in the shorter petioles, which are, however, slender as in that species. The serrations are also slightly sharper and occasionally more irregular. Flowers as in *T. petiolaris*, but with the bract larger and nearly glabrescent, and the sepals and pedicels covered with a less dense and greyish tomentum. Fruit strictly globose, not depressed at the summit, and showing no furrows, but having the same warty surface as that of *T. petiolaris*.

This tree, which is not nearly so pendulous in habit as *T. petiolaris*, is reputed, on account of the dark glossy green of the upper surface of the leaves, to be a hybrid between *T. petiolaris* and *T. euchlora*; but, in the present state of our knowledge of hybrids, it is judicious to say nothing about its parentage until experimental sowings have been made on a large scale of the seed of *T. petiolaris*.⁵

Two small trees of *T. orbicularis*, obtained from Plantières in 1900, are thriving at Kew, one of which has already produced flowers and fruit. They retain their foliage late in the season. (A. H.)

¹ *T. petiolaris*, De Candolle, was founded in 1826 on a branch without flowers or fruit, now preserved in the Geneva Herbarium, which was taken from a tree cultivated in the Imperial Botanic Garden at Odessa; but Lange, in *Flora*, i. 233 (1827), who had seen this tree, states that it was identical in every respect with the ordinary form of *T. argentea* cultivated at Paris; and a drawing at Kew of De Candolle's specimen confirms Lange's opinion. The name *T. petiolaris*, De Candolle, thus disappears, being a mere synonym of *T. tomentosa*.

² The oldest herbarium specimen, which I have seen, is one in fruit from a tree growing in a street at Nancy, collected by Billot in 1861. According to Bunbury, *Arb. Notes*, 67 (1889), the fine tree at Barton was planted by his father; but no exact date can be now ascertained.

³ Cf. Rehder, in *Mitt. Deut. Dend. Ges.* 1904, p. 209.

⁴ Ex Beissner, in *Mitt. Deut. Dend. Ges.*, 1898, pp. 86 and 88. It appears, however, to have been first accurately described by Jouin in *La Semaine Horticole*, 1899, p. 335.

⁵ A branch from a seedling of *T. petiolaris*, raised in the Arnold Arboretum and sent to me by Prof. Sargent in 1910, bears foliage identical with that of the parent. Sargent, *Bull. Pop. Inform.* No. 30 (1912), and in *Gard. Chron.* lii. 88 (1912), states, however, that plants raised in the Arnold Arboretum from the seeds of a tree of *T. petiolaris*, which was growing near *T. americana*, the two flowering at the same time, are identical with trees of *T. spectabilis*. See p. 1686.

Tilia petiolaris is a beautiful weeping tree, which has not been nearly so generally planted as it deserves to be. There are good examples in the Botanic Gardens at Kew, Cambridge, and Glasnevin. At Stowe, near Buckingham, there is a handsome tree, 74 ft. by 6 ft. 8 in. There are two fine trees, girthing 7 ft. 4 in. and 5 ft. 7 in., and about 80 ft. high, growing on the bank of the Thames near Cliveden on the Wharfe Estate, belonging to Lord Boston. A very similar one on the lawn at Barton, Suffolk, was measured by Henry as 83 ft. by 8 ft. 2 in. in 1908. Another at Chiswick House, which has the trunk decayed on one side, measured 77 ft. by 10½ ft. in 1903. At Bicton a handsome tree, near the house, grafted at seven feet from the ground, measured 80 ft. by 5½ ft. in 1906. At Hatherop Castle there is a beautiful specimen of moderate size on the lawn (Plate 374), which has layered naturally; and many plants have been propagated from it also by artificial layers. At Gunnersbury House there is a good tree, which in 1912 measured 56 feet high by 6 ft. in girth at 4 ft. from the ground. At Aldenham there is a tree on the lawn which ripened fruit in 1911 from which I raised seedlings. I noticed many dead bees¹ under it on August 20.

In Scotland it appears to be perfectly hardy at Durriss; and Henry found, in 1905, a tree at Bargaly, 41 ft. by 4 ft. 8 in.

Mr. Bean² saw a fine specimen at Herrenhausen, in Hanover, which was 9 ft. 2 in. in girth in 1908. (H. J. E.)

TILIA MONGOLICA

Tilia mongolica, Maximowicz, in *Mé. Biol.* x. 585 (1880), and *Enum. Pl. Mongol.* 118, t. 11 (1889); L. Henry, in *Rev. Hort.* 1902, p. 476, figs. 214, 215, 217; Rehder, in Sargent, *Trees and Shrubs*, i. 121, t. 61 (1903).

A small tree, scarcely exceeding 30 ft. in height, and flowering when only a few feet high. Young branchlets glabrous, reddish, becoming grey in the second year. Leaves (Plate 407, Fig. 7) about 2½ in. wide, acuminate at the apex, with one or two sharp-pointed lateral lobes; base truncate or cordate; coarsely serrate, with a few large triangular teeth, tipped with long callous points; upper surface dark green, shining, glabrous; lower surface glaucous, with pubescent tufts in the axils at the base and at the junctions of the primary and secondary nerves, elsewhere glabrous; petiole glabrous.

Flowers, six to twelve in a cyme; bract stalked; sepals erect, villous within, glabrous without; petals erect, longer than the sepals; staminodes five, obtuse; stamens, as long as the sepals, thirty-five to forty, in five bundles; style glabrous. Fruit ovoid, mucronulate, without ribs or only slightly ribbed, thick-walled, shortly tomentose.

This species is very distinct in appearance, the small coarsely serrate leaves resembling those of a birch, and opening with a reddish tint in spring.

¹ In 1908, the bodies of innumerable bees, poisoned by the flowers of a tree of *T. petiolaris* at Tortworth, had so much manured the ground under its outer branches, that a very green ring of turf was visible in the autumn following, and was noticed by the Earl of Ducie to be even more conspicuous in 1909.

² *Kew Bull.* 1908, p. 392.

This tree occurs in northern China, at Jehol, and on the Po-hua mountain, west of Peking; and has also been found in the Moni Ula range, north of Ordos, in Mongolia. It was introduced into cultivation by Dr. Bretschneider,¹ who sent seeds from Peking to the Museum at Paris in 1880, and to the Arnold Arboretum in 1882. The specimen in the Jardin des Plantes at Paris is about 20 ft. high. A small tree at Kew flowered, when only 5 ft. high, at the end of July 1907. This species has lately been introduced into the Coombe Wood Nursery by Mr. Purdom, who has been collecting for Messrs. Veitch in northern China. (A. H.)

TILIA PAUCICOSTATA

Tilia paucicostata, Maximowicz, in *Act. Hort. Petrop.* xi. 82 (1890); Schneider, *Laubholzkunde*, ii. 371 (1909); V. Engler, *Monog. Gatt. Tilia*, 87 (1909).

Tilia Miqueliana, var. *chinensis*, Diels, in Engler, *Bot. Jahrb.* xxxvi., *Beibl.* No. 82, p. 75 (1905) (not Szyszylowicz).

A small tree. Young branchlets glabrous, green. Leaves about $2\frac{1}{2}$ in. long and 2 in. wide, ovate, usually truncate and rarely cordate at the base, ending at the apex in a long non-serrate acuminate cusp; green and glabrous on both surfaces, except for minute axil-tufts of pubescence beneath, which are, however, absent at the base of the blade; tertiary veins on the lower surface few, irregular, not parallel, but anastomosing, more or less prominent; margin with regular fine serrations ending in long points; petiole about an inch long, green, glabrous.

Cymes erect, each with seven to fifteen flowers; bracts glabrous, stalked; staminodes present; style pilose at the base. Fruit globose, tomentose, faintly five-ribbed.

This species differs from *T. cordata* and its allies, in the prominent tertiary venation and the green and not glaucous under surface of the leaf, which is usually truncate at the base. It is a native of the provinces of Kansu, Shansi, and Szechwan, in western China, where it was collected by Potanin, Giraldi, and Wilson. The latter sent a living plant² in 1901 to Coombe Wood, which I consider to be probably of this species. From it many grafts have been taken, and it now produces coppice shoots with large leaves, which show at the base of the blade and on the adjoining end of the petiole a trace of scattered stellate pubescence. This is probably a juvenile character, disappearing on adult plants; and a young tree at Kew, one of the grafts, about 8 ft. high, bears leaves similar to those of the adult wild tree, though slightly larger, and in these the stellate pubescence has almost disappeared. (A. H.)

¹ *Hist. Europ. Bot. Disc. China*, ii. 1050 (1898). The seedlings mentioned here as being alive at Kew in 1893 cannot be traced.

² This is probably the plant referred to *T. Miqueliana*, var. *chinensis*, in *Hortus Veitchii*, 381 (1906).

TILIA OLIVERI

Tilia Oliveri, Szyszylowicz, in Hooker, *Icon. Plant.* ad t. 1927 (1890); Schneider, *Laubholzkunde*, ii. 387 (1909); V. Engler, *Monog. Gatt. Tilia*, 114 (1909).

Tilia pendula, V. Engler, ex Schneider, *Laubholzkunde*, ii. 387 (1909), and *Monog. Gatt. Tilia*, 113 (1909).

Tilia mandshurica, Szyszylowicz, in Hooker, *Icon. Plant.* ad t. 1927 (1890) (not Ruprecht and Maximowicz).

A tree, attaining in western China about 50 ft. in height. Young branchlets glabrous. Leaves variable in size, usually longer than broad, averaging 3 to 4 in. in length and $2\frac{1}{2}$ to $3\frac{1}{2}$ in. in breadth, orbicular-ovate, cordate at the base, cuspidate at the apex; margin regularly serrate, with shallow sinuses between the crenate teeth, which are very short and end in cartilaginous points; upper surface dark green, glabrous; lower surface covered with a dense white thin tomentum, without axil-tufts; petiole glabrous, one-half to three-fourths the length of the blade.

Cymes usually much longer than the leaves, each with about twenty flowers, which are similar to those of *T. tomentosa*, but are smaller in size and on short thickened pedicels. Fruit globose, grey tomentose and tuberculate on the surface, thick-shelled, apiculate, $\frac{1}{8}$ in. in diameter.

This species, which promises to be a beautiful ornamental tree, is readily distinguished from the other limes with a pure white under surface to the leaves, by the glabrous branchlets and petioles, and the crenately serrate orbicular leaves.

This species is a native of central China, where it was discovered by me in 1888, in the mountains north of the Yangtze, in the Fang and Wushan districts of Hupeh. *T. Oliveri* was founded by Szyszylowicz on a branch (Henry, No. 7089) from a small shrubby tree, growing in a sunny exposure on high cliffs, and bearing in consequence small leaves, averaging 2 in. in length. Another specimen (Henry, No. 7452 B), gathered by me at no great distance, but in a shaded valley, bore leaves averaging $3\frac{1}{2}$ in. in length, and was identified by Szyszylowicz with *T. mandshurica*, which is a native of northern China. This specimen has been made the type of a new species, *T. pendula*, V. Engler. A third specimen, collected since by Wilson (No. 2274), with leaves intermediate in size, is considered by Schneider to be *T. pendula*, but by Engler to be *T. Oliveri*. A careful examination of the whole material shows that all the specimens belong to one species.

T. Oliveri was introduced by Wilson, who sent seed from central China in 1900. It is now growing vigorously at Coombe Wood, and a small specimen is thriving at Kew. (A. H.)

TILIA MANDSHURICA

Tilia mandshurica, Ruprecht et Maximowicz, in *Bull. Acad. St. Pétersb.* xv. 124 (1856); Maximowicz, *Prim. Fl. Amur.* 62 (1859), and in *Mél. Biol.* x. 586 (1880); Baker and Moore, in *Journ. Linn. Soc. (Bot.)* xvii. 380 (1879); Franchet, *Pl. David.* i. 60 (1884); Forbes and Hemsley, in *Journ. Linn. Soc. (Bot.)* xxiii. 94 (1886); Komarov, in *Act. Hort. Petrop.* xxv. 28 (1907).

Tilia pekinensis, Ruprecht, in *Bull. Acad. St. Pétersb.* xv. 125 (1856), and in Maximowicz, *Prim. Fl. Amur.* 469 (1859); Bayer, in *Verh. Zool. Bot. Ges. Wien*, xii. 49 (1862).

A tree, attaining in Manchuria about 60 ft. in height and 10 ft. in girth. Young branchlets and buds covered with brownish tomentum. Leaves, 4 to 5 in. in breadth and length, orbicular-ovate, usually cordate at the base, cuspidate at the apex; margin, often with one or two lobes, coarsely serrate, the teeth ending in long awn-like points; upper surface with a scattered stellate pubescence, which forms dense tufts at the base of the blade; lower surface densely covered with whitish stellate tomentum, but without axil-tufts; petiole half the length of the blade, stout, brown tomentose.

Flowers similar to those of *T. tomentosa*, but with bracts, pedicels, and sepals more densely covered with a brownish tomentum. Fruit globose, tomentose, and slightly warty, either without ribs or with five indistinct ribs towards the base.

This species is closely allied to *T. tomentosa*; but has larger leaves, with long-pointed serrations and different fruit. Young trees have usually lobed leaves, as is often the case in other species; and *T. pekinensis*,¹ founded on this character, cannot be retained even as a distinct variety.

Tilia mandshurica is widely spread throughout the whole of Manchuria, and also occurs in Korea, where it was found on the Diamond Mountains by Père Faurie. It is not uncommon in the mountains west and north of Peking. It occurs scattered or in groups throughout the broad-leaved forest of these regions. It is known to the Chinese, like all the other species of lime, as the *tuan* tree; and the bark is used for making ropes and sandals.

It was probably introduced by Maximowicz into the St. Petersburg botanic garden; but is extremely rare in cultivation, the only specimen which I have seen being a small tree at Kew, which was procured from Booth of Hamburg in 1871. As it comes into leaf very early in the spring, it is often cut by frost, and is not in a thriving condition.

(A. H.)

¹ Var. *pekinensis*, Engler, ex Schneider, *Laubholzkunde*, ii. 384 (1909).

TILIA MAXIMOWICZIANA

Tilia Maximowicziana, Shirasawa, in *Bull. Coll. Agric. Univ. Tokyo*, iv. 158, t. xviii (1900), and *Icon. Ess. Forest. Japon.* ii. t. 50 (1908); Schneider, *Laubholzkunde*, ii. 385 (1909).

Tilia Miqueliana, Sargent, in *Garden and Forest*, vi. 111, fig. 19 (1893), and *Forest Flora of Japan*, 19, t. 8 (1894) (not Maximowicz).

Tilia Miyabei, Jack,¹ in *Mitt. Deut. Dend. Ges.*, 1909, p. 285.

A tree, attaining in Japan 100 ft. in height and 10 ft. in girth. Young branchlets densely covered with a greyish brown tomentum. Leaves usually large,² about 5 in. in breadth and length, cordate at the base, cuspidate at the apex; margin ciliate, coarsely and regularly serrate, the serrations ending in blunt cartilaginous points; upper surface dark green, with scattered stellate tomentum on the surface between the nerves, and dense tomentum on the nerves, especially at the base of the blade; under surface greyish, densely covered with stellate tomentum, and with conspicuous brownish axil-tufts at the junctions of the nerves; petiole stout, less than half the length of the blade, covered with greyish brown tomentum. Buds covered with greyish or rusty brown tomentum.

Flowers, ten to eighteen in each pendulous tomentose cyme; bract shortly stalked, strongly veined and tomentose on both surfaces, the tomentum brown and very dense on the midrib; sepals lanceolate, acuminate, pubescent on both surfaces; petals keeled, glabrous; staminodes five, keeled, toothed at the apex, as long as but narrower than the petals; stamens sixty-five to seventy-five, united in five bundles, shorter than the petals, each half of the anther on a short stalk; ovary pubescent, ovoid; style glabrous. Fruit globose, about $\frac{1}{3}$ in. in diameter, with a thick woody grey pubescent five-ribbed shell.

This species is a native of Japan, ranging from central Hondo (lat. 36°) northwards to Hokkaido. In Hondo, according to Shirasawa,³ who has observed it in the provinces of Kotsuke, Rikuchu, and Mutsu, it grows at altitudes of 800 to 1600 ft., in deep valleys, in mixed woods with *Alnus tinctoria*, *Populus Sieboldii*, and *Quercus grosseserrata*. It appears to be more common in Hokkaido, where it was seen by Elwes at Sapporo and Asahigawa, in virgin forest at 500 to 750 ft. above sea-level, where it attains about 100 ft. in height and forms a wide-spreading tree, with a stem 10 ft. in girth.⁴ Shirasawa states that its wood is of little use except for firewood; but the bark, after steeping, is plaited by the Ainos into coarse cloth and mats.

There is a small tree of this species at Grayswood, Haslemere, which the late Mr. Chambers procured from the Yokohama Nursery Co. in 1894. It has not suffered from frost, but is rather slow in growth. Elwes has raised plants at Colesborne from

¹ Jack proposes this name on account of the earlier use of *T. Maximowiczii*, Baker, in *Journ. Bot.* xxxvi. 319 (1898), an untenable name for another species. Cf. p. 1657, note 3, B.

² Those on coppice shoots, gathered by Elwes in Hokkaido, are 8 to 10 in. long.

³ Specimens collected by Shirasawa in different localities are now in the Kew Herbarium.

⁴ Sargent says it attains 100 ft. in height in Hokkaido, where it frequently grows in company with *T. japonica*, which is much smaller in size. Cf. p. 1657, note 3, C.

seed sent by Shirasawa in the spring of 1905. These are 3 to 5 ft. in height, and differ from adult trees in having only traces of stellate pubescence on the leaves and branchlets.

(A. H.)

TILIA MIQUELIANA

Tilia Miqueliana,¹ Maximowicz, in *Bull. Acad. Imp. Sc. St. Petersb.* xxvi. 434 (1877), and *Mél. Biol.* x. 587 (1880); Shirasawa, *Icon. Ess. Forest. Japon.* i. text 116, t. 72, figs. 11-24 (1900), and in *Bull. Coll. Agric. Univ. Tokyo*, iv. 160 (1900); Schneider, *Laubholzkunde*, ii. 385 (1909); V. Engler, *Monog. Gatt. Tilia*, 111 (1909).

Tilia mandshurica, Miquel, *Procl.* 206 (1867) (not Ruprecht and Maximowicz); Franchet et Savatier, *Enum. Pl. Jap.* i. 67 (1875).

Tilia Kinashii, Lévillé and Vaniot, in *Bull. Soc. Bot. France*, li. 422 (1904).

Tilia Franchetiana, Schneider, in Fedde, *Repert.* vii. 201 (1909), and *Laubholzkunde*, ii. 386 (1909).

A tree, attaining in Japan about 40 ft. in height. Bark on young trees grey, smooth; on old trunks fissured longitudinally. Young branchlets with a minute grey stellate pubescence, very variable in amount. Leaves (Plate 407, Fig. 9) extremely variable in shape, but usually much longer than broad, averaging 3 to 4 in. in length and 2 to 2½ in. broad, ovate or deltoid; cordate at the base; acute, slightly acuminate or rounded, but rarely cuspidate at the apex; often lobulate and coarsely, irregularly, and sharply serrate, the teeth ending in incurved short callous points; upper surface shining green, with scattered slight pubescence, mostly on the nerves and at the base of the midrib; lower surface covered with a grey stellate tomentum, without axil-tufts; petiole short, less than half the length of the blade, with minute stellate pubescence. Buds grey tomentose.

Flowers, ten to twenty-two in a cyme; bract, peduncle, pedicels, and bracteoles tomentose; sepals ovate, acute, tomentose on both surfaces, shorter than the narrow obovate petals; stamens sixty to seventy-five, united in five clusters; staminodes more slender and shorter than the petals; ovary and base of the style covered with pale hairs. Fruit nearly globose, five-ribbed at the base, grey tomentose and warty.

This species is unknown in the wild state, and only occurs in Japan as a planted tree, most often seen in the courts of Buddhist temples, where it is regarded as sacred. It is reported by tradition to have been introduced from China by a Buddhist priest about the year 1190 A.D.; but it has not yet been found anywhere in that country.² Its extreme variability points to a hybrid origin. The species was founded by Maximowicz on two specimens, which he regarded as two forms: one with ovate-orbicular oblique leaves, long slender cymes, and broad bracts about 4 in. in length; the other with remarkably deltoid nearly symmetrical leaves, short cymes, and narrow bracts about 2½ in. long. It is impossible, however, following the opinions of Schneider and V. Engler, to retain those two forms as two distinct

¹ The tree described and figured under this name by Sargent, in *Garden and Forest*, vi. 111, fig. 19 (1893), and *Forest Flora Japan*, 19, t. 8 (1894), is *T. Maximowicziana*.

² *Tilia Miqueliana*, var. *chinensis*, Szyszlowicz, in Hooker, *Icon. Plant.* ad t. 1927 (1890), collected by me in Hupeh in central China, is referred by V. Engler, *Monog. Gatt. Tilia*, 130 (1909), to *T. chinensis*, Maximowicz, in *Act. Hort. Petrop.* xi. 83 (1890), a plant collected in Kansu. The Kansu and Hupeh plants do not seem to be quite identical; but neither can be considered the same as the Japanese *T. Miqueliana*. They have not been introduced into cultivation.

varieties or species; for the trees cultivated in Europe show great variation, no two specimens being alike, and both deltoid and ovate leaves are occasionally present on the same branch. Recent specimens from Japan, collected by Shirasawa, cannot be exactly matched with either of Maximowicz's specimens.

This species has lately been introduced into England, and the only specimens which we have seen are young trees at Kew, Aldenham, Casewick, and Glasnevin. The tree at Kew, obtained from Hesse's nursery in 1900, is now about 12 ft. high and appears to be thriving. It is also cultivated by Simon-Louis at Plantières, Metz.

(A. H.)

TILIA AMERICANA, AMERICAN LIME, BASS-WOOD

Tilia americana, Linnæus, *Sp. Pl.* 514 (1753); Loudon, *Arb. et Frut. Brit.* i. 373 (1838); Sargent, *Silva N. Amer.* i. 52, tt. 24, 25 (1891), and *Trees N. Amer.* 671 (1905).

Tilia caroliniana, Miller, *Dict.* ed. 8, No. 4 (1768).

Tilia latifolia, Salisbury, *Prod.* 367 (1796).

Tilia nigra, Borkhausen, *Handb. Forstbot.* ii. 1219 (1800).

Tilia glabra, Ventenat, *Mém. Acad. Sc. Paris*, iv. 9 (1802).

Tilia canadensis, Michaux, *Fl. Bor. Am.* i. 306 (1803).

Tilia stenopetala, Rafinesque, *Fl. Ludovic.* 92 (1817).

A tree, occasionally attaining in America 130 ft. in height and 12 ft. in girth. Bark deeply fissured, with ridges broken on the surface into small thin scales. Young branchlets green, glabrous. Leaves (Plate 407, Fig. 1) broadly oval, averaging 5 in. to 6 in. long and 3½ in. to 4½ in. broad, turning yellow in autumn, cordate or truncate at the base, cuspidate at the apex; margin ciliate, with coarse triangular serrations, ending in long callous points; upper surface dull dark green, glabrous; lower surface¹ light green, glabrous, except for minute pubescent tufts in the axils at the junctions of the midrib, primary, and secondary nerves, but absent at the base of the blade; petiole glabrous, 1½ in. to 2 in. long.

Cymes pendulous, many-flowered; bract stalked, broad and rounded at the apex, glabrous except for slight stellate pubescence on the midrib beneath; peduncle glabrous; pedicels slightly pubescent; sepals ovate, acuminate, densely hairy within, slightly pubescent without, shorter than the lanceolate petals; staminodes present. Fruit globose or ovoid, without ribs, covered with thick rufous tomentum; shell thick.

The American lime is readily distinguished from the other species with glabrous branchlets and leaves, by the minuteness of the axil-tufts, which are, moreover, not present at the base of the leaf. In winter, the branchlets are shining, glabrous; buds with three external scales, glabrous except for tufted cilia at their tips.

The leaves are remarkable for their variation in size, an interesting account of which is given by Penhallow.² In Canada, some trees have tolerably uniform leaves, about 3½ in. in diameter. Other trees have in addition many leaves 4½ in. across. On vigorous shoots, especially on epicormic branches, the leaves are often 8 in.

¹ In *T. americana* the midrib and principal nerves are remarkably yellow, and this character is also seen in its reputed hybrids, *T. Molthei*, *T. spectabilis*, and *T. Michauxii*.

² *Canadian Record of Science*, ix. 291 (1905).

wide. This lime coppices freely, and on shoots so produced the foliage is always enormous, reaching a maximum of 10 in. in diameter. This variation is due in part to the amount of nutrition available, which is greatest on coppice shoots, owing to their extensive root system; but the size of the leaves is also much influenced by shade. Trees with large leaves are often known in gardens as *var. mississippiensis*, but this name is erroneous, as there is no reason to suppose that such trees are limited to the Mississippi basin.

Tilia americana, since its introduction into Europe, has given rise to hybrids¹ with other species, especially with *T. tomentosa*, which is probably the other parent in the following:—

1. *Tilia Moltkei*, Schneider, *Laubholzkunde*, ii. 381 (1909).

A tree with leaves similar in shape and serrations to those of *T. americana*, but larger, 6 in. to 7 in. long and 5 in. to 6 in. wide, and differing in the lower surface, which is pale or greyish green, more or less covered with scattered stellate pubescence, without axil-tufts, but with occasional long hairs on the midrib. Buds, petioles, and branchlets glabrous, and identical with those of *T. americana*.

This tree, which is remarkable for its vigorous growth and handsome foliage, originated² in Späth's nursery at Berlin, and is named after the famous general, who planted a young tree in front of Herr Späth's house in 1888. Specimens are growing at Kew and Aldenham.

2. *Tilia spectabilis*, Dippel, *Laubholzkunde*, iii. 73 (1893).

A tree resembling *T. Moltkei* in the shape, colour, and serration of the leaves, but differing as follows:—Young branchlets apparently glabrous, but showing traces of stellate pubescence. Buds pubescent in their upper half. Leaves (Plate 407, Fig. 11), variable in size, 4 in. to 6 in. long and 3 in. to 5 in. wide; under surface with scattered stellate pubescence, very variable in amount,³ and with long hairs on the principal nerves as well as on the midrib, but without axil-tufts; petiole glabrous or with a few scattered hairs. The flowers are intermediate in character between those of *T. americana* and *T. tomentosa*, and open at Kew three weeks earlier than those of the latter species. The stellate pubescence on the bract, peduncle and pedicels is like that of *T. tomentosa*, but less in amount. The shape of the bract and the size of the flowers are similar to *T. americana*.

This tree has probably been long in cultivation, but I have not been able to trace its origin.⁴ It is often planted in botanic gardens, as at Kew, where there are several specimens, one nearly 40 ft. in height.⁵ At Cambridge a tree, about 35 ft. by 3½ ft. in 1907, has long been labelled *T. heterophylla*; and reputed trees of the latter species usually turn out to be either *T. spectabilis* or *T. Michauxii*.

¹ In America it probably forms hybrids with *T. heterophylla*. See *T. Michauxii*, p. 1689.

² It is mentioned as a new plant, *Tilia americana Moltkei*, in Späth's *Catalogue*, No. 57, p. 71 (1883).

³ In cases where the stellate pubescence on the under surface of the leaves becomes dense and greyish, trees of *T. spectabilis* are often confused with *T. tomentosa* and *T. Michauxii*. They are readily distinguishable from the latter by the absence of axil-tufts, and from the former by the glabrous branchlets. The long hairs on the midrib and nerves seem to be peculiar to *T. spectabilis* and *T. Moltkei*.

⁴ Dippel found it in 1893 in Froebel's nursery under the name *T. alba spectabilis*, and in the Zoeschen arboretum as *T. Blechiana*; but it must have originated much earlier. Cf. *ante*, p. 1678, note 5.

⁵ This tree has been labelled *T. argentea*, and resembles *T. tomentosa* in habit.

3. *Tilia viridis*, Simonkai, in *Math. Term. Koezl.* xxii. 320 (1888).

In addition to the usual form of *T. spectabilis* described above, there appears to be another hybrid of the same parentage, which is represented at Kew by a tree about 25 ft. high, obtained under the name *T. spectabilis* from Späth in 1899. It is closer to *T. tomentosa*, as the buds, branchlets, and upper surface of the leaves are covered with a scattered stellate pubescence, which is denser on the under surface of the leaves than in ordinary *T. spectabilis*. This tree closely resembles, if it is not identical with, a specimen¹ taken from a tree cultivated at Baden in 1835, which was identified by A. Braun with *T. argentea*, var. *virescens*, Spach, in *Ann. Sci. Nat.* ii. 344 (1834). Spach's description was based on a tree in the Trianon, which was said to have been raised from seeds of *T. tomentosa*; and if this account is correct, this tree would appear to have been the first cross observed between *T. tomentosa* and *T. americana*.

DISTRIBUTION

Tilia americana is widely spread, occurring in Canada from the valley of the Assiniboine River and the southern shores of Lake Winnipeg eastward to northern New Brunswick, and extending in the United States southwards to Virginia and along the Appalachian mountains to Georgia and Alabama, and ranging westward to Dakota, Nebraska, Kansas, Indian Territory, and eastern Texas. It grows in rich often moist soil, and formerly occurred as pure forest.² It attains its largest size in the alluvial lands of the lower Ohio river, where Ridgway records a tree 135 ft. in height and 17½ ft. in girth.³

According to Loudon, the American lime was cultivated⁴ by Miller in 1752, but had not been extensively distributed. It is very rare at the present time in cultivation, and the tree at White Knights, mentioned by Loudon as 60 ft. in height, is no longer living. The only specimens which we have seen in England are small trees at Kew, Eastnor Castle, and Liphook. (A. H.)

TIMBER

The wood of the American limes is very similar in character to that of the European species, and according to Sargent is largely used in the United States under the name of whitewood for the manufacture of cheap furniture, carriage panels, and woodenware. He states that, though one of the woods most largely used for making pulp, the quick decomposition of the sap makes it unfit for white paper. It is imported to some extent into Europe under the name of basswood, and has

¹ This specimen is considered by Bayer, in *Verhand. Zool. Bot. Ges. Wien*, xii. 50 (1862), to be a hybrid between *T. tomentosa* and *T. americana*, which he calls *T. argentea-nigra*. V. Engler (*op. cit.* 152) considers it to be *T. cordata* × *T. tomentosa*, but it shows no trace of *T. cordata* parentage.

² In *U.S. Forest Service, Circular 63* (1907), which gives an account of this species, it is said to do well when planted in pure stands, and to be the most prolific of American trees in shoots from the stumps.

³ Sargent, *Bull. Pop. Inform.* No. 30 (1912), and in *Gard. Chron.* lii. 87 (1912), says that it shows its greatest beauty in the forests of New Brunswick, northern New England, and the valley of the St. Lawrence. The leaves of planted trees in eastern Massachusetts are, especially in dry summers, made brown by the red spider, which, however, is easily controlled by spraying.

⁴ In the *London Catalogue of Trees*, 1730, p. 81, the Carolina lime tree is mentioned as "*Tilia*, with leaf more longly mucronate. Seeds sent from Carolina by Catesby in 1726, hardy, and may be propagated as other limes."

partially displaced native limewood in the pianoforte trade on account of its cheapness. Owing to the facility with which large thin sheets can be turned off the log by rotating it against a knife-edge, it is coming into use for three-ply boards, a manufacture which, though only recently invented, is likely to grow rapidly for many purposes. (H. J. E.)

TILIA HETEROPHYLLA

Tilia heterophylla, Ventenat, in *Anal. Hist. Nat. Madrid*, ii. 68 (1800), and *Mém. Acad. Sc. Paris*, iv. 16, pl. 5 (1803); Sargent, *Silva N. Amer.* i. 57, t. 27 (1891), and *Trees N. Amer.* 674 (1905).

Tilia americana, Linnæus, var. *heterophylla*, Loudon, *Arb. et Frut. Brit.* i. 375 (1838).

A tree, attaining in America 60 ft. in height and 12 ft. in girth. Young branchlets glabrous. Leaves similar to those of *T. Michauxii* in size and shape, but differing in being covered beneath with a silvery white tomentum, without axil-tufts, and having finer serrations with shorter straighter points. The flowers appear to differ in the bract¹ pubescent on both surfaces, and the stellate-pubescent peduncle and pedicels. There appears to be no constant difference in the fruit.

Both this species and *T. Michauxii* are readily distinguished from the other white limes by the glabrous branchlets, and the different shape of the leaves, which are usually very oblique at the base, and always longer than broad. *T. pubescens*, Aiton, the white lime of the Gulf States, is not in cultivation, and probably would not live in our climate. It has pubescent branchlets.

T. heterophylla, according to Sargent, is found on rich wooded slopes or near the banks of streams; and ranges from Ithaca, New York, southwards along the Alleghany mountains to northern Alabama, and westward to middle Tennessee, Kentucky, southern Indiana, and Illinois. It is most abundant and of its largest size on the high mountains of North Carolina and Tennessee.

Typical *T. heterophylla* is described by most authors as having the leaves covered beneath with a silvery white tomentum; but Sargent informs me in a letter that Rehder found trees on the mountains of West Virginia, with leaves nearly glabrous beneath,² which he considered to be undoubtedly *T. heterophylla*. Such trees are probably hybrids with *T. americana*; and a further study of the American limes is necessary, as the relationship of *T. Michauxii* and the glabrous forms of West Virginia with *T. heterophylla* in its typical form, is very obscure.

T. heterophylla was introduced, according to Loudon, in 1811; but he had seen no specimens except small trees in the Chiswick Garden; and these may have been *T. Michauxii*, which he did not distinguish as a separate species. Most of the trees which occur in cultivation under this name are either *T. Michauxii* or *T. spectabilis*; and we have seen no living specimens in England which can be identified with *T. heterophylla*. (A. H.)

¹ The bract is said by Schneider to be stalked in *T. heterophylla*, and sessile in *T. Michauxii*; but native specimens show it to be variable in both species.

² *T. eburnea*, Ashe, in *Bot. Gaz.* xxxiii. 231 (1902), usually considered to be a peculiar variety of *T. heterophylla* in the Carolinas and Georgia, is said to lose its pubescence in autumn occasionally.

TILIA MICHAUXII

Tilia Michauxii, Nuttall, *N. Amer. Sylva*, i. 108 (1865); Sargent, *Trees N. Amer.* 673 (1905); Schneider, *Laubholzkunde*, ii. 387 (1909).

Tilia alba, Michaux, *Hist. Arb. Amer. Sept.* iii. 315, t. 2 (1813), and Nuttall, *N. Amer. Sylva*, iii. 84, t. 132 (1865). (Not Aiton, *Hort. Kew.*)

A tree, attaining in America 80 ft. in height and 9 ft. in girth. Young branchlets and buds glabrous. Leaves (Plate 407, Fig. 5) very variable in size, averaging 1/4 to 5 in. in length, and 3 to 4 in. in breadth, always much longer than broad, ovate, very oblique and cordate or truncate at the base, cuspidate at the apex; margin with large triangular serrations ending in long incurved points; upper surface dark green, glabrescent; lower surface covered with a scattered or dense greyish tomentum, very variable in amount, and with conspicuous axil-tufts at the junctions of the midrib, primary and secondary nerves; petiole stout, short, glabrescent.

Cymes, ten- to twenty-flowered; bract tomentose above, glabrous below; peduncle glabrous; pedicels slightly pubescent; sepals lanceolate, pubescent on both surfaces; petals lanceolate, acute, twice as long as the sepals; staminodes present. Fruit globose, marked with five furrows and minutely tuberculate on the grey slightly tomentose surface.

This species was first described and figured by Michaux, who, however, considered it to be the same as the European white lime. Nuttall² based his name *T. Michauxii* on Michaux's description and figure. It appears to have much the same distribution as *T. heterophylla*, but is imperfectly known,³ and in all probability is a hybrid of that species with *T. americana*, resembling the latter in the serrations, axil-tufts, and yellow midribs and nerves of the leaves. The characters of the flowers are intermediate between the two species mentioned. The extreme variability in the amount of the tomentum on the leaves points to a hybrid origin.

It is not very common in cultivation in England; but there are two fine trees at Beauport, which are both grafted; one of these measures 84 ft. by 9 ft. 1 in., and the other is nearly as large. There are also small trees at Kew and Tortworth. There is an ill-shaped tree at Castlemartyr in Ireland, which Elwes found in 1908 to be about 40 ft. by 3 1/2 ft.; some of its leaves were no less than 12 in. long and 9 in. wide. It is cultivated under the name *T. americana rubra* in the Heatherside nursery; and appears to be known in continental nurseries under various names, as *T. americana pubescens*, *T. gigantea*, *T. macrophylla*, *T. hybrida superba*, etc.

(A. H.)

¹ In cultivated trees in Europe the leaves are usually larger, averaging 7 in. long and 5 to 6 in. broad; but this may be a juvenile character.

² Nuttall says: "The *Tilia alba* of Michaux, not being the *T. alba* of Kitaibel and Aiton, it is necessary to change the name, and we propose to call it *T. Michauxii*."

³ I am unable to follow V. Engler's view, that all the trees in the wild state in America, supposed to be *T. Michauxii* by Sargent and others, are simply *T. heterophylla*. Engler restricts the hybrid *T. americana* × *T. heterophylla* to trees found in cultivation in Europe. Wild *T. Michauxii* in America, judging from a considerable number of specimens which I have seen, is readily distinguishable from the true *T. heterophylla*; and I see no reason for supposing that the trees referred by me to *T. Michauxii*, which are in cultivation in Europe, are not originally from America. A small tree at Kew, received from Baltimore, U.S.A., is undoubtedly *T. Michauxii*.

TRACHYCARPUS

Trachycarpus, H. Wendland, ex Gay, in *Bull. Soc. Bot. France*, viii. 429 (1861); Bentham et Hooker, *Gen. Pl.* iii. 929 (1883); Beccari, in Martelli, *Webbia*, i. 41-73 (1905).
Chamærops, Martius, *Hist. Nat. Palm.* iii. 247 (1836-1850) (in part).

TALL unarmed trees, belonging to the order Palmaceæ, with flabellate leaves, without a rachis, deeply divided into numerous plicate segments, which are narrow, entire in margin, and bifid at the apex.

Flowers monœcious; spadices numerous, paniced, sessile between the leaves, and embraced by sheathing coriaceous spathes; individual flowers small; sepals three, ovate; petals three, broadly ovate, valvate; stamens six, with free filaments and short dorsifixed anthers, rudimentary in female flowers; ovary of three carpels, connate at the base, represented in the male flowers by three small subulate processes; stigmas three, recurved; ovules basilar, erect. Fruits, one to three, globose or oblong, with a terminal style; containing one erect seed, which is grooved on the ventral side, and has a small hilum at the base.

Three species¹ of *Trachycarpus* are known, natives of the Himalayas, Assam, Burma, and China.

TRACHYCARPUS FORTUNEI, CHUSAN PALM

Trachycarpus Fortunei, H. Wendland, in *Bull. Soc. Bot. France*, viii. 429 (1861); Masters, in *Gard. Chron.* xxiv. 304, fig. 65 (1885).
Trachycarpus excelsa, H. Wendland, in *Bull. Soc. Bot. France*, viii. 429 (1861); Planchon, in *Flore des Serres*, xxii. 207, t. 2368 (1877); Beccari and J. D. Hooker, in J. D. Hooker, *Flora Brit. India*, vi. 436 (1892); Diels, in Engler, *Bot. Jahrb.* xxix. 233 (1900); Wright, in *Journ. Linn. Soc. (Bot.)* xxxvi. 168 (1903); Masters, in *Gard. Chron.* xxxv. 312, Supply. Illust. (1904); Beccari, in Martelli, *Webbia*, i. 41 (1905).
Chamærops excelsa, Martius, *Hist. Nat. Palm.* iii. 251, t. 125, figs. 2, 3 (1836-1850) (not Thunberg²); Miquel, *Anal. Bot. Ind.* ii. 21 (1851); Gay, in *Bull. Soc. Bot. France*, viii. 410 (1861); Houlet, in *Rev. Hort.* xl. 370, coloured plate (1868).
Chamærops Fortunei, W. J. Hooker, in *Bot. Mag.* t. 5221 (excl. figs. 6, 7) (1860).

A palm, attaining 30 to 50 ft. in height, with the trunk annulately scarred and clothed throughout with old leaf-sheaths. Leaves: lamina sub-orbicular or fan-

¹ The two species, not described by us, as they are scarcely hardy in cultivation, are: *T. Martiana*, Wendland, widely spread in the central and western Himalayas, Assam, and Burma; and *T. Takil*, Beccari, in *Webbia*, 52 (1905), which is a peculiar species occurring in Kumaon. The latter species is cultivated by Prof. Beccari in his garden at Florence. Bean, in *Kew Bull.* 1912, p. 291, quotes Beccari's description and gives a figure of this tree, which is readily distinguishable from *T. Fortunei* by its different habit and by the closer and neater fibre of the trunk.

² *Chamærops excelsa*, Thunberg, *Fl. Jap.* 130 (1784), is plainly from the description another palm, *Rhapis flabelliformis*, Aiton, *Hort. Kew.* iii. 473 (1789). Cf. Sims, *Bot. Mag.* t. 1371 (1811).

shaped, averaging 1½ ft. in length and breadth, deeply cut into numerous linear plicate segments, which are ½ to 1 in. broad, entire in margin, and bifid at the apex; petiole about 1½ ft. long, trigonous or nearly semicylindric in section, convex above, and flat beneath, with the two margins irregularly serrate or dentate towards the base; lower sheathing part furfuraceous, and separating into a network of brown fibres.

Staminate panicles¹ broad, thick, and obtuse, enveloped in a strong stout brownish spathe, at first erect, soon pendent, with arched ramifications; flowers small, numerous, close together, deep yellow-orange. Pistillate inflorescence smaller, less thick than the staminate one, clothed in an acuminate erect spathe, with distant spreading slender ramifications; flowers numerous, not close together, small, pale yellow or greenish. Drupe reniform, hollowed on one side.

This species is variable in habit, the leaves in some individuals being straight and stiff, whilst in others they droop at the tips; and the petioles show a varying amount of serration. There are no grounds, however, for supposing that there are two forms, corresponding to a supposed Chinese and Japanese origin. Plants which are sold as distinct, under the names *Chamærops excelsa* and *C. Fortunei*, are usually imported seedlings, which have been raised in the Riviera from the same batch of seed.

1. Var. *gracilis*, Carrière, in *Rev. Hort.* xlvii. 220 (1875). Petioles, longer and more slender than in the type, abruptly inflexed; laminae more deeply divided with narrower segments. The variety was described from a plant in the Jardin des Plantes at Paris, which was obtained from Thibaut and Keteleer's nursery in 1862.

2. Var. *surculosa*, Henry (*var. nova*). Leaves smaller and stiffer than in the type. Dwarf in habit, and freely reproducing itself by suckers like *Chamærops humilis* of the Mediterranean region. This peculiar variety, which was obtained a few years ago from Japan by Sir E. G. Loder, is possibly a distinct species. It thrives at Leonardslee, where it has produced flowers; but no fruit has yet been noticed.

T. Fortunei is a native of the central provinces of China, where it is certainly wild on the hills and lower slopes of the mountains in Szechwan, Hupeh, Kiangsu, and Chekiang. It is everywhere much cultivated, so that it is impossible to define its original distribution in the wild state. It is commonly planted around Shanghai, where it lives unprotected through the severest winters.² It is also cultivated on the island of Chusan, whence the name given to it of Chusan palm by Fortune,³ who saw it growing wild in great perfection near Yen Chow and on the Sung Lo mountain in Chekiang. It is known to the Chinese as *Tsung*, and is of great economic importance, owing to the large quantity of strong and useful fibre found on the stem at the bases of the leaf-stalks. This fibre, which is similar to the coir

¹ Inflorescences bearing both staminate and pistillate flowers have been noticed by Beccari. The germination of this species is described by Gatin, in *Ann. Sc. Nat. (Bot.)* iii. figs. 28, 29 (1906).

² It is unknown in North China, being killed when planted out at Chefoo and Tientsin. Cf. Gay, in *Bull. Soc. Bot. France*, viii. 412 (1861).

³ Cf. Fortune, *Wanderings in China*, 53, 54 (1847); *Tea Countries*, 58, 88, 117, 318 (1852); *Residence among the Chinese*, 5, 145, 189 (1857); and in *Gard. Chron.* 1850, p. 757, and 1860, p. 170.

obtained from the cocoa-nut, is used for making ropes and cables, which are very durable under water; in the manufacture of hats and rain-cloaks¹ (called *so-i*), which are used by the peasants in wet weather; and in making brushes and mattresses.

This palm is largely cultivated in southern and central Japan, where it is known as *Shuro*, but it does not seem to be a true native,² though it is naturalised in some places.³ It is recorded from Tamsui and Bankinsing in Formosa; but is probably only planted.⁴

This palm was first introduced by Siebold,⁵ who sent seeds from Nagasaki in Japan to Leyden in 1830. Of the plants which were raised, one was sent to Kew in 1837, where it was long an inmate of the Palm House; but it died some years ago. The Chinese plant was introduced by Fortune,⁶ who sent six living plants to Kew in 1849, two of which are still flourishing in the Temperate House, and are about 40 ft. and 50 ft. in height respectively; while two, which were planted out-of-doors, have remained stunted in growth and are only about 10 ft. high. Another of these plants, which was sent to Osborne in 1849, was planted out in front of the royal residence, and had attained⁷ 14½ ft. high in 1881. It is now about 21 ft. high and 2 ft. 4 in. in girth at a foot from the ground. (A. H.)

The Chusan palm is perfectly hardy⁸ in our climate, but grows slowly in the neighbourhood of London and to the northwards. It flourishes best in the south-west of England and in the south of Ireland, where it attains a height of 25 to 30 ft., and ripens seeds regularly. In the grounds of Tregothnan, I found in 1905 self-sown seedlings in the grass, and transferred some of them to my own garden at Colesborne, one of which has borne a temperature close to zero without injury. On the lawn at Williamstrip Park, Gloucestershire, an old specimen has flowered on several occasions. At Duncan House, Torquay, there is a group of about six trees, 14 to 25 ft. high in 1903, around which there are hundreds of young plants, which have come from their seed.⁹

Plate 375 shows a tree planted by the Rev. Hon. T. Boscawen at Lamorran in Cornwall, which was about 25 ft. high in 1905. At Riverhill, near Sevenoaks, the seat of J. T. Rogers, Esq., I saw one of the original seedlings introduced by Fortune, which was 27 ft. by 2 ft. 6 in. in 1911. At Powis Castle, I measured one in 1906, 25 ft. high, girthing 1 ft. 10 in. at the ground, but 3 ft. 4 in. at five feet up.

At Heckfield Place, near Winchfield, Hants, there are two good specimens¹⁰ of different sexes, which were planted in 1869. They measured in January 1912, 17½ feet and 15½ feet respectively.

¹ A rain-cloak and hat, brushes, cordage, and other articles made from this fibre, are displayed in the museum at Kew.

² Makino, in *Tokyo Bot. Mag.* xviii. 20 (1904), divides the species into two forms, var. *typica* and var. *Fortunei*; but in this he simply follows Wendland, and gives no distinguishing characters; moreover, he states of both these supposed forms, that they are planted and not native in Japan.

³ Cf. Franchet and Savatier, *Enum. Plant. Jap.* ii. 2 (1879).

⁴ Cf. Matsumura, *Index Plant. Jap.* ii. 168 (1905). Elwes saw it planted in many places in Formosa up to about 4000 ft. elevation; and the fibre is used for the same purposes as in China. ⁵ *Cat. Rais. Pl. Jap.* 1856, p. 7, note.

⁶ Fortune also obtained seed near Tsee-Kee, north-west of Ningpo, in 1853, from which plants were raised in England.

⁷ Cf. Smith, *Records of Kew Gardens*, 116 (1885).

⁸ Cf. *Gard. Chron.* 1860, pp. 170, 362, where it is stated that this palm suffered much but did not die in Northamptonshire in the severe winter of 1859-1860; while at Swansea, where the temperature fell to 10° Fahr., they were quite uninjured.

⁹ *Gard. Chron.* xxxiv. 329 (1903); one of these palms was figured in *Gard. Chron.* xxiv. 420, Supply Illust. (1898).

¹⁰ Cf. *Gard. Chron.* xv. 12, fig. 4 (1881), and xxiv. 216 (1885).

In Surrey, this palm can be grown very successfully in light dry sandy soil, provided the plants are placed in a sheltered position. In these conditions, they grow slowly, attaining about 10 ft. high in thirty years; but they flower regularly, and are very ornamental.¹ There is a fine specimen, 25 ft. high and 4 ft. in girth, at Joldwynds, near Dorking, the seat of Sir P. Bowman, Bart.

At Wisbech, Lord Peckover has a very old specimen, probably one of the original seedlings, which was 25 ft. high in 1912. A younger tree, planted about thirty-five years ago, is nearly 20 ft. high, and flowers more profusely than the older tree.

In Scotland² there is a good specimen at Ardchapel, Shandon, on Gare Loch in Dumbartonshire, which was planted in 1866 by the late Prof. Swan of St. Andrews. In 1905, it was 11 ft. high, with a girth of 3 ft. 8 in. at five feet from the ground. It has produced flowers regularly since 1881. There are small but thriving specimens in Arran, at Craigard, Lamlash; Whitefarland; and Cromla, Corrie.

In Ireland, it is slow in growth and of no great height in the open at Glasnevin. Two trees at Narrow Water, Co. Down, were 12 ft. high in 1903. It grows well at Mount Usher in Wicklow, where it ripens fruit; and is represented at Fota by several fine specimens, one of which is 25 ft. high.

The Chusan palm was introduced³ into France by seed sent from central China by M. de Montigny in 1851; and was first planted in Algeria in 1853. It exists in the climate of Paris, where it bore 16° Cent. below zero in 1870-1871; and it is hardier⁴ than *Chamærops humilis* at Montpellier, where the temperature occasionally falls to the same point. There are fine specimens⁵ in Brittany, notably one in the park of Porzantrez near Morlaix, which was planted in 1856, and had attained 27 ft. high in 1907. In Spain and Portugal there are fine specimens,⁶ one at Lisbon being 40 ft. high. (H. J. E.)

Brassaiopsis, Seemann, in *Journ. Bot.* ii. 290 (1864) (not Decaisne and Planchon).
Panax, sub-genus *Acanthopanax*, Decaisne and Planchon, in *Rev. Hort.* 1854, p. 105.

DECIDUOUS trees or shrubs, belonging to the order Araliaceæ. Branchlets with or without spines. Stipules inconspicuous or absent. Leaves either compound and three- to five-digitate or simple and palmately lobed.

Flowers small, in paniced or solitary umbels, polygamous or perfect, on pedicels that are not articulated; calyx-tube coherent with the ovary, limb dentate; petals five, rarely four, valvate in the bud; stamens as numerous as the petals and inserted with them on the margin of the disc, filaments filiform, anthers ovate or oblong; ovary usually two-celled, rarely five-celled; styles, two or five, more or less connate at the base, with the apex recurved and stigmatose internally. Fruit baccate, laterally compressed or globose, with a fleshy exocarp; nutlets two to five, crustaceous or cartilaginous, each containing one seed.

About eighteen species are known, natives of Eastern Asia, extending from Amurland and Manchuria, through Japan, Formosa, and China to the Himalayas. The following species is the only one attaining timber size.

ACANTHOPANAX RICINIFOLIUM

- Acanthopanax ricinifolium*, Seemann, in *Journ. Bot.* vi. 140 (1868), and *Revis. Heder.* 86 (1868); Franchet and Savatier, *Enum. Pl. Jap.* i. 193 (1875); Hance, in *Journ. Bot.* 1885, p. 323; Hemsley, in *Journ. Linn. Soc. (Bot.)* xxiii. 340 (1888); Sargent, in *Garden and Forest*, vi. 234, fig. 36 (1893), and *Forest Flora Japan*, 45, fig. 16 (1894); Shirasawa, *Icon. Ess. Forest. Japon.* ii. t. 56, figs. 11-24 (1908); Beissner, in *Mitt. Deut. Dend. Ges.* 1909, p. 289; Schneider, *Laubholzkunde*, ii. 429 (1909).

Kalopanax? *sp.*, Zabel, in *Mitt. Deut. Dend. Ges.* 1904, p. 63.
Brassaiopsis ricinifolia, Seemann, in *Journ. Bot.* ii. 291 (1864).

A tree, attaining in Yezo 80 to 90 ft. in height, and 10 ft. or more in girth. Bark very thick,¹ dark in colour, and deeply fissured. Branchlets stout, reddish brown, glabrous, armed with short stout spines, which are enlarged at the base and are often glaucous. Leaves sub-orbicular, but broader than long, averaging 6 to 10 in. in diameter, sub-cordate at the base, palmately five- or seven-nerved; on adult trees, divided to one-third of the length of the blade by acute sinuses into five ovate-triangular acuminate lobes, serrate in margin, with callous tips to the teeth; upper surface dark green, shining, glabrous; lower surface with slight whitish tomentum on the nerves, forming axil-tufts at their base, where they unite; petioles long and slender, more or less covered with scattered tomentum, especially near the base.

Flowers on long slender glabrous pedicels in many-flowered umbels, arranged in terminal compound panicles, which are sometimes 2 ft. in diameter; small, white in colour, appearing in August and September. Fruit black, globose.

1. Var. *Maximowiczii*, Schneider, *Laubholzkunde*, ii. 429 (1909).

Aralia Maximowiczii, Van Houtte, in *Flore des Serres*, xx. 39, t. 2067-2068 (1874).

This varietal name is applied for the sake of convenience to young trees in cultivation, which only show juvenile foliage. The leaves differ from those characteristic of adult trees, in being deeply lobed, with the sinuses extending more than two-thirds the length of the blade. It is impossible to say whether, as a result of being perhaps propagated by grafts from young seedlings, these trees will preserve the seedling foliage indefinitely, or will, when older, develop normal leaves. Seedlings occasionally show both kinds of foliage; and Siebold's original specimens also bear both shallow- and deeply-lobed leaves, with all intermediate stages.

This species is a native of China, Korea, Japan, Saghalien, and the Liu Kiu Islands. In China, it is widely spread in the central provinces, from Szechwan and Hupeh to Chekiang and Fokien, usually forming a tree 40 to 50 ft. high in the mixed forests on the mountains at no great elevation. It is known to the Chinese as *tz'e ch'iu*;² but its timber is little valued. (A. H.)

In Japan, where the tree is called *hari-giri*, it attains its largest size in the forests of Hokkaido, where, Sargent states, it is often 80 feet in height and 4 or 5 ft. in diameter, with a tall straight stem, covered with furrowed bark, and giving off great limbs, which spread horizontally. In central Hondo, it is smaller in size. Mayr³ who measured a tree in Hokkaido, which was 90 ft. high, states that this species is fast in growth and remarkable for its capacity of enduring shade in the forest. In Kiusiu I saw it in the forest, which covers the lower slopes of the volcano of Kiresima at 2000 to 3000 ft. altitude. Here it is not so fine a tree as in Hokkaido, the largest that I measured being about 60 ft. by 5 ft. 10 in.

A. ricinifolium was introduced into Europe by Van Houtte, who figured in 1874 a young plant, which had been raised from a single seed received from the

¹ The bark is well shown in a photograph of a tree growing in Japan, reproduced by Jack in *Mitt. Deut. Dend. Ges.* 1909, p. 285.

² Cf. Bretschneider, *Bot. Sinic.* ii. 344 (1892) and iii. 480 (1895).

³ *Fremdländ. Wald- u. Parkbäume*, 437 (1906).

1696 The Trees of Great Britain and Ireland

St. Petersburg botanic garden. A tree¹ in the forest garden at Münden, probably derived from Van Houtte's original specimen, was 21 ft. high in 1895.

This species is best raised from seed imported from Japan; but it can be propagated by cuttings of the half-ripened wood, which strike root if placed in gentle heat.¹ Mayr says that it bears transplanting badly, often dying to the ground, but afterwards producing an abundance of suckers from the collar of the root.

It ripens its young shoots well, and is perfectly hardy at Colesborne, where seedlings, that I raised in 1906, are now 4 to 6 feet high. The best specimen that I know in England is in the beautiful grounds of South Lodge, Horsham, the seat of F. D. Godman, Esq., which was, in 1905, 28 ft. high, fifteen years after planting. A solitary specimen at Kew has done badly, and appears to suffer from spring frost. At Westonbirt, there is a vigorous young tree, about 20 ft. high.²

At Grafrath, near Munich, this species has been planted in plots, and has thriven well for so far; but the trees are too young to give as yet any evidence as to their value in forestry.³ M. Hickel states that there is a fine specimen in Messrs. Barbier's nursery at Beuvronne.⁴

TIMBER

Mayr says that this species yields a light timber, which, though disagreeable in odour, is used in Japan for building generally, and for making shafts of spears. Sargent states that the wood is rather hard, straight-grained, and light brown, with a fine satiny surface. The timber has been largely imported into England during the last few years under the name *sen*, by which it is known in Hokkaido. It has been sold in some cases as Japanese ash, and mixed with the timber of *Fraxinus mandshurica*, which it somewhat resembles; but it is better fitted for making furniture than for the purposes for which ash is generally used. (H. J. E.)

¹ Rehder, in *Möller's Deut. Gart. Zeit.* 1st July 1897.

² In *Gard. Mag.* 1888, p. 526, mention is made of a plant then 12 ft. high in Messrs. Veitch's nursery at Coombe Wood. This was disposed of some years ago.

³ Weiss, in *Mitt. Deut. Dend. Ges.* 1912, p. 3, states that it has been tried in groups in the forest at Augsburg, where the trees are about 20 ft. high, but show no sign of being useful.

⁴ Cf. Hickel, in *Bull. Soc. Dend. France*, 1907, p. 153, and 1909, p. 230.

ACACIA

Acacia, Adanson, *Fam. des Plantes*, ii. 319 (1763); Willdenow, *Sb. Pl.* iv. 1049 (1805); Bentham et Hooker, *Gen. Pl.* i. 594 (1865).

TREES, shrubs, climbers, and rarely undershrubs, belonging to the division Mimoseæ of the order Leguminosæ. Branchlets with or without stipular or infra-stipular spines. Leaves alternate, either compound and equally bipinnate with minute leaflets, or reduced to simple phyllodes,¹ which are equivalent to dilated and flattened petioles, with their surfaces placed vertically.

Flowers, yellow or white; in globose heads, cylindrical spikes, or panicles, which are solitary or fascicled in the axils of the leaves; or paniced and ending the branchlets; perfect or polygamous, small, regular: sepals five, four, or three, rarely absent, free or united; petals as many as the sepals, free or united; stamens numerous, free or slightly connate at the base; ovary sessile or stalked, with usually numerous (rarely only two) ovules; style long and slender, ending in a minute stigma. Pod linear or oblong; flat or nearly cylindrical; straight, falcate, or twisted; opening by two valves or indehiscent. Seeds, more or less flattened, usually marked on each face with an oval or horseshoe-shaped depression, oblique spot or ring; funicle filiform or thickened into a flat aril under or around the seed.

About 450 species of *Acacia* are known, natives of the warmer parts of the world, and occurring in Africa, Asia, America, Australia, and Polynesia.

A considerable number of species are cultivated under glass in this country; but in the south-west of England, and in the south of Ireland, four or five species, some of which are shrubs, have succeeded out-of-doors. Two of these species, representative of the two kinds of foliage which occur in the genus, will now be described.

ACACIA DEALBATA, SILVER WATTLE

Acacia dealbata, Link, *Enum. Hort. Berol.* ii. 445 (1822); Loddiges, *Bot. Cab.* t. 1928 (1833); Loudon, *Arb. et Frut. Brit.* ii. 666 (1838); J. D. Hooker, *Fl. Tasm.* i. 111 (1860); Bentham, *Fl. Austral.* ii. 415 (1864); Gamble, *Indian Timbers*, 301 (1902); Rodway, *Tasm. Fl.* 43 (1903).
Acacia irrorata, Sieber, ex Sprengel, *Syst.* iii. 141 (1826).
Acacia decurrens, Willdenow, var. *dealbata*, Von Mueller ex Maiden, *Forest Flora N. S. Wales*, iii. 56 (1908).

An evergreen tree, attaining occasionally in Tasmania 100 ft. in height and

¹ These phyllodes are not leaves turned edgeways, as is shown by the fact that they are not twisted at the base. Moreover, phyllodes are occasionally produced, which bear bipinnate leaves at their ends. On seedlings of the species of *Acacia* with phyllode foliage, the first leaves are bipinnate; succeeding leaves have flattened stalks with fewer leaflets; ultimately only phyllodes are produced.

11 ft. in girth; but usually much smaller. Young branchlets angled, hoary, covered with a minute whitish pubescence. Stipules reduced to inconspicuous scales. Leaves equally bipinnate; rachis 3 to 4 in. long, hoary and pubescent like the branchlets, often glandular; pinnæ ten to twenty pairs, hoary and pubescent, each bearing thirty to forty pairs of crowded linear leaflets, which are about $\frac{1}{6}$ in. long, pubescent, glandular at the sessile base.

Flower heads, in axillary and terminal paniced racemes, globose, yellow, about $\frac{1}{6}$ in. in diameter; flowers twenty to thirty in a head, mostly pentamerous. Pods, straight or curved, flattened, 2 to 3 in. long, $\frac{1}{4}$ to $\frac{1}{2}$ in. wide, not or slightly constricted between the seeds, glaucous on both surfaces.

A. dealbata, which is known in Australia as the silver wattle, occurs in New South Wales, Victoria, and Tasmania. It is widely distributed in Tasmania, where it usually attains 50 ft. in height and 3 to 6 ft. in girth; and yields a timber of little value, which is used for making staves of cheap casks. The bark is not so rich in tannin as that of typical *A. decurrens*,¹ of which species *A. dealbata* is considered to be a variety by Maiden.

A. dealbata was introduced from Tasmania about 1820; and is now much cultivated on the Riviera for its flowers, which are sent in large quantities to Paris and London, under the popular name of "Mimosa." In France this species flourishes on the west coast as far north as Nantes, where, however, it is killed to the ground in severe winters, but nevertheless sends up shoots afterwards with increased vigour.²

(A. H.)

In England,³ it can be grown in the open air in the south-west; and has attained 50 ft. in height after seventeen years growth from seed at Abbotsbury, where it produces flowers annually in great abundance and good seed, from which plants have been raised. At Trebah in Cornwall there is a fine tree of about the same age.⁴ In Ireland, the finest we know is at Derreen (Plate 376), and is believed by the Marquess of Lansdowne to have been planted about thirty-two years. When I measured it in 1910, it was 48 ft. high, with four stems measuring 2 ft. 1 in. to 2 ft. 7 in. in girth.

This species is now completely naturalized in the Nilgiris,⁵ where it is useful for firewood. Gamble says that it is readily reproduced by suckers and coppice shoots. In France it does not thrive on soils containing lime.⁶

(H. J. E.)

¹ Typical *A. decurrens* has branchlets and foliage, which are nearly glabrous and not hoary; and is known in Australia as Green or Black Wattle. A plant, imported from Johannesburg, has been growing since 1909 in the open air at Blackmoor, Liss, Hants, and is now about 4 ft. high. *A. decurrens*, var. *mollis*, Lindley, has tomentose foliage, but the pubescence assumes a golden yellow tinge on the branchlets.

² Cf. Maiden, *Forest Flora N.S. Wales*, iii. 60 (1908).

³ A tree in the Temperate House at Kew is about 50 ft. high, but with a slender stem, about 6 in. in diameter; the bark is broken on the surface into small scales. In *Gard. Chron.* liii. 45 (1913) mention is made of a tree, 70 ft. high and 2 ft. 2 in. in girth, growing in the conservatory at Branksome Hall, Darlington, which was raised from a root-cutting twenty-five years ago.

⁴ *Gard. Chron.* lii. 44 (1912).

⁵ Brandis, in *Indian Forester*, viii. 26 (1882), quotes General Morgan's account of the remarkable change in the period of flowering of this species in the Nilgiris, where it was introduced by seed in 1845. The trees here flowered at first in October, which is the month in which the parents flower in Australia. In 1860, they began to flower in September; in 1870, they flowered in August; in 1878, in July; and in 1882, in June, which is the spring month in the Nilgiris corresponding with October in Australia.

⁶ Cf. Muttet, in *Rev. Hort.* 1896, p. 503.

ACACIA MELANOXYLON, BLACKWOOD

Acacia melanoxylon, R. Brown, in Aiton, *Hort. Kew.* v. 462 (1813); Sims, *Bot. Mag.* t. 1659 (1814); Loudon, *Art. et Frut. Brit.* ii. 663 (1838); J. D. Hooker, *Fl. Tasm.* i. 109 (1860); Bentham, *Fl. Austral.* ii. 388 (1864), and in *Trans. Linn. Soc.* xxx. 481 (1875); Gamble, *Indian Timbers*, 301 (1902); Rodway, *Tasm. Flora*, 42 (1903); Maiden, *Forest Flora N.S. Wales*, ii. 103, plate 57 (1907).

Acacia latifolia, Desfontaines, *Table École Bot. Paris*, 207 (1815).

Acacia arcuata, Sieber, ex Sprengel, *Syst.* iii. 135 (1826).

Acacia brevipes,¹ Cunningham, in *Bot. Mag.* t. 3358 (1834).

An evergreen tree, attaining occasionally, in Australia, 120 ft. in height, and 6 to 10 ft. in girth; but usually only about 80 ft. high. Young branchlets angled, minutely grey tomentose, or rarely glabrous. Stipules absent. Phyllodes coriaceous, glabrous, usually falcate, very variable in size, averaging $2\frac{1}{2}$ to 4 in. long and $\frac{1}{3}$ to $\frac{3}{4}$ in. wide; lanceolate or oblong, gradually tapering to an obtuse or acute apex, which is tipped with a cartilaginous point; much narrowed towards the base; with three or four conspicuous longitudinal veins, connected by anastomosing veinlets; margin entire, cartilaginous. True leaves often present erratically on young trees, bipinnate, with a tomentose rachis and secondary axes, the latter bearing oblong apiculate leaflets, about $\frac{1}{5}$ to $\frac{1}{4}$ in. long.

Flower heads, three to four in an axillary raceme, globose, yellow, about $\frac{1}{5}$ in. in diameter; peduncles $\frac{1}{8}$ to $\frac{1}{3}$ in. long, glabrous; flowers minute, thirty to fifty in a head, pentamerous, with coherent calyces and denticulate sepals; petals free. Pods linear, flat, often curved in a circle, 2 to 4 in. long, about $\frac{1}{3}$ in. broad, with thickened cartilaginous margins, and glaucous coriaceous valves. Seed small, nearly orbicular, with a long dilated pale red funicle, encircling it in double folds.

A. melanoxylon is known in Australia as blackwood, and is widely distributed in Tasmania, Victoria, and New South Wales, extending into South Australia and Queensland. It is most common on rich soil in valleys or grassy ranges; and ascends in the mountains to considerable elevations. It yields a timber of the highest class, which Gamble compares to light-coloured walnut. It is hard and close-grained, taking a fine polish; and is very beautiful when figured. It is used in Sydney and Melbourne for making billiard tables, furniture, gunstocks, coaches, and railway carriages; and is imported by English pianoforte manufacturers.²

(A. H.)

A. melanoxylon was introduced into England about 1808, and is occasionally grown out-of-doors in the south-west. At Abbotsbury, raised ten years ago from seed, it is about 35 ft. high; and seedlings have been raised from it. At Tregothnan, I saw several trees flowering well in 1911, one of which was 35 ft. high by 1 ft. 8 in. in girth.

In the south of France,³ it is the best of the acacias for avenues, as it forms a tall tree regular in habit; and at Hyères there are numerous natural seedlings. It was introduced in 1840 into the Nilgiris in India, where it is completely naturalised.

(H. J. E.)

¹ This is a variety, which appeared in cultivation at Kew, with longer and more falcate phyllodes, attaining 5 to 7 inches in length.

² Cf. Penny, *Tasm. Forestry*, 9 (1905).

³ Pottier, in *Le Jardin*, xxii. 75 (1908).

LAURELIA

- Laurelia*, Jussieu, in *Ann. Mus. Paris*, xiv. 134 (1809); Tulasne, in *Archiv. Mus. Hist. Nat. Paris*, viii. 414 (1855); A. de Candolle, *Prod.* xvi. pt. 2, p. 674 (1868); Bentham et Hooker, *Gen. Pl.* iii. 145 (1880); Perkins and Gilg, in Engler, *Pflanzenreich*, iv. 101, *Monimiaceae*, 76 (1901); Perkins, in Engler, *op. cit.*, Suppl. 46 (1911).
Pavonia, Ruiz and Pavon, *Fl. Peruv. et Chil. Prod.* 127, t. 28 (1794) (not Cavanilles).
Theyga, Molina, *Sag. Chile*, 163 (1810).
Thiga, Molina, *Sag. Chile*, 297 (1810).

EVERGREEN trees, belonging to the order Monimiaceæ; with opposite coriaceous fragrant serrate penninerved leaves, which are without stipules.

Flowers polygamous or diœcious; in simple or paniced axillary cymes; perianth with six to twelve spreading lobes in two or three series. Male flowers, with a flat receptacle, and five to twenty stamens; filaments short, each with two lateral glands at the base; anthers with two oblong lateral cells, which dehisce by valves opening upwards. Female and perfect flowers, with a receptacle at first cup-shaped, bearing stamens, which are often reduced wholly or in part to staminodes, and numerous fusiform villous ovaries, which are tipped with long hirsute styles, and are one-celled, containing an erect anatropous ovule. Fruit, consisting of the enlarged and almost closed receptacle, which has become globose, ovoid, or tubular, and ultimately opens by splitting irregularly into three or four valves; on these are placed the ripened ovaries or achenes, which are ovoid, pilose, and end in a long plumose unbranched style. The valves of the receptacle remain firmly closed in moist air, but spread widely when dry.

Three species of *Laurelia* are known, two of which, not being in cultivation, need only be briefly mentioned:—

1. *Laurelia Novæ-Zelandiæ*, Cunningham, in *Ann. Nat. Hist.* i. 381 (1838). A tree attaining 150 ft. in height in New Zealand.
2. *Laurelia sempervirens*, Tulasne, in *Arch. Mus. Hist. Nat.* viii. 416 (1855).

Laurelia aromatica, Poiret, in Lamarck, *Encycl. Meth. Suppl.* iii. 313 (1813).

Pavonia sempervirens, Ruiz and Pavon, *Syst. Veg. Pl. Peruv. et Chil.* 253 (1798).

This species, with which *L. serrata* has been much confused, has a more northerly distribution, occurring in Peru, as well as throughout Chile, where it is called *laurel* by the inhabitants. It differs from *L. serrata*¹ in having the leaves undulate serrate, with rather distant appressed obtuse teeth; flowers in loose panicles with long pedicels; fruit receptacles fusiform or ovoid; seed plumose throughout, even to the tip of the style. It is a tall tree, very abundant in the evergreen forests, and yielding wood that is easily worked and much used.² (A. H.)

¹ *L. serrata* has sharply serrate leaves; flowers in short crowded panicles, with short pedicels; fruit receptacles globose; seed with the style not plumose at the tip.

² Cf. Castello and Dey, *Jeog. Vej. Rio Valdivia*, 51 (1908).

LAURELIA SERRATA

- Laurelia serrata*,¹ Philippi, in *Bot. Zeit.* xv. 401 (1857); Castillo and Dey, *Jeog. Vej. Rio Valdivia*, 52, fig. 27 (1908); Stapf, in *Bot. Mag.* t. 8279 (1909); Perkins, in Engler, *Pflanzenreich*, iv. 101, *Monimiaceae*, Suppl. 47 (1911).
Laurelia aromatica, Masters, in *Gard. Chron.* xxxvi. 401, fig. 172 (1904) (not Poiret).

A tree, attaining in Chile about 70 ft. in height. Bark greyish, smooth, with persistent brown lenticels, and resembling that of *Zelkova crenata*. Young branchlets, with two pubescent furrows, which have slightly projecting margins. Leaves coriaceous, in opposite pairs, narrowly elliptic or broadly lanceolate, averaging 4 to 5 in. long, and $1\frac{1}{4}$ to $1\frac{3}{4}$ in. wide; tapering to an acuminate apex, usually tipped with a cartilaginous point; cuneate at the base; lateral nerves, ten to twelve pairs, dividing and looping before reaching the margin, which is entire towards the base, but is elsewhere serrate, with sharp teeth directed towards the apex of the leaf or slightly spreading and tipped with a glandular thickening; both surfaces glabrous, except on the slightly pubescent prominent midrib above; petiole $\frac{1}{8}$ to $\frac{1}{4}$ in. long, blackish, densely pubescent on the upper surface.

Flowers, three to nine, in simple or paniced silky cymes; pedicels about $\frac{1}{8}$ in. long. Receptacle in the fruiting stage, globose but constricted at the apex, ultimately splitting irregularly, ashy-grey externally; achenes ovoid, nearly $\frac{1}{2}$ in. long, densely hirsute with spreading hairs, except at the tip of the long and persistent style.

L. serrata is a native of the evergreen forests of southern Chile and northern Patagonia, occurring from Valdivia to the valley of the river Aysen. It is called *huan-huan* by the inhabitants, and seems to be a smaller and rarer tree than *L. sempervirens*; and is said by Castillo and Dey to have an inferior wood, which has an unsupportable odour when freshly cut, yet is much used.

L. serrata was probably introduced about 1860 by Pearce, who collected in Chile for Messrs. Veitch. It is one of the rarest trees in cultivation, and can only be propagated by seed or by layers, cuttings having always failed to take root at Kew. (A. H.)

The only specimens which we have seen are the following:—At Penjerrick, near Falmouth, the seat of R. Fox, Esq., there is a splendid tree in perfect health and looking as if it would become considerably larger, which was in flower in April, 1911, when it measured 47 ft. in height and 3 ft. 4 in. in girth. Another at Kilmacurragh, Co. Wicklow, is about 30 ft. by 3 ft.; but is not so handsome. This tree was procured by the late Mr. Acton from Messrs. Rollison of Tooting about 1868; and from it were drawn the figures cited above in the *Botanical Magazine* and in the *Gardeners' Chronicle*. (H. J. E.)

¹ *Laurelia serrata*, Bertero, in *Mercur. Chil.* 1829, manip. 15, p. 685, translated in *Amer. Journ. Sci.* xxiii. 89 (1833), is a name without any description.

ILEX

Ilex, Linnæus, *Sp. Pl.* 125 (1753); Bentham et Hooker, *Gen. Pl.* i. 356 (1862); Loesener, in *Nova Acta Ac. Leop. Carol.* lxxviii. 8 (1901); Schneider, in *Gartenflora*, lii. 452 (1903), and *Laubholzkunde*, ii. 157 (1907).
Prinos, Linnæus, *Gen. Pl.* 153 (1754).
Aquifolium, Haller, *Enum. Stirp. Helv.* i. 296 (1758).

TREES or shrubs belonging to the order Aquifoliaceæ, mostly evergreen, rarely deciduous. Leaves alternate, simple, usually short-stalked; margin entire, crenate, serrulate, or with spiny teeth; stipules minute, deltoid, often deciduous.

Flowers axillary, solitary or cymose, normally dicecious, regular, usually tetramerous, rarely pentamerous or hexamerous; calyx gamosepalous, hypogynous, with a short tube and four to six lobes, imbricate in the bud; corolla rotate, with four to six petals, free or connate at the base; disc absent. Male flowers, with four to six stamens, alternate with the petals and adhering to them at the base; anthers introrse, with two cells opening longitudinally; ovary rudimentary, either without cells or with empty cells containing no ovules, stigma absent. Female flowers, with four to six stamino-odes, like the stamens, but sterile and small; ovary free, superior, with usually two to four (rarely nine to twenty-two) cells, each usually containing one pendulous ovule; stigma sessile, with as many lobes as there are cells in the ovary. Fruit drupaceous, with the calyx and stigma persistent; epicarp fleshy, containing two to four (or more) one-seeded nutlets. Seed pendulous, with a minute embryo at the apex of the copious albumen.

The genus comprises about 270 species, which are distributed throughout the greater part of the tropical and temperate regions of the world. About twenty-five exotic species are cultivated in Britain, either shrubs or small trees, not coming within the scope of our work; but of these the following four species will be briefly described on account of their relationship to the common holly.

I. *Ilex Perado*, Aiton, *Hort. Kew.* i. 169 (1789); Loudon, *Arb. et Frut. Brit.* ii. 519 (1838).

Ilex maderiensis, Lamarck, *Encycl.* iii. 146 (1789).

A small tree, attaining 30 ft. in height. Young branchlets glabrous. Leaves obovate-oblong, yellowish green, $2\frac{1}{2}$ to 3 in. long, $1\frac{1}{2}$ to 2 in. broad, flat on the surface, thick and coriaceous; apex rounded or minutely cuspidate, and tipped with a slender spine; base rounded or cuneate, decurrent on the glabrous petiole, which has two longitudinal depressions on the lower side; margin not undulate, entire or with a few minute serrations, mostly towards the apex, each tipped with a slender

spine; under surface reticulate. Flowers reddish; fruit ellipsoid, reddish, with nutlets similar to those of *I. Aquifolium*.

I. Perado, in its typical form, is confined¹ to the Madeira Islands, whence it was introduced into England in 1760. It has usually been cultivated since in greenhouses; but Loudon states² that in the Chiswick Garden and several other places near London it bore uninjured the winter of 1837-1838 without protection. It has, however, when tried out-of-doors at Coombe Wood, been always killed in ordinary winters. It is perfectly hardy in Wicklow, where at Kilmacurragh a healthy shrub was bearing fruit in July 1908; and at Powerscourt, where a fine specimen is about 20 ft. high, with a diameter of spreading branches of 24 ft.

It is doubtful if this species has been one of the parents of any of the hybrid hollies.³

II. *Ilex platyphylla*, Webb and Berthelot, *Phyt. Canar.* ii. 135, t. 68 (1836); W. J. Hooker, *Bot. Mag.* t. 4079 (1844).

A tree, attaining 40 ft. in height. Young branchlets minutely pubescent above the insertions of the leaves. Leaves thick and coriaceous, yellowish green, much larger as a rule than in *I. Perado*, 4 to 6 in. long, 2 to 4 in. broad, ovate-oblong, flat on the surface; base rounded or cuneate, decurrent on the glabrous petiole, which shows two longitudinal furrows on the lower side; apex shortly acuminate and tipped with a slender spine; margin not undulate, entire or with few or numerous minute serrations ending in slender spines; reticulate beneath. Flowers white; fruit subglobose, reddish or blackish, with larger nutlets than in *I. Aquifolium*.

This is common in the Canary Islands, and also occurs in the Madeiras, in the latter case associated with *I. Perado*. From the latter species it differs mainly in the larger acuminate leaves. It does not seem ever to have been in cultivation⁴ in England except at Kew⁵ under glass; and there is no evidence that it was concerned in the origin of any of the hybrid hollies.

III. *Ilex balearica*, Desfontaines, *Hist. Arb.* ii. 362 (1809).

Ilex maderensis, Willdenow, *Enum. Pl. Hort. Berol. Suppl.* 8 (1813) (not Lamarck); Moore, in *Gard. Chron.* ii. 751 (1874).

Ilex Aquifolium, Linnæus, var. *balearica*, Lamarck, *Encycl.* iii. 145 (1789); Loudon, *Arb. et Frut. Brit.* ii. 516 (1838).

A small tree, attaining 30 or 40 ft. in height. Young branchlets stout, greenish, densely covered with a minute pubescence. Leaves thick and coriaceous, concave on the upper surface, 3 in. long, 2 in. broad, ovate, shortly acuminate at the apex, which ends in a slender spine; margin not undulate, either entire or with a few (three to ten) irregularly placed serrations, which end in slender spines; base of the blade rounded or cuneate, scarcely decurrent on the minutely pubescent petiole,

¹ *I. Perado*, var. *azorica*, Loesener, in *Nova Acta Acad. Leop. Carol.* lxxviii. 247 (1901), which is the holly of the Azores, differs from the typical form of the Madeiras in having smaller leaves.

² *Trees and Shrubs*, 161 (1842). Loudon, *Gard. Mag.* xiv. 226 (1838), records a shrub of *I. Perado* at Hendon Rectory which was $6\frac{1}{2}$ ft. high.

³ Cf., however, p. 1712, note 1.

⁴ Plants commonly cultivated under this name are, in my opinion, either *I. balearica* or one of its hybrids with *I. Aquifolium*.

⁵ A small specimen now growing in the Temperate House at Kew was sent from the Canaries by Dr. Perez.

which is convex on the lower side. Fruit and nutlets slightly larger than in *I. Aquifolium*.

This species occurs in southern Spain and in the Balearic Islands.¹ It is closely allied to *I. Perado*, but differs in having dense pubescence on the branchlets, and the base of the leaf is not decurrent on the petiole. It is very distinct from the common holly, which has leaves with very undulate margins and large sinuate teeth.

I. balearica is said to have been introduced into England in 1744, and was certainly cultivated in the Royal Garden at Versailles in 1789. It is usually propagated by budding or grafting upon the common holly, and is perfectly hardy at Kew, Cambridge, and Paris, but requires protection during winter in Germany.

This species regularly produces flowers² and fruit in England; and appears to have given rise, in conjunction with the common holly, to a series of hybrids, which began to be noticed about 1800, though they were considered at the time to be simply varieties of the latter species (see p. 1712).

IV. *Ilex opaca*, Aiton, *Hort. Kew.* i. 169 (1789).

A tree, attaining in America 50 ft. in height and 12 ft. in girth. Young branchlets minutely pubescent, becoming pale brown in their first year. Leaves elliptic, about 3 in. long and 1½ in. broad, convex and dull green above, concave and conspicuously reticulate beneath; margin with a few irregular spreading spiny teeth. Fruit dull red, ¼ in. in diameter; nutlets four.

This species, which somewhat resembles the common holly in foliage, is readily distinguishable by the brown branchlets; and is a native of the United States from Massachusetts to Florida, and westward to Indiana and Texas. It was introduced in 1744 into England, and forms a small tree in our climate, which produces flowers and fruit regularly. Though often grown with the common holly in nurseries and botanic gardens, there is no evidence that this species has taken part in the origin of the hybrid hollies. (A. H.)

ILEX AQUIFOLIUM, COMMON HOLLY

Ilex Aquifolium, Linnæus, *Sp. Pl.* 125 (1753); Loudon, *Arb. et Frut. Brit.* ii. 505 (1838); Willkomm, *Forstl. Flora*, 786 (1887); Mathieu, *Flore Forestière*, 58 (1897); Loesener, in *Nova Acta Ac. Leop. Carol.* lxxviii. 248 (1901); Schneider, *Laubholzkunde*, ii. 163 (1907).

A tree, occasionally attaining 50 to 70 ft. in height, and 9 to 12 feet in girth, often shrubby and then rarely over 30 ft. high. Bark smooth, greyish. Young branchlets green or purplish, minutely pubescent. Buds minute, with two acuminate outer scales. Stipules two, usually persistent as withered minute scales at the base of the petiole. Leaves persistent about fourteen months, coriaceous, thick, ovate,

¹ It is probably much more widely spread in the Mediterranean region, but I have been unable to study its distribution. *I. Aquifolium*, var. *platyphylloides*, Christ, in *Ber. Schweiz. Bot. Ges.* xiii. (1903), a tree 30 ft. high occurring on rocky cliffs on the west side of Lake Maggiore in Italy, is probably a form of *I. balearica*.

² In nurseries the male plant of *I. balearica* is sometimes called *I. maderensis*, following the erroneous view of Moore, in *Gard. Chron.* ii. 751 (1874), that it came from Madeira, while the name *I. balearica* is wrongly restricted to the female plant. *I. Aquifolium*, var. *platyphylla* of most nurseries, appears to differ in no respect from *I. balearica*; but see p. 1714.

oblong, or elliptic, 2½ to 4 in. long, 1 to 2 in. broad; acute or acuminate at the apex, usually broad and rounded at the base; dark green and shining above, paler and duller beneath; margin wavy, encircled by a cartilaginous rim, usually with sinuate teeth, each ending in a sharp spine, which spread in different planes; but on the upper branches¹ of old trees entire, or with one or two spinescent teeth towards the apex; primary veins pinnate, six to eight pairs, dividing and looping before reaching the margin; secondary and tertiary veins indistinct; petiole glabrous, short, rounded and not sulcate on the lower side, the base of the blade not being decurrent upon it.

Flowers small, in short axillary cymose fascicles, normally dioecious,² rarely polygamous; sepals four, greenish; petals four, white, placed crossways, slightly connate at the base; stamens four; ovary four-celled, one ovule in each cell. Fruit globose, red, about ⅓ in. in diameter, crowned by the four-lobed stigma, usually containing four nutlets.

The holly is usually bisexual, all the flowers on a tree being either exclusively staminate or pistillate; but, in rare cases, a few perfect flowers, containing both good pollen and well-formed ovules, are produced in addition.³ Dallimore states that female trees, which are isolated, often bear large quantities of berries; but in such cases most of the seed is infertile, and there appears to be no doubt that pollination is always effected by the pollen being brought from another tree by either insects or the wind.

The seeds when sown do not germinate for a long time, two or even three years elapsing before the appearance of the seedlings.⁴ These have two ovate entire obtuse shortly stalked cotyledons, about ⅔ in. long, which are raised above ground on a glabrous caulicle, about an inch in length. The glabrous angled stem gives off in the first year three to five simple alternate leaves, similar to the adult leaves in form, but much smaller, and with small sinuate spiny teeth. These leaves have minute ovate acute black stipules, which are soon deciduous.

VARIETIES

The common holly is variable in the wild state, there being two forms,⁵ one with green and the other with purple branchlets; moreover, differences in habit, in the spinescence of the foliage, and in the colour of the fruit, are not uncommon. The peculiar geographical forms,⁶ which occur wild in western Asia and in China, are not in cultivation. The horticultural varieties, that are usually given in nursery

¹ Kerner, *Nat. Hist. Plants*, Eng. Trans. 433 (1898), believes that the spiny leaves of holly are an adaptation against browsing by ruminants; and points to the fact that on adult trees leaves without spines are only produced on branches beyond the reach of these animals. Withering, *Arrange. Brit. Plants*, ii. 211, note (1796), long ago noticed the same fact, which was also referred to by the poet Southey. Mr. R. A. Phillips tells me that spineless leaves always commence about half-way up wild holly trees in Ireland; and Sir Herbert Maxwell mentions the same fact about wild holly in the wood between Murthly and Dunkeld.

² Darwin, *Forms of Flowers*, 297 (1892) states that the stamens in the female flowers, though quite destitute of pollen, are but slightly shorter than the perfect stamens in the male flowers. The male trees produce a greater number of flowers, and these have smaller corollas than occur in the other sex.

³ Masters, in *Gard. Chron.* xxiii. 27, fig. 8 (1885) and iv. 358 (1888) describes polygamous flowers; and states that occasionally a tree which has hitherto only borne staminate flowers becomes covered with berries.

⁴ Cf. Lubbock, *Seedlings*, i. 337, fig. 240 (1892).

⁵ Cf. Bromfield, in *Phytologist*, iii. 536 (1849).

⁶ Vars. *caspia* and *chinensis*, Loesener, in *Nova Acta Ac. Leop. Carol.* lxxviii. 262, 263 (1901).

catalogues, comprise both the hybrids, which we keep distinct as being of mixed origin; and the true varieties, due only to the common holly, which in many cases have arisen as branch sports, and been subsequently propagated by grafting. The latter usually revert, when old, in isolated branches on the tree, to the type of the common holly.

I. DIFFERING FROM THE TYPE IN HABIT.

1. Var. *pendula*, Loudon, *Trees and Shrubs*, 1113 (1842).

Branches pendulous; leaves as in the common holly. The original tree, from which this variety was propagated by Barron at Elvaston Castle, formerly existed in a private garden in Derby. Loudon also mentions¹ another weeping form, which was discovered about 1842 in Dalkeith Park. There are several good specimens of the weeping holly at Kew, which are clothed to the ground, and somewhat resemble the pendulous form of *Sophora japonica*. Dallimore states that as no leader is formed, it is necessary to keep a shoot tied up, in order to obtain a tall plant.

There are two variegated pendulous forms—var. *aurea pendula*, Waterer's weeping holly, and var. *argentea marginata pendula*, Perry's weeping holly.

2. Var. *fastigiata*, Loudon, *Gard. Mag.* xix. 442 (1843).

Branches erect. Loudon mentions two specimens, one in a garden in Edinburgh, and another in a garden in Derby. The fastigate holly is rare, but is represented at Kew by a small shrub.

II. DIFFERING FROM THE TYPE IN THE COLOUR OF THE FRUIT.

3. Var. *fructu luteo*, Loudon, *Arb. et Frut. Brit.* ii. 509 (1838).

Vars. *chrysoarpa* and *xanthocarpa*, Koch, *Dendrologie*, ii. pt. i. 210, 216 (1872).

Berries yellow. This is one of the oldest known varieties.² Seedlings have been raised in Waterer's and Paul's nurseries, which have produced orange-coloured fruit, and are supposed to have originated from crossing between the yellow and red-fruited forms.³ Loudon mentions a variety⁴ with white berries, and another variety⁵ with black berries, neither of which we have seen.

III. DIFFERING FROM THE TYPE IN FOLIAGE.

A. *Leaves, with both marginal and superficial spines.*4. Var. *echinata*, De Candolle, *Prod.* ii. 14 (1825).

Var. *ferox*, Aiton, *Hort. Kew.* i. 169 (1789); Loudon, *Arb. et Frut. Brit.* ii. 507 (1838).

Ilex echinata, Miller, *Gard. Dict.* ed. 8, No. 2 (1768).

Leaves ovate, about 2 in. long, with their edges rolled backwards; upper surface covered more or less with sharp prickles; margin with irregular large spines. This, which is called the Hedgehog Holly, is the oldest known variety, as it was mentioned by Parkinson⁶ in 1640, and was cultivated at Fulham about 1700. It occurs now only as a male plant; but Parkinson and Martyn refer to it as bearing berries, so that a female form was in all probability formerly in cultivation. Dalli-

¹ Loudon, *Gard. Mag.* xix. 442 (1843).

² In Cole's *History of Plants*, published in 1657, the yellow-berried holly is mentioned as having been found wild near Wardour Castle.

³ Moore, in *Gard. Chron.* ii. 520 (1874).

⁴ Koch, *Dendrologie*, ii. part i. 212 (1872) calls this var. *leucocarpa*, and speaks of it as common.

⁵ Cf. *Arb. et Frut. Brit.* iv. 2545 (1838).

⁶ *Theat. Bot.* 1486 (1640).

more¹ considers this variety to have originated from the typical form directly as a branch sport, which was subsequently propagated by grafting, and which by further sports has given rise to other varieties, like *crispa*.

Two variegated forms of this variety are known:—

Var. *ferox argentea*, Loudon, *op. cit.* 509. Spines and margin cream-coloured; known as the Silver-Striped Hedgehog Holly.

Var. *ferox aurea*, Loudon, *op. cit.* 509. Margin green; centre of the blade with a triangular yellow blotch; known as the Gold-blotched Hedgehog Holly.

B. *Leaves deformed; marginal spines abnormal.*

5. Var. *latispina*, Goepfert, in *Gartenflora*, iii. 318 (1854); Moore, in *Gard. Chron.* ii. 812, fig. 164 (1874).

Leaves thick in texture, broadly oval or quadrangular, with an acuminate apex ending in a long decurved spine; averaging 2 in. long and 1½ in. broad; margin with a few coarse spines, variable in number and direction. Dallimore considers that this variety originated probably as a branch sport from var. *crispa*.

6. Var. *trapeziformis*, Moore, in *Gard. Chron.* ii. 812, fig. 164 (1874).

This variety mainly differs from the last-mentioned in the slightly smaller leaves, which have the margin entire or with only one or two erratically placed spines.

7. Var. *monstrosa*, Goepfert, in *Gartenflora*, iii. 318 (1854); Moore, in *Gard. Chron.* ii. 750, fig. 147 (1874).

Leaves ovate-oblong, 3½ in. long, 1 to 1½ in. broad (exclusive of the spines), resembling var. *latispina* in the long acuminate apex with a deflexed spine, but with a longer blade and more numerous marginal spines, which project in all directions. Dallimore states that this originated in the Handsworth Nurseries.

8. Var. *albo-picta*, Loudon, *Arb. et Frut. Brit.* ii. 508 (1838).

Var. *argentea medio-picta*, Moore, in *Gard. Chron.* iv. 688 (1875).

Leaves similar to var. *monstrosa*, but slightly smaller and variegated; the centre of the blade having an irregular blotch of creamy white, the margin remaining green. This variegated holly is usually called "milkmaid" or "silver milkmaid," and has been known from an early period.

9. Var. *hastata*, Moore, in *Gard. Chron.* ii. 687, fig. 138 (1874).

Var. *kevensis*, Loesener, in *Nova Acta Ac. Leop. Carol.* lxxviii. 266 (1901).

Leaves dark green, coriaceous, ¾ to 1¼ in. long, with two or three pairs of long marginal spines towards the base; the upper half of the blade forming a large entire acuminate or emarginate triangular lobe. This is a dwarf shrub, with purple branches, which originated in the Handsworth Nurseries.

10. Var. *Beetii*, Moore, in *Gard. Chron.* ii. 520, fig. 107 (1874).

Leaves nearly orbicular, about 1½ in. in diameter, dark green, with a thickened margin, and a few (usually five or six) large spines, pointing in various directions. This originated in the Handsworth Nurseries.

¹ *Holly, Yew, and Box*, 68, 69 (1908).

11. Var. *crassifolia*, Aiton, *Hort. Kew.* i. 169 (1789); Loudon, *Arb. et Frut. Brit.* ii. 508 (1838); Moore, in *Gard. Chron.* ii. 752, fig. 152 (1874).

Leaves very thick in texture, lanceolate-oblong, $1\frac{3}{4}$ to 2 in. long, with the apex recurved; margin with triangular teeth, ending in coarse points. This, which is called the Leather-leaf or Saw-leaved Holly, is one of the oldest known varieties,¹ and is remarkably constant in character; no case of a branch reverting to the common holly having been noticed.² It is shrubby with purple branchlets; and always bears pistillate flowers, which ripen into peculiarly flattened fruit.

C. *Leaves small, less than 2 in. long, with regular marginal spines.*

12. Var. *lineata*, Moore, in *Gard. Chron.* ii. 752 (1874).

The form of the common holly with the smallest leaves, which are narrowly lanceolate, $\frac{3}{4}$ in. long, flat, with four or five minute spines on each side. This is a small compact bush with green branchlets. Var. *microphylla*, Moore, *loc. cit.*, appears to differ only in having purple branchlets.

13. Var. *recurva*, Aiton, *Hort. Kew.* i. 169 (1789); Loudon, *Arb. et Frut. Brit.* ii. 507 (1838); Moore in *Gard. Chron.* ii. 687, fig. 138 (1874).

Leaves ovate, acuminate, ending in a long spine, about $1\frac{1}{2}$ in long, curved from base to apex, and usually twisted to one side above the middle; spines divaricate and resembling those of the typical form. This is a dense shrub, and bears staminate flowers.

14. Var. *serratifolia*, Loudon, *Arb. et Frut. Brit.* ii. 507 (1838); Moore, in *Gard. Chron.* ii. 687, fig. 138 (1874).

Var. *myrtifolia*, Goepfert, in *Gartenflora*, iii. 320 (1854); Moore, in *Gard. Chron.* ii. 687, fig. 138 (1874).

Leaves ovate-lanceolate, $1\frac{1}{2}$ in. long, $\frac{1}{2}$ to $\frac{3}{4}$ in. broad, with divaricate spines similar to those of the type. This forms a dense pyramidal shrub.

Several variegated small-leaved forms are known, which may be mentioned here:—

Var. *myrtifolia aureo-maculata*; centre of the leaf with deep yellow blotches.

Var. *myrtifolia aureo-marginata*; centre of the leaf mottled, margin pale yellow.

Var. *myrtifolia elegans*; leaf with a green centre and a narrow golden edge; and

Var. *Ingrami*; leaf mottled with irregular white streaks, margin pinkish.

15. Var. *angustifolia*,³ Loudon, *Arb. et Frut. Brit.* ii. 507 (1838); Moore, in *Gard. Chron.* ii. 752, fig. 154 (1874).

Leaves lanceolate, about $1\frac{1}{2}$ in. long and $\frac{1}{2}$ in. broad, often ending in a long acuminate entire apex; spines numerous, regular, slender. This is a female tree, and is very distinct in its narrow erect almost fastigiate habit, and its elegant small leaves. At Kew, Tortworth, and elsewhere, there are specimens 30 to 40 ft. high,

¹ First described by Hanbury, *Complete Book of Gardening* (1770), as the saw-leaved holly.

² Cf. Dallimore, *Holly, Yew, and Box*, 67, 90 (1908).

³ Var. *angustifolia*, Hohenacker, in *Bull. Soc. Nat. Mosc.* iii. 319 (1838), was found wild in woods near Lenkoran, on the south-west coast of the Caspian Sea; and is a form of var. *caspia*, Loesener, differing from the horticultural variety here described.

as straight as a lance, and always very pointed at the top. It bears small, but not numerous berries.

Variegated forms of this are known:—

Var. *angustifolia albo-marginata*; a small shrub; leaves as in the green variety, but creamy white on the margin; and

Var. *angustifolia aureo-maculata*, centre of the leaf unevenly marked with yellow.

16. Var. *handsworthensis*, Moore, in *Gard. Chron.* ii. 520, fig. 108 (1874).

Leaves ovate, acuminate, $1\frac{1}{2}$ in. long, $\frac{3}{4}$ in. broad, with numerous regular strong spines, pointing towards the apex, the margin only slightly undulate. This has neat and elegant foliage, and originated in the Handsworth Nurseries.

17. Var. *ciliata*, Loudon, *Arb. et Frut. Brit.* ii. 507 (1838); Moore, in *Gard. Chron.* ii. 752, fig. 153 (1874).

Leaves ovate-lanceolate or ovate, $1\frac{1}{2}$ to 2 in. long, $\frac{1}{2}$ to 1 in. wide; margin scarcely undulate, with regular slender spines. This is a male tree at Kew, with purple branchlets and dark foliage.

18. Var. *ovata*, Moore, in *Gard. Chron.* ii. 752, fig. 149 (1874).

Ilex ovata, Goepfert, in *Gartenflora*, iii. 321 (1854); Koch, *Dendrologia*, ii. pt. i. 216 (1872).

Leaves ovate, with a broad truncate or rounded base, $1\frac{1}{2}$ to 2 in. long, $1\frac{1}{4}$ in. broad; margin slightly undulate with small sinuate teeth, tipped with minute spines. This remarkably distinct-looking holly is only known in the staminate form, and has purple branchlets. It is slow in growth. It is undoubtedly a sport of the common holly, as branches with ordinary leaves of the latter are often present on old specimens.

D. *Leaves 2 to 4 in. long, with regular marginal spines.*

19. Var. *Foxii*, Moore, in *Gard. Chron.* ii. 752, fig. 150 (1874).

Leaves broadly ovate, 2 to $2\frac{1}{2}$ in. long, $1\frac{1}{4}$ to $1\frac{1}{2}$ in. broad, with distant sinuate spinous teeth of moderate size on the slightly undulate margin. This variety, which is only known in the staminate form, is very distinct in appearance.

20. Var. *whittingtonensis*, Moore, in *Gard. Chron.* ii. 687, fig. 138 (1874).

Leaves lanceolate or narrowly elliptic, $2\frac{1}{2}$ to 3 in. long, 1 in. broad, dense shining green on the upper surface; margin undulate with numerous stiff divaricate spines. This is a distinct variety, bearing staminate flowers.

21. Var. *Fisheri*, Moore, in *Gard. Chron.* ii. 520, fig. 105 (1874).

Leaves ovate, with a broad base and an entire triangular apex, 3 in. long, $1\frac{1}{2}$ to 2 in. broad; dark shining green above; margin slightly undulate, with large sinuate spiny teeth, variable in number, one to eight on each side. This is a vigorous handsome tree, which originated in the Handsworth Nurseries. It has green branchlets and is a male.

22. Var. *aurea regina*, Moore, in *Gard. Chron.* v. 44 (1876).

Leaves similar in shape to var. *Fisheri*, but variegated; margin broad, well-defined, deep golden yellow; centre of the blade mottled with different shades of green. This beautiful holly is usually called "Golden Queen," and bears staminate flowers.

23. Var. *Lichtenthalii*, Simon-Louis, *Cat.* 1880-1881, p. 50.

Leaves oblong or narrowly elliptic, 4 in. long, 2 in. broad; dark dull green above; midrib beneath yellow; margin slightly undulate, and with large regular sinuate spiny teeth. This is a distinct large-leaved form, with purplish branches, and is possibly of hybrid origin.

24. Var. *alcicornis*, Moore, in *Gard. Chron.* ii. 433, fig. 90 (1874).

Var. *Robinsoniana*, Dallimore, *Holly, Yew, and Box*, 76 (1908).

Leaves narrowly elliptic, mostly with an entire cuneate base, about 3 in. long and 1 in. broad (exclusive of the spines); margin undulate, with numerous large spiny teeth, $\frac{1}{2}$ in. or more long, variously directed. This variety, which is distinct in appearance, has green branchlets, and is a free grower. It was originally sent out by Lawson.

E. *Leaves variable in margin, some quite entire, others with spiny teeth.*

25. Var. *donningtonensis*, Moore, in *Gard. Chron.* ii. 687, fig. 138 (1874).

Leaves lanceolate, $1\frac{1}{2}$ to 2 in. long, $\frac{1}{2}$ in. broad, very variable, either entire in margin or with a few irregular divaricate spines; usually recognisable by some of the non-spiny leaves bearing one or two peculiar curved lobes at the base. This variety, which has dark purple branchlets, always bears staminate flowers; and originated in the Handsworth Nurseries.

26. Var. *Smithiana*, Moore, in *Gard. Chron.* ii. 520, fig. 106 (1874).

Leaves lanceolate or elliptic, 2 to $2\frac{1}{2}$ in. long, $\frac{3}{4}$ in. wide, similar to the last in having leaves both entire and with a few irregular spines, but considerably larger and not showing the peculiar lobes at the base. This always has staminate flowers.

27. Var. *heterophylla*, Aiton, *Hort. Kew.* i. 169 (1789); Loudon, *Arb. et Frut. Brit.* ii. 506 (1838).

This name was originally given to the wild form of the common holly, in which spiny leaves occur near the ground and entire leaves in the upper branches of the tree; but it is now often applied to the next variety, and to intermediate forms.

Two variegated varieties occur:—

Var. *heterophylla aureo-marginata*; leaves of two kinds, entire and spiny, with an irregular golden margin; and var. *heterophylla aureo-picta*, leaves mostly entire and blotched with yellow in the centre.

28. Var. *integrifolia*, Goepfert, in *Gartenflora*, iii. 320 (1854); Moore, in *Gard. Chron.* ii. 812, fig. 164 (1874).

Leaves mostly ovate, entire; flat, but slightly twisted at the apex; about 2 in. long and 1 in. broad; acute, acuminate, or rounded at the apex. Leaves bearing a few spines are usually present. This variety occurs in both sexes.

29. Var. *Watereriana*, Moore, in *Gard. Chron.* vi. 232 (1876).

Leaves oval, 1 to $1\frac{1}{2}$ in. long, either entire or with a few irregular small spines; edged with a broad irregular band of golden yellow. Waterer's Golden Holly is a staminate form with green branchlets, which are striped with yellow. It is a neat, dense, slow-growing variety.

F. *Leaves all (or nearly all) entire in margin; spines absent, except at the apex, which usually terminates in a spiny point.*

30. Var. *laurifolia*, Loudon, *Arb. et Frut. Brit.* ii. 507 (1838); Moore, in *Gard. Chron.* ii. 812 (1874).

Leaves narrowly elliptic or oblong-lanceolate, entire, flat, about 2 to 3 in. long, and 1 in. broad; rarely a few leaves are present bearing one or two spines. This is known only as a male plant.

Several variegated forms are known:—

Var. *laurifolia sulphurea*; mottled green in the centre, with a broad band of sulphur yellow along the margin.

Var. *laurifolia aurea*, with a narrow bright golden yellow margin; and

Var. *laurifolia aureo-picta*, blotched in the centre with deep golden yellow.

31. Var. *marginata*, Loudon, *Arb. et Frut. Brit.* ii. 507 (not Moore).¹

Var. *scotica*, Moore, in *Gard. Chron.* ii. 812, fig. 164 (1874).

Leaves obovate or oblong, rounded and spineless, or with a slight cuspidate spine at the apex, 2 to $2\frac{1}{2}$ in. long, 1 to $1\frac{1}{2}$ in. broad; margin entire, undulate, strongly thickened; upper surface often marked near the apex with a cup-like depression.

This peculiar holly, which is occasionally cultivated under the erroneous name *I. Dahoon*,² is now generally named var. *scotica*, but seems to be without doubt the plant appropriately called var. *marginata* by Loudon. It is considered by Dallimore to have arisen as a branch sport from var. *crispa*, and often shows leaves approaching in character those of the latter variety; but in opposition to this view may be mentioned the fact that var. *marginata* is always female, while var. *crispa* is a staminate form.

Two variegated forms occur, which are known as:—

Var. *scotica aureo-picta*, a handsome variety which originated in the Cheshunt Nursery; it has leaves variegated with golden yellow in the centre; and

Var. *scotica aurea*, a dwarf form, having leaves with a broad golden edge.

32. Var. *crispa*, Loudon, *Arb. et Frut. Brit.* ii. 507 (1838).

Var. *calamistrata*, *revoluta*, and *contorta*, Goepfert, in *Gartenflora*, iii. 319 (1854).

Var. *tortuosa*, Waterer, ex Moore, in *Gard. Chron.* ii. 812, fig. 164 (1874).

Var. *marginata*, Moore, in *Gard. Chron.* ii. 812, fig. 164 (1874) (not Loudon).

Leaves spirally twisted and variously folded, about 2 in. long and 1 in. broad, shining green; margin much thickened, undulate, entire, or with one or two erratically placed spines; apex rounded or prolonged into a long stout decurved spine.

This variety, which is called the Screw-leaved Holly, is always a male tree, and is supposed by Dallimore to be a branch sport of var. *echinata*, as it occasionally bears leaves like those of the latter in having spines on the upper surface.

Var. *crispa aureo-picta* has leaves variegated with gold blotches. It often produces branches with green leaves, and occasionally has leaves with superficial spines.

¹ Var. *marginata*, Moore, is var. *crispa*, Loudon.

² *I. Dahoon*, Walter, is a native of the southern United States, and is apparently now not in cultivation. It was killed at Kew in the great frost of 1895. Cf. *Kew Bull.* 1896, p. 10.

G. Variegated Hollies.

Many of the variegated hollies have been mentioned above, where they are placed with the green varieties, which they resemble. Of these the most useful for ornament are var. *Watereriana* (see No. 29), var. *aurea regina* (see No. 22), and var. *argentea marginata pendula* (see No. 1). A few remain to be noticed.

33. Var. *aureo-marginata*, Loudon, *Arb. et Frut. Brit.* ii. 508 (1838). Leaves like the common holly, but yellow in margin, with the centre of the blade showing various shades of green. This includes a considerable number of sub-varieties, the most noteworthy of which are var. *aureo-marginata angustifolia* and var. *aureo-marginata bromeliæfolia*.

34. Var. *albo-marginata*, Loudon, *Arb. et Frut. Brit.* ii. 508 (1838). Leaves like the common holly, but with a silvery white or cream-coloured margin. Of the numerous sub-varieties, the best are var. *argentea regina*, "Silver Queen," and var. *handsworthensis argenteo-variegata*, "Handsworth New Silver Holly."

35. Var. *aureo-picta*, Loudon, *Arb. et Frut. Brit.* ii. 509 (1838). This variety, which is usually known as var. *aurea medio-picta*, or "Gold Milkmaid," has leaves like the common holly in shape, but with their centre irregularly marked with a large golden yellow blotch.

36. Var. *lutescens*, Petzold and Kirchner, *Arb. Musc.* 350 (1864).

Var. *flavescens*, Moore, in *Gard. Chron.* vi. 616 (1876).

Leaves like the common holly in size and shape, but differing in having a soft yellow tinge when young, which usually lasts throughout the season, but is best marked on the side of the tree which is most exposed to the light. This beautiful variety is known as Moonlight Holly, the dark central mass of green foliage with light yellow terminal shoots giving the effect of a shrub seen by moonlight.

HYBRIDS

The following, which are usually considered to be varieties of the common holly, are of hybrid origin, the parents being probably *I. balearica* and *I. Aquifolium*.¹ These hybrids are not known to produce branches which revert to the type of the common holly. They are vigorous trees, characterised by large leaves, with the margins flat or much less undulate than in the case of *I. Aquifolium*, the spinous teeth being also less sinuate, in these characters approaching *I. balearica*.

I. Leaves conspicuously reticulate beneath.

1. *Ilex Wilsoni*, Fisher, *ex Proc. Hort. Soc.* 1899, p. cxix.; Dallimore, *Holly, Yew, and Box*, 143 (1908).

Ilex Aquifolium, var. *latifolia*, Loudon, *Arb. et Frut. Brit.* ii. 507 (1838).

Ilex Aquifolium, var. *princeps*, Moore, in *Gard. Chron.* xiii. 45, fig. 8 (1880).

¹ Chambers, *Vestiges of Creation*, 310 (1851), quotes from the *Gardener's and Farmer's Journal*, 1848, p. 164:—"The following was related to us by Mr. M'Nab (of the Edinburgh Botanic Garden): he had sown the seeds of *I. balearica*, from which he had produced the common holly. He had also raised from the seeds of the tender Madeira holly (*I. Perado*) a variety identical with that known as Hodgins's holly; and although the offspring of a tender parent, yet like Hodgins's variety, it was also quite hardy." From this it would appear that *I. Perado* may have taken part in the origin of some of the hybrid hollies.

Leaves broadly ovate or oval, 3 to 5 in. long, 2½ in. wide, flat or slightly concave and shining above; conspicuously reticulate beneath; margin with numerous regular spiny teeth directed towards the apex, ¼ in. long, and lying in the plane of the blade.

This is one of the most ornamental hollies, and is a pistillate form, producing abundance of large berries. *I. Wilsoni* was exhibited in 1899 by the Handsworth Nurseries (where there is now a specimen 13 ft. high) as a new kind of seedling origin; but is apparently identical with var. *princeps*, from the same firm, described by Moore¹ a few years earlier. It seems also to be the same as var. *latifolia*, sold by Lawson in Loudon's time.

2. *Ilex Mundyi*, Dallimore, *Holly, Yew, and Box*, 142 (1908).

(?) *Ilex Aquifolium*, var. *nigra*, Moore, in *Gard. Chron.* ii. 433 (1874).

This differs mainly from *I. Wilsoni* in the dull and not shining upper surface of the leaf, the marginal spines of which are directed outwards rather than towards the apex. This is a male plant, which was sent out about twenty years ago by the Handsworth Nurseries, where the tallest specimen is now about 10 ft.

3. *Ilex Lawsoniana*, Dallimore, *Holly, Yew, and Box*, 141 (1908).

Ilex Aquifolium, var. *Lawsoniana*, Moore, in *Gard. Chron.* v. 624, fig. 110 (1875).

A variegated form, like *I. Mundyi* in the shape and texture of the leaf, which is, however, often sub-entire in margin; the centre of the blade is marked with broad irregular blotches of yellow. It is one of the handsomest of the golden hollies,² but often reverts to the green state.

II. Leaves not conspicuously reticulate beneath.

4. *Ilex attaclerensis*, Dallimore, *Holly, Yew, and Box*, 139 (1908).

Ilex Aquifolium, var. *ataclerensis*, Loudon, *Arb. et Frut. Brit.* ii. 507 (1838); Moore, in *Gard. Chron.* ii. 752 (1874).

Leaves broadly ovate, 3 to 3½ in. long, and 2 to 2½ in. wide, sub-entire, or with short spiny sinuate teeth variable in number and mostly near the apex of the blade; margin slightly undulate; petiole purplish, often ¾ in. long, with the base of the blade decurrent on it for a short distance.

This is a very fine male tree with purplish branchlets which originated at Highclere in the early part of the nineteenth century.

5. *Ilex Hodginsii*, Dallimore, *Holly, Yew, and Box*, 140 (1908).

Ilex Aquifolium, var. *Hodginsii*, Moore, in *Gard. Chron.* ii. 433 (1874).

(?) *Ilex Aquifolium*, var. *Shepherdii*, Goeppert, in *Gartenflora*, iii. 318 (1854) (not Moore³).

Leaves ovate or elliptic, 3 to 4 in. long, 2¼ to 3 in. broad, dark green and very shining above; margin undulate and with rather distant regular large triangular

¹ Moore states that var. *princeps* was raised from "the seed of *I. Aquifolium nigrescens* crossed with a male seedling from *I. balearica*."

² Gumbleton, in *Gard. Chron.* iii. 595 (1888), states that *I. Lawsoniana* originated in "Hodgen's nursery at Clough-jordan in Tipperary," whence grafts were sent to Messrs. Lawson at Edinburgh. This is an error, and should read "Hodgins's nursery at Dunganstown."

³ *Ilex Aquifolium*, var. *Shepherdii*, Moore, in *Gard. Chron.* ii. 751 (1874), judging from the description and Moore's specimen in the Kew Herbarium, was identical with *I. Hendersoni*, or only differed from it in the yellowish green leaves being shining and not dull above.

divaricate spiny teeth. This has purplish branchlets, and is very vigorous in growth. It is a staminate form, and is said¹ to be the best holly for planting in towns, being less affected by smoke than the other kinds.

Vars. *nobilis* and *belgica*, Moore, in *Gard. Chron.* ii. 433 (1874), are scarcely distinct from *I. Hodginsii*. A form of the latter, called *I. Hodginsii*, "King Edward VII.," with leaves mottled in the centre, and having a broad yellow margin, was put in commerce in 1898 by Messrs. Little and Ballantyne. Var. *nobilis variegata* has smaller leaves than *I. Hodginsii*, with a yellow blotch in the centre and a broad green margin.

I. Hodginsii is sold under the name *I. Shepherdii*, by the Handsworth Nurseries, who inform us that Mr. Shepherd, past curator of the Liverpool Botanic Garden, received two varieties of seedling hollies from Hodgins, nurseryman in the early part of the nineteenth century at Dunganstown near Wicklow.² The late Mr. Holmes obtained for the Handsworth Nurseries a stock of these varieties, one of which he named *I. Shepherdii* and the other *I. Hendersoni*, the latter name after a friend of the curator. Fine specimens of the original grafted plants still exist at Handsworth. Mr. Holmes always asserted that it was to the variety *I. Shepherdii* that other nurserymen subsequently applied the name *I. Hodginsii*.³

6. *Ilex nigricans*, Henry.

Ilex Aquifolium, var. *nigricans*, Goeppert, in *Gartenflora*, iii. 319 (1854).

Ilex Aquifolium, vars. *atrovirens* and *nigrescens*, Moore, in *Gard. Chron.* ii. 751, 752 (1874).

Leaves ovate, $2\frac{1}{2}$ to $3\frac{1}{2}$ in. long, $1\frac{1}{2}$ to 2 in. broad, dark shining green above; differing from *I. Hodginsii* in the margin being almost flat or only slightly undulate, with smaller sinuate teeth, ending in long slender spines, often very regular and numerous. Under this name may be included perhaps two or three distinct forms, sold as *maderensis*, *maderensis atrovirens*, *platyphylla*, etc., the nomenclature of which is at present confused in different nurseries.

7. *Ilex Hendersoni*, Dallimore, *Holly, Yew, and Box*, 140 (1908).

Ilex Aquifolium, var. *Hendersoni*, Moore,⁴ in *Gard. Chron.* ii. 752, fig. 148 (1874).

Leaves elliptic or ovate, $2\frac{1}{2}$ to 3 in. long, $1\frac{1}{2}$ to 2 in. broad, dull yellowish green above; mostly entire or sub-entire, or with a few short sinuate spinous teeth, the margin being only slightly undulate. This is a female tree, which produces large red fruit, but in no great abundance.

8. *Ilex camelliaefolia*, Henry.

Ilex Aquifolium, var. *camelliaefolia*, Koch, *Dendrologie*, ii. pt. i. 210 (1872); Moore, in *Gard. Chron.* ii. 812, fig. 164 (1874).

Leaves ovate-oblong, about 4 in. long and 2 in. broad, entire or with a few small sinuate spiny teeth, the margin being slightly undulate; upper surface deep green and very shining; petioles and branchlets purplish. This is a very vigorous tree, with dense foliage, and is a female, bearing larger and darker coloured fruits than the common holly.

¹ Hibberd, in Robinson, *Eng. Flower Garden*, 468 (1893).

² Cf. Loudon, *Arb. et Frut. Brit.* i. 116 (1838).

³ It is preferable to use *I. Hodginsii*, as it is now more commonly known, appearing as an alternative name in the Handsworth Catalogue. *I. Shepherdii* is ambiguous, having been applied to both varieties.

⁴ Cf. p. 1713, note 3.

I. Aquifolium, var. *Marnocki*, Dallimore, *Holly, Yew, and Box*, 84 (1908), differs mainly from the preceding in the leaves being peculiarly twisted about the middle. Messrs. Fisher, Son, and Sibray tell us that it arose at Handsworth as a chance seedling about forty years ago, and state in their catalogue that it "bears immense berries on the two- and three-year-old wood, forming sprays of vermilion red colour from 1 to 2 ft. long." Their largest specimen is about 16 ft. high.

DISTRIBUTION

The common holly is a native of western and southern Europe, and extends in two or three geographical forms into Asia Minor, the Caucasus, northern Persia, and China. It cannot live in regions¹ where the winter temperature is low, its distribution in Europe being limited to the north and eastward by the January isothermal line of 32° F., so that it is unknown in Russia and Sweden and in the eastern parts of Germany and Austria. It occurs in Norway only on the islands² and fjords along the west coast from Christianssund (lat. 63° 10') southwards, and is also met with in west Jutland and on the island of Rugen. It exists here and there in Germany, west of a line drawn from Mecklenburg to Bonn, and also in the Black Forest. It is more abundant in the Alps, where it ascends to 4000 feet elevation in Switzerland and in the Tyrol. In France³ it is most common in the central and southern departments, growing, according to Fliche, on all soils that are not marshy, but preferring those deficient in lime; it is usually shrubby, but attains large dimensions in Vendée and Corsica.⁴ Throughout its area it is most often seen as underwood or small trees in the shade of the broad-leaved forest; but it also grows in many places amidst scrub or in rocky situations in full sunlight.

(A. H.)

CULTIVATION

Though the holly is usually looked upon and treated as a shrub, yet in many parts of England it attains the dimensions of a forest tree, which on account of its beautiful foliage and berries has always been one of the greatest ornaments of our natural woodlands and hedgerows. As it is a most useful nurse to oaks, beeches, and other valuable timber trees, and forms excellent shelter for game, it should be encouraged and planted in all places where the soil suits it.

Holly is hardy in all parts of Great Britain; and though it will grow on almost any soil, thrives especially on deep sandy loam and on soils with cool subsoil, grows well on chalky and limy soils, and in very moist climates on thin rocky hillsides. It sows itself freely where rabbits are kept down, but grows slowly at first.

The berries should be gathered in winter, and mixed with sand or light soil in which they decay slowly; but as the seeds rarely germinate until a year has elapsed,

¹ Cf. A. de Candolle, *Geog. Bot. Rais.* i. 147, 162, pl. 1 (1855), who gives much information concerning the distribution of the holly.

² Holly grows on some of the islands near Bergen, in Hardanger and Sogn fjords; and attains on Amuglen over 30 ft. in height and 5 ft. in girth.

³ Cf. vol. iii. p. 560, note 4.

⁴ I have two specimens living at Colesborne, which I brought home in 1903 from the Sila mountains in Calabria, where holly grows at 4000 to 5000 ft. altitude.—H. J. E.

it is better to keep them in sand until the following spring, as is done with haws. When sown the beds should be covered with leaves, fern, or branches, to keep out the frost and drought until they begin to germinate. A rich light soil is best to encourage rapid growth when young, and after two years in the seed-bed the seedlings should be transplanted in the month of May with as little damage as possible to the tender roots. I have found that the seedlings grow faster under a wall with a north aspect than in the full sun. At four years old the seedlings should again be transplanted, and the strongest of them, which may then be 2 to 3 ft. high, can be planted out, either in early autumn if the soil is cool and moist enough, or just before growth commences in May. In the latter case a mulch will be desirable, as they suffer from drought after transplanting, and in my experience it is never wise to transplant¹ hollies between November and the end of March.

In forming holly hedges care must be taken to have the ground thoroughly clean and deeply dug beforehand, and to keep the young plants free from grass and weeds, which often choke the young trees. For want of this precaution, and even in spite of it, deaths occur on dry or poor ground which may permanently ruin the regularity of the hedge; and a great deal of money and time are wasted by planting holly hedges and not attending to them afterwards. Holly bears pruning well, and requires attention when young to make a regular and even hedge, and as the growth of the different varieties is very variable, it is important that all the plants should be from the same source.

When variegated hollies are required, they are budded or grafted; and as this is an operation requiring time, experience, and suitable stocks, it is better to purchase the varieties from a nursery. Messrs. Fisher, Son, and Sibray, of the Handsworth Nurseries near Leeds, have long been celebrated for their hollies, which may be transplanted successfully, if due care is taken, up to 5 or 6 ft. high.

The holly, though an indigenous species, suffers from cold in very severe winters, as in 1838, when the thermometer fell at Chiswick on 20th January to $-4\frac{1}{2}^{\circ}$ Fahr. Lindley² states that the holly in this year "was extensively affected in several places in the middle and north of England; this plant, however, offered very different powers of resisting cold, some of the varieties proving much hardier than others, and, according to Mr. M'Intosh, those which are variegated more so than the plain kinds." In 1837-1838 *I. balearica* was not in the least hurt about London.² Moreover, in 1905, when the temperature at Kew fell to 2° Fahr. on 8th February, none of the varieties of *I. Aquifolium* seems to have suffered.³

REMARKABLE TREES

The holly occurs in woods and copses throughout the greater part of the British Isles, ascending⁴ to 1000 feet in the Highlands, but seems to be commonest and of

¹ Cf. *Gard. Chron.* 1848, p. 99.

² Cf. *Kew Bull.* 1896, p. 9.

³ Moss, in Tansley, *Brit. Veg.* 126 (1911), states that "the holly is found in almost every oak wood on the Pennines, but although it sometimes produces flowers it rarely fruits." This is due no doubt to the altitude and prevalent low temperature in these woods.

² In *Trans. Hort. Soc.* ii. 226, 275 (1842).

its largest size in the moister and milder parts of Ireland, Wales, and southern England. It is a very characteristic tree of the New Forest, and is not uncommon in parts of the Chiltern Hills, where large specimens may be seen on the roadside between Wyfold and Reading.

There are few places in Great Britain where the holly grows in greater size and abundance, and forms such an important feature in the scenery, than in the New Forest, where, since the red deer were killed off, it has increased very fast; and in some of the old woods of oak and beech forms almost impenetrable thickets, which not only add to the beauty of the scenery, but protect many young oaks and beeches from being eaten off by the ponies. I am inclined to think that but for these hollies the number of saplings which are coming up would be so small that the timber trees would in time disappear, and though deer, sheep, and rabbits all browse on and bark hollies in winter, they bear the shade of oak very well. In Mark Ash some of the hollies are over 50 ft. high, with straight trunks, and the annual growths here are over a foot long.

In all the beautiful country about Midhurst and Haslemere the holly grows very well, and is cut by gypsies for whip-sticks, which when straight and slender are the best in England, being light and elastic. I have not seen here, however, any trees so remarkable for size as those which grow in Hertfordshire and Bedfordshire on sandy and gravelly loam. At Russells, near Watford, in 1907, I saw a group of trees in a thick shrubbery from 70 to 75 ft. high, but crowded by beech trees, and not well shaped. In Rod's Wood, Teppingley, near Ampthill, Henry measured in 1909 a fine specimen, 60 ft. high and $11\frac{1}{2}$ ft. in girth, at a foot from the ground, just below the point where it divided into about seven stems.

On the oolite of the Cotswold Hills it is common on old downs and in hedge-rows, but though often forming trunks of 4 to 5 ft. in girth does not attain as great height as on better soil.

On the coast of Suffolk the holly grows remarkably well on sandy soil in Orwell Park, where in a natural wood of oak and holly I saw many 50 ft. high and more, with clean stems 15 to 20 ft. high, and over 5 ft. in girth. Mrs. Rivis tells us that part of Staverton Wood, near Butley, consists of numerous old holly trees crowded together, and with their stems clear of branches to a considerable height.

At Rougham Hall, Norfolk, in 1907, I measured a splendid weeping silver holly 50 ft. by 4 ft. 11 in., with a bole 15 ft. high, the finest of the sort I have seen.

On the Steiperstone hills, south of Shrewsbury, a natural forest of hollies was said to have existed in which trees of great size were found; one is mentioned 14 ft. in girth;¹ but when I visited this place in 1909 I found that part of the land was now planted, and on the open part the hollies were injured by cattle, and by being lopped for Christmas decorations, so that I could find no old ones more than 20 to 30 ft. high, and few seedlings coming up.

At Doddington Hall, near Lincoln, Lord Kesteven in 1907 measured a splendid holly about 50 ft. high, and $9\frac{1}{2}$ ft. in girth at 4 feet from the ground.

¹ *Notes and Queries*, ser. v., xii. 508.

At Mount Edgumbe, Henry saw in 1911 a fine holly about 60 ft. high, with a clean stem of 25 ft., measuring 6 ft. in girth.

The longest holly hedge in England is probably one bounding the park at Tyntesfield, near Bristol, the seat of G. A. Gibbs, Esq. Planted on a bank 3 feet high it extends by the side of the public road for about two miles. It is about 4 ft. high and 3 feet thick, and is very dense and even. At Kew there is a fine holly hedge surrounding the shrub nursery,¹ which is 315 yards long, the greater part of it 9 feet high and 4 feet wide, but one portion as much as 12 feet high and 7 feet in width. A remarkable holly hedge² of great length at Keele Hall, Staffordshire, is 25 feet high and 30 feet in thickness. Near Bagshot a fine holly hedge³ around a private garden is 100 yards long and 40 feet high.

At Gorddinog, Llanfairfechan, North Wales, there is a remarkable avenue of yews, originally planted alternately with hollies, which the owner Colonel Henry Platt, C.B., considers to be very old, one yew tree bearing the date 1654 cut into the bark, with the figures stretched by age to a foot in length. Most of the hollies have died of old age, the largest one, which was 42 ft. high and 8 ft. 8 in. in girth, succumbing last year. A few remain, about the same height, all very decayed, and none exceeding 5½ ft. in girth.

The finest golden variegated holly that we know of is growing in the Isle of Man at Kirby Park, the seat of G. Drinkwater, Esq. In January 1913 it was 46 ft. high and 6 ft. 8 in. in girth at one foot from the ground, above which it divides into three stems, forming a beautiful narrow pyramid of foliage.

In Scotland the holly is quite as much at home as in England, and attains as great a size. Hutchison, who gives a complete list⁴ of the remarkable holly trees in Scotland, states that they are most abundant in Morayshire and Aberdeenshire, in the basins of the Findhorn, Spey, and Dee, where the climate is mild, and there are numerous woods of ancient date. In Darnaway Forest, Morayshire, there are thousands of hollies, many of large dimensions, the finest, measured by the forester in 1891, being 42 ft. high with a clean bole of 16 ft., girthing 9 ft. 4 in. at five feet from the ground. These grow amidst oaks in a soil of reddish clayey loam, and are supposed to be 200 years old. The most remarkable collection of varieties of the holly is at Ochertyre, Perthshire. Some of the oldest holly trees in Scotland appear to be at Glenkill, near Lamlash, in the Isle of Arran, the finest measuring in 1891 50 ft. in height and 8 ft. 3 in. in girth at three feet from the ground. An ash-tree, 30 ft. high and 2 ft. in girth, was growing, naturally grafted, on one of these hollies, the junction being about three feet from the ground, where the holly was 8 ft. 1 in. in girth.

Hunter records⁵ a grand holly tree at Gourdiehill, Perthshire, which had a stem

¹ Dallimore, *Holly, Yew, and Box*, 32 (1908).

² Cf. *Gard. Chron.* xiii. 10, fig. 5 (1893).

³ Described in *Gard. Chron.* xxvi. 424 (1899). A photograph of this is reproduced by Robinson, *English Flower Garden*, 467 (1893).

⁴ *Trans. Highland and Agric. Soc. Scotland*, iv. 80-94 (1892).

⁵ *Woods of Perthshire*, 495 (1883).

28 ft. long, as clean and smooth as a pillar, and holding a girth of 6½ ft. throughout its length.

Christison records¹ a holly at Fullarton House, near Troon, 30 to 40 ft. high, with a bole² 6 ft. long and 11 ft. 9 in. in girth, in 1891. Loudon³ mentions a holly at Blair Drummond which grew in sandy loam, and measured 59 ft. by 8 ft., but it is no longer living.

Sir Joseph Sabine in *Trans. Hort. Soc.* vii. 194 (1830), gives a long account of some remarkable holly hedges in Scotland, of which those at Tynninghame, East Lothian, the seat of the Earl of Haddington, extended altogether to a length of 2952 yards. The most striking were those on both sides of a grass walk 36 feet wide, extending from the North Berwick road to the mansion. This walk was 743 yards long, and the hedges 15 feet high, and 11 feet broad at the base; another was 170 yards long, 25 feet high, and 13 feet wide. Most of these were planted by Thomas, the sixth Earl, in 1712; but when I visited the place in 1905 I found that they had become old and ragged, many of the bushes having died. The largest tree that Sabine mentions here in 1830 was 54 ft. by 5 ft. 3 in. at three feet from the ground, but I measured one no less than 71 ft. by 4 ft. 9 in. drawn up among beech trees, but not a handsome specimen.

The most remarkable groups of hollies I have seen anywhere are on the holly bank at Gordon Castle, growing on a moist gravelly old red sandstone soil facing west. These are in clumps, and many have evidently sprung from the same stool. Sabine counted seventy-three groups, containing 508 trees, of which eighty-seven had clean trunks from 8 to 14 ft. long. The largest he measured, which grew at the bottom of the bank, were 52 ft. by 5 ft. 7 in. with a bole of 10½ ft., and 43 ft. 9 in. by 4 ft. 9 in. with a bole of 8½ ft. He mentions one clump which then contained fifty-five trees growing on an area 134 ft. in circumference, and from 1½ to 3½ ft. in girth, which I believe to be the same that I saw in April 1904, not knowing that it had been previously described. I counted fifty-four trees 30 to 40 ft. high, averaging about 3 ft. in girth, and containing about 6 to 7 feet of timber, so that on an area of about a quarter of an acre there must have been over 300 feet of timber.⁴ Plate 377 gives a very good idea of this wonderful group, which appeared to me, as it did to Sir J. Sabine, to have been the work of nature, but Mr. Webster, the gardener, could give me no record of their age and origin. The Duke of Richmond, however, tells me that they were flourishing in 1760, as they are alluded to in an account of Gordon Castle written at that time.

At Colinton House, Midlothian, the seat of J. Erskine Guild, Esq., there are some holly hedges, supposed to have been planted between 1670 and 1680, which are still in good health; and as I am informed by the gardener, Mr. Bruce, are

¹ *Trans. Bot. Soc. Edinburgh*, xx. 387 (1896). This tree was photographed by Paxton, who presented in 1894 to the library of the Edinburgh Botanic Garden a book of photographs and measurements of thirty remarkable trees in Ayrshire.

² Renwick, in *Trans. Nat. Hist. Soc. Glasgow*, vii. pt. iii. 263 (1904), gives the girth in 1903 as 11½ ft. at five feet from the ground.

³ *Gard. Mag.* xvii. 507 (1841), where a list of measurements in 1836 of all the remarkable trees at Blair Drummond is given.

⁴ In *Gard. Chron.* iii. 51 (1875), Mr. Webster says that one of the trees here measures 7 ft. 9 in. at three feet, and 7½ ft. at ten feet, and another 8½ ft. in the narrowest part of the trunk two feet from the ground.

now in better condition than they were twenty-five years ago. Some parts of them are solid green, and quite thick from base to top. The height of the tallest is 40 ft. after clipping, which is done once in two years. The broadest part at the base is 21 ft. through, and where protected from rabbits the leaves touch the ground. They grow on light dark loamy soil, with a sandy or gravel subsoil, but hollies here thrive equally well on clay with a rocky subsoil. These are supposed to be the oldest and the tallest holly hedges in Scotland, and perhaps in the whole of Great Britain.

The holly, according to Mr. R. A. Phillips, is distributed throughout Ireland, but is more abundant in the non-calcareous districts of the west, south, and south-east than elsewhere. It also occurs on the islands¹ off the west coast. In Ireland it formerly attained an enormous size, the most famous tree being one on Innisfallen Island, Killarney, which Hayes recorded² as 15 ft. in girth in 1794; but I could find no trace of it in 1909. There were also remarkable woods in which holly grew nearly pure, and produced valuable timber in quantity. The late Earl Annesley informed Henry that out of a wood of this kind by the lake at Castlewellaun his brother sold in 1871 more than £500 worth of holly timber; but in 1906 the largest tree which remained was scarcely 6 ft. in girth. Near Mount Usher, in Wicklow, Henry measured in a wood in 1904 a tree 70 ft. in height and 6 ft. in girth.

TIMBER, ETC.

The wood of the holly is white, hard, and heavy; and has a fine close grain, being very homogeneous in texture. It takes a good polish, and is used for making mathematical instruments, for inlaying, and for turnery. Pulley-blocks for ships were formerly made of holly. When dyed black, it is a cheap substitute for ebony. Dallimore states³ that snuff-boxes were, in the early part of the last century, made out of the knots and burrs that are sometimes found on the trunk. Young straight quickly grown shoots are used for making walking-sticks and whip handles.

Bird-lime is made out of the mucilaginous bark of the young shoots.

(H. J. E.)

¹ Praeger, in *Proc. R. I. Acad.* xxxi. pt. 10, pp. 19, 21, 25, records it for Clare Island.

BUXUS

Buxus, Linnæus, *Syst. Nat.* 9 (1735), *Gen. Pl.* 284 (1737), and *Sp. Pl.* 983 (1753); Baillon, *Monog. Buxac.* 58 (1859); Müller, in De Candolle, *Prod.* xvi. pt. i. p. 13 (1869); Bentham et Hooker, *Gen. Pl.* iii. 266 (1880); Pax, in Engler and Prantl, *Nat. Pflanzenfam.* iii. 5, p. 133 (1892); Van Tieghem, in *Ann. Sci. Nat.* v. 289 (1897); Hutchinson, in *Kew Bulletin*, 1912, p. 52.

EVERGREEN trees or shrubs belonging to the family Buxaceæ. Young branchlets quadrangular. Leaves opposite, coriaceous, simple, entire, penninerved, shortly stalked, without stipules. Flowers monœcious, without petals, in axillary clusters, which are composed of several staminate flowers, and usually a central single pistillate flower. Staminate flower: sepals four, in two opposite pairs; stamens four, each opposite a sepal, with a thick filament inserted beneath the rudimentary ovary, and with a two-celled anther, which dehisces longitudinally. Pistillate flower; sepals four to seven, occasionally ten, some of which may represent bracts, imbricated; ovary free, three-celled, crowned by three peripheral styles; ovules, two in each cell. Fruit,¹ a capsule, crowned by the three persistent styles, three-celled, each cell containing two seeds, or occasionally only one by abortion; capsule, when ripe, splitting longitudinally, through the three styles and the dorsal sutures, thus producing three two-horned valves; the endocarp afterwards opens down six lines, suddenly expelling the seeds, which are trigonous, shining, black, and smooth.

The above description is restricted to the section *Eu-buxus* of the genus,² which comprises about ten species, two, natives of tropical Africa and Socotra, and about eight species, natives of the Mediterranean region, Caucasus, Persia, Himalayas, China, and Japan. The following synopsis briefly deals with those which are in cultivation:—

I. *Branchlets glabrous, or occasionally with a few minute hairs near the nodes.*

1. *Buxus japonica*, Müller, in De Candolle, *Prod.* xvi. 1, p. 20 (1869); Shirasawa, *Icon. Ess. Forest. Japon.* ii. t. 38, figs. 16-32 (1908).

Buxus sempervirens, Linnæus, var. *japonica*, Makino, in *Tokyo Bot. Mag.* ix. 281 (1895), and xv. 169 (1901); Hayata, in *Journ. Coll. Sci. Tokyo*, xx. 3, p. 82, t. vi. c. (1904).

A shrub or small tree, with glabrous branchlets. Leaves coriaceous, very similar to those of *B. sempervirens* in size and appearance, but usually more oval and occasionally almost orbicular, $\frac{3}{4}$ to 1 in. long and $\frac{1}{2}$ in. broad, emarginate and rounded

¹ Cf. Marshall Ward, *Trees*, iv. 154, fig. 147 (1908).

² The other sections of the genus, which are sometimes regarded as distinct genera, are *Buxella*, which includes four species, natives of Madagascar, tropical and south Africa; and *Tricera*, comprising about a dozen species, natives of the West Indies.

at the apex; upper side of the short broad petiole pubescent, the leaf elsewhere being glabrous. Flowers of both sexes sessile, similar to those of *B. sempervirens*, but with the rudimentary ovary of the staminate flower much enlarged and as long as the inner sepals.

This is wild in the mountains of Japan, where it has given rise in cultivation to several peculiar forms, one of which with almost orbicular leaves, puckered and uneven on the surface, has been introduced into Europe. The typical form is rare; but is represented at Kew by a shrub about 3 ft. high.¹

2. *Buxus microphylla*, Siebold and Zuccarini, in *Abh. Ac. München*, iv. 2, p. 142 (1845).

Buxus sempervirens, var. *microphylla*, Blume, ex Miquel, in *Ann. Mus. Lugd. Bat.* iii. 128 (1867); Hayata, in *Journ. Coll. Sci. Tokyo*, xx. 3, p. 83, t. vi. D. (1904).

Buxus japonica, var. *microphylla*, Müller, in De Candolle, *Prod.* xvi. 1, p. 20 (1869).

A low shrub, with very slender branchlets, which are glabrous or with a few minute hairs above the nodes. Leaves thin and membranous, spatulate, lanceolate or elliptic, about $\frac{1}{2}$ in. long and $\frac{1}{6}$ to $\frac{1}{4}$ in. broad, emarginate at the apex, slightly pubescent on the upper side of the very short broad petiole. Flowers, as in *B. japonica*.

This species² occurs wild in Japan, in the provinces of Shimoso, Awa, and Tosa. It is a very distinct plant, with small thin leaves, and has lately been introduced into Kew.

3. *Buxus Harlandi*,³ Hance, in *Journ. Linn. Soc. (Bot.)* xiii. 123 (1873).

A small shrub, attaining 1 to 2 ft. in height, with densely crowded foliage. Young branchlets very slender, glabrous or occasionally with a few minute hairs above the nodes. Leaves oblanceolate, very narrow in proportion to their length, $\frac{3}{4}$ to $1\frac{1}{4}$ in. long, $\frac{1}{6}$ to $\frac{1}{4}$ in. wide, emarginate at the apex, very tapering at the base, quite glabrous throughout, or with slight pubescence on the upper side of the petiole. Flowers similar to those of *B. japonica*, sessile in both sexes, with the rudimentary ovary of the staminate flower as long as the inner sepals; but with the style of the pistillate flower as long as the ovary.

This shrub, which is very distinct in appearance, occurs in central and southern China, where it is found growing in the shingly or rocky beds of rivers and streams. It has been in cultivation about ten years at Kew, where it is a dwarf shrub.⁴

II. *Branchlets minutely puberulous.*

4. *Buxus balearica*, Lamarck, *Encyc.* i. 511 (1753); Willdenow, *Sp. Pl.* iv. 337 (1805).

Buxus sempervirens, var. *gigantea*, Loiseleur, in Duhamel, *Traité des Arbres*, i. 82, t. 23 (1801).

¹ *B. Fortunei rotundifolia*, of some French nurseries, is probably a prostrate form of *B. japonica*.

² *B. stenophylla*, Hance, in *Journ. Bot.* vi. 331 (1868), wild in the province of Fukien, in China, is closely allied to, if not identical with *B. microphylla*. *B. sempervirens*, var. *riparia*, Makino, in *Tokyo Bot. Mag.* xxvi. 293 (1912), a shrub 3 ft. high, growing beside the river Yoshino, in the province of Tosa, is said to be intermediate between *B. japonica* and *B. microphylla*.

³ This species was founded by Hance, on specimens gathered in Hong-Kong; but his sheet, No. 322, so-named, includes two different plants, one, the true *B. Harlandi*, and the other, resembling *B. japonica* in the shape of the leaves, but differing in having pubescent branchlets.

⁴ *B. Fortunei*, Carrière, in *Rev. Hort.* xlii. 519 (1871), also sometimes known as *B. longifolia*, Hort., judging from specimens cultivated under this name in France, is identical with *B. Harlandi*.

A shrub or small tree. Young branchlets with a minute pubescence, only visible with a strong lens. Leaves light green, coriaceous, larger than those of the common box, but similar in shape, elliptic, 1 to $1\frac{1}{2}$ in. long, $\frac{1}{2}$ to $\frac{5}{8}$ in. wide, emarginate at the apex, minutely pubescent on the upper side of the short petioles, but glabrous elsewhere. Staminate flowers shortly stalked; pistillate flowers with the styles as long as the ovary.

This species¹ occurs in the Balearic Isles, and in the province of Granada, in Spain, on the coast at Nerja, near Malaga, and on the Sierra de Almijara, at 2000 feet elevation. Loudon² states that it was introduced into England in 1780. It is perfectly hardy, the oldest specimen at Kew being about 23 ft. high.

III. *Branchlets densely pubescent.*

5. *Buxus sempervirens*, Linnæus. See p. 1724.

6. *Buxus Wallichiana*, Baillon, *Monog. Buxac.* 63 (1859); Hayata, in *Journ. Coll. Sci. Tokyo*, xx. 3, p. 84, t. vi. E. (1904).

Buxus sempervirens, J. D. Hooker, *Fl. Brit. Ind.* v. 267 (1887) (not Linnæus); Gamble, *Indian Timbers*, 592 (1902).

Buxus sempervirens, Linnæus, var. *liukiensis*, Makino, in *Tokyo Bot. Mag.* ix. 279 (1895), and xv. 169 (1901).

Buxus liukiensis, Makino, in *Tokyo Bot. Mag.* xvi. 179 (1902); Schneider, *Laubholzkunde*, ii. 140 (1907).

A shrub or small tree. Branchlets densely pubescent. Leaves lanceolate, 1 to $2\frac{1}{4}$ in. long, $\frac{1}{4}$ to $\frac{1}{2}$ in. wide, rounded or emarginate, with a short point at the apex; petiole densely pubescent, the pubescence spreading along the midrib on the upper side. Flowers of both sexes sessile; rudiment of the ovary in the male flower very short, dilated and slightly four-lobed at the apex; styles in the pistillate flower as long as the ovary, persisting elongated and erect on the fruit.

B. Wallichiana is widely spread in Asia, occurring in India in the Suliman and Salt ranges, and in the Himalayas from Kumaon to Bhutan (but not in Sikkim), at 4000 to 8000 feet. It is common in the mountainous districts of central and southern China, and is the only species known at present in the Liu Kiu Islands and Formosa. Its distribution³ in the Himalayas is local and peculiar; but it mainly grows along the banks of streams in moist and sheltered places, preferring a northerly aspect; and is met with on sandstone as well as on limestone. It often occurs in considerable quantity, attaining a large size, trees being recorded as much as 5 ft. in girth; but is slow in growth, averaging, according to Gamble, about twenty rings per inch of radius. In China,⁴ the box is known as *huang-yang*, and is of consider-

¹ *B. longifolia*, Boissier, *Diag. Fl. Orient.* 107 (1853), and *Fl. Orient.* iv. 1144 (1879), of which I have seen no specimens, is said to occur in the mountains of Syria; and appears to be closely allied to *B. balearica*. It is entirely distinct from *B. longifolia*, Hort., which appears to be a synonym of *B. Harlandi*. Cf. p. 1722, note 4.

² *Arb. et Frut. Brit.* iii. 1341 (1838). His account of the size and distribution of this species, which has been followed by Dallimore, *Holly, Yew, and Box*, 229 (1908), is erroneous. So far as I can learn, *B. balearica* is a small tree or shrub, not exceeding thirty feet in height; and does not occur wild except in the localities mentioned above. Nyman, *Consp. Fl. Europ.* i. 647 (1878), records it for Sardinia; but this is doubtful.

³ A dwarf box with very small leaves occurs in the Himalayas at high elevations; and has been referred to *B. japonica*, var. *microphylla*, Müller, by Hooker, *Flora Brit. India*, v. 267 (1887); but is much more pubescent than the Japanese plant, and is probably a distinct species.

⁴ The species of box in China require further study. *Buxus Henryi*, Mayr, *Fremdländ. Wald- u. Parkbäume*, 451 (1906), described from specimens (No. 3387) collected by me on cliffs near Ichang, in central China, has glabrous branchlets,

able economic importance in the mountains north of Ichang, in Hupeh, where it is a tree of considerable dimensions.

B. Wallichiana is very rare in cultivation; but thrives at Kew, where specimens, about 6 or 7 feet high, produce flowers and fruit regularly. (A. H.)

BUXUS SEMPERVIRENS, COMMON BOX

Buxus sempervirens, Linnæus, *Sp. Pl.* 983 (1753); Loudon, *Arb. et Frut. Brit.* iii. 1333 (1838); Baillon, *Monog. Buxac.* 59 (1859); Müller, in De Candolle, *Prod.* xvi. 1, p. 19 (1869); Willkomm, *Forstl. Flora*, 802 (1887); Mathieu, *Flore Forestière*, 306 (1897).
Buxus arborescens, Miller, *Dict.* ed. viii. No. 1 (1768).

A shrub or small tree, attaining about 30 ft. in height and 3 ft. in girth. Young branchlets densely pubescent with short white hairs, which are more or less retained in the second and third years. Leaves persistent five or six years, coriaceous, opposite, oval or elliptic, averaging 1 to 1¼ in. long and ½ in. broad, rounded and usually emarginate at the apex; shining and dark green above; duller and yellowish green below; secondary nerves pinnate, often forked, conspicuous on the upper surface; margin entire; tapering at the base to a very short petiole, which is pubescent like the branchlets, the pubescence extending along the midrib on the upper surface, and on the edges of the base of the blade.

Flowers small, white; both sexes sessile; rudimentary ovary of the staminate flower scarcely half as long as the inner sepals; styles of the pistillate flower short, about half as long as the ovary. Capsule ovoid, longer than broad, brown when ripe, crowned by short spreading styles; seeds trigonous, smooth, shining, black. The seedling¹ has two oblong obtuse glabrous cotyledons about ½ in. long, raised above ground on a glabrous caulicle about 1½ in. long; primary leaves opposite, decussate, elliptic, shortly stalked.

VARIETIES

A considerable number of varieties of the common box are in cultivation, most of which have arisen in gardens and nurseries—the variation in the wild state² being slight.

1. Var. *angustifolia*, Loudon, *Arb. et Frut. Brit.* iii. 1333 (1838).

Buxus angustifolia, Miller, *Gard. Dict.* ed. viii. No. 2 (1768).

Leaves oblong-lanceolate, about 1 in. long and ½ in. wide. This is said to occur

lanceolate leaves as much as 3 in. long, and ¾ in. broad; staminate flowers on long pedicels, with a minute and linear rudimentary ovary. This species, which is allied to *B. balearica*, has remarkably fine foliage and conspicuous flowers; but has not yet been introduced. It has lately been fully described and figured by Dümmer, in *Gard. Chron.* lii. 423, fig. 182 (1912).

¹ Cf. Lubbock, *Seedlings*, ii. 481, fig. 639 (1892).

² The typical form of the species was distinguished as var. *arborescens*, by Linnæus, *Sp. Pl.* 983 (1753), a name kept up by Loudon, *Arb. et Frut. Brit.* iii. 1333 (1838). Var. *grandifolia*, Müller, in De Candolle, *Prod.* xvi. 1, p. 19 (1869), wild in Spain, Greece, and the Caucasus, is scarcely distinguishable, though occasionally the leaves are longer and more lanceolate than in the type.

wild in Algeria; and is commonly shrubby. An upright tall-growing form of this is known as var. *salicifolia elata*.

2. Var. *myrtifolia*, Loudon, *Arb. et Frut. Brit.* 1333 (1838).

Buxus myrtifolia, Lamarck, *Encyc. Meth.* i. 511 (1783).

Leaves dark green, oblong-lanceolate, smaller than in the last variety, about ¾ in. long and ¼ in. wide. This is a low shrub, which was described by Lamarck, from specimens obtained from M. Cels' nursery at Paris, where it probably originated.

3. Var. *myosotifolia*, Dallimore, *Holly, Yew, and Box*, 227 (1908).

Leaves resembling those of var. *myrtifolia*, but still smaller, about ½ in. long and ¼ in. broad, lanceolate, dark green. This is a dwarf shrub.

4. Var. *rosmarinifolia*, Baillon, *Monog. Buxac.* 61 (1859).

Leaves lanceolate or spatulate, more slender and thinner in texture than the last variety, about ½ in. long and ¼ in. wide, marked beneath with whitish dots and tubercles. This variety, which is also known as var. *thymifolia*, grows to be a bush 5 or 6 ft. high.

5. Var. *suffruticosa*, Linnæus, *Sp. Pl.* 983 (1753).

Buxus suffruticosa, Miller, *Gard. Dict.* ed. viii. No. 3 (1768).

Leaves oval or obovate, ½ in. long and ¼ in. wide. This is the well-known dwarf variety, which is used for edging beds in gardens. It has been in cultivation for several centuries at least, and is occasionally called var. *nana* or var. *humilis*.

6. Var. *latifolia*, Dallimore, *Holly, Yew, and Box*, 226 (1908).

Under this name are included several forms, in which the leaves are broader than usual, averaging 1 in. long and ¾ in. wide. In var. *latifolia bullata*, Späth, the leaves are uneven with peculiar swellings. Var. *handsworthensis*, Fisher, with broadly oval leaves, is vigorous in growth, and suitable for making hedges.

7. A considerable number of variegated forms are in cultivation. Those with leaves normal in size, or nearly so, are:—Var. *argentea* or var. *argenteo-marginata*, leaves white in margin; var. *aureo-marginata*, leaves yellow in margin; and var. *aureo-maculata*, leaves spotted with yellow. Var. *elegantissima*, Koch, *Dendrologie*, ii. pt. i. 477 (1872), is a distinct form with small oval leaves, variegated with white, and with many of the leaves deformed.

8. Var. *pendula*, Simon-Louis, *Cat.* 1869, p. 21. Tree-like in habit, and graceful in outline, the secondary branches and branchlets being pendulous.

9. Var. *pyramidalis*, Simon-Louis, *Cat.* 1869, p. 21. Pyramidal in habit, with upright branches.

DISTRIBUTION

The common box is a native of western Europe, the Mediterranean region, the Caucasus, and northern Persia. It is probably a true native of England; and in the south and east of France¹ is widely spread in the Jura, Dauphiné, Languedoc,

¹ Chatin, in *Bull. Soc. Bot. France*, viii. 364 (1861), considers the box to be naturalised in many localities in France, which are mainly in the neighbourhood of abbeys and castles that date from the middle ages. He mentions the forest of Marly, Vaux-de-Cernay, Neauphle-le-Château, Arthieul near Magny, Roche-Guyon, Chantilly, Nemours, Provins, and Jaux near Compiègne. He adds that it is abundant on the millstone grits and sandstones of Vaux-de-Cernay, near Paris, and on granite at Mauves-sur-Loire.

Provence,¹ and Pyrenees,² and occurs in a few scattered spots in the north of the departments of Meuse and Meurthe-et-Moselle, extending across the frontier into Belgium. It is recorded for Germany from one locality in Baden. Farther south it is common in the southern Tyrol, Istria, Dalmatia, the Balkan States, and Greece. It is also met with in Italy, Spain, and Portugal; and is a rare plant in the cedar forests of Algeria. In Europe, it is usually a gregarious shrub, often growing on arid hills or mountains on limestone³ soil in the Mediterranean region. It is cultivated in Norway as far as lat. 67° 56' on the coast, and in Sweden up to lat. 59° 7'.

The box attains its largest size in the Caucasus,⁴ where it is very common in the coast region along the Black Sea from Sotschi to Batoum, at elevations between sea-level and 4000 ft. It also grows wild in Talysch, but in other parts of the Caucasus is a doubtful native, though it is often planted, being considered a holy tree by the natives. The finest trees grow inland from the Black Sea, at about 2500 ft. altitude, where they are commonly 30 to 40 ft. in height, with stems 8 to 12 inches in diameter. Formerly still larger trees were known, Köppen⁴ mentioning 50 ft. in height and 2 ft. in diameter as the maximum size. Many large trees are of enormous age, 500 to 600 annual rings having been counted by Medwejew; but nearly all these are rotten at the heart. The box grows usually in the Caucasus in narrow bands along rivers and streams as undergrowth in the great forests of oak, ash, and beech; and is rarely found mixed with conifers. It thrives best in moist, rainy, sheltered, and shaded spots. The woods of box tree in Georgia are mentioned⁵ by Marco Polo. Until about 1890 the export of boxwood from the Black Sea to England, France, and Turkey, was enormous, averaging 2340 tons annually for the years 1883-1887.

Consul Stevens, in his *Trade Report⁶ for Batoum* for 1895, states: "Although all the private forests of boxwood have been exhausted, the Government up to the present still refuse to sell or allow boxwood to be cut in their extensive forests throughout Abkhasia; consequently the total exports from the Caucasus have not exceeded 1200 tons."

The box appears to be very common in the Elburz mountains in northern Persia, especially in the forests of Mazanderan, whence the export of boxwood in 1906 amounted to 125,864 pieces, weighing about 1560 tons.⁷

Whether the box is a native of England or not is doubtful; but it is certainly

¹ Tansley in *Gard. Chron.* lii. 113, fig. 51 (1912) describes the peculiar shrubby vegetation, which grows on the southern slopes of the hilly regions of Provence, at about 4500 ft. elevation. This consists of isolated bushes, with bare rock between them, of box, lavender, and *Genista cinerea*. The north slopes are covered with beech woods, in which there are holly and box, the latter being very abundant inland.

² On the south side of the Pyrenees, above Venasque at 5000 ft. altitude, I saw, in 1912, much box, forming dense scrub on sunny slopes; and it is the prevailing undergrowth in many of the valleys of the western Pyrenees on the French side. In the forest near Esterencby, south of St. Jean-Pied-de-Port, box attained 30 ft. high on limestone, and was being felled for making prayer-beads.

³ It is most commonly found on limestone; but occurs frequently on other soils, as in the cases mentioned (p. 1725, note 1) by Chatin; and according to De Candolle, *Geog. Bot. Rais.* i. 426 (1855), it grows on schist in the Pyrenees, on granite in Brittany, and on volcanic soil in Auvergne. Gèze, in *Bull. Soc. Bot. France*, lv. 464 (1908), states that at Villefranche it is not calcicole.

⁴ Cf. Radde, *Pflanzen-verb. Kaukasuslând.* 145, 182, 201 (1899), and Köppen, *Holgewächse Europ. Russlands*, ii. 1-9 (1889).

⁵ *Foreign Office Ann. Series*, No. 1717, p. 27.

⁶ Yule, *Marco Polo*, i. 50, 54 (1871).

⁷ *Consular Report for Resht*, No. 3864, p. 25.

naturalised, if not truly indigenous, in a few localities. It was cultivated¹ in Britain by the Romans; and as it seeds itself freely in the south of England, it may have spread from abandoned villas. It was well known in Anglo-Saxon times, the earliest mention, I was informed by the late Dr. Skeat, being in the "Corpus Glossary" of Latin and English words, which was written about 750 A.D. In this work *box* is given as the Anglo-Saxon equivalent of the Latin word *buxus*. The word *box* begins to appear early in place-names,² the oldest example known to Dr. Skeat being *Box-ōra* (i.e. box-bank), the old name of Boxford, Berks; and there must have been box trees here at an early date. In the thirteenth century, numerous names of places occur with *box*, as La Boxe, Le Boxe, Hundred de Boxe, Boxen, Boxford, Boxhale, Boxhey, Boxore, Boxley, Boxland, Boxstead. These place-names show that box was well known in former times; but whether it was wild or cultivated, there is no means of determining.

Professor Babington³ believed that the following extract from the beginning of Asser's *Life of King Alfred* showed that it was plentiful in Berkshire 1000 years ago: "Berrocsaire; quæ paga taliter vocatur a Berroc sylva, ubi *buxus* abundantissime nascitur." Gough's *Camden*, 155 (1789), says: "The last remains of Boxgrove⁴ in Sulham parish, near Reading, whence the county probably took its name, were grubbed up about forty years ago."

Gerard,⁴ writing in 1597, says: "The box tree groweth upon sundry waste and barren hills in England." Ray⁵ in 1696 records it growing at Boxhill near Dorking, at Boxley in Kent, and at Boxewell in the Cotswolds.

At the present day, box is apparently wild in several places in the south of England, the most famous being Box Hill in Surrey, where many acres on the western slopes are covered with a mixture of yew, box, and other trees. The occurrence of the box-tree here was first recorded by Merrett⁶ in 1666. Count Solms-Laubach suggests⁷ that the box and yew trees of Box Hill might probably be the remains of a native forest which originally clothed the North Downs. He urges the unlikelihood of such a soil as that of Box Hill being planted at all, and the improbability of any one hitting upon such a combination as yew and box for the purpose. Manning and Bray, *History of Surrey*, i. 560 (1804), give the following account: "The Downs, which rise from the opposite bank of the Mole, are finely chequered with Yew and Box trees of great antiquity, to a considerable height. Of the latter of these in particular there was formerly such abundance that that part of the Downs which is contiguous to the stream, and within

¹ Clement Reid, at a meeting of the Linnean Society, London, on 2nd December 1909, said that Box leaves have been found in three different rubbish heaps in the Roman remains at Silchester. The branches may have been used for wreaths.

² The names of places with box, given by Spelman, *Villare Anglicum* (1653) and by Adams, *Index Villaris* (1680) are Box (Wilts), Boxend (Beds), Boxford (Berks and Suffolk), Boxley (Kent), Boxted (Essex and Suffolk), Boxwell (Gloucester), and Boxworth (Berks and Cambridge). Some of these, as we know from the old spelling, do not indicate the box tree; thus Boxworth near Cambridge means the "farm of the buck." In some cases these places seem to be connected with the Roman occupation of Britain, as Boxmoor House (Herts), near which a Roman dwelling-house was discovered in 1851; but where the places occur on the chalk downs, the presumption is that the tree is indigenous.

³ *Phytologist*, iv. 873 (1853). Cf. Stevenson, *Asser's Life of King Alfred*, pp. 1, 156, 157 (1904), who states that Berroc Wood was identified with Boxgrove by Francis Wise in 1738.

⁴ *Herball*, 1225 (1597).

⁵ *Syn. Meth.* ii. 310 (1696). Box does not appear to be growing wild at the present time near Boxley in Kent.

⁶ *Pinax. Rerum Nat. Brit.* 18 (1666).

⁷ Cf. article by G. R. M. Murray, in *Journ. Bot.* xxxix. 27 (1901).

the precinct of this Maner, hath always been known by the name of Box Hill. Here was formerly also a Warren with its Lodge; in a lease¹ of which from Sir Matthew Brown to Thomas Constable, dated 25th August 1602, the Tenent covenants to use his best endeavours for preserving the Yew, Box, and all other trees growing thereupon; and in an account of the rents and profits for one year to Michaelmas, 1608, the receipt for Box trees cut down upon the Sheep Walk on the hill is £50. I have seen also an account of this Maner, taken in 1712, in which it is supposed that as much had been cut down² within a few years before as amounted to £3000."

E. S. Marshall³ says: "He must be very sceptical who doubts it being native on the steep slopes of Box Hill, above Burford Bridge. I have also seen it growing rather plentifully a mile or more away towards Betchworth." Bromfield⁴ says: "Box is profusely abundant on most parts of Sidon Hill, in Highclere Park (Hants), scattered over its shelving sides as if quite spontaneous, and said to disperse itself freely by seed;" but he avers that it was certainly planted here. Thus the natural appearance now of the box on Box Hill, Surrey, is no sure proof of its being indigenous there.

Another locality where the box occurs apparently wild is the Chiltern Hills; as on the chalk downs⁵ between Ashridge and Berkhamstead, where there are some very old-looking trees. Near here, on the top of Dunstable Downs, there is a place named Boxstead. On the Chequers Court estate, about half a mile from Ellesborough Church, near Wendover, box has all the appearance of being indigenous⁶ over a considerable area. Mr. Raffety of High Wycombe tells me that box is thickest here in two valleys, known locally as Ellesborough Warren and Kimble Warren, the bushes being about 20 ft., with numerous seedlings of all ages. It extends up over the adjoining spur of the Chiltern Hills to an altitude of 500 feet, the chalk subsoil being near the surface, and the exposure almost due south-west. Messrs. Sprague and Hutchinson state⁷ that some of the stems are 8 in. in diameter, and that the only tree which has obtained a place amongst the box thickets is the elder.

There is a place named Boxe in Domesday Book for Herts, section xxviii.; but the village⁸ so-called no longer exists, being now part of Wymondley. Mr. H. Clinton-Baker tells me of a field at the Priory, Wymondley,⁹ around which is a broad

¹ Barrington, in *Phil. Trans.* lix. 23 (1769) quotes from *A Journey through England*, printed in 1722: "Box Hill was first planted by that famous antiquary the Earl of Arundel, with box wood, designing to have a house there; but want of water made him alter his resolution and build one at Albury hard by." This is erroneous, as the Earl of Arundel was only sixteen years old in 1602, when Box Hill was already covered with box and yew, according to the lease cited above.

² Ellis, *Timber Tree Improved*, 103 (1745), says that "great quantities of box were felled off the Chalky Downs near Dorking in 1716, which paid its owner several hundred pounds."

³ In *Journ. Bot.* xlv. 346 (1907).

⁴ In *Phytologist*, iii. 817 (1850).

⁵ Cf. W. G. Smith, in *Journ. Bot.* xxxix. 73 (1901).

⁶ Loudon, *Derby Arboretum*, 50 (1840), says: "There are extensive native woods of the box tree on the estate of Sir Robert Russell at Chequers in Buckinghamshire."

⁷ *Gard. Chron.* lii. 404 (1912). The southern end of Ellesborough Warren is Velvet Lawn, a favourite meet of the hounds.

⁸ Chauncy, *Hist. Antig. Herts.* ii. 126 (1826), says: "The Vill or Parish of Box was situated between the parishes of Stevenage, Chivesfield, and Walkerne; and this parish was called Box from a great wood which retains the name to this day." Boxbury Farm and Box Wood are in the parish of Walkern; but there are no box trees in these places at the present time.

⁹ It is worth recording here that a chestnut tree, mentioned in Domesday book, still survives at Wymondley. Mr. H. Clinton-Baker tells me that it is a mere shell, no less, however, than 19 ft. in diameter, and still bearing fruit.

belt (about 10 yards in width) of box trees, which average 20 ft. in height, some being 2 feet in girth. (A. H.)

REMARKABLE TREES

Though a native of countries much hotter than Britain, and known to most people only as a bush, box is capable of attaining large dimensions in England, and may under favourable circumstances become a small tree. The largest I have seen in this country are in the Hermitage Road in Hitchin, where there is a row of about forty trees, many of which attain 25 to 30 feet in height, and 2 to 2½ ft. in girth, the largest being 35 feet by 2 ft. 10 in. Mr. Seebohm informed me that this line of trees formerly grew on private property¹ which he bought, and opened a new road on which they now stand between an old wall and iron railings which protect them.

At Beckford Hall, Gloucestershire, there is a walk 3 yards wide on each side of which a line of box trees grow which are from 30 to 31 feet high and 20 to 30 inches in girth. A monastery once stood here, and the trees are supposed to be about 800 years old, which is probably twice or three times their real age.

At Boxwell Court,² Gloucestershire, the seat of the Rev. O. Huntley, a wood of box trees exists which must be of very great age. Mr. Huntley showed me in the will of his ancestor, Henry Huntley, dated 1556, the following passage: "I will that it shall be lawful for the said Anne my wife, to cut and fell all my boxe, reserving the young store, at any time or times at her pleasure within the space of the said five years." It is thus clear that 350 years ago this wood was looked on as a valuable possession; and that the trees were coppiced, as they are now. It is possible that they were planted by some monk or returned Crusader, and are not, as some have supposed, wild. This wood lies on a steep slope just below the level plateau of the Cotswolds at an elevation of 500 to 600 feet and extends for about 800 yards along the slope which faces south. They grow very thickly and form a dense shade under which nothing grows, and show every sign of having been regularly cut over and reproduced from the stool; in one place fresh plants have been planted in rows, 5 feet apart, which now form tall slender poles clean to 10 or 15 feet high, many of which have died from overcrowding. In other parts the shoots average 20 to 25 ft. high, and though the average girth is not above 6 to 8 in. yet there are a few stems of 2 ft. and over, the thickest that I measured being 2 ft. 10 in. and 3 ft. 4 in. in girth. Mr. Huntley tells me that, though an uncle of his is reputed to have sold a

¹ W. Wilshire, M.P., who owned this property, states in Loudon, *Gard. Mag.* xv. 236 (1839), that these box trees were, in 1839, sixty in number, forming a hedge about 180 ft. long. They then averaged 36 ft. in height, and 3 ft. 3½ in. in girth at 2 ft. from the ground; and were very old, thin, and ragged. They were supposed to have been planted as a border, and allowed to grow up through neglect; but their exact history was unknown. Cf. J. E. Little, in *Journ. Hitchin Nat. Hist. Club*, May 1891, who adds that in the park at Ilxton, near Hitchin, box is very luxuriant, forming tall hedges along the drives.

² Rudge, *History of the County of Gloucester* (1803), states: "Boxwell, anciently Boxewelle. This name is derived from a box wood of about 16 acres, within a warren of 40 acres, from which arises a considerable spring. This is the most considerable wood of the kind in England, excepting Boxhill in Surrey; and from the name, which has now been on record for more than seven centuries, it must have been of long standing."

Ray, *Syn.* ii. 310 (1696), speaking of box trees, says: "At Boxwel in Coteswold in Gloucestershire, and at Boxley in Kent, there be woods of them.—*Mr. Aubrey's Notes.*" Cf. p. 1727, note 5.

quarter of an acre for £70, between 1858 and 1863, yet now he can only get £1 a ton for the wood, and at that low price no one seems to want it. In parts of the wood where rides have been cut, or openings made by the falling of trees, seedlings spring up abundantly; but the growth of the shoots from the stool seems very slow, owing perhaps to the rabbits, which are hard to keep out.

Mr. Cedric Bucknall describes¹ another wood of box trees, between Wotton-under-Edge and Alderley, clothing the hill-side for a considerable distance, and with abundance of natural seedlings.

In Ireland perhaps the best specimens of box are those growing in the grounds of the Earl of Rosse at Birr Castle.

TIMBER

The wood of the box tree is dense and homogeneous, with a very fine grain; and is said to be the nearest approach to ivory of any wood known. Boxwood is unrivalled for wood-engraving, and is used for turnery and inlaying, and for making rules, scales, and other mathematical instruments. It is also employed in making shuttles and rollers that are used in textile factories. A good account of boxwood, with information about the best modes of felling, seasoning, and shipping, is given by Gamble,² who quotes largely from a letter written by Messrs. J. Gardner and Sons, Liverpool. Boxwood from the Caucasus, whence formerly the main supply was drawn, is now being replaced, except for the very best articles, on account of its increasing cost, by "West Indian boxwood,"³ by *Buxus Macowani* from South Africa, and by other woods, belonging to different and often quite unallied genera.

(H. J. E.)

¹ In *Journal of Botany*, xxxix. 29 (1901). Cf. also J. H. White, *Flora of Bristol*, 523 (1912).

² *Manual of Indian Timbers*, 592-593 (1902).

³ Sir David Prain, Director of Kew Gardens, informs me that "West Indian boxwood" is not really shipped from the West Indies, but from Venezuelan ports; and that its botanical origin is still unknown. It was erroneously stated in *Kew Bull.*, 1904, p. 11, to be *Tabebuia pentaphylla*, Bentham and Hooker, a Bignoniaceous tree, which is known in the West Indies as "white cedar." H. Stone, *Timbers of Commerce*, 169, plate xii. fig. 105, gives an account of the so-called "West Indian boxwood," which he confuses with "white cedar," although he rightly questions the accuracy of the determination of *Kew Bull.*, 1904, p. 11. "West Indian boxwood" is used for making parasol and umbrella handles, shuttles, rulers, thermometers, etc.—A.H.

CRATÆGUS

Cratægus, Linnæus, *Sp. Pl.* 475 (1753); Bentham et Hooker, *Gen. Pl.* i. 626 (1865); Koehne, *Deut. Dend.* 227 (1893); Sargent, *Trees N. Amer.* 363 (1905); Schneider, *Laubholzkunde*, i. 766 (1906).

Oxyacantha, Medicus, *Phil. Bot.* i. 150 (1789).

Azarolus, Borkhausen, *Först. Bot.* ii. 1224 (1803).

Mespilus, sub-genus *Cratægus*, Ascherson and Graebner, *Syn. Mitteleurop. Flora*, vi. pt. ii. 12 (1906).

TREES or shrubs, belonging to the order Rosaceæ, usually armed with simple or branched spines, which are either axillary accompanying a bud, or terminate a short shoot. Leaves usually deciduous, alternate, simple, stalked, usually lobed, serrate; stipules often foliaceous and persistent on the long shoots. Buds small, globose, with numerous imbricated scales.

Flowers, in corymbs, which are terminal on short lateral leafy branchlets; with quickly deciduous linear bracts and bractlets; pedicellate, regular, perfect; calyx superior, with an urceolate, campanulate, or obconic calyx-tube, and five lobes, which are reflexed after the flower opens and either fall off or persist enlarged on the fruit; petals five, inserted with the stamens on the edge of a disc lining the calyx-tube; stamens 5, 10, 15, 20, or 25, with filaments broad at the base and incurved; ovary composed of one to five carpels, concealed in the bottom of the calyx tube and adnate to it; styles, one to five, free, with dilated truncate stigmas; ovules two in each cell, erect. Fruit, a false berry or haw, usually umbilicate at the apex, and often crowned by the marcescent calyx-teeth, composed of the fleshy calyx-tube, which encloses one to five stones or nutlets, each containing one seed, the other ovule having aborted.

This genus is widely spread in the extratropical regions of the northern hemisphere, occurring in Europe, Asia Minor, Siberia, Himalayas, China, and Japan; and with numerous species in North America. Schneider admits about 150 species in all; but Sargent and other American botanists have already described over 500 species in America alone, most of which may be regarded as varieties or hybrid forms. At least sixty species are in cultivation, all of which are either shrubs or small trees, not coming within the scope of our work. The native Whitethorn, which is described below, is now usually considered to comprise two species.

Cratægus is closely allied to *Mespilus*, of which it has been made a section by some botanists. The following hybrids, one of which is doubtful, between the two genera are worthy of brief mention.

1. *Mespilus grandiflora*, Smith, *Exot. Bot.* i. 33, t. 18 (1814).

Mespilus lobata, Poiret, in Lamarck, *Encyc. Meth. Suppl.* iv. 71 (1816); W. J. Hooker, in *Bot. Mag.* t. 3442 (1835).

Mespilus Smithii, De Candolle, *Prod.* ii. 633 (1825); Loudon, *Arb. et Frut. Brit.* ii. 878 (1838).

Cratægus lobata, Bosc, *Nouv. Cours. Agric.* ii. 223 (1821).

Cratægus grandiflora, Koch, in *Verh. Ver. Bef. Gartenb.* i. 227 (1853).

Cratægus oxyacantho-germanica, Gillot, in *Bull. Soc. Bot. France*, xxiii. p. xiv. (1876).

Pyrus lobata, Nicholson, *Kew Hand-list Trees*, 195 (1894) (not Koch).

Cratæmespilus grandiflora, Camus, in *Journ. de Bot.* xiii. 326 (1899).

A tree, attaining about 25 ft. in height. Branchlets pubescent, with short aborted spines. Leaves very variable in shape, entire or three- to five-toothed near the apex, or five- to seven-lobed and finely serrate, pubescent beneath. Flowers large, white, fragrant like a hawthorn, solitary or two to five in a corymb; calyx segments lanceolate, soon reflexed; petals five; stamens twenty; styles one to four; disc lobed. Fruit ovoid or globose, reddish brown, $\frac{1}{2}$ in. in diameter, crowned by the sepals, with usually two or three nutlets, which are sterile.

This tree, the origin of which is unknown, is considered by most botanists to be an accidental hybrid between *Cratægus oxyacantha* and *Mespilus germanica*; but Koehne¹ considers it to be an independent species, possibly native of the Caucasus. Five apparently wild shrubs were found in 1875 at Saint-Sernin-du-Bois, near Autun, in Seine-et-Loire, in a hedge around the ruins of an old priory, by Dr. Gillot,² whose interesting article should be studied. This remarkable tree, of which there is a good specimen³ at Kew, near the Director's office, was in cultivation at Paris about 1800; and possibly earlier in England, as Loudon mentions old trees at Syon and other places near London.

2. Two very remarkable graft hybrids⁴ originated about 1885 in the garden of M. Dardar, at Bronvaux, near Metz; and have been propagated by Simon-Louis. On a very old medlar tree, that had been grafted on a stock of hawthorn, two peculiar branches⁵ were observed to arise just beneath the graft. One of these branches, from which has been propagated the form known as *Cratægo-Mespilus Dardari*,⁵ differed from the medlar in the branches being spiny, and the flowers in corymbs; while the leaves and fruit were like those of the medlar but smaller. The other branch, which has been propagated as *Cratægo-Mespilus Asnièresi*,⁶ was more like the hawthorn, the leaves being lobed and the flowers like *Cratægus monogyna* in form and arrangement; but the branchlets and leaves were pubescent as in the medlar. These two graft hybrids, which are now in cultivation at Kew, are said by Mr. Bean⁷ to be very different in appearance. The *Asnièresi* form has remained true to type, and is a small tree of great elegance and beauty. The *Dardari* form, according

¹ *Deut. Dend.* 230 (1893).

² *Cf. Rev. Hort.* lxxi. 470 (1899), where Dr. Gillot states that it resembles *Mespilus* more than *Cratægus*, and is of undoubted hybrid origin.

³ There are several trees in the Green Park, London, and a fine one at Tortworth.

⁴ The history of these graft hybrids has been given by Simon-Louis and by Bellair in *Revue Horticole*, lxxi. 403, 482, 530 (1899); and by Koehne, in *Gartenflora*, l. 628 (1901). R. P. Gregory, in *Gard. Chron.* l. 185, fig. 86 (1911), gives Baur's explanation of their anatomical structure.

⁵ A third branch was subsequently produced on the original tree at Bronvaux, also from the junction of the stock and scion; but on the opposite side to that occupied by the first two branches. It had at its base pure hawthorn; but was transformed towards the extremity into the *Asnièresi* form.

⁶ Jouin, in *Le Jardin*, 1899, p. 22.

⁷ Bean, in *Kew Bull.* 1911, p. 268, figs. 1 and 2.

to Mr. Bean, behaves to some extent like *Laburnum Adami*, and bore at Kew in 1911 three distinct kinds of foliage and flowers on the same specimen. One of its branches was like the *Asnièresi* form; another branch was a pure medlar; and all the other branches were the *Dardari* form. Neither of the two hybrids has as yet shown a branch of pure hawthorn. (A. H.)

CRATÆGUS MONOGYNA, HAWTHORN, WHITETHORN

Cratægus monogyna, Jacquin, *Fl. Austr.* iii. 50, t. 292, fig. 1 (1775); Willkomm, *Forstl. Flora*, 835 (1887); Mathieu, *Flore Forestière*, 162 (1897); Schneider, *Laubholzkunde*, i. 781 (1906).

Cratægus oxyacantha,¹ Linnæus, *Sp. Pl.* 477 (1753) (in part); Druce, *List of British Plants*, 26 (1908).

Cratægus oxyacantha, Linnæus, var. *monogyna*, Loudon, *Arb. et Frut. Brit.* ii. 834 (1838).

Cratægus oxyacantha, Linnæus, sub-species *monogyna*, Hooker, *Student's Flora*, 127 (1870).

Mespilus monogyna, Allioni, *Fl. Pedem.* ii. 141 (1785); Willdenow, *Enum. Pl. Hort. Berol.* i. 524 (1809); Ascherson and Graebner, *Syn. Mitteleurop. Flora*, vi. 2, p. 27 (1906).

A shrub or small tree, attaining occasionally about 40 ft. in height. Bark greyish, broken on the surface into small scales. Young branchlets glabrous or with scattered pubescence. Leaves, variable in shape and size, usually broadly ovate, averaging $1\frac{3}{4}$ in. long, and $1\frac{1}{2}$ in. wide at the broad almost truncate or occasionally cuneate base; pinnatifid with five or seven deep lobes, separated by narrow sinuses; margin serrate; upper surface with scattered white hairs; lower surface pale green, with similar pubescence mainly on the midrib and nerves; petiole slender, $\frac{1}{2}$ to 1 in. long, slightly pubescent.

Flowers, variable in number in the corymb; calyx-tube and pedicel pubescent; sepals five, triangular, soon reflexed, persistent on the fruit; petals five, usually white, but occasionally pink, even in the wild state;² stamens fifteen or twenty; style one.³ Fruit, ellipsoid or ovoid, reddish, with one stone, which is either smooth or marked with shallow furrows.

The seeds, when sown, do not germinate till the second year. The seedling⁴ has two obovate-oblong cotyledons, which are about $\frac{2}{3}$ in. long, $\frac{1}{4}$ in. broad, shortly stalked, glabrous, obscurely three-nerved, and raised above ground by a glabrous caulicle about 1 to $1\frac{1}{2}$ in. long. The pubescent stem bears alternate serrated leaves, the first three of which are small, cuneate, and three-lobed; those succeeding becoming larger and deeply five-lobed.

¹ *C. oxyacantha*, Linnæus, included both species; but this name was early limited to the two-styled species by Jacquin, who separated the one-styled species as *C. monogyna*. All botanists until lately have followed Jacquin's nomenclature of the two species, which is adopted by us. Recently much confusion has been caused by one or two writers, who restrict the name *C. oxyacantha*, Linnæus, to the one-styled species. These authors are obliged to use another name, *C. oxyacanthoides*, Thuillier, for the two-styled species.

² Briggs, *Flora of Plymouth*, 143 (1880), records a bush with pink flowers, and another with deep red flowers. In hedges near Cambridge shrubs with pink flowers are not uncommon.

³ *C. kyrtostyla*, Fingerhut, in *Linnaea*, iv. 372, t. iii. fig. 1 (1829), is a form of *C. monogyna*, in which the flowers have a peculiar curved or deflexed style. F. A. Lees, *Flora of W. Yorkshire*, 231 (1888), states that most old gnarled thorns in parks and pastures show this peculiarity.

⁴ Cf. Lubbock, *Seedlings*, i. 500, fig. 324 (1900), where the seedling of this species is described under the name *C. oxyacantha*.

This species is more pubescent than *C. oxyacantha*, has a differently shaped leaf, and is readily distinguishable, apart from the single style, in the flower and solitary stone in the fruit. It is apparently much more variable in the wild state than the other species; but some of the supposed varieties may be due to hybridising. Certain forms, which are plainly intermediate in various ways between the two species, are recognised as hybrids by continental botanists¹ under the names: *C. media*, Bechstein, *Diana*, i. 88 (1797); and *C. intermixta*, Beck, *Fl. Niederr. Oesterr.* ii. 1, p. 706 (1892).

The commonest hybrid form in England has leaves like those of *C. monogyna*, but with flowers having a glabrous calyx-tube and pedicel. White states² that there are several trees of this kind near Bristol, one of which on Leigh Down was noticed to be the last to bloom in 1881, a year remarkable for the abundant blossom of the hawthorn.

In south-eastern and southern Europe there are peculiar races or allied species, which are not in cultivation in this country, and need not be more than alluded to.³

The following varieties have arisen in cultivation:—

A. Differing from the type in habit.⁴

1. Var. *flexuosa*, Dippel, *Laubholzkunde*, iii. 459 (1893).

Cratægus oxyacantha, var. *flexuosa*, Loudon, *Arb. et Frut. Brit.* ii. 835 (1838).

Branches spinescent, dense, flexuose, twisted or like a corkscrew. This peculiar variety originated in Smith's nursery at Ayr, and is represented at Kew by a shrub about 15 ft. high.

2. Var. *salisburyifolia*, Nicholson, *Kew Hand-list Trees*, 205 (1894).

Cratægus oxyacantha, var. *salisburyifolia*, Späth, *Cat.*, No. 59, p. 61 (1884).

Branches similar to those of var. *flexuosa*, but without spines. Leaves with few and obtuse lobes somewhat like those of a Ginkgo tree in shape. This is represented at Kew by a shrub about 5 ft. high, which was planted in 1885.

3. Var. *pendula*, Dippel, *Laubholzkunde*, iii. 459 (1893).

Cratægus oxyacantha, var. *pendula*, Loudon, *Arb. et Frut. Brit.* ii. 832 (1838).

Branchlets pendulous. Several forms are known. One is said by Loudon to have been picked out of a bed of seedlings at Somerford Hall. Anderson, curator of the Chelsea Botanic Garden in 1830, obtained several pendulous varieties by grafting shoots which were taken from the witches' brooms, that are occasionally

¹ Focke, who describes the hybrid in Koch, *Syn. Deutsch. Flora*, i. 859 (1892), says that it is common in northern and central Germany, where it is more generally distributed in hedges and plantations than the true species.

² *Flora of Bristol*, 300 (1912).

³ *C. azarella*, Grisebach, *Spicil. Fl. Rum.*, i. 88 (1843) is a very pubescent form, which occurs in the Balkan States, Hungary, and Transylvania. *C. hirsuta*, Schur, *Enum. Fl. Trans.* 206 (1866), is very similar and widely distributed in the Mediterranean region. The following are peculiar local forms:—*C. Insegnae*, Bertolini, *Fl. Ital.* vii. 629 (1847), a native of Sicily; *C. granatensis*, Boissier, *Elenchus*, 41 (1838), wild on the Sierra Nevada in Spain; and *C. brevispina*, Kunze, in *Flora*, 1846, p. 737, a native of southern Spain.

⁴ In *Kew Hort.* 1899, p. 489, it is stated that a form without spines was found in 1893 as a seedling in M. Hémeray-Proust's nursery at Orleans; but I have not seen it in commerce. A compact dwarf spineless variety (var. *inermis compacta*) is advertised by Simon-Louis.

found as conglomerations of slender branches on old trees.¹ A weeping tree² at Edinburgh, reputed to be over 300 years old and a favourite of Queen Mary, survived till 1836; and from it was propagated a form known as var. *reginæ*, or Queen Mary's Thorn.

Var. *pendula variegata*, a weeping form with variegated leaves; and var. *pendula rosea*, a weeping shrub with pink flowers, are also in cultivation.

4. Var. *ferox*, Schneider, *Laubholzkunde*, i. 781 (1906).

Cratægus oxyacantha, var. *ferox*, Carrière, in *Rev. Hort.* 1859, p. 348.

Cratægus oxyacantha, var. *horrida*, Carrière, in *Flore des Serres*, xiv. 201, t. 1468 (1861); Regel, in *Act. Hort. Petrop.* i. 119 (1870); Lynch, in *Gard. Chron.* xxiv. 13, fig. 5 (1898).

Branches pendulous, and armed with tufts of several spines. Carrière, who was unaware of the origin of this variety, states that seedlings raised from its seeds in the Jardin des Plantes at Paris reverted to the ordinary form.

5. Var. *stricta*, Nicholson, *Kew Hand-list Trees*, 205 (1894).

Cratægus oxyacantha, var. *stricta*, Loudon, *Arb. et Frut. Brit.* ii. 832 (1838).

Fastigate in habit, with upright branches. This was discovered in 1826 in a bed of seedlings in Ronalds's nursery at Brentford, and was said by Loudon to resemble the Lombardy poplar in shape. A tree so named at Kew, about 20 ft. high, is pyramidal, with ascending branches, but is not fastigate. The truly fastigate form is sold by Smith of Newry and by Späth of Berlin.

6. Var. *ramulis aureis*, Nicholson, *Kew Hand-list Trees*, 205 (1894).

Var. *xanthoclada*, Zabel, ex Späth, *Cat. No.* 148, p. 91 (1911-1912).

Branchlets of a bronze colour, conspicuous in winter. A shrub of this at Kew, obtained from Simon-Louis in 1885, is about nine feet high.

B. Differing from the type in foliage.

7. Two variegated forms, mentioned by Loudon,—var. *foliis argenteis*, leaves mottled with white, and var. *foliis aureis*, leaves variegated with yellow,—are still in cultivation, but are of little ornamental value.

8. Var. *laciniata*, Dippel, *Laubholzkunde*, iii. 459 (1893).

Cratægus oxyacantha, var. *laciniata*, Loudon, *Arb. et Frut. Brit.* ii. 830 (1838); Regel, in *Act. Hort. Petrop.* i. 119 (1870).

Leaves deeply pinnatifid, with irregularly serrated lobes. This occurs in hedgerows, in company with the typical form. F. A. Lees states³ that in Yorkshire, Worcestershire, Lincolnshire, and Berkshire, it flowers much less freely than the other forms.

9. Var. *filicifolia*, Koehne, *Deut. Dend.* 238 (1893).

Cratægus oxyacantha, var. *filicifolia*, Van Houtte, *Flore des Serres*, xx. 51, t. 2076 (1874).

Leaves broad, fan-shaped, deeply divided into numerous curled segments. This beautiful variety, which resembles *Adiantum farleyense* in foliage, does not

¹ Cf. Loudon, *Gard. Mag.* ix. 596 (1833).

² Figured by Loudon, *Arb. et Frut. Brit.* ii. 833, fig. 556 (1838).

³ *Flora W. Yorkshire*, 231 (1888). It is recorded for Warwickshire by Bagnall, *Flora of Warwickshire*, 107 (1891).

seem to be in cultivation¹ in England. There are several other varieties² with peculiar cut leaves, none of which I have seen.

C. Differing from the type in flowers.

10. Var. *semperflorens*, Dippel, *Laubholzkunde*, iii. 460 (1893).

Crataegus oxyacantha, var. *semperflorens*, André, in *Rev. Hort.* liv. 354 (1882) and lv. 140, fig. 26 (1883).

A low bushy shrub, which numerous flowers, which appear more or less continuously throughout the season from May to autumn. This was found about 1879 at Poitiers by M. Bruant, in a bed of seedlings of the common hawthorn, and was subsequently propagated by grafting. A shrub at Kew is about 2 ft. high.

11. Var. *præcox*, Dippel, *Laubholzkunde*, iii. 459 (1893). Glastonbury Thorn.³

Crataegus oxyacantha, var. *præcox*, Loudon, *Arb. et Frut. Brit.* ii. 833 (1833).

Flowers, usually appearing at Christmas or early in January, and not ripening into fruit, the leaves being somewhat later; a second crop of flowers, which produce fruit, is borne in May and June. The original tree,⁴ which grew at Glastonbury, was mentioned by Turner in 1562, and by Gerard in 1597, and had the appearance of a very old tree, when it was seen by Withering⁵ in 1793. From this tree the variety was propagated. A specimen, growing near the Temperate House at Kew, is irregular in the time of flowering, which depends upon the nature of the season. Bean states⁶ that, with a mild November and December, the tree at Kew will flower about Old Christmas Day (6th January); but if cold weather sets in before New Year, the flowers may not open till March or April. In 1908, owing to the unusual warmth of the autumn, it was in full blossom in the first week of November, before the leaves had fallen, so that it was carrying flowers, fruit (derived from the flowers of the preceding May), and foliage simultaneously.

D. Differing from the type in fruit.

12. Var. *eriocarpa*, Dippel, *Laubholzkunde*, iii. 460 (1893).

Crataegus oxyacantha, var. *eriocarpa*, Loudon, *Arb. et Frut. Brit.* ii. 831 (1838).

¹ Var. *filicifolia* is advertised by Späth, *Cat.* No. 148, p. 91 (1911-12).

² Var. *pinnatifida*, Dippel, *Laubholzkunde*, iii. 458 (1893), is identified by Schneider, *Laubholzkunde*, i. 785 (1906), with *C. microphylla*, Koch, *Die Weissdorn*, 68 (1884), which is a Caucasian species, not apparently in cultivation, though it is given in the Kew Hand-list. Koehne, *Deut. Dendr.* 238 (1893), however, considers it to be a hybrid between *C. monogyna* and *C. oxyacantha*.

³ Chevallier, in *Ann. Soc. Agric. Sci. Départ. Indre et Loire*, xxx. 70 (1850), describes a similar sport of *Prunus spinosa*, to which is attached a similar legend. At the Château du Chabrol, St. Patrice, on the Loire, midway between Saumur and Tours, there is a large blackthorn, called *Pépine miraculeuse*, which flowers every year in the last week in December, even in the severest seasons. The legend is that St. Patrick, while on his way to Tours in A.D. 395, reposed one night in winter under the shade of this tree, which burst forth into flowers and leaves to shield him from the cold. The tree did not appear to be very old in 1850, but is now of considerable size, judging from a photograph sent me by M. Hickel. This curious variety, which may be named *Prunus spinosa*, var. *præcox*, does not seem ever to have been propagated.

⁴ Parkinson, *Theat.* 1025 (1640), mentions other trees of the same kind at Romney Marsh and at Nantwich. Plot, *Nat. Hist. Oxfordshire*, 159 (1705), mentions a very old tree, which flowered at Christmas, in Lord Norrey's park in Oxfordshire; but was uncertain whether it was a graft from the Glastonbury tree or an original specimen of the variety.

⁵ *Arr. Brit. Pl.* 459 (1793). Cf. Loudon, *Gard. Mag.* ix. 122 (1833). However, James Howel, *Dodona's Grove*, 55 (1644), implies that the original thorn was destroyed by Puritan fanatics, one of whom "was well served for his blind zeale, who, going to cut down an ancient white Hawthorne tree, which, because she budded before others, might be an occasion of Superstition, had some of the prickles flew into his eye and made him Monocular."

⁶ *Kew Bull.* 1908, p. 452. Cf. also J. W. White, *Flora of Bristol*, 302 (1912), who mentions a specimen at Ipswich, which flowered 14th November 1885, and another at Evesham, which was in flower on 26th November, 1899.

Fruit woolly pubescent. This variety is rare; but is occasionally found in the wild state, as in the Isle of Wight, where it is recorded by Bromfield.¹ It is said² to occur near Breslau, in Silesia.

13. Var. *maurianensis*, Didier, in *Bull. Soc. Dauph.* ix. 385 (1882).

Fruits very large, $\frac{1}{2}$ to 1 in. long, and $\frac{2}{3}$ in. or more wide. This variety was described from specimens found in Savoy, and occurs also in hedges near Toulon.³

Mr. J. W. White records⁴ two trees, with branches bending down under the weight of numerous large haws, which were found in 1909 near Bristol, one on a low cliff near Walton-by-Clevedon, the other in Chelvey Batch wood. The fruits were very handsome, and four times larger than the typical form, averaging $\frac{3}{8}$ in. long and $\frac{1}{2}$ in. wide.

As both *C. monogyna* and *C. oxyacantha* have been much confused, it is impossible to give an accurate account of their separate distribution. The common hawthorn, comprising both species, is a native of Europe, and of the mountains of Algeria and Morocco; and extends from Asia Minor and the Caucasus, through Armenia, Persia, and Afghanistan to the western Himalayas, where it grows between 6000 and 9000 feet elevation.⁵ It grows wild in Norway as far north as lat. 62° 55', in Sweden as far as Upsala, lat. 59° 52', and in Finland to lat. 61° 30'. In Russia, it is common in Livland, Kazan, and Orenburg, and throughout the southern provinces except in the Steppes. It occurs mainly in hedges, waste places, and on the margins of woods, ascending in the Alps to about 3000 feet altitude.

C. monogyna is by far the commoner of the two species in Britain, where it is found in hedges and woods from Moray and Islay southwards; and it is met with in all districts in Ireland. It is the most commonly planted hawthorn either for hedges or for ornament; and most of the large trees in parks are referable to this species, though some of them look as if of hybrid origin.

The hawthorn lives to a great age, probably to three or four hundred years.⁶ Old trees often grow irregularly, so that ribs are formed upon their stem, which assume a vertical or a spiral direction. As years go on, these rib-like projections become larger, and the intervening channels deeper. Ultimately, when decay begins at the heart and spreads outwards, the projecting parts become separated and appear to be a number of subordinate stems, which are, however, united at the base, and bear on their inner surface, instead of bark, remains of the decayed heart-wood.⁷

(A. H.)

¹ In *Phytologist*, iii. 288 (1848).

² Ascherson and Graebner, *Syn. Mitteleurop. Flora*, vi. pt. ii. 30 (1906).

³ Described as var. *macrocarpa*, Reynier, ex Albert and Jahandiez, *Plantes Vasc. du Var*, 185 (1908).

⁴ *Flora of Bristol*, 300 (1912), where these two trees are assigned to var. *splendens*, Druce, a name which cannot be retained, as var. *splendens*, Koch, *Dendrologie*, i. 159 (1869), much earlier in date, was applied to forms with pink and scarlet flowers. Mr. White identifies this large-fruited variety with *Oxyacanthus folio et fructu majore* from Oxfordshire of Merrett's *Pinax* (1667). Ray, *Syn.* 454 (1724), states that it was also found by Sherard in Northamptonshire.

⁵ The forms in southern Europe, northern Africa, and Asia, are apparently very distinct varieties or allied species; and require further study. Cf. Schneider, *Laubholzkunde*, i. 782 (1906).

⁶ Lees, in *Gard. Chron.* iii. 688 (1875), states that he counted over 300 annual rings in the stem of a tree about 1 ft. in diameter, that grew on the Malvern Hills.

⁷ Cf. Purchas, in *Journ. of Bot.* iii. 366 (1865), who points out that stems growing close together, which have commenced as independent trees in a hedge, are surrounded on all sides by bark, and are thus readily distinguishable from the peculiar stems described above. Lees, in *Gard. Chron.* iii. 688, figs. 142, 143 (1875), gives illustrations of trees with divided stems at Garnstone, Herefordshire, and at Upper Wyck, near Worcester.

CULTIVATION

The hawthorn, though it grows on almost all soils, succeeds best in a rich loam, and does well on strong clay. It is propagated by seeds, which as they lie over for a year, should be mixed with ordinary soil or sand in pits or heaps, where they are kept until the second year following, when they may be sown in February or March. Young plants should be removed from the seed bed at the end of the first year, and after standing in nursery lines for two years, be planted out. The varieties are budded or grafted on seedlings of the common species.

The most important use of the hawthorn is as a hedge plant. Though hedges appear to have been in use in England from the time of the Romans, they were not generally planted to enclose ordinary fields and meadows till about the end of the seventeenth century. Dr. Walker states¹ that the first hedges in Scotland were planted by Cromwell's soldiers in East Lothian and Perthshire.

Fine old hawthorns, with trunks of great girth and wide-spreading branches, exist in many parks throughout the country; and tall slender specimens are occasionally seen, drawn up in woods. We may mention a few, remarkable for age, though doubtless there are many quite as large that we have not heard of.

An immense old thorn, at Hethel in Norfolk, was first mentioned by Marsham, who, in a letter to the Bath Society about 1740, made its girth 9 ft. 1 in. at four feet from the ground. Grigor² states on the authority of H. Gurney, Esq., that the first Sir Thomas Beevor, who owned the place towards the end of the eighteenth century, put a railing round it, which was subsequently repaired, and the spreading limbs propped up by Mr. Gurney. Grigor says that the trunk measured 12 ft. 1 in. at one foot, and 14 ft. 3 in. at five feet, whilst the branches, though several large ones had been lost, spread over an area 31 yards round. Both the trunk and the large branches were then hollow, but the wood sound and hard. Sir Hugh Beevor in 1895 found it to be 13½ ft. at eighteen inches from the ground where the girth was least. Miss Eaton sent me a photograph in 1903 which showed branches supported by numerous props. Mr. Edwards, who photographed the tree in September 1912, tells me that the tree now consists of several stems formed by the splitting of the original trunk. The branches, which now measure 37 yards round, are sound and covered with leaves and fruit, though bearing many tufts of mistletoe. It is protected from cattle by a rail; and the branches are supported by numerous props (Plate No. 378).

In the park at Holwood House, Kent, Mr. A. D. Webster records³ a tree, which in 1888 was 14 ft. 6 in. in girth at three feet from the ground, above which it divided into six limbs, measuring at a yard from the fork, 4 ft. 2 in., 4 ft., 5 ft. 8 in., 2 ft. 8 in., 4 ft. 4 in., and 3 ft. 5 in. respectively. Its height was 42 ft., with a spread of branches 63 ft. in diameter. This tree was growing in strong clayey loam, and was in perfect health.

Mr. Edwin Lees described⁴ a remarkable hawthorn at Lenchford, in Worcester-

¹ *Essays on Nat. Hist.* 54 (1812).

² *Eastern Arboretum*, 282 (1841).

³ *Trans. Roy. Scot. Arbor. Soc.* xii. 311 (1889).

⁴ *Gard. Chron.* iii. 688, figs. 141, 146 (1875).

shire, which was 60 ft. high and 9 ft. in girth in 1875; and another in Downton Park, Herefordshire, which was over 50 ft. in height. He also mentioned others of considerable size in the same counties.

At Chideock Manor, Dorset, there is a remarkable thorn, about 25 ft. high and 6 ft. in girth, with wide-spreading branches and very pendulous branchlets, the diameter of the spread being about 40 ft.

In Lilford Park, Northamptonshire, where there are many fine thorns, I measured, in 1906, a tree no less than 51 ft. in height, but only 5 ft. in girth.

In the pleasure grounds of Hatfield House, Herts, there is a tree, which Henry measured in 1911 as 48 ft. by 3 ft. 8 in. In Ware Park, in the same county, Mr. H. Clinton Baker found in 1910 a tree 30 ft. by 12 ft. 5 in.

Within the walls of Rothesay Castle, in the island of Bute, there was growing in 1878 a remarkable thorn which Mr. James Kay described¹ as follows: "Though the tree was blown down thirty-nine years ago, it is still vigorous and healthy. The extreme length of the tree as it now lies, measuring from the original surface of the root, is 47 ft.; present vertical height, 28 ft.; circumference, three feet up, 6 ft. 8½ in.; four and a half feet up, 6 ft. 6½ in.; six feet up, 6 ft. 10 in." This tree dates from some time after 1685, when the Castle was burnt; and its age in 1878 did not probably exceed 190 years.

TIMBER

The wood of the hawthorn is white, often tinged with red; and is hard, heavy, and difficult to work, but with a fine grain and susceptible of a good polish. It is not much used, as it seldom can be obtained of sufficient size, and is usually spoiled by defects or knots. It is occasionally employed by turners, and was formerly found suitable for teeth of mill-wheels. Mr. W. G. Smith, who made many woodcuts for the *Gardeners' Chronicle*, states² that hawthorn wood is quite as good for engraving as ordinary boxwood, and possesses a far better colour. The best box, however, cuts a little smoother, as it has a somewhat closer grain. (H. J. E.)

CRATÆGUS OXYACANTHA, HAWTHORN, WHITETHORN

Cratægus oxyacantha,³ Linnæus, *Sp. Pl.* 477 (1753) (in part); Jacquin, *Fl. Austr.* iii. 50, t. 292, fig. 2 (1775); Loudon, *Arb. et Frut. Brit.* ii. 829 (1838); Willkomm, *Forstl. Flora*, 838 (1887); Mathieu, *Flore Forestière*, 163 (1897); Schneider, *Laubholzkunde*, i. 780 (1906).

Cratægus oxyacantha, var. *vulgaris*, De Candolle, *Prod.* ii. 628 (1825).

Cratægus oxyacantha, sub-species *oxyacanthoides*, Hooker, *Student's Flora*, 127 (1870).

Cratægus oxyacanthoides, Thuillier, *Fl. Envir. Paris*, 245 (1799).

Mespilus oxyacantha, Crantz, *Stirp. Austr.* i. 39 (1763); Allioni, *Fl. Pedem.* ii. 141 (1785); Willdenow, *Enum. Pl. Hort. Berol.* i. 524 (1809); Ascherson and Graebner, *Syn. Mitteleurop. Flora*, vi. 2, p. 25 (1906).

A shrub or small tree, similar to *C. monogyna* in bark and habit. Young branchlets glabrous. Leaves obovate or ovate, usually with three shallow lobes, the terminal

¹ *Trans. Roy. Scot. Arbor. Soc.* ix. 76 (1879).

² In *Gard. Chron.* iii. 689, note (1875), it is stated that figures 142 and 143 on p. 688 were engraved on hawthorn wood.

³ Cf. p. 1733, note 1.

one being often lobulate; margin irregularly serrate; upper surface dark green, shining, glabrous; lower surface pale green, glabrescent or slightly pubescent on the midrib; petiole slender, usually glabrous.

Flowers, variable in number in the corymb; peduncle, pedicel, and calyx-tube glabrous; sepals five, triangular, spreading, persistent on the fruit; petals five, white; stamens fifteen or twenty; styles usually two, rarely in some flowers one or three. Fruit ovoid or globose; stones two or three, rarely one, flattened on the inner surface, convex with deep longitudinal furrows on the outer surface.

This species is very distinct in appearance, and in England as a rule comes into flower a fortnight earlier than *C. monogyna*.

VARIETIES

This species is apparently much less variable in the wild state¹ than *C. monogyna*, but has given rise to some remarkable garden forms.

1. Var. *multiplex*, Loudon, *Arb. et Frut. Brit.* ii. 832 (1838).

Var. *flore pleno albo*, Rodigas, in *Flore des Serres*, xv. t. 1509, fig. 2 (1862).

Crataegus monogyna, var. *alba plena*, Rehder, in Bailey, *Cyc. Amer. Hort.* i. 396 (1900).

Flowers white, double, produced in great profusion and dying off a beautiful pink colour.² This variety, the origin of which is unknown, differs little from the type in other respects, having two-styled flowers with glabrous pedicels and calyx-tubes, and glabrescent three-lobed leaves.³

2. Var. *rosea*, Loudon, *Arb. et Frut. Brit.* ii. 832 (1838).

Petals pink, with white claws; in other respects similar to the type. This is a single pink variety, which is occasionally found wild.

3. Var. *punicea*, Loddiges, *Bot. Cat.* t. 1363 (1828); Loudon, *Arb. et Frut. Brit.* ii. 832 (1838).

Var. *flore punicea*, Rodigas, in *Flore des Serres*, xv. t. 1509, fig. 2 (1862).

Petals larger than in var. *rosea*, dark red and without white on the claws. This is the handsome single crimson variety, which was first raised in Scotland, and afterwards propagated by Loddiges, who budded it upon the common whitethorn.

4. Var. *Gumpperii bicolor*, Van Houtte, in *Fl. des Serres*, xvi. t. 1651 (1866).

Flowers single; petals white, edged with a pink margin. This originated at Stuttgart about 1860, and is probably of hybrid origin, as the flowers, while having a glabrous calyx-tube, bear only one style.

¹ Var. *integrifolia*, Wallroth, *Sched. Crit.* 219 (1822), a name given to shrubs having obovate leaves with three very shallow lobes, can scarcely be retained as a variety, as such leaves are common in the typical form of the species. Similarly, var. *auriculata*, Dippel, *Laubholzkunde*, iii. 457 (1893), said to have persistent large stipules, is doubtfully distinct, as the retention of the stipules depends on the vigour of the branches, and is common enough in the ordinary form of the species.

² Späth, *Cat.* No. 148, p. 91 (1911-1912), advertises var. *candido-plena*, a new variety with double flowers that remain pure white.

³ M'Nab, in *Trans. Bot. Soc. Edin.* vi. 284 (1860) gives an account of a tree with double white flowers in the Edinburgh Botanic Garden, which retained most of its leaves during the preceding winter, some remaining green till 12th May 1859. It then flowered and produced normal single flowers.

5. Var. *punicea flore pleno*, Loudon, *Arb. et Frut. Brit.* ii. 832 (1838), and *Trees and Shrubs*, 377 (1842).

Var. *flore rubro pleno*, Rodigas, in *Flore des Serres*, xv. t. 1509, fig. 3 (1862).

Flowers double, pink. This is said by Loudon to have been imported about 1832 by Masters of Canterbury, and to bear flowers not so brilliant in colour as the single crimson variety. It differs from typical *C. oxyacantha* in the pubescent leaves and calyx-tube, and is possibly a hybrid.

6. Var. *coccinea flore pleno*, Paul, in *Florist and Pomologist*, vi. 117 (1867).

Var. *floribus coccineis plenis*, Lemaire, in *Illust. Hort.* t. 536 (1867).

Crataegus monogyna, var. *Pauli*, Rehder, in Bailey, *Cyc. Amer. Hort.* i. 396 (1900).

Flowers double, deep scarlet. This originated about 1858 in Mr. Christopher Boyd's garden near Waltham Cross, as a single branch on a tree of the double pink variety, which was about 25 years old and nearly 30 feet high. This branch was observed to bear flowers of a deep scarlet colour, year after year, whilst all the other branches on the tree continued to produce flowers of the original pink colour. It was propagated by Messrs. Paul, who showed it at the International Horticultural Exhibition in 1866, under the name "Paul's New Double Scarlet Hawthorn," by which it is still known.

7. Var. *Gireoudi*, Späth, *Cat.* No. 104, p. 89 (1899-1900).

Young shoots pink, bearing new leaves, which are mottled with white and pink. This is represented at Kew by a spreading bush about 6 ft. high, received from Späth in 1899.

8. Var. *aurea*, Loudon, *Arb. et Frut. Brit.* ii. 831 (1838).

Var. *xanthocarpa*, Lange, *Rev. Spec. Crategi*, 71 (1897).

Fruits yellow. This variety, which has been in cultivation over a hundred years, bears freely and is very showy.

9. Var. *leucocarpa*, Loudon, *Arb. et Frut. Brit.* ii. 831 (1838).

Fruit white. Plot, *Nat. Hist. Oxfordshire*, 158 (1705), mentions¹ a tree with white haws in a hedge near Bampton; but it does not appear to have been propagated, and this variety was unknown to Loudon.

The following is either a geographical form or a closely allied species:—

10. *Crataegus polyacantha*, Jan, *Elench. Hort. Parm.* 8 (1826).

Crataegus oxyacantha, sub-species *monogyna*, var. *polyacantha*, Nicholson, *Kew Hand-list Trees*, 343 (1902).

Leaves small, about $\frac{3}{4}$ in. long and broad, tri-lobed. Young branchlets, petioles, peduncles, pedicels, and calyx-tubes densely covered with white woolly pubescence. This is a small shrub, native of Sicily and Calabria. It is in cultivation at Kew.

¹ Cf. Ray, *Syn. Meth.* 453 (1724). A form with fruit larger than usual, occurring in the south of France and Switzerland, has been distinguished as var. *macrocarpa*, Le Grand, *Stat. Bot. Forez*, 119 (1873), ex Rouy and Camus, *Flore de France*, vii. 4 (1901), identical with *C. macrocarpa*, Hegetschweiler, *Fl. Schweiz*, 464 (1840).

DISTRIBUTION

C. oxyacantha is widely spread throughout Europe, occupying nearly the same territory as *C. monogyna*, but being much less common. Willkomm believes it to be more prevalent in the north than in the south of Europe. In France, according to Mathieu, it does not grow in the region of the olive; while elsewhere it is comparatively rare, and scarcely ever attains the dimensions of a tree. I saw it in 1912 in the interior of the Forest of Orleans, forming a large shrub, and growing in shade, as it does in the Gamlingay Wood, near Cambridge.

It is doubtfully wild in Scotland and Ireland; and is apparently indigenous only in the midland, eastern, and south-eastern counties of England. It is recorded for many stations in Kent, Surrey, Middlesex, Oxfordshire, and Cambridgeshire. It is not mentioned as a native plant for the northern or western counties in any of the published floras in which the two species are distinguished. In England, as far as we know, it is usually a shrub; and we have no records of any large trees of this species.

(A. H.)

SALIX

Salix, Linnæus, *Sp. Pl.* 1015 (1753); Forbes, *Salic. Woburn.*, 1-294 (1829); Andersson, *Monog. Salic.* 1-180 (1863), and in De Candolle, *Prod.* xvi. 2, p. 191 (1868); Bentham et Hooker, *Gen. Pl.* iii. 411 (1880); Buchanan White, in *Journ. Linn. Soc. (Bot.)* xxvii. 333-457 (1890); Camus, *Saules d'Europe*, 9-40 (1904); Schneider, *Laubholzkunde*, i. 23 (1904).

TREES or shrubs, with scaly bark, and slender terete branchlets, which are often easily separated at the joints. True terminal buds are not developed,¹ the top of the branchlet dying off in summer, and leaving a minute scar close to the uppermost axillary bud, which prolongs the branch in the following season; buds apparently covered by one scale, which is composed of two scale-like leaves fused together, as indicated by their keeled margins. Leaves deciduous,² alternate, rarely sub-opposite, simple, variable in shape, penni-nerved, stalked; stipules oblique, serrate, either small and early deciduous, or large, leafy, and persistent, often conspicuous on barren vigorous young branches. On branches from which the leaves have fallen the leaf-scars are crescentic and 3-dotted, and accompanied on each side by a minute stipular scar.

Flowers, appearing in some species before the leaves, in others after the leaves, dioecious, in catkins, each of which terminates a short shoot, and bears numerous flowers on a slender axis; each flower, with one or two honey-glands, placed front and back at its base, and subtended by a scale, which is usually entire in margin. Staminate flowers, with two or three to twelve stamens, inserted on the base of the scale, with slender filaments, free or more or less connate, and two-celled anthers opening longitudinally. Pistillate flowers; ovary free, stalked or sessile, one-celled, with four to eight ovules on each of the two placentæ; crowned by a style, which is often extremely short or obsolete, with two stigmas, which are either entire or bifid. Fruit, an acuminate capsule, separating when ripe into two recurved valves. Seeds minute, narrowed at the ends, dark brown or nearly black, furnished with long silky hairs.

About 160 species of *Salix* are known, distributed from the Arctic regions southwards to the Andes of Chile in the New World, and to South Africa, Madagascar, Himalayas, Burma, Malay Peninsula, Java, and Sumatra in the Old World. Most of the species are shrubs or small trees; and in the following account we have only dealt with the few species in cultivation which attain a large size, including *S. Caprea*, on account of its interest to foresters. These may be distinguished as follows:—

¹ However, in § *Chamaelia*, Dumortier, in *Bijdr. Naturk. Wetensch.* i. 56 (1826), which includes Arctic and Alpine under-shrubs, like *S. reticulata*, Linnæus, there are true terminal buds, giving rise to catkins in the following year. The species of this section in some respects are intermediate between *Salix* and *Populus*.

² *S. Bonplandiana*, H. B. K., a native of Mexico, is said to have persistent leaves. Cf. Dode, in *Bull. Soc. Dend. France*, 1909, p. 151.

I. *Leaves ovate or oval.*

1. *Salix Caprea*, Linnæus. See p. 1745.
Leaves oval, elliptic or ovate, 2 to 3 in. long, $1\frac{1}{2}$ in. broad, irregularly crenate; lower surface bluish grey, tomentose.
2. *Salix pentandra*, Linnæus. See p. 1747.
Leaves fragrant when bruised, ovate to ovate-lanceolate, about 3 in. long and $1\frac{1}{4}$ in. broad, abruptly acuminate, minutely serrate, glabrous on both surfaces.

II. *Leaves lanceolate.*

A. *Mature leaves not ciliate in margin, green above, green or glaucous beneath.*

* *Leaves broadly lanceolate, with coarse serrations, which are not close together.*

3. *Salix speciosa*, Host. See p. 1756.
Leaves, broader than in *S. fragilis*, 4 to 6 in. long, $1\frac{1}{4}$ to $1\frac{1}{2}$ in. broad, glabrous except for a few scattered hairs on the slightly glaucous under surface. Young branchlets pubescent or glabrescent.
4. *Salix fragilis*, Linnæus. See p. 1754.
Leaves about 4 in. long, $\frac{3}{4}$ to 1 in. broad, glabrous except for a few scattered hairs on the glaucous under surface. Young branchlets pubescent.
- ** *Leaves narrowly lanceolate, with fine close serrations.*
- (a) *Young branchlets crimson, glabrous; clay-coloured in the second year.*
5. *Salix decipiens*, Hoffmann. See p. 1755.
Leaves, 2 to 3 in. long, $\frac{1}{2}$ to $\frac{3}{4}$ in. broad, similar to those of *S. fragilis*, but smaller and green beneath.
- (b) *Young branchlets green, becoming a brilliant yellow in winter and the following year.*
6. *Salix vitellina*, Linnæus. See p. 1768.
Leaves, 2 to $2\frac{1}{2}$ in. long, $\frac{3}{8}$ to $\frac{1}{2}$ in. broad, green above, glaucous beneath; with scattered appressed hairs, sparse above, more abundant beneath. See No. 11A.
- (c) *Young branchlets green, becoming olive green or brownish grey in the second year.*
7. *Salix babylonica*, Linnæus. See p. 1749.
Leaves, $2\frac{1}{2}$ to 4 in. long, $\frac{1}{2}$ to $\frac{3}{4}$ in. wide, tapering to a long slender filamentous apex; when mature, glabrous and glaucous beneath. Branchlets pendulous, always injured in England by spring frost.
8. *Salix elegantissima*, Koch. See p. 1751.
Leaves similar to those of *S. babylonica*, but broader, and more coriaceous, and less glaucous on the lower surface. Branchlets pendulous, uninjured in England by spring frost.
9. *Salix Salamonii*, Carrière. See p. 1750.
Leaves similar to those of *S. babylonica*, but with scattered appressed long hairs on both surfaces. Branches ascending, with pendulous branchlets, which are not injured by frost in England.

B. *Mature leaves ciliate in margin, covered more or less on both surfaces with appressed silky hairs.*

10. *Salix alba*, Linnæus. See p. 1759.
Leaves 2 to $2\frac{1}{2}$ in. long, $\frac{3}{8}$ to $\frac{1}{2}$ in. wide, covered with silky pubescence, densest on the whitish under surface. A wide-spreading male or female tree, with pendulous or spreading branchlets; ovary and fruit sessile.
11. *Salix cœrulea*, Smith. See p. 1763.
Leaves similar to those of *S. alba*, but thinner in texture, more translucent, less pubescent, the lower surface being bluish grey and not white. A pyramidal female tree, with ascending branches and erect terminal branchlets; ovary and fruit shortly pedicellate.
- 11A. *Salix vitellina*, Linnæus. See No. 6.
Leaves occasionally ciliate till autumn, with both surfaces more or less appressed-pubescent. This is readily distinguishable by the bright yellow branchlets in winter. (A. H.)

SALIX CAPREA, SALLOW, GOAT WILLOW

Salix Caprea, Linnæus, *Sp. Pl.* 1020 (1753); Loudon, *Arb. et Frut. Brit.* iii. 1561 (1838); Anderson, *Monog. Salic.* 75 (1863), and in De Candolle, *Prod.* xvi. 2, p. 222 (1868); Willkomm, *Forstliche Flora*, 487 (1887); Buchanan White, in *Journ. Linn. Soc. (Bot.)* xxvii. 385 (1890); Mathieu, *Flore Forestière*, 465 (1897); Camus, *Monog. des Saules*, 202 (1904).

A small tree, occasionally attaining 40 ft. in height. Bark smooth and greenish at first, ultimately ridged and fissured. Young branchlets, with a minute tomentum, becoming more or less glabrescent in the second year. Buds ovoid-conic, minutely tomentose or glabrous. Leaves oval or elliptic, about 2 to 3 in. long and $1\frac{1}{4}$ to $1\frac{3}{4}$ in. broad; apex acuminate, with the point usually directed to one side; base broadly cuneate, often unequal; upper surface light green, slightly shining, glabrous except for slight pubescence on the midrib and nerves; lower surface bluish grey, reticulate, covered with a whitish tomentum; margin irregularly crenulate, undulate, or rarely almost entire; petiole more or less tomentose; stipules oblique, reniform or half cordate, dentate.

Flowers appearing early, before the leaves; catkins sub-sessile, with scale-like leaves at the base, very silky, on account of the spatulate scales, brown or blackish towards the apex, and pubescent with long hairs. Staminate flowers; stamens two, free, glabrous. Pistillate flowers; ovary tomentose on a long pedicel, much surpassing the gland in length; style short, with two stigmas, which are usually emarginate or rarely bifid. Capsules on long pedicels, narrow, elongated, covered with greyish silky hairs.

VARIETIES AND HYBRIDS

I. *S. Caprea* is variable in the wild state. The catkins, which are usually sessile or sub-sessile, are occasionally provided with leafy peduncles. The branchlets and

buds, which are normally glabrous, are occasionally pubescent. Varieties, differing in the leaves, have been distinguished:—

1. Var. *orbiculata*, Kerner, in *Verh. Zool. Bot. Ges. Wien*, x. 248 (1860). This is the typical form of the species, in which the leaves are broadly oval, slightly cordate at the base, and with the apex bent to one side.

2. Var. *elliptica*, Kerner, *loc. cit.* Leaves elliptic and tapering at both ends. This is said to be the more common form in northern and mountainous districts.

3. Var. *sphaelata*, Wahlenberg, *Fl. Carpat.* 319 (1814).

Var. *alpina*, Gaudin, *Fl. Helv.* vi. 240 (1830).

Salix sphaelata, Smith, *Brit. Bot.* iii. 1066 (1805), *Eng. Bot.* t. 2333 (1812), and *Eng. Flora*, iv. 224 (1828); Loudon, *Arb. et Frut. Brit.* iii. 1563 (1838).

Leaves small, tomentose on both surfaces. This is an alpine form, which occurs in the Highlands of Scotland.

4. Var. *pendula*, Petzold and Kirchner, *Arb. Musc.* 576 (1864).

Salix Kilmarnocki, Nicholson, *Kew Hand-list Trees*, ii. 213 (1896).

Pendulous in habit, usually grafted on a stock about 4 ft. high, and forming a weeping shrub, which is known as the Kilmarnock Willow. This was discovered¹ in 1840 on the banks of the river Ayr, and was propagated by Lang, nurseryman at Kilmarnock. The original tree died of old age about 1884.

II. *S. Caprea* is closely related to both *S. cinerea* and *S. aurita*, which are bushy species. Intermediate forms, which are often difficult to discriminate, have been referred to the following hybrids:—

5. *Salix Reichardtii*, Kerner, in *Verh. Zool. Bot. Ges. Wien*, x. 249 (1860).

This hybrid between *S. Caprea* and *S. cinerea* is rare, only a few examples from Perthshire, Fifeshire, Worcestershire, and Kent being recorded by Buchanan White. Both parents are common; but they do not flower at the same time, and are rarely met with together, as *S. Caprea* is most frequent in woods, whilst *S. cinerea* grows chiefly on river banks.

6. *Salix capreola*, Kerner, *ex* Andersson in De Candolle, *Prod.* xvi. 2, p. 223 (1868).

This hybrid between *S. Caprea* and *S. aurita* is also rare, as the periods of flowering of the two species are not identical. There are pistillate specimens at Kew from Derbyshire and Surrey; and Buchanan White mentions other localities in Perth, Worcestershire, and Somerset.

DISTRIBUTION

The common sallow or goat willow is widely distributed, occurring in Europe, the Caucasus, Siberia, Amurland, Manchuria, and Korea. In Europe it exists in every country, extending as far north as Iceland and Lapland, and as far south as southern Spain, Italy, and Greece. It is most commonly found in woods on the plains and lower hilly regions, but reaches 3300 feet elevation in Norway and 4500 feet in the Carpathians. It grows on almost all soils, on those which are moist, marshy, or even peaty, as well as in dry rocky or stony ground. It attains its largest

¹ Cf. Rev. Dr. Landsborough, in *Ann. Kilmarnock Glenfield Ramblers' Soc.*, 1893-1894, p. 20.

size in East Prussia, Lithuania, and the Russian Baltic provinces, where, according to Willkomm, it is often a fine tree, 30 to 50 ft. in height. It is naturally regenerated by seed, and when cut down produces vigorous coppice shoots. It can be propagated by cuttings and by sets. (A. H.)

The sallow is common in all parts of the British Isles, growing in woods and copses, and in waste places, but rarely attains a large size. It is often 20 to 30 ft. in height, and sometimes produces a trunk a foot in diameter, but seems to be a short-lived tree. The finest which I have seen is growing by the roadside two miles below the lodge at Guisachan, Inverness-shire, and measured in 1910 about 50 ft. by 6 feet. It is the only willow which commonly grows from seed, and in some of my plantations is so abundant that it may be called a forest weed.

It is usually looked upon by foresters as a useless tree; but it has proved valuable in fixing loose and shifting soil on river embankments and similar situations, as it is so readily propagated by cuttings. Mitchell¹ says: "It is the best underwood that we have. It makes good fences, and sheep hurdles made of it will always last a year or two longer than those made of hazel; and no soil or situation comes wrong to it, wet or dry." In Sussex it is used for making truck-baskets and handles of rakes, and also for fencing, as it is light and tough, and splits easily.²

Though the wood is of a nice pinkish colour, it is too small, as a rule, to have any recognised value. In northern Russia (as well as formerly in Scotland) the bark, which contains 7 per cent of tannin, is sometimes used for tanning leather.

(H. J. E.)

SALIX PENTANDRA, BAY WILLOW

Salix pentandra, Linnæus, *Sp. Pl.* 1016 (1753); Loudon, *Arb. et Frut. Brit.* iii. 1503 (1838); Andersson, *Monog. Salic.* 35 (1863), and in De Candolle, *Prod.* xvi. 2, p. 206 (1868); Willkomm, *Forstliche Flora*, 475 (1887); Buchanan White, in *Journ. Linn. Soc. (Bot.)* xxvii. 359 (1890); Mathieu, *Flora Forestière*, 449 (1897); Camus, *Monog. des Saules*, 84 (1904).
Salix fragrans, Salisbury, *Prod.* 393 (1796).

A tree, occasionally attaining 30 to 40 ft. in height, but often shrubby in the wild state. Young branchlets glabrous, dark brown, shining as if varnished. Buds ovoid, pointed, dark brown, shining, viscid. Leaves fragrant when bruised, ovate, ovate-oblong, or ovate-lanceolate, averaging 3 in. long and 1¼ in. broad, glutinous when young, coriaceous when fully grown; rounded at the base, abruptly acuminate at the apex; glabrous on both surfaces, dark green and very shining above, pale and dull beneath; margin closely and finely serrate, the serrations tipped with dark red glands; petiole, about ½ inch long, glabrous, with two or three glands near its junction with the blade, and expanded at its origin from the branchlet, where there are one or two glands probably representing stipules.

Catkins, appearing with or after the leaves, terminating a branchlet which bears four or five leaves, spreading; axis pubescent. Staminate catkins 1½ in. long, densely

¹ *Dendrologia*, 56 (1827). Cf. Smith, *Eng. Flora*, iv. 227 (1828), who states that the wood and branches make the best hurdles, being tough, flexible, and durable. The wood was also used for the cutting-boards of shoemakers.

² *Gard. Chron.* xlv. 19 (1909).

crowded with flowers; scales pubescent at the base; stamens usually five, rarely four to ten, unequal in length, with long hairs on the base of the filaments; and with two glands, the one beneath the scale often three-lobed, the other quadrate or broadly crescentic. Pistillate catkins, $1\frac{1}{2}$ in. long; scales about half as long as the ovary, fringed with long hairs; ovary stalked, glabrous, about $\frac{1}{5}$ in. long, narrowly conic-subulate, with a short style, dividing into two arms, each of which is bifid; glands¹ two, one minute beneath the scale, the other quadrate and half the length of the pedicel. Capsules, $\frac{1}{4}$ inch long, on distinct pedicels, glabrous, narrow and elongated.

This species varies in the size and shape of the leaf, broad-leaved and narrow-leaved forms being distinguished by Andersson as vars. *latifolia* and *angustifolia*; but intermediate forms are common. Buchanan White states that in Britain, *S. pentandra* is a bushy shrub in the wild state, but that when cultivated, it becomes a tree with broader and larger leaves than those of the wild plant.

The bay willow is a very distinct-looking species, on account of its broad glabrous shining leaves, which resemble those of a *Prunus*; but is readily recognised to be a willow by its buds with a single scale. The flowers are fragrant, with an odour similar to that of the bay or true laurel (*Laurus nobilis*); and the leaves exhale the same fragrance, especially when bruised.

The following hybrids have *S. pentandra* as one of the parents:—

1. *Salix Meyeriana*, Rostkovius, ex Willkomm, *Berlin Baumz.* 427 (1811).

Salix cuspidata, Schultz, *Prod. Fl. Starg. Suppl.* 47 (1819); Borrer, in Smith and Sowerby, *Eng. Bot. Suppl.* v. tt. 2961-2962 (1863); Buchanan White, in *Journ. Linn. Soc. (Bot.)* xxvii. 360 (1890).

Salix tinctoria, Smith, in Rees, *Cycl.* xxxi. No. 13 (1815).

Leaves similar to those of *S. pentandra*, but narrower and more cuspidate at the apex. Pistillate catkins more slender and more tapering, and bearing narrower and more cylindrical capsules with longer pedicels. Stamens usually four.

This hybrid, of which the parents are supposed to be *S. pentandra* and *S. fragilis*, is said to be somewhat common on the Continent; but in England is rare in the wild state. It is recorded as a pistillate plant in Shropshire by Buchanan White. There are also specimens in the Kew Herbarium collected in 1895 on Wybunbury Bog in Cheshire by Linton. Dr. Moss adds to this distribution Herefordshire and Westmoreland in England, and Co. Mayo and Co. Kildare in Ireland; and tells me that it is occasionally planted in osier beds in Cambridgeshire and Suffolk. There is a fine tree in the Glasnevin Botanic Garden, about 40 feet high by 4 ft. in girth in 1912. Sir F. Moore states that it was obtained from Smith of Worcester, as the Purple King Willow, a name given to it on account of its purplish shoots. He adds that it is a quick grower, flowering early in spring, with beautiful large staminate catkins, the twigs being useful for house decoration.

2. *Salix hexandra*, Ehrhart, *Beit.* vii. 138 (1791); Buchanan White in *Journ. Linn. Soc. (Bot.)* xxvii. 361 (1890).

Salix Ehrhartiana, Smith, in Rees, *Cycl.* xxxi. No. 10 (1815).

Leaves lanceolate, long acuminate at the apex, silky pubescent at first, but

¹ Fraser, *Proc. Roy. Hort. Soc.* xxxv. p. cxv (1909), showed specimens of flowers of *S. pentandra*, with proliferation of the posterior gland, giving rise to two or three additional pistils.

soon becoming glabrous; dark green and very shining on the upper surface; minutely glandular-serrate; petiole slender, nearly $\frac{1}{2}$ in. long. Stamens four to six.

This hybrid, the parents of which are supposed to be *S. pentandra* and *S. alba*, is known on the Continent in the staminate form. Buchanan White refers to it two specimens: one, a shrub with pistillate catkins, growing near Duddingston, Edinburgh, and the other, a barren specimen from a bush at Restennet, near Forfar. It has recently been found¹ in the Lake District in Cumberland and Westmoreland.

S. pentandra is a native of nearly the whole of Europe—except the extreme south—the Caucasus, and northern Asia, as far east as Kamtschatka and Amurland, and apparently extending to the province of Yunnan, in China. It grows mainly on river banks, and in marshy places, ascending in peat mosses in the Alps to 4000 ft. elevation. It grows in similar situations in Britain² from Argyle and Moray southwards to Derbyshire, ascending in Northumberland³ to 1300 ft. In Ireland,⁴ it is frequent and native in the north, becoming less common southwards, till in Kerry and Cork it appears only as an introduction. (A. H.)

The bay willow makes a handsome tree, with very distinct foliage, but is rather slow in growth. The finest specimens we have seen are:—one at Kew, on the lawn near the Palm House, which measured, in 1907, 58 ft. by 9 ft. 8 in. at eighteen inches above the ground, its trunk forking at three feet. Another at Woburn was 50 ft. by 5 ft. in 1908, with a short bole. A handsome tree at Beauport, Sussex, measured in 1911 about 35 ft. by 6 ft., with a bole 6 ft. long, another near the keeper's lodge not being quite so large. (H. J. E.)

SALIX BABYLONICA, WEEPING WILLOW

Salix babylonica, Linnæus, *Sp. Pl.* 1017 (1753); Loudon, *Arb. et Frut. Brit.* iii. 1507, and iv. 2588 (1838); Andersson, *Monog. Salic.* 50 (1863), and in De Candolle, *Prod.* xvi. 2, p. 212 (1868); Willkomm, *Forstliche Flora*, 471 (1887); Mathieu, *Flore Forestière*, 453 (1897); Burkill, in *Journ. Linn. Soc. (Bot.)* xxvi. 526 (1899); Camus, *Monog. des Saules*, 65 (1904).

Salix pendula, Moench, *Meth.* 336 (1794).

Salix propendens, Seringe, *Saules de la Suisse*, 73 (1815).

Salix Napoleonis, Schultz, *Arch. Fl.* 239 (1856).

A tree, attaining 30 to 40 ft. in height, with rough ridged bark, and usually with a short trunk, and wide-spreading branches, the ultimate branchlets being very long and pendulous. Branchlets slender, glabrous except near the nodes. Leaves linear-lanceolate, about $2\frac{1}{2}$ to $3\frac{1}{2}$ in. long, and $\frac{1}{2}$ to $\frac{3}{4}$ in. broad, tapering at the apex into a long slender acuminate thread-like point, cuneate at the base, slightly pubescent when young, perfectly glabrous when fully grown, bright green and shining above, pale and covered with a glaucous bloom beneath; margin finely serrate, the serrations often ending in minute sharp incurved points; petiole $\frac{1}{6}$ in. long, without glands, glabrous or slightly pubescent; stipules early deciduous.

¹ *Journ. Bot.* xxviii. 229 (1900).

² Hooker, *Student's Flora*, 355 (1878).

³ Baker and Tate, *Fl. Northumberland and Durham*, 248 (1868), state: "Frequent in damp woods and by stream sides, ascending in Coquetdale to Harbottle, in Allendale to 450 yards, and in Teesdale to the junction of the Whey Sike with Harwood Beck."

⁴ Praeger, in *Proc. Roy. Irish Acad.* vii. 282 (1901).

Only female trees are known in cultivation. Catkins terminating branchlets with one, two, or three leaves, very slender, green, curved, about 1 in. long; axis pubescent; scale about $\frac{2}{3}$ rds the length of the ovary, pilose at the base, ciliate, ovate-acuminate; ovary sub-sessile, about $\frac{1}{10}$ in. long, ovate, glabrous, ending in a very short style, which is divided into two stigmatic arms, each of which is bilobed; gland posterior, quadrate, emarginate or bilobed.

VARIETY AND HYBRIDS

I. The following variety is known in cultivation:—

1. Var. *annularis*, Ascherson, *Fl. Brandenburg*, 630 (1864).

Var. *crispa*, Loudon, *Arb. et Frut. Brit.* iii. 1514 (1838).

Salix annularis, Forbes, *Sal. Woburn*. 41, t. 21 (1829).

Leaves folded and rolled up, so as to form a ring or spiral, otherwise as in the type. This remarkable variety, which is called the ring-leaved willow, is of unknown origin;¹ but undoubtedly is a sport of *S. babylonica*, and like it is a female tree. W. Masters of Canterbury stated² that his father gave fifteen shillings for a plant 6 in. high, but had no clue as to where or how the variety had originated. He mentions an instance of a ring-leaved willow, which after being planted twenty years, produced a single branch with leaves of the ordinary form, which continued to be borne for years afterwards on the same branch and its ramifications.

There is a fine specimen on the lawn near the Palm House at Kew, which was, in 1912, 56 ft. high with a trunk 11 ft. in girth at three and a half feet from the ground, above which it divides into two stems. Lord Kesteven measured in 1906 a fine specimen, 57 ft. by 7 ft., on a farm near Caythorpe, Grantham.

II. The following trees, often considered to be varieties of *S. babylonica*, are probably hybrids:—

2. *Salix Salamonii*, Carrière, in *Rev. Hort.* xl. 463 (1869) and xlix. 444 (1877).

Salix babylonica Salamonii, Simon-Louis, *Cat.* 1869, p. 85; Carrière, in *Rev. Hort.* xlv. 115 (1872).

A tree with a tall straight stem, and ascending branches, forming when young a pyramidal crown; ultimate branchlets pendulous, but not so long as in *S. babylonica*. Young branchlets pubescent near the nodes, becoming glabrous. Leaves similar in shape, size, and colour to those of *S. babylonica*, but pubescent with scattered appressed long hairs on both surfaces. Only pistillate trees are known; catkins similar to those of *S. babylonica*, but with the axis more pubescent and the scales furnished with long cilia.

This remarkable tree, which is supposed to be a cross³ between *S. babylonica* and *S. alba*, is very distinct in habit, forming when young a handsome pyramidal tree, which grows with astonishing vigour and is not injured in our climate by frost

¹ Dole, in *Bull. Soc. Dend. France*, 1909, p. 153, believes that this may have originated from a witches' broom; and states that he obtained a similar sport as a cutting, which was taken from an abnormal growth on a *Salix alba*.

² *Gard. Chron.* 1855, p. 726. Cf. Darwin, *Animals and Plants under Domestication*, i. 408 (1890).

³ Schneider, *Laubholzkunde*, i. 36, note (1904), supposes it to be identical with *S. sepulcralis*, Simonkai, in *Termes. Füz.* xii. 157 (1890), said to have been found in Hungary. Camus, *Monog. Saules*, 235 (1904), identifies with the last-named, *S. alba*, var. *tristis*, Trautvetter, *Fl. Alt.* iv. 255 (1833), described from an Altai specimen.

in spring, as is almost invariably the case with the common weeping willow. Though not so pendulous in habit as the latter, it has graceful drooping branchlets.

This tree originated on the estate of Baron de Salamon, near Manosque (Basses Alpes) some time before 1869, when it was put on the market by Simon-Louis of Metz. Carrière recommended this tree, on account of its vigour,¹ for the production of timber; and stated that it grew on all soils, even on dry soils and on limestone, where the weeping willow refused to grow, or remained stunted and yellow. *S. Salamonii* comes nearly as early into leaf and retains its foliage almost as late in the season as *S. babylonica*.

There are several old trees of *S. Salamonii* on the borders of the lake at Kew. The exact age of these is unknown; but they much surpass in size the true weeping willows beside them.² At Casewick, where Lord Kesteven has planted *S. Salamonii* as a park tree, it thrives well, and has attained 35 ft. in height at eighteen years old.

3. *Salix pendulina*, Wender, in *Schrift. Natf. Ges. Marburg*, ii. 235 (1831).

Salix blanda, Andersson, *Monog. Salic.* 50 (1863), and in De Candolle, *Prod.* xvi. 2, p. 212 (1868); Camus, *Monog. Saules*, 232 (1904).

Salix elegantissima, Koch, in *Wochschr. Ver. Bef. Gartb.* xiv. 380 (1871), and *Dendrologie*, ii. pt. i. 505 (1872).

Under these names are possibly included three slightly different hybrids of the same parentage, *S. babylonica* and *S. fragilis*. They are wide-spreading trees, with long and pendulous branchlets, differing only slightly in habit from *S. babylonica*, but much more hardy than this species, and on that account often cultivated in Germany where the true weeping willow is killed by severe frost. I have not been able to study the three forms; but a tree at Kew, labelled *S. elegantissima*,³ obtained from Dieck in 1889, has leaves more coriaceous and slightly broader than those of *S. babylonica*; both surfaces glabrous, slightly glaucous beneath. Catkins occasionally androgynous,⁴ usually only pistillate, shorter than in *S. babylonica*; axis pubescent; ovary shortly pedicellate, about $\frac{1}{10}$ in. long, slightly pubescent at the base, with two stilar arms, each arm bilobed; scale two-thirds the length of the ovary, very pilose; glands irregular, usually two,—one narrowly oblong between the scale and the ovary,—the other, posterior, nearly quadrate, and occasionally bilobed.

Koch states that this tree, which on the Continent is often sold in commerce as *S. Sieboldii*, is fast in growth, with very long branchlets, almost reaching to the ground. There is a thriving specimen at Glasnevin, about 25 ft. high, which is labelled *S. blanda*. In the Botanic Garden at Leyden there is a handsome tree, about 40 ft. by 3 ft. in 1912, which is labelled *S. Petzoldii pendula*.⁵

¹ In *Garden and Forest*, x. 497 (1897), it is said to be the fastest-growing willow in California, where, at the Chico Forestry Station, stems cut back in February 1896 to 2 ft. from the ground, were 31 to 32 ft. high in August 1897.

² A vigorous young tree on the bank of the Cam, Trinity College, Cambridge, was 35 ft. high by 4 feet in girth in 1912. Its pyramidal crown with ascending upper branches contrasts much with the older but lower adjacent weeping willows, which have broad flattened crowns and spreading branches.

³ Both *S. blanda* and *S. elegantissima* were described as having perfectly glabrous ovaries; but notwithstanding this, the Kew tree, received from Dieck, is probably *S. elegantissima*. Ascherson and Graebner, *Syn. Mitteleurop. Flora*, iv. 73 (1908), correctly describe *S. elegantissima* as having a pubescent ovary; and on that account doubt its being a hybrid between *S. babylonica* and *S. fragilis*. Following Koch, they believe that it was introduced from Japan by Siebold; and if this is the case, *S. fragilis* could scarcely have been one of the parents.

⁴ As Camus points out, androgynous catkins are common in the hybrids *S. blanda* and *S. sepulcralis* which he describes.

⁵ Cf. Lauche, *Haupt-Katalog Muskauer Baumschulen*, 1905, p. 32.

DISTRIBUTION

S. babylonica was the name given by Linnæus¹ to the common weeping willow cultivated in Europe, which he erroneously supposed to have been identical with the trees growing by the rivers of Babylon, which are mentioned in Psalm cxxxvii. 2. The latter are, without doubt,² a species of poplar, *Populus euphratica*. The original home of the weeping willow appears to be central and southern China, where it is commonly found on the banks of rivers and canals, as well as in gardens. Fortune³ observed this tree, identical in all respects with that cultivated in Europe, in the neighbourhood of Shanghai and Canton, and also near Ningpo, where it is sometimes planted around graves.

The typical form of the species, that long cultivated in Europe and prevalent in central and southern China, is always a female tree, with long pendulous branchlets. In the neighbourhood of Peking⁴ a variety is more common, which may be distinguished as var. *pekinensis*, Henry. This is an upright tree, with ascending branches, which is known in both sexes. The foliage is practically identical⁵ with that of the typical form; but there is a marked difference, not only in habit, but in the pistillate catkins, which are extremely short and compact in this variety, not exceeding $\frac{1}{2}$ in. in length, often on leafless peduncles; ovaries wider, ending in two short undivided stigmas; scales nearly glabrous. Var. *pekinensis* is represented at Kew by a tree, about 15 ft. high, originally from Peking, which was obtained from the Arnold Arboretum in 1905. This tree, like the common weeping willow, is injured regularly by spring frosts.

From China the weeping willow was early introduced into Japan, where it is now cultivated and naturalised in many places.⁶ During the Middle Ages it was probably carried westward to Persia, Asia Minor, and Turkey; and it is now also "cultivated in Baluchistan, Northern India, and the Punjab, and less commonly in the plains farther east, and also in Kurdistan."⁷

The first mention of the tree in European literature is by Petiver,⁸ who refers to a specimen gathered in China by Cunningham in 1701, but which cannot now be found in the British Museum. The first mention of the tree in the Levant was by Tournefort⁹ in 1719; and it is possible that either he or Wheler, who travelled in Asia Minor and Greece in 1675-1676, introduced it into western Europe.

¹ First described by Linnæus, in *Hort. Cliff.* 454 (1737).

² Cf. Koch, *Dendrologie*, ii. pt. i. 507 (1872). *S. babylonica* is not now found in Babylonia. See p. 1771, note 4.

³ *Wanderings in China*, 118, 136 (1847), and *Residence Among the Chinese*, 52 (1857). The weeping willow is apparently depicted by Nieuhoff, *L'Embassade des Provinces Unies vers China*, i. 189 (1665), in a view of Tonnau, a village on the river Wei in the province of Shantung.

⁴ Cf. Bretschneider, in *Journ. N. C. Branch, R. Asiat. Soc.* xv. 15, 30 (1880), and *Bot. Sinic.* ii. 359 (1892). The name of *S. babylonica* in China is *yang-liu*. The weeping form is rare at Peking, where it is distinguished as *ch'ui-yang-liu*.

⁵ The serrations of the leaves in var. *pekinensis* are more distantly placed, and without the cilia, which are present in the typical form. These slight differences may be due to the different ages of the specimens.

⁶ Franchet et Savatier, *Enum. Pl. Jap.* i. 459 (1875).

⁷ Brandis, *Indian Trees*, 637 (1906).

⁸ *Mus. Petiv. Cent.* 997 (1703), where it is referred to as follows: "Yang-diu chinensibus. Arbor salicis folio ramulis pendulis. Frequently painted on Japan work. Of the wood they make arrows."

⁹ *Corollarium*, 41 (1719), where it is described as follows: "*Salix orientalis, flagellis deorsum pulchre penitentibus, hujus etiam meminit Wheler Itin.*" Wheler, *Journey to Greece and Asia Minor*, 217 (1682), saw near Brusa, and not far from Mt. Olympus in Asia Minor, a tree which appears from his description to have been a weeping willow.

The weeping willow was introduced into England some time before 1730, as it was on sale in London, according to a catalogue¹ published in that year. Collinson states² that it was introduced by Mr. Vernon, Turkey merchant at Aleppo, who planted it at his seat in Twickenham Park, where Collinson saw it in 1748. The latter says that this tree was the original of all the weeping willows in England; and adds that he measured one in 1765 at Mr. Snelling's at Godalming, which, though only fifteen years old, was 6 ft. in girth.

There was a famous weeping willow, planted by Pope in front of his villa at Twickenham, which was felled³ in 1801, when the story was given in *St. James's Chronicle*, August 25-27, of that year,⁴ that this tree was the first one planted in England, having been introduced as a withy round a package from Spain; but doubtless Pope's tree was a cutting from Mr. Vernon's willow.

Another celebrated tree was the weeping willow in St. Helena, which was planted in 1810, and was a favourite of Napoleon. After his death cuttings were brought to England, and planted in many places, where they were called Napoleon's willow, but differed in no respect from the ordinary form.⁵ There is a weeping willow at the Fountain Pond, Cassiobury, which formerly bore a plate⁶ stating that it had been a cutting from the tree in St. Helena. This tree fell and sustained considerable damage; but it has been replanted, and, according to Mr. Daniel Hill, who measured it in 1912, is 36 ft. high and 4 ft. 7 in. in girth. (A. H.)

The weeping willow strikes freely from cuttings, and grows rapidly in good soil beside water; but is very liable to have the young shoots killed by frost, and is not nearly so hardy as the hybrid *S. Salamonii*. It is one of the earliest trees to come into leaf, and the latest in retaining its foliage, being frequently green in December.

The finest trees known to Loudon were those at various places on the banks of the Thames, which were 50 to 60 ft. high in 1838; but it is doubtful if any of these now survive, as it is not a long-lived tree. The best that I have seen is perhaps a tree (Plate 379) on the Promenade, Cheltenham, which was planted about 1860, and is still thriving, although its limbs have been supported by iron rods for some years. It measured in 1911 about 75 ft. by 9 ft., and on 24th November 1911, after a severe frost, it still retained most of its leaves.

There are several picturesque trees,⁷ but of no great height, growing on the banks of the Cam, behind the Colleges of Cambridge. These are exceeded in size by one

¹ Miller, *Catalogus Plantarum, a Catalogue of Trees, Shrubs, Plants, and Flowers, which are propagated for sale in Gardens near London*, p. 71 (1730), where it is mentioned as "*S. orientalis*, T. Cor. 41. The weeping willow *vulgo*."

² Dillwyn, *Hortus Collins.* 48 (1843), quoted by Loudon, *Gard. Mag.* xix. 64 (1843). Aiton, *Hort. Kew.* v. 356 (1813), states that the weeping willow was first cultivated in 1692 in the Royal Garden at Hampton Court, but gives no authority for this. If true, the introduction into Western Europe was probably made by Wheler. Aiton quotes Plukenet, *Phytographia*, t. 173, fig. 5, which is not the weeping willow.

³ Corbett, in *Mem. Twickenham*, 285 (1872), states that this tree perished and fell to the ground in 1801. The wood was worked up by an eminent jeweller into all sorts of trinkets and ornaments, which had an extensive sale. The Empress of Russia took cuttings from Pope's willow in 1789 for the gardens at St. Petersburg.

⁴ Phillips, *Sylva Florifera*, ii. 263 (1823).

⁵ Loudon, *Arb. et Frut. Brit.* iv. 2588 (1838), and *Trees and Shrubs*, 758 (1842). Forbes, *Salic. Woburn.* 43 (1829) states that a plant raised from a cutting of the St. Helena tree was identical with the common weeping willow.

⁶ D. Hill, in *Trans. Herts. Nat. Hist. Soc.* xiv. pt. ii. 132 (1911).

⁷ These trees are comparatively young, and have replaced the original trees, which were planted in 1760. Cf. Willis and Clark, *Archit. Hist. Univ. Camb.* ii. 646 (1886).

in the Fellows' Garden of King's College, which was about 45 ft. high and 10 ft. in girth in 1912, with the trunk decayed and mended with cement.

The weeping willow attains¹ a much greater size and beauty in warm countries than it does in England. I have seen none finer than in Chile, where it is often planted by the sides of the irrigation canals, and enjoys a long and warm summer.

(H. J. E.)

SALIX FRAGILIS, CRACK WILLOW

Salix fragilis, Linnæus, *Sp. Pl.* 1017 (1753); Smith, *Fl. Brit.* iii. 1051 (1804), *Eng. Bot.*² t. 1807 (1808), and *Eng. Flora*, iv. 184 (1828); Andersson, *Monog. Salic.* 41 (1863), and in De Candolle, *Prod.* xvi. 2, p. 209 (1868); Willkomm, *Forstliche Flora*, 472 (1887); Buchanan White, in *Journ. Linn. Soc. (Bot.)* xxvii. 368 (1890); Mathieu, *Flora Forestière*, 450 (1897); Camus, *Monog. des Saules*, 76 (1904).

A tree, attaining about 70 ft. in height. Bark rough, strongly ridged, and divided into broad deep fissures. Young branchlets slightly pubescent, glabrous in the second year. Buds appressed to the branchlet, compressed, shining, glabrous. Leaves lanceolate, about 4 in. long and $\frac{3}{4}$ in. broad, gradually tapering above into a long caudate oblique acuminate apex, cuneate at the base, silky when young; upper surface in summer glabrous, shining; lower surface glaucous or glaucescent, with scattered silky appressed hairs; margin coarsely serrate, each serration tipped with a conspicuous reddish brown gland; petiole $\frac{3}{8}$ in. long or more, pubescent, usually with two glands at the insertion of the blade.

Catkins appearing with the leaves, terminating short branchlets, which bear three or four usually entire leaves; axis densely pubescent. Male catkins, about 2½ in. long; scales concave, oblong, truncate or cuspidate, glabrous within, pubescent without, margin fringed with long hairs; stamens two, filaments as long as the scale, slightly pubescent at the base, anthers yellow; glands two, the posterior transversely oblong, the anterior half its size and narrowly oblong. Female catkins about 2 in. long; scales concave, lanceolate, pilose at the base, ciliate, with long hairs; ovary distinctly stalked (pedicel $\frac{1}{5}$ in. long), one-third longer than the scale, fusiform, glabrous, $\frac{1}{6}$ in. long, gradually narrowing to the apex, which ends in a short style, divided into two arms, each of which is bilobed; only one gland,³ which is posterior, usually present, quadrate, entire in margin, much shorter than the pedicel. Fruiting catkins about 3 in. long, with a pubescent axis, and distinctly stalked capsules.

S. fragilis is called crack willow, on account of the ease with which the branchlets disarticulate, especially in spring. It is readily distinguishable by its

¹ *Salix Safsaf*, Dode, in *Bull. Soc. Dend. France*, 1906, p. 62, fig. (not Forskal), received from Palermo, where it was introduced by Schweinfurth from Egypt, is indistinguishable from *S. babylonica*; but is remarkably fast in growth and may be a hybrid. A specimen in the nursery of the Jardin des Plantes at Paris, which I saw in 1912, though only three years old from a small cutting, was 20 ft. high and 15 in. in girth. M. Dode states that this is perfectly hardy at Paris, none of the shoots being damaged by frost.

² One of the male flowers in *Eng. Bot.* t. 1807, has three stamens; and it is possible that the male plant figured is a hybrid like *S. speciosa*.

³ The presence of two glands in the pistillate flower of *S. fragilis* is very rare, and abnormal.

nearly glabrous coarsely glandular-serrate large leaves, ending in a long point directed to one side. When adult the stem is covered with a much rougher bark than that of *S. alba*, the depressions between the ridges being broad and deep; on this account buyers of willow timber usually designate it as the "open-bark willow." It is of no value for making cricket bats, as its wood lacks the necessary strength, lightness, and elasticity.

VARIETIES AND HYBRIDS

True *S. fragilis* does not seem to be a very variable plant; but peculiar forms, more or less resembling it, are known, which are supposed to be of hybrid origin. These are described below. The twigs in some trees become dull grey in the second year, whilst in others they assume a brilliant orange colour. Varieties founded on the size of the leaf or on the colour of its lower surface are not sufficiently distinct to be worth naming; and the two forms, vars. *britannica* and *genuina*, Buchanan White, in *Journ. Linn. Soc. (Bot.)* xxvii. 368 (1890) based on the relative length of the bract and flower, are untenable, as this depends simply on the age at which individual flowers are observed.

The following are supposed to be hybrids:—

1. *Salix decipiens*, Hoffmann, *Hort. Sal.* ii. 9, t. 31 (1791); Smith, *Eng. Bot.* t. 1937 (1808); Forbes, *Sal. Woburn.* t. 29 (1829); Buchanan White, in *Journ. Linn. Soc. (Bot.)* xxvi. 348 (1890).

Salix fragilis, var. *decipiens*, Koch, *Syn. Fl. Germ.* 643 (1837).

Salix cardinalis, Veitch, *Cat. Trees and Shrubs*, 1910, p. 75.

A shrub or small tree. Young branchlets crimson or dark red, glabrous; becoming in the second year polished and yellowish white or of a clay colour. Leaves glabrous, smaller than those of *S. fragilis*, 2 to 3 in. long, $\frac{1}{2}$ to $\frac{3}{4}$ in. broad, more oblong, more parallel-sided, usually less narrowed and often rounded at the base; under surface pale dull green, scarcely glaucous; serrations finer, sharper, and closer together than in *S. fragilis*. This is supposed to be a hybrid between *S. fragilis* and *S. triandra*, and occurs in both sexes. The catkins of the female plant are intermediate between these two species; while the number of stamens in the male plant is usually two, rarely three.

S. decipiens, according to Buchanan White, is widely spread, but not abundant in Britain; and is usually found growing in company with *S. triandra* and *S. fragilis*. He mentions various localities from Perth to Somerset. There are specimens in the Kew Herbarium from Dorset, Sussex, and Essex. This species was said by Forbes¹ to be cultivated for basket-work, producing when cut crimson-coloured annual shoots, which are very remarkable in appearance. It appears² to be largely used at the

¹ *Sal. Woburn.* 57, t. 29 (1829). Cf. also Loudon, *Arb. et Frut. Brit.* iii. 1515 (1838). Smith, *Eng. Bot.* t. 1937 (1808), states that Crowe found it in several osier beds in Norfolk and Cambridgeshire, where it was known as white Welsh osier.

² Cf. Ellmore and Okey, in *Journ. Board Agric.* xviii. 915 (1912), who refer to it as *Salix alba*, var. *cardinalis*.

present time for the same purpose in Belgium; and when imported is called "Belgian red willow." It is occasionally planted for ornament, appearing in some nursery catalogues under the name *S. cardinalis*.

2. *Salix speciosa*, Host, *Sal.* 5, t. 17 (1828); Buchanan White, in *Journ. Linn. Soc. (Bot.)* xxvii. 353 (1890).

Salix fragilis, var. *latifolia*,¹ Andersson, in De Candolle, *Prod.* xvi. 2, p. 209 (1868).

A large tree, similar in bark and habit to *S. fragilis*. Young branchlets slightly pubescent, glabrous in the second year. Leaves longer and broader than those of *S. fragilis*, up to 6 in. long and $1\frac{3}{4}$ in. wide; broadly lanceolate, with a long acuminate often curved apex; pubescent when young; when mature, upper surface dark green, shining, glabrous; lower surface pale, glabrescent, or with scattered appressed hairs; margin coarsely glandular-serrate; petiole $\frac{3}{4}$ in. long, often with one to four glands at the junction with the blade.

Staminate catkins, $2\frac{1}{2}$ in. long; flowers crowded on the densely pubescent axis; scale, shorter than the stamens, and covered with long white silky hairs; stamens usually two, rarely three, glabrous or pilose at the base; glands two, variable, entire or lobed. Pistillate flowers not seen.

The above description is drawn up from an old tree¹ on the side of the lake at Kew, which has been named *S. triandra* \times *fragilis*,² by Linton. It is identical with some trees, which have been called "open-bark willow," by Carter, and is perhaps not very rare in Britain.

3. *Salix viridis*, Fries, *Nov. Pl. Suec.* 283 (1828); Andersson, in De Candolle, *Prod.* xvi. 2, p. 210 (1868); Buchanan White, in *Journ. Linn. Soc. (Bot.)* xxvii. 364, 371 (1890).

(?) *Salix rubens*, Schrank, *Baier Fl.* i. 226 (1789)

Salix excelsior, Host, *Sal.* 8, tt. 28, 29 (1828).

Salix palustris, Host, *Sal.* 7, tt. 24, 25 (1828).

Salix montana, Forbes, *Sal. Woburn.* 37, t. 19 (1829).

Salix fragilis-alba, Wimmer, *Denkschr. Schles. Ges.* 156 (1853).

A tree similar in size to the reported parents, *S. alba* and *S. fragilis*, with spreading branches, and usually more or less pendulous branchlets. Young branchlets variable, glabrous or pubescent. Leaves intermediate between these two species, variable in size, shape, colour, and pubescence; darker green, less shining, more finely serrated, and less oblique at the apex than those of *S. fragilis*; longer and broader than those of *S. alba*, and soon becoming glabrescent.

Staminate catkins narrower and larger than in *S. fragilis*. Pistillate catkins more slender than in that species; ovary shortly but distinctly pedicellate; capsules intermediate in size between *S. alba* and *S. fragilis*.

¹ Specimens which were sent from Kew to Buchanan White in 1887 and 1888, and are now preserved in his herbarium at Perth, show that this tree was then labelled *S. fragilis*, var. *latifolia*, a name accepted by White.

² *S. alopecuroides*, Tausch, *Ind. Hort. Canal.* (1821), ex Andersson, in De Candolle, *Prod.* xvi. 2, p. 203 (1868); A. Kerner, in *Verh. Z. B. Ges. Wien*, 69 (1860); Koch, *Dendrologie*, ii. pt. i. 516 (1872), is the name given to the hybrid *S. triandra* \times *fragilis*, which occurs on the continent. This, judging from Tausch's specimen, preserved in the Cambridge Herbarium, is quite distinct from *S. speciosa*, Host.

Numerous forms of *S. viridis*¹ occur, some being close to *S. fragilis*, others nearer to *S. alba*; and no exact definition of this hybrid is possible; but it is easy to recognise when *S. alba*, *S. fragilis*, and *S. cœrulea* are excluded. According to Buchanan White, *S. viridis* is widely distributed in Britain, occurring from Cornwall and Surrey to Perth; but it is less abundant and more local than the parents, *S. alba* and *S. fragilis*. The second-class bat willow is often *S. viridis*.

S. viridis doubtless grows to as large a size as either of the parents, with which it is generally confused. The largest² we know are growing beside a stream at Thornbury, Gloucestershire. One tree is 60 ft. high by 18 ft. in girth. Near it are two trees growing from the same root, one of which is 65 ft. by 11 ft. 6 in. and the other 60 ft. by 15 ft. 7 in., according to measurements which were kindly taken for us by Mr. Samuel Fudge in July 1912.

4. *Salix Russelliana*, Smith, *Fl. Brit.* iii. 1045 (1804), *Eng. Bot.* t. 1808 (1808), and *Eng. Flora* iv. 186 (1823); Forbes, *Sal. Woburn.* 55, t. 28 (1829); Loudon, *Arb. et Frut. Brit.* iii. 1517, fig. 1311 (1838).

Salix fragilis, var. *Russelliana*, Koch, *Syn. Fl. Germ.* 643 (1837).

A tree, remarkably vigorous in growth, with long, straight and slender branches, not angular in their insertion like those of *S. fragilis*. Leaves in the young state white and silky pubescent beneath; when fully grown, lanceolate, acuminate, $3\frac{1}{2}$ in. long, $\frac{5}{8}$ in. wide, finely serrate, with scattered appressed hairs on the under surface near the midrib. Pistillate trees only known, with flowers similar to those of *S. fragilis*, having pedicellate ovaries and bipartite styles, but with looser catkins.

This seems, judging from the type specimens in Smith's herbarium at the Linnean Society, to be a form of *S. viridis*, which is not clearly known to botanists³ at the present time. The normal leaves are well figured by Loudon (fig. 1311); those depicted by Sowerby (*Eng. Bot.* t. 1808) from coppice shoots are larger than the normal leaves, and have the glands on the petiole often developed into slender leaflets.

S. Russelliana was sent to Woburn about 1800 by Mr. Bakewell from Leicestershire, and was called the Dishley or Leicester Willow. It seems to have been extraordinarily vigorous, as Lowe, *Agric. Survey of Notts*, p. 118, is quoted⁴ for the fact that "this willow in a plantation yielded at eight years' growth poles which realised a net profit of £214 per acre." It was also remarkable for the large per-

¹ Scaling mentions in his pamphlet, *Salix or Willow*, i. *Cat.* p. 8 (1871) and ii. 19 (1872) two willows, which he sent out in 1871 from his nursery at Basford, Notts:—(1) *S. sanguinea*, the branches of which were brilliant red in winter. This was obtained by Scaling some years previously in the Ardennes, where it was known as the red willow. (2) *S. basfordiana*, with branches of a deep orange colour. This appeared as a seedling in the nursery, and grew with great vigour.

Salter, in *Gard. Chron.* xvii. 298, figs. 41, 42 (1882), apparently confused these two distinct trees, which he described as *S. basfordiana*. There are two trees at Kew under this name—a male, No. 58, which is a form of *S. viridis*, and a female, No. 80, which is identical with *S. vitellina*. Whether these correspond to Scaling's *S. sanguinea* and *S. basfordiana* is uncertain.

² These trees have pubescent leaves, simulating those of *S. alba*, but larger and thinner. They also differ from the latter species in having distinctly pedicellate fruit.

³ *S. Russelliana* has been misunderstood by most botanists since Smith's time. White's view that it was true *S. fragilis*, while Smith's *S. fragilis* was *S. viridis*, is untenable.

⁴ Duke of Bedford, in Forbes, *Sal. Woburn.*, p. v (1829). The frontispiece represents Johnson's Willow.

centage of tannin contained in the bark, which exceeded, according to Mr. Biggin's analysis,¹ even that of the oak.

The Rev. W. Dickenson assured the Duke of Bedford and Sir James Smith that the tree known as Johnson's Willow,² which grew between Lichfield and Stow Hall, was *S. Russelliana*. This tree, which was so called because Dr. Johnson frequently rested under its shade, was figured by Loudon, *Arb. et Frut. Brit.* iii. figs. 1312, 1313, who states that it was about 60 ft. high, with a great bole, about 20 ft. in length, which girthed,³ in 1810, 21 ft. at six feet from the ground. It contained 130 cubic ft. of timber, and was perfectly sound. It was blown down in 1829, when it was supposed to have been 130 years old.

Mr. L. Fosbrooke, of Ravenstone Hall, Ashby de la Zouch, believes that *S. Russelliana* still occurs in Leicestershire in the Trent valley, where the trees are supposed to be female *S. fragilis*. They differ in foliage from male trees of true *S. fragilis*, according to Mr. Fosbrooke, who tells me that though they grow fast when young, they become round-topped as they approach maturity, and are certainly not nearly as vigorous as *S. caerulea*. I have not been able to examine specimens of these trees; and cannot say whether they are identical with the original *S. Russelliana*, which may have been a solitary sport or hybrid of exceptional vigour, now lost to cultivation.

DISTRIBUTION

The distribution of *S. fragilis* in the wild state cannot be determined with certainty, as it has been largely planted outside of its original area; but it is supposed to be indigenous in the greater part of Europe and in western Asia. It is not wild in Norway, but occurs there as a planted tree as far north as lat. 64° 5'. In Sweden it is also only known in cultivation, the male tree being seen occasionally in Werm-land and Schone, and the female tree in the district round Kalmar. It is wild in Jutland, in the island of Oesel, and in Russia,⁴ where it extends as far north as Esthonia, Livland, Kostroma, and Kazan; but is absent from the Crimea. It is widely spread in the Caucasus, Persia, and Asia Minor. Farther east it is cultivated⁵ in the Kuram valley, in Gilgit, Ladak, and Lahaul, as well as at Quetta, where it was found by Lace at 5600 ft. elevation.

In Europe it extends southwards to Spain and Portugal, Sicily, and Greece. It is planted largely in northern and central Germany, where it is wild in many localities; but in southern Germany, Austria, and Hungary, it is only seen in river valleys, where it prefers a deep loamy soil; and ascends along the edges of streams in the mountains, as high as 1700 ft. altitude in the Bavarian Alps, and 2500 ft. in Transylvania. In order to succeed it requires considerably more moisture in the soil than *S. alba*, and on this account is most often seen on the Continent generally, on the banks of rivers, streams, and lakes, being rare in the interior of the forests.

¹ Davy, *Agric. Chem.* 89 (1814) analysed the bark of a large tree of the "Leicester Willow" and found it to contain more tannin than any other British tree, having a little more than coppice oak, and three times as much as the "common willow."

² See note 4, p. 1757.

³ Withering, *Arr. Brit. Plants*, ii. 68 (1818) gives these measurements on the authority of Rev. W. Dickenson. Loudon, *Derby Arboretum*, 55 (1840), states that a young tree, raised from the branches of Johnson's Willow, was growing at Lichfield in 1836, when it was 20 ft. high.

⁴ Köppen, *Holzgew. Europ. Russlands*, ii. 257 (1889).

⁵ Brandis, *Indian Trees*, 637 (1906).

The crack willow is probably wild in marshy ground in Britain from Perthshire southwards; but it is extremely difficult to decide in what stations it is really indigenous. It is supposed to have been introduced¹ into Ireland, where however it is often seen as a planted tree. (A. H.)

This species occasionally attains as great dimensions as *S. alba*. In *Gard. Chron.* i. 447 (1874), E. Lees figures some remarkable old willows. The largest of these (*S. fragilis*) grew in the Wye valley near Ross, and was over 70 ft. in height, with a girth of 24 ft. at two feet from the ground. Mr. H. Marshall can find no trace of this tree at the present time.

Jackson, *Syon House Trees and Shrubs*, 29 (1910), mentions an immense tree on the south side of the lake in a decaying condition. "Judging from the length of the bole, which is now prostrate, this may well have been the specimen mentioned by Loudon² (p. 1521) as being 89 ft. high and about 13 ft. in girth, and called by him *Salix Russelliana*."

In Messrs. Samson's nursery at Kilmarnock there was a crack willow, which in 1904 measured, according to Mr. Renwick, 80 ft. high, with a bole 22 ft. in length and girthing 16 ft. 1 in. at five feet from the ground. This tree was blown down in November 1911, when the trunk was found to be much decayed at the heart. No shoots have sprung from the root since. Mr. Renwick³ records a tree at Bruntwood Mains near Galston, Ayrshire, which measured 13 ft. 1 in. in girth in 1902, when it was reputed to have been 62 years old. (H. J. E.)

SALIX ALBA, WHITE WILLOW

Salix alba, Linnæus, *Sp. Pl.* 1021 (1753); Smith, *Eng. Bot.* t. 2430 (1812), *Eng. Flora*, iv. 231 (1828); Forbes, *Sal. Woburn.* 271, t. 136 (1829); Loudon, *Arb. et Frut. Brit.* iii. 1522 (1838); Andersson, *Monog. Salic.* 47 (1863), and in De Candolle, *Prod.* xvi. 2, p. 211 (1868); Willkomm, *Forstliche Flora*, 469 (1887); Buchanan White, in *Journ. Linn. Soc. (Bot.)* xxvii. 370 (1890); Mathieu, *Flore Forestière*, 451 (1897); Camus, *Monog. des Saules*, 69 (1904).

A tree, attaining about 90 ft. in height and 20 ft. in girth, with more or less ascending branches, but with spreading or pendulous ultimate branchlets. Bark less deeply fissured than in *S. fragilis*, the depressions between the ridges being narrower and shallower than in that species. Young branchlets covered with whitish appressed pubescence, partly retained in winter and in the following year. Buds flattened, appressed against the twig, silky pubescent. Leaves lanceolate, 2 to 2½ in. long, rarely exceeding ½ in. in width, tapering to a long acuminate, straight or curved apex; upper surface greyish green, more or less covered with silky white appressed pubescence; lower surface whitish, densely covered with similar pubescence; margin densely ciliate, and with minute glandular serrations; petiole short, pubescent.

Catkins, appearing with the leaves, on short lateral leafy branchlets; axis densely tomentose; flowers crowded. Staminate catkins, about 1½ in. long;

¹ Praeger, in *Proc. Roy. Irish Acad.* vii. 283 (1901).

² Loudon's identifications of these large willows are very uncertain.

³ *Trans. Nat. Hist. Soc. Glasgow*, vi. pt. iii. 353 (1902).

stamens two, united and pubescent at the base; glands two, anterior quadrate and entire, posterior small and ligulate; scale concave, ciliate, half the length of the stamens. Pistillate catkins, $1\frac{1}{2}$ in. long; ovary sessile, glabrous, about $\frac{1}{10}$ in. long, ovoid, abruptly narrowed towards the apex; style short, the two arms apparently undivided (really slightly bilobed); scale, fringed with long hairs, and as long as the ovary; gland, one, posterior, quadrate. Fruiting capsules sessile, $\frac{1}{8}$ in. long.

S. alba appears to be very variable in the size and pubescence of the leaves; but doubtless some of the varieties attributed to *S. alba* are forms of the hybrid, *S. viridis*, in which the characters of *S. alba* are dominant. The following form is in cultivation:—

1. Var. *argentea*, Wimmer, *Sal. Europ.* 17 (1866).

Var. *splendens*, Andersson, in De Candolle, *Prod.* xvi. 2, p. 211 (1868).

Var. *leucophylla*, Simon-Louis, *Cat.* 1869, p. 85.

Var. *regalis*, Beissner, in *Gartenflora*, xxvi. 40 (1877).

Salix splendens, Bray, ex Opiz, *Boehm. Gew.* 110 (1823).

Salix regalis, Wesmael, in *Bull. Cong. Bot. Brux.* 1864, p. 280.

Young branchlets and leaves on both sides covered with dense silvery white tomentum. This is highly effective in beds in gardens when cultivated in masses, the single stems being kept about 12 ft. high by pruning. At Glasnevin there is a thriving tree about 35 ft. high.

DISTRIBUTION

S. alba is widely spread through central and southern Europe, extending southwards to Algeria and Morocco, and eastwards to western and northern Asia. It is impossible to define its northern limit in Europe, as its natural area has been much extended by planting; but, according to Schübeler, it is not wild in Scandinavia, where it is occasionally planted as far north as lat. $63^{\circ} 52'$ in western Norway. In Russia,¹ it is probably wild as far north as southern Livonia, Vitebsk, Smolensk, Moscow, Vladimir, Kostroma, Viatka, and Perm; and is common in the Crimea, where it attains a large size. It is widely spread in the Caucasus, north Persia, and Asia Minor; and occurs in Siberia as far east as Lake Baikal; but it is only cultivated² in the northern Himalayas and in western Tibet.

It is doubtfully wild in northern Germany, where it is, however, planted to a considerable extent. Farther south, it is undoubtedly indigenous in southern Germany, Austria, the Balkan peninsula, Italy, Spain, and the greater part of France.³ In central and southern Europe, it is often the dominant tree in the forests of the alluvial plains and in the woods on the banks of rivers, as on the Danube and its great tributaries, where it either forms pure stands or grows in mixture with *Quercus pedunculata*, *Populus nigra*, and *Salix fragilis*. It grows in similar situations to the last species, but thrives in lighter and more sandy soils. It ascends the river valleys in the mountains to 1400 ft. in the Bavarian Forest, to 2700 ft. in the Bavarian Alps, to 2900 ft. in Transylvania, to 3200 ft. in the Caucasus, and to 5400 ft. in the Sierra Nevada. The comparatively low altitude

¹ Köppen, *Holzgew. Europ. Russlands*, ii. 259 (1889).

² J. D. Hooker, *Flora Brit. India*, v. 629 (1888).

³ It is common on the banks of all the large rivers of western France from the Seine to the Adour; and appears to be the sole native large willow in these situations where I saw no *S. fragilis* in 1912.

which it attains in the mountains is not due to the fall in temperature, as it ripens seed and grows to be a fine tree in Livonia.

The white willow is supposed to be indigenous in Britain in marshy ground from Sutherland southwards; and is considered by Praeger¹ to be probably in Ireland an original tree of river banks, but now generally planted.

Witches' brooms² on this species are apparently formed by the irritation set up by a mite (*Eriophyes salicis*), which causes a shoot to branch repeatedly and produce small narrow soft leaves, the whole mass often measuring a foot in diameter, and turning bright red in autumn.

The white willow was early introduced into North America, where it is now planted both in Canada and the United States. Together with *S. fragilis*, it has proved very useful as a windbreak in the prairie regions, and where timber is scarce is valuable for fuel. It is also a useful tree for reclaiming and holding the soil along streams. The wood is fairly durable in contact with the soil, and has been employed for fence-posts in the north-western plains of the United States. Pinchot³ recommends that it should be grown as coppice, when required for posts or fuel; and says that plantations should be tilled frequently till they are well shaded. This cultivation destroys weeds, and prevents excessive evaporation of moisture from the soil.

(A. H.)

REMARKABLE TREES

A tree at Bury St. Edmunds, figured by Strutt, *Sylva Britannica*, plate xxiii, as the Abbot's Willow, is one of the largest white willows of which we have record. It was measured by a surveyor, named Lenny, in 1822, when it was 72 ft. high by $18\frac{1}{2}$ feet in girth, and was estimated to contain 440 feet of timber. Loudon was informed that it was almost dead in 1836.

The largest white willow known to us is at Haverholme, near Sleaford, in the park east of the priory, and measured⁴ in 1907 about 80 ft. high by $25\frac{1}{2}$ ft. in girth, with a spread of branches about 80 ft. in diameter. A photograph, for which I am indebted to Miss F. H. Woolward (Plate 380) shows it to be past its prime; but though partly decayed, it is said to be still increasing in girth.

At Water Hall farm, Bayfordbury, Herts, there is a tree, about seventy years old, which Mr. H. Clinton-Baker measured in 1912. It is about 65 ft. high; and has a short bole, 27 ft. in girth at one foot from the ground, and divided at four and a half feet up into two stems, the larger of which is 17 ft. in girth at six feet from the ground.

At Compton Wynyates, Kington, a beautiful old mansion belonging to the Marquess of Northampton, there is a group of sound healthy trees from 80 to 90 ft. high, one of which girthed 10 ft. 4 in. in 1905.

At Highclere, there is a fine tree, a picture of which by Alfred Parsons, now in the possession of Lady Carnarvon, was reproduced by Robinson, *Wild Garden*, 258 (1895). It formerly had three stems, but the two largest were blown down some

¹ *Proc. Roy. Irish Acad.* vii. 283 (1901).

² *Proc. Roy. Hort. Soc.* xxxvi. pt. ii. p. cxvii. (1910).

³ *U. S. Dept. Agric. Forest Circ.* No. 87 (1907).

⁴ Measured by Mr. J. Cowanec. In *Woods and Forests*, 1884, p. 642, this tree was said to have been, in 1881, 27 ft. 4 in. in girth at one foot from the ground, 20 ft. 5 in. at four feet, and 28 ft. at seven feet. The branches spread 40 ft. on one side, and 28 ft. on the other. Cf. *Gard. Chron.* xiv. 362 (1893).

years ago. Mr. Storie informs us that the stem remaining, which leans to one side, is over 50 ft. in height and girths 13 ft. at five feet from the ground.

At Fawsley Park, Daventry, a tree, of which a photograph was reproduced in the *Journal of the Northampton Natural History Society* for 1882, was said to have been no less than 102 ft. high and 9 ft. 2 in. in girth. This tree was blown down in February 1882; and apparently all that now survives is a small tree, grown from a cutting, specimens of which were kindly sent us by Lady Knightley of Fawsley.

In Scotland, Henry measured in 1904 two trees at Palnure, Kirkcudbright, which were 86 ft. by 10 ft. 8 in., and 82 ft. by 12 ft. 9 in.

At Coodham House, Kilmarnock, there are two great trees, the largest of which was 17 ft. 1 in. in girth in 1904, when it was measured by Mr. Renwick. Mr. J. M'Gran, the gardener, informs us that in 1910 it was about 60 ft. high, and girthed 17 ft. 8 in. at three feet from the ground, 19 ft. 8 in. at five feet, and 21 ft. at six feet.

At Moncreiffe I saw in 1907 a remarkable old willow, of which the original trunk, now broken, measured 19 ft. 4 in. in girth. The branches had become rooted in several places; and one of these, now severed from the trunk, is over 6 ft. in girth. The total circumference of the branches is 106 paces. The foliage of this tree, of which we have not seen flowers, is not so white as usual; and it may be a form of *S. viridis*.

In Ireland we have no records of any very large trees; but in Mucksna Wood, a mile from Kenmare, I saw by the road-side in 1910 some very fine willows, which the Marquess of Lansdowne believes to have been planted eighty or ninety years ago. I measured one of these 85 ft. by 9 ft. 10 in.

The white willow attains a large size in Germany. T. Schube¹ gives reproductions from photographs of two enormous trees which are growing in Silesia, one at the Primkenauer factory, 20 ft. in girth, and the other, with a taller stem not quite so thick on the road between Stronn and Korschlitz. The largest willow² in Berlin, which grew beside a canal and had a girth of 23 ft., fell to the ground in 1894. Beissner reports³ a tree, 92 ft. high and 9 ft. in girth in 1907, which is growing in a park at Hohenmistorf in Mecklenburg. As the park was laid out in 1854, this willow probably dates from that year.

TIMBER

The wood of this species is used for making cricket-bats of an inferior kind, those of the best class being mainly obtained from *S. cœrulea*. Apart from this special use, the wood of the white willow is of considerable value, though it is not so much esteemed now as formerly. It is tough, and indents without splintering from blows or hard usage, and is used on that account for brakes on railway waggons, and for the sides and bottoms of carts; it is also used for the rims of riddles and milk-pails, and by turners for making toys. It is also valuable for hurdle-making. G. W. Newton states⁴ that George Stephenson had a high opinion of willow, as forming durable blocks for paving. Gorrie states⁵ that "in roofing it has been known to stand one hundred years as couples, and with the exception of about $\frac{1}{2}$ in. on the

¹ *Mitt. Deut. Dend. Ges.* 1910, p. 52, figs. 8 and 9.

⁴ *Timber Trees*, 34 (1859).

⁵ Loudon, *Gard. Mag.* i. 45 (1826).

outside, the wood has been found so fresh at the end of that period as to be fit for boat-building." Boards of willow were laid for floors in 1700.¹ (H. J. E.)

SALIX CÆRULEA, CRICKET-BAT WILLOW

Salix cœrulea, Smith, *Eng. Bot.* t. 2431 (1812), and in Rees, *Cycl.* xxxi. 141 (1819); Aiton, *Hort. Kew.* v. 365 (1813) (not Forbes).

Salix alba, var. *cœrulea*, Smith, *Eng. Flora*, iv. 231, 232 (1828); Loudon, *Arb. et Frut. Brit.* iii. 1523 (1838); Bean, in *Kew Bulletin*, 1907, p. 312, plate, and 1912, p. 205.

Salix viridis, Pratt,² in *Journ. Roy. Agric. Soc.* lxxvi. 22 (1905), and *Quart. Journ. Forestry*, i. 325, fig. No. 02 (1907) (not Fries).

A tree, attaining 100 ft. in height, with ascending branches, making a narrow angle with the stem, and forming a pyramidal crown.³ Terminal branchlets erect, not spreading or drooping. Bark smoother than in *S. alba*. Young branchlets appressed pubescent, becoming reddish brown in winter and the following year. Leaves similar to those of *S. alba*, but thinner in texture, more translucent, and less densely pubescent; lower surface not white, but bluish grey; margin ciliate, with minute glandular serrations.

Pistillate catkins, differing from those of *S. alba* as follows: ovary⁴ slightly stalked, more tapering at the apex, about $\frac{1}{6}$ in. in length; each of the two style-arms distinctly bilobed; scale more concave, about two-thirds the length of the ovary. Fruiting capsule, nearly $\frac{1}{4}$ in. long, on a distinct short pedicel.

This remarkable tree, which is best distinguished by its pyramidal habit, with stiff ascending branches and branchlets, is *par excellence* the true cricket-bat willow, as it exceeds the other kinds in rapidity of growth. Bean calls it the "best close-bark willow." In addition to its different habit, the leaves are readily distinguishable from those of *S. alba* by their different colour, and also by their translucency, as when viewed against the light with a lens, the tertiary venation is always plainly visible. In the forms⁵ of *S. viridis*, which approach *S. alba* in foliage, the leaves simulate those of *S. cœrulea* in colour and translucency, but are considerably larger and are also more coarsely serrate in margin; and no form of *S. viridis*, known to me, has either the peculiar habit or rapid growth of *S. cœrulea*.

S. cœrulea is considered by most botanists to be a variety of *S. alba*; but it differs from the latter in the flowers, which approximate in their size and shape and stalked ovaries to those of *S. fragilis*; and it is possible that *S. cœrulea* may be the first cross between these two species, most of the characters of *S. alba*, if this hypothesis is correct, being dominant.

S. cœrulea was first distinguished by Smith, who was unable to find any botanical

¹ Ellis, *White Woods*, quoted by Mitchell, *Dendrologia*, 56 (1827).

² Mr. E. R. Pratt at first accepted, on Mr. Linton's identification of certain specimens, the name *S. viridis* for the true cricket-bat willow, though in *Journ. Roy. Agric. Soc.* lxxvi. 22 (1905), he agrees that the East Anglia cricket-bat willow has leaves indistinguishable from those of *S. cœrulea*.

³ Owing to the fastness of growth of *S. cœrulea*, the nodes are at greater intervals, and the crown of foliage in consequence is remarkably sparse. The bark is darker in colour than that of *S. alba*.

⁴ Bean, *Kew Bull.* 1907, p. 313, states that the ovaries of *S. cœrulea* are identical with those of *S. alba*. A careful examination shows that the pyramidal tree with bluish foliage has always the distinct flowers described above.

⁵ These forms of *S. viridis* are often referred to *S. alba*, var. *cœrulea*, especially on the Continent; but I restrict the name *S. cœrulea* to the pistillate pyramidal tree here described.

character to separate it from *S. alba*, except "that the under side of the leaves loses at an early period most of the silky hairs." However, he went on to say: "Its qualities are of the highest importance. The superior value of the wood and bark, the rapid growth as well as handsome aspect of the tree, its silvery blue colour, its easy propagation and culture, in dry as well as wet situations, all render it so superior to our common white willow, that a cultivator might justly think lightly of any one who should tell him that there was no difference between them." He states that a cutting planted in Norfolk "became in ten years a tree 35 ft. high and 5 ft. 2 in. in girth, which is a rapidity of growth beyond all comparison with the common white willow." Succeeding botanists have applied the name *cœrulea* to pendulous slow-growing trees, of which the foliage is bluish white beneath; but I consider that Smith distinctly described the quick-growing pyramidal tree which is now recognised by cultivators as the true cricket-bat willow; and his specimen of *S. cœrulea* in the herbarium of the Linnean Society, London, is undoubtedly this tree.

Apparently no staminate tree¹ of *S. cœrulea* exists; and Smith knew it only as a female tree.

The origin of *S. cœrulea* is obscure; but it appears to be confined to the eastern counties of England, where it has been known² since 1804 at least. Bean,³ relying upon Shaw, states that it is only found at the present time in Essex, Hertford, and Suffolk; but it undoubtedly occurs also in Norfolk and Cambridgeshire; and is said to have been formerly a rare tree in Kent and Surrey. Dealers restrict their purchases to the eastern counties, and have not yet ever found any suitable willow for making bats in other parts of Britain or on the Continent. It is probable, however, that *S. cœrulea*, when planted in other parts of the British Isles, will prove satisfactory, as there is no reason for believing that the peculiar qualities of the wood of this tree are dependent upon the climatic conditions of the eastern counties.

Mr. J. A. Campbell, who planted in 1904 about 150 trees of *S. cœrulea* at Arduaine, Lochgilhead, Argyllshire, has received a favourable report⁴ from Mr. D. J. Carter, willow-dealer at Waltham Cross. One of these trees, which was cut down in 1912, when it was 6 in. in diameter, would, if it had been large enough for making bats, have fetched the normal price. This tree was too small to give a certain result; but judging from Mr. Carter's report, *S. cœrulea*, grown in the west of Scotland, where the rainfall is 60 inches annually, apparently retains the qualities which render its timber so valuable in East Anglia, where the climate is dry and sunny, and the mean summer temperature much higher than in the west.⁵

Loudon identified *S. cœrulea* with the upland or red-twigged willow of Pontey⁶;

¹ Forbes, *Sal. Woburn*, 273, t. 137 (1829), describes as *S. cœrulea*, a male tree, which is doubtless a form of *S. viridis*.

² Smith, *Fl. Brit.* iii. 1072 (1804), refers to it as a bluish, quick-growing variety of *S. alba*.

³ *Kew Bulletin*, 1907, p. 313.

⁴ Cf. Bean, in *Kew Bulletin*, 1912, p. 205.

⁵ Notwithstanding the above statement, I should hesitate to advise the planting of this willow in any part of Scotland or the west of England, until it has been proved by actual sale that the timber is of equal value to that grown in the eastern counties. Even supposing that it should prove to have the same qualities when large enough, it is not easy to convince leading manufacturers that their reputation is worth risking; and though eminent cricketers whom I have consulted do not seem to judge bats so much by the appearance of their wood, as by their balance, handle, and weight, they would rather pay a high price for a bat which is guaranteed by the maker than use a substitute whose durability and driving powers are more or less uncertain.—H. J. E.

⁶ *Profitable Planter*, 72 (1814). Sang, Nicol's *Planter's Kalendar*, 68 (1812), says that the red-twigged willow "forms a large tree and has a fine silvery foliage; it is probably the same as the upland willow of Mr. Pontey."

but the latter's description is vague and uncertain; and I have been unable to find any accounts of this remarkable tree as early as the eighteenth century.

S. cœrulea is much faster in growth than either *S. alba* or any of the varieties of *S. viridis*. It is true that well-shaped trees of the latter kinds, grown with clean stems on proper soil, are frequently purchased at a fair price¹ by bat-makers; yet *S. cœrulea* should always be preferred for planting. It comes to market earlier, on account of its rapid growth; and produces a wood light in weight,² very elastic and tough, which is found to be the most suitable for making the best kinds of cricket bats.³

CULTIVATION

The best account of the cultivation of this tree is given by Mr. E. R. Pratt, from whose article⁴ I shall quote largely.

The choice of soil is most important, as many failures are due to the prevalent idea that willows will thrive in any wet or marshy situation. This is erroneous, and soils sodden with stagnant water or of a peaty nature should be avoided. The best ground is undoubtedly rich light alluvial land by the side of a running stream; but good willows are also seen growing in fertile loam, where there is a good supply of moisture. Clay and gravel soils are usually quite unsuitable. If willows are planted in grass land beside a stream, they must be protected against cattle, during the whole period of their growth; and, in all cases, rabbits must be excluded.

In peaty soil, except in very rare cases where the drainage is good and the properties of the peat modified in consequence, willows never thrive, and after a few years often die. In such cases the soil, when examined, proves to be very acid in reaction; and the willows are frequently attacked by a fungus, *Physalospora gregaria*, Saccardo, which produces cankerous spots on the young stems. The epidermis at first looks as if scorched, then dries up, turns brown, and becomes cracked by the protrusion of very small black spots (the fruit of the fungus); it ultimately peels off, exposing the inner part of the stem. Dr. T. Johnson, who has given a good account,⁵ with figures, of this fungus, believes that its ravages are much favoured by raw peaty soil; and certainly, in some cases, it is the cause of extensive failures in willow plantations. In wet or marshy situations, where there is great growth of grass, the willow seems more liable also to the attacks of the beetle, *Saperda carcharias*, Linn.

Though rooted cuttings are frequently advertised by nurserymen, there seems to be no doubt that it is much more advantageous to plant large sets. Scaling,⁶ who had great experience, says: "All varieties of tree willows grow better and more

¹ Two trees in Suffolk, growing in good soil, which I examined before they were cut down—both *S. alba*, but one male, and the other female—were sold at 6s. 8d. per cubic foot in 1910; but these trees, twenty years after planting, had only attained 14 in. in diameter, and had short stems which made only four bat lengths.

² Mr. L. Fosbrooke, Ravenstone Hall, Leicester, states in *Gard. Chron.* xxxix. 46 (1906), "The close-barked white willow is *Salix cœrulea*. It is the quickest grower of all the tree willows in a moist soil, reaching 18 in. in diameter in as many years. The quicker the growth, the lighter the timber, and the better the price."

³ Mr. E. R. Pratt, in *Quart. Journ. Forestry*, i. 336 (1907), shows that the specific gravity of the wood of *S. alba* (male trees) exceeds that of *S. cœrulea* (female trees) by 14½ per cent.

⁴ *Journ. Roy. Agric. Soc.* lxi. 19-34 (1905).

⁵ *Proc. Roy. Dublin Soc.* x. pt. ii. 153-166, plates 13-15 (1904).

⁶ *Salix or Willow*, i. Cat. p. 8 (1871).

vigorously from cuttings than from rooted plants." Gorrie¹ found that shoots of the white willow "6 to 8 ft. long and about 2 in. in diameter succeed better than rooted plants; they require to be put from 18 in. to 2 ft. deep, in marshy soil, which should be drained." At the present time, it is the invariable custom amongst expert growers of cricket-bat willow to use large sets, up to 20 ft. long and 3 in. in diameter, and scarcely smaller than 6 to 10 ft. long by 2 in. in diameter. The sets are best obtained from young trees that have either been felled for sale or that have been specially pollarded for the purpose; and should never be taken from the tops of old trees, as these are seldom straight, and require much trimming. A young tree, about ten years old, gives the best sets when pollarded, and can be again pollarded every five years for six or seven times till decay sets in. The sets should be cut in early spring. Mr. Pratt, after trimming them for four-fifths of their length, has them tied up in bundles of ten, and kept in water for a month, after which they are planted out.

As the willow is a light-demanding tree, and the grower's object is to produce, as quickly as possible, a short stem clean of branches for about 12 to 15 ft., a good crown of foliage must be preserved from the start, and the trees should be planted so wide apart that they do not interfere with each other by lateral shade. If closely planted, they grow more slowly, and often develop an elliptical instead of a circular stem. The distance apart along the side of a stream should not be less than 10 yards. Close planting to kill undergrowth or grass is a mistake, as the latter, if necessary, can be removed by cultivation, though this is seldom done.

Holes may be made for the sets by driving in a stake two or three feet deep, which can afterwards be levered out. The sharpened end of the set is then dropped into the hole, and tightly rammed in position. It is very important to insert the set deeply and firmly, so that it may not be shaken by the wind. The after care consists in rubbing off in the first three years, with the gloved hand, as high up as possible, the buds which appear on the stem, so as to prevent the development of side shoots. Mr. Pratt advocates the pruning of the stem afterwards to a height of 25 ft., but this is seldom if ever done in Herts or Essex, where growers are content with a stem clear of branches to 12 or 15 ft.

Willow trees become saleable to bat-makers, when they are about 15 in. in diameter at six feet from the ground, or about 13 in. at twelve or fifteen feet up. The original set remains as a useless core in the centre of the stem. As the width of a bat is about $5\frac{1}{2}$ in. and the clefts are taken radially, the minimum diameter should be $5\frac{1}{2}$ in. + $5\frac{1}{2}$ in. + 2 or 3 in. (the diameter of the set) = 13 or 14 in. The trees may of course be allowed to grow for another period of years, until a second ring of clefts is formed around the first ring, or even for a further period; but it is usually most profitable to dispose of the trees when they are young.

The trees are generally sold standing, and are deemed of first quality when the stem is straight, clear of knots or branches, and covered with a smooth scaly bark, which is indicative of rapid growth. As the length of a bat is about 28 in., the trees

¹ Loudon, *Gard. Mag.* i. 46 (1826). J. Harrison, *New Method*, 20-24 (1766) recommended, in planting willows, the use of sets 16 ft. long, with all the side branches pruned off; to be preserved from cattle by three stakes two feet from the set, tied up with thorns; and an after treatment of disbudding.

as soon as felled, which is done in winter, are cross-cut into lengths of 28 to 30 in., and these in turn are split into clefts. The clefts are split up along the radii so that the annual rings run from the front to the back of the bat. The best clefts come from the lower part of the tree, which is far tougher than the upper portion. In the best bats I have counted from seven to nine annual growths.

The clefts are ultimately fashioned into blades, which are subjected to hydraulic pressure; and it is here that the value of *S. caerulea* shows itself, as blades made of *S. fragilis* are unable to stand the requisite amount of pressure. The further process of manufacture is detailed in a pamphlet¹ written by W. E. Bussey, which should be consulted by those interested in the growth of willow.

The extraordinary value of the true cricket-bat willow is not exaggerated in the following statement,² made by Mr. John Barker of Pishiobury, Sawbridgeworth: "A good set costs 1s. to 1s. 6d., and, if planted in a suitable soil and does well, is worth from £5 to £8 in fifteen years." He instances a case where a piece of land was bought for £50, and planted with willows, which were sold, when sixteen years old, for £2000 in 1905.

The following figures have been given to us by a reliable grower of willows in Herts. In December 1910 he sold twenty-four trees which grew on the bank of a stream, and had been thirteen years planted, for an average of £5 per tree. In January 1912 he sold eleven willows, which had been planted fourteen years previously, for £81. These trees averaged 55 to 60 ft. in height, and were clear of branches for about 18 ft., their stems ranging from 42 to 46 in. in girth at five feet from the ground. The best tree contained 12 cubic feet of timber, available for making bats, and as it sold for £8, the price per cubic foot came to 13s. 4d. In 1906 fifty-three trees growing on the same property were sold for £190. These had short stems, averaging 13 in. in diameter, and yielding only three bat lengths.

Many trees of remarkable size, but comparatively young, have been felled for conversion into cricket bats. One of the largest on record³ was a tree at Boreham, Essex, which was planted in 1835, and felled in 1888, when it was 101 ft. high and 5 ft. 9 in. in diameter. It weighed upwards of eleven tons, and was perfectly sound. It was felled by B. Warsop and Sons, who made from it no less than 1179 bats.⁴

Mr. H. Clinton-Baker tells us of another willow which grew in a field at Aspenden, near Buntingford, and was purchased by the same firm. It was 6 ft. in diameter, at three feet from the ground, and divided at five feet up into two stems, which were clear to a height of 50 ft., where they still measured 2 ft. in diameter.

Mr. Stuart Surridge purchased for £25 in 1910 a tree near St. Albans, which was about 80 ft. high and measured 5 ft. in diameter at three feet from the ground. Judging from a photograph, it had a clean stem of about 16 feet. He states that the largest tree known to him grew at Robertsbridge, in Sussex, and measured 21 ft. in girth. This was felled in 1902, and produced over 1000 cricket bats.

Sir Thomas B. Bevor made the following note in his copy of Evelyn's *Sylva* :

¹ Published in 1910 by Geo. G. Bussey and Co., Queen Victoria St., London, E.C.

² *Gard. Chron.* xxxix. 62 (1906).

³ *Trans. Eng. Arbor. Soc.* iv. 122 (1899).

⁴ Mr. Edwin Savill informs us that he sold a tree in 1911 for £70, but he has no measurements. The dealer told him that the number of feet utilized worked out at £1 per cubic foot.

"Mar. 12, 1808. Willow tree, planted about eighteen years in a meadow at Wortham, in Suffolk, in length about 22 ft., and measured, at four feet from the ground, 7 ft. 10 in., and in its bark appearing as green as when young. This willow is now found to be the cœrulean willow, and was taken down in 1816, and cut into boards which measured 22 in. broad; and increased (in the last) eight years in girth to 11 ft. 8 in."

There are many fine trees on the Copped Hall estate, near Epping, where the agent, Mr. P. W. Dashwood, informed me in 1907 that he had refused a short time previously an offer of £1500 for 100 trees to be selected by the purchaser. He sold one tree for £25 which was afterwards re-sold for £40 to another dealer. This tree had a stem $3\frac{1}{2}$ ft. in diameter, and was clean of branches for about 25 ft.; it yielded eleven lengths of bats, twenty-eight inches being allowed for a bat-length.

In 1910 I measured at Ryston, Downham, Norfolk, a true *S. cœrulea* which was twenty years old and growing in good soil—alluvial silt over clay. It was 80 ft. high by 5 ft. 4 in. in girth. A male *S. alba* of the same age growing beside it was 65 ft. high by 3 ft. 11 in. in girth. Mr. E. R. Pratt sent me a photograph of a tree, growing on the bank of the river Wissey at Hilgay, south of Downham, which, in October 1912, measured 84 ft. in height, and 6 ft. 5 in. in girth. This tree was planted in 1889; and is growing very rapidly, as it was only 5 ft. 6 in. in girth in February 1910.

Elwes saw in 1907 a fine tree growing in a meadow near Spains Hall, Braintree, Essex, which was considered by Mr. A. W. Ruggles-Brise, to be a true cricket-bat willow. It was quite sound and healthy, and measured 90 ft. by $12\frac{1}{2}$ ft.

The illustration (Plate 381) is reproduced from a negative for which we are indebted to Mr. M. C. Duchesne. It was taken from a tree in a meadow called Hartham, near Hertford, of which the grazing is annually let by the municipality. The soil and situation are considered ideal for growing willow. (A. H.)

SALIX VITELLINA, GOLDEN WILLOW

Salix vitellina, Linnæus, *Sp. Pl.* 1016 (1753); Smith, *Eng. Bot.* t. 1389 (1805), and *Eng. Flora*, iv. 182 (1828); Host, *Salix*, tt. 30, 31 (1828); Forbes, *Salic. Woburn.* 39, t. 20 (1829); Loudon, *Arb. et Frut. Brit.* iii. 1528 (1838).

Salix alba, Linnæus, var. *vitellina*, Stokes, *Bot. Mat. Med.* iv. 506 (1812); Seringe, *Ess. Saule Suisse*, 83 (1815); Andersson, in De Candolle, *Prod.* xvi. 1, p. 211 (1868); Buchanan White, in *Journ. Linn. Soc. (Bot.)* xxvii. 371 (1890); Camus, *Monog. Saules*, 75 (1904).

(?) *Salix basfordiana*,¹ Scaling, *Salix or Willow, Cat.* p. 8 (1871), and ii. 19 (1872).

A tree, attaining about 60 ft. in height, with spreading branches. Young branchlets, pubescent at the tips and near the nodes, becoming glabrous and bright yellow in winter, and in the following year. Leaves lanceolate, averaging $2\frac{1}{2}$ in. long and $\frac{3}{8}$ in. wide, gradually tapering to a slender acuminate caudate apex; shining green above, bluish white beneath, with scattered appressed silky hairs, usually slight

¹ Cf. page 1757, note 1.

on the upper surface, more abundant beneath; serrations minute with incurved glandular tips; margin either ciliate throughout the season, or with the cilia deciduous in summer; petiole slightly pubescent.

Catkins terminating short leafy branches and appearing with the leaves; axes white tomentose, densely flowered. Staminate catkins, 1 to $1\frac{3}{4}$ in. long, curved; stamens two, rarely three, base of filament slightly pilose; scales concave, ovate-lanceolate, almost glabrescent, slightly ciliate, nearly twice as long as the stamens; glands two, posterior quadrate and usually bilobed, anterior smaller and usually entire. Pistillate catkins, very slender, $1\frac{3}{4}$ in. long; ovary with a distinct pedicel, which is twice as long as the posterior bilobed quadrate gland, conic, glabrous, about $\frac{1}{8}$ in. long, ending in a short style; stylar arms spreading and bilobed; scale as long as the ovary, pubescent on both surfaces.

S. vitellina is related to *S. alba*, but is distinct in the flowers, and has narrower and less pubescent leaves. The flowers are occasionally unstable, three stylar arms and three stamens being present instead of two, and the ovary is often peculiarly inflated towards the apex. *S. vitellina* is variable as regards the amount of the pubescence; in one form the leaves are scarcely pubescent on the upper surface, and the margin becomes non-ciliate; while in another form there is appressed pubescence on both surfaces, often dense beneath, and the cilia are retained on the margin till late in the season. *S. vitellina* is possibly of hybrid origin, and though long known in cultivation and naturalised in many parts of Europe is very doubtfully wild. Smith states¹ that Crowe found it wild in pastures at Ovington, near Watton, Norfolk.

The following varieties are known:—

1. Var. *pendula*, Späth, *Cat.* No. 69, p. 110 (1888).

Branchlets pendulous. Leaves narrow, non-ciliate. This is a beautiful weeping tree,² which is often sold under the erroneous name of *S. babylonica*, var. *aurea*.

2. Var. *britzensis*, Späth, *Cat.* No. 57, p. 67 (1883).

Young branchlets bright red, pubescent. Leaves appressed-pubescent on both surfaces, ciliate till autumn. This is a staminate tree. It is the finest of all the coloured willows, the twigs assuming a beautiful red colour in winter. A thriving specimen at Glasnevin is about 40 ft. high, and is narrowly pyramidal in habit.

The golden willow is planted for ornament both in England and the Continent, and is occasionally cultivated in osier beds.³ It is very striking in winter, and seems to thrive in this country, though Smith states that the twigs are often killed by severe cold, like those of *S. babylonica*. We have seen no trees of great size, the finest being probably two trees at Glasnevin, which are about 65 ft. in height and 8 ft. in girth. These are probably of considerable age, and have rough bark like that of *S. fragilis*. It was early introduced into North America, where it is now very common in New England. (A. H.)

¹ *Fl. Brit.* iii. 1050 (1804).

² Dode, in *Bull. Soc. Bot. France*, lv. 655 (1910), considers this to be a hybrid between *S. vitellina* and *S. babylonica*, and names it *S. chrysocoma*, Dode.

³ Cf. Ellmore and Okey, in *Journ. Board. Agric.* xviii. 914 (1912), who say that it is one of the toughest willows grown, if used with the bark on in a green state. Hence it mostly produces rods, which are used for tying purposes.

POPULUS

Populus, Linnæus, *Gen. Pl.* 307 (1737) and 456 (1754), *Sp. Pl.* 1034 (1753); Wesmael, in De Candolle, *Prod.* xvi. 2, p. 323 (1868), in *Mém. Soc. Sci. Hainaut*, iii. 186-250 (1869), and in *Bull. Soc. Bot. Belg.* xxvi. pt. i. p. 371 (1887); Bentham et Hooker, *Gen. Pl.* iii. 412 (1880); Schneider, *Laubholzkunde*, i. 2-23 (1904), and ii. 869, 870 (1912); Dode, in *Mém. Soc. Hist. Nat. Autun.* xviii. 1-76 (1905); Ascherson and Graebner, *Syn. Mitteleurop. Flora*, iv. 14-54 (1908); Gombocz, in *Math. Termes. Közl.* xxx. 5-238, with two maps (1911).

DECIDUOUS trees, belonging to the natural order Salicaceæ. Terminal buds large, with one or two outer pairs of opposite scales at the base, and several imbricated scales above; axillary buds smaller, with fewer scales, the lowest of which is short, broad, and open next the stem; scales accrescent, marking when they fall the base of the branchlet with ring-like scars. Branchlets terete or angled, with five-angled pith, and showing, when the leaves have fallen, three-dotted leaf-scars, on the sides of which are visible two minute scars left by the early deciduous stipules. Leaves simple, alternate, penninerved, usually long-stalked; entire, dentate, or lobed; often different in shape, pubescence, and margin on the long and on the short shoots.

Flowers without honey, fertilised by the wind, appearing before the leaves in early spring; diœcious, in pendulous stalked catkins, which arise from buds in the axils of the leaf-scars of the previous year or at the ends of short shoots. Catkins bearing on a slender axis numerous flowers, each of which is subtended by a caducous stalked lobed, dentate, or lacinate scale (bract). Perianth absent, replaced by a stalked disc. Male flowers densely crowded; stamens four to twelve, or twenty to sixty, with short white filaments, and purple or red two-celled anthers, arising from the oblique, flat or concave disc. Pistillate flowers not so dense in the catkin as the male flowers; ovary sessile in the oblique cup-shaped disc, one-celled, with two, three, or four placentæ; style short or obsolete, with as many entire or bifid stigmas as there are placentæ. Fruiting catkins elongated, ripening early before the leaves are fully grown; capsule one-celled, separating when ripe into two to four recurved valves, girt at the base by the persistent disc.¹ Seeds numerous, minute, without albumen, elliptic, compressed, acuminate at the apex, surrounded by tufts of long white silky hairs, attached to their short stalks and deciduous with them. Seedling,² with two stalked suborbicular cotyledons, sagittate at the base, thick and succulent; primary leaves either in opposite pairs as in *P. canescens*, or alternate as in the black poplars.

¹ In section *Turanga* the disc is deciduous, and does not persist on the fruit.

² An account of the germination of poplars, with figures of the seedlings, is given by Miss F. II. Woolward, in *Journ. Bot.* xlv. 417, t. 487 (1907). Cf. also Hinkel, in *Bull. Soc. Dend. France*, No. 25, p. 88 (1912).

The poplars are typical light-demanding trees, incapable of bearing shade, their branchlets and leaves dying when not exposed to full light. This is well seen when two Lombardy poplars are planted close together, the shade of the taller of the two killing the branches on the adjacent side of the other. In connection with this demand for light, which necessitates sparse branches and foliage, the poplars normally shed many of their smaller branchlets in autumn. The process¹ by which this is effected is similar to that by which the leaves are cast off,—a zone of corky tissue being formed at the point where the rupture subsequently takes place,—the branchlet leaving when it falls a circular scar on the main branch to which it was attached.

The genus *Populus* comprises about twenty-five species, inhabiting the extra-tropical regions of the northern hemisphere from the Arctic Circle southwards; in North America extending to Lower California and northern Mexico; throughout Europe and northern Africa; and in Asia, extending as far south as Asia Minor, Syria, Mesopotamia, Persia, Afghanistan, the Himalayas, China, and Japan. Towards the extreme north certain species often form great forests; elsewhere poplars are most common in alluvial land bordering rivers, streams, and swamps; but occasionally they form a part of the deciduous forests.

The genus is divided into five sections; and the following key, based mainly on the characters of the leaves and buds, includes all the species in cultivation, with the more important hybrids; and in addition, three species, mainly of botanical interest, which we have not seen in England in the living state.

I. *TURANGA*, Bunge, *Beit. Kennt. Fl. Russ.* 498 (1848).

This section differs from the others in the remarkable polymorphic leaves, and in the deeply cleft disc of the flowers, which does not remain persistent at the base of the fruit.

1. *Populus euphratica*, Olivier.²

Northern and eastern Africa, Syria, Mesopotamia, Persia, Turkestan, Afghanistan, north-west India, Mongolia, north China.

A tree 50 ft. high. Leaves coriaceous, greyish green, of the same colour on both surfaces; on young trees, linear or oblong, entire, short-stalked, and willow-like; on old trees extremely diverse, ovate, oblong, rhombic, or orbicular, lobed or cut, long-stalked.

Not hardy in Great Britain.³ This poplar, and not a willow,⁴ is the '*arabim*' of the Psalms, cxxxvii. 2, the trees growing by the rivers of Babylon, on which the Jews in captivity hanged their harps.⁵

¹ This natural fall of branchlets, effected by a vital process, was termed *cladopsis* by Berkeley, in *Gard. Chron.* 1855, p. 596. It has been observed in oaks and willows, as well as in poplars, and Shattock gave a complete account of it in the case of the aspen in *Journ. Bot.* xxi. 306 (1883). This phenomenon appears to have been first noticed by J. Main, *Hort. Register*, iv. 193, fig. A (1835), where a fallen branch of the black poplar is figured.

² *Voy. Emp. Othom.* figs. 45, 46 (1807). This is a very variable species, which has been variously treated by botanists. Gombocz, in *Math. Termes. Közl.* xxx. 71, 72 (1911), recognises several varieties, and treats *P. pruinosa*, Schrenk, as a distinct species. *P. illicitana*, Dode, in *Bull. Soc. Dend. France*, 1908, p. 163, lately found near Elche in Spain, appears to be only naturalized there, and is identical with the ordinary form of the species in Morocco and Algeria.

³ Späth, *Catalogue*, No. 91, p. 51 (1893-1894), states that a plant sent to Lauche from Turkestan in 1881 soon died. It was reintroduced by General Korolkow, who sent it to Späth in 1892.

⁴ *Salix babylonica*, Linnæus, was so called, because it was erroneously supposed to be the tree of the Psalms. Cf. p. 1752.

⁵ Cf. Koch, *Dendrologie*, ii. pt. i. p. 507 (1872), and Ascherson, in *Sitzb. Ges. Nat. Fr. Berlin*, 1872, p. 92.

II. LEUCE, Duby, in De Candolle, *Syn. Pl. Fl. Gall.* i. 427 (1828).

White poplars and aspens.—Bark smooth on young stems, ultimately breaking on the surface into rough rhombic cavities. Buds variable, tomentose and dry, or glabrous and viscid. Leaves variable, tomentose or glabrous; lobed, dentate, or serrate. Flower scales fringed with long hairs; stamens few, about ten; capsules slender, oblong.

A. White poplars.—Leaves densely tomentose on the long shoots; less tomentose or glabrescent, and different in shape on the short shoots.

2. *Populus alba*, Linnæus. Europe, North Africa, Asia Minor, Caucasus, Central Asia, Himalayas. See p. 1777.

Leaves on the long shoots palmately lobed, snowy white beneath; on the short shoots oval, dentate, greyish beneath.

3. *Populus tomentosa*, Carrière. North China. See p. 1786.

Leaves on the long shoots triangular-ovate, without lobes, biserrate, grey tomentose beneath; on the short shoots, with a few sinuate teeth, glabrescent beneath.

4. *Populus canescens*, Smith. Western Europe. See p. 1780.

Leaves on the long shoots ovate-deltoid, greyish white beneath, with irregular triangular serrated teeth; on the short shoots suborbicular or broadly ovate, glabrescent beneath, with a few sinuate teeth.

B. Aspens.—Leaves on the long and short shoots not markedly different, glabrous or glabrescent beneath.

* *Branchlets glabrous.*

5. *Populus tremula*, Linnæus. Europe, North Africa, Asia Minor, Caucasus, Siberia. See p. 1787.

Leaves suborbicular, $1\frac{1}{2}$ to 2 in. in diameter, thin in texture, acute or rounded at the apex; margin with rounded or sinuate teeth.

6. *Populus tremuloides*, Michaux. North America. See p. 1791.

Leaves orbicular or ovate, $1\frac{1}{2}$ to 2 in. in diameter, thin in texture, cuspidate at the apex; margin ciliate, finely and regularly serrate.

** *Branchlets slightly tomentose.*

7. *Populus Sieboldii*, Miquel. Japan. See p. 1794.

Leaves ovate, 3 in. long, 2 in. wide, thick in texture, shortly acuminate at the apex; margin with minute sinuate teeth or glandular serrations.

8. *Populus grandidentata*, Michaux. North America. See p. 1792.

Leaves ovate-deltoid, 3 to 4 in. long, 2 to 3 in. wide, thin in texture, acuminate; margin with a few sinuate triangular large teeth.

III. AIGEIOS, Duby, in De Candolle, *Syn. Pl. Fl. Gall.* i. 427 (1828).

Black poplars.—Trees with furrowed bark. Buds viscid, but not very odorous. Leaves green on both surfaces, with a clearly defined translucent border.

A. *Leaves never ciliate in margin.*

9. *Populus nigra*, Linnæus. Europe, Caucasus, Siberia. See p. 1795.

Leaves rhomboid, about 3 in. long, 2 in. broad, cuneate at the base, gradually tapering above into a long acuminate apex; glands never present at the base. Stigmas always two. Stamens fifteen to thirty, purple.

Branchlets and petioles glabrous in var. *typica*, pubescent in var. *betulifolia*.

The Lombardy poplar (p. 1798) is the fastigate form of var. *typica*; and var. *plantierensis* (p. 1802) is the fastigate form of var. *betulifolia*.

B. *Leaves ciliate in margin.*

* *Glands absent at the base of the leaf.*

10. *Populus Fremontii*, Watson. North America. See p. 1794.

Leaves on young cultivated trees, reniform or rhombic, with a cuneate base; on old trees deltoid with a truncate base; about $2\frac{1}{2}$ in. wide; apex cuspidate; serrations few, coarse, and incurved. Stigmas three. Stamens about sixty, with dark red anthers.

** *Glands always present on the base of the leaf.*

11. *Populus monilifera*, Aiton. North America. See p. 1807.

Branchlets rounded. Leaves deltoid-ovate, about 3 in. wide, shallowly cordate or truncate at the base, cuspidate at the apex; serrations sinuate, with incurved tips, fewer and coarser than in the hybrids. Stigmas three or four. Stamens fifty to sixty.

12. *Populus angulata*, Aiton. North America. See p. 1810.

Branchlets angled. Leaves triangular-ovate, longer than broad, up to 7 in. long, and 5 in. broad, truncate or cordate at the base, acute or shortly acuminate at the apex. Stigmas four. Stamens fifty to sixty.

*** *Glands variable at the base of the leaf, absent or one or two in number.*

Hybrids between the European *P. nigra*, and one or other of the American *P. monilifera* and *P. angulata*. Leaves with irregular marginal cilia, which are often sparse, and usually deciduous in summer; serrations not coarse and sinuate.

* *Branchlets glabrous.*

13. *Populus serotina*, Hartig. See p. 1816.

Branches ascending, wide-spreading. Leaves unfolding latest of all the poplars and with a red tint, ovate-deltoid, about 3 in. wide, with a broad truncate base, and a short cuspidate or acuminate apex. A staminate tree; stamens twenty to twenty-five.

14. *Populus regenerata*, Schneider. See p. 1824.

Similar to *P. Eugenei* in habit, with foliage like that of *P. serotina*, but unfolding a fortnight earlier. A pistillate tree; stigmas usually only two.

15. *Populus Eugenei*, Simon-Louis. See p. 1826.

A narrow columnar tree, with ascending short branches. Leaves unfolding early with a reddish tint, smaller than those of *P. serotina*, broadly cuneate at the base, with a slender sharp-pointed non-serrated acuminate apex. A staminate tree; stamens about twenty.

16. *Populus marilandica*, Bosc. See p. 1828.

A tree with irregular branches. Leaves early in unfolding, rhomboid, cuneate at the base, tapering above into a long acuminate apex. A pistillate tree; stigmas variable, two, three, or four.

17. *Populus Henryana*, Dode. See p. 1829.

A tree with irregular branches. Leaves opening early, not tinged with red, ovate-triangular, cuneate at the broad base, and ending in a long acuminate apex. A staminate tree; stamens thirty to thirty-five. Flower buds pubescent.

** *Branchlets pubescent.*

18. *Populus robusta*, Schneider. See p. 1829.

Branchlets grey. Leaves unfolding early with a deep red tint, variable in shape, ovate-deltoid or rhomboid; cuneate, rounded, or truncate at the base; acuminate at the apex; petioles pubescent. A staminate tree; stamens twenty.

19. *Populus Lloydii*, Henry. See p. 1830.

Branchlets yellow. Leaves similar to those of *P. robusta*, but smaller; petioles pubescent. A pistillate tree; stigmas usually two.

IV. TACAMAHACA, Spach, in *Ann. Sci. Nat.* xv. 32 (1841).

Balsam poplars.—Trees with rough furrowed bark, and fragrant foliage. Buds very viscid, exhaling a strong balsamic odour. Leaves whitish beneath, without a clearly defined translucent cartilaginous border; petioles rounded or quadrangular, channelled on their upper side.

A. *Branchlets rounded, without projecting ribs, except occasionally on vigorous shoots of young trees.*

* *Branchlets and petioles pubescent.*

20. *Populus candicans*, Aiton. North America. See p. 1834.

Leaves broad, ovate-deltoid, palminerved and cordate at the base, 5 to 6 in. long, 4 in. wide, ciliate in margin.

21. *Populus tristis*, Fischer. Himalayas (?). See p. 1840.

Leaves narrow, ovate, palminerved and cordate or rounded at the base, 4 in. long, 2 in. wide, ciliate in margin.

22. *Populus Maximowiczii*, Henry. Japan, Amurland, Manchuria, Korea. See p. 1838.

Leaves nearly orbicular, oval, or elliptic; palminerved and subcordate at the rounded base; 4 in. long, 3 to 3½ in. wide; densely ciliate in margin, and pubescent on the midrib, nerves, and veinlets of both surfaces.

23. *Populus suaveolens*, Fischer. Siberia, Mongolia. See p. 1841.

Leaves ovate or ovate-lanceolate, palminerved and rounded at the base, abruptly contracted into an acuminate apex, 3 to 3½ in. long, 1¼ to 2 in. broad; margin ciliate; glabrous on both surfaces.

** *Branchlets and petioles glabrous.*

24. *Populus balsamifera*, Linnæus. North America. See p. 1832.

Leaves ovate, palminerved and rounded at the base, 4 to 5 in. long, 2 to 3 in. wide, sparsely and minutely ciliate in margin.

25. *Populus angustifolia*,¹ James. Rocky Mountains of North America. See p. 1831.

Leaves lanceolate, resembling those of *Salix fragilis* in shape, cuneate at the base, greenish beneath, 2 to 4 in. long, ¾ to 1 in. wide; lateral nerves, fifteen pairs, all pinnate.

B. *Branchlets with projecting linear ridges.*

* *Branchlets pubescent.*

26. *Populus laurifolia*, Ledebour. Altai Mountains. See p. 1842.

A wide-spreading tree. Leaves lanceolate, 3 to 5 in. long, 1 to 2 in. broad, rounded at the base, gradually tapering to an acuminate apex, finely and regularly serrate.

27. *Populus berolinensis*,² Dippel. A hybrid. See p. 1844.

A narrow columnar tree. Leaves ovate or ovate-rhombic, 3 in. long, 2 in. wide, rounded or cuneate at the base, contracted at the apex into an acuminate point, crenately and occasionally irregularly serrate.

** *Branchlets glabrous.*

28. *Populus Wobstii*, Schröder. A hybrid. See p. 1843.

Branchlets only slightly ribbed in the first year, the ribs more apparent in the second year. Leaves lanceolate, tapering to a narrow rounded base, 4 to 6 in. long, 2 in. broad; ciliate in margin; nerves all pinnate.

29. *Populus Simonii*, Carrière. North China. See p. 1839.

Leaves rhombic-elliptic, cuneate and pinnately nerved at the base, contracted at the apex into a short cuspidate point, 3 in. long, 1¼ in. broad.

30. *Populus trichocarpa*, Torrey and Gray. Western North America. See p. 1836.

Young stems with bark peeling off in papery shreds. Leaves ovate or ovate-deltoid, palminerved and rounded or subcordate at the base; 5 in. long, 3 in. broad; whitest beneath of all the balsam poplars.

V. LEUCOIDES, Spach, in *Ann. Sci. Nat.* xv. 30 (1841).

Trees with rough bark, breaking into loosely attached plates. Leaves very large, cordate, simply serrate, covered when unfolding with greyish tomentum, which speedily disappears except on the nerves beneath; petioles rounded, much shorter than the blades, which do not flutter in the wind. Buds pubescent, viscid. These poplars are not easily propagated by cuttings.

31. *Populus lasiocarpa*, Oliver. Central China. See p. 1846.

Leaves ovate-cordate, longer than wide, about 9 in. long, and 6 in. broad; green beneath, with uniform serrations, extending regularly to the sinus at the base.

32. *Populus heterophylla*, Linnæus. United States, from the Mississippi valley eastwards to the Atlantic coast. See p. 1846, note 2.

¹ This species is very distinct from the other balsam poplars, in the willow-like leaves, which are not whitish beneath.

² This hybrid differs from the balsam poplars in the very narrow translucent border on the leaves, which are less fragrant and greenish, or only slightly whitish beneath. *P. rasumowskyana* and *P. petrowskyana* are similar hybrids, of which I have not seen complete material. See pp. 1843, 1844.

Leaves ovate-cordate, nearly as broad as long, 4 to 7 in. long, 3 to 6 in. wide; pale beneath, with regular serrations except at the base, where they are few and wide apart. (A. H.)

THE RAISING OF POPLARS FROM SEED

No good description or illustration of the germination of poplars seems to have been published in England before that of Miss Florence Woolward¹ in 1907.

I have never found in England a poplar grown from seed either naturally or by nurserymen; and though Grigor² describes the process, it seems doubtful whether he ever practised it; and all my own attempts to raise poplars from seed were fruitless, until I followed nature as closely as possible. Having observed that poplars only germinated freely on the sandy banks of rivers, I sowed seed as soon as ripe on a pot of sand, and placed the pot in a pan of water in the full sun. Germination was then extremely rapid, according to Miss Woolward, in ten hours to two days. I found that after four days no more seeds came up, and that in all cases the proportion of germinating seed was quite small. In five or six days the cotyledons are well developed, but the growth of the young plants is very slow and does not exceed 2 to 5 inches in height in the first season. Some one-year seedlings of *P. nigra*, sent me from the banks of the Allier in central France, were only 3 to 4 inches above ground, though their thick rather fleshy root was 6 to 10 inches long. Some seedlings of *P. monilifera* from the banks of the St. Lawrence in Canada, collected by Mr. Jack, were equally small; as were some of *P. nigra* raised by Mr. Hankins from seed collected at Bury St. Edmunds.

Miss Woolward and I also raised *P. canescens* from seed collected at Upcot near Colesborne, where both sexes of this tree grow on my own property; and she raised *P. marilandica* from seed of a tree in Kew Gardens. In both cases the seedlings were much less vigorous than cuttings from the same trees.

I also raised seeds collected under a tree, which I believe to be *P. monilifera*, of American origin, in the botanic garden at Padua, which was perhaps fertilized by a *P. alba*, the only poplar growing near it; but none of those seedlings have shown the least sign of hybrid origin, and have grown slowly and seem tender as compared with poplars raised from cuttings.

I am therefore convinced that, though we may succeed, by crossing different species, in obtaining new races of superior vigour, like *P. Eugenei* and *P. robusta*, the raising of poplars from seed is not a practice which can be recommended for general purposes. Some species of poplar are said to be difficult or impossible to strike from cuttings, among which Grigor includes *P. alba* and *P. canescens*, but I have found no difficulty in the case of the latter. In the case of species which will not strike, recourse must be had to layers, root-suckers, or grafting. (H. J. E.)

¹ *Journal of Botany*, xlv. 417, t. 487 (1907).

² *Arboriculture*, 328 (1881). Hickel, in *Bull. Soc. Dend. France*, No. 25, p. 88 (1912), gives directions for raising poplars from seed, which he has followed with success at Versailles.

POPULUS ALBA, WHITE POPLAR

Populus alba, Linnæus, *Sp. Pl.* 1034 (1753); Loudon, *Arb. et Frut. Brit.* iii. 1638 (1838) (in part); Willkomm, *Forstl. Fl.* 516 (1887); Mathieu, *Flore Forestière*, 483 (1897); Schneider, *Laubholzkunde*, i. 21 (1904); Ascherson and Graebner, *Syn. Mitteleurop. Fl.* iv. 17 (1908); Boissier, *Flora Orient.* iv. 1193 (1879); Hooker, *Fl. Brit. India*, v. 638 (1888); Aigret, in *Ann. Trav. Publ. Belg.* x. 1213 (1905); Gombocz, in *Math. Termes. Kozl.* xxx. 141 (1911).
Populus major, Miller, *Dict.* ed. viii. No. 4 (1768).
Populus nivea, Willdenow, *Berl. Baumz.* 227 (1796).

A tree, similar in size and bark to *P. canescens*. Young branchlets and buds densely white tomentose.¹ Leaves (Plate 408, Fig. 1), very variable in size and shape, dependent upon the position and vigour of the branchlets and on the age of the tree; on vigorous long shoots and suckers, large, up to 4 or 5 in. in diameter, ovate, palmately three- to five-lobed; lobes triangular, with deep sinuses; margin ciliate with minute glandular teeth; subcordate at the rounded or broad base, acute at the apex; dark green and slightly tomentose above; covered beneath with a dense snowy white tomentum; petiole rounded, tomentose. Leaves on short shoots (and occasionally at the base of the long shoots), elongated oval, rounded at the base, with a few sinuate teeth, usually covered beneath with a thin greyish tomentum; in some cases (var. *denudata*, Wesmael) glabrescent; in some forms, broad and suborbicular like the similarly placed leaves of *P. canescens*, but uniformly tomentose beneath, and with fewer teeth in the margin; petiole tomentose.

Pistillate catkins similar to those of *P. canescens*, but more silvery in colour; scales obovate to lanceolate, with minute teeth, and fringed with long hairs; stigmatic lobes four, green, erect, long and linear, each of the two pairs united at the base. Staminate catkins² (probably not perfectly developed), 1 inch long; axis tomentose; scales concave, spatulate, dentate, fringed with long hairs; disc pubescent; stamens six.

Spread over an immense area, *P. alba* is very variable in the form of the foliage, and might be divided into several distinct geographical races; but the wild specimens in herbaria are scanty and incomplete; and only a few important varieties will be here mentioned. *P. canescens*, a native English tree, and *P. tomentosa*, wild in North China, are easily distinguishable; and are treated here as distinct species.

1. Var. *nivea*, Aiton, *Hort. Kew.* iii. 405 (1789).

This is the typical form³ of the species described above. It has been long in cultivation in western Europe, where it is known in gardens as var. *argentea*, var. *acerifolia*, var. *arembergiana*, etc. It appears to be indigenous in eastern and south-eastern Europe, in the Caucasus, in Persia, Turkestan, Afghanistan, and the Altai Mountains, where specimens have been gathered by travellers. In Kashmir, according to Mr. Lovegrove, of the Forest Department, from whom I have received specimens, the typical form is fairly common in the wild state, attaining on an average 90 ft. in height and 8 ft. in girth.

In cultivated trees, the leaves are extraordinarily variable in size and shape, but it

¹ The suckers of *P. alba* are described by Dubard, in *Ann. Sci. Nat.* xvii. 163 (1903).

² The only male flowers of *P. alba* which I have been able to examine were produced by a small tree at Kew, labelled var. *nivea*, and did not seem to be properly developed. Most, if not all, of the white poplars in Britain are female trees.

³ Gombocz, *op. cit.* 148, 149, recognizes as forms of var. *nivea*, the slight variations, which are doubtfully constant, called by Dode, *op. cit.* 21, 22, *P. triloba*, *P. Treyviana*, *P. Paletskyana*, *P. heteroloba*, *P. Morisetiana*, and *P. palmata*.

is doubtful if these constitute distinct varieties; on one tree I have observed ordinary branches with small leaves, varying in shape from oval and slightly toothed to trilobed, and more vigorous shoots showing large palmately lobed leaves. Old trees put forth feeble long shoots, on which the terminal white leaves are often imperfectly developed.

2. Var. *subintegerrima*, Lange, in Willkomm and Lange, *Prod. Fl. Hisp.* i. 233 (1861).

Var. *integrifolia*, Ball, in *Journ. Linn. Soc. (Bot.)* xvi. 668 (1878).

Populus subintegerrima, Dode, *op. cit.* 20 (1905).

Populus monticola, Brandegee, in *Zoë*, i. 274 (1890); Sargent, in *Garden and Forest*, iv. 330, fig. 56 (1891), vi. 190 (1893), and vii. 313, fig. 51 (1894).

Populus Brandegeei, Schneider, *Laubholzkunde*, i. 23 note, and 803 (1906).

Leaves coriaceous, often sub-evergreen; on the long shoots ovate or orbicular, sub-cordate or cuneate at the base, sub-entire or irregularly and slightly toothed, white beneath; on the short shoots almost orbicular, slightly sinuate or quite entire, grey beneath.

A native of southern Spain, Algeria,¹ and Morocco, where it was gathered in the greater Atlas by Hooker. It occurs also in the Canaries and the Azores. It appears to have been introduced into Mexico by the Spaniards, and has been found, apparently naturalised, along streams in the high mountains of Lower California, where it is called *guerigo* by the inhabitants. According to Sargent,² who speaks of it as a distinct native American species, its wood in this locality is quite unlike that of the other poplars, being light red, satiny, and useful for making furniture.

Similar forms³ occur near Askabad, east of the Caspian Sea, and in Kashmir.

3. Var. *pyramidalis*,⁴ Bunge, in *Rel. Bot. Mém. Ac. St. Pétersb.* vii. 498 (1851).

Var. *Bolleana*, Lauche, *ex* Huttig, in *Deut. Gart.* 500 (1878); Masters, in *Gard. Chron.* x. 502 (1878) and xviii. 556 (1882).

Populus Bolleana, Carrière, in *Rev. Hort.* liii. 40, 123 (1881), and lxiii. 188, fig. 48 (1891); Masters, in *Gard. Chron.* xviii. fig. 96 (1882).

Resembling the Lombardy poplar in habit. Leaves on the long shoots palmately 3- to 5-lobed, very white tomentose beneath; on the short shoots orbicular, with coarse triangular teeth, green beneath with traces of tomentum.

The fastigate form of the white poplar was first described by Bunge from specimens found by Lehmann in 1841, apparently wild⁵ on the bank of a stream on the north side of the Karatau mountain, between Bokhara and Samarkand. It appears to have been introduced⁶ in 1872 into Hoser's nursery at Warsaw, from a cutting sent by Col. Korolkow.⁷ Lauche procured it for the Horticultural Society of Potsdam from the same source in 1875.

¹ Collected near Ronda in Spain, by M. P. Price, and near Affreville in Algeria by A. Henry. A specimen from Gibraltar, in the Cambridge Herbarium, has slender female catkins, 4 to 5 in. long, with a woolly axis and pedicellate flowers; scales long, concave, irregularly toothed or lacerate; styles 4, spreading.

² In *Garden and Forest*, vi. 190 (1893).

³ Specimens in the Kew Herbarium.

⁴ *P. alba*, var. *croatica*, Wesmael, in De Candolle, *Prod.* xvi. 2, p. 324 (1868) is an erroneous name founded on *P. croatica*, Waldstein and Kitaibel, in *Flora*, xv. 2 Beil. p. 14 (1832), which is a narrow form of *P. nigra*. Cf. Koch, *Dendrologie*, ii. pt. i. p. 489 (1872).

⁵ Lehmann also saw it planted at Bokhara, where he gathered a leafless branch bearing staminate flowers, on 5th March 1842.

⁶ Cf. *The Garden*, 10th Dec. 1887, p. 543.

⁷ According to Carrière, *Rev. Hort.* lxiii. 188 (1891), it was introduced by Col. Korolkow, under the name of *P. alba pyramidalis* into various places in France in 1878, as Orleans, Segrez, Angers; and was first sold by Simon-Louis in 1879-1880. E. Morren, in *Belg. Hort.* 1879, p. 269, says that it was sent to Späth from Tiflis by Scharrer in 1879.

The oldest tree in England is probably a fine specimen at Kew, growing near the large Ginkgo tree, which measured 67 ft. by 4 ft. 8 in. in 1910. Another at Terling Place, Essex, planted in 1886, measured, in 1910, 60 ft. high by 3 ft. 3 in. in girth. A good specimen at Over Bridge, near Gloucester, was 55 ft. high in 1911. The largest tree we know of in Germany is one at Späth's nursery, which in 1908 was 66 ft. by 4 ft. It was first sent out from here in 1879.

4. Var. *globosa*, Späth, *Cat.*, No. 66, p. 3 (1886); Dippel, *Laubholz.* ii. 191 (1892).

A small tree or shrub, of dense habit, oval in outline, with small slightly lobed deltoid cordate leaves, grayish beneath, and said to be pink in the young state. This has been propagated by Späth of Berlin, since 1886, when it originated in their nursery from a cutting of *P. alba*; but is little known in England.

5. Var. *Richardi*. Leaves yellow on the upper surface, the colour lasting throughout the season. This was shown at the International Horticultural Exhibition of 1912 by Richard, nurseryman at Naarden-bussum, near Amsterdam.

6. Var. *pendula*, Loudon, *Arb. et Frut. Brit.* iii. 1640 (1838). Branchlets pendulous. This is mentioned by Loudon as a continental variety not introduced in 1838. It has lately been noticed¹ at Breslau; but we have seen no specimens.

DISTRIBUTION

Both the grey and the white poplars have been so widely planted in Europe that their exact distribution in the wild state is very uncertain. According to Willkomm, *P. alba* is certainly not a native of northern Germany, or of Scandinavia, though it thrives as a planted tree in Norway as far north as lat. 68°. Apparently *P. canescens* is a native of the British Isles, central and northern France, and of the Rhine valley in Baden and Alsace; while typical *P. alba* is more southerly and easterly in its distribution, occurring throughout the Mediterranean region in Spain and Portugal, Italy, the Balkan States, Greece, Algeria, Morocco, Syria, and Asia Minor, and extending northwards into the Alps and Carpathian ranges, being a characteristic tree of the alluvial flats of the Danube and all its tributaries from Bavaria, throughout Austria and Hungary, to its mouth in the Black Sea. Farther east, *P. alba* occurs in Russia, the Caucasus, western Siberia, the north-western Himalayas, and western Tibet. It is usually a native of low-lying moist woods, especially those fringing the banks of rivers; but it ascends in the valleys of the Alps, and in Spain and Italy to about 2000 feet elevation.

The white poplar is certainly not indigenous in England, and records of it as a wild tree all probably refer to *P. canescens*, which often shows a considerable amount of white foliage on the long shoots on young and vigorous trees. Turner,² in 1568, says, "As touching the whyte aspe, I remember not that I ever saw it in any place in England," and he appears to have known the tree, as he says it was plentiful in Germany and Italy. The date of the introduction of *P. alba* is uncertain.³ The

¹ Behnsch, in *Mitt. Deut. Dend. Ges.* 1906, p. 212.

² *Herball*, 99 (1568).

³ Hartlib, *Complete Husbandman* (1659), *ex* Loudon, *op. cit.* 1641, states that some years before the time of his writing, 10,000 aables were sent into England from Flanders, and transplanted into many counties. These trees were probably *P. canescens*.

white poplar is often called *abele* in England, but this is the Dutch name, *abeel*,¹ of *P. canescens*. The white poplar is known in Dutch and Belgian nurseries as *peuplier blanc de Hollande*.

The true white poplar has never become a common tree in England. Most of the large trees known as white poplars that we have seen are *P. canescens*, and it is impossible to separate the two species in Loudon's account of them. There are three good trees of *P. alba* at Bayfordbury, Hertford, the largest of which was 95 ft. by 10 ft. 4 in. in 1911. Mr. J. E. Little of Crofton, Hitchin, who has kindly sent specimens, tells me that between Norton Mill and Radwell Mill, near Baldock, Herts, on the bank of the river Ivel, there are four large white poplars, about 80 feet in height and 12 to 13 feet in girth. At Syston Park, Grantham, Miss F. H. Woolward, in 1905, measured a tree 105 ft. by 10 ft. 10 in. In Ireland the finest are at Adare Manor, where Mr. R. A. Phillips measured a tree 80 ft. by 9 ft. in 1910. Another at Nenagh was 60 ft. by 5 ft. in 1911. All these trees bear female flowers.

Pynaert² saw in 1882, at Troyes in France, a true white poplar which measured 140 ft. in height and 21 ft. 3 in. in girth, at six and a half feet above the ground. It divided at thirty-one feet up into three main stems, the largest of which girthed 14 ft. 9 in.; while the total spread of branches was 260 ft. in circumference. This magnificent tree, which was supposed to be about 400 years old, was destroyed³ by a storm on 1st February, 1902. I saw, in 1912, a fine tree in the botanic garden at Toulouse, 90 ft. high by 8 ft. in girth. (A. H.)

POPULUS CANESCENS, GREY POPLAR

Populus canescens, Smith, *Fl. Brit.* iii. 1080 (1805), and *Eng. Flora*, 245 (1828); Smith and Sowerby, *Eng. Bot.* xxiii. t. 1619 (1806), and vii. 114, t. 1392 (1840); Loudon, *Arb. et Frut. Brit.* iii. 1639 (1838); Bromfield, in *Phytologist*, iii. 841 (1850); Schneider, *Laubholzkunde*, i. 23 (1904); Dode, in *Mém. Soc. Hist. Nat. Autun*, xviii. 26 (1905); Aigret, in *Ann. Trav. Publ. Belg.* x. 1214 (1905).

Populus alba, Linnæus, var. *β*, *foliis minoribus*, Lamarck, *Fl. Franc.* ii. 235 (1778).

Populus alba, Linnæus, var. *canescens*, Aiton, *Hort. Kew.* iii. 405 (1789).

Populus alba, Willdenow, *Berl. Baumz.* 227 (1796) (not Linnæus); Hunter, in Evelyn, *Silva*, i. 208, plate (1801); Smith, *Eng. Bot.* t. 1618 (excl. description) (1806).

Populus alba, Linnæus, var. *genuina*, Wesmæel, in De Candolle, *Prod.* xvi. 2, p. 324 (1864).

Populus alba, Linnæus, var. *typica*, Gombocz, in *Math. Termes. Közl.* xxx. 151 (1911).

Populus megaleuce and *alba*, Dode, *op. cit.* 24, 25 (1905).

Populus hybrida, Reichenbach, *Icon. Fl. Germ.* xi. 29, t. 615 (1849) (not Bieberstein⁴).

Populus Steiniana, Bornmüller, in *Gartenfl.* xxxvii. 173, figs. 37, 38 (1888).

Populus Bachofenii, Reichenbach, *Icon. Fl. Germ.* xi. 29, t. 616 (1849) (not Wierzbicki⁵).

¹ Murray, *New Eng. Dict.* i. 15 (1888), says that the Dutch name corresponds to an old French word, *abel*, derived from late Latin, *abellus*, a name given to the white poplar in the twelfth century. Worlidge, *Syst. Agric.* 96 (1681), speaks of the *abele* tree as "a finer kind of white poplar."

² *Bull. Arbor. Belg.* 1882, p. 190.

³ *Ibid.* 1902, p. 72.

⁴ Bieberstein, *Fl. Taur. Cauc.* ii. 422 (1808), describes *P. hybrida*, a doubtful plant which, *op. cit.* iii. 633 (1819), he abandons, as not being different from *P. alba*. A specimen, however, in the Cambridge Herbarium, labelled "*P. hybrida*, M. B., Caucasus," is quite distinct from *P. alba*, and appears to be a form of *P. canescens* with orbicular leaves, sinuately toothed, and glabrous beneath. It bears fruiting catkins 4 in. long.

⁵ *P. Bachofenii*, Wierzbicki, in Rochel, *Banat. Reise*, 77 (1838), is said by Gombocz, *op. cit.* 148, to be a form of *P. alba*, var. *nivea*, and identical with *P. heteroloba*, Dode, authentic specimens of which I cannot distinguish from typical *P. alba*, var. *nivea*.

A large tree, attaining 100 ft. or more in height and 15 ft. in girth. Bark on young stems thin, smooth, grey or whitish; on older stems breaking on the surface into small roughened dark-coloured rhombic cavities, which ultimately unite together, making the bark towards the base of old trunks deep and longitudinally furrowed. Young branchlets, towards the top of the long shoots, covered with a dense whitish tomentum, which towards their base and on the short shoots diminishes in quantity, the twigs becoming dull grey or shining and glabrescent. Buds ovoid, more or less tomentose, according to their position on the branchlet. Leaves (Plate 408, Fig. 3) of two kinds—on long shoots and on suckers ovate-deltoid, cordate, acute, dark shining green and slightly tomentose above, covered beneath with a thick greyish tomentum; margin ciliate, with a few triangular teeth, variable in size, and like the rest of the margin irregularly glandular-serrate; petiole rounded, tomentose. Leaves on the short shoots, suborbicular or broadly ovate, subcordate, obtuse; margin non-ciliate, with a narrow translucent border, and a few sinuate non-serrate teeth; dark green, shining and glabrescent above; lower surface light green, with traces of scattered grey tomentum; petiole laterally compressed, glabrescent or slightly tomentose.

Staminate catkins,¹ 2½ to 4 in. long; axis tomentose; scales obovate, toothed, yellowish brown, fringed with hairs at the apex; pedicels pilose; disc oblique, entire in margin, glabrous; stamens eight to fifteen. Pistillate catkins about 1 in. long; with similar scales; disc pubescent; ovary glabrous, with four spreading sub-sessile yellowish simple stigmatic lobes.² Fruiting catkins, 3 to 4 in. long; capsules glabrous, two-valved. The stigmatic lobes like those of *P. alba*, are simple and undivided; whereas in *P. tremula*, each lobe is deeply scalloped and waved.

Populus Bogueana, Dode, *op. cit.* 24 (1905), is a vigorous form of *P. canescens*, in which the leaves on the long shoots are very large, 5 in. or more in length and breadth; and appears to be now sold by some nurserymen as *P. tomentosa*, the white poplar from Peking. A tree of this at Kew, obtained from Simon-Louis in 1904, is now about 25 ft. high. Another at Grayswood, obtained from Barbier in 1906, is 15 ft. high and very thriving. There are also small trees with similar large foliage in the Botanic Gardens at Edinburgh and Glasnevin. I found this form wild in the forest of Orleans, where it was growing evidently from vigorous suckers of the typical grey poplar beside it.

By *P. canescens*,³ Smith meant the common grey poplar in England, which I have described above. It differs mainly from typical *P. alba* in the lesser amount of

¹ A tree in the Cambridge Botanic Garden bore monocious catkins in 1907, the staminate flowers at the base, the pistillate towards the apex. Similar cases are recorded by Penzig, *Pfl. Teratologie*, ii. 321 (1894), and by Baillon, in *Bull. Soc. Linn. Paris*, 1897, p. 658.

² The eight stigmas, figured by Smith, *Eng. Bot.* xxiii. t. 1619 (1806), have not been observed by any other botanist, and were probably abnormal. In *Eng. Bot.* vii. 114, t. 1392 (1840), the number of stigmas is said to be inconstant, but I have found them invariably four.

³ The grey and white poplars were first distinguished by Lobelius, *Icon. Pl. seu Stirp.* ii. 193 (1591). Their synonymy is much involved, but has been clearly elucidated in an interesting article by Tidestrom, in the *American Midland Naturalist*, i. 113 (1909), to which the reader interested in such matters is referred. I am not at all certain that Smith clearly understood the distinctions between the two species, as Sowerby's plate of *P. alba*, t. 1618 (1806), is the leaf of a vigorous shoot of *P. canescens*; and Smith's statement that *P. alba* is not uncommon in moist woods (in England) is erroneous, as the latter is never seen in England, except as a planted tree. Most of his description refers to *P. alba*; and his specimen in the herbarium of the Linnean Society, London, certainly belongs to this species.

the tomentum on the branchlets and leaves, the latter having a different shape. It is adapted to the humid and mild climate of western Europe; while *P. alba*, with its dense protective covering against evaporation of water, is a native of drier and more continental regions.

In the grey poplar, as in the white poplar, the leaves are fundamentally of two kinds, different in shape, margin, tomentum, and petiole; but conveniently distinguished as "white leaves" and "green leaves." Some shoots bear only white leaves, some only green leaves; whilst others have green leaves towards the base and white leaves towards the tip. The green leaves may be greyish beneath or nearly devoid of tomentum. The size of the white leaves is inconstant, and depends on the vigour of the branchlets. In old trees the green leaves are preponderant, especially on the lower branches; and such trees are popularly known as *P. canescens*. In younger trees, and on the upper branches of older trees, the white leaves are conspicuous; and such trees are often erroneously called *P. alba*. In addition to this variation, occurring on the same tree in its different stages of growth, there are differences in the foliage of different trees, which require further study.

A peculiar form, in which the leaves are thinner in texture, orbicular and not deltoid in outline, and nearly glabrous beneath, is considered by Dr. C. E. Moss to be possibly the hybrid *P. canescens* × *P. tremula*. Two pistillate trees¹ with this foliage, one at Hitchin, and another growing beside a stream between Caverham and Icklingham, Suffolk, have pink stigmas, the colour of which suggests the influence of *P. tremula*. These two trees flower a fortnight earlier than ordinary *P. canescens*. Staminate trees with similar foliage have been found both in England and Ireland. Mr. R. A. Phillips, who sends specimens² from Lorrha, Tipperary, points out that the catkins are shorter than in the typical grey poplar, about 1½ in. long, with fewer (4 to 7) stamens, and narrower scales. There is also a difference in habit, the round-leaved trees have thick stiff ascending branches and short erect twigs; while the ordinary form has spreading branches and pendulous twigs.

In *P. tremula*³ the foliage is all of one kind, similar in form to the green leaves of *P. canescens*, but devoid of any trace of tomentum. The theory that typical *P. canescens* is a hybrid⁴ between *P. alba* and *P. tremula* rests on this apparent similarity of foliage, and is not supported by evidence from the floral organs. Female trees of the grey poplar are, however, rare, and the pistillate flowers have only been examined in a few cases. So far as I can judge, *P. canescens* is a good species, being the

¹ The pistillate tree with pink stigmas is *P. canescens*, Dode, in *Mém. Soc. Hist. Nat. Autun*. xviii. 26 (1908) (not Smith).

² Mr. Phillips recently sent me another form with leaves intermediate in shape and with flowers having eight stamens.

³ The suckers of *P. tremula* bear leaves which, in their shape and in the presence of a slight tomentum, simulate the white leaves of *P. canescens*.

⁴ The older continental botanists, as Reichenbach, *Icon. Fl. Germ.* xi. 30, t. 617 (1849), and Hartig, *Naturgesch. Forst. Culturpfl.* 434 (1851), considered *P. canescens*, Smith, to be identical with the pubescent form of the aspen, *P. tremula*, var. *villosa*. This has silky hairs on the leaves and branchlets, very different from the tomentum of *P. canescens*. The occurrence of true hybrids between *P. tremula* and *P. alba* is possible on the Continent. Radde, *Pflanzenverb. Kaukas.* 153 (1899), saw a group of trees near Sotschi on the eastern shore of the Black Sea, which he considered to be of this origin, as the trees strongly resembled *P. tremula*. Reehinger, in *Verh. Zool. Bot. Ges. Wien*, xlix. 284 (1899), discusses the hybrids in Austria. Adamovic, *Veg. Balkanlând.* 145 (1909), reports similar hybrids in eastern Roumelia. Cf. also *P. albo-tremula*, Krause, in *Jahrb. Schles. Ges.* 1848, p. 130.

western representative in Europe of the white poplar. It appears to be common in France, extending eastward to the Rhine valley; and is known in Belgium and France as *franc-picard* or *grisard*. It often attains an immense size in France, the finest that I have seen being one in the Botanic Garden at Toulouse, which was 100 ft. in height and 12 ft. in girth in 1912. In Holland, where it is wild on the dunes near Haarlem,¹ it is always called *abeel*, a name which is often erroneously applied to the white poplar by English writers. The grey poplar is undoubtedly a native² of England, and is the tree referred to by old authors as the white poplar; but has been probably always better known to woodmen and peasants as the aspe.

(A. H.)

Both the grey and white poplars were known to Evelyn,³ who spoke of the first as the white "to be raised in abundance by every set or slip. Fence the ground as far as any old poplar roots extend and they will furnish you with suckers innumerable, to be slipped from their mothers and transplanted the very first year, but if you cut down an old tree you shall need no other nursery." Later on, he says: "There is something a finer sort of white poplar, which the Dutch call abele, and we have late much of it transported out of Holland. They are also best propagated of slips from the roots, the least of which will take, and may in March, at three or four years' growth, be transplanted." The latter was still an uncommon tree in Plot's time, for he says:⁴ "Of unusual trees now cultivated in Oxfordshire is the abele tree, advantageously propagated by Sir J. Croke of Waterstock, by cutting stakes out of the more substantial parts of the wood; which put into moist ground grew more freely than willows, coming in three or four years' time to an incredible height."

French and English authors agree that the white poplar will not bear lopping like the black poplars; and though I have no experience in this matter, yet as I have never seen a pollarded tree I presume that the grey poplar is equally liable to injury when large branches are cut. It seems able to attain its largest dimensions in poor stiff soil, and in cold situations, provided that there is sufficient moisture in summer; and though I cannot say that the tree is equal to the black Italian poplar from an economic point of view, or equal to *P. alba* as an ornamental tree, yet as the illustration shows, it is a stately tree when well grown.

The range of this tree in Great Britain is obscure, because it has been planted for a long period.⁵ Watson⁶ says, "It is given as an unquestioned native in the floras of Surrey, Essex, Herts, Suffolk, Norfolk, Cambridge. In the floras of Tyne and North Yorkshire it is reduced to the grade of denizen. And if I rightly know the distinction between *alba* and *canescens*, I should now deem the latter native, and the former planted, as seen in Surrey and elsewhere."

Though the male tree is found of large size in many counties, the female is in

¹ Mr. L. Springer, a distinguished landscape gardener of Haarlem, says that the true white poplar will not endure the sea wind on the coast of Holland.

² Clement Reid, *Origin of Brit. Flora*, 150 (1899), states that leaves collected by Prestwich in interglacial beds at Greys, Essex, suggest *P. canescens*, though they may belong to *P. tremula*. The latter species is only recorded from one locality, Caerwys, Flintshire, in neolithic deposits; so that the geological evidence as to the existence of poplars in England is very scanty.

³ *Sylva*, 78 (1679).

⁴ *Natural History of Oxfordshire*, 175 (1705).

⁵ Loudon quotes M'Culloch, that it is the only tree found in the island of Lewis, but probably he mistook the aspen for it.

⁶ *Topographical Botany*, i. p. 357 (1873).

my experience very rare, the only ones I have seen being two rather stunted specimens of considerable age, which grow on my land by the side of a watercourse in a meadow on Upcot Farm, near Withington, Gloucestershire. There are male specimens close to them, and in some seasons fertile seed is produced, from which, in 1907, a few seedlings¹ were raised by Miss F. Woolward. Two of these were planted at Colesborne, but one was weakly from the first and the other was killed by a fungoid disease soon after I planted it out. I have never seen a natural seedling of this or of the white poplar in England.

REMARKABLE TREES

The finest grey poplars that we have seen are in a group called the Grove in the park at Longleat. Mitchell,² writing in 1827, mentions these as being then 100 ft. high, with trunks 3 to 4 ft. in diameter, and 40 to 60 ft. of clear bole. In *Trans. Eng. Arbor. Soc.* v. 391 (1903), an illustration of one of these trees from a photograph by A. C. Forbes was given. He calls it an abele poplar, and gives the measurement of the largest as 120 ft. by 15 ft. 3 in., and the cubic contents 450 ft. Ten trees in this grove, all with straight clean boles of 50 to 80 ft., then averaged 115 ft. by 13 ft., with an average cubic content of 240 ft. When I last visited Longleat in 1909 I found the majority of them still healthy, and measured one which was 125 ft. by 11 ft.

There are several very fine trees at Colesborne, one of which (Plate 382) has two stems rising from the base, and measuring 115 ft. by 10 ft. and 10 ft. 3 in. respectively. These trees sucker freely, and some young trees grown from the suckers, which have been pruned but not transplanted, are growing very fast—about 40 ft. in ten years.

In a field about a mile from Overbury Court, near Tewkesbury, Mr. F. R. S. Balfour discovered a tree 86 ft. high, with a trunk 18 ft. long by 18 ft. 10 in. in girth and with very large spreading branches. At Kingston Lacy, Dorsetshire, a tree with many suckers round it measured, in 1906, 118 ft. by 13 ft. 9 in. At Strathfieldsaye I measured in 1905 a tree 108 ft. by 16 ft., which had a sucker coming up 80 yards from its base. In the park at Syon House there is a well-shaped tree 101 ft. by 12 ft. 5 in.³ In the home park of Windsor Castle there is a short avenue of grey poplars close to the bank of the Thames, below Victoria Bridge. Mr. Mackellar informs us that these were planted between 1840 and 1850, and measured in January, 1913, 90 to 100 ft. in height and 9 to 12 ft. in girth. At Gilbert White's old home at Selborne, the tallest tree is a grey poplar, which Mr. H. B. Watt⁴ measured in 1912 as 109 ft. high by 9 ft. 5 in. in girth. At Youngsbury, Ware, Hertford, a tree measured 95 ft. by 10 ft. 4 in. in 1911.

In Wales I have seen none of any great size; and I have not heard of any remarkable ones in the eastern or northern counties.

In Scotland, where the tree is common, Mr. J. Renwick⁵ tells us of two very

¹ *Journ. Bot.* xlv. 417, t. 487 (1907). ² *Dendrologia*, 51 (1827). ³ A. B. Jackson, *Cat. Trees Syon*, 22 (1910).
⁴ *Selborne Magazine*, xxiii. 122 (1912). ⁵ *Glasgow Naturalist*, iii. 119, pl. ii. (1911).

large trees at Mauldslie Castle, Lanarkshire, the seat of Lord Newlands, which in 1911 measured 100 ft. by 21 ft. 3 in. at two feet from the ground, and 117 ft. by 16 ft. 5 in. at two feet nine inches from the ground. Both these trees suffered severely in the great gale of October 5, 1911, the larger tree losing one of its heavy limbs. Walker, *Essays of Natural History*, 49 (1812), states: "In the year 1769 there was a row of abeles at Stevenston, East Lothian, which was soon after cut down. It contained 122 trees, all about 80 ft. high and from 20 to 30 ft. of clear trunk, without a branch. The trunks were 5 to 7 ft. in circumference, and yet they stood only 7 ft. distant from each other. They were planted in a deep moist soil, were then eighty years old, and afforded a great quantity of timber. It is doubted whether or not the abele is a native of England. It certainly has the appearance of being an indigenous tree in several parts of Scotland. It was planted in many places about the end of the last and in the beginning of the present century, but it has since been neglected." The tallest recorded in the *Old and Remarkable Trees of Scotland* was at Glenarbuch in Dumbartonshire, and was said to be 110 ft. by 12 ft. in 1867.

In Ireland the grey poplar is found on the banks of the Suir, Nore, Barrow, and other rivers in the south, where it may very possibly be wild; and Mr. R. A. Phillips has sent us specimens of several trees, one of which, growing near Birr, was 90 ft. by 12 ft. in 1910. I measured a tree at Markree Castle, Sligo, which in 1909 was 120 ft. by 13 ft. There are two fine trees at Abbeyleix, one of which was 100 ft. by 13 ft. 4 in. in 1910.

In Belgium and France this tree is known as *grisard*, and is often mistaken for the white poplar. I have not noticed any of remarkable size.¹

TIMBER

I am inclined to think that the timber is of superior quality to that of the black Italian poplar; and from what I heard in Belgium and France,² that opinion is also held there. But this may depend on the age of the trees and the rate of growth, which, according to Crowe,³ who paid much attention to this tree in Norfolk, is slower than that of any other British poplar. It is rarely distinguished by the timber merchants in England. Messrs. Howes and Sons, Norwich, however, inform me that "it is the only poplar found to be of any service in the coach-building trade. It is light in weight, exceedingly strong, and can be cleaned up into a nice finish to receive the paint." They pay for the best quality of the wood of this tree, which they know under the name of abele, about 2s. 6d. per foot, as compared with about 1s. 3d. for the wood of the black Italian poplar, which is much less durable and not so firm in texture. I prefer to use it at home for cart bottoms and linings, and for flooring cottage bedrooms, for which its toughness and non-inflammable nature make it valuable.

(H. J. E.)

¹ In *Mitt. D. Dendr. Ges.* 1904, p. 18, a tree was recorded at Schloss Dyck, near Dusseldorf, which, at about 95 years old, was 48 metres high by 3½ metres in girth. The height is evidently much exaggerated.

² Mouillefert, *Essences Forestières*, 301 (1903), says that its fine-grained wood is one of the best of the poplars.

³ Smith, *Eng. Flora*, iv. 244 (1828), who obtained his information from Crowe, states that "the wood is much finer than that of any other British poplar, making as good floors as the best Norway fir in appearance, and having moreover the valuable property, that it will not, like any resinous wood, readily take fire." Cf. *Gard. Chron.* 1848, p. 172.

POPULUS TOMENTOSA

Populus tomentosa, Carrière, in *Rev. Hort.* x. 340 (1867); Wesmael, in De Candolle, *Prod.* xvi. 2, p. 325 (1868), and *Mém. Soc. Sc. Hainaut*, 228, t. 17 (1869); Schneider, *Laubholzkunde*, i. 21 (1904); Dode, in *Mém. Soc. Hist. Nat. Autun*, xviii. 25 (1905); Gombocz, in *Math. Term. Közl.* 140 (1911).

Populus alba, Burkill, in *Journ. Linn. Soc. (Bot.)* xxvi. 535 (1899) (not Linnæus).

Populus alba, Linnæus, var. *tomentosa*, Wesmael, in *Bull. Soc. Roy. Bot. Belg.* xxvi. 373 (1887); Burkill, in *Journ. Linn. Soc. (Bot.)* xxvi. 535 (1899).

Populus alba demodata, Maximowicz, in *Bull. Soc. Nat. Mosc.* i. 49 (1879) (not Hartig).

Populus pekinensis, L. Henry, in *Rev. Hort.* lxxv. 355, fig. 142 (1903).

A large tree, similar in size and bark to *P. alba*. Branchlets grey tomentose. Buds ovoid, slightly tomentose, chestnut brown. Leaves (Plate 408, Fig. 2) on the long shoots of old trees, 4 to 6 in. long, 3 to 5 in. broad, triangular-ovate, without lobes or lobules, subcordate or truncate at the broad base, acuminate at the apex; margin with a few (not exceeding ten on each side) sinuate teeth; dark shining green above, glabrescent beneath with traces of grey tomentum. Leaves on the long shoots of vigorous young trees, similar in shape, but the margin biserrate with acute glandular teeth, and the lower surface covered with a grey tomentum. Leaves on the short shoots, small, ovate or triangular, cuneate at the base, sinuately toothed, glabrous beneath. Flowers not seen.

This fine poplar, which attains an enormous size in north China,¹ was discovered by Simon at Siwan, north-west of Peking. His specimen, described by Carrière, is identical with those in the Kew Herbarium, collected near Peking by Sir Rutherford Alcock and by Prof. Sargent, and with another gathered in Shantung by the Rev. A. Williamson, which is preserved in the Edinburgh Herbarium. Gombocz records it also for the mountains of Shensi, and Kiaochow in Shantung. Elwes, in 1912, saw old trees in the grounds of the Summer Palace, Peking, which were about 75 ft. high and 10 ft. in girth. This poplar is called *pai-yang* by the Chinese.²

A young living plant sent from Peking in 1897 by Père Provost to the Museum at Paris, where it was propagated, has grown vigorously, and was in 1912 about 35 ft. high by 2 ft. 3 in. in girth. We have seen no trees in England of this species.³ Jack⁴ introduced in 1905 into the Arnold Arboretum cuttings from Peking, which have produced thriving and hardy young trees. He states, however, that it is more readily propagated by grafting.

(A. H.)

¹ According to Schneider, it was collected also by Père Giraldi, farther south in Shensi; but the latter's specimen is identified by Diels, *Flora von Central China*, 274 (1901), with *P. tremula*, and is possibly *P. wutaica*, Mayr, *Fremdländ. Wald- u. Parkbäume*, 494, fig. 215 (1906).

² Cf. Bretschneider, *Bot. Sinic.*, ii. 359 (1892), who refers to this tree as *P. alba*.

³ The trees often sold by French nurserymen as *P. tomentosa* appear to be *P. Bogueana*, Dode. Cf. *ante*, p. 1781.

⁴ *Mitt. Dent. Dent. Ges.* 1909, p. 281.

POPULUS TREMULA, ASPEN

Populus tremula, Linnæus, *Sp. Pl.* 1043 (1753); Loudon, *Arb. et Frut. Brit.* iii. 1645 (1838); Wesmael, in *Mém. Soc. Sc. Hainaut*, iii. 229 (1869), and De Candolle, *Prod.* xvi. 2, p. 325 (1864); Willkomm, *Forstl. Flora*, 521 (1887); Mathieu, *Flore Forestière*, 486 (1897); Schneider, *Laubholzkunde*, i. 19 (1904); Dode, in *Mém. Soc. Hist. Nat. Autun*, xviii. 30 (1905); Ascherson and Graebner, *Syn. Mitteleurop. Flora*, iv. 24 (1908); Gombocz, in *Math. Termes. Közl.* xxx. 123 (1911).

Populus australis, Tenore, *Ind. Sem. Hort. Neap.* 1830, p. 15.

Populus græca, Grisebach, *Spic. Fl. Rum.* ii. 345 (1844) (not Aiton, *Hort. Kew.*).

A tree, occasionally attaining in Scandinavia, Russia, France, and Germany 100 ft. in height and 6 to 8 ft. in girth, but usually much smaller, especially in the British Isles. Bark of young trees smooth, thin, greenish or whitish; on old trunks thick, with small rhomboidal fissures, as in *P. alba*, and ultimately deeply furrowed. Young branchlets glabrous, rounded, shining, with orange lenticels. Buds ovoid, acute, shining brown, slightly viscid, with ciliate scales, the uppermost of which are slightly pubescent. Leaves (Plate 408, Fig. 4) suborbicular, variable in size, averaging 2 in. in diameter, thin in texture, truncate or subcordate at the base, rounded or acute at the apex; margin with a narrow translucent border, and a few rounded or sinuate small teeth; tomentose when young, speedily becoming glabrous on both surfaces, pale or glaucous beneath; venation pseudo-five-palmate; glands¹ at the base two, cup-shaped, well-developed on the terminal leaves of long vigorous shoots, absent on the basal leaves and on those of the short shoots; petioles slender, glabrous, laterally compressed, often as long as the blade. Leaves on young plants and on sucker shoots, and in rare cases on sporadic branches of adult trees, different in shape and much larger, 4 to 5 in. long, 3 to 4 in. broad; ovate, acuminate at the apex, truncate or cordate at the base, greyish and slightly woolly beneath, glandular-serrate, with short pubescent terete petioles.

Catkins sub-sessile, densely and greyish tomentose; axis pubescent; scales long persistent, obovate, deeply lobed and fringed with long white hairs; flowers dense, numerous, on very short pilose pedicels. Stamens about 10, with short filaments and purple anthers, on an oblique disc with an entire and incurved margin. Ovary glabrous; stigmas two, reddish, each divided, forming four widely dilated curving arms; disc funnel-shaped, oblique, glabrous; capsule two-valved.

This species in the wild state displays a considerable amount of variation in the shape, size, and colour of the leaf, and in the amount of pubescence on the branchlets and leaves. The most noteworthy² are:—

1. Var. *Freynei*, Hervier, in *Bull. Herb. Boiss.* iv. app. i. 18 (1896), and *Rev. Gen. Bot.* viii. 177 (1896). Leaves rhombic, cuneate at the base, ciliate, pubescent beneath when young. Central France and Prussia.

¹ According to Kerner, *Nat. Hist. Plants*, Eng. Trans. i. 238, fig. 55 (1898), these glands exude resin and serve for absorbing water in rainy weather; but Trelease, in *Bot. Gaz.* vi. 284 (1881), states that they contain honey at the beginning of the season, and are visited by bees and other insects.

² Var. *purpurea*, Simon-Louis, ex Späth, *Cat. No.* 102, p. 108 (1898-1899), with purplish young leaves, does not seem to differ from the type, as seen in cultivation at Kew.

2. Var. *villosa*, Wesmael, in De Candolle, *Prod.* xvi. 2, p. 325 (1868).

Populus villosa, Lange, *Syll. Soc. Ratisb.* i. 185 (1824), and ex Reichenbach, *Fl. Germ. Excur.* 173 (1830).

Populus canescens, Reichenbach, *Icon. Fl. Germ.* xi. 30 t. 617 (1849) (not Smith); Hartig, *Forstl. Kulturpfl.* 434 (1851).

Branchlets and leaves at first densely pubescent with long silky hairs, more or less persistent in summer. This variety¹ appears to be quite as common in the wild state as the typical glabrous form.

The origin of the following cultivated form is unknown:—

3. Var. *pendula*, Loudon, *Arb. et Frut. Brit.* iii. 1646 (1838).

Populus pendula, Burgsdorf, *Anl. Anpfl. Holzart.* ii. 175 (1787).

Branchlets pendulous. Usually seen as a small grafted tree.

The common aspen is widely spread through Europe, northern Africa, Asia Minor, the Caucasus, and Siberia, being replaced by closely allied species in China, Japan, and the Himalayas. It occurs in every European country; but is absent from the south of Spain, Sicily, and the islands in the western Mediterranean. It is much more common in the north, where it reaches the Arctic Circle both in Europe and Asia; and either in pure woods or mixed with birch covers extensive tracts in Scandinavia, Russia, and Siberia. Towards the south, it only occurs as a scattered tree in mixed woods; and ascends in the Pyrenees to 6000 ft., and in the Alps to 4000 ft. In England it is not uncommon in coppiced woods; but it is of more frequent occurrence in the Highlands of Scotland, ascending to tree limit.

The aspen is a short-lived tree, rarely attaining an age of over 100 years. When cut down, it produces coppice shoots of no great vigour, and usually reproduces itself in such cases by abundant suckers,² which are given off to a considerable distance by its widely-spreading superficial roots. (A. H.)

As an ornamental tree the aspen is in northern countries one of the most beautiful, on account of the splendid red and yellow tints which the leaves assume in autumn; but in England these colours are seldom seen in the same degree, and though the bright pale green of its trembling leaves gives it a certain beauty, it is hardly worth growing in any quantity. It is not particular about soil, and may serve to clothe waste places such as old pit banks. It is one of the latest trees to come into leaf in spring.

The largest trees I have noticed in England are two at Little Sodbury Manor, in Gloucestershire, which do not much exceed 60 ft. in height. Sir Hugh Beever tells me that he has seen none larger in the eastern counties. There are four trees forming a handsome group near the river Gade at The Grove, Watford, the largest being 54 feet by 3 ft. 3 in. in 1904. These were photographed³ by Mr. Henry Irving.

In Wales the tree does not seem common, but apparently attains a greater size than it usually does in England. In May 1911 I saw some large trees at an

¹ M. Dode informed me that in the Forêt de Bondy this variety attains 35 metres in height.—H. J. E.

² The suckers of *P. tremula* are described by Dubard, in *Ann. Sc. Nat.* xvii. 160 (1903).

³ Reproduced by Groom, *Trees and their Life Histories*, figs. 192, 193 (1907).

elevation of about 800 ft. at Abergwessin in North Breconshire. The Welsh name for it in this district is *aethnen*; but at Hafodunos, in North Wales, W. Jones, the head gardener, told me that the local name was *tafoden merched*, which means "women's tongues." In the Isle of Man a name of the same meaning, *chengey-ny-mraane*, was used.

In the Highlands, where it ascends to the upper limit of trees—in Braemar up to at least 1600 ft.¹—it seems commoner, and attains larger dimensions. I have never seen any, however, which in size equal those in the north of Norway, the largest I know of being a tree on the shores of Loch Garry, which Captain Ellice of Invergarry found in 1910 to be about 60 ft. by 7 ft.² In the birch woods of Strathglass, Glenaffric, and Guisachan the aspen occurs in clumps which appear to have grown from suckers, but old trees are scarce. The largest I saw was a fallen tree above the falls in Glenaffric, which, when standing, was about 50 ft. high, with a trunk 7 ft. in girth. The belief³ of the Highlanders, who call the aspen *crithean* or *critheac*, that the Cross of Christ was made of this tree still exists both among Catholics and Protestants in this district. I was assured by reliable persons that it is looked on as an accursed tree, and that no Highlander will use the wood for any purpose, even for fuel.⁴ Notwithstanding this belief, I saw on the croft of Peter Macdonald at Balnath, near the head of Glen Urquhart, a group of well-shaped aspen about 40 ft. high, which, as he told me, he had trained up from suckers, and were about forty years old.

In Ireland, the aspen is recorded from almost every county, but is by no means a common tree. Mr. R. A. Phillips informs us that it is native on mountain cliffs, rocky lake shores, the banks of rivers, and in old hedgerows in uncultivated bogland districts, and also on the islands off the west coast. In the mountains of Kerry and Antrim it is a mere bush, but in the lowlands is a small tree, rarely over 40 ft. in height. The finest which he has seen grows on the edge of the river Nore near Durrow, and measured 65 ft. by 5 ft. in 1908.

According to Schübeler it extends in Scandinavia as far north as Alten (lat. 70°), where it attains 60 ft. in height, and in the south ascends to 3500 ft. The tallest aspens that he mentions in Norway grew some miles east of the farm of Viken, in Nidervan, and were 90 to 100 ft. high; whilst at Femrade, in Sogndal (lat. 61°), there was a very old aspen 58 ft. high, with a girth of 16 ft. at four feet from the ground. I saw myself in Junkersdal, in lat. 67°, trees of 80 feet high and 6 to 7 ft. in girth, which were finer than any I know in Great Britain.

In France, Mouillefert says, that though common in the damper parts of the forest on sandy or gravelly soils, it is rare on dry or calcareous formations, and that owing to the freedom with which it produces suckers it tends to supersede other trees in suitable places.

¹ White, *Flora of Perthshire*, p. 268, says that it ascends to 2100 ft. in Athole, and 1400 ft. in Rannoch; and that both the forms—*villosa*, Lange, and *glabra*, Syme,—occur in the county.

² Loudon mentions trees of much greater size at various places in England and Scotland, but there is little doubt that they were *P. canescens*.

³ Cf. Loudon, *op. cit.* 1648, and Cameron, *Gaelic Names of Plants*, 70 (1883).

⁴ Cf. Carmichael, *Carmina Gadelica*, 104 (1900), who states that in Uist the hateful aspen is banned. If it still exists in Uist, it is now an uncommon tree, as I saw none in North or South Uist in 1910.

Though usually looked on as a forest weed, it is possible that when grown naturally from suckers thickly enough to clean the stems from branches, it may have some value for making matches. In Sweden it is largely employed for this purpose, and according to Schübeler 1,400,000 cubic ft. were thus used in 1882, and valued at 70 ore (about 8d.) per cubic foot. Cargoes of poplar timber, which I believe to be mainly aspen, are now imported from the Baltic for making matches, and cost delivered in Gloucester from 38s. to 48s. per load of 50 cubic ft. caliper measure.

It is also largely used for pulp-making, for which it is very suitable; but it could scarcely be produced here in sufficient quantities at a price that would compete with the produce of northern Europe and America.

On this subject, however, a valuable paper¹ by Weigle and Frothingham on the American aspens should be consulted, as these species resemble our native aspen in life-history, characteristics, and uses. The conclusions of these authors may be summarised as follows:

1. No other trees have so wide a distribution in Europe and Asia as the aspens, *P. tremula* covering 140° of longitude and 35° of latitude, whilst *P. tremuloides* ranges over 112° and 41° respectively.

2. They are both pre-eminently cold- and moisture-loving trees, requiring a very short season of growth and thriving—as *P. tremula* does at Colesborne—where frosts may occur during every month of the year.

3. For their best growth they require deep fresh or moist, porous and well-drained soils; but they will grow on thin dry soil and in poorly drained situations.

4. They are strikingly intolerant of shade; and this applies even more strongly to the suckers by which they are commonly reproduced, and which are often mistaken for seedlings. The latter are rarely seen in England.

5. Their growth is rapid during the first twenty to thirty years, and though they may attain considerable size, yet they are short-lived, usually decaying before 100 years of age, and often much sooner; and root-suckers do not produce such large or well-shaped trees as seedlings.

6. They are best managed as a pure crop under a short rotation; and on account of their extreme light-demanding character require timely thinning.

7. The wood produces the best and whitest pulp, which can be produced and manufactured, more cheaply than other species, into paper which is peculiarly suitable for books and magazines. As the fibre is too short to make good paper alone, it is mixed with a proportion (usually about 40 per cent) of sulphite spruce pulp which adds strength. The finished paper is tough, white, and easily sized, and though inferior to rag paper for the finest uses, is much cheaper.

Waste land suitable for profitable planting of *P. tremula* (and possibly also *P. canescens*) might be found in some parts of Scotland and Ireland; and experiments in this direction are advisable.

In France, according to Mouillefert, the wood is valued for charcoal, but as firewood it burns out very quickly.

(H. J. E.)

POPULUS TREMULOIDES, AMERICAN ASPEN

Populus tremuloides, Michaux, *Fl. Bor. Amer.* ii. 243 (1803); Sargent, *Silva N. Amer.* ix. 158, t. 487 (1896), and *Trees N. Amer.* 154 (1905); Schneider, *Laubholzkunde*, i. 19 (1904); Dode, in *Mém. Soc. Hist. Nat. Autun*, xviii. 33 (1905).

Populus trepida, Willdenow, *Sp. Pl.* ii. 803 (1805); Loudon, *Arb. et Frut. Brit.* iii. 1649 (1838).

Populus tremuliformis, Emerson, *Trees Massachusetts*, 243 (1846).

Populus atheniensis,¹ Ludwig, *Neue Wilde Baumz.* 35 (1783), ex Koch, *Dendrologie*, ii. 486 (1872); Koehne, *Deut. Dend.* 80 (1893).

Populus græca,¹ Loudon, *Arb. et Frut. Brit.* iii. 1651 (1838) (not Aiton); Lauche, *Deut. Dend.* 316 (1883).

A tree, attaining in America 100 ft. in height and 9 ft. in girth. Bark like that of *P. tremula*. Young branchlets slender, glabrous, shining reddish brown, with orange lenticels. Buds ovoid, sharp-pointed, shining brownish, slightly viscid, with glabrous scales. Leaves (Plate 408, Fig. 5) ovate to nearly orbicular, 1½ to 2 in. in diameter, thin in texture; truncate, rounded or cuneate at the base; shortly cuspidate at the apex; glabrous on both surfaces, pale beneath; margin with a narrow translucent border, ciliate especially on the leaves of the short shoots, finely glandular-serrate; pseudo-three- to five-palminerved at the base, where the glands in occurrence and appearance are like those of *P. tremula*; petiole slender, glabrous, laterally compressed, variable in length, often as long as the blade. Leaves on sucker shoots, similar to those of *P. tremula*, but glabrous on both surfaces, with ciliated margins.

Flowers scarcely distinguishable from those of *P. tremula*, but with more slender catkins, smaller in all the parts of the flowers; disc of the pistillate flower crenate.

1. Var. *pendula*. A weeping form, with pendulous branches, always grafted.

This is generally known as the *Parasol de St. Julien*, which is said² to have been first propagated by Messrs. Baltet, who found in 1865, on the bank of a canal at St. Julien, near Troyes, a tree with weeping branches, which they crown-grafted on the white poplar, and considered to be a weeping form of *P. tremula*.

It is said by Koch³ to have been much more common in commerce in 1872 than the weeping variety of the common aspen, and it is possible that the preceding history is applicable rather to a weeping variety of *P. tremula*.

2. *P. cercidiphylla*, Britton, *N. Amer. Trees*, 180 (1908), seems to be a form with small entire or undulate leaves, which was found in Wyoming by Dr. C. C. Curtis in 1900. (A. H.)

¹ Loudon describes this poplar under both the names *P. trepida* and *P. græca*, and states in *Gard. Mag.* 1840, p. 231, and *Trees and Shrubs*, 823 (1842), that *P. græca* was "named after the village called Athens, on the banks of the Mississippi, where the tree grows abundantly." *P. atheniensis* is said by Koehne to derive its name from the town of Athens in New York State, whence it was introduced. *P. græca*, Aiton, *Hort. Kew.* iii. 407 (1789), was insufficiently described, and said to be a native of the Greek archipelago.

² Cayeux, in *The Garden*, 1886, p. 2. The pendulous variety of *P. tremuloides* is called *Parasol de St. Julien*, in Simon-Louis's catalogue, 1899-1900, and appears to be now always sold in France under this name. Späth, *Catalogue*, No. 57, p. 61 (1883), identifies the *Parasol de St. Julien* with *P. canescens pendula*; and the latter name, now no longer employed, would seem to show that Späth's tree was rather a weeping *P. tremula* than a pendulous form of *P. tremuloides*.

³ *Dendrologie*, ii. pt. i. 487 (1872).

The American aspen is similar in its habits to the common species, and is widely spread throughout North America, from southern Labrador, the eastern shores of Hudson's Bay, the mouth of the Mackenzie river, and the Yukon valley in Alaska, southwards to Pennsylvania and Nebraska, and through all the mountain regions of the west to central California, the San Pedro mountain in Lower California, northern Arizona, New Mexico, and the state of Chihuahua in Mexico. It is common in the east on moist sandy soil, and often borders the western prairies with a wide belt; and to the northward is often mixed with spruce and birch. In the mountain regions of the western and Pacific states, it ascends to 10,000 ft. above the sea. Sargent says that on account of its remarkable power of germinating on burnt soil, and rapidly covering mountain sides which have been devastated by fire, it has had a greater influence than any other tree on the composition and distribution of the subalpine and boreal forests of North America. Macoun says that in the Northwest, Athabasca, and Mackenzie districts it is everywhere common on dry soil, but not on alluvial flats, and that it reproduces freely after a forest fire by root-suckers, but not from seed.

It is said to have been introduced¹ in 1779 by Hugh, Duke of Northumberland; but we have seen no trees of considerable size, and the weeping variety appears to be now the only kind usually cultivated.

Loudon says that a tree in the Chiswick Garden was 12 ft. high eight years after planting; and on account probably of its northern habitat it produced leaves so early that on the 20th April 1835 they were cut by frost. It is so like the aspen of the old world in appearance that even if it would grow, it is hardly worth cultivation except in botanic gardens. (H. J. E.)

POPULUS GRANDIDENTATA

Populus grandidentata, Michaux, *Fl. Bor. Am.* ii. 243 (1803); Loudon, *Arb. et Frut. Brit.* iii. 1650 (1838); Sargent, *Silva N. Amer.* ix. 161, t. 488 (1896), and *Trees N. Amer.* 155 (1905); Schneider, *Laubholzkunde*, i. 17 (1904); Dode, in *Mém. Soc. Hist. Nat. Autun*, xviii. 28 (1905). Gombocz, in *Math. Termes. Közl.* xxx. 138 (1911).

A tree, attaining in America 70 ft. in height and 6 ft. in girth; bark like that of the common aspen. Young branchlets covered at first with a greyish tomentum, persistent more or less during summer. Buds ovoid, acute, grey tomentose. Leaves (Plate 408, Fig. 7) on the long shoots, 3 to 4 in. long, 2 to 3 in. broad, ovate-deltoid; truncate, rounded, or cuneate at the base; acuminate at the apex; glabrescent and dark green above; lower surface pale or glaucous green, glabrescent or with traces of the grey tomentum, which is dense at the time of unfolding of the leaves; margin with a narrow translucent border, and with a few sinuate triangular teeth, but entire near the base; petioles slender, laterally compressed, glabrescent. Leaves on the short shoots, oval, with sharper teeth, and often with two glands at the summit of the petiole.

¹ Loudon, under *P. græca*, p. 1651.

Catkins with deep narrowly lobed scales, fringed with long hairs; differing chiefly from the other aspens in the pubescent disc and ovary; stamens six to twelve; style divided into four long filiform lobes; capsule two-valved.

This species is much less widely spread in North America than the other aspen (*P. tremuloides*), apparently requiring a moister soil, and mainly growing in deep sand on the banks of rivers and swamps. It occurs in Ontario, southern Quebec, Nova Scotia, and New Brunswick, extending southward in the United States to north Delaware on the coast, and along the Alleghany Mountains to North Carolina, and westwards to Minnesota, Wisconsin, Illinois, Indiana, Kentucky, and Tennessee.

According to Dame and Brooks,¹ it is best distinguished from *P. tremuloides* in early spring, by the colour of the unfolding leaves, which are cottony white, whilst those of *P. tremuloides* appear yellowish green. The leaves when open are much larger and more coarsely toothed, and the buds divergent, dull, and dusty-looking; whilst those of *P. tremuloides* are mostly appressed and highly polished with a resinous lustre. In Canada it generally grows on sandy soil, mixed with pines, and is often mistaken for aspen. It is never a large tree, though usually larger than *P. tremuloides*, and as Elwes saw it, near Ottawa, is a straggling, ill-shaped tree of 40 to 50 ft. high, liable to be broken by the wind, and of little or no value either for use or ornament.

Though introduced, according to Loudon,² in 1772, it has always been a scarce tree in England, and the only specimen at Kew died about a year ago. At Grayswood, Haslemere, a tree obtained from Meehan in 1887 is only 16 ft. high, and apparently this species does not thrive in our climate.

The weeping grafted tree, commonly cultivated under the name *P. grandidentata*, var. *pendula*, differs from that species in flowers and other characters,³ and may be distinguished as follows:—

Populus pseudo-grandidentata, Dode, in *Mém. Soc. Hist. Nat. Autun*, xviii. 31 (1905).

Populus tremula, Linnæus, var. *pseudo-grandidentata*, Ascherson and Graebner, *Syn. Mitteleurop. Flora*, iv. 26 (1908).

Young branchlets stout, dark reddish, with orange lenticels, covered with whitish tomentum in spring, which persists in summer at the base of the shoots. Buds viscid, tomentose near the top of the branchlet, glabrescent elsewhere. Leaves (Plate 408, Fig. 8) similar in shape and dentation to *P. tremula*, but larger, 3 to 4 in. in diameter, and thicker in texture; margin with a translucent border, ciliate in spring. Staminate catkins, 2 in. long, with a slender pubescent axis; pedicels glabrous; stamens five, on an oblique glabrous shallow spatulate disc, which is entire in margin; filaments slender, white; anthers red.

The origin of this plant is unknown, but it is probably a hybrid; and if it came

¹ *Trees of New England*, 32 (1902).

² *Trees and Shrubs*, 823 (1842). It was introduced earlier into France, as it is well figured as *P. tremula, ampliori folio*, by Duhamel, *Traité des Arbres*, ii. 178, pl. 38, fig. 8 (1755).

³ In *P. grandidentata* the leaves are ovate, long acuminate, with fewer and larger teeth than in the weeping tree; stamens more numerous, with short filaments; pedicels and disc pubescent.

from America may be a cross between *P. tremuloides* and *P. grandidentata*.¹ It appears to have been first mentioned by Simon-Louis² in 1869. Koch³ speaks of it as a pendulous tree existing in England in 1872. There are good specimens at Abbotsbury and at Glasnevin. (A. H.)

POPULUS SIEBOLDII

Populus Sieboldii, Miquel, in *Ann. Mus. Bot. Lugd. Bat. (excl. pl. masc.)* iii. 29 (1867); Wesmael, in De Candolle, *Prod.* xvi. 2, p. 327 (in part) (1864); Schneider, *Laubholzkunde*, i. 17 (1904); Dode, in *Mém. Soc. Hist. Nat. Autun*, xviii. 32 (1905); Gombocz, in *Math. Termes. Közl.* xxx. 131 (1911).

Populus tremula, Linnæus, var. *villosa*, Franchet and Savatier, *Enum. Pl. Jap.* i. 465 (1875) (not Wesmael); Maximowicz,⁴ in *Bull. Soc. Nat. Mosc.* liv. 49 (1879); Shirasawa, *Icon. Ess. For Japon*, i. text 37, t. 18, figs. 1-10 (1900).

Populus rotundifolia, Simon-Louis, ex Dippel, *Laubholzkunde*, ii. 192 (1892).

A tree, attaining in Japan 60 ft. in height. Young branchlets stout, covered in spring with a dense white tomentum, persistent in part during summer. Buds more or less tomentose, not viscid. Leaves (Plate 408, Fig. 6) thicker in texture than those of *P. tremula*, densely tomentose and ciliate when young, glabrescent in summer, dark shining green above and yellowish or pale beneath, about 3 in. long and 2 in. broad, ovate, rounded or cuneate at the base, abruptly contracted into a glandular short acuminate apex; margin with a translucent border, minutely (varying even on the same leaf) sinuately toothed or glandular serrate; basal glands usually well developed; petiole slender, pubescent, laterally compressed. Flowers similar to those of *P. tremula*, but with the disc slightly pubescent.

This species, which is very distinct in appearance from the common aspen, appears to be confined to Japan, where it was collected at Aomori by Elwes.

It appears to have been introduced by Simon-Louis about 1887, but the only tree which I have seen is a grafted one at Glasnevin, planted in that year, which has only attained a height of 15 ft. and is not very thriving. (A. H.)

POPULUS FREMONTII

Populus Fremontii, Watson, in *Proc. Am. Acad.* x. 350 (1875); Sargent, *Silva N. Amer.* ix. 183, t. 496 (1896), and *Trees N. Amer.* 164 (1905); Dode, in *Mém. Soc. Hist. Nat. Autun*, xviii. 40 (1905); Gombocz, in *Math. Termes. Közl.* xxx. 76 (1911).

Populus monilifera, Torrey, in *Sitgreave's Rep.* 172 (1853) (not Aiton).

A tree, attaining 100 ft. in height and 15 ft. in girth; bark at first smooth and thin, ultimately becoming on old trunks deeply fissured into broad rounded scaly

¹ Nuttall, *Gen. Pl.* ii. 239 (1818), describes as *P. grandidentata*, var. *pendula*, a tree "with pendulous branches, as in the weeping ash, on the Alleghany Ridge, Pennsylvania, rare." Loudon, *op. cit.* 1651, states that there was a tree bearing this name in the Horticultural Society's garden in 1838; but that its branchlets were not pendulous. There is, therefore, no evidence that Nuttall's tree, seen only in the wild state, was ever introduced into cultivation.

² *Cat. Général*, 1869, p. 73, where it is called *P. grandidentata*, var. *pendula*, and is described as a weeping form with large teeth to the leaves.

³ *Dendrologie*, ii. pt. i. 488 (1872).

⁴ The staminate specimen described by Miquel, which is preserved in the Leyden Herbarium, is a species of *Carpinus*, according to Maximowicz.

ridges. Young branchlets glabrous. Buds small, viscid. Leaves on old trees deltoid, about 2½ in. broad, truncate at the base, and abruptly contracted at the apex into broad short entire points: on young cultivated trees (Plate 409, Fig. 13), reniform or rhombic, with a cuneate base and a similar apex; serrations few, coarse, with incurved points; margin with dense minute cilia, discernible with a good lens; glands absent at the base; petiole glabrous.

Staminate catkins, 2 in. long; axis glabrous; disc broad, oblique, entire in margin; stamens sixty, with dark red anthers. Pistillate catkins, 2 in. long; pedicels short; disc crenate, cup-shaped; stigmas three, irregularly and crenately lobed. Fruiting catkins, 4 to 5 in. long; capsule thick-walled, three- to four-valved.

This species grows on the banks of streams in California, Lower California, Nevada, southern Utah, southern Colorado, and western Texas.

It¹ has only lately been introduced into cultivation, and small specimens may be seen at Kew and Glasnevin.

Var. *Wislizeni*, Watson, in *Amer. Journ. Sci.* xv. 136 (1878).

Populus Wislizeni, Sargent, *Silva N. Amer.* xiv. 71, t. 732 (1902), and *Trees N. Amer.* 165 (1905); Dode, in *Mém. Soc. Hist. Nat. Autun*, xviii. 39 (1905); Gombocz, in *Math. Termes. Közl.* xxx. 78 (1911).

This appears to have similar foliage, and is mainly distinguishable by the long pedicels of the flowers. It is the common poplar in the Rio Grande valley of western Texas and New Mexico, and the adjacent parts of Mexico. (A. H.)

POPULUS NIGRA, BLACK POPLAR

Populus nigra, Linnæus,² *Sp. Pl.* 1034 (1753); Loudon, *Arb. et Frut. Brit.* iii. 1652 (1838); Wesmael, in De Candolle, *Prod.* xvi. 2, p. 327 (1868), and in *Mém. Soc. Sc. Hainaut*, iii. 258 (1869); Willkomm, *Forstliche Flora*, 527 (1887); Mathieu, *Flore Forestière*, 491 (1897); Schneider, *Laubholzkunde*, i. 5 (1904); Dode, in *Mém. Soc. Hist. Nat. Autun*, xviii. ("groupe nigra") 37 (1905); Ascherson and Graebner, *Syn. Mitteleurop. Fl.* iv. 36 (1908); Gombocz, in *Math. Termes. Közl.* xxx. 85 (1911).

A tree, attaining above 100 ft. in height and 20 ft. in girth, usually with a straight and single stem, but occasionally dividing near the base into several limbs; with wide-spreading stout and irregular branches, not slender and regularly ascending as in many of the hybrids. Bark deeply furrowed on old trunks, and often covered with large burrs. In all its forms this species is readily distinguishable from the American species and the hybrids by the leaves, non-ciliate on the margin, without glands at the base, and when well-developed gradually tapering from the middle of the blade to a long acuminate apex.

The black poplar, and apparently all the poplars of the same section, rarely if ever produce suckers while the trees are living, but if one is cut down suckers are

¹ According to Dode, the trees introduced are var. *Wislizeni*; but until they flower their identification is uncertain. However, Späth, *Cat. No.* 95, p. 89 (1895-1896), states that the young plants first introduced in 1894 were obtained from Colorado, where only the typical form of the species exists.

² By this name Linnæus meant the black poplar inhabiting temperate Europe; though he quotes a Virginian poplar *ex Herb. Gronov.* It is most convenient to assume, as the typical form of the species, the tree planted by Linnæus at Upsala, which is still living, and from which I gathered specimens in 1908.

produced abundantly from the roots. Root cuttings are as readily propagated as ordinary cuttings. Dubard, in *Ann. Sc. Nat.* xvii. 147 (1903), gives an elaborate account of the peculiarities of the suckers of this tree.

This species comprises two distinct forms, one glabrous in all its parts, the other more or less pubescent, described in detail as follows:—

1. Var. *typica*, Schneider, *op. cit.* 5; Ascherson and Graebner, *op. cit.* 39. Continental Black Poplar.

Young branchlets rounded, glabrous, ashy grey in the second year. Buds reddish, viscid, glabrous, closely appressed to the twig at their base, with a sharp apex curving outwards. Leaves on the long shoots (Plate 409, Fig. 11), about 3 in. long, and 2 in. broad, cuneate at the base, gradually tapering from about the lower third, where they are widest, towards the long acuminate apex; glabrous; dark green above, light green below; margin with a narrow translucent border, non-ciliate, finely and crenately glandular-serrate; petiole glabrous, laterally compressed. On the short shoots the leaves are smaller, broader at the base, which is often less cuneate, and truncate or rounded; and similar leaves often occur on old trees even on the long shoots.

Catkins about 1½ in. long, with early deciduous scales, which are broadly obovate, and divided into numerous irregular, linear entire or lanceolate toothed lobes; axis glabrous. Staminate flowers sub-sessile; stamens twenty to thirty on an oblique concave non-ciliate glabrous disc, which is slightly waved and upturned in margin; filaments white, thread-like, as long as the deep red anthers. Pistillate flowers shortly stalked; ovary glabrous, globose, in a cup-like glabrous disc; stigmas two, dilated, crenate in margin, closely appressed at first to the sides of the upper part of the ovary. Capsules two-valved, glabrous, on long pedicels.

2. Var. *betulifolia*, Torrey, *Fl. New York*, ii. 216 (1843); Skan, in *Bot. Mag.* t. 8298 (in part¹) (1910); Schneider, *Laubholzkunde*, ii. 870 (1912). English Black Poplar.

Var. *viridis*,² Lindley, *ex Loudon, Arb. et Frut. Brit.* iii. 1652 (1838).

Var. *betulaefolia*, Wesmael, in De Candolle, *Prod.* xvi. 2, p. 328 (1868).

Var. *hudsonica*, Schneider, *Laubholzkunde*, i. 5 (1904); Ascherson and Graebner, *Syn. Mitteleurop.* Fl. iv. 39 (1908).

Populus nigra, Michaux, *Fl. Bor. Am.* ii. 244 (1803) (not Linnæus).

Populus hudsonica, Michaux f., *Hist. Arb. Amer.* iii. 293, t. 10, fig. 1 (1813), and *N. Amer. Sylva*, ii. 114, t. 96, fig. 1 (1819).

Populus betulifolia, Pursh, *Fl. Amer. Sept.* ii. 619 (1814); Loudon, *Arb. et Frut. Brit.* iii. 1656 (1838); Dode, in *Mém. Soc. Hist. Nat. Autun*, xviii. 48 (1905).

Populus nigra, Vaillantiana, and *Muelleriana*, Dode, in *Mém. Soc. Hist. Nat. Autun*, xviii. 48 (1905).

Young branchlets rounded, covered with a dense short pubescence, orange or yellow in the second year. Buds greenish, tinged with brown, viscid, otherwise as

¹ The female catkins figured show ovaries with three stigmas, and were taken from a hybrid tree (*P. Lloydii*) growing near Turnham Green station. Cf. p. 1831, note 1.

² Lindley's specimen in the Cambridge Herbarium is a vigorous branch from a young tree of *P. nigra*, var. *betulifolia*. This is confirmed by a tree labelled var. *viridis* in the Cambridge Botanic Garden. Loudon's description of this variety, "leaves of a brighter green than the species," is inadequate; and the name var. *viridis*, though older than that of var. *betulifolia*, cannot be used. Mackie, in Loudon, *Gard. Mag.* xiii. 230 (1837), says that var. *viridis* was discovered at Bealings, near Woodbridge, and had been grown in his nursery at Norwich for twenty years.

in var. *typica*. Leaves¹ (Plate 409, Fig. 12) similar in shape, colour, size, and margin to those of var. *typica*, but slightly pubescent when young; petioles pubescent.

Catkins 1½ to 2 in. long, as in the typical variety, but with a pubescent axis; stamens in the specimens examined, fewer, about twelve to fifteen; scales, ovary, and stigmas, identical. Fruiting catkins—on the Bury St. Edmunds tree, which was probably fertilised by staminate trees of the same variety close beside it—about 4 in. long, with ovoid capsules about ¼ in. in length, glabrous and tuberculate on the outer surface; seed oblanceolate, yellowish, about ⅓ in. long, covered with dense cottony hairs enveloping the whole catkin after the dehiscence of the capsules.

Forms, in which glabrous catkins are associated with pubescent leaves and branchlets, occur; and on this account I have refrained from making var. *betulifolia* a distinct species.²

The pubescent variety of the black poplar is the only form occurring in England in the wild state; and it is also a native of the greater part of France, from Normandy and Picardy to the foot of the Pyrenees. In 1912 I saw it apparently wild in many places, as in hedges on hills not far from Argentan, where it grows in a small and stunted form. It is most common, however, as a fine tree, often with a burry trunk, along the banks of the great rivers, as on the Seine at Mantes, on the Loire near Tours, on the Garonne in the vicinity both of Bordeaux and of Toulouse, on the Adour between Bayonne and Dax, and on the Gave de Pau, where there are two good trees in a meadow opposite the shrine at Lourdes. This poplar is also frequently planted in botanic gardens, as at Le Mans, Tours, and Montauban, a fine tree in the latter place measuring 90 ft. by 13 ft. There is a specimen in the Montpellier Herbarium, gathered at Ganges on an island in the river Herault; but I have seen no specimens from Provence.³ It is remarkable how this variety has escaped the notice of British botanists, though it has been collected from early times, as there are specimens in the British Museum⁴ gathered by Plukenet and Buddle towards the end of the seventeenth century.

This tree was first distinguished by the younger Michaux, who found it growing on the banks of the Hudson river above Albany, and mentions large specimens planted in New York city; but adds that he never saw it in the forest. Sargent⁵ in 1896 stated that it was growing then on an island in the Delaware river near Easton, Pennsylvania; but in a letter to Kew, dated 31st July 1902, he mentions only a single specimen known to him, an old tree near Boston;⁶ and adds that it is

¹ On very old trees the leaves are smaller, truncate or occasionally subcordate at the base, and with a shorter acumen at the apex. These appear to be *P. Muelleriana*, Dode.

² *P. nigra*, var. *pubescens*, Parlatores, *Fl. Ital.* iv. 289 (1867), was described from trees growing in moist valleys at S. Martino, Palermo; and is recorded in Thessaly by Halacsy, *Consp. Fl. Græc.* iii. 136 (1904). A specimen in the Cambridge Herbarium has branchlets, leaves, petioles, and female catkins covered with long white hairs; and is much more pubescent than trees growing in England. *P. hispida*, Haussknecht, which I have not seen, is probably the same as var. *pubescens*.

³ Pardé, in *Bull. Soc. Dend. France*, 1911, p. 255, states that *P. nigra* is pretty common in Provence; but this is probably var. *typica*.

⁴ *Herb. Sloan*, 83, fol. 8, and 126, fol. 6.

⁵ *Silva N. Amer.* ix. 153, note (1896). In the Montpellier Herbarium there is a specimen of this tree labelled "*Populus*, New York, growing planted opposite Dr. Hosack's door in Broadway, May 7, 1807." Another specimen named *P. hudsonica*, Michaux, was taken from a tree growing at Versailles in 1808.

⁶ This is no doubt the tree which I saw growing on the shore of Jamaica Pond, when staying with Prof. Sargent in 1904, and recognised at once as the English black poplar by its burry trunk and foliage.—H. J. E.

sold in the United States by Ellwanger and Barry of Rochester under the name of *P. elegans*.¹ There is little doubt that this poplar was introduced into the United States in the eighteenth century from England.

3. Var. *italica*, Du Roi, *Harbk. Baumz.* ii. 141 (1772). Lombardy Poplar.

Var. *pyramidalis*, Spach, in *Ann. Sc. Nat.* xv. 31 (1841).

Populus italica, Moench, *Bäume Weissenstein*, 79 (1785).

Populus dilatata, Aiton, *Hort. Kew.* iii. 406 (1789).

Populus pyramidata, Moench, *Meth.* 339 (1794).

Populus pyramidalis, Borkhausen, *Forstbot.* i. 541 (1800).

Populus fastigiata, Poirét, in Lamarck, *Encycl.* v. 235 (1804); Loudon, *Arb. et Frut. Brit.* iii. 1660 (1838).

Branches directed nearly vertically upwards, forming a narrow fastigiata tree. A sport of the typical glabrous variety of *P. nigra*, differing in no respect except in habit.² The leaves are variable, many being the same as those of the ordinary form; but others are often broader than long, truncate or subcordate at the base, with a short acuminate apex, due to increased vigour, as is usual in this species.

The common Lombardy poplar is a staminate tree, always reproduced by cuttings; and for aught we know, all the numerous individuals planted throughout the world may have originated from a single tree, as happened, without any doubt, in the case of the upright form of the common yew. No instances of a second origin have been recorded.

A few trees³ of similar habit, though with branches not quite so vertically inclined, have been observed bearing pistillate flowers.⁴ Plate 383, reproduced from a photograph sent to us by the late Prof. W. Blasius, shows a remarkable female tree at the village of Greene, near Kreiensen, in the Duchy of Brunswick, which has ascending and not erect branches, and differs considerably in habit from the ordinary Lombardy poplar. There is a good specimen at Kew with nearly erect branches, about 50 feet high, which was covered with woolly catkins in 1908. It produced flowers in the spring of 1910, which did not, however, ripen into fruit

¹ This is referred to as a variety of *P. nigra*, commonly sold by nurserymen in the United States, by L. H. Bailey, in *Cornell Univ. Bull. Agric.* No. 68, p. 227 (1894).

² I carefully compared in 1908, in Serbia, the branchlets, foliage, and buds of a Lombardy poplar with those of some wild common black poplars growing near it, and did not detect the slightest difference. The bark of some trees in this region, and also in Algeria, is remarkably whitish; while the colour of their third year and older twigs is peculiarly greyish. This form has been named *P. thevestina*, Dode, in *Mém. Soc. Hist. Nat. Autun*, xviii. 52 (1905). Siehe, in *Mitt. Deut. Dend. Ges.* 1912, p. 123, describes the remarkable pale bark of the Lombardy poplar in Asia Minor. Cuttings were obtained in Algeria by Mr. A. W. Hill in 1910, which are now growing in the nursery at Kew. Vigorous shoots from near the base of old Lombardy poplars at Cambridge show the same coloration.

³ Spenner, *Fl. Friburg*, i. 274 (1825), mentions a female tree near the Carthusian monastery at Friburg in Germany. Another was reported to have been noticed in the University Botanic Garden at Göttingen in 1828 (cf. Denson, in Loudon, *Gard. Mag.* vi. 419 (1830)). Loudon, *Derby Arboretum*, 57 (1840), states that the female tree was introduced in 1840 into the Horticultural Society's garden from Monza near Milan. There is a specimen in the Kew Herbarium, sent from Karlsruhe by A. Braun in 1845, and others undated, which are labelled Frankfort-on-Oder and Switzerland. Mr. W. L. Wood also noticed, in 1910, two smaller trees with pistillate catkins growing in the Walpole Road, Twickenham.

⁴ *P. pannonica*, Kitaibel, *ex Besser, Pl. Enum. Volhynia*, 38 (1822), and Reichenbach, *Icon. Fl. Germ.* xi. 30, t. 619 (1845) (figured with rhombic acuminate leaves), is possibly the correct name of the female Lombardy poplar. Besser, in *Flora*, 1832, ii. Suppl. 14, states that *P. croatica*, which was published at the same time as *P. pannonica*, is the name that should be applied to the supposed cross between typical *P. nigra* and the Lombardy poplar, which grew in the Theresa garden at Vienna, the sex of which is not mentioned. It was supposed to occur wild on the Dnieper. Zawadzki, *Enum. Pl. Galic.* 117 (1835), saw fine specimens of this on the Dniester in Podolia. Petzold and Kirchner, *Arb. Musc.* 593 (1864), state that they received *P. fastigiata*, var. *pannonica*, from many sources, but never were able to discover any distinguishing characters. Cf. also *P. nigra*, var. *pannonica*, Dippel, *Laubholzkunde*, ii. 198 (1892).

in this season, though there are staminate trees at no great distance. It opens its flowers at the same time as the Lombardy poplar. The latter is about three weeks earlier than the native black poplar, an indication of its southern origin.¹ The history of these pistillate trees is quite unknown; but they may have arisen as the result of hybridisation between the staminate Lombardy and the ordinary poplars.

The staminate Lombardy poplar appears to have originated on the banks of the river Po in northern Italy, probably in the beginning of the eighteenth century, as it was unknown to classical writers² and is not mentioned by mediæval Italian authors.³ Moreover, it was not noticed by Ray and other English travellers in Italy in the seventeenth century. Séguier,⁴ an old writer, states that it was known anciently in Lombardy, and mentions a superb avenue, which he saw in 1763 at Colorno, the residence of the Duke of Parma. It was apparently carried⁵ by the Genoese to the Levant; and there are no grounds for supposing that it originated in Asia Minor or Afghanistan, as Royle,⁶ who first made this statement, simply relied on the fact that it bore a native Persian name.⁷ W. G. Browne,⁸ who travelled in Asia Minor in 1798, makes the first reference to its occurrence in western Asia, where he states that it abounds all over the plain of Damascus, and when old becomes rugged and uncouth, as usual in other regions.

It was introduced from Lombardy into France in 1749; and is usually stated to have been brought into England and planted at St. Osyth's in Essex, in 1758, by the Earl of Rochford, who was ambassador in Turin at the time. It was possibly, however, first planted at Whitton some years earlier by Archibald, Duke of Argyll, who died in 1761, as the tree still growing there in 1838 was much larger than any of the others recorded by Loudon, being 115 ft. high and 19 ft. 8 in. in girth at 2 feet from the ground.⁹

¹ Sargent, *Silva N. Amer.* ix. 154, note (1896), says that the fact that the Lombardy poplar does not suffer in the cold of the Canadian winter, shows that it originated in a climate much more severe than that of northern Italy. (The winter in the plain of the Po, it may be stated, is very cold, the mean temperature being below 35° Fahr.; and in Milan the thermometer sometimes sinks below zero.) Prof. Budd, quoted by L. H. Bailey, *Cornell Univ. Bull. Agric.* No. 68, p. 228 (1894), however, explains that the Lombardy poplar, grown in Canada, was imported from Voronej in central Russia, where it has become acclimatised, and is perfectly hardy. The Russian hotanists assured him that its hardiness depended on the region from whence it was obtained. Bailey, *Survival of the Unlike*, 297 (1896), in an interesting chapter on acclimatisation of trees, states that cuttings of the white poplar, taken from trees at Montpellier and at Geneva, which were planted at the latter place, differed as much as twenty-five days in their time of coming into leaf; and similar results were obtained at Ithaca (New York) with cuttings of the Lombardy poplar.

² The often quoted lines of Ovid, *Met.* ii. 345-360, and of Virgil, *Æneid*, x. 190, do not refer to this tree, as has been supposed. The poplars depicted by Perugino (1446-1524), as in a picture in the London National Gallery, are slender, but not with vertical branches, and are probably *Populus alba*. Cf. Rosen, *Die Natur in der Kunst*, 293 (1903).

³ Rostafinski, in *Verhandl. K. K. Zool. Bot. Gesell. Wien*, xxii. 170 (1872), states that it was introduced from Italy into Poland by King Sobieski, who reigned from 1624 to 1696, and that the original trees are still standing in the garden of the Wilanow Castle, near Warsaw. Miss Ivanovska, at my request, examined the old poplars there, which proved to be all of the ordinary wide-spreading form; and Prof. Rostafinski in a letter acknowledges that he made a mistake.

⁴ *Hist. Plant. Nat. Envir. Verone*, ii. 267 (1745).

⁵ Fougeroux de Bondaroy, in *Mém. d'Agric., Paris*, 1786, p. 84.

⁶ *Illust. Bot. Him.* i. 344 (1839). Griffith's statement that it is wild near Kabul, at 7000 ft. altitude, is not confirmed. Aitchison, in *Trans. Bot. Soc. Edin.* xviii. 162 (1891), says: "I only met with this tree cultivated in orchards or near houses in Afghanistan and north-east Persia."

⁷ Boissier, *Fl. Orient.* iv. 1194 (1879), doubts its existence in the wild state in western Asia; and his reference to it being perhaps wild in the Karatau mountain in Turkestan is an error, as the wild fastigiata poplar in this locality is *P. alba*, var. *pyramidalis*. Cf. p. 1778.

⁸ *Travels in Africa, Egypt, and Syria*, 397, 408 (1799). Siehe, in *Mitt. Deut. Dend. Ges.* 1912, p. 123, states that in Asia Minor the Lombardy poplar is extensively cultivated and is a most useful tree, producing after twenty or thirty years' growth, long slender but tough beams, which are much used in house-building.

⁹ Loudon, *Arb. et Frut. Brit.* i. 58 (1838).

According to Sargent,¹ it was brought to America in 1784 by W. Hamilton, who planted it in his garden at Woodlands near Philadelphia.

The Lombardy poplar appears to be a short-lived tree, and is said to be dying out in Germany. As it does not now apparently attain the immense size recorded in former years, there may be some truth in the opinion advanced by Focke² that as all the trees have been raised by cuttings since the origin of the first sport, they may now be dying of old age. (A. H.)

The most reliable account we have of the introduction of this tree is that given by Aiton, *Hortus Kewensis*, iii. 406 (1789), who states that it was brought by Lord Rochford from Turin, where he was ambassador about 1758. He planted cuttings at St. Osyth's Priory in Essex, where two trees now much decayed still survive. I am indebted to Mr. J. Edge, the gardener there, for photographs and measurements of the larger of these trees, which show a large hollow stump divided into two trunks about 20 feet high and measuring 18 ft. in girth at 3 feet from the ground. Living branches have sprung from different places in the trunk, two of which attain a height of about 50 feet.

Loudon records a large tree of the same age as the last, which was blown down at Canterbury in 1836; but the tallest tree mentioned by him was at Great Tew in Oxfordshire, said to have been 125 feet high when only fifty years old. A tree was recorded by Thomas Hogg, forester at Hampton Court, Herefordshire,³ as growing at Wharton Court farm near that place, which in 1879 was said to measure no less than 160 feet. I visited this place in 1905 and found no trace of its remains; but if the height was correct, which from the other measurements given of trees on the estate seems probable, it was much taller than any that I have measured in England or France.

Sir Hugh Beevor tells me of a tree at Pitchford, Shropshire, which in 1907 was 120 ft. by 14 ft. 8 in.; and I have measured many of 100 to 115 feet, but none which can be said to stand out from the average of mature trees. Henry measured a tree at Shiplake House, near Henley, which was 105 ft. by 10 ft. 10 in. in 1905; and another at Alderbourn Manor, Gerard's Cross, which was 100 ft. by 12 ft. in 1912, and visible for many miles around. An old tree in Lensfield Road, Cambridge, 90 ft. high in 1904, of which a photograph was sent me by Mr. Lynch, was removed in 1912.

J. Smith⁴ recorded a tree growing at Fox Mills near Romsey as 125 ft. by 13 ft. 2 in., but when I was there in 1900 I could not find it; and another at Greatbridge House, near Romsey, which was 130 ft. by 13 ft. 9 in. These died in 1881, no doubt from the effects of the inclemency of the weather in 1879-80.

The seasons of 1879-81 appear to have killed a very large number of Lombardy poplars in the eastern and midland counties, not perhaps so much by their excessive

¹ Sargent, *op. cit.* 154, note (1896).

² In *Gart. Zeit.* September 1883, quoted in *Gard. Chron.* xx. 571 (1883). Cf. also *Rev. des Eaux et Forêts*, xxiv. 277 (1885). Manetti's letter quoted by Loudon, *Gard. Mag.* xii. 450 (1836), is rather obscure, and his statement that plants were raised in Italy from seed, which preserved the characters of their parents, is extremely doubtful. In the Cambridge Herbarium, however, there is a specimen, with female flowers and fruit, of a poplar sent by Manetti, which he considered to be the female Lombardy poplar.

³ *Trans. Scot. Arb. Soc.* ix. 151 (1879).

⁴ *Ibid.* xi. 534 (1887).

cold, as because of the two unusually cold and wet summers. A paper on the subject by Mr. H. D. Geldart¹ gives many interesting particulars; and all his correspondents seem to agree that the damage was much greater than in the colder winter of 1860-61, when the thermometer at Audley End near Saffron Walden went down on Christmas morning to -11° . Mr. Geldart quotes the replies received by Mr. Southwell to his inquiries as to the death of Lombardy poplars in other parts of England as follows. Twenty miles round York, death or severe injury was almost universal; in Wilts, they had suffered very much; in west Dorset, most of them were killed or seriously injured; near Doncaster, all were more or less killed; but at Oxford among the College gardens it was the exception to find a damaged tree; and Mr. C. B. Plowright wrote that in the west of England the Lombardy poplars did not seem to be injured at all.

In Scotland it was, according to Dr. Walker, introduced at New Posso in Tweeddale as early as 1765 from cuttings sent by the Earl of Hertford, and was extensively distributed some years later by Lord Gardenstone; but the climate of most parts of Scotland is evidently too cold or too wet to suit this tree, as none of those mentioned by Loudon are still alive so far as I can learn, except one at Brahan Castle, Ross-shire, that was 70 ft. by 6 ft. in 1838. When I visited this place in 1907 I found a fine tree 98 ft. by about 9 ft., which may be the same. Six miles north of Inverness, on the high-road to Beauly, I also saw four well-shaped trees, of which the largest was 90 ft. by 11½ ft., showing the excellent climate of that district. Mr. Renwick tells us of one near Braidwood, Lanarkshire, which was 93 ft. by 10½ ft. in 1910; this was blown down on 5th November 1911.

In France the Lombardy poplar is common, though now on account of its inferior growth often replaced by the hybrid poplars. It commonly attains 110 ft. to 120 ft. in height, but I have seen none approaching the trees near Rouen mentioned by Loudon² which, according to M. Dubreuil, were then 150 ft. high. A tree³ at the Trianon, Versailles, was 17½ ft. in girth at four feet from the ground in 1888.

The Lombardy poplar has been planted largely in the irrigated districts of Utah, and, according to F. C. Sears,⁴ rows of tall Lombardy poplars, marking the irrigation canals, are a feature in the landscape. (H. J. E.)

In Chile,⁵ especially about Valparaiso, the Lombardy poplar is largely planted, both in gardens and on the margins of the irrigation canals, where it grows so rapidly as to be ready for felling in fifteen years. Its timber is used for indoor work in houses. Dode states⁶ that in Chile and Argentina there is a form of the Lombardy poplar which keeps its leaves evergreen.

Mr. Lovegrove has sent us specimens of the Lombardy poplar from Kashmir, where it is planted along roads, and often attains 100 ft. in height and 7 ft. in girth.

¹ *Trans. Norf. and Norw. Nat. Soc.* iii. 354-366 (1880-1884). Cf. *Gard. Chron.* xv. 764, 798, and xvi. 246 (1881), where instances are given of the death of many trees also in the north of France and in Belgium.

² *Arb. et Frut. Brit.* iii. 1670 (1838).

³ *Garden and Forest*, i. 174 (1888).

⁴ *Ibid.* x. 357 (1897).

⁵ Dr. W. Balfour Gourlay, in *Trans. Bot. Soc. Edin.* xxiv. 74, plate 7 (1910). It is much attacked in Chile by the quintral, *Loranthus tetrandus*.

⁶ *Bull. Soc. Dend. France*, 1908, p. 29, and 1909, p. 152, where this form is named *P. pyramidalis*, var. *Thaystiana*, Dode.

Its timber is used in house-building, and lasts well when protected from rain. A tree 5 ft. in girth sells for 12 to 26 shillings.

4. Var. *plantierensis*, Schneider, *Laubholzkunde*, i. 803 (1906).

Populus fastigiata plantierensis, Simon-Louis, *Cat.* 1884-1885, p. 51.

Populus plantierensis, Dode, in *Mém. Soc. Hist. Nat. Autun*, xviii. 43 (1905).

A fastigate form of var. *betulifolia*, similar to the Lombardy poplar in habit and foliage, but with reddish pubescent petioles, and shortly pubescent branchlets. It originated in Simon-Louis's nursery at Plantières, near Metz, whence it derives its name, and is said to occur in both sexes, and to be the result of a cross between the Lombardy poplar and var. *betulifolia*; but this origin is unlikely. The original tree is a male, and when measured by Elwes in 1908 was 74 ft. by 5 ft. It is claimed for it that it is more vigorous than the ordinary fastigate poplar, and not liable to die off at the top, as is frequent in the latter. There are specimens at Kew about 25 ft. high.

5. Var. *viadri*, Ascherson and Graebner, *Syn. Mitteleurop. Flora*, iv. 40 (1908).

Populus viadri, Rüdiger, in *Abhand. Naturw. Ver. Reg. Bez. Frankfurt*, viii. *Mon. Mitt.* 12 (1891); Koehne, in *Verh. Bot. Ver. Brandenb.* xxxvii. p. xxviii (1895), and in *Gartenflora*, xxxix. 447 (1890).

A narrow pyramidal tree, with ascending branches, which in branchlets, buds, and foliage resembles the typical glabrous form of the species.¹ It occurs along the banks of the Oder, near Frankfort, whence it derives its name (*Viadrus* being the Latin name for this river). It is said to produce pistillate flowers identical with those of *P. nigra*; but a tree² at Kew, about 25 ft. high, produced staminate flowers in 1910. These differ slightly from the type in occasionally having peculiar scales deeply bilobed at the summit. (A. H.)

DISTRIBUTION

The distribution of the black poplar is very wide in Europe, but difficult to define accurately, as it has been much planted in former times. In Norway and Sweden, Schübeler only knew it as a planted tree, and figured a very large one, which from its burry trunk has the appearance of the English tree. This grew on the banks of a river at Ronneby in Sweden; and when measured in 1882 by Prof. Wittrock, was, at four feet from the base, 34 ft. 8 in. in girth, dividing into two main trunks a little higher up; and this is the largest girth of which I have any record.

In the Botanic Garden at St. Petersburg a tree, supposed to have been planted by Peter the Great, measured in 1908 about 90 ft. high by 17 ft. in girth, forking low down, and with a large burr on its trunk.

In north Russia it extends to 57° N., according to Von Herder; but in the St. Petersburg Herbarium I found a note by Kusnetsov stating that it was found at

¹ Koehne, who mentions trees of both sexes in *Deut. Dend.* 84 (1893), describes this peculiar poplar as a hybrid, *P. candicans* × *nigra*, but he afterwards withdrew this very unlikely hypothesis. The leaves are more cuspidate at the apex than in ordinary *P. nigra*, and it is possible that *P. viadri* is a hybrid, but I have seen no pistillate flowers. *P. viadri* appears to have been introduced into cultivation by Späth, as it is mentioned as a novelty in his *Catalogue*, No. 91, p. 96 (1893-1894).

² Another tree at Kew, labelled *P. viadri*, also obtained from Rüdiger, is different in habit, having spreading and not ascending branches. It is pistillate, and appears to differ in no respect from *P. nigra*, var. *typica*.

Emetskoie on the Dwina in lat. 63° 30'. It is found on the Volga¹ as far south as Astrachan, and on the Ufa river, where, according to Loffiewsky, it attains 100 ft. high. I also found specimens in the herbarium under the name of *P. nigra* from Zlataoust on the southern Ural, from Tobolsk and Barnaoul, and from the Yenesei river in lat. 66° N., collected by Brenner, with very small leaves. In France I saw a large female tree at Chenonceaux, near Tours, which measured 100 ft. by 10 ft. 10 in. in 1908. At Dijon there is in the Botanic Garden a very large tree² of this species, probably the oldest in Europe. It is said from historical documents to be over five centuries old, and bears an inscription to the effect that in 1866 it was at the ground 12 metres, and at two metres high 8 metres in girth, and contained about 40 cubic metres—about 1400 cubic feet of timber. It is quite hollow at the base, the shell being only a foot or so in thickness, and has deeply ridged bark, 4 to 6 in. in thickness. As nearly as I could estimate, its present height is about 125 ft., but having lost several branches has probably been taller. Its girth at 5 ft. is 26 ft. 7 in. The leaves though small are typical in shape, but the trunk is not as burry as in English trees. I could not learn whether it is male or female. M. Mathey, inspector of forests, told me that the black poplar which was formerly common around Dijon is now growing scarce, being superseded, as in England, by *P. serotina*.

In Spain and Portugal I only saw small and stunted trees; and in Italy I have seen none which looked like true *P. nigra*. In Austria it is common in the valley of the Danube; and in the Prater at Vienna there are many good-sized trees. In Greece, Heldreich records it from Mt. Pelion. In Morocco, Maw and Ball collected specimens in the Atlas at 3000 to 4000 feet.

In Great Britain it has been occasionally confused by local botanists with *P. serotina*; and I can find nothing in the older works, such as those of Evelyn, Miller, and Boutcher, to show that these authors knew the tree from personal observation. Though rare in most parts of England it seems to be a native of the counties on the Welsh border, where it is still fairly common; and it is probably indigenous in Norfolk, Suffolk, Cambridgeshire, and Essex. It is so very distinct in trunk, foliage, and time of leafing from *P. serotina*, that it is extraordinary that so little notice has been taken of it either by botanists or foresters, and as the trees given below have in almost every case been visited and identified by ourselves, it is very likely that it will be found in other districts now that attention has been called to it.

The English tree may be recognised in mature specimens by its trunk being usually covered more or less with large burry excrescences, which are formed by a mass of abortive buds, and which do not seem to be found to the same extent in Continental specimens; secondly, by its flowering later and leafing earlier than the much commoner black Italian poplar; and, thirdly, by the shape of the leaves, and also by the green and not reddish tint of the young foliage. As this tree does not seem to have been propagated by nurserymen for many years past, young trees

¹ Loudon, *Trees and Shrubs*, 824 (1842), states that it abounds on the banks of the Vistula, whence the mottled wood of knotty trunks was brought to Berlin and made into ladies' workboxes. Concerning *P. vistulensis*, Hort., see Jacquin, *Ann. de Flor.* ii. 96 (1833), and *Rev. Hort.* 1865, pp. 305, 346, and 405.

² Figured in *Gard. Chron.* xxi. 641, fig. 123 (1884), and in *Rev. Hort.* iii. 184, fig. 11 (1854).

are rarely seen, and the species appears to be dying out in all parts of England, except on the Welsh borders and in East Anglia. The glabrous Continental form is very rarely planted in Britain.

REMARKABLE TREES

In the south-western counties I have seen none except at Dunster in Somerset, where, in a meadow below the castle there is an old hollow stump 24 feet in girth, from which a large limb has extended and taken root some way off, and thrown up two stems 5 and $5\frac{1}{2}$ ft. in girth, but only about 40 ft. high. There are three other large trees near the park gate south-east of the castle, the first 92 ft. by 17 ft measured over a large burr, the second about 90 ft. by $16\frac{1}{2}$ ft., also very burry.

In Hants I have seen none, but am told by Mr. J. Smith of Romsey that an old pollard exists near that town 15 ft. by 7 ft. 9 in. In Sussex there is a tree in the park at Beauport about 100 ft. by 8 ft. In Kent in Penshurst Park there are some small, old, and very stunted trees.

In Middlesex by far the finest are two at Syon. These are rather shut in by other trees, and in 1905 were¹ about 110 ft. by 17 ft. 8 in. In the MS. catalogue at Syon a tree of this species was recorded as 120 ft. by 15 ft. in 1849. There are two trees on Wandsworth Common, and Miss Woolward tells me of a young female tree near the Serpentine Bridge. In the Green Park there are three trees in a group about 100 yards from Piccadilly opposite Down Street.

In Suffolk on the banks of the Larke in the Abbey grounds at Bury St. Edmunds there are several old trees, one of which was figured by Strutt,² and was said by him to be 90 ft. by 15 ft., and to contain 551 cubic ft. of timber. I could not identify this particular tree in 1907, when on 7th April I found them covered with bright red male flowers, which gave a beautiful effect in the sun. A female tree here was only just showing flower at the same date, but produced fertile seeds later, from which Mr. Hankins, forester at Culford Park, raised numerous seedlings, thirty of which planted out in a plot measured 5 to 7 ft. high in November 1911.

A tree at West Stow, near Bury St. Edmunds, which measured 92 ft. high by 19 ft. in girth, was felled in March 1912. It had immense spreading superficial roots; and the original set, about 4 in. in diameter, was recognisable in the centre of the butt, being separated from the older wood by a ring-shake. Near the base of the trunk Mr. Hankins counted 225 annual rings. The timber was quite sound, the first length measuring 39 ft. by $42\frac{1}{2}$ in. quarter-girth or 489 cubic ft., the total contents being 748 cubic ft.; a plank of it is now in the Cambridge Forestry Museum.

At Islington Hall, King's Lynn, there is a magnificent tree, which was measured by Mr. A. P. Long in October 1912, as follows: total height, 108 ft.; girth at five feet from the ground, 17 ft. 3 in.; volume of the bole (36 ft. in length to the point where the first branch is given off), 361 cubic feet; total volume, 620 cubic feet.

¹ A. B. Jackson, *Cat. Trees Syon*, 22 (1910), gives the height of these trees as 128 ft.

² *Sylva Britannica*, t. 24.

At Weeting Park near Thetford there are two large trees in the park about 90 ft. high and 17 ft. 4 in. in girth, whose trunks are covered with large burrs. Mr. Howell, the gardener here, told me that a much larger one had been blown down some time before my visit, the trunk of which was no less than 20 ft. in girth at eight feet from the ground. The rings in the wood showed this tree to be over 200 years old. At St. Helens, Norwich, in Mr. Skelton's garden on the banks of the Wensum, there are two fine trees, one of which in 1908 was 95 ft. by $15\frac{1}{2}$ ft.

In Essex it is rare, but at Audley End, in a withy bed below the park, there are three trees, one of which measured 115 ft. by 15 ft. on 18th March, 1907, when it was not yet in flower. At Stanstead Bury, Hertford, Mr. H. Clinton Baker found a tree bearing pistillate catkins, and 85 ft. by 12 ft. 9 in., in April 1911. At Bishop Stortford Henry has seen a large female tree.

In Gloucestershire the tree is quite rare, the only ones I know of being a small tree by the roadside on Crickley Hill, and another on the banks of an old canal at Coombe Hill, half a mile west of the Gloucester and Tewkesbury Road. Miss F. Woolward discovered a female tree about 60 ft. high, near Bourton on the Water; and at Forthampton Court, near Tewkesbury, there are four trees about 90 ft. by 15 to 16 ft., by a pond north of Mr. Yorke's house. In Herefordshire the tree, I am told by Mr. T. E. Groom of Hereford, is not uncommon in the Wye valley, while Mr. Openshaw of Wofferton Court farm informs me that it was more abundant fifty years ago. In Worcestershire, Lees,¹ who seems to have known the tree better than recent botanists of the county, says, "A few scraggy native black poplars appear in various localities by brooksides, but this tree appears to be dying out." At Arley Castle there is a fine tree planted in the park, which is about 100 ft. by 15 ft.

In Shropshire I have seen more than in any other county, the finest being a tree at Oakley Park, Ludlow, which in 1908 was about 100 ft. by 15 ft. 10 in. Between Craven Arms and Lydbury North there are several comparatively young trees planted by the roadside about 90 ft. by 6 to 7 ft. In a meadow near Walcot Park a line of trees in which *P. nigra* and *P. serotina* are mixed, shows the difference of size, habit, and period of shedding their leaves very plainly. On 28th October 1908, *P. nigra* had shed all its upper leaves, while those of *P. serotina* were still green. *P. nigra* here averaged about 70 ft. by 6 ft., whilst *P. serotina* were about 100 ft. by 9 ft., all being apparently planted at the same time. Between Oswestry and Whittington on the main road are several large but not very old trees. Strutt says that the black poplar is oftener found in Suffolk and in Cheshire than in any other counties, but I can hear of none in the latter county.

The largest I have seen in Wales are at Gwernyffed Park, Breconshire, where there is a tree in a belt west of the lodge gate, overgrown with ivy, which is about 90 ft. by 17 ft. At Maesllwyth Castle, Radnorshire, there are two fine trees in the park, with burry trunks, measuring about 85 ft. by $15\frac{1}{2}$ ft. in 1907.

In the north I have seen none except at Alnwick, where in a field by the road between the town and the castle there is an old tree. Mr. A. C. Forbes tells me of a female tree near Hexham.

¹ *Botany of Worcestershire*, xl. (1867).

In Scotland it seems quite rare, and whether it is truly native seems doubtful. The finest I have seen is in the park at Gordon Castle, which in 1908 was about 100 ft. by 15½ ft. At Smeaton Hepburn I measured in 1911 a tree 90 ft. by 8 ft. 7 in. Mr. Renwick tells me of two trees at Auchentorlie, Dumbartonshire, of which the best measured 94 ft. by 12 ft. 8 in. in 1909; and of two trees at The Ross, Lanarkshire, one of which, bearing pistillate flowers, and 87 ft. by 14½ ft., was greatly injured by the storm of 5th November, 1911; the other measured 80 ft. by 12 ft. 5 in. in 1912. At the foot of the former tree, *Lathraea squamaria*, a parasitic plant, is growing. Mr. Renwick measured, in 1909, a fine tree at Cambusnethan House, Lanarkshire, 102 ft. by 11 ft. 8 in.; four trees at Dalzell House in the same county, the largest of which was 99 ft. by 17 ft. 7 in.; and a tree at Kilkerran, Ayrshire, 88 ft. by 15 ft. 3 in.

Selby¹ mentions an immense tree growing at Maxwellheugh near Kelso, which had a trunk 16½ ft. high and 31 ft. at the base, 21 ft. at two feet and 18 ft. at ten feet, respectively in girth, which was computed to contain over 900 ft. of timber, and, supposing it to be the black Italian poplar, says that it could not be above sixty years old.² But Sir George Douglas of Springwood Park, Kelso, informs me that this tree, which had to be cut down in 1902 as it overhung the road, and was decaying and dangerous, was, according to reliable oral tradition, nearly as large one hundred and twenty years previously; and in any case must have been a great deal older than Selby supposed. It was 21 ft. in girth at five feet from the ground when felled, and was said to have been 92 ft. high in 1859. Sir George Douglas further tells me that Andrew Brotherstone, a botanist of Kelso, called it the black Italian poplar. Particulars of it were sent to the Edinburgh Botanical Society, but Professor Balfour informs me that no trace can now be found of this in the records of the Society. Mr. G. Leven, forester at Bowmont Forest, informs us that the gardener who cut it down and a local nurseryman state that it was a black Italian poplar.

In Ireland it seems to be doubtfully native. I have seen none in positions where they seem really wild. Stunted trees which look like *P. nigra* are common by the roadsides in several counties, but the only fine trees I have seen are as follows:—At New Ross, Wexford, by the road about 500 yards south of the town, an old tree with a hollow trunk about 90 ft. by 18 ft. This is a female, and produced good seed in 1907, from which Miss Woolward raised seedlings.³ At Mallow Park, close to the bridge out of the town, a very large tree⁴ with a burry trunk, which in 1909 measured 90 ft. by 19½ ft. At Muckross, on the green near the hotel, an old tree about 70 ft. by 13 ft., which Mr. Greany, resident agent for the Muckross estate, told me was the only one he knew in the district. (H. J. E.)

¹ *British Forest Trees*, 202 (1842).

² M'Kay and Renwick, in *Trans. Nat. Hist. Soc. Glasgow*, iv. pp. 251, 261 (1891), found this tree to be 19 ft. 9 in. in girth at six feet three inches above the ground, in 1893.

³ Cf. *Journ. Bot.* xlv. 417, t. 487 (1907).

⁴ There are two photographs of this tree in the Timber Museum at Kew, which were sent in 1878, with a note that the girth in that year was 17 ft. 2 in. at 4½ ft. and 18 ft. 1 in. at 6 ft. above the ground.

POPULUS MONILIFERA, CANADIAN BLACK POPLAR

Populus monilifera,¹ Aiton, *Hort. Kew.* iii. 406 (1789); Willdenow, *Sp. Pl.* iv. 805 (1805); Watson,² *Dendr. Brit.* ii. t. 102 (1825) (excl. the staminate flowers); Hartig, *Naturges. Forstlich. Culturpfl.* 436 (1851).³

Populus virginiana,⁴ Fougereux de Bondaroy, in *Mém. d'Agric. Paris*, 1786, i. p. 87 (1787).

Populus canadensis,⁵ Michaux, *Hist. Arb. Amer.* iii. 297, t. 11 (1813); Loudon, *Arb. et Frut. Brit.* iii. 1655 (1838) (not Moench, Hartig, or Koehne).

Populus deltoidea,⁶ Sudworth, in *Bull. Torrey Bot. Club*, xx. 44 (1893) (in part).

Populus deltoidea,⁶ Sargent, *Silva N. Amer.* ix. 179, t. 494 (1896), and *Trees N. Amer.* 163 (1905) (in part).

A tree, attaining in America 100 ft. in height and 20 ft. in girth. Bark deeply divided into broad rounded scaly ridges. It is readily distinguishable in cultivation from *P. angulata* by its different foliage and the less angular branchlets, which are rarely marked with projecting ribs, but are similar in their greenish colour, with white lenticels. Buds brownish, viscid. Leaves (Plate 409, Fig. 14) smaller than in *P. angulata*, and broader in proportion to their length, averaging 3 in. in width, deltoid-ovate, abruptly cuspidate-acuminate at the apex; base wide, shallowly cordate, occasionally truncate; glabrous, marked at the base of the blade by two glands; margin with a narrow translucent border, densely ciliate, with sinuate serrations fewer and coarser than in *P. angulata*, absent on the base and at the apex, their glandular tips being incurved; petiole laterally compressed.

Catkins about 3 in. long; axes and pedicels glabrous; scales large, dilated at their apex, and irregularly divided into filiform lobes. Stamens 40 to 60; disc broad, orbicular or quadrate, oblique. Pistillate flowers; disc broad, cup-shaped; ovary sub-globose, 3- or 4-celled with 3 or 4 stalked dilated lobed stigmas.

¹ This is the oldest certain name for the northern form of the American black poplar, which is represented in the British Museum by a specimen from Fothergill's garden bearing staminate flowers, labelled *P. monilifera* in Solander's hand-writing. Fothergill lived 1712-1780, and his garden was at Upton, Westham.

² Watson figures a pistillate tree, growing at Kew in 1822, which was certainly the American species; but is no longer living, most of the poplars planted at Kew in early days having died or been removed. Watson mentions also a pistillate tree at Cottingham, near Hull, the only other specimen which he had seen. The staminate trees which he refers to as being plentiful were *P. serotina*.

³ Cf. *P. carolinensis*, Moench, p. 1810, note.

⁴ *Populus virginiana*, according to Fougereux, was a pistillate tree, usually named in collections "Peuplier de Canada," and very sensitive to frost when young. He probably meant the true northern species. Usually in France, the "Peuplier de Virginie" was a synonym of the "Peuplier Suisse," the hybrid *P. serotina*. Fougereux's name is wrongly used in *Journ. Bot.* l. 132 (1912).

⁵ Michaux's name, *P. canadensis*, is accompanied by an accurate description. *P. canadensis*, Moench, *Bäume Weiss.* 81 (1785), identical with *P. latifolia*, Moench, *Meth.* 338 (1794), is possibly one of the female hybrids, *P. regenerata* or *P. marilandica*, but must remain a doubtful name. These names of Moench are supposed by Dode, *op. cit.* 65 (1905), to indicate *P. canadensis*, but this is improbable, as Moench clearly describes the latter species as a variety of *P. balsamifera* with cordate leaves. *P. canadensis* is usually erroneously applied by Continental botanists to the various hybrid poplars which are commonly met with in cultivation. See pp. 1816, 1824, 1828. It is wrongly used for the Black Italian Poplar in *Journ. Bot.* l. 132 (1912).

⁶ Both these names, *deltoidea* and *deltoidea*, are modifications of *Populus deltoide*, Marshall, *Arb. Amer.* 106 (1785). This is an incomplete description of a poplar growing on the banks of large rivers in Carolina and Florida, and is perhaps meant for *P. angulata*. Dode, *op. cit.* 40 (1895), says: "Quant à la notation *deltoidea*, il semble absolument impossible de lui donner un sens quelconque, Marshall ne l'ayant fait suivre que de quelques mots équivoques."

Fruiting catkins, 6 to 8 in. long; capsules 3- to 4-valved; seed with long white hairs, enclosing the catkins, when the capsules dehisce, in a dense mass of cotton.

1. Var. *occidentalis*, Rydberg, in *Mem. New York Bot. Garden*, i. 115 (1900).

Populus occidentalis, Britton, ex Rydberg, *Fl. Colorado*, 91 (1906); Gombocz, in *Math. Termes. Közl.* xxx. 79 (1911).

Populus Sargentii, Dode, in *Mem. Soc. Hist. Nat. Autun*, xviii. 40 (1905); Britton, *N. Amer. Trees*, 178 (1908).

Leaves smaller, deltoid, truncate at the base, abruptly contracted at the apex into a long acuminate point, with few and coarse serrations.

This is the common black poplar in western North America, east¹ of the Rocky Mountains from Saskatchewan and Alberta southwards to New Mexico and western Texas; and is the characteristic tree on the river flats of the western prairies.

P. monilifera is distinguishable from all the hybrids by the dense persistent cilia on the margin of the leaf, the peculiar few hooked serrations, the abrupt cuspidate apex, and the constancy of the glands at the base; and when flowers are obtainable by the large number of stamens (about sixty), and the shape of the stigmas. It has been confused by most dendrologists with the hybrids, which both on the Continent and in England have entirely supplanted it in cultivation. It has become an extremely rare tree; and the only specimens which we know of in England are a tree apparently past its prime, though probably not over sixty years old, at Bradwell Grove, Burford (Oxon), the seat of W. H. Fox, Esq., which Elwes measured in 1910 and found to be 91 ft. by 9 ft. 3 in.; and another at Penrice Castle, Glamorgan-shire, about 80 ft. high and 13 ft. 9 in. in girth. The stem of the latter has deeply furrowed bark, and gives off the first branch at twenty-seven feet up; above are numerous wide-spreading branches.

An old tree in the Cambridge Botanic Garden was cut down two years ago, but a cutting from it is now making vigorous growth. Elwes has also obtained cuttings from America, which are thriving at Colesborne.

DISTRIBUTION OF *P. MONILIFERA* AND *P. ANGULATA*

P. monilifera and *P. angulata* are considered by modern American botanists and foresters to constitute a single species, which they term *P. deltoidea*, Marshall, with the following distribution, according to Sargent:—Province of Quebec and the shores of Lake Champlain, through western New England and New York, Pennsylvania west of the Alleghanies, and the Atlantic states south of the Potomac river to western Florida; and westwards as var. *occidentalis* to the base of the Rocky Mountains from southern Alberta to northern New Mexico; comparatively rare and of smaller size in the east and in the coast region of the south Atlantic states and east Gulf states; a large and abundant tree along the streams between the Alleghany range and the Rocky Mountains.

P. monilifera and *P. angulata* are undoubtedly connected by intermediate forms; and the view that they constitute one species is possibly true in a wide sense, but

¹ It is reported to occur in Idaho by M. E. Jones, *Montana Botany Notes*, 24 (1910).

they are very different in cultivation, and herbarium specimens justify them being kept separate. Var. *occidentalis*, Rydberg, more closely allied to *P. monilifera* than to *P. angulata*, may also rank, when further studied in the field, as a third species.

I am unable to limit correctly the distribution of the two species, but *P. monilifera*¹ is undoubtedly the poplar, wild in Ontario, Quebec, New England, New York, and Pennsylvania. *P. angulata*² appears to be that common in the basin of the Mississippi, and in the southern Atlantic states and the Gulf states.

Michaux states that *P. angulata* attains its most northerly point in lower Virginia, but is more common in the two Carolinas, Georgia, and Louisiana, growing in the marshy basins of the great rivers, ascending the Mississippi from its source to its junction with the Missouri, and continuing along the latter for a hundred miles. He had only seen *P. monilifera*³ along the river Genesee in New York, in some parts of Virginia, and on several islands of the Ohio river; but believed from reports that it occurred in the Mississippi valley as far south as the Arkansas river. (A. H.)

P. monilifera is not generally distributed or common either in Canada or New England so far as I saw. Macoun states⁴ that along the Grand Trunk Railway in Ontario there are many young trees which had grown from western seed carried by the railway cars, and he speaks of trees "over 50 ft. high, and some at least 2 ft. in diameter," at Big Stick Lake, north of the Cypress hills in Manitoba.

In New England it seems to be commonest in the Connecticut valley, where Dame and Brooks⁵ speak of it as a stately tree 70 to 100 ft. high; and Emerson mentions a tree which he found at New Ashford in 1838, not over sixty years old, which was 20 ft. 5 in. in girth. Mr. Foxworthy sent us a photograph of a tree with a wide-spreading crown growing near Ithaca, New York. This measured 80 ft. by 13 ft., with the trunk dividing into three main stems at about twenty feet from the ground. Self-sown seedlings found by Mr. Jack on the sandy shore of the St. Lawrence, near Chateaugay, on 15th August 1895, where the fruit was ripe on 30th May, were only 4 to 6 in. long, with 4 to 8 small crenate ovate-lanceolate leaves.

S. C. Mason, of the Agricultural College, Kansas, gives a good account of *P. angulata* in that state in *Garden and Forest*, iv. 182, and figures a large tree on the banks of the Kansas river which shows its habit in the west. This tree was 24 ft. in girth near the ground, and was 80 ft. high, with a spread of over 80 feet. Another was 104 ft. high, and as much in the spread of its branches. A tree cut on the Saline river had a stump 8 ft. across, and furnished ninety-six loads of wood. Though most of the large old trees have been cut by the early settlers to build their houses and stockades, the tree is now largely planted for fuel.

¹ Herbarium specimens from Ontario, Vermont, New York, and Ohio are *P. monilifera*.

² Herbarium specimens from the banks of the river Ohio, "near North Bend," collected by C. W. Short in 1833, and from Missouri and New Orleans, collected by Drummond, are *P. angulata*, var. *missouriensis*. Specimens gathered by Sargent at Augusta, Georgia, have pubescent leaves and petioles, and may be another variety.

³ Michaux describes this species under the name *P. canadensis*, and lays great stress on the difference in hardness between it and *P. angulata*. He considered the latter to be a native only of the southern states, as its shoots were always injured by a few degrees of frost.

⁴ *Cat. Canadian Plants*, i. 457 (1883).

⁵ *Trees of New England*, 34 (1902).

Ridgway, in *Proc. U.S. Museum*, 86 (1882), speaking of *P. angulata*, states that it is a very common tree on rich bottom lands and along alluvial banks of streams, where it occasionally attains immense size. Trunks of 5 to 6 ft. diameter are not uncommon, while trunks of 7 to 8 ft. are sometimes found, the stem being usually more than 50 feet clear. The largest measurements were as follows:—

	Girth.	Bole.	Height.	Measured by
In Posey Co., Ind.	18	70	165	C. Schneck.
In Wabash Co., Ill.	18 $\frac{3}{4}$	75	175	Dr. J. Schneck.
In Gibson Co., Ind.	24	—	—	R. Ridgway.

TIMBER

The timber varies very much in quality, a variety known as yellow cottonwood being much the best. Mason says that he has known strong and good houses built from it whose joists and sheathing boards were straight and sound thirty years after they were put up. But the timber of some trees is soft, spongy, and worthless. Sargent says that the wood is very difficult to season, and is apt to warp badly in drying, but of late years has been used in the Mississippi valley for packing-cases and other coarse work. (H. J. E.)

POPULUS ANGULATA, CAROLINA POPLAR

Populus angulata, Aiton, *Hort. Kew.* iii. 407 (1789); Michaux f., *Hist. Arb. Amer.* iii. 302, pl. 12 (1813); Loudon, *Arb. et Frut. Brit.* iii. 1670 (1838); Schneider, *Laubholzkunde*, i. 9 (1904); Dode, in *Mém. Soc. Hist. Nat. Autun*, xviii. 38 (1905); Gombocz, in *Math. Termes. Közl.* xxx. 81 (1911).

Populus carolinensis,¹ Fougereux de Bondaroy, in *Mem. d'Agric. Paris*, 1786, i. 90 (1787); Dode, *op. cit.* 37 (1905).

Populus heterophylla, Du Roi, *Harbk.* ii. 150 (1772) (not Linnæus).

Populus balsamifera, Miller, *Gard. Dict.* ed. 8, No. 5 (1759) (not Linnæus).

Populus angulosa, Michaux, *Fl. Bor. Amer.* ii. 243 (1803).

Populus macrophylla, Loddiges, *Cat.* (1836), ex Loudon, *op. cit.* 1671 (1838).

Populus Besseyana, Dode, *op. cit.* 38 (1905).

A tree, attaining over 100 ft. in height and 15 ft. in girth. Bark deeply and regularly furrowed on old stems. Young branchlets angled, glabrous, greenish with white lenticels; on vigorous shoots, with projecting ribs, persistent two or three years. Buds greenish, glabrous, only slightly viscid. Leaves (Plate 409, Fig. 15) always longer than broad, averaging, when well-developed, 7 in. long and 5 in. wide, triangular-ovate; base broad, truncate, subcordate or deeply and narrowly cordate; apex acute or shortly acuminate; glabrous and firm in texture when

¹ *P. carolinensis*, Moench, *Bäume Weissenstein*, 81 (1785), is said by Willdenow, *Sp. Pl.* iv. 805 (1805) and by Hartig, *Naturges. Forst. Culturpf.*, 436 (1851) to be identical with *P. monilifera*, Aiton; but this is uncertain, and Moench's plant may have been the female tree of *P. angulata*.

mature, slightly pubescent when young; with two to six glands at the base of the blade, irregular in shape and size, either on the petiole or on the adjoining margin; margin, with a narrow translucent border, ciliate, crenately glandular-serrate, the teeth close together, except near the apex, where they are wanting, and on the base, where they are coarser and wide apart; petiole laterally compressed, greenish, pubescent at first, glabrous later.

Catkins, about 2 to 3 in. long; scales small, cucullate or concave, dentate and without long linear lobes; axis and short pedicels glabrous. Stamens, thirty to forty, on an oblique glabrous disc; filaments slender, white; anthers red. Ovary sessile, globose, glabrous, in a deep five-lobed glabrous cup-shaped disc; stigmas three or four, yellowish, widely dilated, crenulate, often subdivided each into two lobes, spreading upwards or horizontally outwards from the apex of the ovary. Fruit not seen.

The female tree of typical *P. angulata*, which is in cultivation in Europe, has branchlets less winged than those of the staminate tree, and is often distinguished as *P. angulata cordata*, though its leaves are as often truncate as cordate. At Plantières, Metz, it is said¹ to be very hardy, as young trees bore without injury a temperature of -23° Cent. in December 1859; whereas the staminate tree is killed by a temperature of -12° to -15° Cent. The pistillate tree is represented at Kew by a specimen about 35 ft. high, which was obtained from Simon-Louis in 1885. A similar tree at Glasnevin regularly bears flowers, which have been drawn by Miss F. Woolward. There is an old tree of this at Plantières, which produced² fertile seed in 1860, and was 7 ft. in girth² in 1905.

1. Var. *missouriensis*, Henry. This variety has branchlets and leaves similar to those of typical *P. angulata*, but differs in the flowers, which are like those of *P. monilifera*. The scales of the flowers of both sexes are large, lacinate and fimbriate; while the stamens are 40 to 60, as in the latter species.

Var. *missouriensis*, judging from specimens in the Kew Herbarium, which agree with those sent to me by Rehder from North Bend on the Ohio river, appears to be the ordinary wild form of *P. angulata* in the Mississippi basin. This variety is in cultivation³ in the south of France and in Italy; but requires further study.

Typical *P. angulata* has not yet been identified, so far as I know, in the United States; and is possibly a form with peculiar flowers, in which the scales have become modified, that has arisen in cultivation in the cooler climate of western Europe. It may, however, yet be found wild in the Carolinas or in Virginia, whence *P. angulata* is reputed to have been originally introduced into Europe. (A. H.)

¹ Thomas, in *Rev. Hort.* 1861, p. 75. It is called *P. cordata*, by Simon-Louis, *Cat. Gen.* 1869, p. 72, where it is said to have been a long time in their nurseries, and to be of unknown origin.

² Letter to Kew from Jouin. Its leaves appear earlier than those of the European poplars, and were opening on 15th April 1911, and were fully out on 6th May 1911; whilst those of *P. serotina* do not come out at Metz till late in May, as M. Jouin told me.—H. J. E.

³ Specimens with staminate flowers collected by Elwes in the Borilly Park at Marseilles, and others of both sexes sent to me from Turin by Prof. Voglino, belong to var. *missouriensis*. Possibly all the trees in cultivation in the south of France and in Italy belong to this variety; but I see no means of distinction in the absence of flowers. The habit of these southern trees is scarcely distinct.

REMARKABLE TREES

The most remarkable tree in Europe is one at Danny Park, Sussex, the seat of W. H. Champion, Esq., of which Plate 384, reproduced from a photograph taken by Mrs. F. D. Godman in 1910, gives a good idea. When this wonderful tree was planted it is impossible to say, but Mr. Champion's grandfather told him that it was an old tree when he came to Danny about 1815; and judging from a drawing of the house made in 1787, in which a tulip-tree probably of the same age is shown as a small tree, it may have been planted about 1760. The branches extend over a space 150 yards round, as measured by Mr. Champion, and the spread on the longer axis is about 60 yards. The main stem was about 80 ft. in length and 12 ft. 10 in. in girth in 1909. It is a male tree, and flowers in April, holding its leaves till late in November. Cuttings have failed to root, but two trees were propagated by grafting on stocks of *P. serotina*, and these are growing at Conyboro, Lewes, the seat of Lord Monkbretton. An illustration of this tree was published in *The Garden*, xxv. 189 (1898), but the ground plan which I am able to give of it, from accurate measurements made by Mr. J. P. Williams, is the only way by which the extraordinary ramifications and rooting of its branches can be understood.

Another large male tree is at Syon Park, which in 1905 was 92 ft.¹ by 9 ft.; but this may not be the same as the one figured by Loudon, *Arb.* vii. 277, as 83 ft. high in 1838. I showed this tree to Prof. Sargent, who admitted it to be distinct from *P. monilifera*, but said that he had never seen any trees like it in America.

There are two male trees on the bank of the Thames in the playing fields at Eton, of considerable size, which keep their leaves till the end of November. Another at Beauport, in the lower part of the park, was 80 ft. by 6 ft. 4 in. in 1909, and, as Sir A. Lamb tells me, retains its leaves till the middle of December unless there has been a severe frost, which seems a good proof of its southern origin.

In Scotland I have seen none; but in Queen's County, Ireland, at Abbeyleix, the seat of Viscount de Vesci, there is a spreading tree of no great age, which in 1910 measured 63 ft. by 4 ft. It is a female tree and was obtained from Smith of Newry.

In France there are many old trees, especially around Paris. A large one at Baleine, near Moulins-sur-Allier, was blown down shortly before my visit in May 1909; and the log, which measured 14 metres long by 3.75 metres in girth, was sold for 140 francs. In the Parc Borilly at Marseilles there were a number of fine trees, all males, in full flower on 17th March 1910, whilst the trees which M. Coste, the head gardener, called *peuplier de Virginie* (*P. serotina*), growing close by, were not yet in bloom. (H. J. E.)

In the south of France in many places this species replaces the hybrid poplars, which are commonly planted farther north, as an avenue and roadside tree. There is a remarkable avenue, over a mile long, in the forest of Thétieu, near Dax, the trees averaging 90 to 110 ft. in height, and 7 to 9 ft. in girth, with stems clear of

¹ In Jackson's *Catalogue of Trees at Syon* the height is given as 111 ft.

branches to 30 or 40 ft. Near Puyoo I noticed, in 1912, some very large trees bearing mistletoe. In the park at Toulouse, this tree is largely planted in walks and

GROUND PLAN OF CAROLINA POPLAR AT DANNY PARK

avenues, and averages over 100 ft. in height, and 7 to 8 ft. in girth, much surpassing in size *P. nigra* which has been planted beside it. No tree in this region appears to have such a great demand for light; and in consequence it readily loses its lower

branches, and quickly produces clean stems with useful timber. Prof. Voglino,¹ who has made a careful study of the poplars in cultivation in the park of Santena, near Turin, states that this species grows more slowly, but attains a greater height than *P. serotina*. The wood, though slightly darker in colour, is much stronger, and is always very free from knots. Young trees, however, have brittle branches, which suffer severely even from slight falls of snow. (A. H.)

HISTORY OF THE AMERICAN BLACK POPLARS AND THEIR HYBRIDS IN EUROPE

P. angulata was early introduced into France, as it is mentioned as a well-known tree by Duhamel du Monceau,² who described it in 1755 as the "peuplier noir de Virginie à très grandes feuilles, et dont les jeunes pousses sont relevées d'arêtes qui les font paraître quarrées." This species was in cultivation³ in England in 1738.

The second American species of black poplar, *P. monilifera*, Aiton, appears also to have been early introduced into France, where, according to Michaux, it was probably imported from Canada. He accurately describes it under the name *P. canadensis*, and states that in cultivation it did not succeed in compact and clay soil and frequently branched into two near the base of the trunk. It was mentioned⁴ by Fougereux de Bondaroy in 1786 as the *Peuplier de Canada*, though he also called it *P. virginiana*, and states that he had only seen the pistillate tree. It is said⁵ to have been introduced into England in 1769.

Poplars hybridise very freely, especially in France, where seedlings are much more frequently found⁶ than in England; and probably the first hybrid to be selected was the tree now known as *P. serotina*, which, according to tradition, has been known in France as the *peuplier suisse* since the middle of the eighteenth century.⁷ Its botanical characters show that it is a cross between one of the two American black poplars, presumably *P. monilifera*, and the glabrous form of the European *P. nigra*. It is quite unknown in America.⁸ Michaux, who erroneously named it *P. monilifera* in 1813, is clear on the subject, as he states that "neither my father, myself, nor any of the educated English who traversed the Atlantic states, and a great part of the states of the West, ever found this species of poplar." He adds that it was commonly called *peuplier suisse* because it was more cultivated in Switzerland than elsewhere; and that only the male tree existed in France, which was always propagated by cuttings.

¹ *I Nemici del Pioppo Canadense di Santena*, 8 (1910). This valuable work, pp. 130, figs. 1-16, appeared in *Ann. R. Acad. Agric. Torino*, liii. (1910), and gives an account of the fungoid and insect enemies of the cultivated black poplars.

² *Traité des Arbres*, ii. 178, pl. 38, fig. 8 (1755). The figure represents exactly *P. angulata*.

³ A branch, gathered by Miller in the Chelsea garden in 1738, is preserved in the British Museum.

⁴ In *Mém. d'Agric. Paris*, 1786, p. 87.

⁵ Loudon, *Trees and Shrubs*, 825 (1842), under *P. canadensis*.

⁶ Loudon, *Trees and Shrubs*, 827 (1842), stated that many thousands of seedlings came up annually in the walks of Fontainebleau, most of which were destroyed, but some varieties had been selected from them.

⁷ It seems to have been the poplar described and figured by Duhamel, *Traité des Arbres*, ii. 178, pl. 39, fig. 5 (1755), as "*P. nigra, foliis acuminatis, dentatis, ad marginem undulatis, ou mal à propos osier blanc.*" It was supposed by Duhamel to be a variety of *P. nigra*, and was planted in vineyards, instead of willow, where it was treated as coppice, the shoots being cut annually. Fougereux, in *Mém. d'Agric. Paris*, 1786, i. 80, states that it grew with great vigour even in dry soils, and was called *osier blanc* in the districts south of Paris, and *alain* in other places.

⁸ Prof. Sargent assured us that he had seen no tree in America which resembled *P. serotina*.

He quotes from Foucault that its branches are less spreading than the Canadian poplar, and that on account of its more rapid growth and greater aptitude to thrive on dry soils, it had been very largely planted in all parts of France.

Poiret's account¹ of the black poplars existing in France in 1804 is instructive.

He enumerated five kinds:—

1. *P. nigra*, European species.
2. *P. angulata*, American species.
3. *P. monilifera*, American species, accurately described.
4. *Peuplier suisse*, which he regarded as of European origin, and therefore gave

it the botanical name of *P. nigra helvetica*; but he added that it resembled in many ways the next kind.

5. *P. canadensis*, apparently a hybrid from the description.

Mirbel,² also in 1804, distinguished five black poplars in cultivation:—

1. *P. nigra*.
2. *P. angulata*.
3. "*P. monilifera*, Aiton, with ciliate leaves," the true American species.
4. *Peuplier suisse*, also known as "*P. virginiana*, Hort. Paris."
5. "*P. monilifera*, Hort. Paris, with non-ciliate leaves," quite distinct from *P.*

monilifera, Aiton, and commonly known as *peuplier de Canada*.

I am unable to identify with certainty the second hybrid, *P. canadensis*, Poiret, or *P. monilifera*, Hort. Paris; but it was evidently distinct from the *peuplier suisse*, and was not the true American species; and possibly may have been identical with *P. regenerata*, which originated independently in 1814, near Paris.

Poiret,³ in 1816, added another poplar to his list of 1804, *P. marilandica*, Bosc, which on account of its rhombic leaves, with long points, similar to those of *P. nigra*, appears to be a second cross, probably the glabrous form of *P. nigra*, pollinated by *P. serotina*.

P. angulata, on account of its remarkable large leaves and conspicuously winged branchlets, was never confused with the other species and hybrids, and has continued to be cultivated both in England and on the Continent. The other American species, which was difficult to grow except in favourable moist soils, gradually ceased to be cultivated, and is now a rare tree in Europe. As the existence of hybrids was not suspected, both botanists and cultivators assumed the hybrids to be true species from America; and in course of time there were practically only four black poplars generally recognised in France:—

1. *P. nigra*.
2. *P. angulata*, known generally as *peuplier de Caroline*.
3. *P. serotina*, known either as *peuplier suisse* or *peuplier de Virginie*; always a staminate tree.
4. *P. marilandica* and *P. regenerata*, known commonly as *peuplier de Canada*, both pistillate trees.

The origin of the other hybrids is mentioned in their descriptions, which follow;

¹ In Lamarck, *Encycl. Meth.* v. 235-239 (1804).

² In *Nouveau Duhamel*, ii. 186 (1804).

³ In Lamarck, *Encycl. Meth. Suppl.* iv. 378 (1816).

and none appears to have arisen in England, except possibly *P. Lloydii*, one of the parents of which is the English or pubescent form of the black poplar.

P. serotina was first accurately and completely described by Hartig; and this name is preferable to *P. nigra helvetica* or *P. helvetica*. It has always been known in England as the black Italian poplar, and appears to have been imported from France, sometime before 1787, when Messrs. Dickson of Hassen-deanburn, Scotland, sold some stock to Pontey.¹ Mr. A. Dickson, much later, in 1813, informed Pontey¹ that this poplar was obtained by his firm from a gentleman in Scotland, who received it from his son in America; but this account is unreliable, as there is no evidence that this poplar originated in America, and it fails to explain the name "black Italian poplar," by which it was always sold. As *P. serotina* and the Lombardy poplar came into England about the same period, both poplars, arriving from the Continent, were supposed to be from Italy, and hence the name.

(A. H.)

POPULUS SEROTINA, BLACK ITALIAN POPLAR

Populus serotina, Hartig, *Naturges. Forst. Culturpf. Deutschl.* 437 (1851); Schneider, *Laubholzkunde*, i. 11 (1904); Dode, in *Mém. Soc. Hist. Nat. Autun*, xviii. 44 (1905); Ascherson and Graebner, *Syn. Mitteleurop. Fl.* iv. 44 (1908).

Populus helvetica, Poederlé, *Man. de l'Arbor*, ii. 148 (1792).

Populus monilifera, Michaux f., *Hist. Arb. Amer. Sept.* iii. 295, pl. 10, fig. 2 (1813) (not Aiton, *Hort. Kew.*); Loudon,² *Arb. et Frut. Brit.* iii. 1657 (1838) (excluding the pistillate tree).

Populus nigra helvetica, Poiret, in Lamarck, *Encycl. Méth.* v. 234 (1804).

Populus virginiana, Mirbel, in *Nouveau Duhamel*, ii. 186 (1804) (not Fougeroux).

Populus canadensis, Mathieu, *Flore Forestière*, 495 (excluding the pistillate tree) (1897) (not Michaux).

A large tree of hybrid origin (cf. p. 1814), attaining 130 ft. or more in height and 18 to 20 ft. in girth, with a single undivided straight stem, free from burrs, and slender wide-spreading ascending branches; bark regularly furrowed. Young branchlets at first green, turning brownish yellow in summer, glabrous, with white lenticels, slightly angled, becoming greyish and terete in the second year. Buds brownish, viscid. Leaves (Plate 409, Fig. 16), opening latest of all the poplars, with a reddish bronze tinge, glabrous, averaging on adult trees 3 in. in breadth and length, ovate-deltoid, with a broad truncate base and a short cuspidate or acuminate apex; margin crenate-serrate, with the serrations few and wide apart at the base of the blade; cilia short, at first continuous on the two sides of the blade and sparse on the base, deciduous in summer; glands near the insertion of the petiole, variable, one, two, or none being present; petiole reddish. On young plants and vigorous shoots, the branchlets have projecting ribs like those of *P. angulata*, and the leaves are much larger, up to 5 or 6 in. in length or more.

Staminate catkins about 3 in. long; axis glabrous; flowers on very short glabrous pedicels; scales early deciduous, obovate, with short irregular lobes

¹ *Profitable Planting*, 218 (1814).

² Loudon, in *Gard. Mag.* xiii. 536 (1837), says that this "is a very doubtful native of America, and much more likely, in our opinion, to be an improved European tree."

terminating in long filaments; stamens about twenty to twenty-five, with long slender white filaments and deep red anthers; disc oblique, shallow, concave, glabrous, crenate or slightly lobed in margin.

1. Var. *erecta*, Henry.

Populus monilifera erecta, Selys-Longchamps, in *Bull. Soc. Bot. Belg.* iii. 11, 13 (1864).

A fastigate form¹ of *P. serotina*, with which it agrees in sex, branchlets, buds, and leaves, the latter being late in unfolding.² (A. H.)

More remarkable for its habit than its size is this poplar, which was described by the late Baron de Selys-Longchamps, a distinguished Belgian naturalist. I visited the Château de Longchamps near Waremmé, about twenty miles west of Liège in 1908, on purpose to see these trees, and am indebted to the baron for a photograph (Plate 385), which shows their peculiar habit very well. The original tree was planted in a meadow close to the village of Willines in 1818, and was procured by chance from a neighbouring nursery. It is somewhat past its prime, and measures about 120 ft. by 8 ft. 8 in., having a somewhat less fastigate habit than Lombardy poplars growing in the same field. It is a male tree with reddish petioles. The trees shown in the photograph were grown from cuttings of it, which were planted in 1862. The tree which has been pruned measures 120 ft. by 7 ft. 4 in.; the unpruned one 120 ft. by 8 ft. 2 in. The Lombardy poplar planted next to it at the same time is only 100 ft. by 6 ft. 4 in. The earlier leafing of the Lombardy poplars is well brought out in the photograph. On the other side of the same meadow there is a line of poplars, which though they seemed identical in foliage with *P. serotina*, had whitish bark; and I was informed by M. Edmond de Selys, who has now succeeded his father, that these were liable to be injured by a canker in the branches, from which the dark-barked form planted in the same field was free.

I may add that as an ornamental tree, the fastigate form seems to be at least as good as the Lombardy poplar, whilst its timber is more valuable, its growth more rapid, and its hardiness superior. Cuttings from the fastigate variety were kindly sent me by the baron, and are growing vigorously at Colesborne. Henry saw in 1912 a specimen about 25 ft. high in the Calmpthout Nursery near Antwerp.

(H. J. E.)

2. Var. *aurea*,³ Henry.

Populus canadensis aurea van Geerti, André, in *Illust. Hort.* xxiii. 26, t. 232 (1876); Dippel, *Laubholzkunde*, ii. 200 (1892).

A sport, with yellow foliage, probably referable to *P. serotina*. This form was produced spontaneously on a single branch of a large tree in 1871; and was propagated by Ch. Van Geert in his nursery, which is now the Société Horticole de Calmpthout. We have seen no flowers or large trees of this variety; and the yellow colour of the foliage at Kew does not last throughout the season. (A. H.)

¹ This tree has been erroneously identified by Koch and other German dendrologists with the *peuplier régénéré* of Carrière, which is a pistillate tree, of quite independent origin. See p. 1824.

² Specimens obtained by Elwes from the trees planted in 1862. Baron Selys-Longchamps, in *Belg. Horticole*, 1864, p. 257, states that there were two original trees of the fastigate variety, which were planted in 1818 with 60 ordinary *peupliers suisses*. They resembled the latter in all respects, except in habit; but proved to be less vigorous, as they had not attained, 46 years after planting, as great a girth.

³ Simon-Louis, *Catalogue*, 1869, p. 73, mentions a variety with variegated leaves, which we have not seen.

CULTIVATION

Though no English writer has as yet fully realised the economic importance of the black Italian poplar, and though consumers have hardly recognised the value of its timber for many purposes; yet in France and Belgium it is more generally planted than any other tree, and, as I shall be able to show, will produce a quicker and larger return than any other, if properly grown and converted into timber. None of the poplars are particular as to soil, provided it is moist in summer; and though, like all other trees, they grow faster and larger on good than on bad soils, yet they succeed in cold wet and undrained valleys and meadows, and are resistant to frost at all seasons, and are little liable to fungoid and insect attacks. From an ornamental point of view the black Italian poplar is inferior to the grey and the white species, but its large red clusters of flowers appearing in spring on the bare branches are very beautiful, and its extremely rapid growth makes it suitable for situations where no other tree will attain a large size in a lifetime.

Before planting poplars it is important to have a variety which has proved hardy and vigorous on a similar soil and situation; and though nothing seems likely to surpass *P. robusta* and *P. Eugenei* where the climate suits them, I shall not give up the propagation of the red-petioled *P. serotina* until the others have proved their ability to endure the worst vicissitudes of our climate. The green-petioled variety, though it seems equally vigorous and hardy in any soil, is not so erect, and seems to have more spreading branches.

Owing to the general confusion between this tree and the true black poplar which has prevailed among English botanists and foresters, few of whom seem to have distinguished the two trees, I must point out that many of the statements¹ which have been made about the latter species really apply to the former.

Grigor states² that on a sandy soil (probably in Morayshire) the black Italian poplar in a mixed plantation, twenty-four years planted, measured 60 ft. by 3½ ft., when larch was 48 ft. by 3 ft. 4 in., beech 40 ft. by 2½ ft., sycamore 34 ft. by 2 ft. 1 in., and Scotch elm 33 ft. by 3 ft.

Thirty trees planted by my father in a cold clay soil not worth 5s. per acre, in a situation remarkably subject to late and early frosts, in forty-eight years averaged 120 cubic feet and realised £3 each; and two trees planted by myself in a clay soil close to the stream at Colesborne attained in fifteen years 56 ft. by 5 ft. 3 in. and 50 ft. by 3 ft. 2 in. respectively. Fifteen trees felled recently in a more shaded position and closer together in the same valley were at eighty-five to ninety years old of considerably smaller girth, and had increased but little during the last thirty years, some of them being more or less decayed and hollow at the base. This lot, though much older, only averaged 70 cubic feet, and proved to me that a sunny situation and plenty of room are essential. In another part of the same valley where the land is

¹ In *Trans. Surveyors' Institution*, 1904, p. 226, my advocacy of *P. serotina* as a valuable timber tree was erroneously printed under the heading Black Poplar, instead of Black Italian Poplar; and my remarks have been quoted by Nisbet and Sir Herbert Maxwell (in Green, *Encyclopædia of Agric.* iii. 308) as referring to *P. nigra*.

² *Arboriculture*, 326 (1868).

densely covered with meadowsweet and rushes, and where water often stands on the surface in winter, poplars of the ordinary red-petioled kind ten years after planting are about 35 feet high, whilst one with green petioles, distinguished by its greyer bark and more spreading habit, is 44 ft. by 2 ft. 1 in.

Forbes¹ agrees with me that about fifty years is the most profitable age at which to cut this tree; but he recommends that it should be planted at 6 ft. apart unmixed with other trees, in which I disagree with him—first, because at least three-quarters of the trees planted would be worthless as thinnings, and, secondly, because if it is desired to make a plantation close enough to suppress side branches the common alder seems to me the most suitable tree. I should not plant poplars nearer than 15 or 20 feet apart, and would fill up the intervals with alder, which could be cut out for clog soles at about thirty years, when it had attained 6 to 8 in. diameter, leaving the poplars to stand at the rate of about 50 to the acre. Assuming that the alder would pay the rent of the land, which it ought to do, 50 poplars, averaging 80 ft. at £2 a-piece, would give a very handsome return for the interest of the outlay on planting and pruning them.

In France, where the cultivation of poplars is well understood, the general practice is to plant them in lines at about 20 ft. apart along the sides of ditches, and leave the intervening spaces in pasture; and in this way the trees attain a profitable size much quicker than if planted as closely as advised by Forbes.

As the tree can be very quickly and easily struck from cuttings, the only question to consider is whether they shall be planted without roots where they are intended to grow, as is done with willows, or kept in a nursery till larger. I have tried both methods, and think that the latter is best, as the tree gets a start sooner, and is not so liable to be choked by the rank vegetation which is always found in places suitable to it. The best way to procure strong cuttings is to take one- or two-year shoots from stools; side branches may be used, but they are not so erect in habit, and require more pruning. These cuttings are best from 4 to 6 ft. long, put in during early spring, and in good soil will make strong plants in one season. If left longer than a year they do not transplant so well. After the tree has begun to grow freely, it will make 3 to 5 ft. of annual growth; and it is important to prune the side branches before they become too thick. This pruning should be carried on with a pruning chisel up to 30 or 40 ft. high, in order to avoid knots and make clean timber, and is best done in summer.

In cold and shady situations the branches are apt to die off, and a canker produced by *Didymosphaeria populina* sometimes affects the trees.²

In a brochure which is published by M. Marion,³ he recommends planting either large cuttings, put into the ground at a depth of 1 to 2 ft., or rooted plants in pits; and in both cases advises that the grass shall not be allowed to grow over the roots till the trees are well established. He recommends a width of 6 to 10 yards for avenues, or 4 yards apart in lines, and that the trees shall never be mixed with or crowded by other trees, as they must have plenty of room to grow well—150 to

¹ *English Estate Forestry*, 82 (1904).

² Cf. Hartig, *Diseases of Trees*, Eng. Trans., 104 (1894).

³ *Petit Manuel du Propriétaire Sylviculteur* (Librairie Horticole, Paris (1909)).

200 to the hectare ($2\frac{1}{2}$ acres) being thick enough on the ground. He finds that though they grow best on damp soil, yet it should be drained first if the water stagnates; and that successive crops may be taken, at periods of thirty years, without diminishing the growth, provided the old stumps are grubbed. Pruning is considered essential, and this must be frequently attended to, up to a height of 20 to 30 ft. Though poplars are often pruned nearly up to the top in France, it is evidently very prejudicial to their good growth. The mistletoe, which infests these trees to such an extent in most parts of France, is not allowed to remain on the branches at Pontvallain, but when it appears on the trunk it cannot be eradicated, and usually ends by killing the tree.

REMARKABLE TREES

One of the largest poplars in England was cut down in March 1907, near Cassio Bridge, Herts, and was sold to Messrs. East and Son, of Berkhamsted. It was described and figured in the *Timber Trades Journal* of 13th April 1907, and when measured by Sir Hugh Beevor in 1902 was 130 ft. high and 16 ft. 11 in. in girth, and the contents of the butt alone were 56 ft. by $42\frac{1}{2}$ in. quarter girth, making 701 cubic feet. With the top and branches it was said to contain upwards of 1000 ft. of timber. Messrs. East inform me that at 15 ft. from the butt they counted only 97 rings, which would make the age of this tree little over 100 years. Probably no other tree on record in England has attained so great a size in so short a time. Sir Hugh Beevor tells me that another tree near the same place, though not quite so tall, measures 18 ft. in girth at 6 ft. from the ground.¹

A very large tree was blown down early in January 1908 in the meadow of Christ Church, Oxford. It was mentioned in the *Oxford Times* of 18th January 1908 as a Lombardy poplar, but leaves sent me by the late Prof. Fisher show that it was *P. serotina*. The approximate measurements of the trunk were given as follows: length 55 ft., girth 16 ft. at twelve feet from base, timber contents 1056 cubic feet, weight about 20 tons. The removal of this tree by a traction engine, aided by several horses, took several days.

Mr. A. B. Jackson measured in 1912 a tree growing in a dell by the stream near the old church at Albury, Sussex, which he could not make less than 150 ft. high, though on account of its situation it is difficult to measure accurately; its girth was 15 ft. 3 in.

At Shalford House, near Guildford, the property of Col. H. H. Godwin-Austen, F.R.S., there stands in a damp meadow an immense tree of this species, which in 1911 measured about 110 ft. high by 23 ft. in girth. Its upper branches were much damaged by a violent storm some years ago; and I am informed by its owner, who has a good photograph of it, that it was formerly at least twenty-five feet higher. It forks first at about ten feet up, and gives off very large branches at about twenty feet, which spread to a width of thirty-seven paces. This tree is known to have been

¹ Cf. D. Hill, in *Trans. Herts. Nat. Hist. Soc.* xiv. 133 (1911).

planted by Charles X. of France, who lived at Shalford House during his exile from France, sometime between 1789 and 1814.

Among notable trees of this species which I have measured are two at Belton, near Grantham—one in a meadow by the bridge, which, though difficult to measure, I believe to be at least 130 ft. high by 16 ft. in girth. Another by a pond in the private grounds is 125 ft. by 15 ft. (Plate 386). Most of the large trees of *P. serotina* at Belton were planted about 1818, and began to fall to pieces in 1907, from natural decay. After the death or cutting of the tree (but never before) suckers are produced.

Another even larger grows on the banks of a pond near the approach to Woburn Abbey; and though it has been injured by the wind, measured, in 1905, 125 ft. by 19 ft. 3 in.¹ On the banks of the Thames there may be larger trees than any I have seen; but at Fawley Court, near Henley, I saw one about 105 ft. high by 16 ft., with a clean bole 50 ft. long; and at Mapledurham, near the mill, there is a group of very tall slender trees, one of which measured, in 1907, 135 ft. by 6 ft. 7 in.

At Bicton, just outside the gardens, there is a very fine tree of this species, which I believe to be about 130 ft. high, though I could not measure it exactly, by $17\frac{1}{2}$ ft. in girth. Sir Hugh Beevor measured a tree at Petworth in 1904 which was 114 ft. by 18 ft. 10 in., with a bole 20 ft. long. At Mote Park, Maidstone, there is a group of fine trees, one of which in 1902 was 120 ft. by $11\frac{1}{2}$ ft. At Godinton, near Ashford, in Kent, I counted 100 rings on the stump of a tree 15 ft. in girth. At Hawstead, near Bury St. Edmunds, I measured in 1905 one of a row of young trees in a rich meadow, which, though only 6 ft. in girth, was 116 ft. high.

At Plas Machynlleth, Montgomeryshire, I saw in 1912 a black Italian poplar, about 100 ft. high, and $19\frac{1}{2}$ ft. in girth at 3 ft. up under a large limb, and $17\frac{1}{2}$ ft. in girth at 6 ft. from the ground, above the limb; a label attached to the tree stated that it was planted in 1794 by Sir John Edwards.

In Scotland the black Italian poplar is not so common as in England, but seems to grow equally well. At Scone Palace, Henry measured in 1904 one no less than 132 ft. high by 15 ft. 4 in. in girth, which eleven years previously was 14 ft. 9 in. It carried its full girth nearly to the first branch, over forty feet from the ground. Another, also measured by Henry, at Monzie, Perthshire, was 125 ft. by 9 ft. 2 in., with an absolutely straight trunk drawn up by beech trees, and clean to 71 ft. There are two good trees near Achnacarry, the seat of Cameron of Lochiel, one of which in 1910 measured 105 ft. by $10\frac{1}{2}$ ft. Renwick in 1909 measured two trees at Cambusnethan House, Lanarkshire, 112 ft. by 11 ft. 1 in. and 119 ft. by 11 ft. 5 in. respectively.

In Ireland it has not been planted so generally as in England. The best I have seen are at Adare, Co. Limerick, near the river, a tree 95 ft. by 15 ft., in 1909; at Abbeyleix, Queen's County, several fine old trees, one of which was 120 ft. by 13 ft. 4 in. in 1910.

On the Continent there are many large trees, of which the most interesting are those at Brunswick which formed the types described by Hartig. I visited Brunswick on purpose to see them in June 1910, and am much indebted to the late Dr. Blasius and to Mr. A. Hollmer for their guidance. The largest tree stands in the

¹ In 1911 this tree had increased in girth to 20 ft. 6 in.

Theatre Park, close to a pond, and is about 110 ft. by 18 ft. 9 in., with a bole about 30 ft. long. The habit was more spreading than usual in England, and the young leaves seemed less bronzy in tint. The second is a double-stemmed tree from a common base, in front of the Grand-ducal residence; it is about 110 ft. high, the two stems measuring 14 and 15 ft. respectively. The third, said to be the actual type described by Hartig, stands in the Railway Park, and has the trunk much covered with ivy. It was severely lopped about ten years ago, and now measures about 105 ft. by 16 ft. 4 in., but has been taller. All these trees are males and appear to be of the same age, probably about a hundred years.

In Denmark the black Italian poplar is rather commonly planted by the road as a shade tree; and I measured a fine old tree at Gisselfeld, the seat of Count Daneskjold-Samsö, 120 ft. by 14 ft. 9 in., in 1910. How far east and south this poplar has extended we are unable to say, as Hartig's description has been apparently overlooked by foresters, and many of the trees in Germany¹ named *P. canadensis* are *P. serotina*.

TIMBER

The timber of the various species of poplar is, or has been in the past, so little valued by merchants that "Acorn," in his work on English timber, speaks of it as hardly worth hauling for any great distance from the place where it grows. For many years it was supposed to be the best material for making railway brake-blocks, which are now commonly made of iron, and was also used for beds of wagons and wheel-barrow, for second-class spade handles, and to some extent for other purposes,² but its use for packing-case making has been entirely ignored in England.

In France, however, this poplar is one of the most common and abundant timbers, and is almost the only material used in making wine-cases and packing-boxes of all descriptions; and there is no reason why it should not be so used in England, except the very low price of foreign deal. From fivepence to eightpence per foot is the price which I have been able to realise for standing trees of black Italian poplar containing 100 ft. and upwards, growing seven to nine miles from a station; but I have no doubt that, for well-grown trees whose lower branches have been pruned when young, and which can be converted with little waste, eightpence to a shilling per foot could be obtained when near the place of conversion.

"Acorn" states that in buying poplar standing, the merchant is almost sure to gain a considerable advantage if the trees are measured or estimated in one length, as they carry their girth higher and taper less than most trees. I have had good evidence of this myself; as a tree, which was estimated standing to contain 110 to 125 ft., and sold on the higher estimate, actually contained 130 ft. as measured in one length after felling, and 165 ft. when measured in three lengths, as it would have been cross-cut for sawing.

¹ In *Mitt. Deut. Dend. Ges.* 1904, p. 19, a tree at Schloss Dyck, near Düsseldorf, named *P. monilifera*, which is probably *P. serotina*, is said to be 57 metres high by 5.25 metres in girth; but the height measurement is probably much exaggerated.

² A large quantity of black Italian poplar is used as blocks for polishing plate glass in the course of its manufacture at St. Helens and other places. Cf. also *Quart. Journ. Forestry*, vi. 264 (1912).

The conversion of poplar timber into boards for various purposes requires considerable experience, which English sawmills do not seem to possess. A number of specimens were shown in the Franco-British Exhibition of 1908 which displayed great ingenuity in conversion; and I am assured by reliable authorities that, when properly cut and seasoned, poplar boards are considered a perfectly suitable wood on which to lay veneers, and are used in France for all but the highest qualities of furniture. The increasing price of mahogany and of white wood (*Liriodendron*), on which veneers in England are laid, seems to point to an increased demand for poplar. Mr. A. Howard gave me some handsomely figured veneers showing a good deal of satiny lustre, cut from a flitch of poplar wood which he bought in France. These I have used for the front of a large bookcase, made from the burry wood of an old black poplar (*P. nigra*) grown in Herefordshire. From an ornamental, as well as from a structural point of view, the result is satisfactory.

M. Breton-Bonnard,¹ President of the French Timber Merchants' Society, classifies the timber of the various poplars as follows:—

White Poplar, Grey Poplar.—Considered the best poplar wood; wood white, light, tender and soft, capable of taking a good polish. Used by furniture makers, largely by railway companies for wagon-building, by coach-builders for the panels and bodies of carriages and carts, and in mines and for boat-building. It must be thoroughly dry, as it warps when green.

Aspen.—Used when sound for the same purposes, also for matches, toys, turning, carving, broom handles, and for packing-cases and paper pulp.

Black Poplar (P. nigra).—This wood, which is very stiff, warps much if cut soon after it is felled, and ought to lie a year in the log before converting. It is valued by trunk makers, and for wagon beds, and other objects subject to rough usage.

All the Hybrids.—All kinds of cheap furniture and painted work, packing-cases, for laying veneers, etc.

He states¹ that poplar sawdust is the best litter for stables and pig-sties, and the cheapest litter used by the Paris Omnibus Company, and gives figures to prove that the manure produced from it was equal or superior in effect, on beetroot and wheat, to that produced by peat-moss litter or straw. He gives¹ the following table, representing the returns of *peupliers régénérés* on the assumption that the increase in diameter is 10 millimetres, or $\frac{2}{5}$ inch per annum:—

Age.	Diameter at 1.33 m. from the Ground.	Girth at the same height.	Length of Timber.	Cubic Contents, $\frac{1}{4}$ Girth Measure.	Value at 17 francs per cubic metre = about 5d. per foot.
5 years.	0.08 m.	0.25 m.	5 m. = 16 ft.	Cubic Metres. ...	Francs. ...
10 "	0.18 m.	0.56 m.	8 m. = 25 ft.	0.09	1.53
15 "	0.28 m.	0.86 m.	10 m. = 33 ft.	0.30	5.10
20 "	0.38 m.	1.20 m.	12 m. = 39 ft.	0.70	12.00
25 "	0.48 m.	1.50 m.	14 m. = 45 ft.	1.26	21.42
30 "	0.58 m.	1.82 m.	16 m. = 54 ft.	2.10	35.70
35 "	0.68 m.	2.05 m.	18 m. = 60 ft.	3.30	56.10
40 "	0.78 m.	2.48 m.	20 m. = 66 ft.	4.80	81.60

¹ *Le Peuplier*, 176, 179, 182 (1902).

These returns, which are possible when the trees have been well cultivated, justify the common saying in France that poplar ought to produce one franc per tree annually. The price given in the table is often exceeded where the trees are of good size and in a favourable situation. Twenty-five to thirty francs per cubic metre is a common price, as I was informed by M. Marion at Pontvallain. M. Breton-Bonnard says that in 1900 the poplars of the valley of the Ourcq, near Paris, were sold at fifty francs per cubic metre and upwards; and he knew a case where a landowner took a meadow on a thirty years' lease, planted it with poplars, and, after paying the rent with the hay¹ and grazing, was able, by cutting down the trees before the end of his lease, to buy the land with the profit.

I certainly know of land in England, which could be bought at £10 per acre or less, that would produce in forty to fifty years poplars containing an average of 100 cubic ft., and if there were only thirty trees to the acre, and the price sixpence per foot, this would amount to 3000 cubic ft., worth £75 per acre.

According to Mathey,² the timbers of the different poplars may be distinguished as follows:—

A. Species in which the heart- and sap-wood are confused.

Black and Lombardy Poplars.—Heart-wood with black veins in old trees.

Black, Italian, and other Hybrid Poplars.—Heart-wood uniformly white or slightly reddish.

B. Species in which the heart- and sap-wood are distinct.

White Poplar.—Sap-wood white; heart-wood distinctly reddish.

Grey Poplar.—Sap-wood reddish; heart-wood reddish-brown.

C. *Aspen.*—Heart- and sap-wood confused in trees growing in the forests of the plain; heart-wood distinct and vinous red in trees growing on the hills and mountains.

(H. J. E.)

POPULUS REGENERATA

Populus regenerata, Schneider, *Laubholzkunde*, i. 7 (1904).

Peuplier régénéré, Carrière, in *Rev. Hort.* 1865, pp. 58 and 276; Lambin, in *Rev. Hort.* 1873, p. 47.

Populus canadensis, var. *grandifolia*, Dieck, *Nacht. Haupt. Verz. Zöschén*, 1887, p. 16.

A tree of hybrid origin (cf. p. 1815), resembling *P. serotina* in branchlets and foliage, but bearing pistillate flowers, and unfolding its leaves about a fortnight earlier. Pistillate catkins similar to those of *P. marilandica*, but with usually only two stigmas.

This hybrid, according to Carrière, originated in 1814 in the nursery of M. Michie at Arcueil near Paris, and was apparently a seedling of unknown origin,

¹ Balzac, *Vie de Province*, i. 255 (1855) gives calculations by Eugénie Grandet, showing that the loss of hay, due to the shade of the poplars which he had planted in lines on good grass land on the banks of the Loire, near Saumur, was not made up by the proceeds of the sale of their timber, if compound interest was allowed. Grandet drew the conclusion, not generally accepted in France, that poplars could only be grown at a profit on poor soil. A correspondent in the *Gard. Chron.* 1855, p. 102, states that near Diss in Norfolk, 336 black Italian poplars, which were planted at intervals between 1819 and 1822, were sold in 1854 for £124. They grew on an area of 4½ acres; and whilst the trees were standing, the pasture beneath them was let at five shillings an acre. This tree grows in low, marshy, boggy land, where almost every other species ceases to thrive.—A. H.

² *Traité d'Exploitation Commerciale des Bois*, i. 23 (1906).

though one of the parents was supposed to be *P. serotina* (*peuplier suisse*). Carrière believed it to be simply the pistillate form of the latter, distinguishable by its greater vigour and more conical stem, swollen at the base and not so cylindrical as *P. serotina*. M. Romanet of Montmirail obtained some plants, which he multiplied under the name of *Peuplier régénéré*; and M. Bujot, of Chiary near Château Thiery (Aisne), sold others as *Peuplier Bujot*, a name no longer in use. In 1865 this poplar had become very common in the valley of the Ourcq, and was then sold by M. Terré, at Lizy-sur-Ourcq (Seine et Marne).

The *Peuplier suisse rouge*, one of the two so-called "Eucalyptus" poplars, now propagated by M. Marion in his nurseries at Pontvallain, Sarthe, is identical in all its characters with *P. regenerata*, being a female tree with similar foliage and flowers. I examined flowers which were kindly sent to me in the spring of 1911; and I obtained good specimens of branches with leaves, when I visited Pontvallain in August 1912. This tree was chosen as the fastest-growing variety of poplar in 1880, by M. Sarcé, grandfather of the present proprietor. It had been obtained by a continuous selection for many years, as sets for planting, of the uppermost and straightest branches of the most vigorous trees. The variety is said to have been called *rouge* on account of the reddish colour of the petioles, which is supposed¹ to distinguish it from the other kind of "Eucalyptus" poplar in the same nursery. The latter, known as *Peuplier suisse blanc*, because it is reputed to have whitish petioles, is a less vigorous tree, which is propagated only to a slight extent, its sole merit being that it forms a straighter stem. This variety opens its leaves late in the season, fifteen days after the *Peuplier suisse rouge*, and is reputed to be a male tree.² It is apparently a form of *P. serotina*, with which it agrees in leaf, but I have had no opportunity of examining the flowers.

The cultivation of poplars at Pontvallain is extensive, covering about 500 acres. The land, which is flat and intersected by a stream, is laid out in grass meadows of small size, around which are single or double lines of poplars, pruned up to 30 ft., and at least 12 ft. apart. Experience here shows that this is the best method of obtaining a quick and large yield of timber. Poplars, especially the quick-growing kinds, being light-demanding trees, do not bear well any lateral shade. Attempts to grow them crowded in large plantations never succeed, as all the trees, except those on the outside, remain very slender, and yield timber too small in diameter to be of any value for planking. The soil here is a sandy loam, and is rich in humus, as it was formerly a coppice of oak and hornbeam. The growth of the red "Eucalyptus" poplar is astonishing on this soil, almost double that of the other kind in diameter, and somewhat more in height. The stems are invariably curved near the base, which is attributable to its rapid increase in height while in the young stage. At thirty-five years old they average at least 100 ft. in height, and 7 ft. in girth, producing over 100 cubic feet of timber, which is worth about 100 francs. Elwes, who visited Pontvallain in May 1908, measured two trees in an avenue planted twenty-two years; one was 114 ft. by 6 ft. 2 in.; the other was 118 ft. by 6 ft. 10 in.

¹ No difference in the colour of the petioles was discernible in August.

² Cf. Breton-Bonnard, *Le Peuplier*, 62 (1902).

Whether either of the "Eucalyptus" poplars will equal in vigour the black Italian poplar, if planted in this country, remains to be proved; but the trial is worth making, as they are evidently most profitable to grow in France.

Other reputed forms of *P. regenerata* or of *P. serotina*, which are classed under the term *Peupliers régénérés*, are mentioned by M. Breton-Bonnard; but none of these have as great a reputation as those which are propagated at Pontvallain.

Specimens sent by the late Dr. Blasius from trees growing in the garden of Cramer von Klausbruch at Brunswick, which he considered to be the pistillate form of *P. serotina*, are similar in foliage to *P. regenerata*.

This hybrid has lately come into cultivation in England, the only large tree which I have seen being one in the Queen's Cottage grounds, Kew, which displays no vigour of growth. A tree at Kew, obtained under the name *P. deltoidea erecta* from Dieck in 1889, and now about 35 ft. high, produced female flowers in 1911, which showed it to be identical with *P. regenerata*, of which it has the foliage and habit. A female tree at Glasnevin, cultivated under the name *P. régénéré*, and about 60 ft. in height and 4 ft. 11 in. in girth in 1912, resembles *P. Eugenei* in habit, and is very thriving. It was obtained from Simon-Louis in 1892.

Mention may be made here of a peculiar poplar¹ at Beauport, Sussex, 60 ft. by 3 ft. in 1909, which was blown down in August 1912, the day before I last visited this remarkable collection of trees of all kinds. It differed from *P. regenerata* in having smaller leaves, 2 to 2½ in. long and broad, similar to those of *P. monilifera*, var. *occidentalis*, in shape, size, and few coarse serrations; but like the hybrids in the sparse ciliation of the margin and the irregular number (0, 1, or 2) of glands at the base. It bore female catkins in April 1912; and the flowers with only two stigmas showed also its hybrid origin. A similar tree, judging from a specimen in the Kew Herbarium, grew at Carlsruhe in 1845.

(A. H.)

POPULUS EUGENEI

Populus Eugenei, Simon-Louis, ex Koch, *Dendrologie*, ii. pt. i. p. 493 (1872); Schneider, *Laubholzkunde*, i. 9 (1904); Dode, in *Mém. Soc. Hist. Nat. Autun*, xviii. 46 (1905); Ascherson and Graebner, *Syn. Mitteleurop. Fl.* iv. 45 (1908).

Peuplier Eugène, Carrière, in *Rev. Hort.* 1865, p. 58.

Populus pyramidalis meetensis, Mathieu, in *Gartenflora*, xxxvi. 674 (1887), translated in *Gard. Chron.* ii. 818 (1887).

A narrow pyramidal tree of hybrid origin, with a straight undivided stem and numerous short branches, mostly ascending at an angle of 30° to 45° with the stem. Young branchlets glabrous, slightly angled. Buds small, reddish-brown, viscid. Leaves (Plate 409, Fig. 17) unfolding early in the season, with a reddish tint, smaller than those of *P. serotina*, averaging 2½ in. in width, usually broadly cuneate, rarely

¹ This peculiar hybrid appears to be identical with *P. incrassata*, Dode, *op. cit.* 41 (1905), described as a pistillate tree, having flowers with two stigmas; leaves thick in texture, moderate in size, deeply cordate at the base, acuminate at the apex. The leaves of the Beauport tree, often cordate, occasionally truncate at the base, agree with those of a specimen kindly given me by Dr. Dode as the type of his *P. incrassata*.

truncate at the base, and terminating in a slender sharp-pointed non-serrated acuminate apex; margin with coarse crenate incurved serrations, few and wide apart on the base, and sparsely ciliate except near the insertion of the petiole, which with the midrib and veins is usually of a reddish tint; glands at the base variable in number.

Staminate catkins, 1½ to 2 in. long; axis slender, glabrous; scales obovate, concave, with irregular lobes ending in long filaments; disc shallow, cup-shaped, glabrous, entire in margin; stamens about fifteen to twenty, with white thread-like filaments and red anthers.

Messrs. Simon-Louis informed Carrière in 1865 that this tree, which bears staminate flowers, originated in their nursery at Plantières in 1832. It appeared in a seed-bed of silver firs, so that it was impossible to know from what poplar the seed had come. It is supposed to be a seedling of *P. marilandica* (*P. canadensis*, Hartig), which had been pollinated by a Lombardy poplar. The shape of the leaves, intermediate between those of the supposed parents, and the narrow pyramidal habit confirm to some degree this explanation of its origin.

(A. H.)

So far as I know, no attempt has ever been made by English nurserymen to improve poplars by selection, or to raise them from seed; but on the Continent, where they seed much more freely, some varieties have been selected by the firm of Simon-Louis frères at Metz. On this rich deep calcareous loam, poplars succeed to perfection; and the original tree of *P. Eugenei* is a marvellous instance of the size which a planted tree may attain in a man's lifetime. This was planted in 1834, and measured about 140 ft. high in August 1908. I was unable to see the topmost branch from the measuring point. At the ground it was 39 ft. round, at five feet 22½ ft. The main trunk divides at about 30 ft. into several immense limbs, one of which, broken off by the wind, was about 85 ft. long. A younger tree, planted in 1870 in rather better soil, measured, in 1908, 128 ft. by 14 ft., with a clean bole 56 ft. long, and contains 500 to 600 cubic feet, which at thirty-eight years old must I think, be a record for any species of planted tree. As M. Jouin told me that the rapidity of growth increases after the first twenty years, this tree is likely to surpass its parent.

I have planted this variety at Colesborne, where its growth, though not so rapid as in France, is very satisfactory, and have found it to resist late and early frosts without injury.

There are eight examples of this tree at Kew, which were procured from Metz in 1888. The two largest measured¹ in June 1912, 90 ft. by 5 ft. 1 in. and 84 ft. by 4 ft. 5 in.; whilst the others ranged from 50 to 60 feet in height and 2 ft. 4 in. to 3 ft. 5 in. in girth. All preserve the narrow pyramidal form, and are growing vigorously in sandy soil. The bark is slightly fissured into narrow longitudinal ridges. Another tree at Glasnevin in poor soil, planted in the same year, was about 55 ft. high and 4 ft. 5 in. in girth in April 1913.

(H. J. E.)

¹ Cf. *Kew Bull.* 1911, p. 310, where the height of the largest tree is given in excess.

POPULUS MARILANDICA

Populus marilandica,¹ Bosc, *ex* Poiret, in Lamarck, *Encycl. Suppl.* iv. 378 (1816).

Populus canadensis,² Hartig, *Naturges. Forstl. Culturpfl.* 436 (1851) (not Michaux); Koehne, *Deut. Dendr.* 81 (1893); Schneider, *Laubholzkunde*, i. 7 (1904) (in part); Ascherson and Graebner, *Syn. Mitteleurop. Fl.* iv. 33 (1908) (in part).

Populus euxylon, Dode, in *Mém. Soc. Hist. Nat. Autun*, xviii. 41, 69 (1905).

A tree of hybrid origin (cf. p. 1815) less vigorous in growth and not attaining so great a height as *P. serotina*, with branches wider apart and not regularly ascending. Young branchlets glabrous, rounded. Buds small, viscid. Leaves (Plate 409, Fig. 19) considerably earlier in unfolding than *P. serotina*, resembling in shape more those of *P. nigra* than those of the American parent; when well developed about 4 in. long and 3 in. broad, rhomboid, cuneate at the base, tapering above into a long acuminate apex; glabrous; serrations crenate, with incurved points, few and wide apart on the cuneate base; margin with scattered deciduous minute cilia; glands absent or one or two in number at the base; petiole greenish.

Pistillate catkins about 2½ in. long; axis slender, glabrous; pedicels stout, glabrous; scales obovate, with irregular lobes ending in long filaments; disc cup-shaped, glabrous, undulate in margin; stigmas sessile, yellowish, variable in number—two, three, or four—each appressed at the base to the summit of the glabrous globose ovary, and dividing above into two erect arms. Fruiting catkins, fertilised by other kinds of poplars, about 4 or 5 in. long; capsules usually three-valved on slender pedicels, ultimately immersed in the dense white silky wool of the seeds.

This tree, which is always female, is not uncommon on the Continent, where it is usually considered to be the pistillate form of the Canadian species. It is occasionally met with in nurseries; and should not be selected for planting either for ornament or profit, as its masses of cottony catkins in late spring are disagreeable, and its vigour of growth³ is considerably inferior to that of *P. serotina*.

The largest tree of this hybrid which we know in England is growing on the lawn near the Palm House at Kew, and measures 90 ft. by 8 ft. 9 in. Its history is unknown. On 5th July 1907 it was covered with downy seeds, a few of which proved fertile; and there is a young plant at Colesborne which was raised from them by Miss F. Woolward. (A. H.)

¹ The description by Bosc is imperfect, and there is no authentic specimen in the Paris Herbarium. A specimen in the Herbarium at Montpellier, from a tree cultivated in the garden there in 1833 under the name *P. marilandica*, and another in the Kew Herbarium labelled *P. marilandica*, from a tree cultivated at Carlsruhe in 1845, were probably correctly named, and may be accepted as the species meant by Bosc. The name *P. marilandica* may be objected to, as implying that the tree is a native of Maryland; but I prefer it to the later name of *P. euxylon*, Dode.

² Koehne's specimen of *P. canadensis* in the British Museum is identical with the Carlsruhe specimen. So far as I can judge, the hybrid female poplar, which I consider to be *P. marilandica*, is the *P. canadensis* of German dendrologists. Hartig's description is unmistakable, as he refers to its rhombic and scarcely ciliate leaves, with variable glands at the base, and to its peculiar stigmas. Schneider states that *P. canadensis* is nearly always a female tree in cultivation, and figures its rhombic leaves cuneate at the base.

³ Simon-Louis, *Catalogue*, 1869, p. 72, speaking of this tree as *P. canadensis*, states that it is much less vigorous than the *peuplier de Virginie*, meaning by the latter name *P. serotina*, Hartig.

POPULUS HENRYANA

Populus Henryana, Dode, in *Mém. Soc. Hist. Nat. Autun*, xviii. 39 (1905).

A large tree of hybrid origin, similar in bark to *P. serotina*, but differing in habit, forming a wide-branching round-headed crown of foliage. Young branchlets glabrous, becoming dull grey in the second year, with whitish raised lenticels. Buds viscid, with slightly pubescent scales. Leaves (Plate 409, Fig. 18) opening earlier than those of *P. serotina*, and not tinged with a bronzy red tint, ovate to ovate-triangular, about 3 in. long and 2¼ in. wide, truncate or slightly cuneate at the broad base, ending above in a long acuminate apex; serrations small, crenate, numerous, with incurved points; margin sparsely ciliate; glands minute, usually two present, occasionally absent; petiole reddish, glabrous. Leaves on the short shoots smaller, usually as broad as long, ovate, cuneate at the base.

Flower buds with densely pubescent ciliate scales, very viscid. Staminate catkins about 1½ in. long; axis glabrous; scales deeply divided into irregular lobes ending in long or short filaments; disc glabrous; stamens, thirty to thirty-five, with white filaments and dull red anthers.

This hybrid, which has peculiar pubescent buds, is of unknown origin and is staminate. The only tree which we have seen is in the park in front of the house at The Wilderness, White Knights, Reading. It measured in 1907 about 100 ft. by 14 ft., and was probably obtained as a young plant from France, where M. Dode¹ has observed trees of a similar kind. (A. H.)

POPULUS ROBUSTA

Populus robusta, Schneider, *Laubholzkunde*, i. 11 (1904); Dode, in *Mém. Soc. Hist. Autun*, xviii. 45 (1905); Ascherson and Graebner, *Syn. Mitteleurop. Fl.* iv. 45 (1908).

Populus angulata cordata robusta, Simon-Louis, *Catal.* 61 (1899).

A tree of hybrid origin remarkably vigorous in youth, with ascending branches. Young branchlets angled, minutely pubescent; on strong shoots, stout, grey with white lenticels, and with projecting ribs as in *P. angulata*. Buds reddish brown, viscid. Leaves (Plate 409, Fig. 20) unfolding early in the season with a deep red tint,² variable in shape, about 3 in. in length, ovate-deltoid or rhombic; cuneate, rounded, or truncate and sub-cordate at the base; acuminate at the apex; serrations coarse, with incurved tips, few and wide apart on the base; margin with scattered cilia; glands one, two, or absent; petiole reddish, with scattered short hairs.

Staminate catkins, borne on a tree at Glasnevin, 2½ in. long; flowers numerous, crowded; axis glabrous; scales deeply and irregularly lobed, ending in long

¹ M. Dode tells me that there is a fine tree at Paris in the Champs de Mars, near the Eiffel Tower, which was planted about 1888. There was an old tree, no longer living, in the Jardin de Luxembourg. He adds that the propagation by cuttings of this poplar fails in the open air, but succeeds under glass.

² As seen at Kew, it is the most beautiful of all the poplars when coming into leaf.

filaments; disc small, glabrous, oblique; stamens about twenty, with white filaments.

P. robusta is readily distinguished from most of the other hybrid poplars by the minute pubescence on the branchlets and petioles. It is said to have been raised about 1895 at Metz from seed of a female *P. angulata*, supposed to have been fertilised by the pollen of the large tree of *P. Eugenei* which grows near it; but this is improbable, as the branchlets of the latter tree, as well as those of *P. angulata*, are quite glabrous. In all probability the male parent was the common pubescent *P. nigra*, from which *P. plantiervensis*, its fastigiata variety, was also derived at Metz. (A. H.)

I saw in the nursery at Metz a large bed of plants from cuttings put in in 1909, which were 10 to 12 ft. high in 1910, and was told that its stem is straighter and more erect than that of the *peuplier régénéré*. The extraordinary vigour of the young trees justifies M. Jouin in believing that it will, in warm districts at least, surpass *P. Eugenei* in size. Whether it will succeed in England remains to be proved; but it has been largely planted for several years by Baron Aheré in Belgium, and in low damp ground near Metz, which is specially liable to spring frost. I have now had it planted for two years in the same situation in which I grow *P. serotina* at Colesborne. It seems perfectly hardy, but has not yet had time to show whether it is superior in vigour to *P. Eugenei* or *P. serotina*. A tree planted at Glasnevin in 1900 measured 42 ft. by 1 ft. 1 in. in April 1913. It is very narrow, almost columnar in habit, with short ascending branches. (H. J. E.)

POPULUS LLOYDII

Populus Lloydii, A. Henry (*hybrida nova*).

A tall tree of hybrid origin, with bark similar to that of *P. serotina*. Young branchlets slender, covered with a minute erect pubescence; glabrous and yellowish brown in the second year. Buds small, brownish, viscid. Leaves (Plate 409, Fig. 21) about 2½ in. wide and long; truncate, rounded, or cuneate at the base; tapering above into a short non-serrated acuminate or cuspidate apex; margin with crenate serrations, ending in incurved points, ciliate till late in summer; glands at the base minute, variable, often absent; petiole reddish, with a scattered minute erect pubescence.

Pistillate catkins, 2 to 2½ in. long; axis glabrous; pedicels short, glabrous; ovary globose, glabrous, in an oblique cup-shaped entire glabrous disc, crowned by two, rarely three, widely dilated spreading yellow stigmas. Fruiting catkins, about 4 in. long; capsules two-valved.

This remarkable hybrid, of which the parents are probably the common English black poplar (*P. nigra betulifolia*) and *P. serotina*, resembles the former in the pubescent branchlets and petioles, and the latter in the shape, ciliation, and glands of the leaves, which are bronze-coloured when opening. The leaves, being borne on old trees, are probably smaller than normal; and this tree, which is pistillate, is

scarcely to be distinguished in technical characters from *P. robusta*, which is staminate and bears considerably larger leaves, known from young trees only. *P. robusta* appears to differ, however, in the grey and not yellowish colour of the branchlets in their second year. (A. H.)

The only large trees which we have seen of this are at Leaton Knolls, Shrewsbury, the residence of Major Lloyd, who has no record of their origin or date of planting. The largest, which is growing on a hill at the edge of an old pit-hole, now dry, was 120 ft. by 13½ ft. in July 1910. The second tree is 110 ft. by 11 ft. 2 in., and the third is 95 ft. by 10½ ft., as measured by myself in July and by Major Lloyd in September 1910. None of the down lying on the ground in July contained good seed as far as I could see. The trees are clearly of the same age—possibly sixty or seventy years—and being all females, perhaps originated from cuttings of a tree which may have existed in the neighbourhood, where *P. nigra* is not uncommon.

This hybrid may possibly in some cases have been hitherto confused by botanists with *P. nigra*, var. *betulifolia*; but it is apparently rare. The only other specimen which we have seen is a tree¹ in a garden near Turnham Green Station, which is about 35 feet high. It produced numerous natural seedlings in 1907, ten of which were transplanted into the nursery at Kew, and were in 1912 vigorous plants 2 to 3½ ft. high. (H. J. E.)

POPULUS ANGUSTIFOLIA

- Populus angustifolia*, James, *Long's Expedition*, i. 497 (1823); Sargent, *Silva N. Amer.* ix. 171, t. 492 (1896), and *Trees N. Amer.* 159 (1905); Schneider, *Laubholzkunde*, i. 14 (1904); Dode, in *Mém. Soc. Hist. Nat. Autun*, xviii. 58 (1905); Gombocz, in *Math. Termes. Közl.* xxx. 105 (1911).
Populus salicifolia, Rafinesque, *Alsograph. Amer.* 43 (1838) (not Loudon).
Populus canadensis, Desfontaines, var. *angustifolia*, Wesmæl, in De Candolle, *Prod.* xvi. 2, 329 (1868).
Populus balsamifera, Linnæus, var. *angustifolia*, Watson, *King's Rep.* v. 327 (1871).
Populus coloradensis, Dode, in *Mém. Soc. Hist. Nat. Autun*, xviii. 58 (1905).

A tree, attaining in America 60 ft. in height and 5 ft. in girth. Bark smooth, yellowish green, becoming fissured at the base of old trunks. Young branchlets glabrous, rounded, yellowish grey. Buds minute, viscid, sharp-pointed. Leaves (Plate 410, Fig. 26), lanceolate on long shoots, resembling those of *Salix fragilis* in shape, about 2 to 4 in. long, ¾ to 1 in. wide, cuneate at the base, gradually tapering to a gland-tipped acute or rounded apex, glabrous, pale green and not whitish beneath; margin revolute, with close fine glandular serrations; lateral nerves, about fifteen pairs, all pinnate; petiole short, glabrous, flattened above. On the short shoots, the leaves become shorter and broader, almost rhombic in outline.

Catkins densely flowered, glabrous; scales obovate, with irregularly cut dark brown filiform lobes. Stamens twelve to twenty in a cup-shaped slightly oblique disc, with a thickened reflexed margin. Ovary two-lobed, with two stigmas, enclosed

¹ The pistillate catkins of this tree were figured in *Bot. Mag.* t. 8298 (1910), and show three-styled flowers, which never occur in true *P. nigra*. Cf. p. 1796, note 1.

in a shallow cup-shaped crenate disc. Fruiting catkins, 4 in. long; capsule two-valved, glabrous, on a $\frac{1}{8}$ in. long pedicel.

This species is a native of the Rocky Mountain region of North America, usually growing on the banks of streams between 5000 and 10,000 ft. It occurs as far north as south-western Assiniboia, extending southward through the Black Hills of Dakota, Montana, eastern Idaho, Wyoming, Utah, Colorado,¹ to central Nevada, Arizona, and New Mexico.

It is readily distinguishable amongst the balsam poplars by its willow-like leaves, which scarcely show any whitish tint beneath.

It was introduced into cultivation by Späth² of Berlin, who received young plants from Colorado in 1893. It forms at Kew small trees of spreading irregular habit, and may be looked upon as rather a shrub than a tree in this country. (A. H.)

POPULUS BALSAMIFERA, BALSAM POPLAR

Populus balsamifera, Linnæus, *Sp. Pl.* 1034 (*excl. syn.* Catesby et Gmelin) (1753); Loudon, *Arb. et Frut. Brit.* iii. 1673 (in part) (1838); Sargent, *Silva N. Amer.* ix. 167, t. 490 (1896), and *Trees N. Amer.* 157 (1905); Schneider, *Laubholzkunde*, i. 14 (1904); Dode, in *Mém. Soc. Hist. Nat. Autun*, xviii. 62 (1905); Gombocz, in *Math. Termes. Közl.* xxx. 108 (1911).
Populus Michauxi, Dode, *op. cit.* 62 (1905).

A tree, attaining in America 100 ft. in height and 20 ft. in girth. Bark at first smooth, light reddish brown; on old trunks deeply divided into broad rounded ridges. Young branchlets terete, without projecting ridges, glabrous. Buds elongated, sharp-pointed, exuding a yellowish strong-smelling resin. Leaves (Plate 410, Fig. 27) on long shoots averaging 4 in. long and 2 in. broad, ovate, rounded at the base, narrowing towards the apex, which is often abruptly acuminate, glabrous on both surfaces, whitish and often tinged with rusty red beneath; margin minutely and sparsely ciliate, with crenate serrations, ending in short incurved glandular points; lateral nerves about eight pairs, each of the lowest pair giving off at its origin usually one secondary nerve, making with the midrib the base of the blade pseudo-five-palminerved; petiole quadrangular, channelled above, with a minute scattered pubescence. Leaves on short shoots smaller, broader in proportion to their length.

Staminate catkins about 3 in. long; axis with a few scattered hairs; pedicels long and similarly pubescent; scales broadly obovate, often irregularly three-lobed at the apex, with numerous short thread-like divisions; stamens about twenty on an oblique crenate deep saucer-shaped glabrous disc. Pistillate catkins: disc cup-shaped; ovary ovoid, two-lobed, with two nearly sessile large oblique dilated crenulate stigmas. Fruiting catkins 5 in. long; capsule ovoid, curved at the apex, two-valved, on a slender pedicel about $\frac{1}{2}$ in. long.

This species, extending over a wide area in North America, is probably variable; and may hybridise with *P. candicans*. The form distinguished by Dode as

¹ F. von Holdt, of Arvada, Colorado, in *Mitt. Dent. Dend. Ges.*, 1912, pp. 118, 119, describes this poplar in its native home, and gives a fine photograph of it growing on the edge of a mountain lake.

² *Catalogue*, No. 91, p. 49 (1893-1894).

P. Michauxi has slightly pubescent branchlets and leaves which have occasionally a subcordate base, and is intermediate between the two species; but it has the narrow leaves of *P. balsamifera*, and cannot be confused with *P. candicans*, which has broadly ovate deeply cordate leaves. (A. H.)

P. balsamifera is confined to North America, where it is known as Balsam or Tacamahac, and ranges from far north in Alaska and Canada southwards to northern New England, New York, central Michigan and Minnesota, the Black Hills of Dakota, north-western Nebraska, northern Montana, Idaho, Oregon, and Nevada. It is the largest of sub-arctic American trees,¹ attaining its greatest size on the Peace river and other tributaries of the Mackenzie river, where, according to Macoun, it is often nearly 150 ft. high, with a trunk occasionally over 7 ft. in diameter and free of branches from 60 to 100 ft. up. It is the characteristic tree along the streams in the prairie regions of British America, and is common throughout the northern border of the United States, growing on alluvial lands liable to floods and on the borders of swamps.

According to Aiton it was cultivated at Hampton Court in 1692, and was again introduced in 1731, when a tree given by Queen Caroline to Sir Hans Sloane was planted in the Chelsea Botanic Garden. It was introduced² into Scotland in 1768 by seeds sent from Canada. We have seen no pistillate trees of this species, which has become exceedingly scarce in cultivation, being now almost entirely supplanted by *P. candicans*, the balsam poplar usually grown by nurserymen in England. It differs from *P. candicans* in habit, being a narrower tree with ascending branches, and seems to be short-lived in our climate, which is perhaps too warm³ for it.

The largest tree which we have seen in England is one (Plate 387) at Bute House, Petersham, which in 1905 was 71 ft. high by 7 ft. 10 in., and surrounded by a great number of suckers. The leaves of the suckers, as in other species of poplars, attain a large size, occasionally 6 to 8 inches in length. At Kew there are two small trees, obtained from Späth in 1905. At Syston Park, Lincolnshire, there was a tree of considerable size, growing on an island in the lake, which was cut down thirty years ago; but numerous suckers remain, about 18 ft. high, which produce flowers abundantly. A younger tree at Belton, 20 ft. high, planted fifteen years ago, produced staminate flowers, which were drawn by Miss F. H. Woolward. A tree at New Humberstone, Leicester, of which specimens in flower were collected by Mr. H. Burbank, was 50 ft. by 5 ft. 3 in. in 1905. It has since been topped.

In Scotland there is a large tree in the park at Castle Menzies, which looks older than any other I have seen, and in 1907 measured 68 ft. by 11 ft. 10 in. Another very old-looking tree grows by the schoolhouse at Achnacarry, and has bark more like that of an ash than a poplar. It measured in June 1910 about 60 ft. by 7 ft. I also saw several good-sized trees in Glen Urquhart.

¹ E. T. Seton, *Arctic Prairies*, 330 (1912), says: "The balsam poplar attains a large size on the lower Athabasca and the Slave rivers, at least 100 ft. We observed it as far as the eastern extremity of Great Slave Lake, but there it is scarcely more than a shrub. The leaves had partly turned colour near Caribou island on September 22."

² Walker, *Essays Nat. Hist.* 65 (1812).

³ Britton and Shafer, *N. Amer. Trees*, 172 (1908), state that this poplar is not much planted south of its natural range in America, as it does not well endure hot summers.

There are small trees doing badly at Glasnevin; but Mr. R. A. Phillips has seen four thriving trees at Staffordstown, Co. Antrim, the largest of which measured 40 ft. by 4 ft. in 1910.

According to Schübeler, it thrives in Norway as far north as Tromsö, lat. 69° 40', and succeeds in the Gudbrandsdal at an elevation of 1350 ft. (H. J. E.)

POPULUS CANDICANS, ONTARIO POPLAR

Populus candicans, Aiton, *Hort. Kew.* iii. 406 (1789); Michaux, *Hist. Arb. Am.* iii. 308 (1813); Loudon, *Arb. et Frut. Brit.* iii. 1676 (1838); Schneider, *Laubholzkunde*, i. 13 (1904); Dode, in *Mém. Soc. Hist. Nat. Autun*, xviii. 65 (1905); Gombocz, in *Math. Termes. Közl.* xxx. 115 (1911).

Populus Tacamahaca,¹ Miller, *Gard. Dict.* ed. 8, No. 6 (1768).

Populus macrophylla, Lindley, ex Loudon, *Encyc. Plants*, 840 (1829).

Populus ontariensis, Desfontaines, *Cat. Hort. Paris* (1829).

Populus balsamifera, Linnæus, var. *candicans*, Gray, *Manual*, 419 (1856); Sargent, *Silva N. Amer.* ix. 169, t. 491 (1896), and *Trees N. Amer.* 159 (1905).

A tree, similar in size and bark to *P. balsamifera*, but different in habit, with more spreading branches, forming a broad crown of foliage. Young branchlets terete or slightly angled, but without projecting ridges, pubescent. Buds large, reddish brown, sharp-pointed, parallel with the twig, exuding resin; scales ciliate. Leaves (Plate 410, Fig. 22) variable in size, averaging 5 to 6 in. in length, and 4 in. in width, broadly ovate-deltoid; widest near the base, which is cordate, subcordate, or rarely truncate; cuspidate at the apex; margin conspicuously ciliate, with coarse serrations, ending in incurved glandular points; upper surface green, with scattered pubescence, glandular at the junction of the petiole; lower surface whitish, but usually less so than in *P. balsamifera* and *P. trichocarpa*, and with scattered hairs, dense on the midrib and nerves; nervation as in *P. balsamifera*; petiole terete, grooved above, densely pubescent.

Staminate flowers not seen. Pistillate catkins; axis covered with stiff hairs; flowers numerous on short glabrous pedicels; scales broadly obovate, fimbriated with long thread-like lobes; ovary glabrous, half enclosed in a deep cup-shaped glabrous crenate disc, and surmounted by two sub-sessile large dilated crenulate yellowish or orange stigmas. Fruiting catkins,² 6 in. long; capsule, on a glabrous $\frac{1}{8}$ in. long pedicel, with two glabrous tuberculate valves; the whole catkin covered with the down of the seed after the capsules have opened.

A variegated form of the species is known, in which the leaves are blotched with yellow. Specimens of this may be seen at Woburn, and in the Glasnevin and Edinburgh Botanic Gardens.

This species is very distinct from *P. balsamifera*, and is closely allied to *P. ciliata* of the Himalayas, from which it differs in flowers, though the shape of the leaf is very similar.

¹ Miller's diagnosis applies plainly to this species; but his detailed description includes also *P. balsamifera*. I have, therefore, not thought it desirable to resuscitate Miller's name, though the oldest, for the Ontario poplar.

² Described from a tree at Belton, perhaps fertilised by some other species of poplar.

P. candicans appears to be unquestionably¹ a native of North America, though Sargent states that he has seen no wild specimens, and that it "does not appear to be indigenous in New England or eastern Canada, where the pistillate plant² has been used as a shade tree from very early times, as it has been in the Middle States and in Europe." L. H. Barclay,³ however, states that there was a grove of this species, "with many large trees, at South Haven, Michigan, when the first pioneers visited the place, and these appeared to be coeval with the surrounding forest, with which they were interspersed for some distance back from the lake shore." Gates states⁴ that on the west coast of Michigan, north of Waukegan, the sand dunes in some places are surmounted by narrow groves of *P. candicans*, consisting of trees of moderate size, which are associated with *Prunus pumila*. Seedlings of this poplar are rarely found on the dunes themselves, but are common on the adjoining heaths. A specimen in the Kew Herbarium, collected by Fernald along the St. John River in Aristook County, Maine, has a note attached stating that it is common north of lat. 47° along river banks and in low-lying woods. No further information of a positive kind is obtainable concerning its distribution; but Dame and Brooks⁵ state that trees of both sexes are found by collectors in New Hampshire and Vermont; while in central and southern New England the staminate tree is rarely, if ever seen. These authors conclude that the evidence points to the habitat of the wild tree being a narrow belt extending through northern New Hampshire, Vermont, the southern section of Ontario, and Michigan. Macoun says that it is the prevalent balsam poplar in Ontario, and that it is apparently wild in the neighbourhood of Picton, Nova Scotia.

(A. H.)

The Ontario poplar was introduced into England in 1772, and has been widely planted ever since, owing its popularity, no doubt, to the fact that it is more easily propagated by cuttings than the true balsam poplar, which it surpasses also in beauty of foliage. The Ontario poplar has no economic value; and as it is always female,⁶ producing downy fruit in quantity, and also produces suckers freely, it is objectionable in ornamental plantations.

Nearly all the balsam poplars in England belong to this species, and the finest specimen is probably a tree at Syon, which measured, in 1906, 85 ft. by 9 ft. Another at Bayfordbury was 70 ft. by 6½ ft. in 1910. Of the numerous trees which we have seen in other places, none are noteworthy as regards size, 60 to 70 ft. being apparently the average in England for full-grown trees.⁷

(H. J. E.)

¹ Michaux, however, states that it was common in Rhode Island, Massachusetts, and New Hampshire, but always planted. He had never seen it in forests. It is mentioned by Duhamel, *Traité des Arbres*, ii. 181 (1755), as a poplar found in the neighbourhood of Quebec, where it was known as *liard*, with a leaf like a maple, white beneath, and exhaling a very odorous balsam.

² Sargent, however, figures staminate as well as pistillate flowers.

³ In *Bot. Gaz.* v. 91 (1880).

⁴ *Bull. Illinois State Lab. Nat. Science, Urbana*, ix. 287, plate xlvi. fig. 2 (1912).

⁵ *Trees of New England*, 37 (1902). Britton and Shafer, *N. Amer. Trees*, 169 (1908), apparently do not agree with these authors, and simply state: "Evidence that it is wild in Michigan has been adduced, and it is probably indigenous farther to the north-west."

⁶ It is evident from Fougereux, in *Mém. d'Agric., Paris*, 1786, i. pp. 91, 94, that in France at that early period, *P. candicans* was always female, and *P. balsamifera* always male, as is now the case in England. His account is however confused, as he transfers the name *liard* to *P. balsamifera*, and *beauquier du Pérou* to *P. candicans*, the converse being correct.

⁷ In *Mitt. Deut. Dend. Ges.* 1904, p. 19, a tree named *Populus balsamea*, growing at Schloss Dyck near Dusseldorf, was reported to be 38 metres high by 4.25 metres in girth. It is unlikely that this tree was any species of balsam poplar.

POPULUS TRICHOCARPA, WESTERN BALSAM POPLAR

- Populus trichocarpa*, Torrey et Grey, ex Hooker, *Icon. Plant.* ix. t. 878 (1852); Sargent, *Silva N. Amer.* ix. 175, t. 493 (1896), and *Trees N. Amer.* 161 (1905); Schneider, *Laubholzkunde*, i. 16 (1904); Dode, in *Mém. Soc. Hist. Nat. Autun*, xviii. 64 (1905); Jepson, *Flora California*, 346 (1909), and *Silva California*, 188 (1910); Gombocz, in *Math. Termes. Közl.* xxx. 112 (1911).
Populus balsamifera, Linnæus, var. γ , Hooker, *Fl. Bor. Am.* ii. 154 (1839).
Populus balsamifera, Lyall, in *Journ. Linn. Soc. (Bot.)* vii. 134 (1864) (not Linnæus).
Populus angustifolia, Newberry, *Pacific R. R. Rep.* vi. pt. iii. 89 (1857) (not James).
Populus hastata, Dode, in *Mém. Soc. Hist. Nat. Autun*, xviii. 64 (1905).

A tree, attaining on the Pacific coast of North America 200 ft. in height and 20 ft. in girth. Bark of young stems peeling off in papery scales; on old stems grey and deeply divided into broad rounded scaly ridges. Young branchlets glabrous, shining, brown, marked with white linear lenticels, angled and with five prominent ridges on vigorous shoots, often retained in the second year. Buds brownish, very fragrant, resinous, glabrous, elongated, sharp-pointed, parallel with, but not appressed to the twig. Leaves (Plate 410, Fig. 31) variable in size, very large on upper vigorous branches; on lower terminal shoots averaging 5 in. long and 3 in. broad; ovate or ovate-deltoid; slightly cordate, truncate, or rounded at the base; broadest near the base, gradually narrowing towards the gland-tipped acuminate apex; upper surface light green, glabrescent; lower surface whiter than in the other balsam poplars, with a few short scattered hairs; lateral nerves about seven or eight pairs, each of the lowest pair giving off at its origin two secondary nerves, making with the midrib the base of the blade pseudo-seven-palminerved; margin ciliate, with incurved crenate glandular shallow serrations, often absent on large leaves towards the apex; petiole reddish, minutely pubescent, terete, channelled above, about 1 in. in length.

Staminate catkins (described from a living tree at Kew), about $2\frac{1}{2}$ in. long; axis green, pubescent, crowded with numerous sessile flowers; scales with numerous filiform ciliated divisions, quickly deciduous; stamens about fifty, on an oblique orbicular flat glabrous disc, which has an entire ciliate margin; filaments slender, white; anthers deep red. Pistillate catkins, according to Sargent, with a loosely-flowered tomentose axis; ovary densely tomentose, with three nearly sessile broadly dilated, deeply lobed stigmas, enclosed in a crenate or entire deep cup-shaped disc. Fruiting catkin, 4 in. to 5 in. long; capsule sub-sessile, globose, thick-walled, three-valved.

This species, which is readily distinguished from the other balsam poplars by its very white leaves, winged twigs, and bark peeling off in thin papery shreds, was founded by Hooker on a specimen collected by C. C. Parry in 1850, on the Santa Clara river near Buenaventura, California. This specimen and others from southern California in the Kew Herbarium, have small deltoid leaves scarcely acuminate at the apex, and with considerable pubescence on the midrib and veins beneath and on the

petiole; the capsules are also very pubescent. Specimens from Oregon, Washington, and British Columbia have usually larger leaves, much longer than broad, distinctly acuminate, and with less pubescence; and their capsules are sometimes nearly glabrous. The latter form, which is the one in cultivation, is considered by Dode (*op. cit.* 64) to be a distinct species, *P. hastata*; and may, on further investigation in the field, turn out to be worth ranking as a distinct variety, *P. trichocarpa*, var. *hastata*. Jepson also mentions a form *ingrata* from San Bernardino county, which has small lanceolate leaves.¹

This magnificent poplar, the largest of the genus, is a native of the Pacific coast region of North America from southern Alaska to San Diego county in California, extending inland in British Columbia as far as the valley of the Columbia river, and in California to the western slope of the Sierra Nevada. It is reported to occur in eastern Washington² and in western Montana;³ but the balsam poplar in these regions is possibly *P. balsamifera*. *P. trichocarpa* grows mainly in open groves in river valleys, attaining its largest size near sea-level in the coast region north of California; southward, it is a small tree rarely more than 40 ft. high,⁴ ascending to 6000 ft. altitude in the Sierra Nevada in central California. It is most abundant⁵ in Oregon and Washington, where its timber is used for making staves and wooden ware. Jepson states that the wood is light, soft, and fairly close-grained, but not strong. (A. H.)

It is the largest deciduous tree⁶ of the Pacific coast region, attaining its greatest size on Puget Sound, where it is sometimes 200 ft. in height and 6 to 8 ft. in diameter. I saw it in perfection on a farm in Vancouver Island called Swallowfield, some miles north of Duncans, and measured the tree here figured (Plate 388), which was growing in a meadow on rich alluvial soil, and was at least 140 ft. high with a bole 70 ft. long and 28 ft. 3 in. in girth. Another tree, with the top broken, had a bole 80 ft. by 21 ft. 3 in. which I estimated to contain 1300 to 1400 ft. of timber; and on 8th June it was covered with seed capsules which I gathered, but being unable to sow them till I came home, failed to raise any trees. A beautiful picture of a group of these trees on the banks of the Merced river in the Yosemite valley is given in *Garden and Forest*, v. 281.

This species is of recent introduction⁷ in England, the oldest specimen known to us being a tree in the Edinburgh Botanic Garden, which was planted in 1892, and measured in 1906, 39 ft. by 2 ft. 6 in. Another at Grayswood, planted in 1898, measured in 1906, 32 ft. by 2 ft. 1 in. The largest specimen at Kew was obtained from Späth in 1896, and measured 55 ft. by 3 ft. 10 in. in 1911.

¹ Var. *cupulata*, Watson, in *Amer. Journ. Science*, cxv. 136 (1878), was a name given to a specimen from Plumas County, California, with flowers, in which the disc was campanulate and pubescent.

² Piper in *Cont. U.S. Nat. Herb.* xi. 217 (1906).

³ M. E. Jones, *Montana Botany Notes*, 24 (1910).

⁴ Hilyard, *Soils*, 480 (1906), says that this species tolerates white alkaline soil, containing sodium sulphate and chloride; but remains dwarf and stunted on black alkaline soil, containing sodium carbonate.

⁵ Jepson, *op. cit.*

⁶ Dawson, *Cat. Can. Plants*, i. 457 (1884), states that there is some difficulty in separating this tree from *P. balsamifera* in the northern and north-eastern part of British Columbia, and perhaps the tree of the Yukon valley, which he refers to *P. balsamifera*, is the same which Sargent considers *P. trichocarpa*.

⁷ Dieck, *Neuh. Offert. Züschen*, 1889-1890, p. 13, introduced it on the Continent from British Columbia in 1889.

It seems likely to succeed as well and to grow larger in this climate than the common balsam poplar. Those which I have planted in a cold heavy soil and a situation where severe spring and autumn frosts occur regularly, grow very fast and are perfectly healthy. I received them from Messrs. Meehan of Philadelphia in 1903, and one of those measured in 1911 no less than 32 ft. high by 1 ft. 5 in. in girth, though its branches have been cut several times to propagate. On account of its large handsome leaves, which in hot weather diffuse a most fragrant smell for some distance, this is one of the best of all poplars for ornamental planting.

The largest tree on the continent, appears to be one in the Dresden Botanic Garden, which Mr. Bean¹ in 1908 estimated to be 70 to 80 ft. high, with a trunk 5 ft. 10 in. in girth. In the Copenhagen Botanic Garden it is 30 ft. high, and very thriving. A small tree in the Christiania Botanic Garden was also doing well in 1908.

(H. J. E.)

POPULUS MAXIMOWICZII

Populus Maximowiczii, A. Henry, in *Gard. Chron.* liii. 198, fig. 89 (1913).

Populus suaveolens, Regel, *Tent. Fl. Ussur.* 132 (1861); Maximowicz, in *Bull. Soc. Nat. Mosc.* liv. 51 (1879); Komarov, *Fl. Manshurica*, ii. pt. i. 17 (1903) (not Fischer).

Populus balsamifera, Linnæus, var. *suaveolens*, Burkill, in *Journ. Linn. Soc. (Bot.)* xxvi. 535 (1899) (not Loudon); Shirasawa, *Icon. Ess. Forest. Japon*, i. text 37, t. 18, figs. 11-24 (1900).

A tree, attaining 100 ft. in height and 10 ft. in girth. Branchlets densely pubescent. Leaves (Plate 410, Fig. 24), about 4 in. long, and 3 to 3½ in. broad, nearly orbicular, oval, or broadly elliptic; subcordate at the rounded base; cuspidate at the apex; pubescent on the midrib, nerves, and veinlets of both surfaces, whitish or tinged with rusty red beneath; densely ciliate and sharply serrate in margin; petiole densely pubescent. Fruiting catkins 7 to 10 in. long; capsules glabrous, sub-sessile, 3- to 4-valved.

This species, owing to the peculiar shape and pubescence of the leaf, is remarkably distinct from *P. suaveolens*, with which it has been confounded, and is most closely allied to the Himalayan *P. ciliata*. It is the common balsam poplar in eastern Asia, extending from Kamtschatka southwards through Saghalien to Japan, Amurland,² Manchuria, and Korea.

(A. H.)

This is the only poplar which attains a large size in Japan, where it is common in Hokkaido and in the north-eastern district of Honshu, and is called *doro-noki*. I saw it in the central parts of Hokkaido, the largest near Lake Shikotsu being about 100 ft. by 12 ft., growing on river banks and also mixed with other trees in deciduous forests;³ but in some parts of the country there

¹ Cf. *Kew Bull.* 1908, p. 397.

² Elwes found what he believes to be this tree planted at the railway stations on the Siberian Railway near Harbin in May 1912, and brought home cuttings which have rooted at Colesborne. It is recorded for Saghalien by Koidzumi in *Journ. Coll. Sci. Tokyo*, xxvii., art. 13, p. 44 (1910).

³ Such a forest is figured in *Forestry of Japan*, 96, issued in 1910 by the Bureau of Forestry, Department of Agriculture and Commerce, Tokyo. Jack, in *Mitt. Deut. Dend. Ges.* 1909, p. 282, fig. 285, gives an illustration of an old tree in Hokkaido with deeply furrowed bark.

are pure woods of this and *P. Sieboldii*. Both of these poplars are valued for their timber, which is considered the best for matches, and are being planted extensively by private persons. The seed was not ripe till the middle of July, but none of that which I brought home germinated, and I am not aware that any trees of Japanese origin have yet been introduced.

(H. J. E.)

POPULUS SIMONII

Populus Simonii, Carrière, in *Rev. Hort.* 1867, p. 360; Wesmael, in *Mém. Soc. Sc. Hainaut*, iii. 247 (1869); Schneider, *Laubholzkunde*, i. 16 (1904); Dode, in *Mém. Soc. Hist. Nat. Autun.*, xviii. 58 (1905); Gombocz, in *Math. Termes. Közl.* xxx. 105 (1911).

Populus balsamifera, Linnæus, var. *Simonii*, Wesmael, in *Bull. Soc. Roy. Bot. Belg.* xxvi. 378 (1887); Burkill, in *Journ. Linn. Soc. (Bot.)* xxvi. 536 (1899).

A tree, the dimensions of which in the wild state are unknown. Young branchlets glabrous, usually reddish brown, with five projecting ribs. Buds viscid, glabrous, sharp-pointed, parallel with the twig. Leaves¹ (Plate 410, Fig. 28), on young trees rhombic-elliptic, averaging 3 in. long and 1½ in. broad, cuneate at the base, contracted at the apex into a short cuspidate point, glabrous, dull whitish beneath; margin with deciduous cilia and crenulate serrations, ending in minute glandular incurved points; lateral nerves seven to nine pairs, all pinnate; petiole short, often not ½ in. long, channelled above, glabrous, reddish, the red colour being continued along the midrib² on the upper surface of the blade. Leaves on short shoots and on older trees, smaller and on long petioles, which are often 1½ in. in length. Leaves on vigorous shoots and at the summit of the tree, very large, often 5 in. long and 4 in. broad, ovate-elliptical, cuspidate, on petioles ½ to 1 in. long.

Staminate catkins, according to Schneider, 1 in. long; stamens about eight in a cup-shaped disc. Pistillate flowers and fruit unknown.

This species occurs in north China, where it was collected by Simon in 1862, at Si-wan, north-east of Kalgan, and by Bushell³ in 1868 in the neighbourhood of Peking. Simon sent living plants about 1862 to the Museum at Paris, where the original tree, described by Carrière, is still living, and to Simon-Louis at Plantières, Metz.

This poplar is little known in England, where we have only seen small living trees at Kew. Elwes received some short truncheons of this from Peking in 1907, of which, though three months in transit, two grew, and seem likely to succeed at Colesborne. A thriving tree at Grignon, near Paris, which measured 58 ft. by 2½ ft. in 1906, is narrow in habit, with short branches and pendulous branchlets; and young specimens show a similar weeping habit.

Prof. Craig, of the Central Experimental Farm, Ottawa, states⁴ that this tree

¹ This species is remarkable for the variation in the length of the petioles, which appear to remain short only in young trees. The large leaves are characteristic of the summit of adult trees, but may appear on vigorous lateral branches also.

² The midrib is yellow throughout on old trees.

³ Erroneously identified as *P. laurifolia* in *Journ. Linn. Soc. (Bot.)* xxvi. 536 (1899).

⁴ Quoted by L. H. Bailey, in *Cornell Univ. Agric. Station, Bull.* 68, p. 221 (1894).

grows very rapidly in Canada, making a yearly growth of 6 to 10 ft. It is not killed by the severe winters of Manitoba, and is useful for planting where wind-breaks are desired quickly.

P. yunnanensis, Dode, *op. cit.* 63 (1905), agrees in technical characters with *P. Simonii*, from which it mainly differs in the brilliant red colour of the branchlets, petioles, and midrib and nerves on the upper surface of the leaves. As in that species, the glabrous branches have five projecting ribs, and the leaves are variable, both in size and shape, and in the length of their petioles. The leaves on the long shoots of young trees are narrowly elliptic or rhombic-elliptic, 3 to 4 in. long, $1\frac{1}{2}$ to 2 in. wide, glabrous, white beneath, cuspidate at the apex, cuneate at the base, closely crenulate in margin, and with very short petioles, about $\frac{1}{4}$ in. long. On vigorous shoots they are broadly ovate, 5 in. long, $3\frac{1}{2}$ in. wide, with the cuspidate point directed to one side; petioles about 1 in. long.

This poplar, which is very ornamental, is probably a sport or a geographical form of *P. Simonii*; and was introduced from Yunnan, China, in 1906 by a cutting, sent to Dr. Dode, which has been propagated by Chenault of Orleans. There are young and thriving plants at Glasnevin, Casewick, Borde Hill, and Colesborne, the leaves of which were still green on 15th November 1912. (A. H.)

POPULUS TRISTIS

Populus tristis, Fischer, in *Allg. Gartenzeit.* ix. 402 (1841), and *Bull. Sc. Acad. Imp. Pétersb.* ix. 343 (1842); Koehne, *Deut. Dend.* 82 (1893); Schneider, *Laubholzkunde*, i. 13 (1904); Dode, in *Mém. Soc. Hist. Nat. Autun*, xviii. 62 (1905); Ascherson and Graebner, *Syn. Mitteleurop.* Fl. iv. 49 (1908); Gombocz, in *Math. Termes. Közl.* xxx. 98 (1911).

(?) *Populus balsamifera*,¹ J. D. Hooker, *Fl. Brit. India*, v. 638 (1888) (not Linnæus); Gamble, *Indian Timbers*, 691 (1902).

A small tree. Branchlets as in *P. candicans*. Buds viscid, pubescent, ciliate, often subtended by persistent ovate acuminate pubescent stipules. Leaves (Plate 410, Fig. 23), similar to those of *P. candicans* in colour, pubescence, and ciliated margin; but narrowly ovate, about 4 in. long and 2 in. broad, acuminate at the apex, subcordate or rounded at the base.² Flowers and fruit of the cultivated plant unknown.

This species was described by Fischer from a cultivated tree at St. Petersburg, supposed to have been introduced³ from central Asia. Koehne identifies with *P. tristis*, the poplar which has been found by various travellers⁴ in the north-west

¹ *P. balsamifera* is confined to North America, and is very distinct from any of the Asiatic species.

² Glands are only present at the base of large, well-developed leaves.

³ *P. tristis* was mentioned as newly introduced into Germany, by Späth, *Catalogue*, No. 91, p. 96 (1893-1894).

⁴ Thomson, who collected this poplar in the Zaskar district and other places near Leh in Ladak, describes it in *W. Himalaya and Tibet*, 180 (1852), as "a spreading tree, with large cordate leaves, which was first seen in Upper Kunawar, and is common in all the Tibetan villages, up to the highest limit of tree cultivation." It was also collected "in N.-W. India" by Dr. J. S. Stewart (specimens in the Edinburgh Herbarium); and in the Nubra valley in Tibet by Schlagintweit in 1856. It appears to be a pubescent form of *P. ciliata*, modified by a high and arid situation. The latter species, which, so far as we know, is not in cultivation, has much larger, broad ovate-cordate densely ciliate leaves; glabrous branchlets, buds, and pistillate catkins; disc of the flower lobed; and grows at lower elevations in the Himalayas, from 4000 to 10,000 feet.

Himalayas, occurring both wild and cultivated, at high elevations, 8000 to 14,000 ft. Herbarium specimens of this poplar agree with *P. tristis* in the pubescent buds, with occasional persistent stipules, hairy branchlets, and narrow leaves usually rounded but occasionally subcordate at the base. They bear pistillate catkins, 4 to 6 in. long, with densely pubescent axes and pedicels; disc crenate; ovary pubescent, globose, crowned by three two-lobed stigmas; capsule, pubescent with scattered long hairs, and splitting into three valves, each with a deep longitudinal furrow on the outer surface, not seen in any other species. Koehne's identification is probably correct, but the material for comparison is not sufficient.

I am indebted to Späth of Berlin for fresh branches of this poplar which agree perfectly with Fischer's type specimen of *P. tristis*, preserved in the Kew Herbarium. So far as I know, it is rare in cultivation in England. At Grayswood, Haslemere, it is slow in growth, a plant obtained from Späth in 1896 being only about 4 ft. high, but quite healthy. At Kew there are several small specimens, which retain their foliage hanging withered on the branches during winter. There is also a specimen in the Edinburgh Botanic Garden, about 6 ft. high, and not in a thriving state.

(A. H.)

POPULUS SUAVEOLENS

Populus suaveolens,¹ Fischer, in *Allgem. Gartenzeit.* ix. 404 (1841), and *Bull. Sc. Ac. Imp. Pétersb.* ix. 348 (1842); A. Henry, in *Gard. Chron.* liii. 198, fig. 88 (1913).

Populus balsamifera, Pallas, *Fl. Ross.* i. 67, t. xli. fig. 1, A and C (1784) (not Linnæus).

Populus balsamifera, Linnæus, vars. *intermedia* and *suaveolens*, Loudon, *Arb. et Frut. Brit.* iii. 1674 (1838).

A tree, attaining in central Asia 50 ft. in height. Young branchlets terete, slightly pubescent above the nodes. Leaves (Plate 410, Fig. 25) ovate-lanceolate or ovate, 3 to $3\frac{1}{2}$ in. long, $1\frac{1}{4}$ to 2 in. wide, rounded at the base, usually abruptly narrowed towards the acuminate apex; margin ciliate, finely crenate-serrate, with incurved glandular points; nerves running to the margin about eight pairs, the lower two or three pairs arising close together at the base, making it palmately five-nerved; glabrous on both surfaces, whitish beneath.

Staminate catkins not seen. Pistillate catkins about 3 in. long; axis densely pubescent, with white stiff hairs, which are also present on the three-valved globose ovary, and on the extremely short pedicels; disc orbicular, slightly concave, pubescent beneath, with a wavy and densely ciliate margin; stigma two-lobed.

This species in the wild state appears to be variable in the width of the leaf, and in the amount of pubescence on the branchlets and petioles. It has smaller and narrower leaves than any of the balsam poplars, which have whitish leaves beneath.

P. Przewalskii,² Maximowicz, in *Mél. Biol.* xi. 321 (1881), founded on

¹ Fischer's description is founded on Pallas's figure, and agrees with a specimen collected in Soongaria by Schrenk in 1840. Cf. my article in *Gard. Chron.* cited above.

² Dode, in *Mém. Soc. Hist. Nat. Autun*, xviii. 55 (1905), identifies with this species *P. rasumowskyana* and *P. petrowskyana*, hybrid poplars originating in Europe, which resemble in no respect the type specimen of *P. Przewalskii*, preserved in the Kew Herbarium. Cf. pp. 1843, 1844.

specimens collected by Przewalsky in the Ordos territory in Mongolia, seems to be a variety with quite glabrous branchlets and petioles.

P. suaveolens appears to be confined¹ to western and northern Siberia, and to Mongolia. It has sweet-scented foliage, resembling in this respect *P. trichocarpa*. Introduced in 1834, it has apparently never thriven in this country, where we have seen no living specimens, except small stunted trees at Kew. It appears to thrive better in Späth's nursery at Berlin, from which we have received specimens, showing healthy foliage and vigorous shoots. Elwes found a fine tree of it in the rich arboretum at Gissfeld in Denmark, the property of Count Danneskjold-Samsö. It measured 65 ft. by 4 ft., and bore the name of *P. Simonii*. (A. H.)

POPULUS LAURIFOLIA

Populus laurifolia, Ledebour, *Fl. Alt.* iv. 297 (1833), and *Icon. Fl. Ross.* v. t. 479 (1834); Fischer, in *Allgem. Gartenzeit.* ix. 404 (1841); Schneider, *Laubholzkunde*, i. 16 (1904); Dode, in *Mém. Soc. Hist. Nat. Autun*, xviii. 59 (1905); Gombocz, in *Math. Termes. Köz.* xxx. 102 (1911).
Populus balsamifera, Linnæus, var. *viminialis*, Loudon, *Arb. et Frut. Brit.* iii. 1673 (1838).
Populus balsamifera, Linnæus, var. *laurifolia*, Wesmael, in De Candolle, *Prod.* xvi. 2, p. 330 (1868).
Populus Lindleyana,² Carrière, in *Rev. Hort.* 1867, p. 380 (not Booth, *ex Loudon, op. cit.* 1657); Dode, *op. cit.* 59.

A tree, attaining 40 ft. in height. Young branchlets greyish yellow, pubescent especially near the apex, angled with five ridges, which are very prominent in the second year; lenticels few, scattered, lanceolate. Buds elongated, acute, parallel but not appressed to the twig, exuding a brownish strong-smelling resin. Leaves (Plate 410, Fig. 30) on long shoots, 3 to 5 in. long and 1 to 2 in. broad, lanceolate, rounded at the base, gradually tapering to an acuminate apex; margin finely and regularly glandular-serrate and ciliate; upper surface green, pubescent on the midrib; lower surface whitish, with scattered pubescence, most marked on the midrib; petiole short, terete, but channelled above, pubescent. Leaves on short shoots, smaller, oval, abruptly acuminate at the apex, rounded at the base, on long petioles, which are often two-thirds the length of the blade.

Staminate catkins (described from a tree at Kew) about 2 in. long, with a greenish white densely pubescent axis, bearing about thirty flowers; scales large, with about ten densely fringed lobes, and covered with long hairs on both surfaces; stamens about sixty, with short white filaments and red anthers, on a shallow oblique disc, which is entire and ciliate in margin, glabrous on both surfaces, nearly orbicular, and with a projecting point on one side; pedicel $\frac{1}{2}$ in., with a few scattered hairs. Pistillate flowers not seen. Fruit two- to three-valved, slightly pubescent.

¹ *P. suaveolens* is the poplar referred to by Gmelin, *Fl. Sibirica*, i. 152, fig. 33 (1747), who says that it grows in most places on the rivers emptying into Lake Baikal, being a little less in size than the tree willow; while in the upper regions of the Lena, Yenesei, and other northern rivers, it assumes a dwarf form, not exceeding 3 ft. in height.

² Dode keeps this distinct, though it is identical in foliage, on account of its pubescent capsules. Wild specimens of *P. laurifolia*, which I have seen, appear, however, to have pubescent capsules.

P. laurifolia appears to be confined¹ to the Altai mountains; and little is known of its habit in the wild state. It is said to be often planted as a street tree in northern Russia, and apparently thrives in Sweden, where I saw two fine trees in the public park at Gefle, about 70 ft. by 5 ft., in 1908.

Though introduced in Loudon's time, it has always been a scarce tree in England; and the only specimen which we know of considerable size is a tree at Kew, about 30 ft. high, with a furrowed bark, a crooked stem, and pendulous branches and branchlets. There is also a small stunted tree at Beauport, Sussex. This poplar is only suitable for cultivation in this country as a curiosity in botanic gardens; but it is said² to bear pruning well, and on the continent is often trimmed to form pyramidal and globose shrubs.

P. laurifolia is supposed to be one of the parents of the four hybrids which follow.

I. POPULUS WOBSTII, Schroeder, *ex Dippel, Laubholzkunde*, ii. 207 (1892).

This poplar, of which I have only seen branches sent me by Späth, has glabrous branchlets, slightly ribbed and marked with orange lenticels. Buds very viscid. Leaves (Plate 410, Fig. 32), 4 to 6 in. long, about 2 in. broad, lanceolate, widest about the middle, rounded but narrow at the base, gradually tapering towards the blunt acuminate apex, slightly pubescent on the midrib and veins, very white beneath, ciliate and crenately serrate in margin; lateral nerves pinnate at the base; petioles with a few scattered hairs.

Its origin is unknown;³ but it is possibly a hybrid of *P. laurifolia* with *P. tristis*, as surmised by Schneider, *Laubholzkunde*, i. 16 (1904). According to Späth it is slow in growth, and apparently has little to recommend it, except as a curiosity in botanical gardens. I have seen no living specimens in England.

The remaining three hybrid poplars show *P. laurifolia* parentage in the peculiar greyish yellow colour of the branchlets, which are slightly ribbed. The other parent is one of the black poplars, from which the leaves derive the translucent border to their margin, which is, however, very narrow, and can only be made out on careful examination. The foliage and buds have merely a feeble balsamic odour, and the under surface of the leaves is only slightly whitish, being in these respects intermediate between the balsam and the black poplars.

II. POPULUS RASUMOWSKYANA, Schroeder, in Regel, *Russ. Dend.* 133 (1889).

Young branchlets glabrous, angled, with projecting ridges and numerous white lenticels. Buds viscid, sharp-pointed. Leaves on young trees on vigorous shoots, 4 in. long, 3 in. wide, orbicular-ovate, rounded or subcordate at the base, contracted above into a gland-tipped acuminate apex, glabrous except for slight pubescence at

¹ The Chinese specimens referred to this species in *Journ. Linn. Soc. (Bot.)* xxvi. 536 (1899), appear to be *P. Simonii*.

² Cf. Ascherson and Graebner, *Syn. Mitteleurop. Fl.* iv. 47 (1908).

³ *P. Wobstii* appears as a novelty in Späth's *Catalogue*, No. 76, p. 108 (1889-1890); and in his *Catalogue*, No. 95, p. 100 (1894-1895), is said not to be a hybrid, but a narrow-leaved form of *P. suaveolens*; but Schneider controverts this, while admitting the possibility of its being a distinct species.

the base of the midrib on the upper surface, pale beneath; margin glandular-crenate, non-ciliate, with a very narrow translucent border; petiole terete, grooved above. Leaves on older trees smaller, about 3 in. long and $2\frac{1}{2}$ in. wide, elliptic-rhomboidal, with an acute or a short cuspidate apex.

III. *POPULUS PETROWSKYANA*, Schroeder, *ex* Dippel, *Laubholzkunde*, ii. 200 (1892).

Very similar to the last, but with minute pubescence on the branchlets and the petioles. Leaves on vigorous shoots about 5 in. long and 4 in. wide, ovate, cordate at the base, where there are usually one or two glands on the upper surface; contracted above into a long acuminate apex; pale beneath; serrations deeper than in the preceding hybrid.

Both these hybrid poplars¹ originated in the garden of the Imperial Agricultural Institute at Petrowskoje-Rasumowskoje, near Moscow, and were exhibited by Schroeder at the Moscow Exhibition in 1882, with three other hybrid poplars, which do not appear to have been propagated. *P. rasumowskyana* was reported to have originated from a *P. nigra*, pollinated by *P. suaveolens*; and *P. petrowskyana* from a *P. canadensis*,² pollinated by the same species; but in all probability the balsam poplar concerned was *P. laurifolia*.

Both kinds are said by Späth to be vigorous in growth, but apparently are much less known than *P. berolinensis*, and have only lately been tried at Kew. I have no information concerning the habit of adult trees, and am doubtful as to whether these two hybrids are really distinct, the material which I have examined being very scanty.

IV. *POPULUS BEROLINENSIS*.

Populus berolinensis, Dippel, *Laubholzkunde*, ii. 210 (1892); Schneider, *Laubholzkunde*, i. 11 (1904).

Populus hybrida berolinensis, Koch, in *Wochenschr. Gärt. Pflanzenkunde*, viii. 225 (1865), and *Dendrologie*, ii. pt. i. p. 497 (1872).

Populus certinensis, Dieck, *Hauptcatalog. Baumschul. Zöschchen* (1885).

Populus nigra, var. *italica* × *laurifolia*, Koehne, *Deut. Dendr.* 85 (1893).

(?) *Populus pseudobalsamifera*,³ Fischer, in *Allgemein. Gartenseit.* ix. 402 (1841), *ex* Dode, in *Mém. Soc. Hist. Nat. Autun*, xviii. 55 (1905).

A tree, columnar in habit, with short ascending branches, and bark similar to that of *P. serotina*. Young branchlets slightly winged, densely pubescent; older branchlets also pubescent, rounded, yellowish grey. Buds greenish, viscid, sharp-pointed. Leaves (Plate 410, Fig. 29) on long shoots, ovate or ovate-rhombic, 3 to

¹ First mentioned with a brief description as *P. rasumovskoe* and *P. petrowskoe*, Schroeder, in *Gard. Chron.* xviii. 108 (1882). These ill-spelled names were perhaps misprints for the correct names given above, which appear to have been first published with marks of interrogation by Dieck, *Haupt-Catalog Zöschchen*, 1886, p. 56.

² By *P. canadensis*, possibly *P. marilandica* is meant and not *P. monilifera*. The glands at the base of the leaf confirm the correctness of this parentage. Schneider, *Laubholzkunde*, i. 11, gives the different opinions that have been advanced concerning these hybrids. He considers *P. Rasumowskyana* to be a cross between the Lombardy poplar and *P. suaveolens*.

³ Fischer describes here a balsam poplar, commonly cultivated in Russia, the earliest in leaf at St. Petersburg, and on that account probably not a native of Russia. There is no specimen of this poplar available for comparison; and it is doubtful if it is the same as *P. berolinensis*. In any case the name is invalid, as *P. pseudobalsamifera*, Fischer, *ex* Turczaninow, in *Bull. Soc. Mosc.* i. 101 (1838) is the name given earlier to a specimen, collected by Turczaninow near Lake Baikal, which is preserved in the Kew Herbarium, and is *P. suaveolens*.

4 in. long, about 2 in. broad, rounded or occasionally cuneate at the base, contracted at the apex into a long glandular acuminate point; glabrous on both surfaces, greenish or slightly whitish beneath, but never so plainly white as in the ordinary balsam poplars; margin non-ciliate, with a very narrow translucent border, only visible with a strong lens, and usually with regular crenate serrations ending in incurved glandular points, occasionally irregular with shallow lobes; nerves seven to eight pairs, those at the base arising together and making the leaf pseudo-five- to seven-palminerved; glands at the base of the leaf on the upper surface variable, none, one, or two being present; petiole variable in length, with scattered pubescence, terete, with the groove on the upper surface well-marked or not apparent. Leaves on short shoots, small, rhombic.

Staminate catkins, $2\frac{1}{2}$ to 3 in. long; scales pale green with a brownish edge, ending in about fifteen long filaments; axis glabrous, crowded with flowers; stamens about sixty, with salmon-red anthers and very short slender white filaments; disc glabrous, oblique, slightly concave. Pistillate catkins and fruit not seen; according to Koehne the ovary, fruit, and disc are glabrous.

This poplar occurs in both sexes, the staminate tree being the one commonly known as *P. certinensis*, which is a finer tree at Kew than those labelled *P. berolinensis*, which are probably pistillate, though they have not yet flowered; the latter differ in the looser longer pubescence of the branchlets.

This beautiful tree is stated by Koch to have originated in the old Botanic Garden at Berlin, through the pollination of a tree of *P. laurifolia* by the pollen of either an adjacent black Italian poplar or of a Lombardy poplar. It is a remarkable hybrid, between two species belonging to different sections of the genus (a black poplar and a balsam poplar), and shows intermediate characters, the thin translucent border to the leaf being a character of the black poplar, while the viscid buds and slightly whitish leaves show the influence of the balsam poplar parent. The original tree is no longer living, but dried specimens of it in the Berlin Herbarium show that it was pistillate. The origin of the staminate tree is unknown, but the late Herr Späth informed us that he received it under the name of *P. certinensis* from Dieck of Zöschchen in 1885, and from Transon of Orleans in 1886; and, as Dieck's catalogue of 1885 mentions it as "*P. certinensis* (?) *h. Gall.*," it is likely that it came originally from France.

There are two fine examples of the staminate tree at Kew, which were obtained from Dieck in 1889; these measured, in June 1912, 57 ft. by 3 ft. 5 in. and 50 ft. by 2 ft. 8 in. There is also a good specimen, nearly as tall, at Grayswood, near Haslemere; and another at Glasnevin, about 30 ft. high in 1913.

This species was introduced into America by the Arnold Arboretum, and, according to Professor S. B. Green,¹ is perhaps the best poplar for planting on the prairies of the north-west, as it is perfectly hardy in even the most exposed situations, and is rarely if ever affected with leaf rust, which so often checks the growth of the native cottonwood. Its timber is useful for buildings and floors. It grows readily from cuttings, and bears close planting well. (A. H.)

¹ Cf. L. H. Bailey, *Cornell Univ. Agric. Exp. Station, Bull.* 68, p. 213 (1894).

POPULUS LASIOCARPA

Populus lasiocarpa, Oliver, in Hooker, *Icon. Plant.* xx. t. 1943 (1891); Burkill, in *Journ. Linn. Soc. (Bot.)* xxvi. 536 (1899); J. H. Veitch, in *Journ. R. Hort. Soc.* xxviii. 65, fig. 27 (1903); Schneider, *Laubholzkunde*, i. 17 (1904); Dode, in *Mém. Soc. Hist. Nat. Autun*, xviii. 66 (1905); Gambocz, in *Math. Termes. Közl.* xxx. 120 (1911).
Populus Fargesii, Franchet, in *Bull. Mus. Hist. Nat. Paris*, ii. 280 (1896).

A tree, attaining in China about 60 ft. high. Young branchlets angled, more or less covered with a loose pubescence, very short and yellowish on old trees. Buds large, slightly viscid, with pubescent basal scales. Leaves (Plate 408, Fig. 9) larger than in any other species, about 9 in. long and 6 in. broad, ovate, deeply cordate at the base, with a gland-tipped acuminate apex; margin revolute, glandular and crenately serrate, the serrations uniform and regular throughout; upper surface with a dense pubescent tuft¹ at the base, elsewhere glabrescent; lower surface pale green, with a scattered tomentum, dense on the midrib and nerves, pseudo-five- or seven-palminerved at the base; petiole slightly tomentose, about one-third as long as the blade, rounded with a groove above.

Staminate catkins with numerous flowers on a short pubescent axis; stamens thirty to forty, on a thick slightly concave disc, which has a thin and lobed margin. Fruiting catkins, 5 to 8 in. long, axis pubescent; capsules two- to three-valved, densely tomentose, shortly stalked, with a lobed glabrous disc.

This remarkable species, which is closely allied to the North American *P. heterophylla*,² was discovered by me in 1888, in the mountains of central China, where it occurs in the provinces of Hupeh and Szechwan at 4000 to 6000 ft. elevation.

It was introduced by E. H. Wilson in 1904 into Veitch's nursery at Coombe Wood, where it has proved perfectly hardy.³ It is worth cultivating on account of its large handsome foliage.

(A. H.)

¹ On old trees this pubescent tuft covers two large glands, which appear to be absent on the leaves of young trees.

² *Populus heterophylla*, Linnæus, *Sp. Pl.* 1034 (1753). This species (Plate 408, Fig. 10), which grows in swamps in the United States, along the Atlantic coast and in the Mississippi valley, does not thrive in England, where we have seen no living specimens. Loudon, *Arb. et Frut. Brit.* iii. 1672 (1838), mentions two plants at Syon and in the Mile End Nursery, which, though over fifty years old, were only 5 or 6 ft. in height. According to Späth, *Catalogue*, No. 91, p. 51 (1893-1894), it was not in cultivation on the Continent in 1893, but in that year he reintroduced it. Ascherson and Graebner, *Syn. Mitteleurop. Flora*, iv. 52 (1908), state that it is grown in school gardens for the study of the flowers, which are borne on quite small plants.

³ It was awarded a first-class certificate by the Royal Horticultural Society in 1908. Cf. *Proc. R.H.S.* xxxiv., p. cccxi, fig. 111 (1909).

ULMUS

Ulmus, Linnæus, *Gen. Pl.* 68 (1737) and *Sp. Pl.* 225 (1753); Lindley, in Rees, *Cyclopædia*, xxxvii. Nos. 1 to 13 (1818); Planchon, in De Candolle, *Prod.* xvii. 154 (1873); Bentham et Hooker, *Gen. Pl.* iii. 351 (1880); Schneider, *Laubholzkunde*, i. 212 (1904); Ascherson and Graebner, *Syn. Mitteleurop. Flora*, iv. 546 (1911).
Microptelea, Spach, in *Ann. Sc. Nat.* xv. 358 (1841).
Chaetoptelea, Liebmann, in *Vidensk. Medd. Kjöbenhavn*. 1850, p. 76.

DECIDUOUS or rarely sub-evergreen trees, with furrowed bark, and zigzag branchlets, which are often provided with corky wings. Terminal leaf-buds not formed, the tip of the branchlet dying and dropping off early in the season, leaving a small circular scar close to the uppermost axillary bud, the latter in the following season prolonging the branch. Buds composed of numerous ovate rounded scales, imbricated in two ranks, those of the inner rows accrescent, and marking, when they fall, the base of the branchlet with ring-like scars.

Leaves simple, alternate, placed on the branchlet in two ranks, stalked, simply or doubly serrate, penninerved, asymmetrical at the base,¹ the inner half of the blade being the larger. Stipules lateral, entire, free or connate at the base, usually early deciduous.

Flowers minute, perfect, appearing either in early spring before the leaves in the axils of the leaf-scars of the previous year, or in autumn in the axils of the leaves of the current year; in stalked or sub-sessile fascicles or cymes; articulated on slender two-bracteolate pedicels: calyx, campanulate or funnel-shaped, with four to nine short or deeply divided lobes: stamens three to eight, inserted under the ovary, with thread-like filaments, and two-celled dorsifixed extrorse anthers, which dehisce by two longitudinal openings; ovary usually one-celled by abortion, sessile or stalked; style with two spreading lobes, stigmatic on the inner surface; ovule solitary, suspended from the apex of the cell.

Fruit, a samara, ripening in two or three months after flowering, surrounded at the base by the remains of the calyx, notched at the apex, the notch open or closed by the incurved persistent stigmas and ciliate within; seed-cavity in the centre or above it, compressed, slightly thickened in margin, and produced into a thin peripheral reticulate membranous wing. Seed solitary, suspended from the apex of the cavity, without albumen; cotyledons flat, raised above the ground in germination.

¹ Cf. Van Tieghem in *Ann. Sci. Nat. (Bot.)*, iii. 377 (1906), on the peculiar asymmetry in the leaves and stipules of the elm.

The genus *Ulmus* comprises about twenty species, natives of the extra-tropical parts of the northern hemisphere, extending in North America to the mountains of southern Mexico, but not occurring in the Pacific coast region; widely distributed in the Old World, throughout Europe, and in Algeria and Morocco, and spread through Asia in Siberia, Asia Minor, Persia, Turkestan, Afghanistan, the Himalayas, China, Tongking, Japan, and Formosa.

The genus is divided into three sections:—

I. BLEPHAROCARPUS, Dumortier, *Fl. Belg.* 25 (1827).

Orioptelea, Spach, in *Ann. Sc. Nat.* xv. 363 (1841).

Leaves, deciduous in autumn. Flowers opening early in spring before the leaves, on elongated unequal pedicels; calyx oblique, with five to eight unequal short lobes. Samaræ densely ciliate in margin.

Of the species in cultivation, *U. americana*, *U. racemosa*, *U. alata*, and *U. pedunculata* belong to this section.

II. MADOCARPUS, Dumortier, *Fl. Belg.* 25 (1827).

Dryoptelea, Spach, in *Ann. Sc. Nat.* xv. 363 (1841).

Leaves deciduous in autumn. Flowers opening early in spring before the leaves, on very short pedicels; calyx with four to seven equal short lobes. Samaræ non-ciliate.

Of the species in cultivation, *U. montana*, *U. nitens*, *U. campestris*, *U. major*, *U. minor*, *U. pumila*, *U. japonica*, and *U. fulva* belong to this section.

III. MICROPTOLEA, Planchon, in *Ann. Sc. Nat.* x. 260 (1848).

Leaves sub-persistent or tardily deciduous. Flowers opening in autumn, on short pedicels; calyx deeply divided into four to eight equal long lobes. Samaræ ciliate or non-ciliate.

Of the species in cultivation, *U. parvifolia* and *U. crassifolia* belong to this section.

About fifteen species of *Ulmus* are in cultivation, and may be arranged as follows:—

I. *Leaves with sixteen to twenty pairs of lateral nerves.*

* *Leaves, with lateral nerves rarely forked; axil-tufts inconspicuous or absent.*

(a) *Leaves ciliate in margin. Branchlets without corky ridges.*

1. *Ulmus pedunculata*, Fougereux. Europe. See p. 1851.

Leaves usually obovate and widest above the middle, 2 to 4 in. long, biserrate with incurved serrations, smooth above, densely pubescent beneath. Buds elongated, fusiform, sharp-pointed.

2. *Ulmus americana*, Linnæus. North America. See p. 1855.

Leaves oval, widest about the middle, 3 to 5 in. long, biserrate with incurved serrations, scabrous or smooth above, more or less pubescent beneath. Buds ovoid, obtuse.

(b) *Leaves non-ciliate in margin. Branchlets developing corky ridges in the second or third year.*

3. *Ulmus racemosa*, Thomas. North America. See p. 1860.

Leaves oval or elliptic, about 3 in. long, usually sub-cordate at the base, biserrate with incurved points, glabrous and smooth above, slightly pubescent beneath without any trace of axil-tufts.

** *Leaves, with lateral nerves often forked, and with conspicuous axil-tufts.*

(a) *Young branchlets scabrous with numerous minute tubercles. Leaves ciliate in margin.*

4. *Ulmus fulva*, Michaux. North America. See p. 1862.

Leaves oval or obovate, 5 to 7 in. long, scabrous above with minute tubercles and short bristles, densely pubescent beneath, coarsely biserrate.

(b) *Young branchlets smooth. Leaves non-ciliate.*

5. *Ulmus montana*, Stokes. Europe, Asia Minor, Caucasus, Amurland, Manchuria, Japan. See p. 1864.

Branchlets stout, pubescent with stiff hairs. Leaves obovate or oval, 3 to 5 in. long, with short stout petioles, not exceeding $\frac{1}{8}$ in. in length; scabrous above, densely pubescent beneath.

6. *Ulmus vegeta*, Lindley. A hybrid.¹ See p. 1879.

Branches long, straight, and ascending. Branchlets slender, glabrous or with a few scattered hairs. Leaves oval, $3\frac{1}{2}$ to 5 in. long; smooth or nearly so and glabrous above; glabrous beneath except for axil-tufts; petiole $\frac{1}{4}$ to $\frac{3}{8}$ in. long.

II. *Leaves, with eight to fourteen pairs of lateral nerves; very unequal at the base; plainly biserrate; and with conspicuous axil-tufts beneath.*

* *Young branchlets glabrous, or with only a few scattered hairs.*

7. *Ulmus major*, Smith. Europe. See p. 1883.

Leaves broadly oval, 3 to 5 in. long, nearly smooth above, with a scattered minute pubescence on both surfaces, and dense axil-tufts beneath; petiole $\frac{1}{4}$ to $\frac{3}{8}$ in. long, pubescent. Epicormic branches with large corky ridges are usually present on the stem.

8. *Ulmus nitens*,² Moench. Europe, Algeria, Asia Minor, Caucasus, Persia, Turkestan. See p. 1887.

Leaves oval or obovate, 2 to $3\frac{1}{2}$ in. long, shining and smooth above; with scattered minute pubescence on both surfaces in spring, disappearing in summer; glandular beneath; petiole $\frac{1}{4}$ to $\frac{1}{2}$ in. long, pubescent.

9. *Ulmus minor*, Miller. Europe. See p. 1901.

Leaves elliptic, $1\frac{1}{2}$ to $2\frac{1}{2}$ in. long, acute or acuminate at the apex; dull and

¹ The other less common hybrids, having *U. montana* as one of the parents, are described, pp. 1868-1874. Most of these hybrids have leaves with numerous lateral nerves; but differ in habit and other characters from *U. montana* and *U. vegeta*.

² This species is very variable, and only the typical form is here indicated.

slightly scabrous above; glandular and ultimately glabrescent beneath, except for conspicuous axil-tufts; lateral nerves few, 8 to 10 pairs; petiole, $\frac{1}{3}$ in. long.

** *Young branchlets densely pubescent.*

10. *Ulmus campestris*, Linnæus. Southern England, Spain(?). See p. 1903.

Leaves broadly oval or ovate, 2 to 3 in. long; scabrous and minutely pubescent above; covered beneath with a dense soft pubescence: lateral nerves, 10 to 12 pairs; petiole $\frac{1}{5}$ in. long, densely pubescent. Branchlets without corky wings.

11. *Ulmus japonica*, Sargent. Japan, Manchuria. See p. 1923.

Young branchlets light brown, often roughened with minute tubercles or ridges. Leaves obovate or elliptic, 3 to 4 in. long; scabrous above with minute tubercles and short bristles; densely pubescent beneath; lateral nerves 12 to 16 pairs. Branchlets often with corky wings.

- III. *Leaves, with eight to twelve pairs of lateral nerves; often nearly equal at the base; often simply serrate; axil-tufts inconspicuous or absent.*

* *Leaves deciduous in autumn.*

(a) *Branchlets with corky wings.*

12. *Ulmus alata*, Michaux. North America. See p. 1924.

Leaves light green, thin in texture, oblong-lanceolate, about 2 in. long, acute or acuminate at the apex, smooth above, with axil-tufts beneath, biserrate; nerves rarely forked.

13. *Ulmus crassifolia*, Nuttall. North America. See p. 1925.

Leaves light green, coriaceous, oval, 1 to 2 in. long, acute or rounded at the apex, often subcordate at the base, scabrous above, without axil-tufts beneath; often biserrate; nerves usually forked; stipules persistent till May.

(b) *Branchlets without corky wings.*

14. *Ulmus pumila*, Linnæus. Turkestan, Eastern Siberia, Manchuria, Korea, North China. See p. 1926.

Leaves thin and flexible in texture, ovate to ovate-lanceolate, 1 to 2 in. long, acute or acuminate at the apex, scabrous or smooth above, with axil-tufts and scattered minute pubescence beneath.

** *Leaves deciduous in January.*

15. *Ulmus parvifolia*, Jacquin. China, Tongking, Formosa, Japan. See p. 1928.

Leaves coriaceous, obovate or ovate-lanceolate, 1 to $1\frac{3}{4}$ in. long; shining, dark green, smooth and glabrous above; glabrous beneath, but occasionally with axil-tufts near the base. (A. H.)

ULMUS PEDUNCULATA, EUROPEAN WHITE ELM

Ulmus pedunculata,¹ Fougereux, in *Mem. Acad. Roy. Sc.* 1784, p. 215, t. 2.

Ulmus levis, Pallas, *Fl. Ross.* i. 75, t. 48, fig. F. (1784); Ascherson and Graebner,² *Syn. Mitteleurop. Flora*, iv. 548 (1911).

Ulmus effusa, Willdenow, *Fl. Berol. Prod.* 97 (1787) and *Berl. Baumz.* 393 (1796); Loudon, *Arb. et Frut. Brit.* iii. 1397 (1838); Willkomm, *Forstl. Flora*, 559 (1887); Fliche, *Flore Forestière*, 304 (1897).

Ulmus ciliata, Ehrhart, *Beitr.* vi. 88 (1791).

Ulmus octandra, Schkuhr, *Handb.* i. 178, t. 57 (1791).

Ulmus racemosa, Borkhausen, *Forstbot.* i. 851 (1800) (not Thomas).

A tree, attaining about 100 ft. in height and 12 to 20 ft. in girth. Bark similar to that of *U. americana*, smooth at first, then exfoliating in broad thin scales, and ultimately deeply fissured as in the other elms. Young branchlets densely clothed with white short wavy pubescence, partly retained on the branchlets of the second year which are slightly fissured but not finely striate. Buds longer and more sharply pointed than those of *U. americana*; with glabrous scales, which are minutely ciliate in margin. Leaves (Plate 411, Fig. 7), obovate and widest above the middle, or oval, 2 to 4 in. long, and $1\frac{1}{2}$ to $2\frac{1}{2}$ in. wide; very oblique and unequal at the base, the upper side rounded, the lower side rounded or straight; suddenly contracted at the apex into a serrated point; upper surface smooth to the touch, pubescent on the midrib and veins, elsewhere glabrous or with a few scattered hairs; lower surface pale green, covered with a dense short white pubescence; margin coarsely biserrate, with sharp incurved points, ciliate; nerves about sixteen pairs, running straight and parallel to the margin, with one or two rarely forked; petiole $\frac{1}{4}$ in. long, densely pubescent.

Flowers, twenty to twenty-five in a cluster, on long slender pedicels ($\frac{1}{4}$ to $\frac{3}{4}$ in. in length); calyx campanulate, oblique, with five to seven short pink lobes; stamens five to seven, with white filaments and red anthers; ovary green, pubescent on the margins, with white stigmas. Samaræ, on long slender stalks, oval or ovate, $\frac{3}{8}$ to $\frac{1}{2}$ in. long, conspicuously reticulate and glabrous on the surface, densely ciliate in margin with long white hairs; apex with a deep cleft, usually closed by the incurved stigmas; seed situated towards the base of the samara, with its apex close to the base of the notch.

Seedlings, raised in 1909 at Cambridge, were very uniform, all bearing in the first year six to eight pairs of opposite leaves. In 1911, these seedlings still preserved their uniform character, and were readily distinguishable by their ciliate leaves, and the absence of corkiness on the branchlets.

This species, like *U. americana*, is often remarkable in old age for the sharp

¹ This name was published by Fougereux in a paper, read at Paris on 1st September 1784. Pallas's name was published later in the same year, according to a note by Fougereux, appended to his paper when it appeared in the volume of the *Mém. Acad. Roy. Sc.*, for 1784, which was issued in a complete form in 1787.

² *U. alba*, Kitaibel, in Willdenow, *Berl. Baumz.* 318 (1796), judging from the description, and also from a tree so named in the Leyden Botanic Garden, is a variety of *U. nitens*, and not a synonym of this species, as stated by Ascherson and Graebner. *U. alba*, Besser, *Enum. Pl. Volhynia*, pp. 43, 92 (1822), is *U. pedunculata*.

protruding ribs at the base of the trunk, with deep concave recesses between them. The stem, as in the American species, usually produces an abundance of pendulous epicormic shoots. Fliche states that it suckers freely from the roots, and gives abundant coppice shoots.¹ It does not appear ever to form corky wings on the twigs. The leaves usually turn a yellowish colour in autumn.

Klotzsch,² who was curator of the Berlin Herbarium, crossed *U. pedunculata* with "*U. campestris*" (probably *U. nitens*) in 1845; and raised seedlings from both the cross-fertilised seeds and from the seeds of the parent trees; and after eight years' growth under similar conditions, the hybrid seedlings were one-third taller than the others.

VARIETIES

U. pedunculata does not differ from *U. americana* in the characters of the flowers or fruits; and can only be kept distinct³ from that species, on account of its usually smaller and more oblique leaves, which are smooth above to the touch. *U. pedunculata* as described above has usually leaves densely pubescent beneath; but trees with almost glabrous leaves are occasionally seen in cultivation. The most remarkable variety in the wild state⁴ is the following:—

1. Var. *celtidea*, Rogowicz, *Fl. Kief*, 229 (1869); Köppen, *Holzgewächse Europ. Russlands*, ii. 33 (1889); Chitrovo, in *Bull. Soc. Nat. Orel*, i. 50, t. 1 (1907).

Var. *glabra*, Trautvetter, in *Bull. Phys. Math. Acad. Imp. Sc. St. Petersburg*, xv. 349 (1857).
Ulmus celtidea, Litwinow, *Schedæ Herb. Fl. Ross.* vi. 167 (1908).

Leaves oblong-lanceolate, about 1 in. in length, long acuminate at the apex, coarsely and sharply serrate, cuneate and subequal at the base, nearly quite glabrous beneath. Stamens five or six. Samaræ smaller than in the type.

This peculiar elm was found by Rogowicz in 1856 near Chernigof. Lately, another remarkable tree has been discovered near Briansk in the Orel province, which has similarly shaped trees, but much larger in size, 4 to 5 in. long, and pubescent beneath. Seedlings of this tree raised at Kief have broad leaves as in the typical form of the species.

The following horticultural varieties,⁴ none of which are in cultivation in England, have been described.

2. Var. *punctata*, Schelle, *Laubholz-Benennung*, 87 (1903).

Leaves variegated with white.

¹ The leaves on coppice shoots, which I gathered in 1912 near Rochefort in Belgium, are very large, 6 to 9 in. long and 4 to 5 in. broad, oval, with a single long cuspidate point at the apex, nearly equal at the rounded base, scabrous with short bristles on the upper surface, sparsely pubescent beneath.

² In *Monatsbericht K. Preuss. Akad. Wiss. Berlin*, 1854, pp. 535-562, abstracted in *Bull. Soc. Bot. France*, ii. 327 (1855). Klotzsch, whose article is of great interest, seems to have been the first botanist to make experiments in crossing forest trees. In 1845 he also crossed *Pinus sylvestris* and *P. austriaca*, *Quercus sessiliflora* and *Q. pedunculata*, *Alnus incana* and *A. glutinosa*; and in each case raised hybrid seedlings of great vigour; and claimed that by hybridisation, both the rapidity of growth and durability of the timber of forest trees could be augmented considerably. Cf. Darwin, *Animals and Plants under Domestication*, ii. 130 (1868).

³ Jouin showed Elwes in Simon-Louis's nursery at Metz young trees of both species. Those of *U. pedunculata* had much smoother bark; but it is doubtful if this character is a constant one.

⁴ Hayne, *Arz. Gew.* iii. t. 17 (1813), described four varieties, which are unworthy of retention, being based on trifling variations in the flowers and leaves. Zapalowicz, *Consp. Fl. Galic.* ii. 96 (1908), has lately described two varieties, which I have not seen.

3. Var. *aureo-variegata*, Schelle, *loc. cit.*

Leaves spotted with yellow.

4. Var. *erubescens*, Von Schwerin, in *Mitt. Deut. Dend. Ges.* 1911, p. 423. Leaves turning a beautiful red in autumn.

5. Var. *urticæfolia*, Jacques, *ex De Vries, Plant Breeding*, 614 (1906).

A chance seedling, with lacinate leaves, which was raised by Jacques in 1830, and subsequently was multiplied by grafting. This variety appears to be lost, as it is not now known in cultivation.

6. Bolle mentions a pyramidal form, which is growing in the cemetery at Fredericksfelde near Berlin.

DISTRIBUTION

U. pedunculata is a native of central Europe, being distributed from eastern France to Russia. It is not a native of the British Isles or of Scandinavia,¹ and is nearly absent from the Mediterranean region, being unknown in Spain and Portugal, only recorded from two stations in northern Italy, and very rare in Greece.

It appears to be most widely spread in Russia,² where it is prevalent except in the extreme north and the region of the steppes, its northern limit extending from southern Finland across Lake Onega, the valley of the Dwina as far north as lat. 63°, and Perm, to the western side of the Ural range. It usually occurs scattered in the broad-leaved forests, but is more common than *U. montana* in the governments of Tula and Moscow. In Russia³ it is planted along the railways as a protection against snowdrifts in winter. It also occurs in the Crimea and the Caucasus.

It is a rare tree in Belgium, Holland, and Denmark; but is met with in central and northern Germany, especially in Brandenburg,⁴ where the finest trees occur on the banks of the Havel and Spree, some being 100 feet in height and 20 ft. in girth. In Germany it usually grows in damp deciduous woods, and on the swampy banks of streams and lakes. It is recorded for a few stations in Switzerland,⁵ Montenegro, Roumania, Bulgaria, and Servia, where I saw in 1909 a tree about 50 ft. high on the banks of the Drina, near Zvornik. (A. H.)

In France it is only found in the north-east, in a few stations, though according to Fliche⁶ it has probably been more abundant, as it occurs mostly on rich and fertile soils in the plains which are now cultivated. It is most numerous in the south-east of the department of the Ardennes in the forest of Mondieu and at Stenay, both in the valley of the Meuse. It never grows in quantity, but is scattered in mixture with *Quercus pedunculata* in damp places, associated with ash, willow, aspen, birch, and alder. It is also found near Gray in the upper Saône valley, and

¹ Schübeler says it grows well on the south and west coast of Scandinavia, and Elwes saw it planted near Stockholm.

² Köppen, *Holzgewächse Europ. Russlands*, ii. 26 (1889). It occurs in Finland on the shores of the Gulf, but Elwes did not see it in the forest of Raivola.

³ *Garden and Forest*, 1890, p. 475.

⁴ Bolle, in *Garden and Forest*, 1888, p. 381.

⁵ Dr. Christ says it occurs wild only at Schaffhausen; but I have a specimen from Mr. A. B. Jackson, collected at the foot of the Harderberg, near Interlaken.

⁶ In *Bull. Soc. Bot. France*, xlvi. 381 (1901).

near Luneville, in the Meurthe valley. M. Guinier, of the Forestry School at Nancy, to whom I am indebted for the above information, was good enough to show me this tree on the banks of the Moselle, just below the Château de la Fli, near Liverdun, on 5th May 1911 when it was in flower, and the leaves about half expanded. The trees were not large, and their bark seemed more scaly than that of *U. montana*. Though the habit seemed more pendulous than that of the wych elm, I do not think the tree could be certainly distinguished in winter except by the buds, and some trees looked as though they might be hybrids. Reuss states¹ that a few trees of *U. pedunculata* occur in the forest of Fontainebleau. M. Jouin at Plantières, near Metz, informed me that, as this species is much less subject to the attacks of the elm-leaf beetle² than *U. nitens*, it is likely to be much more generally planted in that part of France, but the wood is considered inferior to that of the other elms by those who distinguish it.³ Loudon⁴ mentions in 1841 an enormous tree of this species, with three great trunks, in the nursery ground at Neuilly, near Paris; but we do not know if it is still living. I saw a log under this name in the Hungarian Exhibition at London in 1908, which was very similar in appearance to *U. montana*.

In Belgium, according to Huberty,⁵ this tree is only found in the district about Rochefort, where it grows on calcareous soil in fertile valleys on the edge of woods, but is rather local, and of no economic importance. The largest tree I heard of grows at the mouth of the Gouffre de Belvaux, where a stream disappears in the limestone rock and comes up again some way off at Han-sur-Lesse, celebrated for its extensive caverns. This tree was pollarded many years ago, and has a sound trunk about 15 ft. high by 16 ft. in girth, its total height being about 60 ft. It has been figured by Huberty.⁵ I could find no other trees of the sort near it except some small bushy ones apparently produced from suckers.

Hempel and Wilhelm⁶ give an illustration of a tree, about 80 ft. high, in the Prater at Vienna, which has wide-spreading branches. I saw this elm in June 1910 in west Slavonia, in the virgin forest of Subanja, which is mainly composed of old oak trees, with a mixture of hornbeam, lime, maple, and ash.

Loudon states that the date of the introduction of this species is unknown; and

¹ *Compte Rendu Congrès Internat. Sylviculture, Paris, 1900*, p. 683.

² *Galericella luteola*, Müll. (more widely known as *G. xanthomelana*, Schr.), a small beetle belonging to the family Chrysomelidae, 6 to 8 mm. long, pale sordid yellow or yellowish brown above, with a stripe along the outer margin of the elytra, a short line on each side of the scutellum, a central and two lateral spots on the thorax, and a spot on the head, black. This insect is very destructive to the foliage of young elms both in its larval and perfect states; and, as I was assured by M. Jouin, is a serious hindrance to the raising of elms in his nursery. It is not, however, a native of Britain, and in the opinion of Mr. G. C. Champion, a competent coleopterist who has observed its ravages on the Continent, the climate of this country is unsuitable for its establishment, even if it were introduced with plants. In America, where it was introduced from Europe in 1837, its depredations have of late years attracted considerable attention. Pardé, in *Bull. Soc. Dend. France*, 1909, p. 100, agrees with Jouin as to the comparative immunity from this pest of *U. pedunculata*.

³ Fliche, in *Bull. Soc. Bot. France*, xlviii. 381 (1901), states that the wood is little esteemed, partly on account of its pale yellowish colour, whence it is called *orme blanc*; but mainly because it fails in strength and elasticity, and is unfit for many purposes for which the other elms are valuable. It even makes poor fuel; and is always classed in commerce with soft woods, like poplar, etc.

⁴ *Gard. Mag.* xvii. 389 (1841).

⁵ In *Bull. Soc. Cent. Forest. Belg.* xi. 634, pl. xii. (1904).

⁶ *Bäume u. Sträucher des Waldes*, iii. 9, figs. 234, 235 (1889). The botanical details are well illustrated in t. 39 of this work.

the only large tree which he mentions, one at White Knights, which was 63 ft. high in 1838, is no longer living.

The finest specimen in England is a tree (Plate 389) at Syon,¹ which is 90 ft. in height and 12 ft. 8 in. in girth. This was long supposed to be *U. americana*; but it agrees better in the characters of the foliage with *U. pedunculata*, and like the latter species at Kew and elsewhere, produces flowers regularly every year, which is not the case with trees of *U. americana* in this country. There are two good specimens at Kew, one about 25 ft. high, which was obtained from Späth in 1895. It produced good seed in 1909, from which seedlings were raised at Cambridge. Another tree, obtained from Booth in 1872, is about 35 ft. high, and very thriving.

At Ugbrooke Park, Devonshire, the seat of Lord Clifford of Chudleigh, I found in April 1908 a row of seven large trees, in the park near the house, which I at once recognised by their flowers, though the leaves were not yet out. I saw these again on 28th November of the same year, when the leaves had fallen about three weeks previously, though those of the English elm were still of a golden colour. Their buds were more swollen than those of the Dutch elms near, which also had some leaves on, and the bark and habit differs from that of English and wych elms. I could find no suckers near any of the trees,² one of which is figured in Plate 390. The average height was 80 to 85 ft., and the girth of ten trees, three of which are on the other side of the avenue above the oaks, varied from 11 ft. to 14 ft. 8 in. Neither Lord Clifford nor the gardener, Mr. Abraham, could tell me anything of the age or history of these trees, which must have been brought from abroad over a century ago.

(H. J. E.)

ULMUS AMERICANA, AMERICAN WHITE ELM

Ulmus americana, Linnæus, *Sp. Pl.* 226 (1753); Loudon, *Arb. et Frut. Brit.* iii. 1406 (1838);

Sargent, *Silva N. Amer.* vii. 43, t. 311 (1895), and *Trees N. Amer.* 289 (1905).

Ulmus mollifolia, Marshall, *Arb. Amer.* 156 (1783).

Ulmus pendula, Willdenow, *Berl. Baumz.* 519 (1811).

Ulmus alba, Rafinesque, *Fl. Ludovic.* 115 (1817), and *New Fl.* iii. 39 (1836), (not Kitaibel).³

Ulmus floridana, Chapman, *Flora*, 416 (1865).

A tree, attaining in America 120 ft. in height and 30 ft. in girth. Bark grey, divided by deep fissures into broad scaly ridges. Young branchlets occasionally glabrous but usually clothed with a soft white pubescence, more or less retained on the second year's branchlets, which are fissured but not finely striate on the surface. Buds ovoid, obtuse, with glabrous ciliate scales. Leaves (Plate 411, Fig. 11) oval, usually widest about the middle or below it, 3 to 5 in. long, 1½ to 2½ in. wide; oblique and unequal at the base, with the upper side rounded and the lower side straight;

¹ In the Syon catalogue of 1849, this tree is noted as having then measured 85 ft. by 10 ft.

² These trees were found to be infested with the elm Psylla (*Psylla ulmi*, L.), but the circumstance is not of economic importance, since there is no reason to believe that this insect is more detrimental to the elm than is its congener *Psylla alni* to the common alder. The nymphs of the elm Psylla live in the axils of the leaves on the ends of the twigs, and enter the imago state in June. The imagines do not hibernate, but lay their eggs in the autumn; a circumstance which would point to the introduction of the species with young trees. It is remarkable that the elm Psylla has never been found in this country on any other species of elm.

³ Cf. p. 1851, note 2.

abruptly narrowed at the apex into a serrated point; upper surface dark green, smooth or scabrous to the touch, with scattered stiff short hairs arising from minute tubercles; lower surface pale, covered with a soft dense pubescence, conspicuous on the midrib and nerves, and occasionally forming minute axil-tufts at their junctions;¹ nerves sixteen to twenty pairs, running straight and parallel to the margin, only one or two being forked; margin coarsely biserrate with sharp incurved points, ciliate; petiole $\frac{1}{4}$ in. long, densely pubescent.

Flowers, about twenty in a cluster, on long slender pedicels (about $\frac{1}{2}$ to $\frac{3}{4}$ in. in length); calyx broadly campanulate, oblique, with six to eight short pinkish lobes; stamens six, seven or eight, exerted, with white filaments and red anthers; ovary green, with ciliated margins, and white stigmas. Samaræ, on long slender stalks, ovate or elliptic, $\frac{3}{8}$ to $\frac{1}{2}$ in. long, with prominent reticulations, glabrous on the surface, densely ciliate on the margin with long white hairs; with a deep notch at the apex, closed by the incurved stigmas. Seed towards the base of the samara, with its apex close to the base of the notch.

This tree, which never develops corky ridges on the branchlets, usually produces short pendulous epicormic shoots on the stem. It is very variable in habit, as is well seen in the trees at Hargham in Norfolk. In America, when growing in the forest, the stem is usually undivided for a great height, and surmounted by a compact crown. When growing in the open the tree shows well-marked differences in habit, which are described by Dame and Brooks,² as follows:—

“1. In the vase-shaped tree,³ usually regarded as the type, the trunk separates into several large branches, which rise, slowly diverging 40 to 50 ft., and then sweep outward in wide arches, the smaller branches and spray becoming pendent.

2. In the umbrella form, the trunk remains entire nearly to the top of the tree, when the branches spread out abruptly, forming a broad shallow arch, fringed with long drooping branchlets.

3. The slender trunk of the plume elm⁴ rises, usually undivided, a considerable height, begins to curve midway, and is capped with a one-sided tuft of branches and delicate elongated branchlets.

4. The drooping elm⁵ differs from the type in the height of the arch, and greater droop of the branches, which sometimes sweep the ground.

5. In the oak form the limbs are more or less tortuous, and less arching, forming a wide-spreading rounded head.”

Only a few horticultural varieties are known:—

1. Var. *pendula*, Aiton, *Hort. Kew.* i. 320 (1789).

Branches wide-spreading and arching downwards, with pendulous branchlets. This is said by Aiton to have been cultivated by Mr. James Gordon in 1752.

¹ Loudon says that *U. americana* is readily distinguished by the peculiar membrane in the axils of the veins. This membrane, uniting the base of the nerve with the midrib, is usually present only on the nerves of the outer half of the leaf.

² *Trees of New England*, 95 (1902).

³ Figured by Sargent, in *Garden and Forest*, iii. 287 (1890).

⁴ A tree of this kind, called the “feathered” form by Sargent, growing at Sandwich, New Hampshire, is figured in *Garden and Forest*, iii. 467 (1890).

⁵ The Clark elm at Lexington, with pendulous branches, which sweep the ground, is figured in *Garden and Forest*, iii. 443 (1890).

There are two specimens at Kew, about 20 ft. high, which were obtained from Späth in 1896. These occasionally develop stray branchlets, bearing enormous leaves, 7 in. long by $4\frac{1}{2}$ in. broad.

This is probably not quite the same as Beebe's weeping elm, which was distributed by Meehan as *U. fulva*, var. *pendula*, but which, according to Sargent¹ is really a form of *U. americana*. It was propagated from a tree, resembling in habit a weeping willow, which was found growing wild near Galena, Illinois.

2. Var. *aurea*, Temple, *ex* Rehder, in Bailey, *Cycl. Amer. Hort.* 1880 (1902). Leaves yellow. This was found in Vermont by F. L. Temple.

U. americana,^p which is known, on account of the light colour of its bark, as “white elm” in America, is widely distributed, occurring from southern Newfoundland through Canada to the northern shores of Lake Superior and the eastern base of the Rocky Mountains, ascending the Saskatchewan river to lat. $54^{\circ} 30'$; and extending through the United States southwards to Florida, and westwards to the Black Hills of Dakota, western Nebraska, western Kansas, Indian Territory, and the valley of the Rio Concho in Texas.

The tree does not occur in pure stands, but sparingly in mixture with oak, ash, plane, tulip tree, and other hard woods; and attains its best development on deep fertile alluvial soil. It, however, readily adapts itself to less favourable soils, and is a hardy tree enduring great extremes of temperature and moisture. It is somewhat intolerant of shade.²

This species produces coppice shoots, when the tree is cut down; and at Hargham, numerous suckers, some of which are now trees 30 ft. in height, were produced after a tree had been felled. No suckers are produced, so far as we know, by living trees either in this country or in America. (A. H.)

No tree has attracted more attention among American writers, or is more dear to the natives of New England, than the American elm, which is a conspicuous ornament and the favourite shade tree in the older cities, and has quite a literature of its own.

Though some of the historic trees mentioned by Emerson and other writers are now dead or decayed, there are still many splendored survivors of the original forest. Among these none is larger and more symmetrical than the Lancaster Elm in Massachusetts, which Prof. Sargent showed me in May 1904. It grows on deep sandy soil in the rich valley of the Nashua river, and measured 105 ft. by 24 ft. at five feet from the ground. The roots spread so widely that at ground level they are 45 ft. round. The trunk forks at 10 ft. into three tall stems; and though some holes and cracks show that the tree is past maturity, these wounds have been so carefully stopped with cement, by its owner, Mr. J. E. Thayer, that it may live for many years. Plate 391, for which I am indebted to Mr. A. H. French, of Brookline, Mass., gives an excellent picture of it.

A monster elm³ on the Avery Durfee farm in Wayne County, New York,

¹ *Garden and Forest*, i. 286 (1889).

² Cf. Pinchot, *U.S. Forest Circ.* No. 66 (1907), which gives directions for planting this tree in the United States.

³ *Garden and Forest*, iii. 60 (1890).

between Palmyra and Marion, measures, at two feet above the ground, 33 ft. 10 in. in circumference, and at five feet above the ground 20 ft. 10 in. It is 60 ft. to the first limb; and the total amount of lumber in the body of the tree is 16,250 board ft. Eighty years ago, when the farm was cleared, this tree was left as a landmark. It was then a giant amongst the surrounding forest trees.

A very fine elm, presumably of this species, which differs much in habit from any *U. americana* that I have seen, is figured and described¹ by Mr. T. H. Hoskins, who, however, does not say what the species is. The tree is evidently a relic of the original virgin forest, and grows near the highway at Derby Line close to the Canadian boundary in Orleans County, Vermont. It has a clean bole for more than half its height with a very small head, and measures 102 ft. in height with a girth of 18 ft. 2 in. at five feet from the ground.

To give an idea of the rapidity with which this species grows I may cite Emerson, who says,² quoting from the *N. E. Farmer*, vii. 299, "An elm tree nearly opposite the house of Heman Day, Esq., in West Springfield, was planted by him on 8th January 1775, when it was a sapling carried in the hand. In 1829 the trunk was 18 ft. in circumference to the height of 12 ft. above the ground, where it divides into branches which overhang a circle of more than 300 ft. in circuit covering 7500 square ft. of area." It had thus grown 216 in. in girth in fifty-four years, or at a rate of 4 in. a year. In 1845 this tree was carefully measured by a gentleman at Springfield, who found it 7 ft. in diameter at three feet from the ground, and 7 ft. 4 in. at eleven feet. The spread of the top was 134 ft.

CULTIVATION

According to Loudon this tree was introduced to England by James Gordon in 1752, though unnoticed in Miller's Dictionary published sixteen years later. It appears to have been short lived, as none were to be found in Loudon's time either at Kew or Syon, and the only specimens he mentions as then living in England were young trees 15 to 30 ft. high in the Horticultural Society's Garden at Chiswick. We have been able to recognise no old trees of it now in the country, and very few young ones. Of these the best are those at Hargham, Norfolk, where they were planted by Sir Thomas Beevor about 1854. Here there are now thirty trees varying somewhat in habit. The largest of these is one of a group of three by a sunk fence south-west of the house, and measured 85 ft. by 7½ ft. in 1911. Another in 1905 measured 68 ft. by 8 ft. 4 in. (Plate 392). A third near the farm buildings has more spreading and drooping branches, some of which have been broken by wind; its leaves are thicker and more glabrous than those of the others. I showed fresh specimens of these to Dr. N. L. Britton of New York, who thought that they all belonged to *U. americana*. I could find no suberous branchlets on any of these trees, but noticed on 24th August 1909, that their leaves were much eaten by caterpillars, which had not

¹ *Garden and Forest*, v. 303, fig. 55 (1892).

² *Trees and Shrubs of Massachusetts*, ii. 332 (1875).

injured the native elms. They seldom flower, but one of these trees has borne seed from which plants were raised in 1909. The soil on which they grow is a light sandy loam of one or two feet depth on the chalky boulder clay. At one spot only, and in a hawthorn thicket, two young trees about 30 feet seem to have sprung from suckers. The parents of these, a thickly-planted cluster, died about seventeen years ago. Sir Hugh Beevor states that there are six trees of the same age at Wilby Hall, about a mile and a half from Hargham; and says that this species has a distinctive charm and moreover very rarely suckers, and that he will plant it for ornament in future at Hargham, in preference to other elms.

Another tree, growing at Hildenley, Yorkshire, was raised from seed by the late Sir Charles Strickland about 1870 and measured in 1905 44 ft. by 3 ft. There are also two small trees by the garden road at Tortworth; a small tree in Silkwood, Weston Birt; small trees planted by myself in Congham Wood, Norfolk, which are growing fairly well in sandy soil; and several at Colesborne which at present do not seem to suffer from the lime in the soil.

In Scotland Henry found a tree at Methven, Perthshire, which in 1904 was about 60 ft. by 5½ ft. Loudon says that in 1828 there was a tree in the Botanic Garden at Edinburgh which we cannot now find.

In Ireland Henry saw in 1903 the stump of a tree¹ blown down in that year which grew in Trinity College Botanic Garden, Dublin, and was said by the late F. W. Burbidge to have been 80 ft. high.

In France it seems to succeed no better than in England; and M. Jouin informs me that many specimens in the east of France and in Alsace grown as *U. americana* are in reality *U. pedunculata*.

TIMBER

Sargent says of this wood that it is heavy, hard, strong, tough, difficult to split, and rather coarse-grained, light brown in colour, with thick sap wood which is paler. It is largely used in the States for wheel hubs, saddle trees, flooring, and cooperage, and in boat- and ship-building. It is now imported to London in the form of boards which are used as a cheap substitute for coffin boards. I am informed by Mr. A. H. Ross of the Toronto University that a great deal of what is now known in the trade as rock elm, a name properly used for *U. racemosa*, is really taken from *U. americana*; and judging from the specimens I have seen, and from those in Hough's *American Woods*, the two are difficult to distinguish. (H. J. E.)

¹ The lower part of the stem of this tree, which is 21 in. in diameter and shows eighty-two annual rings, is preserved in the Forestry Museum at Avondale.

ULMUS RACEMOSA, ROCK ELM

Ulmus racemosa, Thomas, in *Amer. Journ. Sci.* xix. 170 (1831) (not Borkhausen¹); Sargent, *Silva N. Amer.* vii. 47, t. 312 (1895), and in *Bot. Gaz.* xlv. 225 (1907).
Ulmus Thomasi, Sargent, *Silva N. Amer.* xiv. 102 (1902), and *Trees N. Amer.* 290 (1905).

A tree, attaining in America 100 ft. in height and 10 ft. in girth. Bark deeply divided by wide irregular interrupted fissures into broad flat scaly ridges. Young branchlets densely clothed with soft white pubescence, more or less persistent in the second year, when the branches are smooth, brown, and not finely striated; usually in the third year furnished with three or four irregular corky wings. Buds conic, sharp-pointed, with chestnut-brown scales, covered with appressed hairs and ciliate in margin. Leaves (Plate 411, Fig. 10) elliptic or oval, averaging 3 in. long and 1½ in. broad, unequal and usually subcordate at the base, shortly acuminate at the apex; upper surface glabrous, smooth, shining; lower surface with a scattered minute white pubescence throughout, conspicuous on the sides of the midrib and on the nerves, not forming axil-tufts; lateral nerves fourteen to eighteen pairs, running parallel and straight to the margin, occasionally forked; margin biserrate, non-ciliate; petiole ¼ in. long, glabrescent.

Flowers in a racemose inflorescence, about 1½ in. long, composed of two or three cymes, each with about three flowers; axis pubescent; pedicels slender, up to ⅜ in. long, pubescent; calyx funnel-shaped, with six to eight rounded red lobes; stamens six to eight, with slender filaments and red anthers; stigmas pale green. Samara obovate or oval, ½ to ¾ in. long, with a slight notch at the apex, pubescent on both surfaces, and densely ciliate with long white hairs on the slightly thickened margin.

The rock elm is distributed in Canada from the province of Quebec westward through Ontario, where it mainly grows on limestone, and extends southwards in the United States through northern New Hampshire to southern Vermont and northern New Jersey, and westward through northern New York, southern Michigan, and central Wisconsin to north-eastern Nebraska and western Missouri. It is rare in the east and towards the extreme western and southern limits of its range; and is most abundant and of its largest size in Ontario and the southern peninsula of Michigan. It grows mainly on dry gravelly uplands, on low heavy clay soils, and on rocky slopes and cliffs, in company with the sugar maple, butternut, lime, white ash, beech, and other trees, but is less abundant everywhere than *U. americana*.

U. racemosa is one of the rarest of American trees in this country, the only specimens which we have seen being a tree at Kew, about 25 ft. high and doing very badly, which was obtained from Sargent in 1875; a smaller tree in the Edinburgh Botanic Garden, which is not thriving; and another about 20 ft. high, growing slowly at Tortworth. The tree at Kew has never produced flowers or fruit, and scarcely ever develops foliage of a normal size or appearance, as it is hurt by both late and early frosts. Judging from these specimens, this species, like certain

¹ *U. racemosa*, Borkhausen, *Forstbot.* i. 851 (1800), is *U. pedunculata*, Fougereux.

other Eastern American trees, as white oak and black ash, is totally unsuitable for our climate. (A. H.)

Plants at Colesborne, received from Meehan in 1903, have succeeded better, though this may be only for a time. These are now about 14 ft. high, and show the characteristic corky branches, but bear leaves much smaller in size and with fewer nerves than those on adult trees in America. This small foliage is probably characteristic of the juvenile stage in the life of the tree, and matches a branch which I gathered at Ottawa. In France the tree seems to thrive no better, the only specimen which I have seen being a poor tree at Segrez, and it does not exist in the National Arboretum at Les Barres.

TIMBER

Macoun¹ says:—"The rock elm grows in southern Quebec and westward to Lake Superior, being best developed in south Ontario, to which part of Canada it is, as a commercial wood, now confined. It is much superior to the other elms, and for many purposes unequalled by any other wood. It is tough, strong, elastic, and very heavy. Its chief use is in the manufacture of agricultural implements, bicycle rims, and wheel stock. It is largely used in bridge- and ship-building and for heavy furniture. When highly polished the wood is very beautiful, and repays a greater expenditure of time in polishing than is usually given to elm."

Known in the trade as Canada rock elm, this wood long had a high reputation among ship- and boat-builders, perhaps, because it was grown very slowly in dense forests, and free from knots and defects. A large quantity of elm still comes under this name to the Liverpool and London importers, but it is difficult to say what proportion of it is genuine rock elm.

Laslett² gives a good account of its properties and resistance to transverse, tensile, and crushing strains from experiments made by him in the Royal Dockyards, where in his time 600 to 700 loads were annually used for garboards and planking on account of its durability under water, and for ladder-steps and gratings on account of its clean whitish appearance. Laslett said that it was one of the slowest grown woods he knew of, making only 1 in. in diameter in fourteen years. I have seen in the yard of Messrs. White and Company, the well-known boat- and yacht-builders of Cowes, a square log 59 ft. long and only 9½ in. square at 56 ft. from the butt, in which with a lens upwards of 250 annual growths could be counted. This was being cut into gunwales for boats. The wood is also used by makers of agricultural implements in this country, who complain of the difficulty of getting it of reliable quality. As the supply of the genuine slow-grown rock elm seems to be rapidly diminishing, whilst logs of good size are now worth 3s. 6d. per foot and upwards, it seems as though a substitute must be sought for, and may be found in home-grown wych elm if this was closely crowded on suitable land. (H. J. E.)

¹ *Forest Wealth of Canada*, 24 (1900).

² *Timber and Timber Trees*, 225 (1875), where the rock elm of Canada is erroneously named *U. americana*.

ULMUS FULVA, SLIPPERY ELM

Ulmus fulva, A. Michaux, *Fl. Bor. Amer.* i. 172 (1803); Loudon, *Arb. et Frut. Brit.* iii. 1407 (1838); Bentley and Trimen, *Medicinal Plants*, t. 233 (1880); Sargent, *Silva N. Amer.* vii. 53, t. 314 (1895), and *Trees N. Amer.* 293 (1905).

Ulmus americana, Linnæus, var. *rubra*, Aiton, *Hort. Kew.* i. 319 (1789).

Ulmus rubra, F. A. Michaux, *Hist. Arb. Amer.* iii. 278, t. 6 (1813).

(?) *Ulmus pubescens*,¹ Walter, *Fl. Carol.* 112 (1788); Sudworth, *U.S. Forest. Bull.* No. 17, p. 60 (1898); Pinchot, *U.S. Forest. Circ.* No. 85 (1907).

A tree, attaining in America 70 ft. in height and 6 ft. in girth. Bark with shallow fissures and covered with large thick appressed scales. Young branchlets, fawn-coloured, with numerous minute tubercles, and densely clothed with a short white pubescence; those of the second year tuberculate, fissured but not finely striate on the surface; remaining smooth and not developing corky ridges in the third and fourth years. Buds ovoid, with reddish brown scales, covered with long silky appressed hairs. Leaves (Plate 411, Fig. 8) oval to obovate-oblong, about 5 to 7 in. long and 2 to 3½ in. broad, very oblique and unequal at the base, acuminate at the apex; upper surface scabrous with minute sharp-pointed tubercles, and short stiff hairs; lower surface densely clothed with white soft pubescence, conspicuous on the midrib and veins, and forming axil-tufts at their junctions; lateral nerves about sixteen pairs, often forking before reaching the margin, which is ciliate and coarsely biserrate; petioles stout, ½ to ¼ in. long, glandular, densely pubescent.

Flowers in crowded fascicles on short pedicels; calyx campanulate, with a narrow tubular part below; sepals five or six, faintly pink, often irregular in size; stamens five, six, or seven, with white filaments and dark red anthers; stigmas tinged with pink on their inner side. Fruit nearly orbicular or obovate, ½ in. in diameter, rounded or slightly emarginate at the apex, with a minute notch closed by the incurved stigmas, pubescent over the seed-cavity, but elsewhere glabrous and non-ciliate; seed in the centre of the samara.

The slippery elm is distributed from the valley of the lower St. Lawrence southwards to western Florida, central Alabama and Mississippi, and the valley of the San Antonio river in Texas, and westwards through Ontario to north Dakota, eastern Nebraska, and northern and western Kansas. Throughout its entire range it is less common than *U. americana*, often occurring as a solitary tree in open woods, or less frequently on the moist banks of streams in almost pure stands. It is always a small tree, the largest measured by Emerson being 6 ft. 10 in. in girth. It thrives best in rich alluvial soil, but grows fairly well on rocky hill sides, and is often found on dry limestone ridges. It is called *orme gras* by the French Canadians, and is more common than *U. americana* in some localities near Montreal.²

The inner bark is fragrant and mucilaginous, and is officinal in the United States

¹ It is not certain whether the description by Walter, which is unsatisfactory, refers to *U. fulva* or another species, and his name, though older than that of Michaux, cannot be adopted.

² *Garden and Forest*, 1894, p. 413.

Pharmacopœia. It is frequently chewed by children, and when macerated in water yields a thick and abundant mucilage, which was formerly used as a refreshing drink for colds. The powdered inner bark is used for poultices, and is said to preserve butter and lard from rancidity if the latter are melted with it.¹

The date of introduction of *U. fulva* into England was unknown to Loudon, who mentions no large trees. It is probably short-lived in our climate, as we have seen no specimens except young trees, of which there are good examples, 15 to 20 ft. high, at Kew. It is rare except in botanic gardens; but there is a tree at Hildenley of no great size, and another at Colesborne, procured from Simon-Louis, which seems healthy at present.

The timber is not of much importance commercially, and is not found anywhere in great quantity. Macoun² says that it is more durable than that of the other elms, and is better suited for railway ties, fence-posts, and rails. Pinchot³ recommends the planting of the slippery elm in the Mississippi valley, as it grows fast in youth, and can be utilised for fence-posts when quite young, since the sapwood, if thoroughly dried, is quite as durable as the heartwood.

U. fulva has been much confused with the following species:—

ULMUS ELLIPTICA, Koch, in *Linnaea*, xxii. 599 (1849), and *Dendrologie*, ii. pt. i. 420 (1872) (not⁴ Koehne, Schneider, or Ascherson and Graebner).

A tree,⁵ similar in size and habit to *U. montana*. Young branchlets pubescent, smooth and not tuberculate as in *U. fulva*. Leaves similar to those of *U. montana*, in being nearly sessile, with the inner side of the base overlapping the branchlet; elliptic, 3½ to 6 in. long, 1½ to 2¼ in. wide, scarcely scabrous above, sparingly pubescent and with inconspicuous axil-tufts beneath; lateral nerves 18 to 20 pairs, often forked; biserrate in margin. Samaræ, obovate or oval, ¾ in. long, ⅝ in. wide, emarginate at the apex, with a minute aperture formed by the incurved stigmas; seed-cavity in the centre, and pubescent on both surfaces, the rest of the samara being glabrous and non-ciliate.

This species is closely allied to *U. montana*, differing mainly in the pubescence on the centre of the samara, in which respect it resembles *U. fulva*; but the samara in the latter species is much smaller. *U. elliptica* is imperfectly known,⁶ but is said by Koch to form extensive woods in the Caucasus, which are either pure or mixed with other broad-leaved trees. It is not in cultivation, so far as I know.

The trees cultivated by Späth, under the names *U. elliptica* or *U. Heyderi*,⁷ are

¹ Flückiger and Hanbury, *Pharmacographia*, 557 (1879). Cf. also Loudon, *Gard. Mag.* xv. 574 (1839), and xvi. 231 (1840).

² *Forest Wealth of Canada*, 24 (1900).

³ *U.S. Forest Circular*, No. 85 (1907).

⁴ *U. elliptica*, Koehne, *Dendrologie*, 136 (1893), Schneider, *Laubholzkunde*, i. 216, fig. 136 (1904), and Ascherson and Graebner, *Syn. Mitteleurop. Flora*, 550 (1911), is *U. fulva*.

⁵ This description is drawn up from a specimen in the Kew Herbarium, collected by Markowicz in the Caucasus, which agrees with Koch's description. Markowicz wrote a pamphlet on this elm, which was published at Moscow in 1900. Elwes saw specimens in the St. Petersburg Herbarium which were collected in Abchasia and near Alagir in Ossetia.

⁶ Köppen, *Holzgewächse Europ. Russlands und Kaukasus*, ii. 41 (1889), and other Russian botanists regard *U. elliptica* as a dubious species.

⁷ Späth, *Catal.* No. 57, p. 4 (1883). Koehne's description of *U. elliptica* was apparently taken from one of these trees, which produced flowers and fruit in Späth's nursery, and not from the typical tree in the Caucasus.

identical in all respects with *U. fulva*. This is remarkable, as I am informed by Mr. Jensen that one of these trees was obtained from Dieck,¹ while another was sent from Tashkend by Koopmann. There must be some error in the account of their origin, as it is improbable that *U. fulva* is either wild or cultivated in Turkestan. (A. H.)

ULMUS MONTANA, WYCH ELM

Ulmus montana,² Stokes, in Withering, *Bot. Arrange. Veget. Great Brit.* i. 259 (1787); Smith,³ *Eng. Bot.* t. 1887 (1808); Loudon, *Arb. et Frut. Brit.* iii. 1398 (1838); Mathieu, *Flore Forestière*, 302 (1897).

Ulmus campestris, Linnæus, *Sp. Pl.* 225 (1753) (in part); Miller,⁴ *Gard. Dict.*, ed. 8, No. 1 (1762); Willkomm, *Forstl. Flora*, 555 (1887).

Ulmus glabra,² Hudson, *Fl. Angl.* 95 (1762) (not Miller); Rehder, in *Mitt. Deut. Dend. Ges.* 1908, p. 157; Moss, in *Gard. Chron.* li. 217 (1912).

Ulmus scabra,⁴ Miller, *Gard. Dict.* ed. 8, No. 2 (1762); Schneider, *Laubholzkunde*, i. 216 (1904), 805 (1906); Ley, in *Journ. Bot.* xlviii. 67 (1910); Ascherson and Graebner, *Syn. Mitteleurop. Flora*, iv. 560 (1911).

Ulmus suberosa, Michaux, *N. Amer. Sylva*, ii. 244, pl. 129, fig. 2 (1819) (not Moench, Ehrhart, or Smith).

A tree, attaining 120 ft. in height and 20 ft. or more in girth. Bark remaining smooth on the stem and branches for many years, ultimately on the trunk divided by shallow longitudinal fissures into scaly plates. Young branchlets stout, more or less covered with stiff hairs; in the second year smooth or slightly fissured, not showing the fine striation of *U. nitens*. Buds conical, obtuse, with dark brown scales, which are ciliate in margin and densely pubescent on the surface with yellowish brown hair. Leaves (Plate 412, Fig. 13) variable in size and shape, but averaging 3 to 5 in. long, and readily distinguishable from the other species by the short stout densely pubescent petioles, not exceeding $\frac{1}{8}$ in. in length; mostly obovate-elliptic, very unequal at the base, cuspidate-acuminate at the apex, on vigorous branches and coppice shoots often with three cuspidate points; sharply biserrate; lateral nerves fifteen to eighteen pairs, often forked; upper surface scabrous with scattered short hairs; lower surface with a soft white pubescence, dense on the midrib and lateral nerves, forming axil-tufts at their junctions, and scattered on the surface between the nerves.

Flowers twenty to thirty in a cluster, on very short pedicels, regularly pentamerous, hexamerous, and heptamerous; calyx campanulate, contracted towards the base into a narrow wrinkled tubular part, about $\frac{1}{6}$ to $\frac{1}{7}$ in. long; sepals five, six, or

¹ *Neuh. Offer. Nat. Arb. Züschen*, 1889-1890, p. 22.

² The oldest tenable name for this species appears to be *U. glabra*, Hudson; but as *U. glabra*, Miller, has been much used for another species, I retain *U. montana*, Stokes, as a name which has been long in use, and never applied to any other species.

³ Smith's description applies to *U. montana*; but the leaves are badly drawn in the figure, the stalks being too long. *U. nuda*, Ehrhart, *Beit.* v. 160 (1790), vi. 86 (1791), judging from his specimen in Smith's herbarium at the Linnean Society, is *U. montana*.

⁴ Miller, whose account of the elms is very confused, gives two names to *U. montana*, his No. 1 being "the common rough or broad-leaved witch elm, very common in the north-west counties of England, where it is generally believed to grow naturally in woods." His No. 2 is "the witch hazel or rough and very broad-leaved elm," also said by him to "grow naturally in some of the northern counties of England." Woodmen in the Chiltern Hills and in Sussex (cf. p. 1874) at the present day sometimes similarly attempt to make a distinction between the wych elm and the wych hazel.

seven, pinkish; stamens five, six, or seven, with deep pink filaments and red anthers; stigmas red. Fruit, very shortly stalked, oval, about 1 in. long and $\frac{3}{4}$ in. broad, glabrous except in the interior of the notch, non-ciliate, rounded or pointed at the apex, with a minute notch, usually closed by the incurved stigmas. Seed in the centre of the samara, with its apex distant from the base of the notch.

The seedling¹ of *U. montana* differs from that of *U. nitens* in all the leaves above the first two pairs being alternate in the first year, and considerably larger than in the latter species. The stem is stout and usually bent to one side near the apex, and attains at the end of the first season about 6 to 12 in. in length, developing about nine to thirteen leaves in all.

The flowers of *U. montana*, which is a tree of more northerly distribution than the other European elms, are scarcely ever injured by late frosts; and in consequence ripe seed is produced regularly every year in most parts of Britain, often in great abundance and invariably fertile.

U. montana never produces suckers² in England, differing in this respect from all the other British elms. There is, however, in the neighbourhood of Cambridge, in hedgerows, a peculiar elm, closely resembling *U. montana*, but producing suckers, though in no great quantity. This elm³ is a low tree, with wide-spreading branches, forming a globose crown of foliage, and seems to be less vigorous in growth than ordinary *U. montana*. The leaves and buds cannot be distinguished from those of the last, but the branchlets are glabrous, or nearly so. The flowers of one tree which I examined differ from those of *U. montana* in the irregular number of the sepals and stamens; calyx-tube funnel-shaped and scarcely narrowed into a tubular basal part, with five or six lobes; stamens five or six, or often four, one occasionally being aborted and sterile; filaments white, not pink as in *U. montana*. Samaræ similar to those of the last, but rarely ripening, being injured by late frosts. The suckers bear small leaves, 2 to 3 in. in length, with a long acuminate apex, and often one or two additional points on each side of it. This peculiar elm³ is probably one of the descendants of the Huntingdon elm, in which nearly all the characters of *U. montana* appear; but differing in the irregularity of the flowers, the infertile samaræ, and in the occurrence of suckers.

VARIETIES

U. montana shows little variation in the wild state; but trees growing in dense woods usually bear smaller and thinner leaves than those which stand in the open.

I. The following geographical form has been described:—

1. Var. *laciniata*, Trautvetter, in Maximowicz, *Fl. Amur.* 246 (1859); Maximowicz, in *Mél. Biol.* ix. 25 (1872); Shirasawa, *Icon. Ess. Forest. Japon.* ii. t. 15, figs. 1-9 (1908).

¹ Cf. *Journ. Linn. Soc. (Bot.)* xxxix. 292, pl. 22 (1910).

² Mr. A. P. Long saw in 1912 several large trees of *U. montana* producing suckers freely in the Sihlwald, near Zurich. The leaves of these suckers differ in no respect from those produced by the peculiar Cambridge trees here described; but the leaves and branchlets of adult trees are like those of typical *U. montana*.

³ This hybrid may be named *U. Mossii* after Dr. C. E. Moss, who drew my attention to it.

Ulmus major, var. *heterophylla*, Maximowicz and Ruprecht, in *Bull. Acad. Ptersb.* xv. 139 (1857).

Ulmus laciniata, Mayr, *Fremdländ. Wald- u. Parkbäume*, 523 (1906).

Ulmus scabra, var. *heterophylla*, Schneider, *Laubholzkunde*, i. 218 (1904).

Young branchlets glabrous or with a few scattered hairs. Leaves, at the end of the branchlets, large, 6 to 7 in. long, 3 to 4 in. wide; usually with three, occasionally five, large cuspidate-acuminate lobes; upper surface scabrous, with minute tubercles, each of which bears a short bristle; lower surface covered with a dense soft pubescence. Samara, about $\frac{7}{8}$ in. long, $\frac{1}{2}$ in. wide; narrower than in the type.

This is a common form of *U. montana* in eastern Asia, where it is widely spread, but apparently mixed with the typical form in Amurland, Manchuria, Saghalien, and Japan. Both normal and tricuspidate leaves occur occasionally on the same individual tree. Similar leaves¹ in all respects occur on coppice shoots and on epicormic branches of *U. montana* in Europe, but are rarely seen on ordinary branches. In eastern Asia the peculiar tricuspidate leaves occur normally on adult trees; and young trees raised in the Arnold Arboretum from Japanese seed preserve the remarkable character of the foliage.

Sargent states² that in Japan this variety is usually a small tree, about 30 ft. high; but Mayr says that it attains 100 ft. in height in the broad-leaved forests of central Yezo.

The inner bark of this tree is taken off in narrow strips by the Ainos, and after being soaked in water, is woven into a coarse cloth, from which they make their garments. It is also woven into baskets, of which Elwes brought home specimens. The wood is not used at present to any extent; but may possibly become a substitute for Canadian rock elm when the latter becomes scarce.

II. The following varieties have arisen in cultivation:—

2. Var. *fastigiata*,³ Loudon, *op. cit.* 1399.

Ulmus Fordii and *Ulmus exoniensis*, Loudon, *op. cit.* 1399.

Branches directed vertically upwards. Leaves clustered at the ends of short shoots, dark green, small, obovate, more or less uneven and wrinkled on the surface; margin with coarse serrated teeth.

This variety was raised at Exeter by Mr. Ford about 1826, and hence is generally known as Ford's elm or the Exeter elm. The finest specimen which we have seen is one in Canon Ellacombe's garden at Bitton, which was 65 ft. by 12 ft. in 1908. There are two good trees at Bayfordbury, 45 ft. by 5 ft. 8 in., and 35 ft. by 6 ft. 8 in. in 1911. At Drumlanrig Castle, Elwes measured a fine specimen 60 ft. by 8 ft. in 1911. One at Dawyck is reported by Mr. F. R. S. Balfour to be 48 ft. by 7½ ft. in 1911.

¹ Leaves gathered by Elwes in Croatia, and others taken by me from the epicormic branches of a tree at Wyfold Grange, Henley, are identical with specimens collected in Japan by Elwes, who found it growing with *U. japonica* in a virgin forest near Asabigawa in Yezo. Trees with tricuspidate leaves occurring in Galicia have been named *U. montana*, var. *corylifolia*, Zapalowicz, *Consp. Fl. Galic.* ii. 98 (1908). Similar trees are said by Koch, *Dendrologie*, ii. pt. i. 415 (1872), to have been propagated in gardens under the names *U. tricuspis*, *U. tridens*, *U. triserrata*, and *U. intermedia*.

² *Garden and Forest*, vi. 323 (1893), and *Forest Flora of Japan*, 57 (1894).

³ There are several small trees at Kew, with ascending branches, which have been obtained under various names, as var. *etrusca*, var. *gigantea*, and var. *macrophylla fastigiata*; but none of these appear to me to be distinct enough to deserve a special name.

A sub-variety with yellowish foliage, known as var. *fastigiata aurea*, is occasionally seen in botanic gardens. A tree at Kew, 20 ft. high, which was obtained from Lee in 1879, is narrowly pyramidal and not strictly fastigiata in habit.

3. Var. *cinerea*, Lavallée, *Arb. Segrez.* 237 (1877).

Ulmus cinerea, Planchon, in De Candolle, *Prod.* xvii. 160 (1873).

Branches stunted and tortuous, the upper ascending, the lower more or less pendulous. Leaves crowded and similar to those of var. *fastigiata*, from which var. *cinerea* appears to differ only in not being fastigiata in habit.

This is represented at Kew by a tree about 25 ft. high, of unknown origin. Elwes found a small tree of it in the late Mrs. Robb's garden at Liphook.

4. Var. *pendula*, Loudon, *op. cit.* 1398.

Var. *horizontalis*,¹ Petzold and Kirchner, *Arb. Musc.* 564 (1864).

Ulmus pendula, Loddiges, *Cat.* 1836.

Ulmus horizontalis, Loudon, *op. cit.* 1398.

Branches horizontally spreading, branchlets more or less pendulous. This is the common weeping wych elm, which is much planted as an ornamental small tree, and is usually grafted high on a stock of the common species. It occasionally attains 30 ft. in height, and bears flowers and fruit abundantly every year. Booth states² that this variety was found in a bed of seedlings in the Perth nursery about 1816. He purchased the plant, from which all the stock, both in England and on the Continent, originated. A fine tree in the Glasnevin Botanic Garden (Plate 393) is grafted at 10 ft. from the ground, and grows to a height of about 30 ft., with a circumference of branches of 54 paces.

5. Var. *pendula Camperdowni*, Hort.

Branches and branchlets pendulous, forming a globose head, in marked contrast to the flat stiff-looking crown of var. *pendula*, Loudon. The original plant grew at Camperdown House, near Dundee; and, according to Mr. Mitchell, of Messrs. R. B. Laird and Sons, Edinburgh, was of considerable age thirty years ago, and quite prostrate in habit, creeping along the ground amongst other elms. There are good specimens of both these weeping elms in the Grange Cemetery, Edinburgh; and the difference in habit is well shown in a photograph by Mr. A. D. Richardson, reproduced in *Gard. Chron.* l. 221, fig. 105 (1911).

6. Var. *crispa*, Loudon, *op. cit.* 1399.

Ulmus crispa, Willdenow, *Enum. Pl. Hort. Berol.* 295 (1809).

Ulmus urticæfolia, Audibert, *Cat. Hort. Tonn.* 23 (1817).

Leaves very narrow, linear to oblanceolate, wrinkled, lacinate, with numerous incised curved teeth. This variety usually forms a small tree with pendulous branches. There is a fine specimen, about 25 ft. high, at Howden and Company's nursery, Inverness, and smaller ones at Kew, Revesby, and elsewhere.

¹ Var. *horizontalis* is the name generally used in continental nurseries for the common form of the weeping wych elm (var. *pendula*, Loudon); while their var. *pendula* is either identical with or very similar to *U. pendula Camperdowni*.

² In Loudon, *Gard. Mag.* 1843, p. 442.

Var. *crispa aurea*, Schelle, *Laubholz-Benennung*, 86 (1903), is a form of the preceding, with yellowish leaves.

7. Var. *libro rubro*,¹ Planchon, in De Candolle, *Prod.* xvii. 160 (1873).

Inner bark of the young branchlets deep red in colour. A tree of this at Kew, about 20 ft. high, was obtained from Van Houtte in 1871. It appears to differ in no respect from the type, except in the colour of the inner bark. This variety is said by Loudon² to have been found by M. de Vilmorin in a wood near Verrières some time before 1840. Loudon explains that it was propagated by grafting, and was not a local peculiarity arising from something in the soil, as in the case of the blue flowers of *Hydrangea*.

8. Var. *nana*, Simon-Louis, *Cat.* 1869, p. 98.

A shrub, attaining about 6 ft. in height, with wide-spreading horizontal branches, stunted branchlets, and small leaves. This variety, the origin of which is unknown, forms at Kew a peculiar slow-growing hemispherical bush, which has not increased appreciably in size for many years.³

9. Var. *atropurpurea*, Späth, *Cat.* No. 57, p. 4 (1883-1884).

Leaves dark purple and folded. This was raised from seed in Späth's nursery; but is very similar to or perhaps identical with *U. purpurea*, Koch, *Dend.* ii. pt. i. 416 (1872), of which there was a fine specimen growing in front of Petzold's house at Muskau.

10. Var. *lutescens*, Schelle, *Laubholz-Benennung*, 86 (1903).

Leaves of a beautiful yellow colour. I saw a fine specimen in the Calmpthout Nursery, Belgium, where it was cultivated under the name *U. americana aurea*. Loudon⁴ states that in Mr. Jessop's garden at Derby he found a variety, the leaves of which were of a fine yellow colour at the time of expanding in May. This tree was planted by Pontey, and known as the gallows elm, because the original tree grew near a gallows at York.

HYBRIDS

U. montana is one of the parents in the following hybrids:—

1. *U. vegeta*, Huntingdon elm. See p. 1879.
2. *U. major*, Dutch elm. See p. 1883.
3. *Ulmus Smithii*, Henry. Downton elm.

Ulmus montana, var. *Smithii*, Hort. Kew.

Ulmus pendula, W. Masters, *Hortus Duroverni*, 66 (1831) (not Willdenow).

Ulmus glabra, var. *pendula*, Loudon, *Arb. et Frut. Brit.* iii. 1405 (1838).

A tree with ascending branches, and long pendulous branchlets. Young branchlets stout, more or less pubescent with long hairs. Leaves (Plate 412, Fig. 24) firm in texture, oval, about $3\frac{1}{2}$ in. long and $1\frac{3}{4}$ in. wide, very unequal at the base, long

¹ *U. campestris rubra*, Simon-Louis, *Cat.* p. 97 (1869), from the description is identical with this variety, which appears in more recent catalogues under the name given above.

² *Derby Arboretum*, 52 (1840). Loudon, *op. cit.* 51, states that a similar variety of the white mulberry, *Morus alba*, var. *Morettiana*, was then cultivated in the Jardin des Plantes at Paris; "the soft wood or cambium of the current year's shoot was of a deep red."

³ Cf. *Woods and Forests*, 1884, p. 482, where an account of this remarkable bush at Kew is given. It may have originated from a witches' broom.

⁴ *Gard. Mag.* xv. 449 (1839).

acuminate at the apex; upper surface shining, dark green, glabrous, smooth; lower surface with scattered pubescence and with axil-tufts; margin coarsely biserrate; lateral nerves fourteen to sixteen pairs, very prominent beneath, straight, close, parallel, occasionally forked; petiole $\frac{1}{2}$ in. long, densely pubescent.

Flowers irregular in the number of the sepals and stamens; calyx funnel-shaped, $\frac{1}{10}$ to $\frac{1}{8}$ in. long, with four, five, or six bright pink lobes; stamens, three to five, with whitish filaments and dark red anthers; stigmas bright red. Samara obovate, $\frac{3}{4}$ in. long, $\frac{5}{8}$ in. broad, emarginate at the wide apex, with a shallow rounded notch not closed by the incurved stigmas; seed above the centre of the samara.

This tree has usually slight corky ridges with peculiar brown fissures on the branchlets of the third and fourth years. The leaves are thicker in texture, and with more nerves than those of *U. nitens*.

It was raised in Smith's nursery at Worcester, from seeds obtained from a tree in Nottinghamshire. Some of the seedlings were purchased by Mr. Knight of Downton Castle; and one of them, which turned out to be of weeping habit, was propagated. There are two Downton elms at Kew, about 25 ft. and 35 ft. high. One of these produced ripe fruit in 1909, from which I raised twenty-nine seedlings, very unlike in appearance, twenty-six having alternate leaves, and three having opposite leaves. Mr. Knight informed Loudon¹ that he had raised plants of various kinds from the seed of the Downton elm; and specimens of these seedlings, representing seven remarkably different elms, which were sent from Downton Castle in 1835, are preserved in the Kew Herbarium. A Downton elm, labelled *U. Smithii*, was 25 ft. high at Glasnevin in 1912.

4. *Ulmus belgica*,² Burgsdorf, *Anleit. Holzart.* 270 (1805) (*excl. syn.* Du Roi, Miller). Belgian Elm.

Ulmus latifolia, Poederlé, *Man. de l'Arbor.* ii. 117 (1792); Petzold and Kirchner, *Arb. Musc.* 561 (1864) (not Moench³).

Ulmus bataviana, Koch, *Dendrologie*, ii. pt. i. 414 (1872).

Ulmus campestris, var. *bataviana*, Simon-Louis, *Cat.* 1869, p. 96.

Ulmus campestris, var. *belgica*, Lavallée, *Arb. Segrez.* 235 (1877).

Ulmus campestris, var. *latifolia*, Gillekens, *Arboric. Forest.* 38 (1891) (not Persoon⁴).

Ulmus hollandica, Späth, *Cat.* No. 113, p. 158 (1903-1904) (not Miller⁵).

Ulmus montana, var. *hollandica*,⁶ Huberty, in *Bull. Soc. Cent. Forest. Belg.* xi. 566 (1904); Aigret, in *Ann. Trav. Publ. Belg.* x. 1230 (1905).

A vigorous tree, with a straight rough-barked stem, and widely extending branches, forming a broad crown of foliage. Young branchlets more or less pubescent with scattered long white hairs, which are usually deciduous in summer,

¹ *Arb. et Frut. Brit.* iii. 1404, paragraph 1 (1838).

² The adoption of this name, justified by Burgsdorf's description, "Die holländische Ulme, le Yypreau de Holland," will avoid the confusion that has been almost universal of this elm with the "Dutch elm" of England, and with *U. hollandica*, Miller. The latter is an uncertain name, and cannot signify the Belgian elm, which has not the corky bark on the twigs, characteristic of Miller's Dutch elm. Cf. p. 1883, note 1.

³ *U. latifolia*, Moench, *Meth.* 333 (1794), appears to be *U. montana*, to which Moench referred *U. hollandica* as a form. While these sheets were passing through the press, I have been able to consult the *Mannuel* by Poederlé, one of whose names for the Belgian elm, *U. latifolia*, is possibly its oldest certain name.

⁴ *U. campestris*, var. *latifolia*, Persoon, *Syn. Pl.* i. 291 (1805) is an uncertain name.

⁵ Cf. note 2 above.

⁶ *U. montana hollandica*, Planchon, in De Candolle, *Prod.* xvii. 160 (1873) is a doubtful name.

but are occasionally retained in the second year. Leaves (Plate 412, Fig. 18) obovate-elliptic, $3\frac{1}{2}$ to 5 in. long, $1\frac{1}{2}$ to 2 in. wide, very oblique at the base, abruptly contracted at the apex into a long serrated point; upper surface slightly scabrous, with a minute scattered pubescence; lower surface densely covered with a soft pubescence, conspicuous on the midrib, and with white axil-tufts; lateral nerves fourteen to eighteen pairs, often forked; margin coarsely biserrate; petiole $\frac{1}{8}$ to $\frac{1}{5}$ in. long, densely pubescent.

Samaræ differing little from those of *U. montana*, except in their smaller size, about $\frac{7}{8}$ in. long and $\frac{5}{8}$ in. wide, obovate, rounded and slightly emarginate at the apex, below which is a minute aperture formed by the incurved stigmas. Seed in the centre of the samara, at the base of which the persistent calyx is five-lobed, with remains of five stamens.

This elm is readily distinguishable from *U. montana* by the glabrescent and more slender twigs, and by the narrower leaf, which is usually prolonged at the apex into a long serrated point. The appearance of the stem in mature trees is very characteristic, as it is remarkably cylindrical, being rarely swollen or buttressed at the base, and tapers less than other elms. The tree produces suckers, but not very freely. These have pubescent branchlets, and scabrous leaves, similar in shape to those of the parent tree.

This tree is said by Huberty,¹ who quotes Poederlé's *Manuel de l'Arboriste*, ii. 117 (1792), to have been cultivated in the eighteenth century in the nurseries of the Abbey of Dunes, which was first established at Furnes and later was transferred to Bruges. It was then known by the Flemish name of *Hollander's olm* or elm of Holland, but is now more commonly called *orme gras*.² It is undoubtedly a hybrid, as Mr. Springer,³ who sowed its seed, obtained mixed seedlings, of which I have received specimens. One of these is three weeks later in losing its leaves than the parent. Samaræ which he sent me in 1911 were very variable in size, but uniform as regards the position of the seed in the centre. Those which I sowed failed to germinate. This elm is always propagated in nurseries⁴ by layering; and is most extensively cultivated in Belgium and Holland, where it is the principal tree⁵ planted along the roads, as well as in parks and avenues. It grows with astonishing vigour, much faster than other elms, according to Mr. Huberty, who states that it yields a soft wood, little used by carriage builders, but valuable for making furniture.

¹ *Bull. Soc. Cent. Forest. Belg.* xi. 564 (1904). This elm is probably referred to in the Dictionary of the French Academy, published in 1694: "Ypreau, espèce d'orme à larges feuilles qui est venu premièrement des environs de la ville d'Ypres." Ypres is not far distant from Furnes and Bruges; and it is in this district that the other peculiar elms of Belgium, the Klemmer and Dumont varieties, have originated. Plukenet's *Ulmus hollandica* was possibly the ypreau. The word ypreau, which is also written ypreau and ipreau, meaning elm, was first used in 1432, according to Godefroy, *Dict. Anc. Lang. Franc.* x. 873 (1902); and only in the nineteenth century came to mean the grey poplar in the north of France; but it is still used in Flanders for the hybrid elm. Cf. *Bull. Soc. Cent. Forest. Belg.* ii. 817 (1895), and xi. 572 (1906). Gleditsch, *Forstwissenschaft*, i. 285 (1775), thought that the Holland "Yper" originated from the wild elm of North America, but there is no evidence of hybridisation with either *U. americana* or *U. pedunculata*.

² It is often called *orme gras de Malines*, because it has been long propagated by the nurserymen of this city; but there are no grounds for believing with Gillekens, *Arboric. Forest.* 39 (1891), that it originated at Malines.

³ *Mitt. Deut. Dend. Ges.* 1910, p. 272.

⁴ Attempts have been made to divide the Belgian elm into numerous varieties; but only two kinds are ordinarily propagated in Belgian and Dutch nurseries, viz., *orme gras* and *orme Dumont*.

⁵ Aigret, in *Ann. Trav. Publ. Belg.* x. 477 (1905), gives a table of the numbers of the various species of trees planted along the main roads in Belgium. The elm is the most numerous, 294,725 out of a total of 806,985 trees.

A fine plantation of these elms is reported¹ near Châtelineau, in the Parc de Presles, where on deep fertile soil, resting on limestone, there are sixty-one trees to the acre, averaging $4\frac{1}{2}$ ft. in girth, with a total volume in the round of 3500 cubic ft. These trees are said to be only thirty-four years old. I measured in 1912 a young Belgian elm, which had just been blown down in the Royal Park of Laeken. It was 108 ft. high by 4 ft. 8 in. in girth; but I was unable to count the annual rings. In the poor soil of the Brussels Park, one of these elms averaged² six rings to the inch of radius during the first eighty years. Huberty gives³ a good photograph of two Belgian elms, growing on the road between Jemelle and Rochefort, which, though only forty-eight years old, are 9 ft. in girth. Others near Genappe, thirty-five years old, are 4 to 5 ft. in girth; while some fifty-eight years old are only 7 ft. round.

The elms which were planted in the park at Brussels by Zimmer in 1790, have been described by M. Bommer,² who states that they have passed their prime, and that many are suffering from the attack of *Polyporus squamosus*. These elms are very fine trees, growing in sandy soil. The leaves, when seen by Elwes on May 9, 1911, were not fully out, and there were no flowers visible. They have trunks clear of branches to 40 to 60 ft., probably due to pruning, with a total height of 110 ft. to 125 ft.

In the park at Haarlem, and in the "Bosch" at the Hague, there are many fine trees of the same type, on a somewhat similar soil. Some of those at the Hague, which looked quite young, were 120 ft. or more in height; and Elwes was told by Mr. Westbrook, superintendent of the municipal parks and nurseries at the Hague, that the best elms in the country were grown in the large nurseries at Oudenbosch and Calmpthout, north of Antwerp. I was informed at these nurseries in 1912, that the Belgian elm was exported to England on rare occasions; but we have seen no old trees of the kind in this country, except one at Kew, about 35 ft. high, which was obtained under the name *U. Pitteursii* from Lee in 1879. It is possible, however, that it may have escaped the notice of ourselves and of our correspondents, on account of its resemblance to *U. montana*.

Hübner reports⁴ that the Belgian elm thrives on the worst soils, and on that account is planted in belts on the margins of pine woods in Prussia. All the indications in Belgium also point to the fact that this elm succeeds better on poor sandy soils than any other variety.

5. *Ulmus belgica*, var. *Dumontii*, Henry. Dumont Elm.

Ulmus campestris, var. *Dumontii*, Nicholson and Mottet, *Dict. Prat. Hort.* v. 383 (1898).

Ulmus montana, var. *Dumontii*, Aigret, in *Ann. Trav. Publ. Belg.* x. 1231 (1905).

Branches ascending, forming a narrow pyramidal tree. This scarcely differs from the common Belgian elm, except in height, and like it, is propagated by layering.⁵ The original tree is said to have been found about 1865 in the park of M. Dumont at Tournai, where it was growing amidst a plantation of ordinary *orme gras*; and was subsequently propagated and sold under the name of *orme Dumont*.

¹ *Bull. Soc. Cent. Forest. Belg.* xvi. 346 (1909).

² *Ibid.* iv. 105-109 (1899).

³ *Ibid.* xi. 571, t. vi. (1904).

⁴ *Mitt. Deut. Dend. Ges.* 1908, p. 122.

⁵ I have not been able to examine specimens from adult trees. Young nursery plants of *orme gras* and *orme Dumont* are very similar, and resemble *U. montana* in foliage and branchlets, more than the old trees do.

On account of its narrow form, it has become a favourite tree for planting in streets; but is believed not to be so fast in growth as the ordinary Belgian elm. It is much planted in the neighbourhood of Lille, Roubaix, and Tournai; and grows well in the district of Ypres. The finest avenue of this elm is said¹ to be on the road between Wareme and the park of Longchamps; but a specimen brought from there by Elwes, who describes the trees as having the habit of the Wheatley elm, is indistinguishable in branchlets and foliage from *U. montana*. There are peculiar clipped avenues of the Dumont elm in the streets near Moser's nursery at Versailles.

6. *Ulmus Klemmeri*,² Späth, *Cat.* No. 104, p. 134 (1899); Huberty, in *Bull. Soc. Cent. Forest. Belg.* xi. 495 (1904), and xii. 173, pl. xxi. (1905). Klemmer or Flanders Elm.

Ulmus campestris, var. *Klemmer*, Gillekens, *Arboric. Forest.* 40 (1891); Aigret, in *Ann. Trav. Publ. Belg.* x. 1224 (1905).

A tall tree, narrowly pyramidal in habit, with ascending branches, and a straight cylindrical stem, covered with smooth bark. Young branchlets slender, pubescent with short hairs that are deciduous in summer. Leaves ovate, about 3 in. long and 2 in. broad, shortly acuminate at the apex, oblique at the base; scabrous and glabrescent above; lower surface smooth to the touch, covered with a minute pubescence, and with small axil-tufts; lateral nerves about twelve pairs, often forked; margin regularly biserrate. Aigret states that the seed is situated close to the emargination of the samara.

This elm, though similar in some respects to the southern variety of *U. campestris*, is probably a hybrid between *U. nitens* and *U. montana*, but closer to *U. nitens*, in the size of the leaf and the position of the seed in the samara. Leaves on vigorous shoots from the stem are like those of *U. belgica*, in texture and size, and it is possible that the Klemmer elm may be a seedling of the latter, but its origin is unknown.³

The Klemmer elm is propagated by layering, and is widely planted in West Flanders, in Belgium, and the adjoining Departement du Nord of France, where it is much esteemed on account of its rapid growth and excellent timber. Its wood is superior to that of *U. belgica* in strength and elasticity, and is preferred by wheelwrights. It grows to a great height, and on account of its narrow form is suitable for planting in streets in towns and along roads in the country. Gillekens states that six trees, which he planted in 1878 amidst a plantation of oaks that were about 20 ft. high, soon outgrew the latter, and in 1891 had attained 60 ft. in height and 2 ft. 9 in. in girth. The finest trees were those recently felled near Alveringhem, which were 10 to 12 ft. in girth. There are good specimens in the avenues adjoining the town of Ypres, which I saw in 1912. The Klemmer elm is sold⁴ by French nurseries, and is represented at Kew by two specimens about 15 ft. high, which were obtained from Barbier in 1908.

¹ *Bull. Soc. Cent. Forest. Belg.* ix. 839 (1902).

² *Klemmer*, signifying climber in Flemish, is the name given to this elm in Flanders on account of its ascending habit and great height. The name *Klemmeri*, implying a supposed person named Klemer, is objectionable, but must be maintained.

³ Cf. p. 1895, note 1.

⁴ I was informed that this elm was also obtainable in nurseries at Ypres and Bruges.

7. *Ulmus Pitteursii*, Petzold and Kirchner, *Arb. Musc.* 566 (1864).

Lorme Pitteurs, Morren, in *Journ. Agric. Prat.* 1848, p. 114, and in *Belgique Horticole*, ii. 133 (1852).

This name was given to two varieties which were obtained as seedlings of the *orme gras* in 1845, by M. de Pitteurs at St. Trond near Liège. One variety, described as making annual shoots of 3 ft. in length, and with large leaves, 8 in. long and 7 in. broad, is now little known; but is probably identical with elms propagated by layers, called *orme St. Trond*, which I saw in Looymans' nursery at Oudenbosch in 1912. These were undistinguishable in the young stage from *U. montana*, but bore leaves 5 to 6 in. in breadth; and are perhaps identical with a variety of the latter species, which is occasionally sold as var. *macrophylla*.¹

The other variety of *U. Pitteursii* apparently differed but little from the ordinary Belgian elm (*U. belgica*) and may be² the form of it which is prevalent in the provinces of Liège and Limburg, if this is really distinct. It is said³ to be represented by a tree so-named in the botanic garden at Liège, which is reputed to have been planted by Morren. This I have had no opportunity of examining.⁴

8. *Ulmus superba*, Henry.

Ulmus montana superba,⁵ Späth, *Cat.* No. 62, p. 102 (1885-1886).

A narrow pyramidal tree, with smooth bark and very ascending branches. Branchlets glabrous, remaining smooth and without fine striations, corky ridges not being developed. Leaves, similar to those of *U. montana* in shape and numerous nerves, but with long stalks; variable in size,⁶ 3 to 4 in. long, 1½ to 2 in. broad, obovate or obovate-elliptic, acuminate at the apex, very oblique at the base; glabrous, dark green, and smooth above; lower surface glabrous, except for minute axil-tufts of pubescence; margin biserrate, non-ciliate; petiole ¼ to ⅓ in. long, with scattered hairs.

Flowers regularly pentamerous; calyx campanulate, like that of *U. montana*, with five pink lobes; stamens five, with pink filaments and red anthers; stigmas white. Samaræ not seen.

This tree is probably identical with the variety⁵ of the same name described long ago by Morren; but this is uncertain. Späth states that it is much esteemed at Magdeburg as a street tree. A tree at Kew, obtained from him in 1900, and now about 25 ft. high, is remarkably fast in growth, and peculiar in its narrow pyramidal habit. Another tree at Kew, labelled *U. montana macrophylla fastigiata*,

¹ Possibly identical with *U. campestris*, var. *macrophylla*, Spach, in *Ann. Sc. Nat.* xv. 363 (1841).

² Cf. Gillekens, *Arboric. Forest.* 40 (1891).

³ Aigret, in *Ann. Trav. Publ. Belg.* x. 1230 (1905).

⁴ Koch, *Dendrologie*, ii. pt. i. 417 (1872), states that *U. Pitteursii* had scabrous branchlets and brownish leaves. Petzold and Kirchner, *Arb. Musc.* 566 (1864), describe it as having oblong ovate obtuse-toothed dark green leaves, which were reddish brown at the time of unfolding.

⁵ *U. montana superba*, Morren, in *Journ. Agric. Prat.* 1848, p. 411, is said to have been introduced into Belgium in 1845 under the name *superba* from Osborne's nursery at Fulham. Morren figures a form of *U. montana* with leaves, up to 10 in. long and 6 in. broad. Morren, who was unacquainted with *U. montana*, which he believed to be identical with *U. pedunculata*, adds to his otherwise correct account of var. *superba* a description of the flowers and fruits of *U. pedunculata*. *U. præstans*, Schoch, ex *Mitt. Deut. Dend. Ges.* 1912, p. 227, appears to be a name, without any description, of *U. superba*, Henry.

⁶ Specimens sent by Späth, apparently from young trees, have leaves 4 to 5 in. long, 2½ to 3 in. broad, which are said to fall late in autumn.

the history of which is unknown, is about the same height and is similar in all respects.

9. *Ulmus Dawvessci*, Henry.

Ulmus montana, var. *Dawvessci*, Nicholson, *Kew Hand-List Trees*, 139 (1896).

Branches ascending, forming a broad pyramidal tree. Leaves similar to those of *U. montana*, but smaller and thinner in texture, rarely exceeding 4 in. long and $2\frac{1}{4}$ in. wide, with petioles up to $\frac{1}{4}$ in. long. Flowers more irregular than in *U. montana*, funnel-shaped or campanulate with a narrowed tubular base; sepals five or six, pink; stamens four to seven, with bright pink filaments and dark red anthers; stigmas pink.

The irregularity of the flowers, the lengthened petioles, the small leaves, and the peculiar habit of this tree, all point to its being of hybrid origin; but its history is unknown to me. It is represented at Kew by a tree, about 40 ft. high and $2\frac{1}{2}$ ft. in girth, which was obtained from Lee in 1879.

DISTRIBUTION

U. montana is a native of Europe, Asia Minor, and the Caucasus; but seems to be unknown in Siberia,¹ though it occurs in Amurland, Manchuria, and Japan.

In Europe it is a more northerly species than *U. nitens*, and only occurs in the Mediterranean region at high elevations in the mountains, as in the Pyrenees,² Apennines, Balkan States, and Greece. It is not known in Portugal, and is limited in Spain³ to a few mountain woods in Asturias, the Basque Provinces, Aragon, and Navarre. It is the only species in Scandinavia, where it is met with in the wild state as far north as lat. 67° in Norway, and lat. 64° 50' in Sweden. Its northern limit in Russia⁴ extends from southern Finland through Olonetz, Archangel (lat. 62°), and Viatka to Perm (lat. 60° 40'); and it extends southwards to the border of the steppes. In Switzerland, southern Germany, and Austro-Hungary, it is essentially a mountain tree, ascending in the Tyrol and in the Carpathians to 4000 ft. Farther north it descends into the plains, and is common in north Germany on the banks of streams and in alluvial land. It is not known to form pure woods, being always mingled as isolated trees in the mixed broad-leaved forest.

In the British Isles, it is widely spread throughout Ireland and Scotland; and occurs in coppices and woods on hilly ground in most parts of England. In Bucks, Surrey, and Sussex, where it is often seen in coppice, it is commonly known as wych-hazel; while in Scotland and Ireland, it is always known as wych-elm; but the latter name is usually applied to the eastern counties of England, to *U. nitens*, which is a much more common tree there.

Mr. Clement Reid records⁵ the remains of elms in interglacial deposits at

¹ Maximowicz, in *Mé. Biol.* ix. 25 (1872).

² *U. pyrenaica*, Lapeyrouse, *Hist. Pl. Pyrén. Suppl.* 154 (1818), judging from a specimen in Gay's herbarium at Kew, is *U. montana*.

³ Willkomm, *Pflanzenverbräit. Iber. Halbinsel*, 126, 202 (1896).

⁴ Köppen, *Holzgewächse Europ. Russlands*, ii. 43 (1889).

⁵ *Origin of British Flora*, 59, 66, 69, 74, 142 (1899). We are indebted for part of the above information to a recent letter from Mr. Clement Reid.

Grays, Essex, in the form of badly preserved leaves; and in preglacial beds at Happisburg, Norfolk, leaves better preserved, but which cannot be matched with any British elm, being too small for *U. montana*, and having more nerves than the Cornish elm, which it otherwise resembles. He also records elm leaves in a neolithic deposit at Blashenwell, Dorset, and in calcareous tuff of doubtful age at Dursley, Gloucester, and elm wood in Digby Fen, where it was found by Skertchly at a depth of ten feet. The geological evidence¹ throws no light on the present distribution of the elms in Britain. (A. H.)

Sir Herbert Maxwell gives² the following account of names of places, derived from *U. montana* in Britain and Ireland:—

“The old Gaelic name for it was *leam* (lam), plural, *leaman*. Ptolemy's *Leamanonius Lacus* is now Loch Lomond, the lake of the elms, out of which flows the Leven, which is the aspirated form *leamhan* (lavan); and it is interesting to find these two forms again side by side in Fife, where are the Lomond Hills overlooking the town of Leven. The two forms come together again in Warwickshire, where, not far from Leamington is Levenhull—*leamhan choill*, elm-wood, and, in the same neighbourhood, a place called Elmdon. The Lennox, a district formerly written Levenax, is the adjectival form *leamhnach* (lavnah), an elm-wood; and in England the river Leam, giving its name to Leamington, the Leven in Cumberland, the Lune in Lancashire (Alauna of Ptolemy), and in Ireland the Laune at Killarney, must all once have been named *amhuinn leamhan*, elm-river. *Leamh chuill* (lav whill), elm-wood, appears as Barluel in Galloway, the hill-top of the elm-wood; the derivative *leamhraidhean* (lavran or lowran), elm-wood, becomes Lowran and Loring, also in Galloway; and in the same province I have picked up an alternative form to *leamhan*, common in Ireland—namely, *sleamh* (slav) and *sleamhan* (slavvan), whence the names Craigslove and Craigslovan. Yet another derivative, *leamhreach* (lavrah), seems to be the origin of Caerlaverock, *cathair* (caher) *leamhreach*, fortress in the elm-wood.”

REMARKABLE TREES

The finest wych elm that I have seen is one at Studley Royal, Yorkshire (Plate 394), which is not mentioned by Loudon, though many trees in the same park were figured in his work. When I measured it in February 1905 it was 105 ft. high by 23 ft. in girth, at 5 feet up, but the roots spread so much below this, that at the ground it measured 37 to 40 ft. This tree is very sound-looking and has lost no branch of any size.

There is an immense wych elm at Cassiobury Park, the seat of the Earl of Essex, which Henry found in 1904 to be about 100 ft. high by 26 ft. 4 in. in girth with two immense branches coming off near the ground and spreading to a diameter of 153 ft. This type of branching is not uncommon in the wych elm and usually leads to premature decay, as the weight of these great limbs tears out a hole in the

¹ Samuel Hassel, in Loudon, *Gard. Mag.* xiii. 477 (1837), states that remains of “the small-leaved elm” are found deep in the bogs of Somersetshire, and also in the foundations of Roman villas.

² *Scottish Land-Names*, 110 (1894).

trunk. A wych elm with a remarkably burry trunk, which is growing in the same park, is figured in Plate 400.

In the Park at Stowe, Buckingham, there is a large wych elm with the trunk much buttressed, but a very well-shaped handsome and sound-looking tree. It measures about 110 ft. by 19 ft. 9 in.

At Barham Court, Kent, there is a tree which I have not seen; but Mr. H. Key informs me that it covers a quarter of an acre and girths 21 ft. below the fork, where it divides into several large branches, three of which are rooted in the ground and have thrown up strong upright growths.

The largest wych elm in Gloucestershire, which was blown down some years ago before I began to measure trees, grew close to the church at Rendcombe Park, and was said to have been planted to commemorate the Restoration of Charles II. It was an immense tree of very picturesque shape. A tree at Middle Hill near Broadway, Worcestershire, in 1910 had a girth of $24\frac{1}{2}$ ft., and was 85 ft. high with very wide-spreading branches.

Lees¹ gives a very good account of this species and figures some remarkable old specimens, one of which in Earl Bathurst's park no longer exists. He gives a sketch of it showing great limbs supported by props on each side, and says that it was no less than 36 ft. in girth at 3 ft. from the ground, and 47 ft. round the base. Lees also figures a very remarkable pollard with huge burrs at Cradley, Herefordshire, another at Llanthony, and a curious old stump of great age at Shrawley, which has thrown roots 20 to 30 ft. long to the bottom of the sandstone rock on which it grows. Lees quotes from Dr. Bull who says² that in Herefordshire "Weird-like superstitions attach to the wych elm or wych hazel as it is generally called. A spray of wych hazel is at once a potent safeguard against witchcraft, and a wand of awful import in the hand of a witch. It was formerly used as a riding switch, to ensure good luck on the journey. Until quite recently, if not to this very day, not a rural churn was made in the midland districts without a small hole being left in it, for the insertion of a bit of wych elm wood, in order to ensure the quick coming of the butter."

Lord Walsingham sent me a photograph of a very large and handsome wych elm at Rochels near Watton, Norfolk. In Burleigh Park, Notts, I measured in 1903 a tree 110 ft. by $15\frac{1}{2}$ ft., which divided at 10 ft. into three main trunks. At Eaton Hall, Chester, a tree, which I found to be 90 ft. by 20 ft. in 1905, is said to be the finest in Cheshire.

A very fine old tree is growing in Wensleydale, on the village green just before the gate of Bolton Castle, which is said by Spaight³ to have been planted in 1690. When I saw it in 1906 it was sound and healthy and measured 18 ft. in girth. This is a very characteristic tree of the limestone formation in Wensleydale and Yorkshire generally, but I know of no trees larger than this one. Watson⁴ in 1825 mentions as the largest elm which he had seen, a tree growing in the village of Bishop Burton, near Beverley, Yorkshire, which measured $31\frac{1}{2}$ ft. in girth at five feet from the ground, and 44 ft. at the base.

¹ *Gard. Chron.* ii. 102, figs. 20-23 (1874).

² *Trans. Woolhope Nat. Field Club*, 1868, p. 83 (1869).

³ *History of Richmondshire*, p. 293.

⁴ *Dendr. Brit.* i. introduction, p. ii. (1825).

As a remarkable instance of the rapid growth of this tree I may mention one on the lawn in front of the late Sir Charles Strickland's house at Hildenley, Yorkshire, which cannot be more than about eighty years old, as he distinctly remembered that when a boy he could step over it. In 1905, when I saw it, it was 100 to 105 ft. high with a bole clean to about 25 ft. and 13 ft. 3 in. in girth. This may become one of the tallest trees of its sort in England. Another instance is a log which I saw in Mr. G. Miles's yard at Stamford in March 1908, which had recently been cut at Clipsham, near Stamford. On a diameter of 6 ft. 3 in. I counted only 110 rings.

In Piercefield Park, near Chepstow, there stands one of the most symmetrical trees of this kind that I know, which measures about 100 ft. by 18 ft. It was covered with half-ripe samaræ on 15th April 1906, and I noticed everywhere in this year that the wych elms were carrying an unusual crop of seeds, which in some places in Wales were so abundant as to give a distinct pink tinge to the trees, seen from a distance in May before they were in leaf. This was particularly noticed at Llandilo on 25th May 1906, when Lord Dynevor showed me what he considers the finest wych elm in that district, which is growing in a meadow by the river in Dynevor Park. This tree measures about 103 ft. by 17 ft., and was covered with nearly ripe seed, though the leaves in this early district were not yet unfolded.

All of these existing trees, however, were far eclipsed by a tree mentioned in Plot's *Natural History of Staffordshire*, p. 210 (1636), which seems so well attested that I quote it as follows. After speaking of some gigantic oaks he says: "But I scarce think either of them held so many, as the prodigious Witch-Elm that grew at Field in this county, and was felled within memory by Sir Harvey Bagot; which, according to an original paper put into my hands by the Right Worshipful Sir Walter Bagot, Bt., the present proprietor, and, as I had it from the mouth of Walter Dixon, yet living, who was a surveyor of the work, was so very great and tall, That 2 able workmen were 5 days in stocking and felling it down; That it fell 120 foot or 40 yards in length; That the stoole was 5 yards 2 foot diameter; That the tree at the butt end was 17 yards in circumference; That it was 8 yards and 18 inches, *i.e.* $25\frac{1}{2}$ foot about by girth measure in the middle; That 14 loads of firewood, each as much as 6 oxen could draw to the house at Field, being not above 300 yards distant, broke off in the fall; That there was 47 loads more of firewood (as large as the former) cut from the top; That they were forced to piece 2 saws together, and put 3 men to each end, to cut the body of it in sunder; That there was cut out of it 80 pair of nathes¹ for wheels, and 8000 feet of sawn timber in boards and planks, after 6 score per cent, which at 5s. per cent came to 12 pounds, All which is attested (as a thing, I suppose, they foresaw in a little while would otherwise become incredible) under the hands of

Sir Harvey Bagot.
William Cowper, Steward.
Roger Shaw, Baylif.
Walter Dixon, Surveyor.

Lawrence Grews } Cutters.
Humphrey Chetton }
Francis Marshall }
Thomas Marsh } Stockers.

¹ *Nathes* is an old word meaning *naves*.

And so as to the number of Tunns according to the scantlings first above mentioned, they computed it to contain (after their gross country way of measure) 96 tuns of timber, a vast quantity indeed for one tree. But whoever will take the pains to cast it nicely and more artificially, according to the above measured scantlings, will find that it must contain 100 tuns at least of neat timber, a fifth part (which is sufficient in such large butts) being allowed for wast of rind, chips, etc."

Now as one can hardly believe that eight persons would have signed their name to such a statement if they had not believed it to be true, we have dimensions which though they cannot be exact, seem to be unequalled by any hardwood tree on record out of the tropics; and though the quantity of firewood seems incredible, yet if the number of tons be estimated at only 40 ft. to the ton there is something like 4000 cubic ft. of timber, or if the firewood is estimated only at 50 ft. to the load, and the nathes and board at 1000 ft., the volume is 4050 ft., nearly double the contents of the largest tree now standing.

Aubrey,¹ *Natural History of Wilts*, 56 (1685), says:—"At Dunhead, St. Marie's, at the crosse is a wich-hazell not less worthy of remarque . . . for the large circumference of the shadowe that it causeth. When I was a boy, the bowyers did use them to make bowes, and they are the next best to yew."

In Scotland, though the tree is common I have not seen or heard of any of exceptional size. Hunter² mentions a good many, but rarely distinguishes between the wych and other elms. Among these the following may be noticed:—A tree at Moncreiffe House, which has layered itself in several places; and a tree at Kinfauns Castle, Perthshire, for which it is said that £50 was offered forty years ago though only computed to contain 460 feet of timber. It was in 1883 about 70 ft. high by 17 ft. in girth at the smallest place, seven feet from the ground. It was figured by Loudon, *Arb. et Frut. Brit.* iii. 1403, fig. 1244 (1838).

In the *Old and Remarkable Trees of Scotland* the same confusion has taken place, the Scotch elm being considered as a variety only and not distinguished in the returns given, but probably most of them relate to the wych elm. The largest of these was a tree then in a decaying condition at Myres in Fifeshire, stated to be 75 ft. by 20 ft. at 9 feet from the ground, dividing into two main stems 16 ft. and 9 ft. in girth. Loudon³ speaks of an elm near Roxburgh in Teviotdale, called "the Trysting Tree," which, when measured in 1796, was 30 ft. in girth at four feet from the ground. The tallest of which we have any record is a tree measured by Mr. Bean at Dalkeith⁴ which was 125 ft. high by 13 ft. 9 in. at four feet.

Strutt, in his *Sylva Scotica*, plate iv, figures a group of four wych elms at Pollok in Renfrewshire, the seat of Sir John Stirling Maxwell, Bart., which were then in extraordinary health and vigour, and of which the largest, measured⁵ in 1824, was 85 ft. by 11 ft. 10 in., and contained 669 cubic feet of timber. Mr. Renwick informed me that two of these which remained, were cut down in 1905 and were 90 to 96 ft. high and 12 ft. in girth. The other two were blown down about eleven years

¹ Quoted by Rev. T. A. Preston, in *Trans. Wilts. Arch. and Nat. Hist. Soc.* 1888, p. 269.

² *Woods of Perthshire*, 134, 486 (1883). ³ *Arb. et Frut. Brit.* iii. 1402 (1838). ⁴ *Gard. Chron.* xli. 168 (1907).

⁵ Loudon, *Gard. Mag.* xiii. 167 (1837) in an account of the trees at Pollok, states that the largest elm was, in 1836, 90 ft. high and 11 ft. 9 in. in girth close to the ground.

previously. The rings showed the age of the trees to be about 300 years, and there had been practically no growth during the last ten years of their life. Neither the plate in Strutt nor the photograph in *Ann. Anderson. Nat. Soc.* ii. pt. i, frontispiece (1896), show the habit of the wych elm, and I should have supposed these to be English elms except that they produced seed freely every year, even in old age.

Mr. Renwick sends us a list of wych elms, the most remarkable of which are: a hollow tree at Tullichewan Castle, Dumbartonshire, 20 ft. in girth at 2 ft. 5 in. from the ground, the stem being partly covered by burrs; at Woodbank, two trees, 105 ft. by 15 ft. and 100 ft. by 16 ft. 2 in., in 1910; at Strathleven, a tree 90 ft. by 16 ft. 10 in. in 1911; at Ancrum Park, Roxburghshire, a tree, 18 ft. 1 in. in 1893; at Newbattle Abbey, a tree 16 ft. 5 in. in 1896.

In Ireland, *U. montana* is common in the wild state, and is the only species that occurs in rocky and hilly situations in Donegal and Kerry. We have not seen any trees equalling in size those in England or Scotland, the finest specimen probably being one at Charleville, Co. Wicklow, which was 90 ft. high by 17 ft. 4 in. in girth in 1904. In a meadow by the river at Inistioge, Co. Kilkenny, there are two good wych elms, the larger measuring 90 ft. by 14 ft. 11 in. in 1904. At Adare Manor, Limerick, a tree, which had been damaged by a severe gale a short time previously, was 114 ft. by 15½ ft. in the same year.

The largest elm ever known in Ireland was probably one recorded by Hayes,¹ who considered it to be perhaps the finest tree of its species in the world. It grew at St. Wolstans, Co. Kildare, and was supposed to have been planted before the dissolution of the monastery in 1538. It lost two great limbs in 1762, and was blown down in the winter of 1776. Some time before this, the trunk had been carefully measured and was found to be 38 ft. 6 in. in circumference.

Hayes² quotes, as showing the extraordinary vigour of the elm in Ireland, a statement given him by Mr. Herbert of Cahirane, near Killarney:—Six "wyche or native Irish" elms, that were produced by layers from the stool of a tree felled in 1766, measured after twenty-six years' growth, from 3 ft. 11 in. to 5 ft. 1 in. in girth at 5 feet from the ground.

TIMBER, cf. p. 1922.

(H. J. E.)

ULMUS VEGETA, HUNTINGDON ELM, CHICHESTER ELM

Ulmus vegeta,³ Lindley, in Donn, *Hort. Cantab.* 96 (1826); Ley, in *Journ. Bot.* xlviii. 68 (1910).

Ulmus glabra, Miller, var. *vegeta*, Loudon, *Arb. et Frut. Brit.* iii. 1404 (1838).

Ulmus americana, W. Masters, *Hortus Duroverni*, 130 (1831) (not Linnæus).

A tree, attaining about 100 ft. in height and 15 ft. in girth, with a straight bole and long ascending straight branches. Bark similar to that of *U. montana*. Young branchlets stout, with a few scattered hairs, glabrous and occasionally striated in the

¹ *Practical Treatise on Planting*, 135 (1794).

² *Ibid.* 162 (1794).

³ There is no doubt that Lindley meant by this name the Huntingdon elm, although he erroneously gave its habitat as North America, relying on Masters, nurseryman at Canterbury, who called it the American elm, a name by which it is still known in some nurseries.

second year. Buds with minutely pubescent ciliate scales. Leaves (Plate 412, Fig. 16) oval, $3\frac{1}{2}$ to 5 in. long, $2\frac{1}{2}$ to 3 in. broad, very unequal at the base, abruptly contracted at the apex into a long serrated point; upper surface smooth, glabrous; lower surface with slight tufts of pubescence in the axils, glabrous elsewhere, but dotted with numerous minute brown glands; lateral nerves 14 to 18 pairs, often forked; margin coarsely biserrate, non-ciliate; petiole $\frac{1}{4}$ to $\frac{3}{8}$ in. long, more or less pubescent with scattered hairs.

Flowers, twenty to thirty in a cluster, on very short pedicels, very irregular in size and in the number of the sepals and stamens; calyx campanulate with a narrowed wrinkled tubular part at its base, or funnel-shaped, with four or five pink lobes; stamens, three, four, or five, with pale pink filaments and bright red anthers; stigmas bright red. Samaræ on very short pedicels, obovate-oval, about $\frac{7}{8}$ to 1 in. long and $\frac{3}{8}$ to $\frac{3}{4}$ in. broad, glabrous, non-ciliate, rounded at the apex with a short notch closed by the incurved stigmas; seed a little above the centre of the samara, with its apex extending nearly to the base of the notch; seed-cavity long and pointed at both ends.

The Huntingdon elm suckers very freely. Corky wings are never developed on the branchlets. It bears in favourable seasons a great abundance of seed, which is remarkably fertile. Sowings made at Cambridge in 1909, showed that this tree is a hybrid, one of the parents being *U. montana*, and the other uncertain, but probably *U. nitens*. I need not repeat here, the full account of the seedlings of the Huntingdon elm, which appeared in *Journ. Linn. Soc. (Bot.)* xxxix. 292-293 (1910). It is interesting to note that the fact that the Huntingdon elm does not come true from seed was established¹ at the Oxford assizes in 1847, when a nurseryman brought an action against Mr. Rivers of Sawbridgeworth, for supplying seedlings of the Huntingdon elm, which were expected to be the same as grafted plants, but which turned out to be very different.

The Huntingdon elm was raised in Wood and Ingram's nursery at Huntingdon about 1750, from seed, which is said² to have been gathered from some old trees in Hinchingsbrooke Park, near Huntingdon. Mr. John Ingram, who wrote an account² of its origin, in 1847, states that these trees were at that time still living, and were the true English or field elm; but as he wrote one hundred years after the original tree was raised, no reliance can be placed on his identification of the parent tree, which was more likely to have been *U. nitens*, which is still common in Hinchingsbrooke Park.

The name, Chichester elm, which was given to this tree as early³ as 1829, cannot be explained. It was also supposed to be of American origin, and is occasionally sold by some nurseries as *U. americana*. (A. H.)

I visited Hinchingsbrooke Park, the seat of the Earl of Sandwich, on 30th October 1911, with Mr. M. D. Barkley, agent for the estate, to find if possible the trees from

¹ Cf. *Gard. Chron.* 1847, p. 507. Elm seedlings with opposite and with alternate leaves were noticed and figured by Carrière, in *Rev. Hort.* xlvii. 286, figs. 47, 48 (1875); but he was unable to explain their significance.

² *Gard. Chron.* 1847, pp. 507, 526.

³ Lindley, *Syn. Brit. Flora*, 227 (1829). Cf. Loudon, *Arb. et Frut. Brit.* iii. 1404 (1838).

which the original Huntingdon elm was raised. I found four distinct forms of elm. The oldest, which appear to have been growing in hedgerows before the park was enclosed about 1750, are of no great height, though one of them near the north lodge is $20\frac{1}{2}$ ft. in girth. These are an inferior type of Huntingdon elm, and had shed most of their leaves without colouring well. Some taller and straighter trees which are true English elms grow near them, and had their leaves still on and quite green.

About one hundred yards north of the Japanese garden, there is an old tree 80 ft. by $16\frac{1}{2}$ ft. of the true Huntingdon character, having its trunk split to the ground and the leaves nearly all fallen. On the edge of the grove was a group of bushy ill-shaped trees with small glabrous leaves.

Near these, within the grove which is fenced off, are the tallest and finest elms which I saw in the park, one of them being 120 ft. by $17\frac{1}{2}$ ft., the leaves of which, differing from the Huntingdon type, were still on and quite green. Its tall straight trunk had a large wound where a branch had been torn out by the wind. A bed of suckers surrounded this group of trees, some of which have been transplanted to the Huntingdon nursery, in the hope of preserving a better type of Huntingdon elm than the trees now sold, which, as I am informed by Mr. Perkins, proprietor of this nursery, are usually budded on wych elm stocks. This fine elm is probably a seedling of the Huntingdon elm, and may be called the "Hinchingsbrooke" elm.

The Huntingdon elm, though a favourite tree among nurserymen on account of its very rapid growth, and often making an ornamental wide-spreading tree, should not, in my opinion, be planted as an avenue or park tree. Its habit of forking tends to split the trunk in a way that other elms do not show; and out of a large number of trees which I have felled at Colesborne, at about sixty years after planting, hardly one was free from defects caused by this bad habit. I calculated the loss in measurement of the timber on these trees was from 15 to 25 per cent, and the timber, though fit for tinsplate boxes, is pale in colour and soft in texture, compared with English or wych elm. It grows, however, with such rapidity, that it might pay to plant in woods, or if care is taken to prune all the branches when young, up to 40 or 50 ft. As a rule, it loses its leaves a month before the English elm and colours badly, but in the remarkable season of 1911, a row of elms of this variety growing at Colesborne on dry soil with a southern aspect, turned a brilliant yellow, just before the leaves fell in October.

The largest elm I have ever seen, and the largest tree of any kind in Great Britain, grew in the grove of Magdalen College, Oxford, but had never been noticed by arboriculturists,¹ until Mr. W. Baker, Curator of the Botanic Garden, showed it me in July 1905. Though generally supposed to be a wych elm, it was undoubtedly identical in habit and leaves with *U. vegeta*. On October 14th of the same year I saw it again, when its leaves had fallen, whilst the English elms in the same park were

¹ H. A. Wilson, in a *History of Magdalen College*, 286 (1899), states: "Most of the trees in the grove are English elms dating from the Restoration period. Two wych elms were planted probably about the same time as the others. The girth of one of these trees in 1831, at five feet, is stated to have been 21 ft., in 1866 23 ft. 9 in. In June 1899 it measured 26 ft. 5 in. and its height was approximately 130 feet. R. T. Günther, *Oxford Gardens*, 218 (1912), gives a reproduction of a photograph of the great Magdalen elm, which was taken in 1899. He states that there is an error in Wilson's account, as the measurement given of 21 ft. girth in 1831 was really that of another tree which fell in 1861. The latter was estimated to contain 1092 cubic feet.

still green. At my suggestion Mr. G. E. Baker, then Bursar of Magdalen College, removed a scrubby tree which stood near it, in order to allow a photograph (Plate 395) to be taken soon after by Mr. Foster of Burford. I took great pains to measure it accurately from four different positions, and found its height to be 140 ft., and its girth at five feet, 27 ft. I estimated its contents when standing at over 2000 cubic feet, but when I showed it later to some of the most experienced judges of timber in the English Arboricultural Society, their estimates were all lower than mine. On 5th April 1911 this splendid tree was blown down, and on hearing of this I went to Oxford at once with Mr. Foster to photograph and measure it on the ground. I made the total height 142 feet. With the help of my forester, J. Irvine, I made a series of thirty-three measurements of the various pieces and limbs as accurately as possible, Mr. Carter, Bursar of Magdalen, booking them as we measured; and found that if no allowance was made for bark, which was three to four inches thick on the trunk, or for the hollows caused by decay, the total contents were 2787 feet. Professor Somerville,¹ and Sir W. Schlich, F.R.S., afterwards measured the tree on the ground, and agree that my calculation of its cubic contents is nearly accurate. The timber of this tree was much redder than that of any tree of *U. montana* which I have ever seen. No suckers were noticed by me, and none have come up since the fall of the tree. I understand that the President and Fellows of Magdalen College have decided to allow the remains to lie undisturbed as a memorial of the fallen giant.

This tree was so rotten in the interior that the annual rings could not be counted. Judging from its great size, it was probably 200 to 300 years, and cannot be of the same origin as the ordinary Huntingdon elm, if the story of the origin of the latter in 1750 is correct. The independent origin of this hybrid at various times and in different places is not improbable.

Another tree, similar in habit and foliage, still survives in the Grove of Magdalen College, and in 1912 measured about 130 ft. in height, and 23 ft. in girth.

Elsewhere I have seen no old trees except in Hinchingsbrooke Park; but there is a fine specimen² in the Fellows' garden of Trinity College, Cambridge; and another in Victoria Park, Bath. There is at Cambridge, an avenue of Huntingdon elms, known as Brooklands Avenue, which is said to have been planted by Mr. Richard Foster about 1830. (H. J. E.)

¹ Cf. *Quart. Journ. Forestry*, v. 279, fig. (1911).

² Figured in *Journ. Linn. Soc. (Bot.)* xxxix. pl. 20 (1910). According to C. W. King, this tree was planted about 1814, in the presence of Adam Sedgwick. It is now often called Sedgwick's elm.

ULMUS MAJOR, DUTCH ELM

- Ulmus major*,¹ Smith, *Eng. Bot.* t. 2542 (excl. syn.) (1814); Lindley, *Syn. Brit. Flora*, 226 (1818); Loudon, *Arb. et Frut. Brit.* iii. 1396 (1838); Ley, in *Journ. Bot.* xviii. 71 (1910).
Ulmus hollandica,¹ Miller, *Gard. Dict.* ed. 8, No. 5 (1762) (?).
Ulmus hollandica, Moss, in *Gard. Chron.* li. 217 (1912).
Ulmus fungosa, Aiton, *Hort. Kew.* i. 319 (1789) (?).
Ulmus scabra, Miller, var. *major*, Gürke, in Richter and Gürke, *Plant. Europ.* ii. pt. i. p. 73 (1897); Schneider, *Laubholzkunde*, i. 218 (1904).

A tree, attaining in England over 100 ft. in height and 15 ft. in girth, but usually smaller, with a short bole and irregular wide-spreading branches. Bark of the trunk dark coloured, deeply fissured. Young branchlets glabrous or with a few scattered hairs; finely striated, glabrous and bright reddish-brown in the second year. Buds ovoid, with minutely pubescent ciliate scales. Leaves (Plate 412, Fig. 15) broadly oval, 3 to 5 in. long, 2 to 3 in. wide, very unequal at the base, contracted at the apex into a rather long serrated point; upper surface dark green, shining, nearly smooth, with a scattered minute pubescence; lower surface light green, with conspicuous white axil-tufts, prolonged along the midrib between the insertions of the lower lateral nerves, and with a scattered minute pubescence and numerous minute glands; nerves about twelve to fourteen pairs, mostly forked; margin deeply serrate, non-ciliate; petiole $\frac{1}{4}$ to $\frac{3}{8}$ in. long, pubescent.

Flowers, often very numerous (twenty to fifty) in the cluster, on extremely short pedicels, mostly tetramerous, with four calyx-lobes and four stamens (but often irregular with five calyx-lobes and four stamens, five calyx-lobes and five stamens, etc.): calyx, funnel-shaped, lobes pink and unequal; stamens with filaments tinged with pink and with red anthers; stigmas bright red. Samaræ, on very short pedicels, obovate-oval, when mature $\frac{3}{4}$ to 1 in. long, and $\frac{1}{16}$ to $\frac{3}{4}$ in. broad, full and rounded at the apex, which is emarginate, with a short notch usually closed by the incurved stigmas below the emargination; seed in the upper half of the samara, with its apex close to the base of the notch.

U. major may almost always be recognised by the large corky ridges, which are developed only on the epicormic branches of the trunk.² It produces suckers freely, the stems of which often have bright reddish-brown corky ridges, whilst their leaves and branchlets are more pubescent than those of the adult tree.

U. major rarely bears fertile seed; but in 1909, small lots of seed from trees at Brocklesby, Belton, Bayfordbury, and Cambridge produced in each case two seedlings. These eight seedlings are very variable in appearance, those raised from the

¹ *U. major* was described and figured by Smith from specimens gathered in England by E. Foster, and is the first certain name. We have not adopted Miller's name, *U. hollandica*, as his description is uncertain; moreover, it implies a foreign origin for a tree which is undoubtedly indigenous in England. Miller quotes as a synonym of his elm, *Ulmus major hollandica*, Plukenet, *Alm.* ii. 393 (1696), which is described as "*angustis et magis acuminatis samaris, folio latissimo scabro.*" Plukenet's elm cannot be determined, but his description excludes *U. major*. Cf. page 1869, note 2. The usage of "Dutch elm" as a name for *U. major* apparently began in error about 1730.

² In *U. nitens*, var. *suberosa*, which is the true cork-barked elm, the branchlets in the crown of the tree are all corky.

seed of the tree at Belton being exactly like *U. montana*; and I have little doubt that *U. major* is a hybrid, with *U. montana* and *U. nitens* as the parent species.

VARIETIES

The following varieties are assigned with some doubt to *U. major*:—

1. Var. *serpentina*, Henry.

Ulmus serpentina, Koch, *Dendrologie*, ii. pt. i. 417 (1872).

Ulmus montana, sub-species *major*, var. *serpentina*, Dippel, *Laubholzkunde*, ii. 29 (1892).

A small tree, with curved and twisted pendulous branches, forming a dense pyramidal or globose crown. Leaves and branchlets similar to those of *U. major*.

The origin of this variety is unknown. It is said by Koch to be known in nurseries as the parasol elm, and is represented at Kew by a good specimen about 15 ft. high, obtained from Späth in 1896. Another smaller tree at Kew is labelled *U. campestris pendula nova*.

2. Var. *Daveyi*,¹ Henry.

A wide-spreading tree, with irregular branches and pendulous branchlets, differing from *U. major* in the epicormic branches never developing corky ridges. Young branchlets more or less pubescent with long hairs. Leaves similar in shape to that species, but smaller, $2\frac{1}{2}$ in. long, 2 in. broad, and with 10 to 12 pairs of lateral nerves; upper surface shining, smooth, with a scattered minute pubescence; lower surface similar, covered with a dense soft pubescence, and with conspicuous white axil-tufts; petiole densely pubescent. Flowers with the sepals and stamens irregular in number, and the stigmas white or tinged with pink. Samaræ not seen.

This occurs as a rare tree in Cornwall, in the valleys mixed with *U. major*, which it resembles in its wide-spreading habit, but has very pendulous branchlets. It is apparently never very large in Cornwall, where I saw it at Coldrenick and near Perranporth; but in Norfolk and Cambridge, where it is also rare, it reaches 80 ft. in height.

3. A tree at Kew, about 25 ft. high, pyramidal in habit, with ascending branches, which was obtained from Späth in 1896 as *U. campestris*, var. *modiolina*,² has leaves like those of *U. major*, except that they are very scabrous above.

DISTRIBUTION

U. major is widely distributed throughout England, occurring from Cornwall to Essex and Norfolk, and extending as far north as Yorkshire. It ascends to about 1000 ft. altitude in mountain valleys in South Wales.³ In many districts it is the commonest tree in hedgerows; and in Cornwall, where it is associated with *U. nitens*, var. *stricta*, these two elms grow in every valley and are certainly indigenous.

U. major is said to occur in France, Germany, and Russia; but I have seen no

¹ Named after Mr. F. Hamilton Davey, whose researches into the flora of Cornwall are well known.

² This tree is different from *U. modiolina*, Dumont de Courset. See p. 1894.

³ Ley, in *Journ. Bot.* xlviii. 72 (1910).

specimens, and doubt if it is really known by Continental botanists, who apply the name to forms of *U. montana* with large leaves.¹

U. major is usually called "Dutch elm" by foresters and carpenters, and has been supposed by Miller and subsequent writers to have been introduced into England from Holland in the reign of William III. In all probability the elm which was then introduced was not *U. major*, but a vigorous form of *U. montana*. It is difficult to see how the latter could have been *U. major*, a tree which is apparently unknown in Holland.² (A. H.)

CULTIVATION

Though it is difficult to describe the habit of this elm, which is very inferior to that of the true English elm, yet it is easy to recognise, even at a distance, as I have repeatedly been able to foretell by the form alone before reaching a tree, that it would have corky twigs on the trunk. It has been largely planted in the neighbourhood of London, where, as elsewhere, it loses its leaves three weeks or a month earlier than the true English elm. In Kensington Gardens, where most of the elms appear to belong to this species, on 30th October 1911, there was hardly a leaf left on the majority of the elms, whereas throughout the Thames valley true English elms were still green in the hedgerows, and on my own place a week later, after 16° of frost, they were only beginning to turn golden, a colour which the Dutch elm seldom or never assumes. An immense deal of trouble and expense and obloquy has fallen on those responsible for the care of the London Parks because a wholesale lopping of the old elms was considered necessary for the safety of passers-by, after several accidents had occurred from falling branches. I am able through the courtesy of the Right Hon. Lewis Harcourt, who, in 1905, was the Minister responsible for the London Parks, to give an illustration (Plate 396) showing the effect of this lopping after a period of some years. I think it must be allowed that, however ugly they seem at first, they throw out young branches with great rapidity and soon improve in appearance.

This tree in some seasons produces a large quantity of seeds which are nearly always infertile. On 13th May 1906, I noticed three trees growing in a row near the North Lodge at Gatton Park, Surrey, their leaves being much more backward than those of *U. campestris*, but none of the samaræ which were sent me from these trees seemed to have any perfect seed.

¹ Cf. Mathieu, *Flore Forestière*, 302 (1897). *U. major*, Reichenbach, *Icon. Fl. Germ.* xii. 13, t. 665 (1850), is *U. montana*. Michaux, *N. Amer. Sylva*, ii. 224, plate 129, fig. 2 (1819), describes and figures ordinary *U. montana* under the name *U. suberosa* as the Dutch elm.

² In the large collection of specimens of wild and cultivated elms of Holland, which are preserved in the herbarium of the Dutch Botanical Society at Haarlem, I found none identical with *U. major* of England. Most of the supposed wild elms in Holland, as those on the dunes near Haarlem, are *U. nitens*, var. *suberosa*. Mr. Springer sent me a branch of a solitary large elm growing on these dunes, which he supposed to be *U. major*; but the leaves differ in being very scabrous on the upper surface, and belong to a hybrid intermediate between *U. montana* and *U. major*.

U. major may be expected to occur on the continent; but I have not seen any trees of the typical English form, either wild or cultivated, in France, Belgium, and Holland. I have, however, specimens from a wild tree in a wood, near Gray, Haute Saône, intermediate between *U. major* and *U. nitens*.

U. corylifolia, Host, *Fl. Austr.* i. 239 (1827), judging from the description and a type specimen in the Kew Herbarium, is allied to, but not identical with *U. major*. This is said to grow on the banks of streams in mountain woods in Austria.

One of the tallest I know which may be referred to *U. major* is a tree in the heronry at Dallam Tower, Westmoreland, which, being drawn up in a thick wood, has attained a height of about 130 ft., and is clear of branches for 60 or 70 ft.; but is only 10 ft. in girth. A very large tree grows by the lake at Dodington Park, Gloucestershire; the main trunk, 22 ft. in girth, is broken, but a branch remains which, in 1910, was 115 ft. high; the branchlets are very corky. A tree at Laverstoke Park, Hants, 113 ft. by 18 ft., is of a superior type to the common Dutch elm, and may be one of the hybrids. There are trees of *U. major* at Hampton Court, some of large size; at Syon; at Aldenham, a large tree on the east front of the house; at Beaulieu Abbey; and at many places in the south of England.

Many of the large elms in Kew Gardens belong to this species, and one, which was felled in December 1911, was 91 ft. high by 13 ft. 5 in. in girth. Mr. Bean counted on the stump about one hundred and fifty rings, so that this tree was probably planted about 1759, when the botanic garden was formed at Kew.

There are many Dutch elms at Boughton; and I was assured by Mr. Neil, the forester here, that their timber is as good as that of the English elm. It is generally believed by carpenters and wheelwrights to have much more brittle and less valuable timber than the redder wood of the English elm.

Many elms in the eastern counties belong to this species; and though there are some fine true English elms in Essex, yet near the coast of this county, and in Suffolk and Norfolk, we rarely see an elm of large size, which does not seem to be *U. major*. On light and sandy soils it is a scrubby tree, and does not carry its leaves so late or turn such a bright colour in autumn as the English elm.

The avenue of elm at Castle Howard in Yorkshire, which is perhaps the best I know so far north, appears to be, and is considered by Mr. Fell, the forester there, to be, of this type, which in some parts of England is often called by carpenters a "bastard" elm.

Boutcher says¹ that in order to get the true variety he imported it from Rotterdam, to make the mother plants of those he raised in his nursery; and adds that though inferior in beauty and elegance of form, to what he calls the French elm,² it is still a very valuable tree in the climate of Scotland, as "it will succeed in wet obstinate clay, where no tree I know of equal use, and few but aquatics, will grow freely; but in such places it will soon become a stately tree, and though the wood is not equal to the other mentioned kinds, it is still a useful wood, and is often indiscriminately sold to the carpenter with them from their near resemblance."

In all probability Boutcher here referred to the hybrid elm, *U. belgica*, which was cultivated then in Holland; but we have had no specimens from Scotland that can be referred to this. True *U. major* is rare in Scotland, where most of the elms which are not *U. montana* are *U. nitens* of French origin.²

In Ireland *U. major* is the common form in some parts of the country. Many of the elms in the Phoenix Park seem to be Dutch elms, but I have not examined them carefully. It occurs at Loughrea, Co. Galway, and is common at Lismore in the Blackwater valley, Co. Waterford. Here it is known to timber merchants as

¹ *Treatise on Forest Trees*, 19 (1775).

² Cf. p. 1897, last paragraph.

"Irish elm," and the wood is used by wheelwrights. The habit of the tree is generally branchy, and inferior to that of *U. nitens*, which is here erroneously called English elm. (H. J. E.)

ULMUS NITENS, SMOOTH-LEAVED ELM

Ulmus nitens, Moench, *Meth.* 333 (1794); Rehder, in *Mitt. Deut. Dend. Ges.* 1908, p. 157; Moss, in *Gard. Chron.* li. 217 (1912).

Ulmus glabra, Miller, *Gard. Dict.* ed. 8, No. 4 (1768) (not Hudson¹); Smith, *Eng. Bot.* t. 2248 (1811); Loudon, *Arb. et Frut. Brit.* iii. 1403 (1838); Reichenbach, *Icon. Fl. Germ.* xii. 13, t. 664 (1853); Willkomm, *Forst. Flora*, 553 (1887); Schneider, *Laubholzkunde*, i. 219 (1904) (in part); Ley, in *Journ. Bot.* xlviii. 69 (1910).

Ulmus foliacea,² Gilibert, *Exercit. Phyt.* ii. 395 (1792); Sargent, *Arnold Arboretum Bull. Pop. Inform.* No. 11 (1911), and in *Gard. Chron.* l. 202 (1911).

Ulmus campestris, var. *laevis*, Spach, in *Ann. Sc. Nat.* xv. 362 (1841); Planchon, in *Ann. Sc. Nat.* x. 273 (1848).

Ulmus campestris, var. *glabra*, Hartig, *Naturl. Forstl. Kulturpfl.* 458, 460 (1851); Planchon, in De Candolle, *Prod.* xvii. 157 (1873); Ascherson and Graebner, *Syn. Mitteleurop. Flora*, iv. 553 (1911).

A tree, with a straight bole, and wide-spreading branches, with usually pendulous branchlets. Bark grey, deeply fissured in old trunks. Young branchlets slender, glabrous or with a few scattered hairs, usually with the upper margin of the stipule-scars fringed with a tuft of hairs. Buds with minutely pubescent ciliate scales. Leaves (Plate 412, Fig. 23) oval or obovate, 2 to 3½ in. long, 1 to 2 in. broad, very unequal at the base, acuminate at the apex; upper surface dark green, shining, smooth to the touch, in spring pubescent with scattered minute hairs, in autumn glabrescent; lower surface, with conspicuous white axil-tufts, and covered with minute reddish brown glands, in spring pubescent with scattered minute hairs, in autumn glabrescent; margin biserrate, non-ciliate; lateral nerves about twelve pairs, often forked; petiole ¼ to ½ in. long, pubescent.

Flowers, twenty to thirty in a fascicle, on very short pedicels (less than ½ in. in length); tetramerous or pentamerous, but often irregular in the number of sepals and stamens; calyx funnel-shaped, about ¼ to ⅓ in. long, with four or five pink short lobes; stamens, four or five, occasionally three, with pink filaments and red anthers; stigmas white, or rarely pale pink. Samaræ, on very short pedicels, glabrous, non-ciliate, obovate with a cuneate base, about ¾ in. long, and ½ in. broad; broad and rounded at the slightly emarginate apex, with the notch closed by the incurved stigmas; seed in the upper part of the samara, with its apex nearly touching the base of the notch.

Seedling: The two cotyledons are raised above the ground on a short

¹ *U. glabra*, Hudson, *Fl. Angl.* 95 (1762), is the tree almost universally known as *U. montana*; and being earlier than Miller's name, renders the latter inapplicable to the smooth-leaved elm.

² *Ulmus foliacea*, Gilibert, *Exercit. Phyt.* ii. 395 (1792), was founded on a specimen of an elm, which was said to be frequent about Grodno in Lithuania. The description is very imperfect, but probably applies best to *U. nitens*, which occurs in Lithuania. There are no grounds for resuscitating a name like *U. foliacea*, which cannot be identified with certainty.

pubescent caulicle, which ends in a long tap-root; and are sub-orbicular to obovate, $\frac{1}{3}$ to $\frac{2}{5}$ in. long, broad and rounded at the apex, deeply cordate at the base, green above with scattered short bristles, whitish and glabrous beneath; indistinctly veined; margin entire and ciliate; stalklets very short, pubescent. Leaves, arising from the stiff erect pubescent stem in opposite pairs, ovate, sharply serrate or biserrate, scabrous above with papillæ and numerous short bristles, the latter being scattered on the under surface; ciliate in margin; petioles short, pubescent. Seedlings, sown in June, attain in October 6 to 12 in. in height, and bear six to eight pairs of leaves as a rule. The normal alternate foliage of the adult plant appears in the second year; but develops at once on any branch that may be formed in the first year. The pubescent twigs and rough hairy leaves are preserved for a considerable period, the normal foliage and branchlets not appearing till the trees are about ten years old.¹

VARIETIES

This species, being distributed over a wide area (cf. p. 1896), is variable in the wild state, in the amount of pubescence on the branchlets and leaves, and in the presence or absence of corky ridges on the twigs and branches. In the ordinary form in England, the twigs are not suberose.

1. Var. *suberosa*, Henry. Cork-barked Elm.

Ulmus hollandica, Pallas, *Fl. Ross.* 76 (1784) (not Miller).

Ulmus suberosa, Moench, *Verz. Weissenst.* 136 (1785); Reichenbach, *Icon. Fl. Germ.* xii. 13, t. 663 (1850); Hartig, *Naturges. Forst. Cult.* 459, t. 56 (1851) (not Ehrhart,² Smith, Lindley, or Loudon).

Ulmus tetrandra, Schkuhr, *Bot. Handb.* i. 178, t. 58 b (1791).

Ulmus campestris, var. *suberosa*, Wahlenberg, *Fl. Carpat.* 71 (1814).

Ulmus glabra, var. *suberosa*, Gürke, in Ritter and Gürke, *Pl. Europ.* ii. 72 (1897).

Branchlets of the second to the tenth year furnished with corky wings. Leaves and samaræ as in the type (Plate 412, Fig. 19).

This variety is occasionally seen in England, as on trees at Hatfield; and is represented at Kew by four trees of no great size, but of considerable age, which were long labelled erroneously *U. alata*.³ It appears to be a common variety in the forests of central Europe, as in the oak forests on the banks of the Save in Slavonia, where I saw it in 1909, and Elwes in 1910. Elwes also gathered a specimen at Gissselfelde in Denmark in 1910.

A form of var. *suberosa* with small leaves, about an inch in length, is cultivated at Kew, as var. *microphylla pendula*.⁴

2. Var. *stricta*, Aiton, *Hort. Kew.* i. 319 (1789); Schneider, *Laubholzkunde*, i. 220 (1904); Ley, in *Journ. Bot.* xlviii. 70 (1910). Cornish Elm.

¹ Cf. our account of French seedlings of this species, p. 1897. A young seedling is figured in *Journ. Linn. Soc. (Bot.)* xxxix. 292, pl. 22 (1910).

² *U. suberosa*, Ehrhart, *Beit.* vi. 87 (1790), was a general name, applied to all the elms in Europe that were not *U. montana* or *U. pedunculata*. Ehrhart's specimen of *U. suberosa* in Smith's herbarium at the Linnean Society is the "English elm," *U. campestris*, L.

³ Cf. *Gard. Chron.* xix. 453, fig. 66 (1896).

⁴ Distinguished as *U. glabra*, var. *propendens*, Schneider, *Laubholzkunde*, i. 220 (1904).

Ulmus campestris, var. *cornubiensis*, Loudon, *Arb. et Frut. Brit.* 1376 (1838).

Ulmus stricta, Lindley, *Syn. Brit. Flora*, 227 (1829); Moss, in *Gard. Chron.* li. 234 (1912).

A tree, attaining about 80 ft. in height and 15 ft. in girth, rather variable in habit, but usually with a narrow crown, with the upper branches short and ascending, the lower branches spreading and curving upwards at the ends. Bark light grey, fissuring into small plates. Young branchlets often densely pubescent at the insertions of the leaves, elsewhere with scattered hairs. Buds minute, with glabrous scales, slightly ciliate in margin. Leaves (Plate 412, Fig. 20) firm in texture, obovate to oval, 2 to 2½ in. long, 1 to 1½ in. broad, unequal at the base, acuminate at the apex; upper surface dark green, shining, glabrous, smooth to the touch, lower surface lighter green, with conspicuous tufts of pubescence at the junctions of the midrib and lateral nerves, and at the forks of the latter, and with slight tufts usually near the margin at the base of the teeth, elsewhere glabrous or with minute scattered pubescence; lateral nerves about twelve pairs, often forked; margin crenately biserrate, non-ciliate; petiole about $\frac{1}{3}$ in. long, pubescent.

Flowers, fifteen to twenty in small clusters, on very short pedicels, irregular in the number of sepals and stamens, but mostly tetramerous; calyx funnel-shaped, minute, about $\frac{1}{2}$ in. long, with pink lobes; stamens four or five, with pink filaments and dull red anthers; stigmas pink. Samaræ rarely ripening, but when mature, similar to those of typical *U. nitens*, but narrower, obovate, cuneate at the base, about $\frac{2}{3}$ in. long and $\frac{3}{8}$ in. wide; imperfect samaræ are usually broadly obovate, less than $\frac{1}{2}$ in. long.

From ten lots of seed, sent me from different localities in Cornwall, I raised in 1909, thirty-eight seedlings, all of which bore opposite leaves. These plants are now all uniform in appearance; and in all probability the Cornish elm is a pure species.

In Abbeyleix Park, Ireland, there are a few elms, growing with oak trees on the alluvial flat of the river Nore, which are probably indigenous. These are similar in foliage to the Cornish elm; and have similar small tetramerous flowers, few in a cluster, but differing in having white stigmas. These trees produced a few ripe samaræ in 1909, similar to those of *U. nitens*, but scarcely $\frac{1}{2}$ in. long. From these I raised two seedlings, with opposite leaves, which in 1912 resembled the seedlings of the Cornish elm.

The suckers of the Cornish elm, which are freely produced, have pubescent stems, and small leaves, scabrous above with scattered minute tubercles and short bristles. The epicormic branches are usually smooth, but occasionally develop corky ridges, which are, however, never seen on the normal branches in the crown of the tree.

In Cornwall, the tree is slow in growth, but it produces a remarkably tough wood, which is used by wheelwrights for naves, felloes, and framework of waggons; and was formerly utilised as staves for the casks in which cement and china clay were exported, and also for making boxes in which gunpowder was compressed by an hydraulic press, as no other wood was found to bear great pressure so well.

The Cornish elm is undoubtedly indigenous in Cornwall and south Devon,

where it grows abundantly in the hedge rows, reproducing itself regularly by suckers, and possibly by seed in rare years as in 1909. Mr. F. Hamilton Davey tells me that it is plentiful also in parts of Somerset, and says regarding its distribution in Cornwall, that it is fairly common from the Tamar to a little to the west of Penzance. From the extreme north-east of the county to Land's End, it does not approach the coast nearer than a mile or two. It is also rare along the Lizard peninsula, and near the range of granite hills, which run from east to west through the centre of the county. It is a tree of low altitudes, the finest specimens being always found in sheltered valleys, especially in those which run to the south coast.

The Cornish elm was reported¹ by the late Rev. A. Ley to be common in Brittany, and this is confirmed by Dr. C. E. Moss, who observed it in most parts of Brittany, though good specimens were rare on account of the local practice of lopping. (A. H.)

I measured two large trees (Plate 397) of characteristic habit in the lower part of the entrance drive at Coldrenick in Cornwall, the suckers of which were of precisely similar habit. One was 100 ft. by 11 ft. 4 in., the other 92 ft. by 13 ft. 5 in. On the approach to Menabilly House from Fowey, I also saw fine Cornish elms, some over 100 ft. high. I measured one, 95 ft. by 6 ft. 2 in. At Scorrier, near Truro, there are many of these elms, though I saw none of great size; and Mr. John Williams told me that they resist the sea wind, which is here very strong, better than any other tree; and that he plants suckers, which are abundant. The Cornish elm seldom attains a great girth; but a tree at Enys, which Henry saw in 1911, measured 24 ft. in girth at the ground, 17 ft. at five feet up, and 16 ft. at seven feet up; but it was only about 65 ft. high. In the vicarage garden at Perranar-worthal, Henry saw a fine specimen 80 ft. by 11 ft.

In Devonshire I have seen no Cornish elm remarkable for size.

At Shawford, near Winchester, there are four fine trees, not quite of the typical Cornish form, the largest of which measured 125 ft. by 10 ft. 10 in. in 1907. At Bisterne Park, near Ringwood, I saw in 1896 three trees, differing somewhat in habit. One had a very erect trunk and pointed top; and measured 86 ft. by 13 ft. The second was more rounded at the top, and was 90 ft. by 14 ft. The third tree could scarcely be called a true Cornish elm, as it had the pendulous branches of an American elm, and measured 98 ft. by 13½ ft.

At Cowdray, near the ruins, there are three fine trees, of the same habit as the second tree at Bisterne, and not so regular as the Wheatley elm. These measured in 1906, 113 ft. by 13 ft., 113 ft. by 13½ ft., and 110 ft. by 11 ft. 9 in. respectively.

At Bagshot Park, on May 20, 1907, I measured a very fine tree, which had not yet come into leaf, though some seeds were nearly ripe. It measured 98 ft. by 11½ ft. At Arley Castle, there is a tree, No. 351 in the catalogue, which measured 75 ft. by 8 ft. 8 in. in 1907.

In Wales the Cornish elm grows well on the south coast; and at Singleton, the property of Lord Swansea, there is an avenue of them. Mr. Harris, formerly

¹ In *Journ. Bot.* xlviii. 70 (1910).

gardener here, considered this to be the best variety for seaside planting, as it bears the wind well.

In the Edinburgh Botanic Garden there are two trees, nearly equal in size, about 65 ft. by 5 ft. 4 in. in 1908, with small leaves, which seem to be a variety of the Cornish elm.

In Ireland, especially in the south, this tree comes to great perfection. In the Blackwater valley, I measured in 1910, in a meadow two miles east of Lismore, a splendid tree, about 100 ft. by 15 ft. In the avenue to the castle, there are some very tall and slender elms, one of which was 110 ft. by 10 ft. At Mallow Park, the seat of Mrs. Norris, I saw in 1909, some fine elms of similar type, one of which measured 95 ft. by 12 ft. 10 in.; another 95 ft. by 10 ft.; and a third, a very straight tree, about 90 ft. by 6 ft. The Cornish elm is probably native in the south of Ireland, where there are very many old trees of this variety. (H. J. E.)

3. Var. *Wheatleyi*, Simon-Louis, *Cat.* 1869, p. 98. Wheatley or Jersey Elm.

(?) *Ulmus sarniensis*, Loddiges, *ex Loudon, Arb. et Frut. Brit.* iii. 1376 (1838).

A pyramidal tree with stiff ascending long branches, and a narrow pointed crown. Leaves (Plate 412, Fig. 21) similar to those of the Cornish elm, but broader in proportion to their length, and glandular on the petiole and on the midrib, veins, and surface beneath, with less conspicuous axil-tufts. Flowers as in var. *stricta*, but with white stigmas. Fruit rarely ripening, but when mature similar to that of *U. nitens*, with the apex of the seed touching the small circular closed notch. From seed collected by Mr. J. F. Rayner from a tree in Southampton Cemetery, I raised forty-three plants in 1909, half with opposite, and half with alternate leaves. These now look a mixed lot, differing in the size of the leaves and in the presence or absence of corky ridges on the stem; and are not uniform like the seedlings of the Cornish elm.

This tree is generally regarded as a form of the Cornish elm, of which it is probably a seedling; but it differs in the characters noted. It is now generally sold in nurseries as the Wheatley elm; and is occasionally known in Germany and Holland under the erroneous name, *U. campestris*, var. *monumentalis*.¹ The Wheatley elm is so commonly known as the Jersey or Guernsey elm, that in all probability it is identical with the tree propagated by Loddiges as *U. sarniensis*, but Loudon's description of this is inadequate, and points rather to some form of the English elm.

A form of the Wheatley elm with leaves of a fine yellow colour, said to last till autumn, originated in 1900 in the Chester nurseries, and is now sold by Messrs. Dicksons as the "golden Cornish elm." (A. H.)

The finest Wheatley elm² is probably one growing in the public garden on

¹ The Wheatley elm is well figured by Springer in *Mitt. Deut. Dend. Ges.* 1910, p. 271, fig. 273; where Beissner points out that the true var. *monumentalis*, Rinz, *ex Petzold and Kirchner, Arb. Musc.* 554 (1864), is a columnar tree, with a few upright main branches and numerous short twigs bearing dense crowded dark green leaves, which was propagated by Rinz at Frankfort from a sucker of *U. nitens*, var. *suberosa*. A beautiful narrow pyramidal tree in Späth's nursery, called *U. campestris cornubiensis*, bears leaves similar in size and appearance to a common form of *U. nitens*, and differs from the Wheatley or the true Cornish elm.

² A good specimen at Kew is figured in *Card. Chron.* xli. 150, fig. 67 (1907).

the terrace at Richmond, overlooking the Thames, which is over 90 ft. in height (Plate 398).

In Messrs. Rogers' nursery at Southampton, large numbers of this elm are propagated; and I noticed that the grafts have rough leaves at first, and do not produce the typical smooth leaves until they are older. Trees of this variety retain their leaves till late in the season; and at Colesborne, colour well in the autumn. In the Isle of Wight, there are many trees of this type, and an avenue of small ones at Barton Farm, Osborne.

At Stowe, near Buckingham, there are some fine trees of this variety, here called Jersey elm, which produce many suckers. The best that I measured was 85 ft. by 8 ft. 2 in. in 1905. At Merton Hall, Norfolk, Henry measured a fine tree, 86 ft. by 8 ft. 10 in.; and there is a good specimen in Sir Hugh Beevor's grounds at Hargham.

At Monreith, Sir Herbert Maxwell has a number, which are called Southampton elms. These are from 52 to 57 ft. high, fifty-six years after planting, and are nearly as tall as some English elms planted about 100 years ago. These trees, however, are not so well-shaped as in the south of England, and looked as if the climate was too damp for them. In Queen's Park, Glasgow, there are twenty Wheatley elms, which were planted about 1859; they are 46 to 61 ft. in height, and average 6 ft. in girth.

(H. J. E.)

4. Var. *italica*, Henry (*var. nova*). Mediterranean Elm.

Leaves (Plate 411, Fig. 9) coriaceous, similar to those of *U. nitens* in shape and size, mainly differing in the numerous lateral nerves, which are never less than fourteen pairs, and often as many as eighteen pairs. Branchlets and samaræ as in the type. This variety usually has leaves smooth and glabrous above, and glabrescent beneath in autumn, with conspicuous axil-tufts; petiole $\frac{1}{4}$ in. long, pubescent.

This elm appears to be common in Italy, Spain, and Portugal, and also in Algeria. I observed it wild on Montserrat and in the Guadarrama mountains in Spain, where at 3000 to 4000 ft. elevation it attains a height of 70 to 80 ft. Dr. Henriquez sent to Kew on loan a specimen of this elm from Coimbra, in Portugal.

The small elms on which the vines are trained in Italy, north of the Apennines from Parma to Ravenna, are probably a form of *U. nitens*; but as these trees are lopped annually and kept low in stature, their leaves are irregular in size, have usually few nerves, and show a varying amount of roughness and pubescence on different individuals. Near Parma these elms produced good seed in 1911, from which I raised seedlings at Cambridge.

In the courtyard of the Villa Paveri-Fontana at Collecchio, near Parma, there is a remarkable old elm of this variety, about 60 ft. high, with a short, very burry, and rugged bole, 20 ft. in girth, and dividing above into three or four stems. Between Turin and the ancient royal palace at Stupinigi there is an avenue of elms, about six miles long, which was planted in 1781. Prof. Mattivoli, who kindly sent me specimens, tells me that the trees have been badly lopped during the last fifty years, and are not so large or so old as those in the gardens of the palace. The

largest which he measured in this avenue varied from 50 to 70 ft. in height, with a girth ranging from 7 to 11 ft. The largest elms in Turin are in the La Marmora garden, and measure about 100 ft. in height and 12 $\frac{1}{2}$ ft. in girth. These are said to have been planted in 1706.

5. Var. *umbraculifera*, Trautvetter, in *Act. Hort. Petrop.* ii. 590 (1873).

A tree with a dense globose crown of foliage, which is commonly cultivated in Persia, and only differs from ordinary *U. nitens* in its peculiar habit. This elm attains occasionally an enormous size, and is much prized on account of its dense shade and beautiful form. It is said to have been known in Persia for centuries, and has been introduced into the Caucasus and Armenia.¹ Regel, in *Gartenflora*, xxx. 3. t. 1034 (1881), figures a beautiful specimen, apparently of great age and size, which was then growing near Erivan in Russian Armenia. This peculiar elm is known to the Persians as the *narwan*,² and is always propagated by grafting. It was introduced in 1878 by Späth, who received it from a German gardener in the employment of the Shah, and is said to be planted in some of the streets in Berlin.³ There is a fine specimen about twenty years old, grafted at 6 ft. from the ground, in Desfossé's nursery at Orleans.

Var. *umbraculifera gracilis*, Späth, *Cat.* No. 100, p. 121 (1897-1898).

This originated in Späth's nursery from a shoot of the preceding variety, which had been grafted on a standard, and is said to differ only in forming a long oval and not a globose crown. At Kew, a shrub, labelled var. *umbraculifera*, obtained from Simon-Louis in 1904, has numerous ascending branches from the base, no main stem being developed, and forms a globose bush about 6 ft. high.

6. Var. *Rueppellii*,⁴ Späth, *Cat.* No. 73, p. 124 (1888-1889).

A pyramidal tree, with a distinct stem and numerous ascending branches, forming a globose or ovoid crown, and closely resembling var. *umbraculifera* in habit. Branches slightly corky, branchlets pubescent. Leaves similar to those of the Cornish elm in size and shape, but scabrous above. This is represented at Kew by two trees, about 10 ft. high, that were obtained from Barbier in 1902.

7. Var. *pendula*,⁵ Rehder, in Bailey, *Cycl. Amer. Hort.* 1882 (1902).

Branches and branchlets very pendulous. There is a good specimen⁶ of this

¹ Radde, *Pflanzenverbr. Kaukasus*, 305 (1899). A fine tree in the city of Bokhara is figured in *Mitt. Deut. Dend. Ges.* 1910, p. 73. *Ulmus densa*, Litwinow, in *Schede Herb. Fl. Ross.* vi. 163 (1908), is the name given to the wild elm with a dense crown of foliage, which grows in the mountains of Turkestan and Ferghana. Litwinow considers var. *umbraculifera* to be probably a graft of *U. densa*.

² This Persian word is also transcribed *narwand*, *narband*, and *narbum*, and primarily means a pomegranate tree. Probably it has been transferred to this peculiar elm on account of the fancied resemblance of the globose crown to a pomegranate.

³ *Garden and Forest*, ii. 516 (1889). Cf. also *Gartenflora*, xxxvi. 643 (1887). E. Morren, in *Belg. Hort.* 1879, p. 269, states that Späth received this variety from M. Scharrer at Tiflis.

⁴ The origin of this variety is unknown; but it was probably named after T. Rueppell, owner of P. Smith and Co.'s nursery at Hamburg from 1862 to 1899.

⁵ A tree cultivated at Kew as *U. glabra pendula nova* is a common form of the species with drooping branches, which do not form a dense crown of foliage as in true var. *pendula*.

⁶ The outer lower branches of this tree bear abnormal leaves, some of which have one or two small supernumerary leaflets at the base. Other leaves are large and broad, as if composed of two ordinary leaves, and are often cleft from the apex to the base. Some leaves form ascidia. Similar leaves occur on a single lower branch of a tree of *U. nitens* in the Cambridge Botanic Garden. Cf. Worsdell, in *Gard. Chron.* l. 285 (1911), and in *Journ. Roy. Hort. Soc.* xxxvii., *Proc.* cxxiii. (1912). Similar abnormal leaves are present on a specimen at Kew of *U. nitens*, gathered from a large tree in Persia by Dr. Stapf. Delavaud, in *Bull. Soc. Bot. France*, viii. 144 (1861), gives an explanation of the same kind of malformation, which he had observed on an elm at Rochefort.

variety on the lawn in front of the palace at Kew. It is grafted high, and resembles in appearance the weeping form of *U. montana*.

A weeping form of *U. nitens* in Victoria Park, Bath, is known as the Scampston elm, var. *scampstoniensis*, Petzold and Kirchner, *Arb. Musc.* 560 (1864). Schneider states that what he has seen under this name is ordinary *U. nitens*. Loudon says that the Scampston elm came from a place of that name in Yorkshire, and that a tree, 18 ft. high in 1834, which bore this name in the Chiswick garden, was clearly some variety of the glabrous elm, and differed little from the species. Elwes saw the decayed stump of the original tree at Scampston Hall in Yorkshire; and so far as we can ascertain, this weeping variety, if it ever was distinct, is no longer known in nurseries in England.

8. Var. *Dampieri*, Henry.

Ulmus Dampieri and *Ulmus montana Dampieri*, Petzold and Kirchner, *Arb. Musc.* 563 (1864).

Ulmus campestris Dampieri, Späth, *Cat.*

Ulmus campestris, var. *plumosa*, Lavallée, *Arb. Segrez.* 236 (1877).

A tree, fastigate in habit, forming a narrow pyramidal crown. Branches curved. Leaves, crowded on short glabrous branchlets, broadly ovate, 2 to 2½ in. long, 1½ to 1¾ in. broad, smooth and glabrous above, glabrous beneath except for conspicuous axil-tufts; margin incised with serrated teeth.

This beautiful tree, which has been much confused with Ford's elm (the similar variety of *U. montana*), is probably of continental origin.¹ The finest specimens which I have seen are two trees in Antwerp Park, about 45 ft. high, and one in the Leyden Botanic Garden, which was 40 ft. by 4½ ft. in 1912.

A sub-variety of this with yellowish leaves is occasionally seen in botanic gardens, where it is known as *U. Dampieri aurea* or *U. Dampieri Wredei*.²

9. Var. *modiolina*, Henry.

Ulmus modiolina, Dumont de Courset,³ *Bot. Cult.* vi. 384 (1811).

Ulmus tortuosa, Loddiges, *Cat.* 1836, ex Loudon, *Arb. et Frut. Brit.* iii. 1376, 1379 (1838) (not Host).

This is *l'orme tortillard* of the French,⁴ described as a tree with a twisted

¹ Nothing is known of Dampier, after whom this elm is named.

² Named after Wrede, curator of the Arboretum at Alt-Geltow, near Potsdam, where the yellow form originated in 1875 as a branch on a tree of *U. Dampieri*. It received a certificate from the Royal Horticultural Society in 1893, as *U. Wredei aurea*.

³ Dumont de Courset described *U. modiolina* as a pyramidal tree with crowded branches and small leaves. Du Roi, *Harbk. Baumz.* ii. 501 (1772), identified *l'orme tortillard*, which was then much valued in France, with *U. glabra*, Miller (*U. nitens*, Moench). Michaux, *Arb. Amer.* iii. 274 (1813), who advocated its introduction into the United States, said that it could be propagated by layering. Loudon states that it was reported to come true from seed frequently. M. de Vilmorin tells me that his grandfather planted several lines of this variety at Les Barres, which still exist but are growing in poor soil. His specimens include two different trees, one being ordinary *U. pedunculata*, while the other is a peculiar elm with moderately sized leaves, scabrous on both surfaces. The tree in the Jardin des Plantes, Paris, which is now labelled *U. campestris modiolina*, is probably not the original tree, as it is identical with the hybrid elm (*U. belgica*) of Holland and Belgium. The elm cultivated as var. *modiolina* by Späth is closely allied to *U. major* (see p. 1884). Huberty, in *Bull. Soc. Cent. Forest. Belg.* xi. 492 (1904) and xv. 788 (1908), considers this elm to be a special variety with small leaves, which grows slowly even in good soil, but produces the most suitable wood for making naves of wheels; but I have seen no specimens in Belgium. Aigret, in *Ann. Trav. Public. Belg.* x. 1225 (1905), assigns to var. *tortuosa* some hybrid elms with large leaves, which are growing with twisted trunks at Louveigné in the province of Liège.

⁴ The earliest account is by Duhamel, *Exploit. des Bois*, i. 294 (1764), who says that *le tortillard* has not only the most useful wood of all the elms, but has also fine foliage; and adds that it can be raised by seeds, grafts, or layers. Poederlé, *Man. de l'Arbor.* i. 116 (1792) identifies Duhamel's *l'orme tortillard* with the elm called *orme maigre* in Belgium, which is *U. nitens*.

arrangement of the bark and of the fibres of the wood, the stem when old being covered with burrs. This is stated by old writers to be a distinct variety, which produced wood valued by wheelwrights. Koch¹ states that it is a fine tree, with burry excrescences on the trunk, much planted in avenues in the north of France.

It is somewhat doubtful, however, whether this elm was really a distinct variety, as the description points to abnormal growth, which might occur in any kind of elm. M. Hickel informs me that the term *l'orme tortillard* is now applied to small elms of *U. nitens* with twisted and knotty stems, growing as a rule in poor soil.²

10. Var. *variegata*, Dumont de Courset, *Bot. Cult.* vi. 384 (1811); Loudon, *Arb. et Frut. Brit.* iii. 1405 (1838).

Leaves variegated with white, elliptic, 1 to 3 in. long, long-acuminate at the apex, smooth to the touch above, on long petioles. Branchlets glabrous. This occasionally bears branches with green leaves, similar to the ordinary form of *U. nitens*.

This³ was cultivated in 1838 in the Chiswick garden, and differs from the variegated form of the English elm. Elwes saw a very fine variegated smooth-leaved elm at The Mote, Maidstone, 90 ft. by 9 ft. in 1911; another at Leaton Knolls, Shrewsbury, 62 ft. by 5 ft. 8 in. in 1910; one at Woburn, 60 ft. by 5 ft. in 1908; and a fine tree by the roadside at Little Parndon rectory, Essex, which was 85 ft. by 10 ft. in 1907. This was said by the Rev. P. Deedes to be at its best in July, when the leaves are of a golden colour; but they are shed early in autumn. There are also specimens at Beauport, at Stanway, and in Victoria Park, Bath.

Another variegated variety, which is probably derived from *U. nitens*, is in cultivation at Kew, where it forms a wide-spreading tree about 20 ft. high, obtained from Smith of Darley Dale in 1879 under the name *U. campestris variegata nova*. It bears leaves, which are often much reduced in size and entirely whitish. Occasionally branches are produced bearing leaves of normal size, with the variegation confined to the margin, while one or two other branches bear pure green leaves larger than is usual in typical *U. nitens*.

11. Var. *Webbiana*, Lee, ex Simon-Louis, *Cat.* 1869, p. 97.

A tree, pyramidal in habit, with ascending branches and sparse foliage. Leaves folded longitudinally, so that most of the upper surface is concealed; in other respects similar to those of var. *stricta*. There are two good specimens at Kew, about 35 ft. high, which were planted in 1871.

This variety is said⁴ to have been raised in Lee's nursery about 1868; but it seems to be identical with *U. campestris*, var. *concavæfolia*, Loudon, *Arb. et Frut. Brit.* iii. 1378 (1838), which is insufficiently described.

¹ *Dendrologie*, ii. pt. i. 410, where it is referred to *U. montana*. Koch's description possibly refers to *U. Klemerei*. See p. 1872.

² This was the view taken by Planchon, in De Candolle, *Prod.* xvii. 158 (1873). M. Jouin showed me in the nursery of Simon-Louis at Metz, an avenue of what he called "*orme tortillard*," which he said were much liked by wheelwrights. They seemed to be a bad stunted elm, with swellings on the crooked trunks, and are propagated by grafting on stocks of *U. nitens*.—H. J. E.

³ This is probably identical with var. *argenteo-variegata*, Rehder, in Bailey, *Cycl. Amer. Hort.* 1882 (1902), which is the same as var. *folio argenteo-marginata*, Petzold and Kirchner, *Arb. Musc.* 557 (1864). It appears to have been first mentioned by Miller, *Cat. Plant.* 86 (1730), and *Gard. Dict.* ed. 1, No. 7 (1731), as *Ulmus folio glabro eleganter variegata*, the striped witch elm.

⁴ *Gard. Chron.* 1868, p. 918.

Ulmus viscosa, Koch, *Dendrologie*, ii. pt. i. 416 (1872), appears to differ very little from var. *Webbiana*. It is represented at Kew by a stunted specimen, obtained from Booth in 1871.

12. Var. *virens*, Henry. Kidbrook Elm.

Ulmus campestris, var. *virens*, Loudon, *Arb. et Frut. Brit.* iii. 1376 (1838).

A tree, narrowly pyramidal in habit, with long ascending branches, retaining its foliage till December. Branchlets slender, glabrous. Leaves oval, about 3 to 4 in. long, and $1\frac{1}{2}$ to 2 in. wide, long-acuminate at the apex, coarsely biserrate, glabrous and smooth above, slightly scabrous beneath, with numerous glands; lateral nerves, about twelve pairs, remote, often forked. Flowers similar to those of the Huntingdon elm. Samaræ similar, but smaller.

The only specimen of this tree which I have seen is one about 40 ft. high at Ashwell Bury, near Baldock. In habit it somewhat resembles the Huntingdon elm, but is more narrowly pyramidal. It retained its leaves in 1910 till the first week in December. It is probably identical with Loudon's tree, of which he says: "Notwithstanding its name of Kidbrook elm, a place in Sussex, it is a Cornish variety," probably on account of its pyramidal habit. Var. *virens* appears to be unknown in nurseries at the present day.

13. Var. *betulaefolia*, Loudon, *Arb. et Frut. Brit.* iii. 1376 (1838).

Ulmus betulaefolia, Loddiges, *Cat.* 1836.

A tree, pyramidal in habit, with ascending branches. Leaves ovate-oblong, up to $3\frac{1}{2}$ to 4 in. long and $1\frac{1}{2}$ in. broad, long-acuminate at the apex, tapering to a cuneate but unequal base, coarsely biserrate; lateral nerves 12 to 14 pairs.

This tree, which is readily distinguished by its foliage and habit, is represented by a good specimen in the Cambridge Botanic Garden. It is occasionally seen in hedgerows in Herts and Huntingdonshire.

DISTRIBUTION

U. nitens is a native of central, western, and southern Europe, Algeria, Asia Minor, Caucasus, Armenia, Persia, and Turkestan. In eastern Asia it is replaced in Manchuria, Korea, and Japan by the closely allied species, *U. japonica*.

In Europe, this species has a more southerly distribution than *U. montana*, and is unknown in Denmark, Sweden, and Norway as a wild tree, though it is said to occur, possibly planted, on the island of Gothland, in the Baltic. In Russia, it is limited to the southern provinces, its northern limit passing through Grodno, Volhynia, Chernikof, Tambof, Saratof, Samara, and Orenburg. It is especially common in the south-west, occasionally forming pure woods, one of which is said by Köppen¹ to extend for fifteen versts in the valley of a tributary of the river Ingul in Kherson. It occurs in the Crimea, and in the Caucasus, where it grows from sea-level to an altitude of 6000 feet.

¹ *Holgerwächse Europ. Russlands*, ii. 34 (1889).

In Germany the northern limit of this species is not accurately known; but it is a rare tree in the north, except in the river valleys.¹ It is widely spread through Austria-Hungary, the Balkan States, Greece, Italy, Spain, and Portugal.

U. nitens is rare, either wild or cultivated, in Belgium and Holland; but it grows on the dunes near Haarlem. I saw no trees of it in the Ardennes,² where the wild elms are *U. pedunculata* and *U. montana*.³ I found it in a nursery at Malines, where it was called *orme maigre*.

In France it is widely distributed, except in Provence, where it is replaced by the southern variety of *U. campestris*. It is common, however, only in some parts, and rarely if ever forms a prominent feature in the landscape, such as it does in East Anglia. It is apparently wild in Normandy, where it grows often in hedges as a small tree with corky branches and numerous suckers. It is indigenous in certain forests, mixed with oak, notably in the Bois de Vincennes near Paris, where it is associated with *Quercus lanuginosa*. I noticed a few trees growing in the forest of Marly. It constitutes a small percentage of the forest of Thétieu, through which the Adour flows near Dax. The soil here is liable to inundation once or twice a year, and the main species is the pedunculate oak. I estimated many elms in this remarkable forest to be about 70 ft. in height and 5 to 6 ft. in girth. Near Angoulême I noticed this elm in hedges on the road to the forest of La Braconne, one fine tree being 90 ft. in height and 7 ft. in girth. It is also common on the outskirts of the forest of Orleans, where it grows in hedgerows around cultivated fields in better soil than that of the interior of the existing woodland. M. Mathey gives an interesting account⁴ of the remarkable woods, known as *vaiivres*, which occur on the banks of the Saône from Port-sur-Saône near Vesoul to twenty-eight kilometres north of Macon. These moist woods, with an alluvial soil which is frequently flooded, are mainly composed of oak, ash, and glabrous elm, with a sprinkling of aspen, alder, hornbeam, maple, and blackthorn. The herbaceous vegetation is characterised by moisture-loving plants like *Carex brizoides*, *Panicum Crus-Galli*, and *Iris Pseudacorus*. Most of these woods are treated as coppice with standards, the number of the latter that are reserved being often in the proportion of 15 oaks, 2 ashes, and 1 elm; but as the elm is the least valuable, it is not maintained in the overwood, although it increases by suckering in the underwood. The late M. Broilliard stated⁵ that the woods richest in elms are near Gray (Haute Saône), Pontailler, Heuilley (Côte d'Or), Ecuelles, Boyer (Saône-et-Loire), and Truchère (Ain).

The seedling elms⁶ that are imported into England, under the name

¹ Willkomm, *Forst. Flora*, 554 (1887), states that, on the alluvial land along the Elbe in north Germany, small pure woods of this species are not uncommon.

² Reputed wild trees of small size on the side of the river near Rochefort were, I found on enquiry in 1912, elms that had been imported as seedlings twenty-five years previously from a French nursery in Calvados.

³ Specimens of wild elm in the Bois de Colfontaine near Mons, sent me as "*U. campestris*" by M. Quievy, are also *U. montana*.

⁴ *Bull. Soc. Forest. Frauche-Comté*, iv. 494 (1898), and *Bull. Soc. Cent. Forest. Belg.* vi. 87 (1899). I am indebted for specimens of this elm to M. Mourlot, Inspector of Forests at Gray, and to M^{me}. Broilliard.

⁵ *Bull. Soc. Cent. Forest. Belg.* xii. 53 (1905).

⁶ On account of their rough pubescent leaves and branchlets, these seedlings have been much confused with *U. campestris*, the true English elm; but they are undoubtedly *U. nitens*, and agree perfectly with seedlings that I have raised from seed of the latter species gathered in England. Sargent sent me in 1911 seedlings of his "*U. foliacea*," raised from seed gathered in Hungary in 1905; these have corky pubescent twigs and rough hairy leaves and are also *U. nitens*.

U. campestris, from French nurseries at Orleans, Ussy, and elsewhere, are raised from the seed¹ of *U. nitens*. This importation has continued probably without interruption from the time of Evelyn, who refers² to the French elm as having "glabrous and smooth" leaves, and mentions in 1664 "a cloyster of the right French elm in the little garden near to her Majesties the Queen Mothers Chapel at Somerset-house, which were (I suppose) planted there by the industry of the F.F. Capuchines." In all probability many of the glabrous elms that are now growing in parks and pleasure grounds in England and Scotland are of French origin.

In England, *U. nitens* is limited to the southern, midland, and eastern counties. Throughout the east of England, where it is much commoner than *U. montana*, it is usually known, when of wide-spreading habit, as the wych elm. *U. nitens* is unknown, except as a planted tree, in Scotland; but it is probably wild in the south of Ireland, where it is frequent in hedge-rows; and at Abbeyleix, var. *stricta* is scattered amidst oaks on the alluvial flat of the river Nore. Cf. p. 1889.

Many elms may be found in the south and west of England, which differ somewhat in foliage and habit, both from typical *U. nitens*, and its well-marked varieties, described above. It seems unnecessary to describe these in detail or to give them special names. In several cases, in which I sowed seeds of trees, slightly abnormal in foliage and habit, the seedlings produced are not uniform, and show the characters of opposite and alternate leaves in the first year in Mendelian proportions; and are presumably of hybrid origin. Some of these elms have leaves thicker in texture, larger in size, often longer with more numerous nerves; whilst others show peculiar serrations, less obliquity at the base, etc. A tree at Colesborne, from which numerous seedlings were raised in 1909, is a typical instance of this class of elm.³ (A. H.).

REMARKABLE TREES

Among the most remarkable trees of this species is an elm (Plate 399) at Sharpham, near Totnes, the seat of O. Durant Parker, Esq., which was figured as a wych elm in *Gard. Chron.* xxxix. 152 (1906). I found this tree to be a glabrous-leaved elm of unusual habit, with immense branches spreading to a distance on one side of 104 ft., and covering a total area of a quarter acre. Its height when I saw it in 1906 was 80 to 90 ft., and its girth 17 ft. The lateral branches were covered with small spray and ferns, which are favoured by the damp climate.

In Dyrham Park, Gloucestershire, there is an old and decayed glabrous-leaved elm, which in 1906 measured 19½ ft. in girth, but was throwing out much young spray on the live branches.

From West Dean, in Sussex, Mr. F. Arthur sent me specimens of this elm, which is there known as wych elm; its timber sells locally for 1s. per foot.

At Godinton, Kent, a fine tree which has the habit of the weeping Hertfordshire elm, measured in 1907 about 100 ft. by 12 ft.

¹ M. de Vilmorin informs me that the seeds of this elm, which are sold by him as "*U. campestris*," are usually gathered in the neighbourhood of Soissons (Aisne) and Le Mans (Sarthe).

² *Sylva*, 19 (1664).

³ Referred to in *Journ. Linn. Soc. (Bot.)* xxxix. 294 (1910).

Some trees of the same habit, which possibly originated in the nursery at Canterbury, where Masters raised elms of this type, are at Betteshanger, near the church, and in 1907 were 70 to 80 ft. by 7 to 8 ft. in girth.

At Boughton Park, in the broad avenue, which is a hundred yards wide and stretches for a mile in front of the house, are a number of elms, which like those at Cassiobury, and some of those at Hinchingsbrooke, are remarkable for their burry growths and stunted habit. Whether this is due to their having been propagated from suckers of trees having this peculiarity I cannot say, but there are much better-shaped trees in the same avenue which are free from burrs, and have attained a much greater height. Two which I measured were 107 ft. by 18 ft. 4 in., and 104 ft. by 18½ ft. in 1908. Boughton is celebrated for its extensive avenues of elms, planted by "John the Planter," Duke of Montagu, who died in 1749. Most of them are true English elms, and one which I saw in the timber yard had 170 rings, of which only twenty were sapwood, in a diameter of 3 ft. Elm timber at Boughton averages about 1s. per foot, though in an exceptional case it has realised 2s. 6d. per foot. It is much liked for chair seats, on account of its rich colour.

In Hertfordshire and on the western borders of Essex, the most graceful form of this tree may be seen in perfection. Among the largest in this district are the following:—At Bayford Lodge, Bayfordbury, a fine weeping tree, very distinct from an English elm growing beside it, in 1909 was 92 ft. by 11 ft. 9 in. At Amwell Bury, near Ware, Herts, there is a magnificent tree of *U. nitens*, of which Mr. H. Clinton-Baker sends us the following particulars. It is situated on Mr. E. S. Hanbury's property, and in November 1911 measured 133 ft. in height, with a trunk 23½ ft. in girth at five feet, above which it divides into two stems, 15 ft. 2 in. and 14 ft. 6 in. in girth respectively.

At Eastwick rectory, in the Stort valley, the best of a group of four trees near the church was 119 ft. by 10 ft. in 1909; while another was 116 ft. by 6½ ft. A little higher up in a narrow grass field there is a fine tree of the same habit, 113 ft. by 13½ ft. Suckers from these trees are numerous; and Mr. Rivers, of the Sawbridge-worth nurseries, has propagated a number of this type. At Briggins Park, the seat of the Hon. H. C. Gibbs, two splendid trees (Plate 401) stand together by a small lake; the larger was 128 ft. by 12 ft. 10 in. in 1909. On the road from Dunmow to Easton Park, there are a number of weeping elms, which vary a good deal in habit, and appear to belong to this species, but I have not seen them in leaf. At Aldenham, in Sawyer's Lane, there are good trees of this type which, as usual, have rough-leaved suckers; the best measured in 1908 about 108 ft. by 7 ft. 11 in.

At Great Saling, Essex, on the village green, there is a handsome weeping tree (Plate 402), with an immense witches' broom near the top, which in 1907 measured 110 ft. by 20 ft. 9 in. Loudon says¹ that Mr. Jukes, who made drawings of the large elms at Studley Royal, pronounced this elm to be the most handsome that he had seen. It measured, in 1841, 114 ft. in height and 17½ in girth at five feet from the ground.

¹ *Gard. Mag.* xvii. 356 (1841).

At Ryston, near Downham, Norfolk, in 1908, I measured one in a hedgerow which was 95 ft. by 16 ft. 9 in.

At Belton, Grantham, there are large glabrous elms in the grounds; and at Barholm, not far from Stamford, there are two remarkable trees, very wide spreading, with a rounded crown of foliage, of no great height, but 16 ft. 3 in., and 17½ ft. in girth in 1910.

In Gloucestershire there are several old elms on my own property which have similar leaves to *U. nitens*, but which keep their leaves green later in autumn and turn to a brighter colour, which may be due to the locality, for I have noticed that beech, oak, elm, and other trees colour better in the Cotswold hills than in the eastern counties. The timber, though hard and tough, is not so red as that of the English elm, and their habit is more spreading owing probably to their hybrid origin. From one of these just outside my park, which does not lose its leaves till late in November, I have raised numerous seedlings, which vary extremely in habit and vigour, but all have rough leaves at four years old like the suckers of the parent tree. At Toddington Manor there is a fine spreading tree near the house, which in 1910 measured 100 ft. by 15 ft. 2 in.; but most of the elms here and generally in the Vale of Gloucester are true English elms.

In Scotland I have not noticed any large trees of this species; but Mr. Renwick measured a tree at Loudon Castle, 107 ft. by 15 ft. 4 in. in 1910.

In Ireland, Mr. R. A. Phillips informs us that it is common in hedgerows between New Ross and Waterford, and along the river Barrow. At Killarney, Henry measured one in Lord Kenmare's grounds, which was 91 ft. by 12 ft. in 1903.

On the Continent there are many large elms, referred by Continental botanists to *U. campestris*, which are often *U. nitens*. The most famous elm in Germany is a tree standing in the market-place of Schimsheim, near Worstadt in Hesse, which is figured by Seidel in *Woods and Forests*, 1884, p. 577. Willkomm¹ states that this tree is 500 or 600 years old, about 100 ft. high, and 44 ft. in girth at 3 ft. 4 in. above the ground. The trunk is hollow, but otherwise the tree is quite healthy, with abundance of foliage. Neither Seidel nor Willkomm identify the species of this elm. The elm at Worms under which Luther preached is said by Willkomm¹ to be probably *U. nitens*, and is reported by Seidel to be much taller than the Schimsheim elm, and 25 ft. in girth at 8 ft. above the ground. Mr. Springer has sent me a photograph of a wide-spreading smooth-leaved elm at Windesheim Castle, near Zwolle in Holland. This tree measured, in February 1913, 75 ft. in height and 23 ft. 9 in. in girth, with a crown of foliage 106 feet in diameter.

(H. J. E.)

¹ *Forstliche Flora*, 550, note (1887).

ULMUS MINOR, GOODYER'S ELM

Ulmus minor, Miller,¹ *Gard. Dict.* ed. 8, No. 6 (1768); Reichenbach,² *Icon. Fl. Germ.* xii. 12, t. 660 (1850).

Ulmus glabra, Miller, var. *minor*, Ley, in *Journ. Bot.* xlviii. 70 (1910).

Ulmus campestris, Smith, *Eng. Bot.* t. 1886 (1808) (not Linnæus); Lindley, in Rees, *Cyclopædia*, xxxvii. No. 1 (1819).

Ulmus sativa, Moss, in *Gard. Chron.* li. 216 (1912) (not Miller).

Ulmus sativa, Miller, var. *Lockii*, Druce, *List of British Plants*, 63 (1908).

Ulmus Plotii,³ Druce, in *Northampton Nat. Hist. Journ.* 1911, p. 88, and in *Gard. Chron.* l. 408 (1911).

A small tree, 40 to 90 ft. in height, with the stem usually curving at the summit, and a few short stout ascending branches, and pendulous branchlets, forming a narrow crown of peculiar appearance. Young branchlets slender, with a scattered minute pubescence, glabrous and finely striate in the second year. Leaves (Plate 411, Fig. 3) firm in texture, obovate or elliptical, about 1½ to 2½ in. long and ¾ to 1½ in. broad, unequal and often cordate at the base; acute, acuminate, or occasionally rounded at the apex; upper surface dull, scabrous with scattered minute tubercles and minute hairs; lower surface scabrous and densely pubescent with short hairs in spring, later glabrescent, but with conspicuous axil-tufts; biserrate; lateral nerves, eight to ten pairs, often forked; petiole ½ in. long, pubescent.

Flowers, twenty to twenty-five, in small clusters, on very short pedicels, irregular in the number of sepals and stamens; calyx funnel-shaped, about ⅛ in. long, with four, five, or six pink lobes; stamens, three, four, or five, with deep pink filaments and red anthers; stigmas pink. Samaræ rarely ripening, but in 1909 a few were produced, narrowly obovate, ½ in. long, emarginate at the apex, with a triangular open notch; seed in the upper half of the samara.

This tree produces suckers freely. It is possibly a hybrid, as a small packet of seed produced in 1909 fifty-seven alternate-leaved and twenty-eight opposite-leaved seedlings.

¹ Miller, *Gard. Dict.* ed. 8, No. 6 (1768), describes *U. minor* as "the smooth narrow-leaved elm, by some called the upright elm," and adds that "the leaves are narrower and more pointed than the English elm and are smoother; they are later in coming out in the spring than these, but continue later in autumn." He identifies it with *Ulmus minor folio angusto glabro*, which is the elm described by him in *Gard. Dict.* ed. 3, No. 6 (1737) and in ed. 6, No. 10 (1752), as "very common in some parts of Hertfordshire and in Cambridgeshire, where there is scarce any other sort of elm to be seen. This makes a very handsome upright tree, and retains its leaves as late in the autumn as the common small-leaved elm, which is called the English elm by the nurserymen near London; but it doth not come out so early in the spring." As Miller's *U. sativa* is undoubtedly the English elm (our *U. campestris*, L.), there is little doubt that Miller's *U. minor* is Goodyer's elm. The latter was called *U. minor* by Parkinson, *Theat. Bot.* 1405 (1640). Plot's *Ulmus folio angusto glabro* was not cited by Miller, and is *U. campestris*, var. *viminalis*. If *U. minor*, Miller, is objected to, on account of the uncertainty of the description, the tree may be styled *U. minor*, Reichenbach.

² Reichenbach's figure agrees, as regards leaves, flowers, and samare with English specimens of *U. minor*, and he cites correctly Smith, *Eng. Bot.* t. 1886. It is probable that *U. tortuosa*, Host, *Fl. Austr.* i. 330 (1827), is identical with *U. minor*, although Host's specimen in the Kew herbarium is *U. nitens*. *U. tortuosa* was said to be a low tree with a twisted trunk and small leaves, which grew in hilly districts in Hungary.

³ This is not, as Druce supposes, the elm described by Plot, *Nat. Hist. Oxfordshire*, 158 (1677), which is identical with *U. campestris*, var. *viminalis*. See p. 1906. I have examined specimens of the tree at Banbury referred to *U. Plotii* by Druce, and they agree exactly with *U. minor*, as here described. Cf. Moss, in *Gard. Chron.* li. 234, figs. 104, 105, and 106 (1912).

This elm was first described by Goodyer, in Johnson's edition of *Gerarde's Herball*, 1478 (1633), as *Ulmus minor folio angusto scabro*. He says that he saw it once, growing in hedgerows between Lymington and Christchurch, where it has been lately found by Dr. Moss. There are specimens in the British Museum, collected by Buddle and other early botanists; but it has apparently escaped the notice of later writers. So far as I know, it has never been cultivated in nurseries; and nearly all the trees which we have seen, grow in hedgerows and similar situations, where they may be looked upon as indigenous.

U. minor occurs on the Continent, as it is recorded by Reichenbach for Hungary; and there are specimens of it in the Haarlem herbarium from trees growing in Holland; but its distribution has not been worked out—French, German, and Russian botanists having paid little attention to the different kinds of wild elms.

This elm, which is of a remarkably distinct appearance, is common on the Madingley road, Cambridge, where the trees grow, from which I have drawn up my description. It is widely spread in the eastern counties, from Lincoln¹ through Norfolk and Suffolk to Essex, and occurs also in Northamptonshire, Huntingdonshire, Bedfordshire, Oxfordshire, and Hampshire. The usual habit of the tree is well shown in a photograph,² taken by Mr. Druce, of a tree growing near Fine-shade Abbey, Northamptonshire. He has also photographed³ a tree near Banbury, which is over 80 ft. in height.

(A. H.)

There are many elms of this variety in the eastern and midland counties, which are readily known by their smaller leaves, inferior size, and irregular habit. They are known sometimes in these districts as "lock" elms.³ A great many elms on the sandy land of west Norfolk are of this character, and, generally speaking, the hedgerow elms of this county are very inferior in size and shape to those of Essex, Herts, and the south generally. Similar trees grow in the hedges between Grantham and Belvoir Castle.

The finest specimen which we know of *U. minor* is a tree growing in the park at Weston Birt (Plate 403), which was 97 ft. high and 7 ft. in girth in June 1912. At Studley College, Warwickshire, there are about a dozen trees in a field, which are 70 to 80 ft. high, the three largest being 9 ft. 4 in., 9 ft. 6 in., and 9 ft. 9 in. in girth. Mr. C. C. Rogers, who has kindly sent specimens, tells us of a tree at Hagnaby Priory, Spilsby, Lincolnshire, nearly 90 ft. in height and 7 ft. 7 in. in girth.

(H. J. E.)

¹ Ley mentions a tree at Skellingthorpe in south Lincoln.

² Reproduced in *Gard. Chron.* l. 408, figs. 165, 166 (1911).

³ This name indicates the toughness of the wood of this elm, which is difficult to work with tools like the saw or plane, which become "locked," as carpenters say. Sir J. E. Smith, *Eng. Flora*, ii. 20, 23 (1824), states that the wood of this species "is greatly preferred in Norfolk to any other, and sells for nearly double the price, serving more especially for the naves of wheels."

ULMUS CAMPESTRIS, ENGLISH ELM

Ulmus campestris, Linnæus, *Sp. Pl.* 225 (1753) (in part), and *Flora Anglica*,¹ 11 (1754) (not Smith²); Loudon,³ *Arb. et Frut. Brit.* iii. 1374 (1838) (in part); Planchon, in De Candolle, *Prod.* xvii. 156 (1873) (in part); Moss, in *Gard. Chron.* li. 199 (1912).

Ulmus sativa,⁴ Miller, *Gard. Dict.* ed. 8, No. 3 (1768).

Ulmus suberosa, Smith, *Eng. Bot.* t. 2161 (1810) (not Moench or Ehrhart); Loudon, *Arb. et Frut. Brit.* iii. 1395 (1838) (in part); Lindley, *Syn. Brit. Flora*, 226 (1829).

Ulmus atinia, Walker, *Essays Nat. Hist.* 70 (1812).

Ulmus sarculosa, Stokes, var. *latifolia*, Stokes, *Bot. Mat. Med.* ii. 35 (1812); Ley, in *Journ. Bot.* xlviii. 72 (1910).

A tree attaining 130 ft. in height and 20 ft. in girth, with a tall straight stem, and spreading or ascending branches, rather variable in habit, but usually forming in the open a broad or narrow oval crown. Bark dark-coloured, deeply fissured. Young branchlets densely pubescent with short erect white hairs, more or less retained in the second year, when the twigs become finely striate. Buds ovoid, with minutely pubescent ciliate scales. Leaves (Plate 412, Fig. 14) broadly oval or ovate, about 2 to 3 in. long, and 1½ to 2 in. wide, very oblique at the base, shortly acuminate at the apex; upper surface dark green, scabrous, with a scattered minute pubescence, conspicuous on the midrib; lower surface pale green, with broad⁵ conspicuous white axil-tufts prolonged along the sides of the midrib, and covered between the nerves

¹ Linnæus, *Flora Anglica*, 11 (1754), identifies his *U. campestris* with one of the four elms mentioned by Ray, *Syn. Meth.* 468 (1724), namely, No. 1, *U. vulgarissima folio lato scabro*, Gerarde, *Emac.* 1480, which is the English elm. According to the rules of the Vienna Congress, the correct name, as it is the earliest, of the English elm must then be *U. campestris*, Linnæus, which cannot be applied to any other species. Continental botanists usually mean by *U. campestris*, all the European elms, except *U. montana* and *U. pedunculata*. *U. campestris*, Miller, *Gard. Dict.* ed. 8, No. 1 (1768), described as "the common rough or broad-leaved wild elm . . . very common in the north-west counties of England, where it is generally believed to grow naturally in the woods," is *U. montana*, and not the English elm, as asserted in *Gard. Chron.* li. 199 (1912).

² Smith, *Eng. Bot.* t. 1886 (1808), is *U. minor*. See p. 1901.

³ Loudon's account of the English elm is very confused, and his reference to Smith, *Eng. Bot.* t. 1886, is erroneous. He also fails to recognise that *U. suberosa*, Smith, *Eng. Bot.* t. 2161, is the English elm, and is quite different from *U. suberosa*, Moench, which is the corky-twigged variety of *U. nitens*.

⁴ Miller's *U. sativa*, which he calls "the small-leaved or English elm," is in my opinion the tree which is still named English elm and which is described above as *U. campestris*, L. The name "*sativa*" implies that it was commonly cultivated; and Miller states that it was planted near London. No other elm can have been meant, as it is certain that *U. campestris* was known near London under the name of English elm in Miller's time. The Society for the Encouragement of Arts offered a gold medal in 1765 (and also in subsequent years) "for properly planting the greatest number of the small-leaved English elms for raising timber, commonly used for keels of ships and water-works." [Cf. *Museum Rusticum*, iv. 380 (1765).] The elm that was used for making water-pipes was *U. campestris*, L., as is shown by T. H. W.'s clear account of the species around London, in *Gentleman's Magazine*, lv. 453 (1785). John Harrison, nurseryman at Cambridge, plainly means *U. campestris* by the English elm, in his *New Method*, 33 (1766): "That which we call the English elm, is peculiar only to the southern part of this island, where it grows wild in hedgerows; there is not a tree of that kind to be seen in the northern counties, but what has been planted within seventy or eighty years; and these are either in avenues or some plantations near gentlemen's seats." Cf. also Hunter, *Evelyn's Sylva*, 124 (1776). Miller quotes as a synonym Gerarde's *Ulmus minor folio angusto scabro*, of which he took a different view from Ray, as is clearly shown in his *Gard. Dict.* ed. 1, No. 3 (1731), where this elm of Gerarde's is identified with "the common English elm, the timber of which is generally preferred to the rest, and is the largest tree when planted on a kindly soil." It is impossible to suppose that *U. sativa*, Miller, can be the tree which is called by us *U. minor*, as the latter has never been called English elm, has never, so far as we know, been planted anywhere, and never attains a great size. Sir J. E. Smith, *Eng. Flora*, ii. 21 (1824), took the same view as I do regarding Miller's *U. sativa*.

⁵ The axil-tufts are peculiar, broad, and diffused in this species.

with a dense soft pubescence and numerous minute glands; lateral nerves ten to twelve pairs, often forked; petiole $\frac{1}{2}$ in. long, densely pubescent.

Flowers, about twenty in a cluster, on very short pedicels, irregular in the number of stamens and sepals; calyx funnel-shaped, with four or five or six red sepals; stamens three, four, or five, with red filaments and red anthers; stigmas white. Samaræ on very short pedicels, nearly orbicular, $\frac{1}{2}$ in. in diameter, glabrous, non-ciliate, emarginate at the apex, with a short notch closed by the incurved stigmas; seed in the upper part of the samara, with its apex touching the base of the notch.

The English elm occasionally, but rarely, produces epicormic branches with corky wings; but, as a rule, the branches of all parts of the tree, as well as the suckers, are not suberose. The suckers are produced very freely, with leaves and twigs more pubescent than those of adult trees. It rarely bears¹ good seed in England; but in 1909, out of about twenty lots of seed gathered in different places in the south of England, I raised one seedling from a tree at Cambridge, two seedlings from a tree at Bayfordbury, and one seedling from a tree in the Isle of Wight.²

VARIETIES

1. Var. *australis*, Henry.

A tree, often pyramidal in habit, with short branches. Branchlets similar in pubescence to the type. Leaves (Plate 412, Fig. 17) thick and firm in texture, oval, 2 to 3 in. long, $1\frac{1}{4}$ to $1\frac{3}{4}$ in. broad, with a longer and more cuspidate acuminate apex than in the type; scabrous and pubescent above; lower surface densely pubescent, the pubescence conspicuous on the midrib and nerves, with axil-tufts not so well developed as in the typical form of the species; lateral nerves about twelve pairs, very prominent beneath; coarsely biserrate in margin; petiole up to $\frac{1}{2}$ in. long, pubescent. Flowers similar to those of the English elm, but with pale pink sepals, anthers, filaments, and stigmas. Samaræ more obovate than orbicular, but rounded at the base and otherwise similar to the typical form.

This elm differs mainly from the English elm in the thicker texture of the leaves, which have more prominent nerves beneath. It appears to be distributed in the wild state in south-eastern France, Switzerland, and the Riviera. The small elms along the stream on the golf course at Cannes, some on the hills above La Mortola, and others of which I gathered specimens at Pertuis, in Provence, more closely resemble the English elm than any others which I have seen, in branchlets, leaves, and samaræ, but still are not identical. I have also received from Lord Walsingham specimens of this variety from trees growing at Venice;

¹ The English elm has long been known to produce unfertile seed. W. Watkins, *Forest Trees*, 24 (1753), says "I could never find any seed worth gathering on the English elm"; and proceeds to give directions for layering, which he preferred to propagation by root-suckers.

² Loudon, *Arb. et Frut. Brit.* iii. 1384 (1838), states that Masters raised in 1817, from the seed of a common English elm at Lea Park, near Canterbury, a considerable number of seedlings, which comprised about twenty distinct varieties. In all probability this tree was a hybrid. All the elms, however, now standing in Lea Park, judging from copious specimens which I received in 1910, appear to be English elms.

and it probably exists farther to the south and east, as it seems similar to an elm¹ found by Baldacci in mountain woods near Spizza in the extreme south of Dalmatia.

Var. *australis* is occasionally planted in botanic gardens in France, as at Le Mans and Bordeaux; but it seems rare in cultivation. I refer to this variety the elms in the avenue of the Cours-la-Reine, Rouen, which is said to have been planted in 1649 by the Duke de Longueville. The best of these trees still remaining were about 90 ft. by 9 ft. in 1912.

2. Var. *variegata*, Dippel, *Laubholzkunde*, ii. 25 (1892).

Ulmus campestris, var. *foliis variegatis*, Loddiges, *Cat.* 1836, ex Loudon, *Arb. et Frut. Brit.* iii. 1376 (1838).

Leaves striped and spotted with white. This is a very ornamental tree, no doubt of English origin,² as it agrees with the English elm in all its essential characters. So far as I know it never produces fruit. There are two good trees about 50 ft. high at Kew. A fine specimen at Moor Park, Rickmansworth, which was 65 ft. by $7\frac{1}{2}$ ft. in 1910, produces suckers with variegated leaves. Elwes saw, in 1909, a tree 83 ft. by $7\frac{1}{2}$ ft. at Campsea Ashe in Suffolk, also with variegated suckers. These are said to lose their colour if transplanted. Another at Kenwood, without suckers, was 75 ft. by 7 ft. 2 in. in 1909.

U. picturata, Cripps, ex Simon-Louis, *Cat.* 1880, p. 66, of which there is a small tree at Kew, does not appear to differ much from the preceding variety; but has larger leaves.

3. Var. *Van Houttei*, Schneider, *Laubholzkunde*, i. 220 (1904).

Leaves scabrous above and beneath, tinged with yellow. Branchlets pubescent with long hairs.³ The variety,⁴ which is known in catalogues as *U. campestris*, "*Louis van Houtte*," is represented at Kew by several trees about 20 ft. high, obtained from Waterer in 1894.

4. Var. *purpurea*, Petzold and Kirchner, *Arb. Musc.* 558 (1864).

Leaves 2 to $2\frac{1}{2}$ in. long, tinged purple, often folded, irregularly serrate. This is probably of hybrid origin, as it resembles *U. montana* in texture and roughness of surface, but has slender twigs and small leaves. It is grown at Kew under the name *U. montana*, var. *purpurea*.

5. Var. *purpurascens*, Schneider, *Laubholzkunde*, i. 220 (1894).

U. campestris myrtifolia purpurea, Louis de Smet, *Cat. No.* 10, p. 59 (1877).

Leaves small, about an inch long, scabrous above, pubescent beneath, tinged with a purple colour. Branchlets pubescent with long hairs. This is represented at Kew by a grafted tree, about 20 ft. high, obtained from Waterer in 1885.

¹ Var. *dalmatica*, Baldacci, in *Malpighia*, v. 79 (1891).

² Plot, *Nat. Hist. Oxfordshire*, 172 (1677), mentions a striped elm in Dorsetshire.

³ In *Gard. Chron.* xi. 368, fig. 77 (1887), an instance is given of the influence of scion upon stock, where this variety was grafted on *U. campestris* with ordinary green leaves, and the stock subsequently produced a variegated shoot below the graft.

⁴ The origin of this elm is unknown; but it may be the "yellow-leaved elm" referred to by Miller, *Cat. Plant.* 86 (1730), and *Gard. Dict.* ed. 1, No. 8, as "*Ulmus minor foliis flavescensibus*."

6. Var. *Berardii*, Simon-Louis. *Cat.* 1869, p. 96.

A small tree or shrub, with minute leaves, $\frac{1}{2}$ to $\frac{3}{4}$ in. long, firm in texture, deeply incised with a few teeth, almost glabrous; petioles, as well as the young branchlets, pubescent. This peculiar variety, with leaves somewhat resembling those of *Zelkova Verschaffeltii*, but smaller, was raised by Simon-Louis from seeds gathered in 1863 from the large elms growing on the ramparts at Metz. There is a specimen at Kew, about 10 ft. high, which was obtained from Späth in 1902.

At Kew there is a small tree raised from seed collected by me off a tree at Nancy in 1903, which has similar minute leaves, but scabrous above and pubescent beneath, and biserrate in margin. This is one of a number of seedlings raised from the same lot of seed, which differed extraordinarily in the size and other characters of the leaves, showing that the parent tree was a hybrid.

In the Kew herbarium there are remarkable specimens of an elm with minute foliage, which were gathered in Jersey by Oliver in 1874 and 1880, but of which I can learn no particulars. Mr. Miller Christy sent me in 1911 a branch with minute leaves of an elm, like a bush and only 4 ft. high, which grows close to the shore at the foot of the cliff at West Mersea, Essex. Elwes collected a similar specimen in a hedgerow between Bisterne and Ringwood.

7. Var. *viminialis*, Loudon, *Arb. et Frut. Brit.* iii. 1376 (1838).

Ulmus viminialis, Loddiges, *Cat.* 1836.

Ulmus antarctica, Petzold and Kirchner, *Arb. Musc.* 552 (1864).

A tree, with ascending branches, pendulous branchlets, and sparse foliage. Leaves (Plate 412, Fig. 22) incised on the margin with deep serrated teeth: about $1\frac{1}{2}$ to $2\frac{1}{2}$ in. long, obovate-elliptic or narrowly elliptic, often nearly equal at the base, long-acuminate at the apex, scabrous above, slightly pubescent beneath, with conspicuous axil-tufts. Young branchlets slightly pubescent.

This variety is said by Loudon to have been raised by Masters in 1817 from seeds of the common English elm; but it appears to me to be identical with the elm described by Plot¹ in 1677 as occurring in avenues at Hanwell, "where there is a whole walk of them planted in order, besides others that grow wild in the coppices of the park." Plot describes this elm as having a narrow leaf with a peculiar kind of pointed ending, and his figure is unmistakably that of var. *viminialis*. Mr. Druce states² that the avenue at Hanwell is now composed of English elm.

The best tree of this variety that we know of is at Milton Abbey, Dorsetshire, the seat of Sir A. E. Hambro. It measured in 1906 71 ft. by 6 ft. 4 in., and resembled in habit the Cornish elm. A tree in the Cambridge Botanic Garden is about 70 ft. high. There are three trees³ at Kew, two about 35 ft. high, which are labelled var. *viminialis*, and are of unknown origin, but evidently of considerable age; and one precisely alike in foliage, but labelled *U. campestris antarctica*, which was obtained

¹ *Nat. Hist. Oxfordshire*, 158, plate x. fig. 1 (1677).

² In *Gard. Chron.* 1. 408 (1911). Druce's identification of Plot's elms with the tree (which he calls *U. Plotii*) now growing at Banbury and elsewhere is, in my opinion, erroneous. Cf. Moss, in *Gard. Chron.* li. 234, figs. 104-106 (1912). Cf. also p. 1901, note 3.

³ Another tree at Kew, 18 ft. high, which was obtained from Osborne in 1879 and is labelled var. *betulaefolia*, scarcely differs from var. *viminialis*.

from Volxem in 1879, and is now about 35 ft. high. There are also fair specimens at Bradwell Grove (Oxon), Highnam, Tortworth, and Weston Birt. At Gissselfelde, Denmark, a fine tree is about 60 ft. high.

8. Var. *viminialis aurea*, Henry.

Ulmus Rosseelsii, Koch, *Dendrologie*, ii. pt. i. 412 (1872).

Ulmus campestris, var. *aurea*, Morren, *Belg. Hort.* 1866, p. 356, coloured plate; Lemaire, *Illust. Hort.* 1867, t. 513.

Ulmus campestris, var. *antarctica aurea*, Nicholson, in *Kew Handlist Trees*, ii. 135 (1896).

This is a sub-variety¹ of var. *viminialis*, in which the leaves are variegated with yellow. It appears to have originated about 1865 in Rosseel's nursery at Louvain; and is represented at Kew by a grafted tree about 20 ft. high.

9. Var. *viminialis marginata*,² Petzold and Kirchner, *Arb. Musc.* 556 (1864).

Var. *viminialis variegata*, Nicholson, in *Kew Handlist Trees*, ii. 137 (1896).

This is similar to var. *viminialis*, but the leaves are variegated with white. There are good specimens at Bayfordbury and Beauport, and a shrub at Kew about 10 ft. high. At Hamwood, Co. Meath, Elwes saw a tree about 30 ft. high in 1910.

DISTRIBUTION

The "English elm," by which name this species is usually known, is a native of southern England, growing in hedgerows, where it reproduces itself only by suckers. It is common in the Thames valley, extending southwards to the Isle of Wight, where it is abundant, and westwards to Devonshire, whence it ascends the Severn valley through Somerset and Gloucester to Worcester and Warwickshire, and the Wye valley to Herefordshire. It is unknown, except as a planted tree in the east of England, where it is replaced mainly by *U. nitens*; and is totally absent from Cornwall, where it is replaced by the Cornish elm.

This tree on account of the rarity with which it produces fertile seed, has been supposed to be not indigenous; and some writers, without any evidence, have asserted that it was introduced by the Romans. It is unknown in Italy, where the elm on which the vines are trained is quite a distinct variety.³ So far as I can ascertain, it has not been seen in the wild state anywhere but in England; though an allied form occurs in the south-east of France.

The English elm has been largely planted in royal parks and public gardens in Spain. Evelyn,⁴ speaking of this tree, states: "Those incomparable walks and vistas of them at Aranjuez, Casa del Campo, Madrid, the Escorial, and other places of delight belonging to the King and grandees of Spain, are planted with such, as they report Philip the Second to be brought out of England; before which (as that most honourable person the Earl of Sandwich, lately his Majesty's Ambassador

¹ It was exhibited at the London Horticultural Society in 1868 by Lee (*Gard. Chron.* 1868, pp. 914, 1038).

² A specimen of this in the Sherard Herbarium, Oxford, was gathered in the Chelsea Physic Garden in 1713.

³ Cf. *U. nitens*, var. *italica*, p. 1892.

⁴ *Sylva*, 33 (1679). The plantation of elms at Aranjuez is further described by Evelyn, *Sylva*, 303 (1706).

Extraordinary at that Court writ to me) it does not appear that there were any of those trees in all Spain. In that Princely Seat it is, that double rows of them are planted in many places for a league together in length, and some of them forty yards high." Philip II. created Aranjuez a royal residence in 1575, and probably planted the elms about this date.

I visited the Royal Park at Aranjuez in 1911, and found many fine avenues of elms, the largest trees measuring 100 to 120 ft. in height, and 12 to 16 ft. in girth. These differed in no respects from the English elms in Windsor Park or other places in England; and their deeply-furrowed dark-coloured bark has caused this species to be known in Spain as *olmo negro*. None of the trees which I saw looked old enough to date back to the reign of Philip II.; but I was informed that a very old tree which died and was removed in 1910, had a trunk 30 ft. in girth. This was probably one of the three ancient elms¹ noticed here by Lady Holland in 1803.

At Aranjuez, situated at a low altitude in a warm climate, on the banks of the Tagus, the English elm produces every year fertile seed in great abundance; and numerous seedlings were observed by me in a nursery in the park. At Madrid, on a plateau, 500 feet higher, with a cold temperature in spring, there are extensive groves of these elms in the Retiro Park; but the samaræ were empty and contained no seed, as is almost invariably the case in England; and M. Hickel noticed the poor seed on the elms of the same species at Toledo. Farther south in Spain, the English elm probably produces as good seed as at Aranjuez; and the prevalence of this tree in Spain must be due to the ease with which seedlings can be raised.

A large quantity of seed from the English elms in the Royal Park at Aranjuez was sent to me in May 1911, and sown immediately at Cambridge. In spite of the great drought, I raised numerous seedlings, which are very uniform in character, all having opposite leaves, indicating a pure species.

It is possible that the tradition of the introduction of the English elm into Spain from England is incorrect; and that this tree may be a true native of Spain, indigenous in the alluvial plains of the great rivers, now almost completely deforested. As explained under *U. nitens*, var. *italica*, the elm, which occurs wild in the mountains of Spain has different foliage, and it is readily distinguished by its light grey-coloured bark.

(A. H.)

CULTIVATION

The English elm is, so far as we are able to judge after careful study of the genus at home and abroad, a variety peculiar to the southern parts of England,² where it

¹ Cf. Earl of Ilchester, *Spanish Journal of Elizabeth*, *Lady Holland*, 73 (1910), where mention is made of three venerable trees ("either elms or oaks") in front of a small hunting villa built by Charles V. in the garden at Aranjuez. These, according to oral traditions, were said to have been planted by the Emperor Francis I. during his captivity, and by Philip II. Two were flourishing, but one was in a piteous state in 1803.

² We have never seen any specimens from the Continent which are identical with this species, except those planted in Spain which are mentioned above.

has grown in hedgerows from the earliest historical times in great abundance, and has propagated itself by suckers only. We can distinguish it from the other elms by its erect habit, by the rarity of suberose branches, by its dark red heartwood, and especially by the late period to which it holds its leaves, and by the bright golden colour which they assume, in seasons when the elms of all other varieties are comparatively dull in colour. This latter character is constant on all soils and, so far back as I can remember, in all seasons. Two reasons may be suggested to account for its rarely producing seed. One is that reproduction by suckers during a very long period has diminished its floral fertility.¹ The other that being here at the northern limit of its range (if it is a true native of Spain), the seasons are rarely warm enough. Whatever may be its origin, it is one of the finest and most characteristic trees of those parts of England where it thrives; and both from its economic and ornamental value deserves to be propagated in the only way it can be kept true, either by suckers or by layers from stocks of the best type.

So far as we know there is no nursery in this country which has so produced it for many years past, and the results are only too evident in the elms which are now growing in almost all modern places. Soil no doubt has a material influence on the growth of this as of other trees, and a rather heavy and deep soil is necessary to bring it to perfection, but even on the thin dry oolite of the Cotswold hills, the true English elm retains its characteristics, and though slower in growth attains a greater height and bulk than any other tree, except perhaps the beech and the wych elm.

Its true value as a landscape tree may be best estimated by looking down from an eminence in almost any part of the valley of the Thames, or of the Severn below Worcester, during the latter half of November, when the bright golden colour of the lines of elms in the hedgerows, is one of the most striking scenes that England can produce.

Its economic value is also much greater than has been generally realised, for a tree that will, on grassland, of only moderate quality, without detriment to the adjoining pasture, and without any outlay but a moderate attention in trimming the lower branches, produce a log worth from £4 to £5 in a hundred years or less, cannot be ignored as an important element in the value of all grazing districts.

No author that I know has written on the propagation of the elm with so much personal knowledge as William Boutcher, nurseryman at Comely Garden, Edinburgh (now Comely Bank Nursery), whose *Treatise on Forest Trees*, first published in 1775, contains more exact observation on nursery work than most recent books. The elm was a great favourite of his, and I believe that if his advice had been more generally followed, the elms produced during the last century by nurserymen would be much finer than they generally are. Though observant woodmen know that the best and

¹ This is very unlikely, as the English elm in Spain produces ripe and fertile seed in abundance, yet suckers there very freely. Moreover, *U. nitens*, which suckers quite as much as the English elm, produces good seed in abundance in favourable years.

straightest timber trees are those naturally produced in hedges from suckers, yet the practice of budding or grafting elms on the stock of the wych elm has become so general, that I do not know a single commercial nursery in England to-day where true layered English elms can be procured; and though nurserymen assert that the budded trees will produce equally fine specimens, yet one has only to compare the younger trees planted in the last hundred years with the older ones, to see how inferior they generally are.

This practice, however, was recommended as long ago as Miller's time on the grounds mentioned by Hunter, in Evelyn's *Silva* 124 (1776), as follows:—"The practice of grafting will be found a valuable improvement of the English elm, if we consider the nature of the wych elm on which it is grafted. First the wych elm will not only grow to the largest size of all the sorts, but will grow the fastest. This is not to be wondered at, if we examine the root, which we shall find more fibrous than in any of the other elms. Now as all roots are of a spongy nature to receive the juices of the earth for the nourishment and growth of the tree, that tree must necessarily grow the fastest, whose root is most spongy and porous; and therefore the English elm being set upon the root of the wych will draw from the earth a greater quantity of nutriment. The English elm on this basis, will arrive at timber many years sooner than those raised by layers, and be also forced to a greater size."

Boutcher says:¹ "The English elm grafted on the Scots makes both a beautiful and valuable tree, yet it is still inferior in regularity of form, and loftiness of stature, to those raised from their own mother, and as every tree must in some measure partake of the stock on which it is grafted, so this has a near resemblance of the Scots elm in its bark even when young, and when old, like them, grows more loose spreading and less erect than the true English, though when young they are extremely beautiful. Here it may be necessary to observe a practice extremely common among ignorant nurserymen, which is cutting their English elm grafts from those on Scotch stocks, and which, indeed, have the fairest and plumpest buds (a plain indication from whence they immediately proceed, the buds of the Scotch being larger and more turgid than those of the English), but these gentlemen do not regard the quality of the plants they sell, so they are paid for them, or are ignorant that by repeating this practice the English elm may be brought so far to degenerate, as in many graftings this way, to differ very little from the Scots; therefore, whatever kind the stocks are on which you graft the English, let the grafts be taken from trees of the true kind, raised by layers of their own mother. This, however little attended to, nature plainly dictates." Further, he goes on to say: "It may also be proper to notice here that all elms planted in gardens and by the sides of walks, lawns, or avenues, ought to be on Scots stocks, as these produce no suckers, which the English, French, or Dutch do in such quantities as to make it very troublesome and expensive keeping such places clear of them and in good order."

The whole of Boutcher's article on the elm is so valuable that it should be studied by anyone wishing to plant elms.

¹ *Treatise on Forest Trees*, 12-13 (1784).

Many persons at the present time are anxious when planting to obtain quick results; yet the planting of an avenue is an operation which cannot be hurried, or let by contract to persons who have no future interest in it. No doubt the nature of the soil has much influence on the growth and habit of the tree, but even in poor, dry calcareous soils the difference between the old trees grown from suckers in hedges and the trees bought from nurseries is so great that no one can mistake them.

It also frequently happens that elms are budded on stocks raised from seedlings of foreign origin, and these vary so much in their habit and origin, and are usually so much inferior to the true English elm that the results are what we usually see in modern plantings. There is no better proof of this than the young trees planted to fill the gaps in the Long Walk at Windsor, which are a lamentable illustration of carelessness in the propagation of elms.

No tree possesses the power of suckering¹ to a greater extent than the English elm, the roots often extending 50 yards or more; and in order to procure a quantity of young plants, it is only necessary to shut up a small field surrounded by elms of good type, and transplant the most vigorous suckers into a nursery, where they can be pruned and cultivated until 6 to 10 ft. high; or if desired to have them larger they may be transplanted every two or three years and safely moved when as much as 15 or 20 ft. high.

Mr. Knight published² in 1840 a method of propagating elms by using, as cuttings, slender shoots which were pulled out from the trunk near the ground, and then reduced to about an inch in length, with a single leaf at the apex.

If, however, it is desired to produce new varieties, the raising of elms from seed is a very simple matter, provided that the seeds are sown as soon as they are ripe, when they germinate in a few days, and make strong plants in the first year. The variation of most elms that I have sown, except the wych elm, is very great, and natural cross-fertilisation no doubt accounts for this.

The leaves do not show their true character at first, and it would be difficult to judge of their fitness for planting until they have attained a considerable size. If good timber trees are wanted, no variety surpasses the true English elm on its own roots in its own district. For the maritime climate of south-western England, Scotland, and Ireland I would recommend the true Cornish elm on its own roots. For Scotland, and the North of England, Boutcher was probably right in preferring trees of a good local variety budded on the stock of seedling wych elms, but never on that of imported seedlings.

The bark of dead or sickly elms will usually be found to contain the elm-bark beetle (*Scolytus destructor*) in one stage or another. Whether this insect attacks healthy trees has never yet been satisfactorily determined; and the remarks on this point of Dr. T. A. Chapman, an entomologist whose actual experience of Scolytidæ

¹ In *Gard. Chron.* 1872, p. 603, fig. 504, an article by the late W. Ingram, gardener at Belvoir Castle, has a figure showing the extraordinary root-development of an elm growing on the edge of a quarry.

² Loudon, *Gard. Mag.* xvi. 474 (1840).

is probably greater than that of all other English writers on the subject, seem worth quoting. He says:¹ "I do not remember having seen a *felled* elm trunk that *S. destructor* had not attacked, frequently whilst still trying to throw out shoots; yet I have never seen a trace of it in healthy growing trees; these are supposed to resent and repel the attacks of the *Hylesinidae* by pouring out sap into their burrows; and, in the case of *S. pruni*, I have observed burrows less than an inch long, some of which, containing a few eggs already laid, had been abandoned uncompleted by the beetles, apparently on account of the presence of a fluid which must have been sap, as no rain had fallen to account for it; these burrows had been formed in bark that was still nearly healthy, though near some dying bark which had doubtless attracted the beetles." The following is an account of Mr. J. Edwards' experience. Some years ago a large and apparently sound limb of a big elm at Colesborne was broken off, and it was allowed to remain where it fell. This fallen limb in due course showed traces of attack by *Scolytus*, of which, judging from the number of holes in the bark, there must have been some thousands. Up to the present no signs of *Scolytus* can be seen on the tree, which could not have been the case if any of the beetles bred in the bark of the fallen limb had established themselves either in the trunk or the main branches. As a preventive measure it has been recommended² that the bark be smeared with a fermenting mixture of cow-dung, slaked lime, bullock's blood, and tobacco; but I am inclined to think that steps calculated to maintain or increase the vigour of the tree would be more likely to succeed than any bark-dressing whatever. With the view of lessening the numbers of this pest, sickly trees and felled timber, as well as fallen limbs, should be got rid of without delay.

The branches of old elm trees are liable to fall³ without warning in calm weather, especially after heavy rains. Though in some cases the branches have been weakened by fungoid attacks, there is no doubt that in other cases the tree was quite sound when the branches fell. Many fatal accidents have been reported from this cause, as at Powis Castle⁴ in 1899, and in Kensington Gardens a few years ago. The English elm seems to be more liable to drop its branches than any of the other kinds.

ELM AS A WOODLAND TREE

The elm has seldom been considered by writers on forestry as a woodland tree in this country, and is rarely found in plantations⁵ except scattered among other trees. I have seen, however, at several places in the Midlands small areas of

¹ *Entomologist's Monthly Magazine*, vi. 127 (1869-1870). An interesting account of the ravages of this beetle was given by W. S. Macleay, in an article entitled "Abstract of a Report on the State of the Elm Trees in St. James's and Hyde Parks," which appeared in *Edin. Phil. Journ.* xi. 123 (1824).

² W. R. Fisher, Schlich's *Manual of Forestry*, iv. 278 (1907).

³ Cf. correspondence in *Gard. Chron.* xxxviii. 119, 134, 252, 268, 331 (1905), and xxxix. 11 (1906).

⁴ *Gard. Chron.* xxv. 340 (1899).

⁵ In the Forest of Dean, a mixed larch and oak plantation, aged 39 years, in which there were a few English elms, showed the following average measurements taken by Mr. A. P. Long in 1911: larch, 59 ft. high, 41 in. girth; English elm, 54 ft. high, 37 in. girth; oak, 40 ft. high, 26 in. girth.

almost pure elm, probably grown from suckers, which convince me that on suitable soil and near a good market it might prove to be one of the most profitable forms of woodland.

At Brampton, near Huntingdon, I saw on the roadside a belt of elms of moderate quality which stood thick on the ground, and am indebted to M. D. Barkley, Esq., of Huntingdon, for the following particulars:—"The elm belt at Brampton contained 1 acre and 30 poles; there were 330 trees containing 8750 feet of timber. These were left much too thick on the ground to develop properly." I should expect on land worth 20s. to 25s. per acre, in the vale of Gloucester, or on the Oxford clay, about 6000 to 8000 cubic feet per acre from elms grown from suckers that had been properly trimmed, and this should be produced in from 70 to 100 years, according to the quality of the land. Assuming only 9d. per foot to be the price, such a crop would realise £250 to £300 per acre at 100 years, and no other tree except black Italian poplar would be likely to approach this result.

A good system on those properties which are managed systematically in elm-growing districts is to leave in every chain of hedgerow two or three of the best suckers to grow into timber; and these are carefully trimmed every few years to prevent their branches from spreading, and are felled when they contain 50 to 100 feet of timber. Such hedgerow trees are not detrimental to grass land, and produce a sum equal in some cases to 15 or 20 per cent of the rent of the land adjoining.

With regard to the elm as a forest tree on the Continent, Huberty is of opinion that it can only be cultivated profitably on fresh fertile soils, and in situations where it can extend both its branches and its roots without hindrance. *U. montana* is less exacting in its demands on the soil than the other species, and is extremely hardy, having been unaffected by the severe spring frost (-4° Cent.) which severely injured, in the Ardennes on May 26-27, oak, ash, chestnut, Robinia, and larch. *U. montana* keeps pace in youth with the beech, though eventually it is suppressed by the latter in the Forêt de Soignes. The elm is liable to be split by severe frost, when the trunk is exposed by a fall of timber. It requires light and room when it passes the youthful stage. Mouillefert says¹ that the elm, which he calls *U. campestris* (but which is *U. nitens*), forms nearly pure groves in the woods attached to the Agricultural School at Grignon; while Fliche states² that it forms a considerable proportion of the forests in the valleys of the Saône and Adour.

REMARKABLE TREES

Loudon says that the oldest trees on record are perhaps those at Mongewell Park in Oxfordshire, once the property of the Bishop of Durham, but the figure of these in Strutt's work (*Sylva Britannica*, plate xvi.) shows that they were neither

¹ *Essences Forestières*, 160 (1903).

² In Mathieu, *Flore Forestière*, 300 (1897). Cf. p. 1897.

very large nor very old. Of other very old trees mentioned by Loudon the Crawley elm, also figured by Strutt (plate xxii.) is perhaps the finest remaining. It stands in the Brighton road at one end of the town, and was in 1838, 70 ft. high and 61 ft. in girth at the ground. It was then hollow, and measured 31 ft. round the inside, which was closed by a door, and it is said that a poor woman once gave birth to a child in the hollow tree. Now it is a venerable wreck with some living branches; but the great swelling at the base which formed its immense girth is much decayed, and owing to the suckers which have sprung from the ground round it, it is difficult to measure. Miss Smith, who lives opposite the tree, told me that in her youth she had seen twelve people seated at tea in the hollow trunk. The other English elm figured by Strutt, which grew at Chipstead in Kent, was not a very large tree, and died soon after he drew it. None of the other elms mentioned by Loudon seem to have been as large as several which I have measured, as will be seen in the following list drawn up in the alphabetical order of the counties:—

In Bedfordshire there are fine trees at Woburn Abbey and Wrest Park, but most of the big elms in this county are *U. nitens*.

In Berks the best that I have seen are in Windsor Park, where the "Long Walk," leading from the Castle gates to the statue, is still one of the finest and most imposing avenues in the world. I am indebted to Mr. W. C. Squires, who has charge of the trees in Windsor Park, for reading and correcting when necessary, the following account:—The planting of the Long Walk is ascribed by Menzies¹ to the example of Evelyn, who states that in 1664 he planted some land at Says Court with elms, "being the same year that the elms were planted by His Majesty in Greenwich Park." In 1670 Evelyn visited Windsor. "King Charles II.," he says, "passed most of his time in hunting the stag and in walking in the Park, which he was now planting with rows of trees." In 1678, 1679, and 1680, Evelyn was at Windsor again. In 1680 a survey of the land between the Castle and the Great Park was made, and the intervening fields were purchased at a cost of £1242:4:9. We may safely presume that the planting of the Long Walk was at once commenced. The distance from the Castle to the statue is $2\frac{3}{4}$ miles. There were originally 1652 trees. The distance between the two inner rows is 50 yards. The trees are 30 feet apart from each other in two lines also 30 ft. apart, perhaps rather too close for the health of the trees. At the end nearest the Castle the soil is loam from 10 to 15 feet deep overlying chalk, and here the trees have done well and are mostly still sound. Where they have room enough, as in the adjoining part of the Park, there are many really fine trees up to 120 ft. in height and 15 ft. or 16 ft. in girth; but farther on where the soil is clay overlying gravel, and beyond the double gates where it is heavy clay, the trees are much smaller, and many have died at various periods and been replaced with elms of varied character, many of which now are, and never will be anything but an eyesore. Previous to 1861 the condition of this part of the avenue had attracted attention, and a good deal of correspondence on the subject had taken

¹ *History of Windsor Great Park and Forest*, 17 (1864).

place, which will be found in the Report of the Commissioners of Woods to Parliament in March 1861.

Along the Thames valley throughout Berks there are abundance of splendid elms of the best type, but as far as I know none so large as exist farther west.

In Bucks, the same remarks apply to all the alluvial soil; and those in the playing fields at Eton must recall happy days to numbers of our readers, though like some of the older elms in the country they are decaying and being replaced by inferior grafted trees. The two best trees in 1907 were, 113 ft. by 17 ft. 8 in. and 115 ft. by 17 ft. 3 in., as measured by Henry.

In Cambridgeshire we are out of the region of native English elms, but there are some of good size in the College Backs at Cambridge. Two of the largest, which grew in the grounds of St. John's College, and were known as the Sisters, were blown down in the great gale of 14th October 1881. These were recorded at the time by Mr. J. W. Clark,¹ as 10 ft. in girth, and about 130 ft. in height to the topmost branches. Prof. Hughes² counted 218 rings on the base of one of the fallen trunks, showing that these elms were planted a few years after the College grounds were laid out, as is generally supposed, in 1630. Perhaps the finest English elm now at Cambridge is in the grounds of King's College, which measured 130 ft. by 13 ft. in 1906.

In Cheshire the only fair elms that I have seen are in the park at Eaton Hall; but I must confess that I have unduly neglected this county, where, perhaps on account of the soil, trees do not generally attain a large size.

In Cornwall true English elms are rare, if not entirely absent, all those which I have seen being of other species.³

In Cumberland, and in Derbyshire we are too far north to see this tree at home, but there are some fine trees in Kedleston Park.

In Devonshire there are many splendid elms, among which I have seen none finer than those at Powderham. Plate 404 shows a tree which, in 1902, when it was photographed for this work, measured 125 ft. by 22 ft., but when I revisited Powderham in 1906, it had lost a large limb.

In Dorsetshire the finest elms I know of are at Melbury, where a row of seven, known as the Seven Sisters, stand in front of the house, on what was described by the gardener as a thin, but evidently a very fertile soil. The centre tree in this row measured 130 ft. by 17 ft. 10 in. in 1906.

In Essex⁴ there are great numbers of this elm, which may be called the prevalent tree of the county, and it is difficult to select the finest. Mr. J. C. Shenstone

¹ In *Cambridge Review*, 26th October 1881.

² In *Comm. Antiq. Soc. Cambridge*, xxiv. page xxxix (1884).

³ Cf. pp. 1884, 1889.

⁴ Holinshed, *Chronicles*, ii. cap. 22 (1586), says:—"Of elme we have great store in everie high waie and elsewhere, yet have I not seene there of anie together in woods or forrests, but where they have bene first planted and then suffered to spread at their own willes. Of all the elms that ever I saw, those in the south side of Dover Court, in Essex, near Harwich, are the most notable, for they grow in such a crooked maner, that they are almost apt for nothing else but navie timber, great ordinance and beetels: and such thereto is their naturall qualitie, that being used in the said behalfe, they continue longer, and more long than anie the like trees in whatsoever parcell else of this land, without cuphar, shaking, or cleaving as I find."

tells me that in the avenue at Earls Colne he measured a hollow tree 124 ft. by 24 ft. 4 in., but I cannot be sure that this is a true English elm. At Boreham House there is a fine avenue leading to the main road from London to Chelmsford, in which Mr. Shenstone in 1890 measured a tree 132 ft. by 20 ft. which he considered to be the tallest in Essex; but when I was there in 1907 I could find none taller than a double-stemmed tree of which the one half was 125 ft. by 17 ft. and the other broken off at about 25 feet was 23 feet in girth. Nearer the coast elms grow to a great size on the fertile brick earth, but usually are either *U. major* or *U. nitens*.

Gloucestershire holds the record for the tallest elms that I know of, which are at Forthampton Court, near Tewkesbury, the seat of the late J. Reginald Yorke, Esq. A tree, of which I saw the stump, was blown down in March 1895, and was reported by Mr. French, the gardener, in the *Gardener's Magazine* for 6th April of that year, to have been 150 ft. by 20 ft., as measured on the ground with a tape. Mr. Yorke confirmed this statement, assuring me that it was considerably taller than one which I measured in 1906 at the same place, and found to be about 140 ft. by 20 ft. A butt covered with ivy, about 23 ft. in girth over bark, is broken off about 30 ft. high; and its top is said to have been 40 yards long as it lay.

At Badminton there are two immense elms close to the kennels, the largest of which measures 30 ft. in girth or 26 ft. if taken below a large burr. An immense limb has broken off low down; and the top of this tree as well as that of its neighbour, which is 24 ft. in girth, were blown off many years ago. There are many other fine elms and oaks in the park here, but I saw none of equal girth to the one above mentioned.

A splendid old elm, of which Col. Thynne has sent me a photograph, grows near Thornbury Castle, and measures 93 ft. by 27½ ft. Elms containing from 600 to 1000 cubic feet of timber are mentioned by timber merchants as having been felled on several occasions in the vale of Gloucester. The tree mentioned by Loudon under the name of Piffe's Elm, which he says was in 1783 the largest tree in Gloucestershire, was quite small in comparison with many now living. I saw two blown down at Sandywell Park, the seat of C. W. Lawrence, Esq., which each contained over 600 feet.

In the valley of the Coln, close to an old Manor House called Compton Casey, belonging to the Earl of Eldon, there are eleven (formerly twelve) fine elms growing in a row only 90 yards long, which average 13½ ft. in girth and about 115 ft. high. The largest is 16 ft. 9 in. in girth.

At Cirencester, at Ampney, at Williamstrip, at Barnsley, and other places, there are many large trees, which have, as they grow old, a tendency to become very burry at the base, but on the more brashy soil of the Cotswolds they rarely exceed about 110 ft. by 15 ft.

At Huntly Manor, Gloucestershire, the seat of B. St. John Ackers, Esq., there is a remarkable tree of which the text-plate gives a better idea than any description. The watercourse when I saw it in September 1910 was nearly dry, but runs freely

most of the year. Mr. Ackers tells me that if you put a ferret into the root on one side, it can pass through and come out on the other, which shows that the butt is partly hollow, though the tree looks sound and is about 100 ft. high. It is difficult to explain the origin of this curious freak.

In Hampshire the fertile valleys are full of big trees; but on the chalk they are of a more stunted character, and are often *U. major*. The largest true English elm in this county was recorded in 1887 at Broadlands, near Romsey, and, according to Mr. J. Smith of that town, was 110 ft. by 24½ ft.

Herefordshire, though not so remarkable for the size of its elms as for its oaks, is full of fine trees, some of which were recorded by Dr. Bull in the volume of the *Woolhope Transactions* for 1868; and in later volumes other elms are mentioned at Croft Castle and Longworth. The largest I have measured is in the deer park at Hampton Court, a tree with two trunks from the same root, girthing 20 ft. and 16 ft. respectively, and 125 ft. in height in 1908.

The elms of Hertfordshire are mostly of the glabrous-leaved species, and are described under *U. nitens*; but the finest English elm I have seen is in Hatfield Park, and measured in 1905 120 ft. by 20½ ft. The girth in 1911 was found by Mr. Barton to be 21½ ft. At Bayford Church there is a fine tree, apparently quite sound, which was measured by Mr. H. Clinton-Baker in 1911 as 110 ft. by 18 ft. 9 in. Near Bayford Lodge another is 93 ft. by 21 ft. 9 in.; and a record exists that this tree had a girth of 17 ft. 1 in. in 1813.

Kent has a great variety of elms, which appear to be mostly of a different type to those of the Thames and Severn valleys, and as a rule are planted in parks and

pleasure grounds, and not natural in the hedgerows. The best that I have measured is one at Eastwell Park, which in 1907 was 115 ft. by about 20 ft. in girth.

In Lancashire, Leicestershire, and Lincolnshire I have not seen any English elms remarkable for size or beauty. The majority of the trees in these counties look more like hybrid seedlings of foreign origin than true English elms.

On November 23, 1910, I saw at Well Vale, Lincolnshire, the seat of Mr. W. H. Rawnsley, some English elms (Plate 405) which had preserved their leaves quite green after several nights of frost, when the thermometer sank to 17° Fahr. These elms, one of which measured 108 ft. by 8 ft. 2 in., seem to have been grown from suckers; and though they retain their leaves abnormally late in the season—in 1911 till the first week in December—they are English elms, and differ entirely from the Kidbrook elm referred to, p. 1896.

In Middlesex, and all round London, the majority of the elms appear, like those of the London parks, to be foreign seedlings or hybrids; and Loudon did not record a single one of any great size which seems to exist at present, though he gave many details of trees at Hampstead, Fulham, and elsewhere. Though there are many large English elms at Hampton Court, Richmond, Syon, and in Kew Gardens, they seem to be suffering more or less like those in Hyde Park from smoke and old age, and none of the younger trees which have been supplied from nurseries to fill their place appear likely to develop into first-class elms. The tallest that I have measured is at Chiswick House, and this in 1904 was a healthy sound tree 137 ft. by 12½ ft. Another in the grounds of Fulham Palace is 120 ft. by 18 ft. Henry saw one at Hampton Court, with a broken top, girthing 27 ft. 9 in. in 1910; and another at Osterley Park, 108 ft. by 16 ft. 4 in. in 1907.

In Monmouthshire and in South Wales generally, though elms are common enough they are no longer a characteristic hedgerow tree.

In Norfolk I cannot remember to have seen a single really first-class English elm, most of the hedgerow trees being either *U. nitens* or the small-leaved elm (*U. minor*), which, so far as I have seen, is usually a comparatively small and ill-shaped though picturesque tree. Marshall¹ was, I think, not far wrong when he said that there was not, generally speaking, a good elm in the county of Norfolk; and the only elm mentioned by Grigor of great size was what he calls an English elm over 20 ft. in girth.

In Northamptonshire, where oak and ash grow so well, I have seen few very striking elms; and the same may be said of Nottinghamshire, where in the beautiful parks of Thoresby, Rufford, Welbeck, and Clumber they are not so conspicuous a feature as the oaks. At Althorp there are many splendid trees, three of which were measured in 1893 by Mr. F. Mitchell² as follows:—(No. 1) In the pleasure grounds, 117 ft. by 20 ft., with two stems, containing 924 ft. (No. 5) By the carriage drive, 105 ft. by 19 ft. 8 in., also divided, and containing 841 ft. (No. 17) West of Harleston House, 110 ft. by 18½ ft., containing 715 ft. I verified these measurements in 1904, and found that in eleven years they had made but little increase.

¹ *Planting*, ii. 431 (1796). Cf. Loudon, p. 1383.

² *Trans. Roy. Scott. Arb. Soc.* xiii. 90 (1893).

Oxfordshire may be called *par excellence* the county of the elm, and it would be hard to find a place in it, except in the barest parts of the Cotswolds, where they do not form a conspicuous feature of the landscape. Among the parks where they grow best the following may be mentioned:—Barrington, Blenheim, Cornbury, Fawley Court, Heythrop, Thame. At Brightwell Park, among a number of large old elms, I measured in 1905 two trees, 119 ft. by 17½ ft. and 110 ft. by 19 ft. respectively; and probably larger ones can be found. One of the oldest in this county is the "Tubney Tree" at a roadside meet of the Old Berkshire hounds, eight miles from Oxford. This has larger leaves than usual, but no suberose branches. Its trunk is 27 ft. in girth, and still fairly sound, and at about 20 ft. from the ground divides into five ascending limbs, which were topped about twenty-five years ago, and have thrown out many healthy branches. The Rev. H. J. Bidder of St. John's College has a water-colour drawing of this tree, made before it was topped. In Magdalen College Park at Oxford there are some very tall English elms, one being, in 1905, 134 ft. by 13 ft. 5 in.

In Shropshire, notwithstanding the splendid soil, the elms are not so large as the oaks; and in Somersetshire¹ I have neither seen nor heard of any elms of larger size than one in the park at Dunster Castle, which in 1904 measured 120 ft. by 22 ft. The same remarks apply to Staffordshire and Suffolk.

Surrey and Sussex are more remarkable for conifers than for elms, and my local knowledge is not enough to enable me to indicate where the finest elms are to be found. Among the innumerable residences with which these counties are so thickly studded, no part of England would better repay the researches of any one interested in trees; and we have probably missed some of great rarity, though we have visited a great number of places in these counties. Henry measured in 1905 in Betchworth Park, near Dorking, an English elm 122 ft. in height and 23 ft. in girth.

Warwickshire and Worcestershire are, like Oxford and Gloucester, renowned for large and fine elms. Loudon recorded at Coombe Abbey a tree, 150 ft. high and 28½ ft. in girth, which I fear no longer exists, as I could find none nearly as large now standing at that place.

In Mr. Berkeley's park at Spetchley, near Worcester, there are great numbers of large trees, about 200 years of age. I measured one 108 ft. by 21½ ft.; another 127 ft. by 14 ft.; and in front of the house, one with very large spreading branches, 125 ft. by 20 ft. The largest in girth was 22 ft. 8 in., broken off at about 20 ft. up. At Ombersley Court, 6 miles north of Worcester, Lord Sandys showed me the remains of a huge tree, only the ivy-covered stump of which is left, and measures about 23 ft. in girth. From it about 1700 ft. of timber was sold; and I was assured by Mr. Groom of Hereford that this tree contained 2000 ft. of timber. A little way off I measured a tree, which is perhaps the largest sound English elm now standing, and which I found to be 130 ft. high by 23½ ft. in girth; another in the park was 125 ft. by 21½ ft.

¹ Babbage, in Loudon, *Gard. Mag.* xvii. 356 (1841), and xviii. 488 (1842) gave particulars of English elms at Nettlecombe Court—one, only eighty years old, having a clean trunk 32 ft. long, with a middle girth of 12 ft., containing 200 cubic ft. of timber; and another, sixty-nine years old, containing 360 ft. in the trunk, and 120 ft. in the top and branches.

Wiltshire, like the adjoining counties, is full of elms, which attain a large size where the soil is deep. The best that I have measured is at Corsham Court, close to the house, and was 123 ft. by 20 ft. in 1905.

In Yorkshire I have seen no remarkable English elms, even at Castle Howard or Studley, where the wych elm grows to perfection; but in the finer soils of this great county there are no doubt many good trees which we have not heard of.

In Wales the best place for English elms that I know is at Maeslwyd, near the borders of Herefordshire, in the rich valley of the Wye, where there is an avenue containing many fine trees, which attain 110 to 120 ft. in height. In south Wales, where the demand for elm timber is probably greater than anywhere in England, I have seen none worthy of special notice; and in central and north Wales the wych elm is the prevalent species.

In Scotland we know few English elms¹ of importance; but Mr. Renwick measured two trees at Loudon Castle, Ayrshire, 107 ft. by 15 ft. 4 in., and 105 ft. by 16 ft. 4 in., in 1908; and at Milton Lockhart, Lanarkshire, a tree 90 ft. by 15 ft. 1 in. in 1911. Most of the elms in Scotland are *U. montana*.

In Ireland I find no records in my journals of true English elms, except at Adare, the seat of the Earl of Dunraven, where, on the river bank, the finest English elm I have seen in Ireland, was about 120 ft. by 13½ ft. in 1909. There is a beautiful tree at Riverview, Ferrybank, Waterford, of which Mr. T. A. Penrose sent us a photograph. It is growing in deep loamy soil, and measured 91 ft. in height and 14 ft. in girth in 1912. Mr. R. A. Phillips records an English elm at Loughrea, 100 ft. by 12 ft. Most of the hedgerow elms in the east are scrubby and corky twigged. In the south of Ireland the glabrous and Cornish varieties are more generally grown, but only in the demesnes of large landowners, and the timber is here so little valued that when required for large works it is sometimes imported from England.

TIMBER

After the oak and ash, elm is the most important of the non-coniferous timbers grown in England, but its value per foot is inferior to either of them. It varies immensely in different districts, and according to the distance from a sawmill; but it may be put at about 1s. per foot for the best quality of trees, containing from 50 to 200 cubic feet, and 8d. to 10d. for old, faulty, and ill-shaped trees.

Large old elms are often defective in some part of their trunk on account of their liability to lose large limbs from wind; and where limbs have been blown off, or cut off, the stump generally decays, and its decay extends into the body of the tree, unless the wound has been dressed with tar, creosote, or some preservative, and covered with lead or cement.

The removal of elm trees, often weighing many tons, is expensive and difficult; and though engines are now used for the purpose, it is often found economical, where a number are to be felled, to erect a sawmill close by, and cut them up

¹ Walker, *Essays Nat. Hist.* 70 (1812), says: "We have no English elms in Scotland of an old date or of a large size."

into such sizes as they are fit for on the spot; and sometimes large trees are sawn on the ground lengthways into halves so as to make them more portable.

Laslett¹ says that if used where it is constantly under water, or in situations where it is always kept dry, elm is one of the most durable of timbers, but it decays rapidly under any other circumstances. I have seen, however, many old barns and sheds in Hants, Wilts, and Essex covered with elm weather-boards, which, when tarred, have remained sound for a very long period, perhaps over a century.

Elm timber should not be left lying long after it is cut; and when converted into boards must be carefully stacked to dry under cover, as, though it does not crack so much as oak or ash, it twists and warps much more.

Until iron water-pipes were introduced, elm was the favourite wood for this purpose, and old water-pipes are often dug up in London and elsewhere which have remained sound for 200 years or more. I saw one of these at Chirk Castle, which was found at Clerkenwell in 1898, by the new River Water Company, of which Sir Hugh Myddleton, ancestor of the present owner, R. Myddleton, Esq., was the founder. This is said to have been laid down in 1613, and measures 8 ft. long by 14 in. in diameter at the big end. The bore, which is much encrusted by a limy deposit, is 9 in. in diameter at one end and 6 in. at the other. Similar water-pipes are preserved in the museum at Kew and in the Surveyors' Institution in London.

Elm was also formerly much used for the blocks and keels of ships; and most of the large elms cut in Essex are used, I believe, for piles, groynes, wharves, and for the timbering of the sluices, which carry off the flood-water of the Essex marshes, as well as for weather and coffin boards.

In all the counties nearest to south Wales the greater part of the elms which are blown down or felled, are used for making boxes for tin-plates, as it has been found that this wood does not discolour the plates, and there is less waste in converting for this purpose than for any other, the boards being small and thin. The price in these counties therefore depends very much on the prosperity of the tin-plate trade.

A very large quantity of elm is also used for coffin-boards though, according to "Acorn," whose account of this timber is well worth consulting, this branch of trade has lately suffered like all our home industries from foreign competition. The sizes required for this purpose, he says, are 6½ to 7 ft. long by 11 to 14 in. wide, and ¾ to 1 in. thick, and cost about half as much as oak, though the figure is in some cases very handsome when polished.

For the seats of Windsor chairs, elm is also largely used. The greater part of the tip-waggons used by railway and harbour contractors were formerly made of elm, though now in many cases iron and imported timber are preferred. Barge-builders, box-makers, and wheelwrights also consume a large quantity of elm, the latter preferring it to oak for the stocks or hubs of wheels, as well as for felloes of large size; and here again Canadian rock elm (*Ulmus racemosa*) is now a formidable competitor, which tends to keep down the price of home-grown timber.

With regard to the best quality of elm for wheelwrights I have made many inquiries among country tradesmen, whose opinions differ according to the locality.

¹ *Timber and Timber Trees*, 218 (1875).

Wych elm is generally considered, even in the south, the toughest and best for wheel stocks, trees of small size being cut into lengths and bored through the heart to keep them from splitting as they dry. Most country wheelwrights who have a reputation for the durability and soundness of their waggons prefer to select the trees when growing in their own district; but I have not been able to find any agreement as to what they consider the best timber.¹

As one goes north, however, the comparative value of wych elm as compared with English and smooth-leaved elm, increases; and it may be said generally that whilst in the southern and midland counties, English elm is worth a third more than wych elm; in the north, where the former is falling off in size and quality, they are equally valued, and in Scotland wych elm, the native tree of the country, is preferred; and when speaking of elm in Scotland, wych is generally implied. Many wheelwrights speak of "bastard elm," a term which they apply to any trees which do not show in their timber the colour and character which is associated with English elm.

In France the same uncertainty and difference of opinion seems to exist; and I was told by an experienced waggon-builder in Savoy that he preferred the elm stocks imported from Angoulême, to any that were grown in the east of France.

For ornamental purposes or furniture, elm is little used in England, probably because it is liable to the attacks of wood-boring larvæ. Large tables were sometimes made of a solid elm plank, but few examples remain of ancient furniture made from this wood. One of the secondary staircases at Hatfield House is made of elm, which has not warped and shows handsome figure, but it does not seem to be of great antiquity. The best ornamental use, however, to which elm wood can be put is as veneer, cut from the mottled, waved, and curiously veined burrs, which are found not uncommonly on the trunks of old trees, especially of the wych elm. These when cut into board, crack, shrink, and warp so badly that they can hardly be used in cabinetmaking, but in the form of veneer they are sometimes of very great beauty. In rare cases, the outside slab of an elm tree is found full of markings like that of bird's-eye maple, which are due to undeveloped buds. Mr. E. Gimson, of Daneway, near Cirencester, whose reputation as an artistic worker in fine woods is great, showed an elm cabinet with a very rare mottled figure, made from a tree grown in the neighbourhood, which I have never seen equalled.

In Scotland I procured very fine examples of wych elm burr which, when polished, show a deep rich reddish-brown colour, and from which all the lower part of a most handsome bookcase was made for me.

When visiting the palace of Fontainebleau, I was shown the cradle presented by the city of Paris to Napoleon I. for his son and heir. I was assured by the guardian that this was made from a rare and costly foreign wood, but though overloaded with gilt metal-work, I recognised an elm burr, no better than many which are allowed to rot in our English parks, from one of which it probably came. Very handsome solid table-tops are also made from similar burrs, but more often they are too full of holes and rindgalls to be of any value. (H. J. E.)

¹ Cf. p. 1886 for the wood of the Dutch elm, p. 1889 for that of the Cornish elm, and p. 1902, note 3, for that of the small-leaved elm.

ULMUS JAPONICA

Ulmus japonica, Sargent, *Trees and Shrubs*, ii. 1, t. 101 (1907).

Ulmus campestris, var. *japonica*, Sargent ex Rehder, in Bailey, *Cycl. Amer. Hort.* iv. 1882 (1902).

Ulmus campestris, var. *levis*, Fr. Schmidt, in *Mém. Acad. Sci. St. Pétersb.* xii. 174 (1868) (in part).

Ulmus campestris, var. *vulgaris*, Shirasawa, *Icon. Ess. Forest. Japon.* ii. t. 15, figs. 10-21 (1908).

Ulmus campestris, Komarov, *Flora Manchuriae*, ii. 82 (1903) (not Linnæus).

A tree, attaining in Japan about 100 feet in height, and 12 feet in girth. Young branchlets pale brown, often roughened with minute tubercles or ridges, and covered with dense soft pubescence, more or less retained on the branchlets of the second year, which are fissured and roughened with slight corky ridges; in some specimens,¹ prominent corky ridges are developed in the second and third years. Leaves (Plate 411, Fig. 4) obovate or elliptic, about 3 to 4 in. long, and 1½ to 2½ in. wide, oblique at the base, acuminate at the apex; upper surface scabrous with numerous tubercles and scattered bristle-like hairs; lower surface pale green, pubescent throughout with white short hairs, conspicuous on the midrib and nerves, and forming slight axil-tufts at their junctions; lateral nerves twelve to sixteen pairs, prominent beneath, occasionally forking before reaching the margin, which is coarsely biserrate; petiole ½ to ¾ in. long, densely pubescent.

Flowers nearly sessile, regularly tetramerous, with four sepals and four stamens. Fruit narrowly obovate-oblong gradually tapering to the base, glabrous, non-ciliate, about ¾ in. long, and ⅜ in. wide near the apex; notch open, triangular, with the stigmas slightly incurved; seed touching at its apex the base of the notch.

This species is readily distinguished by the peculiar fawn colour of the branchlets in their first season.

This species, which is closely related to the European *U. nitens*, is a native of Japan, Manchuria, and Amurland. Komarov states that it is common throughout Manchuria, growing along rivers and on hill-sides, usually solitary, but occasionally forming small woods. (A. H.)

In Japan, this elm is said by Sargent,² to occur in the mountain ranges of Hondo at 3000 to 5000 feet, where it is a small tree with the branchlets often conspicuously winged. In Hokkaido this tree is much more abundant, growing on the plains almost at sea-level, and on the lower slopes of the mountains. In the streets and environs of Sapporo it is the most conspicuous tree, and attains 80 to 90 ft. in height by 10 to 12 ft. in girth. I measured a tree close to the station at Iwamigawa 110 ft. by 11 ft., with a clean stem 40 to 50 ft. high; but as a rule it has a more branching and pendulous habit, which reminded me, as it did Sargent, of the American elm, but which is as variable as the habit of *U. nitens*. I found a tree of this species growing close to one of *U. montana* in the virgin forest near

¹ Collected by Elwes, in virgin forests at Asahigawa in central Yezo. Cf. also Shirasawa's figure, *Icon. Ess. Forest. Japon.* ii. t. 15 (1908).

² In *Garden and Forest*, vi. 323, fig. 50 (1893), and *Forest Flora of Japan*, 57, t. 18 (1894), where a tree growing near Sapporo is figured.

Asahigawa, and noted that though the bark of the two was indistinguishable, the leaves were very distinct. I did not, however, notice that it produced suckers.

U. japonica was introduced into the Arnold Arboretum by seeds sent in 1895 from Sapporo by Professor Miyabe, and has grown there rapidly. Professor Sargent informs us that in October 1911, the trees which were raised vary from 17 to 30 ft. in height, and 1 ft. 2 in. to 2 ft. 4 in. in girth. Some of them produced flowers in the spring of 1907. This elm is perfectly hardy in eastern Massachusetts, where it promises to become an ornamental tree of great value. It was subsequently introduced into Europe by Späth¹ in 1900.

There are two trees at Kew, one obtained from the Arnold Arboretum in 1897, which is now about 12 feet high; and another obtained from Späth in 1900. There is also a good specimen in the Edinburgh Botanic Garden, about 15 feet high. (H. J. E.)

ULMUS ALATA, WAHOO, WINGED ELM

Ulmus alata, Michaux, *Fl. Bor. Am.* i. 173 (1803); Loudon, *Arb. et Frut. Brit.* iii. 1408 (1838); Sargent, *Silva N. Amer.* vii. 51, t. 313 (1895), and *Trees N. Amer.* 291 (1905).
Ulmus pumila, Walter, *Fl. Carol.* 111 (1788) (not Linnæus).

A tree, attaining in America 50 ft. in height and 5 ft. in girth, with thin scaly bark. Young branchlets minutely pubescent, furnished in the second or third season with two peculiar thin and wide corky wings which persist for many years. Buds ovoid, glabrous, sharp-pointed. Leaves (Plate 411, Fig. 12) deciduous in autumn, thin in texture, $1\frac{1}{2}$ to $2\frac{1}{4}$ in. long, averaging $\frac{3}{4}$ in. broad, oblong-lanceolate or narrowly elliptic, slightly unequal or subcordate at the base, acute or acuminate at the apex; smooth above; lower surface without axil-tufts and glabrescent, except for hairs on the midrib; lateral nerves eight to ten pairs, rarely forking before reaching the margin, which is biserrate and fringed with minute cilia, only visible with a good lens.

Flowers, appearing in spring before the leaves, few in a fascicle, on long pedicels; calyx five-lobed; ovary tomentose, stalked. Samara narrowly elliptic, $\frac{1}{3}$ in. long, contracted at the base into a long slender stalk, tipped at the apex with long incurved stigmas, covered on the surface with long white hairs, which are most numerous on the thickened margin.

This species is readily distinguishable by the corky wings on the branchlets, which differ from those on the other corky elms (except *U. crassifolia*) in being regularly two in number, very thin, and of considerable width (Plate 411, Fig. 12).

U. alata, which is sometimes known by the native Indian name *wahoo*, is indigenous in the warmer parts of the eastern United States, occurring from southern Virginia southward to Florida, and westward to southern Indiana, southern Illinois, Missouri, Arkansas, Indian Territory, and the valley of the Trinity river, Texas. It is usually too small in size to be of any value for timber.

¹ Späth, *Cat.* No. 106, p. 124 (1900-1901).

It is said by Loudon to have been introduced into England in 1820; but it has apparently not thriven in our climate, as we have never found any old trees. It appears to be very rare, if it exists at all, in collections on the Continent. It has lately been reintroduced by Späth of Berlin; and young trees which were obtained from him in 1909, are now to be seen at Kew, where they are already beginning to show the corky branchlets that are characteristic of the species. (A. H.)

ULMUS CRASSIFOLIA

Ulmus crassifolia, Nuttall, in *Trans. Amer. Phil. Soc.* v. 169 (1837); Sargent, *Silva N. Amer.* vii. 57, t. 315 (1895), and *Trees N. Amer.* 294 (1905).
Ulmus opaca, Nuttall, *Sylva*, i. 35, t. 11 (1842).

A tree, attaining in America 80 ft. in height and 9 ft. in girth. Bark deeply divided by interrupted fissures into broad flat scaly ridges. Buds ovoid, acute, $\frac{1}{8}$ in. long, with minutely pubescent scales. Young branchlets slender, covered with a short erect pubescence; glabrous and striated in the second year, when they often begin to develop two shining brown corky wings. Leaves (Plate 411, Fig. 2) oval, about 1 to 2 in. long, and $\frac{1}{2}$ to 1 in. broad; acute or rounded and never acuminate at the apex; slightly oblique with both sides rounded and usually subcordate at the base; upper surface light green, scabrous, with scattered minute hairs; lower surface paler green, with a scattered minute pubescence, conspicuous on the midrib, and not forming axil-tufts; margin serrate or occasionally biserrate, with triangular spreading and not incurved teeth, minutely ciliate; lateral nerves, eight to eleven pairs, usually forked, not regularly parallel; petiole $\frac{1}{8}$ in. long, covered with a minute pubescence. Stipules triangular-lanceolate, $\frac{1}{4}$ in. long, pubescent, clasping the stem by their broad bases, persistent till the leaves are fully developed in May.

Flowers opening in autumn, on slender pedicels ($\frac{1}{3}$ to $\frac{1}{2}$ in. long), three to five in a fascicle; calyx deeply divided below the middle into five to eight narrow pointed lobes; ovary pubescent. Samara, $\frac{1}{3}$ in. long, ovate, deeply notched at the pointed apex, with the stigmas incurved and nearly touching at their tips, pubescent on both surfaces, densely ciliate in margin; seed occupying more than two-thirds of the samara.

U. crassifolia, which is known in North America as the cedar elm, is distributed from the valley of the Sunflower river, Mississippi, through southern Arkansas and Texas to Nuevo Leon in Mexico. In Arkansas, it grows usually on river cliffs and low hill-sides; but is most common in Texas, where it ranges in the west from the valley of the Pecos river to the coast, growing both in deep alluvial soil and on dry limestone hills, and attaining its largest size in the alluvial flats of the Guadalupe and Trinity rivers.

This species is very rare in Europe, the only specimen which I have seen being a tree at Kew, about 15 ft. high, which was obtained from Sargent in 1870. The twigs die off annually; and evidently this species is unsuitable to our climate, and can only be grown as a botanical curiosity in favoured districts in the south of England. (A. H.)

ULMUS PUMILA

Ulmus pumila, Linnæus,¹ *Sp. Pl.* 226 (1753); Trautvetter, in Maximowicz, *Prim. Fl. Amur.* 248 (1859); Planchon, in De Candolle, *Prod.* xvii. 159 (1873); Franchet, *Pl. David.* i. 268 (1884).

Ulmus pumila, var. *transbaicalensis*, Pallas, *Fl. Ross.* i. 77, t. 48, A, B, C, and e (1784).

Ulmus humilis, Gmelin, *Fl. Sibir.* iii. 105 (1768).

Ulmus microphylla, Persoon, *Syn.* i. 291 (1805).

Ulmus campestris, var. *parvifolia*, Loudon, *Arb. et Frut. Brit.* iii. 1377 (1838) (not *U. parvifolia*, Jacquin).

Ulmus campestris, var. *pumila*, Ledebour, *Fl. Ross.* iii. 647 (1851); Maximowicz, in *Mél. Biol.* ix. 23 (1872).

A tree attaining 50 ft. in height in Eastern Asia, but often shrubby. Bark furrowed and scaly, as in *U. nitens*. Young branchlets slender, clothed with a dense short white pubescence, persistent more or less on the second year's branchlets, which are fissured and finely striate. Buds minute, ovoid, pubescent. Leaves (Plate 411, Fig. 1) membranous and thin in texture, ovate to ovate-lanceolate, about 1 to 1½ in. long, and ½ to ¾ in. broad; acute or shortly acuminate at the apex; nearly equal, occasionally subcordate, at the base; upper surface dark green, glabrous or scabrous and minutely pubescent; lower surface lighter green, with a scattered minute pubescence, often conspicuous on the midrib, and with minute often obsolete axil-tufts at the junctions of the midrib and nerves; nerves about ten pairs, often forked; margin simply and regularly serrate; petiole ⅙ to ⅛ in. long, pubescent.

Flowers five to six in a fascicle, appearing in spring, on very short pedicels; tetramerous or pentamerous. Samara orbicular, about ⅞ in. in diameter, glabrous, non-ciliate, with a deep notch at the apex, usually closed by the overlapping incurved stigmas; seed in the centre of the samara, with its apex close to the base of the notch.

VARIETIES

1. Var. *pinnato-ramosa*, Henry.

Ulmus pinnato-ramosa, Dieck, ex Späth, *Cat.* No. 95, p. 113 (1895), and Dieck, *Verk. Verzeich. Zöschen*, 1897, p. 20; Koehne, in Fedde, *Rep.* viii. 74 (1910) and in *Mitt. Deut. Dend. Ges.* 1910, p. 92.

Ulmus turkestanica, Regel, in Dieck, *Hauptkat. Baumeschul. Zöschen*, 1883, p. 36, and in *Gartenflora*, xxxiii. 28 (1884).

A tree of straggling habit, giving off remarkably long shoots, 2 to 3 ft. in length; leaves (Plate 411, Fig. 6) ovate-lanceolate, acuminate.

This elm, which is said to have been introduced by Dieck from western Siberia,

¹ Linnæus founded his species on *U. humilis*, Gmelin, in Ammanus, *Stirp. Ruth.* 180 (1739), and on *U. pumila*, Plukenet, *Alm.* 393 (1696), the latter being described as an elm in Siberia with small leaves. Litwinow, in *Schede Herb. Fl. Ross.* vi. 166 (1908), states that the specimen of *U. humilis*, Gmelin, in the St. Petersburg Herbarium, is *U. pumila*. He has also verified at St. Petersburg the type specimens of *U. pumila*, var. *transbaicalensis*, Pallas, and of *U. microphylla*, Persoon.

appears to differ little from *U. pumila*, and is identical with specimens¹ collected lately in Turkestan by Mr. M. P. Price. It was raised both by Späth and by Von Sivers from seed sent from Turkestan; and produces flowers at Berlin in the middle of April, ripening its fruit in the end of May. Three trees at Kew, labelled *U. pinnato-ramosa*, which were obtained from Späth in 1900, are now about 25 ft. high, and are very vigorous in growth. A small tree named *U. turkestanica*, obtained from the Arnold Arboretum in 1907, is identical with those labelled *U. pinnato-ramosa*.

2. *Ulmus arbuscula*, Wolf, in *Mitt. Deut. Dend. Ges.* 1910, p. 286, was raised in 1902 from seeds gathered from a large tree of *U. montana* in the St. Petersburg Botanic Garden. It bears leaves 1 to 3 in. long, and is supposed to be a hybrid between *U. montana* and *U. pumila*. I have seen no specimens of this tree.

3. *Ulmus Koopmannii*, Lauche, ex Späth, *Cat.* No. 62, pp. 6 and 101 (1885-1886). This is a form of *U. pumila* with small ovate leaves, 1 to 1¼ in. in length. It is represented at Kew by a poor tree, about 15 ft. high, which was obtained from Transon in 1896. Lauche, *Deutsche Dendrologie*, 349 (1883), states that Koopmann sent seeds of the small-leaved elm from Margilan in Turkestan to the Berlin Botanic Garden, where this variety is represented by a tree with a dense oval crown of foliage like *U. nitens*, var. *umbraculifera* in habit; and the same form is now sold by Späth. Koopmann informed Ascherson and Graebner² that this elm is frequently planted in cemeteries in Turkestan, where it is often of great size.

DISTRIBUTION

U. pumila, which was described by Pallas from shrubby specimens gathered in Dahuria, appears to be widely distributed in eastern Siberia, Manchuria, and northern Korea, where, according to Komarov,³ it attains 50 ft. in height, and usually grows solitary in river valleys on stony or sandy ground. Bretschneider⁴ states that it is the common elm in the Peking plain, where it grows very rapidly, forming a stately tall tree. It is much valued by the Chinese for its timber, which is used in making carts. A nourishing white meal, containing mucilage, is obtained from the thick inner bark, and is used as food by the people in the mountains. The use of this meal is ancient in China. *U. pumila* also occurs in Turkestan and in western Tibet, where Thomson collected specimens⁵ at Nubra at 10,000 feet elevation.

U. pumila, though mentioned by Loudon, does not seem to have been introduced in his time; and the only specimens which I have seen are at Kew. One of these, labelled *U. pekinensis*, was obtained from the Arnold Arboretum in 1908. Purdom also sent this species from north China to Messrs. Veitch in 1910.

(A. H.)

I received from Peking in 1908 a section of a branch of this tree about 2 in. in diameter, as that of a poplar, but on potting it leaves were produced; and I have

¹ It also agrees with specimens in the Kew Herbarium, labelled *U. campestris*, var. *pumila*, Ledebour, which were collected by Regel in Turkestan in 1878.

² *Syn. Mitteleurop. Flora*, iv. 557 (1191).

³ *Flora Manchuria*, ii. 88 (1903).

⁴ *Bot. Sinic.* ii. 128 (1892).

⁵ Identified with *U. parvifolia*, Jacquin, by Hooker, *Flora British India*, v. 481 (1888).

now two healthy trees about 5 ft. high, which are quite hardy, and seem to grow well at Colesborne. I have rarely heard of an elm being struck from cuttings.¹

(H. J. E.)

ULMUS PARVIFOLIA

Ulmus parvifolia, Jacquin, *Hort. Schoenbr.* iii. 6, t. 262 (1798); Maximowicz, in *Mél. Biol.* ix. 25 (1872); Franchet et Savatier, *Enum. Pl. Jap.* i. 431 (1875); Forbes and Hemsley, in *Journ. Linn. Soc. (Bot.)* xxvi. 448 (1894); Shirasawa, *Icon. Ess. Forest. Japon.* i. text 68, t. 37, figs. 1-9 (1900).

Ulmus chinensis, Persoon, *Syn.* i. 291 (1805).

Ulmus virgata, Roxburgh, *Fl. Ind.* ii. 67 (1832).

Ulmus campestris, var. *chinensis*, Loudon, *Arb. et Frut. Brit.* iii. 1377 (1838).

Planera parvifolia, Sweet, *Hort. Brit.* 464 (1830).

Microptelea parvifolia, Spach, in *Ann. Sci. Nat.* xv. 359 (1841).

A tree, attaining in China and Japan about 40 ft. in height and 4 ft. in girth. Bark scaling off in small plates, showing the reddish brown cortex beneath. Young branchlets slender, sparingly covered with a short wavy white pubescence, retained more or less on the branchlets of the second year, which are fissured, but not finely striate; on older branchlets corky ridges are not produced. Buds minute, ovoid, pubescent. Leaves (Plate 411, Fig. 5) sub-evergreen, persisting till December or January, ovate- or obovate-lanceolate, thick in texture, 1 to 1½ in. long, ½ to ¾ in. broad, acute at the apex, nearly equal at the base; upper surface dark green, shining, glabrous, smooth to the touch; lower surface lighter green, glabrous except for axil-tufts at the junctions of the midrib with the basal nerves; nerves ten to twelve pairs, usually forked; margin crenately and simply serrate, non-ciliate; petiole, ⅓ to ½ in. pubescent.

Flowers appearing in autumn, in clusters of two to five in the axils of the leaves, on very short pedicels, tetramerous; calyx deeply cleft into four segments; ovary minutely pubescent; stigmas white. Fruit ovate to almost orbicular, about ⅓ in. long, shortly cleft at the apex with convergent densely pubescent stigmas; surface minutely pubescent; seed in the centre of the samara.

U. parvifolia is a native² of China, Tongking,³ Formosa,⁴ and Japan. In Japan, it is confined to the southern parts of Hondo, Skikoku, and Kiusiu, where it is usually a small tree, often only 15 to 20 ft. in height.

In China, it is known as *lang-yii*, and is widely spread throughout the provinces of the Yangtze valley, and southwards, extending to Tongking. The wood is hard, heavy, and tough, but difficult to cleave, and seldom large enough for planking.

U. parvifolia is said to have been introduced into France in the reign of Louis

¹ In *Gard. Chron.* xxxix. 35, fig. 20 (1906), a case is illustrated of elm posts, put in the ground for a pergola, which took root and produced abundant foliage at Redworth, Totnes.

² The western Tibetan specimens referred to this species by Hooker, *Flora British India*, v. 481 (1888), are all barren branches, and appear to be *U. pumila*. Mayr, *Fremdländ. Wald- u. Parkbäume*, 524 (1906), confuses *U. parvifolia* and *U. pumila*, stating erroneously that the former is a native of the cold regions of Manchuria and North China.

³ A specimen in the Kew Herbarium was collected by Balansa in the mountains of Tongking at 2700 feet altitude.

⁴ Collected by me at Bankinsing.

XV. by Abbé Gallois, who supposed it to be the tea-plant, and for a long time it was known as "thé de l'Abbé Gallois."

It appears to have been introduced into England by Mr. James Main¹ in 1794, who brought home some plants from China, which were cultivated in a garden at Hackney. It is, however, very rare in cultivation, though it seems to be perfectly hardy, and is very ornamental, retaining its foliage in England usually till late in December or early in January. A tree² at Kew, about 35 ft. high and 3 ft. in girth, died in 1912; it used to produce flowers occasionally in November, but never set fruit. Another at Beauport, Sussex, grafted on the common elm, was 40 ft. by 3 ft. 8 in. in 1911. There is also a tree at Enys, in Cornwall, about 20 ft. high.

At Verrières,³ near Paris, its growth is rapid, a specimen only twelve years old being 25 ft. in height in 1906. This produces flowers and fruit, but the latter is usually destroyed by frost. There are also good specimens at Segrez and Grignon. A fine tree in the Jardin des Plantes at Paris, about 45 ft. high and 3½ ft. in girth, was just about to open its flowers on 5th September 1902. This tree is remarkable for its large leaves, up to 3 in. long and 1¼ in. wide; and possibly constitutes a distinct variety, which I have not been able to match exactly with any native specimens in herbaria. The finest specimen in Italy is probably one on Isola Bella in Lake Maggiore, which produces good fruit, and measured in 1909 about 40 ft. by 2½ ft.

The largest and finest specimen in the United States is growing in Central Park, New York, near the 72nd Street entrance from Fifth Avenue. It was introduced in 1865 by Thomas Hogg.⁴ (A. H.)

¹ Main was sent as a collector to China in 1791-1794 by Mr. Gilbert Slater of Low Layton, Essex, noted for its extensive gardens and rare plants. Bretschneider, *Hist. Europ. Bot. Disc. China*, 214 (1898), refers to Slater's introductions; but omits all mention of Main. The latter gives an interesting account of his voyage in *The Horticultural Register*, v. 62 (1836).

² The tree at Kew was figured under the erroneous name of *U. pumila* in *The Garden*, February 20, 1904, p. 133. This tree suffered from the disease known as "slime-flux," the trunk exuding a sweet sap, which attracted a large number of wasps during the summer and autumn of 1911. Mr. Bean in *Nature*, vol. lxxxvii. p. 516 (1911), states that this affection is probably due to a yeast, which finds its way to the cambium layer, by means of a wound, and there sets up decomposition of the cells, forming sugary products, which exude from the trunk in solution, and partly ferment into alcohol. Cf. also *Gard. Chron.* l. 323 (1911). Fraser, in *Gard. Chron.* xlix. 59 (1911), also alludes to exudation of sap from elm trees, which may continue for many years, causing the bark to become perfectly white, owing to the death of the green alga, which usually lives upon it.

⁴ *Garden and Forest*, i. 231, 312 (1888).

KOELREUTERIA

Koelreuteria, Laxmann, in *Nov. Comm. Acad. Petrop.* xvi. 561, t. 18 (1772); Bentham et Hooker, *Gen. Pl.* i. 396 (1862).

DECIDUOUS trees and shrubs belonging to the order Sapindaceæ. Branchlets, with numerous lenticels, showing in winter elevated leaf-scars, marked in the centre with numerous dots, and girt with a projecting rim-like margin. Buds all axillary, no true terminal bud being developed, each covered externally by two opposite scales, which are united at first by their apices, but ultimately gape apart, exposing the villous interior of the bud. Leaves alternate, without stipules, either unequally and simply pinnate or equally bipinnate; leaflets opposite, sub-opposite, or alternate, with lobed, toothed, or serrate margins.

Flowers polygamous, irregular, in large terminal panicles. Calyx deeply divided into five unequal lobes. Petals five, yellow, unequal, each with a bifid gland on the base of the lamina, above the woolly claw. Disc oblique, with three to five lobes alternating with the petals. Stamens five to eight, inserted within the disc, exerted, declinate; filaments woolly. Ovary three-angled, pubescent, with an elongated style and a trifid stigma, three-celled, each cell containing two ovules. Fruit, an inflated capsule, membranous, three-winged, splitting loculicidally into three valves. Seeds, two or three in each capsule, usually only one developing on the centre of the septum in the middle of each valve, subglobose, blackish, without an aril; embryo spirally convolute.

Four species are known, natives of China and Formosa, distinguishable as follows:—

I. *Leaves simply pinnate with an odd number of leaflets.*

1. *Koelreuteria minor*, Hemsley, in Hooker, *Icon. Plant.* t. 2642 (1900).

Leaflets, fifteen to twenty-five, small, not exceeding $1\frac{1}{2}$ in. long and $\frac{1}{2}$ in. broad, crenate. Capsule, with orbicular valves, $\frac{3}{4}$ in. in breadth; seed $\frac{1}{8}$ in. in diameter.

This is a rare shrub, which was discovered on the Lienchow river in Kwangtung, China, by Ford in 1887. It has not been introduced, and probably would not be hardy in England.

2. *Koelreuteria paniculata*, Laxmann. See p. 1932.

Leaflets, nine to thirteen, $1\frac{1}{2}$ to 3 in. long, toothed or lobed in margin; occasionally some of the leaflets are so deeply cut that the lobes are distinct, making the leaf incompletely bipinnate. Capsule, with ovate acuminate valves, $1\frac{1}{2}$ in. long, and $\frac{3}{4}$ in. wide; seed $\frac{1}{4}$ in. in diameter.

II. *Leaves bipinnate, with an even number of pinnae, which bear an even or odd number of leaflets.*

3. *Koelreuteria Henryi*, Dümmer, in *Gard. Chron.* lii. 148 (1912).

Leaflets alternate, five to eleven, 3 in. long, glabrous except for axil-tufts beneath, serrate. Branchlets glabrous. Capsule with broadly oval or orbicular valves, about $1\frac{1}{4}$ in. across; seed $\frac{1}{5}$ in. in diameter.

This is a tree, attaining about 50 ft. in height, which was discovered by me in 1894, near Bankinsing in the mountains of central Formosa. It has not yet been introduced, but might possibly be hardy in the milder parts of England and Ireland.

4. *Koelreuteria bipinnata*, Franchet, in *Bull. Soc. Bot. France*, xxxiii. 463 (1886), in *Rev. Hort.* lx. 393, fig. 93 (1888), and *Pl. Delav.* 143, pl. 29, 30 (1889).

Leaflets opposite, sub-opposite, or alternate, nine to thirteen, 3 in. long, pubescent on the midrib and veins, serrate. Branchlets pubescent. Capsule with oval or elliptic valves, rounded at the apex, about $2\frac{1}{2}$ in. long and $1\frac{1}{2}$ to 2 in. broad; seed $\frac{1}{4}$ in. in diameter.

This is a tree, attaining 90 ft. in height in mountain woods in central and south-western China. It was discovered in 1887 by Delavay near Tapintze, north-east of Tali in Yunnan, at 6000 ft. elevation. It was subsequently found by me near Mengtse in the same province, and in the hills north of Ichang in Hupeh. Faber collected it in the mountains near Ningpo in Chekiang.

In 1887 Delavay sent home seed, which germinated freely in the Jardin des Plantes at Paris. One of the seedlings, which has been in the Temperate House at Kew since 1889, is now about 40 ft. high, but has not as yet borne flowers. This species has not apparently been tried in the open air in this country, but is likely to prove hardy in mild districts like Cornwall. It is rare¹ on the Continent, but is reported to be growing at Les Barres² and at the Villa Thuret, Antibes.³ (A. H.)

¹ Simon-Louis, *Cat.* 1908, p. 44, mentions it as very tender to frost at Metz.

² *Frut. Vilmorin.* 42 (1904).

³ Pardé, in *Bull. Soc. Dend. France*, 1911, p. 259.

KOELREUTERIA PANICULATA

Koelreuteria paniculata, Laxmann, in *Nov. Comm. Acad. Petrop.* xvi. 561, t. 18 (1772); Loudon, *Arb. et Frut. Brit.* i. 475 (1838); Hemsley, in *Journ. Linn. Soc. (Bot.)* xxiii. 138 (1886); Masters, in *Gard. Chron.* ii. 563, fig. 111 (1887); Mottet, in *Rev. Hort.* lxxviii. 466, fig. 181 (1906).

Koelreuteria paullinoides, L'Héritier, *Sert. Angl.* 18, t. 19 (1788).

Koelreuteria chinensis, Hoffmannsegg, *Verz. Pfl.* 70 (1824).

Sapindus chinensis, Linnæus, *Syst. Veg.* 315 (1774).

Sapindus sinensis, Gmelin, *Syst. Veg.* 642 (1796).

A tree attaining about 60 ft. in height and 6 ft. in girth. Bark¹ smooth at first, becoming scaly on old trunks. Branchlets glabrous. Buds ovoid, about $\frac{3}{8}$ in. long; outer scales two, glabrous without, villous within, gaping apart in winter; leaf-scars triangular to semi-orbicular, elevated on projecting pulvini. Leaves unequally pinnate, 6 to 12 in. long; rachis pubescent on the upper side; leaflets nine to thirteen, opposite or sub-opposite, ovate, $1\frac{1}{2}$ to 3 in. long, sub-sessile; variously toothed or lobed, the basal lobes occasionally separated by sinuses extending to the midrib; both surfaces slightly pubescent on the midrib and veins.

Panicles terminal, large, 6 to 9 in. long, with pubescence slight on the principal and secondary axes, and dense on the pedicels and calyx; flowers numerous, yellow, clustered in threes, about $\frac{1}{4}$ in. wide. Fruiting capsules, ripe in autumn, with ovate valves, which are acuminate at the apex, and about 2 to $2\frac{1}{2}$ in. long and $1\frac{1}{4}$ in. wide. Seeds globose or slightly pyriform, about $\frac{1}{4}$ in. in diameter, blackish, shining, only two or three maturing in each capsule. Seedling² with two strap-shaped cotyledons raised above ground, followed on the stem by alternate primary leaves, which have three irregularly toothed or lobed leaflets.

VARIETIES

The large deeply cut leaflets,³ borne by some trees, are probably associated with vigorous growth due to soil and similar conditions, and scarcely indicate a distinct variety.

A specimen branch with variegated leaves, which does not seem to have been propagated, was sent to Kew in 1885 by Major Alcock Beck from Eastwaite Lodge, Hawkside, Ambleside.

DISTRIBUTION

K. paniculata is a native of northern China, where it is common in the hills around Peking; and has also been found in the mountains of Shensi, Kansu, and

¹ Schneider, *Dend. Winterstud.* 40, fig. 47 (1903), depicts the scaly bark on an old stem.

² Cf. Kerner, *Nat. Hist. Plants*, Eng. trans. i. 9, fig. 1 (1898).

³ Wyman, in Bailey, *Cycl. Amer. Hort.* ii. 861 (1900), mentions under the name *K. japonica*, Siebold, a form with deeply cut leaflets. Beissner, in *Mitt. Deut. Dend. Ges.* 1898, p. 424, refers to *K. japonica*, a shrub with a "bipinnate leaf, pubescent beneath," growing in the nursery at Plantières, near Metz, but this is not recognised as a distinct variety in the catalogue of Simon-Louis. Cf. also *Hortus Vilmorin.* 338 (1906).

western Szechwan. It was known by the Chinese as the *luan* tree in classical times, when it was planted around the graves of Ministers of State; but is now called *mu-lan-tze* at Peking, where the leaves are used as a black dye and the seeds as beads.¹ It is not recognised by Japanese botanists as a native of Japan,² where it was introduced at an early period by the Buddhist monks, but it is frequently cultivated and occasionally naturalised³ in Hondo.

It was cultivated under glass at St. Petersburg in 1752, and was probably raised from seed sent to Paris about 1747-1751 from Peking by D'Incarville, who introduced about this time other trees from North China, like *Sophora japonica* and *Ailanthus glandulosa*.⁴ *K. paniculata* is said⁵ to have been introduced into England by the Earl of Coventry in 1763. It is perfectly hardy, forming a small ornamental tree, which produces abundant panicles of yellow flowers about midsummer. The leaves, which are elegant in form, often turn a beautiful crimson colour in autumn. It is easily propagated by seeds, by layers in autumn, by cuttings of young branches in spring, or by root-cuttings.

The finest specimen in England is probably one in Waterer's nursery at Knaphill, Woking, which was 40 ft. high by 6 ft. in girth in 1911. Elwes saw a fine tree⁶ at the east corner of the upper north terrace of Windsor Castle in July 1912, when it was covered with a rich crop of flowers. This measured about 40 ft. by $5\frac{1}{2}$ ft. It ripens seeds at Bitton, near Bath, which come up naturally.

In France⁷ it reproduces itself naturally by seed in the neighbourhood of Montpellier; and there is a fine specimen at Verrières, which is considered by Mottet⁸ to be one of the original seedlings, dating perhaps from 1751. In 1906, it measured 62 ft. high and 6 ft. 11 in. in girth, with a spread of branches about 60 ft. in diameter. It produces fruit freely every year. M. Hickel tells me that there is a large tree at Heidelberg; but it does not seem to be hardy⁹ in other parts of Germany where the winter is very severe, as in Silesia. In the United States¹⁰ it is perfectly hardy as far north as Massachusetts, but is liable after a hard winter to have single limbs die back to the trunk. The seeds readily germinate where they fall to the ground, so that in some places in North America it is becoming naturalised. (A. H.)

¹ Bretschneider, *Bot. Sinic.* ii. 381 (1892), and iii. 491 (1895), and *Hist. Europ. Bot. Disc. China*, i. 159, ii. 850 (1898).

² *K. japonica*, Hasskarl, *Cat. Pl. Hort. Bog. Alt.* 226 (1844), was a name given to a shrub of *K. paniculata* that was introduced from Japan into Java.

³ Franchet and Savatier, *En. Pl. Jap.* i. 85 (1875), record a specimen as wild in a wood in Hondo, which was undoubtedly naturalised.

⁴ Cf. vol. i. p. 32. A tree of *Ailanthus glandulosa* in the garden of the Master of Trinity College, Cambridge, is said to have come as a seedling from London in 1758, and is undoubtedly one of the original trees raised from seed sent by D'Incarville in 1751. The old *Sophora japonica* tree (vol. i. p. 42) at Cambridge in all probability dates from the same year.

⁵ Aiton, *Hort. Kew.* ii. 7 (1789).

⁶ A branch with fruit of a tree at Windsor is figured in *Gard. Chron.* ii. 563, fig. 111 (1887).

⁷ Pardé, in *Bull. Soc. Dend. France*, 1909, pp. 103, 114.

⁸ *Rev. Hort.* lxxviii. 466, fig. 181 (1906).

⁹ *Mitt. Deut. Dend. Ges.* 1903, p. 8. A fine specimen, growing in the Royal Garden at Friedrichshafen on the Lake of Constance, is figured in *Mitt. Deut. Dend. Ges.*, 1912, p. 310.

FASTIGIATE BEECH

WE are indebted to Mr. F. R. S. Balfour for the picture of a very remarkable beech which he showed me in 1908, growing close to Dawyck House, Peeblesshire. So far as we know, the habit of this tree is unique; though, according to Koch,¹ a fastigiata beech formerly existed in the nursery of Simon-Louis at Metz. The tree at Dawyck was 48 ft. by 4 ft. 2 in. in 1912; and is supposed by Mr. Balfour to be about forty years old, but to my eye it is much older. It has lately been described and illustrated by H. A. Hesse² of Weener, Hanover, under the name *Fagus silvatica Dawycki*. Young plants have been propagated by layering and by grafting, and two of these are growing well at Colesborne.

¹ *Dendrologie*, ii. pt. ii. 17 (1873). Simon-Louis, who called this form var. *fastigiata*, do not advertise it now in their catalogues. Var. *pyramidalis*, Petzold and Kirchner, *Arb. Mus.* 662 (1864), described as being pyramidal in habit, is unknown to us.

² In *Mitt. Deut. Dend. Ges.* 1912, p. 366.

POSTSCRIPT

BY

HENRY JOHN ELWES, F.R.S.

AND

AUGUSTINE HENRY, M.A.

In the Introduction to the first volume of this work, published in 1906, we stated the objects which we had in view, and which, during the seven years which have now elapsed, we have endeavoured to carry out to the best of our power. If the patience of our Subscribers has been unduly taxed, we can only say that the magnitude of the task which we set before us was even then hardly realised; and that the difficulty of discovering, identifying, describing, and figuring the rare and remarkable trees in Great Britain is one which grew with our knowledge, and with each succeeding volume. The want of order in this work, on which some of our reviewers have remarked, has been really of the greatest service; for by leaving the more difficult and little-known genera to the last, we have been able to make the work more complete and accurate than it would have been if every genus had been taken in its accepted botanical sequence; and though a few additions may be made to the earlier volumes, we know of no really important omissions in them.

Though some local botanists and arboriculturists have studied the native trees of their own counties with more or less care, British botanists, until recently, have taken little notice of the trees which form so conspicuous a feature in the vegetation and scenery of England; and in many counties, whose flora, birds, and insects have been most carefully and accurately studied by local naturalists, we have found no one who, apparently, knew or cared for the trees, and have had to depend largely on our own observations.

An immense quantity of foreign as well as British literature has been referred to, as evidenced by almost every page of the work; but a general bibliography seems unnecessary, as the references are fully given; as well as the authority for nearly every fact, opinion, or observation not made by ourselves.

As it is possible that in the future, questions may arise as to the correct nomenclature of some of the numerous trees that we have described and figured, it is well to say that the herbarium accumulated by us in the course of our work is preserved at Cambridge and at Kew, so that the actual specimens from which

the descriptions and identifications were made can be referred to in case of doubt.

It is impossible to acknowledge in full detail the help that we have received from landowners and their agents, foresters, gardeners, and friends in all parts of Great Britain which we have visited during the course of the work; but we have felt on many occasions that without this help the work would have been impossible.

Amongst those to whom we are most indebted for help, I must especially mention the following:—

Sir William T. Thiselton-Dyer, F.R.S., who has carefully read the proofs of all the volumes except the first, and whose suggestions and advice we have followed in many difficult questions; Mr. Charles Palmer of Stewkley Grange and Manchester, who has also read the proofs with extraordinary care; the Director and staff of the Royal Gardens at Kew, who from first to last have shown a personal interest in our work which has been of the greatest support and assistance. We must here call attention to the fact that the collection of living trees at Kew is, and we hope always will be, so far as its soil and climate will allow, the most complete, correctly named, and well-cared-for in Europe; while its unrivalled library and herbarium, where much of our work has been prepared, and the references checked, have been indispensable in connection with the living specimens.

The staff of the Botanical Department of the British Museum of Natural History, as well as the Directors of the Botanical Gardens at Edinburgh, Glasnevin, Oxford, and Cambridge have afforded us every facility for studying both the trees and herbaria in their charge, and we gratefully acknowledge their assistance.

In the United States we have received much help from the officials of the National Bureau of Forestry, and from many private individuals, amongst whom I must mention Prof. Elrod of the Montana University, Mr. Gifford Pinchot, the late Chief Forester of the United States, and especially Mr. Charles S. Sargent of the Arnold Arboretum, who has given us much valuable information and help on many occasions.

In Canada Messrs. J. M. and W. T. Macoun of Ottawa have been on many occasions most helpful and obliging.

In France we have to thank numerous friends for shewing us many of the finest trees and forests in all parts of the country; amongst them we are especially grateful to MM. Maurice and Philippe de Vilmorin of Paris, Prof. Flahault of Montpellier, M. Leon Pardé, Inspecteur des Eaux et Forêts of Beauvais, M. Hickel of Versailles, M. Guinier of Nancy, M. Jouin of Plantières near Metz, and Mr. Cecil Hanbury of La Mortola in Italy.

In Holland Mr. L. A. Springer of Haarlem, in Belgium Prof. Bommer of Brussels, M. Huberty, Inspector of Forests, Verviers, and the late Baron de Selys-Longchamps, in Germany the late Herr Späth of Berlin and the late Prof. Blasius of Brunswick, and the Directors of the Botanic Gardens we have visited in Germany, Russia, Italy, Sweden, Norway, Spain and Portugal, Bulgaria, and Servia, have all given us most valuable notes and assistance.

In Denmark we have also received much help and information from Forest Inspectors Mundt and Bramsen, who personally conducted us through many interesting forests and private arboreta.

In Japan I have on two occasions received unusual attention and assistance in visiting the most interesting forests, and in procuring good photographs of the trees, for which I shall be ever grateful both to the past and present Ministers of Agriculture, and especially to Dr. H. Shirasawa of Tokyo, and numerous other officials and friends.

Amongst the English landowners, who have afforded us the greatest assistance and kindness on all occasions, I must specially mention His late Majesty King Edward, to whom our work is dedicated, and whose fine trees at Windsor, Sandringham, Balmoral, and Osborne have been frequently mentioned in our pages. The Earl of Ducie, who during a long life has had the pleasure of seeing many rare trees planted by himself come to maturity, and who, perhaps better than any English landowner, has realised the importance of attending to his trees after they were planted. The late Sir Charles Strickland, who often told me that the pleasure of watching the growth of trees which he had himself raised and planted, was the one interest in life which remains undiminished in extreme old age. Sir Hugh Beevor, who has inherited a taste for arboriculture and forestry, and on many occasions has contributed most valuable notes and measurements of remarkable trees in many places. The Dukes of Argyll, Bedford, Northumberland, Portland, Richmond, and Wellington. The Marquesses of Bath, Lansdowne, Ripon, and Waterford. The Earls of Annesley, Bathurst, Bradford, Brownlow, Cawdor, Coventry, Darnley, Fortescue, Ilchester, Leicester, Manvers, Pembroke, Portsmouth, Powis, Radnor, Selborne, Spencer, and Yarborough. The Viscounts Falmouth and Powerscourt. The Lords Bagot, Barrymore, Clinton, Dynevor, Kesteven, Llangattock, Lovat, Methuen, Northbourne, Peckover of Wisbech, Penrhyn, Rayleigh, Redesdale, Sackville, Scarsdale, Sherborne, and Walsingham. Sir C. T. D. Acland, Sir E. Stafford Howard, Sir George Holford, Sir E. Loder, Sir John Stirling Maxwell, Sir Herbert Maxwell, Sir Frederick Moore, Sir John Ross-of-Bladensburg. The Hon. Vicary Gibbs, Mr. H. Clinton Baker, Mr. R. Birkbeck, Mr. F. R. S. Balfour, Brodie of Brodie, Mrs. Baldwyn Childe, Capt. D. Cameron of Lochiel, Major Dent, Mr. W. Steuart Fotheringham, Major Lloyd, Col. Malcolm of Poltalloch, Mr. E. R. M. Pratt, Mr. C. Coltman Rogers, Dr. Herbert Watney, and Mr. R. Woodward, Jr.

For special information respecting the trees of Scotland we are indebted to Mr. John Renwick of Glasgow, and for notes on Irish trees to Mr. R. A. Phillips of Cork and Sir F. W. Moore.

The conditions which determine the successful cultivation of exotic trees in different parts of Great Britain are so complicated by local variations of soil, climate, and elevation that after many attempts I have failed to construct a map which would divide the country into arboricultural regions. The best guide to the possibility of growing any particular species in any given locality is to know

whether it has succeeded reasonably well in any place of similar soil and climate; and as we have recorded the accumulated experience of our predecessors, it may usually be presumed that if no degree of success has been attained it is only a waste of time and money to plant species which have died out or remained in a stunted condition. Generally speaking it may be said that there are four principal types of climate in Great Britain.

The first is characterised by a high summer and a low winter temperature, combined with a low average rainfall; and this includes all those districts in which wheat is the most important agricultural crop, namely the eastern counties as far north as the Humber, and the southern counties as far west as Dorset and the Severn Valley. In many parts of this region where, owing to the influence of sea air or elevation, late spring and early autumn frosts rarely occur, the best climatic conditions for the growth of most exotic trees are found.

Secondly, the south-western counties and the maritime districts of Wales, the greater part of Ireland and western Scotland, where the summer temperature is lower and the winters shorter and milder, and where the rainfall and the humidity of the air is much greater. In this region alone a great many of the rarer trees and shrubs thrive wherever suitable soil and shelter from wind are found; but the trees which require a high summer temperature and abundant sunshine to ripen their wood, such as walnuts, hickories, Catalpas, and many North American species, are not often successful, and do not attain large dimensions or ripen their seeds in normal seasons.

Thirdly, the north-eastern and midland counties and those districts of southern England where the summers are shorter, where late and early frosts are prevalent, or where the soil is too heavy or too wet to suit a great many exotic trees; but many exceptions will be found in this region, especially near the sea, and in this district may be included parts of Scotland bordering on the Moray Firth, where the climate is distinctly more suitable to arboriculture than in the northern and midland counties of England generally.

Fourthly, the mountains of central and northern England, Wales, Scotland, and Ireland, at elevations over 1000 feet, where only a few of the hardier conifers can be grown with much hope of success.

Next to climate, the geological formation and depth of the soil is the most important factor in the successful growth of trees; and this again is variable even in the districts where climate is favourable; so that we find the best instances of arboriculture are scattered in all parts of the country. Generally speaking, the soils which produce the finest hardwoods are on the old red sandstone and lower greensand formations; and though some species attain a large size on other soils, yet wherever heavy clay or thin rocky soils prevail, especially on limestone, many exotic trees will not grow at all, or become stunted and unhealthy as soon as their roots get into the subsoil. As a result of careful soil preparation trees may appear to thrive for a number of years, yet they eventually become sickly or die if nature has not provided a suitable subsoil. Want of knowledge or of attention to these two factors, has led in the past to immense waste of time and money in planting trees which are quite

unsuited to their surroundings, and we have seen numerous instances in all parts of Great Britain which prove how little man can do where nature does not favour his efforts.

Another point which has been insufficiently realised by most planters, but which my own experience has repeatedly proved, is the remarkable variation in the individual constitution of trees of the same species, even when raised from seeds of the same tree under precisely similar conditions. In a state of nature there is a continual struggle for existence among individuals under which only a few of the strongest survive, and these are the seed-bearers from which future generations arise; but when we sow a number of seeds under the most favourable conditions which we can devise, and protect them artificially in their youth against their natural enemies, or when we propagate trees by other means, which are often adopted not because they are the fittest but because they are the quickest and cheapest means of reproducing them, we obtain a variable percentage of weaklings which thrive only under the best conditions, and which when transplanted to less favourable environment are sure sooner or later to succumb. For this reason I have always advocated the raising of forest trees when possible from seed of known healthy parents growing in the same or a similar locality to that where they are to be planted, and rejecting in the nursery all but the most vigorous. This may prove a slower and more costly method than that of buying the trees from a nursery, but I believe it to be the most economical in the end wherever conditions are not very favourable for their growth. With regard to exotic trees which only ripen their seed in this climate in very favourable seasons, I have often found that the seedlings raised from imported seed are more vigorous than those raised from home-grown seed, but my observations, though they have been carried on since 1900, are insufficient to enable me to express a decided opinion on this subject.

When we consider how remarkably variable our climate is, it is clear that a great deal of the success of planting any trees which are more exacting as regards heat, sunshine, or moisture¹ than indigenous species, must depend on a good series of seasons in their youth; for if trees are severely checked by drought, or by late spring or early autumn frosts when young, they suffer much more than when older and better established. Therefore in planting exotic trees it is wise not to depend on one or two individuals, but to plant several of the same species in a group, with the object of selecting the most vigorous and well-shaped when they begin to crowd each other.

Another point which is often forgotten by planters of ornamental trees is the fact that in nature these grow gregariously or mixed with other trees, in more or less thick or shady woods, and not isolated in grass. To use a gardener's expression, "a well-furnished tree" such as a cedar, a Sequoia, or a beech with spreading branches resting on the ground, may be a very beautiful object on a lawn or in a park; but it is not the usual natural shape of these trees; and if the trunk is always

¹ As an instance I may say that at Colesborne the rainfall of June, July, and August, during which months most of the growth of the majority of trees is made, was, in 1911, 3.39 inches, with only 21 days on which rain fell, and in 1912, 22.30 inches, with only 21 days without rain.

sacrificed to the branches, we rarely get such magnificent boles as these trees are capable of producing when planted under more natural conditions.

Another point too often neglected by English arboriculturists is early and regular pruning, which, unless they are planted in close order, is necessary in the case of most broad-leaved and some coniferous trees, until they have attained a considerable size and age. Though the lower branches should not be cut off close to the trunk before it is thick enough to support a well-shaped crown, yet the earlier it is done after the tree has become established, the quicker and better is the wound healed; and the careful planter must continually watch that no branches are allowed to attain undue proportions at the expense of the trunk. With some trees pruning and shortening of large branches is best done in early spring before the sap rises; with others, in July or August, when the tree is in vigorous growth; but though art may do a great deal to form a well-shaped tree, yet unless the soil is deep enough and fertile enough to keep it in health, stunted and stag-headed trees will be the result.

The influence of grass on the roots of trees is a subject upon which a great deal of light has been thrown by the experiments carried on by the Duke of Bedford and Mr. Spencer Pickering.¹ Though opinions differ on the extent to which their conclusions apply to trees universally, and how far they are due to particular soils, yet there can be no doubt that as a general rule the soil should be kept free from grass for a distance of about three feet all round the trunk for some years at least. On the peculiar soil of Colesborne I have found that some trees, among which Scots and Corsican Pine are conspicuous, do not suffer when planted in a thick sward, and actually seem to grow faster and to be more healthy. I am inclined to believe that wherever the soil is deficient in fertility, grass over the roots of trees, though it may check their growth in dry seasons, is better in most cases than a bare soil which has been impoverished by cultivation. Good soil will overcome almost all other obstacles to the growth of trees, and this fact leads me to speak of another question which planters and foresters often insufficiently consider.

Is it more economical and profitable to plant land, which, like many of the natural woods and plantations in Great Britain, has been allowed to remain as woodland only because it was not thought good enough to cultivate; or to plant land which is producing more or less profitable crops? We rarely see the dimensions that trees are capable of attaining in Great Britain, except on the estates of families which for centuries have been rich enough to plant good land, and to leave trees standing after they have attained maturity; and though the largest trees are not always the most valuable, yet the highest quality of timber, which usually fetches a higher price per foot, is rarely produced on inferior land, whilst the quantity per acre that can be grown in a short time is the most important factor in the profit or loss of planting.

In forestry as in agriculture the best land is the most profitable and therefore the cheapest. But when I speak of good land I do not mean that the best land for farming is the best for trees, because trees root so much more deeply than agricultural plants that they can penetrate and feed where the roots of plants cannot reach; and on steep hill-sides especially, trees seem to thrive wherever the rock is suffi-

¹ *Thirteenth Report of the Woburn Experimental Fruit Farm*, London, 1911. See also *Ninth Report*, 1908.

ciently broken up, provided that it contains the chemical elements of fertility; so that the agricultural or grazing value of any particular spot often affords no indication of its value for tree-planting.

Though the world has now been nearly everywhere explored, and the number of trees capable of growing in Great Britain has been more than doubled by fresh introductions since Loudon wrote in 1838, it is very surprising how few, if any, of the newer introductions seem likely to supersede or even to equal our long-trying native and introduced trees. Though no one can be a stronger advocate than I am, both in principle and in practice, of the planting of a great variety of exotic trees, and though in localities where somewhat unusual conditions are found, some of these species—such as Japanese larch, Sitka spruce, Lawson and Nootka cypress, and Douglas fir—do seem likely to be more profitable than older introductions like the European larch, Silver and Spruce firs, yet I can hardly think of any broad-leaved tree, except some poplars which are not yet fully proved, and possibly the grey alder, which seems likely to have much economic value or to supersede our native oak, beech, ash, elm, and sycamore, which to timber merchants are at present the only trees really worth looking at, and which will grow to a large size in almost all parts of our islands. Whether time will prove this to be a fact or not, we have done our best to describe every tree as yet introduced, with the exception of some of the latest introductions from China.

When trees have passed the age of maturity and are beginning to decline in health they usually show it by the death of the upper branches, which is particularly noticeable on very heavy or very dry soils after a long hot summer. If there is no serious decay in the trunk, this decline may often be checked, for a considerable time at any rate, by a top-dressing of leaf-mould mixed with old rotten manure and fertile soil, spread about three inches deep over the area covered by the branches; but such dressing must not be too thick or too strong, especially in the case of conifers, for which pure leaf-mould is perhaps the best manure. When wounds caused by broken branches, fungi, or other injuries appear on the trunk, it is important to fill them as soon as possible. The same principles adopted in filling decayed teeth are perfectly applicable to trees, namely, to clear out all decayed wood as far as possible, to apply an antiseptic to the exposed surface, to fill up the cavity with cement, and to cover with lead any cracks or holes by which water can get into the trunk. When branches become dangerous or inclined to split off, they are often supported by iron rods, bands, and chains; and I believe that when this is done in such a way that the band can be loosened as the branch thickens, it is a safer and more permanent method than passing a rod through a hole in the branch and putting a nut on it to keep it in place.

There are many other special points in the cultivation of trees which only experience can teach, though the general principles are given in works on forestry and arboriculture; and in many cases these special points are dealt with in the pages of our work. Opinions vary and always will vary as to the best systems of planting, and the best mixture to adopt, which depend on the peculiar conditions we have to deal with; but in tree-planting, whether for economic or other objects, it cannot be

too strongly emphasised that a study of local conditions is always essential. The more a man knows of the risks and difficulties which planters have to contend with in most parts of the country, the less willing will he be to offer advice, or to form estimates of cost and expected profits based on experience which is not local. For this reason I look with suspicion on hastily considered working plans and estimates of costs and results which are not supported by local knowledge. Even in old-established forests abroad, where the expenses and profits are based on the experience of centuries, and where nothing is done without the approval of Government foresters, changes are constantly being made in practice to meet the changing conditions of the times; and when we remember that our long-established systems of woodcraft in England have been completely revolutionised in the last fifty years by changes in economic conditions, the duration of which cannot be foreseen, it seems evident that what we think right to-day may turn out to be wrong long before the trees we plant are mature.

Before concluding I should again like to offer a warning word on the question of planting and management for profit, as contrasted with planting for ornament, sport, and shelter. English landowners are sometimes reproached with ignorance and neglect of the principles of pure forestry; but it must always be remembered that the economic, social, and in many districts the climatic conditions of Great Britain, make planting for profit a very uncertain and often a very risky investment. In our work we have endeavoured to show the possibility of cultivating a great number of exotic trees which have not, and probably never will have, any economic value from the forester's point of view, because we believe that when planted in small quantities with sufficient knowledge of their cultural requirements, they will add greatly to the interest, beauty, and residential value of British country homes; and we have illustrated the finest examples of most of the trees which exist in Britain. We ought to aim as far as possible at planting those species which local experience has tested, in situations which are most suitable to them. This warning must apply not only to the rarer species, but to some which have been very extensively planted of late years by enthusiasts in arboriculture, who look only at the successes of others and refuse to look at the failures. I have myself learnt more from my failures than from my successes; and have never been able to understand why in so many cases people are unwilling to show or to write of their failures, when these are due—as they often are—to natural obstacles rather than to want of care or knowledge.

The future of arboriculture in Great Britain is a brilliant one, if landowners are not deterred from planting by ill-considered or hostile legislation; but the future of pure forestry—in England at least—is very problematical. For though there are districts where the land may—under State foresters working on a larger scale than private owners—produce a more profitable return under timber than when used for other purposes, yet I believe that these districts are so few and far between that the establishment of a State industry, financed by taxation, to compete with the long-established private industry of timber-growing would not be justified by any advantage that would result to the country.

(H. J. E.)

In concluding our work there are a few points about which I think it advisable to add some explanatory remarks. First, with regard to its scope, it was intended at the outset to include only those trees which attain timber size in the British Isles. It was found, however, impossible in practice to draw a rigid line between the timber trees and the smaller trees, which like shrubs are cultivated for ornament or curiosity. In the case of genera, which comprise both large and small trees as well as shrubs, our treatment has not been logically uniform. All the species of oak in cultivation have been described in detail, because in this genus shrubs are of exceptional occurrence. On the other hand, only the larger maples have been the subject of separate articles, as it was evident that a brief notice would suffice for the shrubby species. In the case of genera of exceptional interest, as *Pinus*, *Juniperus*, *Cephalotaxus*, all the introduced species, even those of small size, have been treated in full.

The keys for the identification of species are based upon the characters of the twigs, leaves, and buds, and not upon those of the flowers and fruits, as has been usual in botanical works. The latter characters are often not available in the case of trees, the determination of which may be required when they are in the young state, or at some period of the year when flowers and fruit are not present.

When the preparation of the seventh volume was drawing near a close, we saw that it would be impracticable, without unduly deferring the completion of the work, to include many of the new species that of late years have been introduced from China and Japan. On this account, *Eucommia*, *Tetracentron*, *Cercidiphyllum*, *Pistacia*, *Phellodendron*, *Idesia*, *Poliothyrsis*, *Davidia*, etc., have been necessarily omitted. For obvious reasons, I was unable to take up the complete study of such genera as *Cratægus*, which is almost exclusively composed either of shrubs or small trees that are merely ornamental in character; and I have limited my account in this case to a full description of the two indigenous species. Generally speaking, the Conifers have been described exhaustively in our book; but certain rare kinds of which there are only a few specimens of small size in Cornwall and in the mild districts of Ireland, have been left untouched, as *Podocarpus*, *Callitris*, *Tetraclinis*, *Widdringtonia*, *Dacrydium*, and *Phyllocladus*.

Though, as just explained, all the species of trees in cultivation in England, Scotland, Wales, and Ireland, are not included, yet a vast number have been described, as is evidenced by the Index, which extends over 80 pages. The Index has been compiled with great care, and should prove of service to our readers, as it embraces, in addition to the common names and the usually accepted scientific names, nearly all the appellations which have been applied to the various species and their varieties and sports in countless lists, catalogues, and books. The compilation of this synonymy has been a heavy labour and a thankless task. The choice of the correct name of each species has not been always easy.

As some of the reviews of the published volumes criticise certain names which I have adopted, it will be well for me to explain my views on the vexed question of nomenclature. That, in a work of this magnitude, I have refrained from the

invention of new names, except in one case for a species¹ and in two or three cases for hybrids,² gives me a claim to be heard on the subject. In the earlier volumes, I followed the Kew practice of the time, that of selecting as the correct name the oldest one, which had been used under the genus to which the species is now referred. In the latter volumes, I have followed, except in a few instances, the Vienna Rule, that of adopting the oldest specific name, no matter to what genus it had been attached. Most German and American botanists follow this rule "blindly," as one of them remarked to me.

As a result names which have been current for a century, not only in scientific books but in popular literature, have now to give way to supposed earlier names, which have been resuscitated from the works of writers whose descriptions are often so ambiguous as to render it impossible to say what species was actually meant. The strict application of the Vienna Rule is sometimes so difficult that the best authorities disagree thereon. As an example, we are bidden to change the name *Alnus glutinosa*, Gaertner, which has been used for the common alder for over a century in every botanical text-book and Flora. Certain botanists substitute for it the name *Alnus rotundifolia*, Miller, whilst one authority puts forth a strong claim for *Alnus vulgaris*, Hill.³ This displacement of a well-known scientific name by an obscure one is a pedantic and harmful practice. Its absurdity is shown by the fact that some recent writers, who adopt under all circumstances the Vienna Rule, are obliged, in order to specify clearly the species which they mean, to use two names, the second of which is the old-established name in brackets. The common oak is called by these writers⁴ "*Quercus Robur*, Linn. (*Q. pedunculata*)"; while the wych elm is cumbered⁵ with the appellation "*Ulmus glabra*, Huds. = *U. montana*." The confusion of the new practice is doubled, when the Vienna name for a species happens to be (as in the last case) the same as the old-established name for another species of the same genus. Thus, no one now knows without some explanation which species of elm is meant by the term *Ulmus glabra*.

In order to avoid such confusion, I have preserved in certain cases the old-established name, if its use involves no ambiguity. I have thus kept up *Larix europæa*, *Larix americana*, *Larix leptolepis*, *Abies pectinata*, *Quercus pedunculata*, *Betula pubescens*, *Betula verrucosa*, a series of names which have been consecrated by long usage in books on botany, arboriculture, and forestry. If I am wrong in using these names, I err in company with nearly all the writers who have mentioned these trees during the last century.

The postponement to the last volume of the more difficult genera has enabled me to devote time, labour, and travel to their study; and has resulted in a clearer knowledge of the numerous cultivated kinds of elms and poplars, the systematic position of which has been the despair of botanists. The results of the experimental sowings of the seeds of various elms, which I made in 1909, together with a study

¹ Cf. *Populus Maximoviczii*, vol. vii. 1838.

² Cf. *Populus Lloydii*, vol. vii. 1830, *Ulmus Mossii*, vol. vii. 1865, note 2.

³ Cf. Schneider, *Laubholzkunde*, ii. 890 (1912).

⁴ Cf. Schneider, *Laubholzkunde*, i. 197 (1904).

⁵ Cf. Tansley, *British Vegetation*, 148 (1911).

of the history of the Lucombe Oak and its descendants, have thrown much light on a class of trees, which though common in cultivation on account of their vigour of growth, are unknown in the wild state.

These trees undoubtedly originated as chance seedlings, due to accidental cross-fertilisation of two distinct species, and were immediately selected by observant nurserymen as desirable varieties to propagate. Trees like the Black Italian Poplar and the London Plane, which in botanical characters appear to be first crosses in each case, between an American and a European species, can be traced back to 1700, about which date the introduced species was long enough in the country to produce flowers and to fertilise the native species growing beside it.

Other trees, which I consider to be also first crosses, on account not only of their botanical characters but because they are unknown in the wild state, are:— the Common Lime, Huntingdon Elm, and Cricket-Bat Willow, the parents in their case being closely allied European species. All the preceding hybrids were produced accidentally; and similar cases occur periodically in certain nurseries, as at Plantières, near Metz, where two splendid hybrid poplars (*Populus Eugenei* and *P. robusta*) have been picked out of the seed-bed. The first to produce artificial crosses between forest trees was Klotzsch in 1845; and his experiments, though on a small scale, were successful in indicating that extra vigour of growth was obtainable with certainty.

Practically nothing, however, has been done, since his time, to improve the breeds of forest trees; and foresters have never even thought of the possibilities in this direction, though gardeners and farmers have shown the way for centuries. I suggested in a paper read on 7th April 1910 before the Linnean Society that artificial crossing should be tried in the Ash and Walnut, as the quality of the wood of these two valuable trees would be improved by more rapid growth.

During the past three years I have carried on cross-pollination of trees of certain kinds at Cambridge, in Kew Gardens, and near Exeter and Gloucester. These experiments have shown that there are obstacles in the way of obtaining successful results, owing to the difficulty of manipulation on trees swaying in the wind, and to the spring frosts which often injure the pollinated flowers. Moreover, suitable exotic trees, especially of the broad-leaved sorts, are hard to find, as those that exist rarely produce good flowers. I am convinced that such experiments could be carried on much more successfully in stations like Montpellier in France, or Washington in the United States, where suitable trees and a warm climate can be readily found. Nevertheless, I have raised a considerable number of hybrid seedlings, which are now under observation. First-crosses once obtained can readily be reproduced by cuttings or by layers; and the cost of propagation would be very moderate. That this is feasible, is shown by the splendid hybrid elms in Belgium and Holland, all of which are raised by layering in nurseries.

Many interesting problems, which had to be laid aside for the time, arose in the course of the researches which were undertaken in the work of preparation of the seven volumes. To some of these problems, especially those connected with the origin of sports and varieties, I hope to return. The belief is rapidly gaining

ground that all species of trees are comparable, in a greater or less degree, as regards their variation, to the remarkable instance of the Douglas Fir, the Rocky Mountain variety of which differs so much from that growing on the Pacific Coast, while between these two extremes lie a series of intermediate forms. Similar variation is well known in the case of *Pinus Laricio*, the geographical forms of which behave very differently in cultivation. Such differences probably exist in all species with a wide distribution; and in the future, care in the selection of seed may be the most important point in silviculture.

All the bibliographical references in the work have been checked independently, and no effort has been spared to indicate with accuracy the source of our information, where it is not the result of our own observations. Though in the course of our labours, we have had the benefit of mutual criticism, it should be clearly understood that each of us is only responsible for the parts which are signed by his initials. It would be inaccurate to quote both our names, when only one of us has verified the fact or studied the question at issue. As an example,—“Elwes, in Elwes and Henry, *Trees of Great Britain*, v. 1179,” is the correct citation for the account of *Cupressus lusitanica* in Portugal; whereas, “Henry, in Elwes and Henry, *Trees of Great Britain*, v. 1183,” is responsible for the article on *Cupressus arizonica*. It will readily be seen, that while the purely botanical part (including the identification of specimens) has been done by me, that the other part, dealing with distribution, history, and cultivation, has been divided in varying proportions between the two authors.

(A. H.)

ERRATA AND ADDENDA

- Vol. i. p. vii, line 15. The English Elm was not introduced from Italy. Cf. vol. vii. p. 1907.
- i. p. 2, line 32. For Dryander, in Ait. read Aiton.
The leaves of the North American beech are figured in vol. iii. Pl. 202, Fig. 6.
Rehder, in *Rhodora*, ix. 113 (1907), and in *Mitt. Deut. Dend. Ges.* 1907, p. 70, states that the correct name of the American beech is *Fagus grandifolia*, Ehrhart, *Beit.* iii. 22 (1788), and describes three varieties: (1) var. *typica*, Rehder; (2) var. *pubescens*, Fernald and Rehder; and (3) var. *caroliniana*, Fernald and Rehder, the latter having a sub-variety *mollis*.
- i. p. 2, line 39. For north read the north.
- i. p. 4, line 1. Add *Fagus Hohenackeriana*, Palibin, in *Bull. Herb. Boiss.* viii. 378 (1908), is probably a form with large leaves of *F. orientalis*, Lipski.
- i. p. 6, note 2, line 2. Omit the hazel, the cotyledons of which are not aerial. Cf. vol. iii. p. 521.
- i. p. 8, line 40. This is var. *Rohanii*, Masek, in *Mitt. Deut. Dend. Ges.* 1905, p. 196 and 1908, p. 140, described as a purple beech with deeply cut leaves like those of var. *quercoides*, from a tree of which it is said to have arisen through pollination by a purple beech that stood near.
- i. p. 10, line 21. The Weeping Beech at Endsleigh is figured in vol. ii. Pl. 58A.
- i. p. 13, line 31. For Lyons-le-Forêt read Lyons-la-Forêt.
- i. p. 17, line 42. For Buckholt read Buckhold.
- i. p. 29, line 13. For *Vilmoriana* read *Vilmoriniana*.
- i. p. 30, note 1. For 14 read 15.
- i. p. 31, note 1. Add vol. ii. Pl. 126, Fig. 3.
- i. p. 32, line 2. For *Japan* read *Japon*.
- i. p. 38. Concerning *Sophora japonica*, var. *pendula*—
Bretschneider, in *Journ. N. China Br. R. Asiat. Soc.* xv. 15 (1880), states: “The Chinese produce this tree artificially by causing two young trees of *Sophora japonica*, growing close together, to join by grafting, and then turning upwards the roots of one of them.” De Vries, *Mutation Theory*, 101 (1911), says, however, that the Weeping Sophora originated in Joly’s nursery at Paris in 1800.
- i. p. 38, note 1. This note is to be deleted, as the plate mentioned has not been published.

- Vol. i. p. 44. *Araucaria araucana*, Koch, is the correct name of the Chilean Araucaria, according to the Vienna Rules.
- i. p. 44, line 2. For iv. 2432 (1844) read iv. 2432 (1838).
- i. p. 44, line 4. For Rich. read Richard.
- i. p. 44, line 5. For Mirb. read Mirbel.
- i. p. 57, line 31. For develops read develop.
- i. p. 64, line 4. For var. ? *chinensis* read var. ? *chinense*.
- i. p. 65, line 2. For *tulipifera* read *Tulipifera*.
- i. p. 65, line 8. After leaves insert (Vol. iii. Pl. 204, Fig. 7).
- i. p. 66, line 30. After buds insert (Vol. ii. Pl. 126, Fig. 1).
- i. p. 76, line 33. Omit opening red.
- i. p. 76, line 37. Omit the buds open green, and
- i. p. 77, line 1. *Picea morindoides* is fully described under the correct name, *Picea spinulosa*, Henry, in vol. vi. p. 1392. Its native country is Sikkim and Bhutan.
- i. p. 80, line 37. For Serajevo read Sarajevo.
- i. pp. 85, 89. If, as is probable, both the Ajan spruce (*Picea ajanensis*) and the Hondo spruce (*Picea hondoensis*) constitute only one species, its correct name is *Picea jezoensis*, Carrière.
- i. p. 85, line 16, and i. p. 89, line 13. It is doubtful if the distinctions here noted, as regards the colour of the opening buds, are valid. In the specimens of *P. hondoensis* which I have examined, the buds open with a slightly reddish tinge.
- i. p. 88, line 10. For *tremula* read *Sieboldii*.
- i. p. 92, line 26. The specimens in the Kew Herbarium with pubescent branchlets, from the Columbia river, which are mentioned as a variety of *Picea sitchensis*, must be referred to *Picea Engelmanni*.
- i. p. 93, line 3. After 1892 insert xiv. 184.
- i. p. 99, line 6. For *Pruminopitys* read *Prumnopitys*.
- i. p. 100, line 32. *Taxus canadensis*, Marshall, is undoubtedly a distinct species, and is peculiar not only in its shrubby habit but in having monœcious flowers.
- i. p. 107, line 21. For 53 read 31.
- i. p. 107, line 22. For the Hokkaido read Hokkaido.
- i. p. 110, line 32. For 58 read 34.
- i. p. 111, lines 13, 14. For *Cesthuntsensis* read *Cheshuntsensis*.
- i. p. 114, line 18. After mentioned above add (p. 107).
- i. p. 117, line 24. For Low read Lowe.
- i. p. 117, line 32. R. J. Moss, in *Scient. Proc. R. Dublin Soc.* xii. 92 (1909), found 0.6 per cent of taxine in the leaves of the Irish yew (var. *fastigiata*) as compared with 0.12 per cent in the leaves of the female common yew and 0.18 per cent in those of the male common yew, recorded by Thorpe and Stubbs in *Journ. Chem. Soc. Trans.* 1902, p. 874. Moss refers to a case, in which pheasants, which are believed to eat common yew with impunity, were poisoned by the leaves of the Irish yew.
- i. p. 120, line 35. For 54, 55 read 32, 33.

- Vol. i. p. 122, line 22. For Low read Lowe.
- i. p. 123, line 9. For Whittinghame read Whittingehame.
- i. p. 132, line 34. The article on Distribution in China should be signed (A. H.).
- i. p. 139, line 1. For Hempsted read Hemsted.
- i. p. 139, line 28. For Worcestershire read Herefordshire.
- i. p. 142, line 17. The species of the sections *Aucuparia* are treated in detail in vol. vi. p. 1574.
- i. p. 142, line 25. For *Pyrus thianschanica*, Regel, read *Pyrus tianschanica*, Franchet.
- i. p. 142, line 30. For Torrey and Gray read De Candolle. See vol. vi. p. 1574.
- i. p. 142, line 32. *Pyrus sambucifolia*. Add the following note:—Cf. vol. vi. p. 1574, note 3.
- i. p. 144, line 32. For Linnæus read Ehrhart.
- i. p. 148, line 19. For Mountmorris read Mountnorris; for rector read late vicar.
- i. p. 148, line 23. For Lee's read Lees.
- i. p. 149, line 33. For Connaught read Albany.
- i. p. 149, line 34. For Snell read Smelt.
- i. p. 159, line 3. For 915 read 912.
- i. p. 175, line 26. For Seeman read Seemann.
- i. p. 177, last line. For *uniflora* read *aquatica* (cf. vol. iii. 513).
- i. p. 182, and note 1. *Thuja*, the spelling adopted by Linnæus, *Sp. Pl.* 1002 (1753), is to be preferred to that of *Thuya*.
- i. p. 184, line 8. For non A. Murray read not Balfour in A. Murray.
- i. p. 192, lines 6 and 15, and i. 198, line 16. For *Retinospora* read *Retinispora*. Regarding the correct spelling of the word, see vol. v. p. 1146, note 2.
- i. p. 195. The correct name, according to the Vienna Rules, of *Thuya japonica*, Maximowicz, is *Thuya Standishii*, Carrière.
- i. p. 196, line 1. For Komaror read Komarov.
- ii. p. vi, last line. Insert a comma between Ailanthus and Cladrastis.
- ii. p. 202, line 36. For *Cryptomera* read *Cryptomeria*.
- ii. p. 202, line 4. For *Thoujopsis* read *Thujopsis*.
- ii. p. 203, last line. Read *Thujopsis Hondai*, A. Henry.
- ii. p. 208, line 41. For A. read Æ.
- ii. p. 218, line 10. For A. read Æ.
- ii. p. 225, line 6. Add the note:—*Pavia rubra*, Poiret, in Lamarck, *Ency.* v. 94 (1804), is *Æsculus Pavia* (cf. p. 207).
- ii. p. 225, line 17. For A. read Æ.
- ii. p. 228, line 34. For Maximowicz read Masters.
- ii. p. 234. It will probably be better to adopt for this species the name *Tsuga heterophylla*, Sargent, as the correct one under the Vienna Rules.
- ii. p. 240, line 9. For *loc. cit.* read *Timber Trees and Forests of North Carolina*, 1898.
- ii. p. 244. The correct name for this species is *Tsuga dumosa*, Sargent.
- ii. p. 282. Moss, in *Journ. Bot.* 1910, p. 6, and Schneider, *Laubholzkunde*, i. 197 (1904), adopt the name, *Quercus Robur*, Linnæus, for the pedunculate or common oak.
- ii. p. 282, line 25. After Branchlets insert (Pl. 78, Fig. 1).

- Vol. ii. p. 283, line 3. After Leaves insert (Plate 79, Fig. 1).
- ii. p. 285, line 12. For (1844) read (1838).
- ii. p. 285, line 15. For *comptonæfolia* read *comptoniaefolia*.
- ii. p. 288, line 30. For Boenn. read Boenninghausen. A fuller account of the hybrid oak, *Quercus intermedia*, Boenninghausen, is given by Dr. C. E. Moss, in *Journ. Bot.* 1910, pp. 1, 34, plate 502.
- ii. p. 291, line 14. *Quercus sessilis*, Ehrhart, cannot be adopted as the correct name of the sessile oak, as it was unaccompanied by any description. Cf. Moss, in *Journ. Bot.* 1910, p. 2, and Schneider, *Laubholzkunde*, i. 196 (1904), and ii. 901 (1912).
- ii. p. 291, line 22. After Branchlets insert (Pl. 78, Fig. 2).
- ii. p. 291, line 25. After Leaves insert (Pl. 79, Fig. 8).
- ii. 294, line 2. Read *Quercus lanuginosa*, Lamarck, *Fl. Franc.* ii. 209 (1778); Thuillier. Insert the following reference as a new line:—*Quercus Robur*, var. *lanuginosa*, Lamarck, *Encyc.* i. 717 (1783).
- ii. p. 376, line 18. For unlikely read likely.
- ii. p. 379, title. Add Dahurian Larch.
- ii. p. 382, line 5. Insert A remarkable tree at Henham Hall, Suffolk, which according to the Earl of Stradbroke was planted between 1790 and 1803, is grafted on a common larch stock, forming a trunk about 6 ft. high and 7 ft. 4 in. in girth. It divides into numerous branches, which extend horizontally for a distance of about 100 ft., supported on larch poles. None of the branches rise more than two or three feet above this level; and when Elwes saw the tree in August 1909, they were covered with new and old cones.
- There are two good specimens of the Dahurian larch at Stanage Park, Herefordshire, which measured about 80 ft. by 5 ft. in 1910. They were planted as *Larix pendula* in 1836.
- ii. p. 383, title. Add Kurile Larch.
- ii. p. 384, title. Add Japanese Larch.
- ii. p. 393, note. Insert reference ¹.
- ii. p. 398, line 27. For *albertiana* read *Albertiana*.
- ii. p. 409, line 18, and ii. 410, line 18. The form of *Pinus Laricio*, which occurs in the mountains of the central, north-eastern and south-eastern provinces of Spain is identical with that of the Cevennes and Pyrenees, and is to be referred to var. *tenuifolia*. The best account of the *Pinus Laricio* of Spain is given by S. E. Cook, *Sketches in Spain*, ii. 228, 234, 237, 244 (1834); and the name *P. hispanica*, Cook, *op. cit.* 234, may be added to the synonymy of this tree. Laguna, *Flora Forestal Española*, i. 80 (1883), gives full details of its distribution.
- ii. p. 424, line 6. Omit rarely. For 6 read 8.
- ii. p. 428, line 23. For *Guilandina diocus* read *Guilandina dioica*.
- ii. p. 433, line 6. After regular insert full stop.
- ii. p. 435, line 11. Insert A tree standing close to Weston Birt House, measured by Elwes in October, 1912, was 47 ft. by 3½ ft.

- Vol. ii. p. 437, line 18. For DIPTERA (*sectio nova*) read DIPTERA, A. Henry (*sectio nova*).
- ii. p. 438, line 26. For *Juglans fraxinifolium* read *Juglans fraxinifolia*.
- iii. p. 452, line 23. Add Interesting details concerning the flowers, cones, and seedlings, as well as the rate of growth of the cedars, are given by Hutchison, in *Trans. Roy. Scott. Arbor. Soc.* xiii. 200 (1893).
- iii. p. 452, line 24. The seedling here described was that of *Pinus halepensis*; and this paragraph should be transferred to vol. v. p. 1100.
- iii. p. 471, line 12. For last January read in January 1907.
- iii. p. 475, line 25. After now add (1907).
- iii. p. 480, line 23. For *albertiana* read *Albertiana*.
- iii. p. 485, line 25. For Endlichler read Endlicher.
- iii. p. 489, line 10. For 1888 read 1870.
- iii. p. 489, line 27. For *Thuja Craigana*, Murray, read *Thuja Craigana*, Balfour, in Murray. The correct name of the Incense Cedar of North America is *Libocedrus Craigana*, Low, ex R. Brown, in *Trans. Bot. Soc. Edin.* ix. 373 (1868). Cf. A. Henry, in *Gard. Chron.* liii. 325 (1913).
- iii. p. 490, line 30. For Murray read Balfour, and for *Thuja* read *Thuja*.
- iii. p. 492, line 35. For Park read Place.
- iii. p. 494, note 2. The new species from Formosa has been named *Cunninghamia Konishii*, Hayata, in *Gard. Chron.* xliii. 194 (1908). Cf. Clinton-Baker, *Illust. Conif.* iii. 84 (1913), and Elwes, in *Quart. Journ. Forestry*, vi. 274 (1912). It has not yet been introduced.
- iii. p. 513, note 1. For 1904 read for 1903. Add Cf. vol. i. p. 177 and note 3.
- iii. p. 540, line 29. For *Ostrya Ostrya*, Sargent, read *Ostrya Ostrya*, Karsten, *Deutsch. Fl.* 20 (1895); Sargent.
- iii. p. 545, lines 1 and 23; 546, lines, 8, 11, 21, 24, and 37; 547, lines 9, 11, and 16; 548, line 13; 549, line 1; 550, line 18; 553, line 29. For Oerstedt read Oersted.
- iii. p. 553, line 21. After now add (October, 1907).
- iii. p. 553, line 33. For Foster read Forster.
- iii. p. 558, note 1. *Arbutus canariensis* is said, by W. Fitzherbert in *Gard. Chron.* lii. 44 (1912), to be 30 ft. high at Abbotsbury. It is perfectly hardy at Rostrevor, where I saw a shrub 10 ft. high in May 1913.
- iii. p. 563, line 33. For *Brit.* 1119 read *Brit.* ii. 1119.
- iii. p. 564, line 28. For Klotzch read Klotzsch.
- iii. p. 565, line 31. For *procera*, Lindley, read *procera*, Douglas, ex Lindley.
- iii. p. 573, line 27. After var. *scotica* add A. Henry.
- iii. p. 576, note 2. Add Cf. vol. v. p. 1130, note 2.
- iii. p. 586, line 5. For 162 read 131.
- iii. p. 595, line 23. For *Primer* read *Pruner*.
- iii. p. 599, line 5. For Schneider ex read Schneider, *Laubholzkunde*, i. 803 (1906);
- iii. p. 600, line 17. For *cordifolia*, Schneider, ex read *cordiformis*, Schneider, *Laubholzkunde*, i. 803 (1906), and ii. 1008 (1912);
- iii. p. 601, line 32. For Schneider ex read Schneider, *Laubholzkunde* i. 803 (1906);

- Vol. iii. p. 604, note. For Schneider by read Schneider, *Laubholzkunde*, i. 803 (1906) and ii. 872 (1912);
- iii. p. 605, line 29. For Schneider *ex* read Schneider, *Laubholzkunde*, i. 804 (1906);
- iii. p. 620, line 18. The evidence is now almost conclusive that *Platanus acerifolia*, Willdenow, the London Plane, is of hybrid origin, the parents being *P. occidentalis*, Linnæus, and *P. orientalis*, Linnæus.
- iii. p. 627, line 5. For *hybridus* read *hybrida*.
- iii. p. 640, note. For *mandschuricum* read *mandshuricum*.
- iii. p. 642, line 31. For *villosa* read *villosum*.
- iii. p. 652, line 22. For *austriaca* read *austriacum*.
- iii. p. 654, line 30. After paces add (Plate 185).
- iii. p. 657, line 38. For sugar maple read common sycamore.
- iii. p. 664, note 3. For 1889 read 1899.
- iii. p. 669, line 20. For M. E. Louis read M. Jouin.
- iii. p. 677, line 24. For *nigra* read *nigrum*.
- iii. p. 690, line 31. For trees, read trees (Plate 195).
- iii. p. 703, note. Add *Silva of California*, 143 (1910).
- iii. p. 706, line 7. For he wrote read this was written.
- iii. p. 706, line 35. After now add (1907).
- iii. p. 707, line 5. For 106 read 196.
- iii. p. 709, line 27. After now add (1907).
- iii. p. 709, line 28. After now add (1907).
- iv. p. 714, line 23. For all other conifers by read all other conifers except *Keteleeria* by. Cf. vol. vi. 1473.
- iv. p. 728, line 25. Insert The Marquess of Bath informed Elwes in 1910 that Col. Thynne had measured a silver fir near the house at Longleat which was 144 ft. by 17 ft. 4 in. in 1909.
- iv. p. 731, note 2. For 1896 read 1894.
- iv. p. 739, line 21. For *Panachaica* read *panachaica*.
- iv. p. 747, line 33. For a read at.
- iv. p. 756, line 15. For inch read inches.
- iv. p. 782, line 2. For 1840 read 1839.
- iv. p. 812, line 37. For *Pseudotsuga japonica*, Sargent, read *Pseudotsuga japonica*, Beissner, in *Mitt. Deut. Dend. Ges.* 1896, p. 62; Sargent.
- iv. p. 817, line 22. For in the Yellowstone Park in read from the Yellowstone Park in Wyoming to.
- iv. p. 818, line 11. For 3 read 1.
- iv. p. 824, line 10. For pine read fir.
- iv. p. 854, lines 9, 10. For *Icon. Forest. Japon.* read *Icon. Ess. Forest. Japon.*
- iv. p. 854, line 12. For Seeman read Seemann.
- iv. p. 860, line 20. For 898 read 900.
- iv. p. 862, line 1. For 907 read 905.
- iv. p. 862, line 5. For 904 read 912.
- iv. p. 862, line 19. For *longicuspis*, Blume, read *longicuspis*, Siebold and Zuccarini.

- Vol. iv. p. 862, line 36. For 906 read 907.
- iv. p. 862, note 1. For 21 read 25.
- iv. p. 863, line 15. For 905 read 906.
- iv. p. 876, line 2. For 124 feet read 97 feet.
- iv. p. 884, line 5. Schneider, *Laubholzkunde*, ii. 832 (1912) adopts the earlier name, *Fraxinus obliqua*, Tausch, in *Flora*, xvii. 521 (1834) for *F. Willdenowiana*, Koehne; and states that Lingelsheim identifies it with a wild specimen found by Bornmüller in Anatolia.
- iv. p. 904, line 13. For Hildenley at read Hildenley in.
- iv. p. 912, line 33. For 265 read 264.
- iv. p. 915, line 21. For *Pittcursii* read *Pitteursii*.
- iv. p. 918, line 8. For Hertfordshire read Herefordshire.
- iv. p. 918, line 38. For University Park read Christ Church Meadows.
- iv. p. 919, line 10. For 61 feet in girth read 61 feet in height.
- iv. p. 922, line 25. For Stukeley read Stewkley.
- iv. p. 940, line 17, and note 2. The variety in Japan has been described as a distinct species, *Alnus serrulatoides*, Callier, in Fedde, *Repert.* x. 229 (1911).
- iv. p. 946, line 24. For *montrosa* read *monstrosa*.
- iv. p. 952, line 16. For *multinervis*, Schneider, read *multinervis*, Callier, *ex* Schneider.
- iv. p. 953, line 24. Delete comma after *Flora*.
- iv. p. 963, note 2. For *Eriophes* read *Eriophyes*.
- iv. p. 971, line 21. For 225 read 255.
- iv. p. 989, line 6. For *dahurica* read *davurica*.
- iv. Plate 264, Fig. 16. For *lancelotata* read *lanceolata*.
- v. p. 1013, line 15. For Bewdley read Bromsgrove.
- v. p. 1029, note 1. For *Rusticanum* read *Rusticum*.
- v. p. 1031, line 24. For Burwood House, near Cobham, Surrey, read Bearwood, near Wokingham.
- v. p. 1080, note 7. For saved read sowed.
- v. p. 1100, line 24. For *Pithyusa* read *pithyusa*.
- v. p. 1100, line 31. For *Eldarica* read *eldarica*.
- v. p. 1102, line 38. After *P. halepensis* insert (Plate 287).
- v. p. 1103, note 3. For Strangways read Steven. Cf. p. 1100 and note.
- v. p. 1107, line 32. For Solander in Aiton read Aiton.
- v. p. 1113, line 12. For Solander in Aiton read Aiton.
- v. p. 1124, line 36. For Burwood House, Surrey, read Bearwood, Berks.
- v. p. 1130, note 2. For Klotsch read Klotzsch.
- v. p. 1134, line 26. For *Mackintoshiana* read *Macintoshiana*.
- v. p. 1139, line 23. For *Aboretum* read *Arboretum*.
- v. p. 1140, line 1. For Solander in Aiton read Aiton.
- v. p. 1142, line 5. For 5 ft. 3 in. read 5.23 in.
- v. p. 1142, line 6. For 6 ft. 4 in. read 6.4 in.; for 8 ft. 3 in. read 8.3 in.

1942 The Trees of Great Britain and Ireland

- Vol. v. p. 1150, line 9. *Cupressus Hodginsii*, Dunn, has been made the type of a new genus, and is now known as *Fokienia Hodginsii*, A. Henry and H. H. Thomas, in *Gard. Chron.* xlix. 66, 84, figs. (1911). Cf. Clinton-Baker, *Illust. Conif.* iii. 85 (1913), who gives particulars regarding its introduction into cultivation.
- v. p. 1179, note 1, line 4. For Parlatores read Antoine.
- v. p. 1188, line 18. For Maichi read Imaichi.
- v. p. 1200, line 28. Insert (H. J. E.).
- v. p. 1203, note 2. For *pygmea* read *pygmaea*.
- v. p. 1229, note 5. For *schochiana* read *Schochiana*.
- v. p. 1235, note 2. After Small, read in *Bull. Torrey Bot. Club*, 1901, p. 157.
- v. p. 1257, line 21. For 317 read 318.
- v. p. 1257, line 24. For 318 read 317.
- v. p. 1289, between lines 19 and 20. Add as a synonym, *Quercus austriaca sempervirens*, Hort., a name by which this oak is still occasionally known in some nurseries.
- v. p. 1315, line 17. For *cerquhino* read *cerquinho*.
- vi. p. 1372. Two varieties of the Hondo spruce, vars. *reflexa* and *acicularis*, have recently been described by Shirasawa and Koyama, in *Tokyo Bot. Mag.* xxvii. 129, pl. ii. figs. 1-17 (1913).
An allied species, *Picea Koyamai*, Shirasawa, was published in *Tokyo Bot. Mag.* xxvii. 128, pl. ii. figs. 28-35 (1913).
- vi. p. 1374, line 3. Add Shirasawa and Koyama describe and figure *Picea Maximowiczii* in *Tokyo Bot. Mag.* xxvii. 130, pl. ii. figs. 18 to 27 (1913).
- vi. p. 1380, line 25. For Solander in Aiton read Aiton.
- vi. p. 1411, line 3. For Timbal read Timbal-Lagrave.
- vi. p. 1481, line 3; 1483, line 6; 1485, line 11; 1487, line 22; 1489, lines 12 and 23; 1490, line 29. For *Bull. Soc. Dend. France*, i. read *Bull. Soc. Dend. France*, ii.
- vi. p. 1487, line 18 and note 2. It will be advisable to adopt for this species the oldest name, *Catalpa ovata*, Don, and to abandon that of *C. Kaempferi*. Rehder, in Sargent, *Plant. Wilson*, ii. 304 (1912) agrees with me that this species is truly wild in Central China, and that *C. Henryi*, Dode, cannot be maintained even as a variety.
- vi. p. 1489, line 24. *Catalpa Duclouxii*, Dode, and *C. sutchuenensis*, Dode, in *Bull. Soc. Dend. France*, ii. 204 (1907), are considered by Rehder, in Sargent, *Plant. Wilson*, ii. 304 (1912), to be identical, and constitute a glabrous variety of *C. Fargesii*, Bureau, which varies much in pubescence.
- vi. p. 1569, line 11. For Solander in Aiton read Aiton.
- vi. p. 1580, note. Add The rowan (*Pyrus Aucuparia*) is called quicken tree in Wicklow and other parts of Ireland.
- vi. p. 1585, line 1. Schneider, *Laubholzkunde*, i. 806 (1906), adopts for this species the name *Magnolia virginiana*, Linnæus, *Sp. Pl.* 535 (1753), instead of *Magnolia glauca*.
- vi. p. 1616, note 2. For *E. Gunnii* read *E. coccifera*.
- vii. p. 1736, note 3. For Chevallier read Blin. Cf. *Bull. Dend. Soc. France*, 1913, p. 122.
