G

GADAMER, HANS-GEORG
(1900–2002)

Hans-Georg Gadamer, a Heidelberg philosopher and student of Martin Heidegger, is best known for his hermeneutic philosophy put forward in his *Wahrheit und Methode* (*Truth and Method*, 1960). Widely regarded as the most significant German philosopher after Heidegger, Gadamer wrote on Plato, Georg Wilhelm Friedrich Hegel, Heidegger, Aristotle's practical philosophy, reason in an age of science, aesthetics, poetics, Paul Celan, and other topics.

BIOGRAPHY

Gadamer was born in Marburg and grew up in Breslau. His mother died when he was four. His father was a well-known university research scientist in pharmacological chemistry. In 1919 Gadamer's father was called from the University of Breslau to a research chair at the University of Marburg. Gadamer entered Marburg as a second-year student with interests in literature, art history, and classical philology. But he was soon drawn to the great neo-Kantian philosopher and Platonist, Paul Natorp, under whom he completed his doctoral dissertation in 1922 on pleasure in the Platonic dialogues. In 1923 Gadamer jour-

neyed for the summer semester to Freiburg to hear Heidegger, who was offering bold new interpretations of Aristotle and other philosophers. When Heidegger moved to Marburg in the fall of that year, Gadamer became his assistant and he remained so until 1928. During this time Gadamer also studied with Nicolai Hartmann, took seminars in classical philology under Paul Friedländer and others, and in 1927 was certified in classical philology. In 1928 he completed his habilitation under Heidegger on "Plato's dialectical ethics," based on the *Philebus.*

Gadamer remained another ten years in Marburg waiting for a call to a full-time teaching appointment. After 1933 his chances for a call were practically blotted out by his not being in good standing with the Nazis. But he remained active in the academic life at Marburg, which boasted some of Germany's leading intellectuals—Rudolf Bultmann in theology; Hartmann; Stefan George, the charismatic poet; Richard Hamann, the iconoclastic art historian; and finally, Friedländer and others, who represented the great philological tradition of Ulrich von Wilamowitz-Moellendorff.

In 1938 Gadamer was finally called to a chair in philosophy at Leipzig, where he was able to survive through the war years as a politically unthreatening classical

humanist. Because of his political integrity he was elected rector at Leipzig after the war. In 1947 he managed to escape the stultifying atmosphere of the new communist regime by being called to a position at Frankfurt University. He was at Frankfurt but two years when in 1949 he was called to fill Karl Jaspers's chair at the University of Heidelberg.

Gadamer remained in Heidelberg as chair in philosophy until his retirement in 1968. A gifted lecturer, he concentrated in the 1950s on topics that later became part of *Truth and Method.* At the same time, he worked to revive Hegel studies in Germany, and rebuilt a war-shattered department into one of the strongest in Germany. In 1952, along with Helmut Kuhn, he founded the *Philosophische Rundschau,* a journal dedicated to reviewing current books and discussing major issues in philosophy.

After 1968 Gadamer continued to lecture and offer seminars in Heidelberg as an honored emeritus professor, but now he allowed himself to accept invitations to speak in other countries and to serve as a guest professor at various universities, especially in the United States and Canada. This fed a growing interest in hermeneutics in the United States, an interest manifested in the number of dissertations and books being written on the subject. English translations of Gadamer's works began to appear: *Truth and Method* (1975), *Philosophical Hermeneutics* (1976), and *Hegel's Dialectic* (1976) being among the first.

WORKS

In *Truth and Method* Gadamer's concepts can be logically divided into those within *Truth and Method* and those in the shorter writings after it. The latter category includes further writings defending and defining hermeneutics, writings in modern and ancient philosophy, and in aesthetics and poetics.

In *Truth and Method* Gadamer articulated the most detailed and nuanced account of the "event of understanding" in the history of philosophy. He based much of his thinking on Heidegger, Hegel, and Plato. From Heidegger's *Origin of a Work of Art* he drew strength for a powerful reassertion of the "truth" of art, and from Heidegger's *Being and Time* and later writings he drew concepts that called into question the goal of objectivity in interpretation. From Hegel and Plato he drew emphases on tradition, history, and dialogue. From Wilhelm Dilthey and Heidegger he drew an emphasis on the horizonal character of consciousness and the operativeness of history in all understanding. Understanding, he argues, takes place in a consciousness in which history—that is,

tradition—is always already at work, shaping, predisposing, predefining what the process of understanding involves. His term for this is *wirkungsgeschichtliches Bewußtsein,* "effective historical consciousness," and the encounter with the other, as person or as text, is a matter of *Horizontverschmelzung.*

In *Truth and Method* Gadamer shows the development after Kant of fateful conceptual turns in the course of eighteenth- and nineteenth-century philosophy, philology, and hermeneutics that have led to present presuppositions about understanding and the conditions for its possibility. He traces the dream of scientific objectivity in humanistic and social scientific knowledge in the nineteenth century, especially in Friedrich Daniel Ernst Schleiermacher and Dilthey, and the promising philosophical transformation of this "problematic" of understanding through Heidegger's phenomenological analysis of existential temporality and the historical situatedness of and the participation of history in understanding. He accepts Heidegger's description of the "forestructure" of understanding, adding to it his concept of an "anticipation of completeness" in all understanding. He argues that the process of understanding has the structure of a dialogue and can be likened to a game in that it follows rules and operates in a language that transcends it; thus, he emphasizes the "linguisticality" (*Sprachlichkeit*) of understanding and even ultimately its ontological character: "Being that can be understood is language," he asserted (*Truth and Method,* p. 432). Finally, one of the most distinctive and important of the contributions of *Truth and Method* is its insistence on a moment of "application" in all understanding.

The book's overarching goal, however, was to cause the artwork to be seen in a new way. While the title might lead one to expect it to be concerned with methods in the *Geisteswissenschaften,* Gadamer's professed aim is to defend the claim of artworks to be "true." In Gadamer's view the experience of encountering truth in great works of art demonstrates the limits of a science-oriented concept of understanding; the meaning and power of such artworks elude scientific modes of understanding. Gadamer wrote a good deal in explanation and defense of *Truth and Method.* These writings are now collected in volume two of his collected works.

Gadamer's writings on modern philosophy range through the Continental tradition since Kant and are influenced principally by Plato, who casts a shadow even over his modern writings; by Heidegger, about whom he wrote more than about any other modern philosopher; by Hegel, whose importance in modern philosophy

Gadamer repeatedly defended; and by Edmund Husserl whose phenomenology Gadamer used and treated as a major element in his thought. Most of his essays on ancient philosophy are directly or indirectly connected with Plato. From Plato he draws his model of dialogue, in which partners participate in quest of a truth that transcends the individual seeker. Gadamer's ethical thinking as well as his dialectical hermeneutics go back to Plato's "dialectical ethics" of respect for the other person, of openness, of seeking to strengthen the partner's case in order not merely to win a debate to one's own satisfaction but to move together toward truth, a result that benefits both sides and that both sides affirm.

Art and poetry were a major theme in Gadamer's writings throughout his career. In 1934 Gadamer wrote on "Plato and the Poets," and in the 1940s he was writing essays on Johann Christian Friedrich Hölderlin, Johann Wolfgang von Goethe, Karl Leberecht Immerman, and Rainer Maria Rilke. His articles after *Truth and Method* tend to select more sober and difficult poets such as Stefan George, Gottfried Benn, and Paul Celan. His essays on aesthetics and poetics continue to emphasize the truth of art, the need for dialogical openness, and the priority of the artwork's character of play. At the same time, another issue arises: What about basically nonrepresentational poetry? What about the "no longer beautiful" poetry of the modern (or postmodern) dark lyric? After a number of writings that struggle successfully with the dark lyric, such as *Wer bin ich und wer bist du?* (Who am I and who are you?; 1973), on poet Paul Celan, Gadamer poses the problem in somewhat different terms. For Gadamer it is a "task of philosophy" to develop a context within which one can still recognize and deal with—or "understand"— modern and postmodern art.

Gadamer's essay "The Relevance of the Beautiful" presents a twentieth-century defense of such art. In this essay experience becomes the reference point, even group experiences as one finds them in the historical record. Gadamer includes, not just experiences recorded in artworks or great poetry, which would create a circular argument, but in anthropological records of such things as (1) the role of play in human life, (2) the high experiences of festiveness in our own and other cultures, and (3) the power of participation in symbolic religious rites. In groping for an explanation of the power of art and a defense of its legitimacy, Gadamer offers an analysis of three categories—play, symbol, and festival.

In his essay "The Truth of the Artwork" (1960), Gadamer pointed to a threefold insufficiency of scientific thinking: (1) the insufficiency of scientific thinking, by itself and without recourse to standards outside itself, to grapple with ethical problems such as human rights, abortion, ecology, or planning the future; (2) its incapacity to account for the experience of beauty in art and poetry or to lay down principles for its creation; and (3) its insufficiency to meet, or even account for, the spiritual needs of human beings. All these suggest that a recourse to the absolute priority of scientific presuppositions cannot serve us well in dealing with the encounter with ethical problems, artworks, or the divine. Art, like ethics and the divine, seems to move beyond the competence of the categories of scientific thinking. And they can claim to be "true." This is a major theme both in *Truth and Method* and in later writings.

In "Wort und Bild" (Word and image; 1992) Gadamer takes the final step and attempts to articulate aesthetic categories that apply both to plastic/pictorial arts and arts of the word. Among the several concepts to which he turns are the Greek concept of the fine (*kalon*) and to our experience of the rightness and absoluteness of art.

GALEN
(129—c. 216 CE)

Galen (Aelius or Iulius Galenus of Pergamum), a doctor and philosopher, was the son of a rich architect. Born in modern-day Bergama in western Turkey, he was introduced as a student to all the main philosophical theories of classical antiquity. On his own admission, this led him only into a confusion from which he was rescued by considering mathematics, which henceforth provided him with a paradigm for understanding truth and falsehood. From 145, following the appearance of the healing god Asclepius to his father in a dream, he turned to medicine. He sat at the feet of medical teachers in Pergamum, Smyrna, and Alexandria, as part of what is the longest recorded medical education from the ancient world. In 157 he returned to Pergamum as doctor to the gladiators of the high priest, but in 162 he traveled to Rome, the imperial capital. There he quickly established a reputation as a doctor, anatomist, and philosopher, not always to the delight of his many competitors. In 166 he left Rome hurriedly but was recalled in 168 by Emperor Marcus Aurelius to join him and his brother on campaign in northern Italy. After his return to Rome in 169, he seems to have spent the rest of his life in Italy as a physician to the emperor's household although he made at least one visit to Pergamum. The traditional date for his death, c. 200, is based on an early misunderstanding of a comment, preserved by Arabic authors, that divided his life into seventeen years as a student and seventy as a doctor. A date of death around 216 fits better with the internal evidence from his many treatises and would allow him to continue writing major treatises on medicine and pharmacology well into the first decade of the third century, or even later.

Galen was an enormously prolific author, credited with more than 350 treatises on subjects ranging from attic comedy to vivisection, and from logic to pharmacology. Roughly half of these survive today, in whole or in part, mainly in his native Greek but also in Arabic, Hebrew, Persian, and medieval Latin versions. These translations are of great importance, particularly when the originals have been lost, for they frequently deal with philosophical issues that seem to have held little interest for the Byzantine. New discoveries of previously unknown treatises can be expected as major libraries in the Muslim world are opened to scholars and more works of medieval Arabic and Jewish philosophy are published. The recent recovery of new fragments in Arabic of the lost *On Scientific Discovery* suggests that a complete copy of the work Galen thought his greatest contribution to philosophy may eventually be found.

Galen's interest in philosophy can be followed throughout his life, from his very early *On Medical Experience* to his last work, *On My Own Opinions*. He regarded philosophy as essential to the proper practice of medicine: The best doctor was also a philosopher, whether or not he realized it. Conversely, a knowledge of medicine was valuable for philosophers, a conjunction Galen

traced back to Plato whose notions of the body in the *Timaeus* Galen derived from a (unhistorical) friendship with Hippocrates. In turn, Galen visualized Hippocrates as a Platonic philosopher, a claim that contributed to the growing dominance of Hippocrates as the symbol of the medical profession.

Fundamental to medicine was logic, both for structuring accurate diagnosis and for distinguishing between various degrees of certainty. Some suppositions could be proved to be true, others shown to be false, others were merely plausible and could be adopted only provisionally. Still others, such as the nature of god or the eternity of world, were incapable of proof or refutation and were best left to idle sophists. But Galen often muddled these important distinctions, either by treating the merely plausible as if it were true or by choosing as *obvious* and *universally agreed* bases for discussion facts or ideas that themselves were disputed by some of his opponents.

Galen's formal logic, on which he wrote several books, is impressive in its rigor and clarity. The Arabs' attribution to him of the discovery of the fourth syllogism may be right, or it may simply reflect Galen's extension of earlier debates about argument. Throughout his writings he stressed the importance of accuracy and clarity of expression, to avoid confusion, and to allow discussion with those offering different points of view. Ambiguity, on which he wrote an extant tract, was harmful to medicine as well as philosophy, and a sound training in logic he considered necessary for everyone. His demands for a mathematical precision in debate are not, however, fully borne out by his own practice, and his overwhelming powers of rhetoric often obscure his unscrupulous representation of the illogicality of his opponents.

His philosophy and his medicine reinforced each other. Where empirical observation was not enough by itself, logic and understanding of the theories of other philosophers could bridge the gap. Conversely, the facts of medical life exemplified and justified the cosmological and psychological doctrines of philosophers. His discussions of the value of empiricism in relation to understanding the causes of disease, one of the goals of the true doctor, show an awareness of the epistemological difficulties involved and an understanding that an experienced practitioner might reach the correct conclusion without having to go through the necessary chain of causation. He might also be a swifter and safer option than a callow youth, no matter how brilliant the youth's reasoning abilities. Galen's entire approach was eclectic, rejecting the dogmatism of the philosophical schools of his own day in favor of the "twin legs" of reason and experience.

Galen's medicine was based on an Aristotelian physics combined with a Platonic psychology. His universe, made up of the four Aristotelian elements in various combinations or mixtures, had been overseen by a purposeful Creator, or Nature, and worked along the interconnected principles favored by the Aristotelians and Stoics. His explanations for the working of drugs, for instance, involved Aristotelian language and concepts. He was convinced that each part of the body had been designed teleologically, for a particular purpose, and any alteration or imbalance in its basic elements, qualities, or humors resulted in illness. Galen's defense of teleology, as evinced in the human hand and in the elephant's trunk, is arguably superior to that of Aristotle's, and his exposition of what he termed the "natural faculties" is far from the simplistic presentation familiar from later denunciations of Galenism.

Whereas he believed strongly in the existence of the soul, he refused to be drawn to any definitive statement about what the essence of the soul was. The Aristotelian and Stoic notions of an undivided controlling power within the body he vigorously rejected as being inconsistent with the facts of anatomy. His systematic dissections of a variety of animals convinced him that there were three almost independent systems within the body corresponding to the three parts of Plato's soul, as described in the *Republic* and *Timaeus*: the brain and nerves, concerned with thought and sensation; the heart and arteries, responsible for life and energy; and the veins and liver (a more precise rendering of Plato's *belly*), responsible for nutrition and growth. Galen never proclaimed a strict parallelism between the three systems, which was achieved only by later followers such as Avicenna and Averroes, and he devoted much more space to the first two than to the third. This lack of systematization was the result both of his enormous fecundity of ideas and his methods of composition, for most of his books were originally oral presentations, taken down by trained shorthand writers, and not carefully crafted treatises written at leisure. Not surprisingly, they are often repetitive and leave many knots untied.

The heart, for Galen, was the source of natural heat, and the place where a small amount of venous blood, mixed with air, was transformed into vigorous arterial blood. His repetition of the earlier experiments of Erasistratus (c. 304–250 BCE) proved convincingly that the arteries contained blood and not *pneuma* alone, as Erasistratus had argued. But his vitalist predilections con-

vinced him that the movement of arterial blood was not the result of any quasi-mechanical motion of the heart but brought about by the forcible contraction of the arteries controlled by natural powers within their thick coats. Just as most venous blood remained within the veins until it was absorbed as nutriment or excreted, so most arterial blood remained within the arteries. A tiny portion was transformed in the rete mirabile, a vascular plexus at the base of the skull (not found in humans but in some animals Galen dissected), to become psychic pneuma, which was refined still more in the networks of the brain to act as the means of transmission of sensation and the commands of the brain. Contrary to Aristotle and the Stoics, he could find no evidence for the heart as the seat of sensation and thought, especially since he could trace its nerves back to an origin in the innermost cavities of the brain. Galen's experimental dissections of the spinal cord in animals are among the most impressive ever performed, combining a precision of dissection with a careful planning and elucidation of what was to be achieved, and were not superseded until the mid-sixteenth century.

Galen's anatomical conclusions he believed far too important to be left entirely to doctors. In two of his longest treatises, *On the Usefulness of Parts* and *On the Opinions of Hippocrates and Plato*, he explained the consequences of his discoveries in Aristotelian and Platonic terms, respectively. Similarly, his comments on the *Timaeus* stressed the truth of many of Plato's observations and suggested that he must have gained his anatomical knowledge from the great Hippocrates himself. Plato was his favorite philosopher: Galen's writings are permeated with Platonic phraseology, and he wrote summaries of the *Timaeus* and other Platonic dialogues that are partially extant in Arabic.

A man of austere morality—Galen claimed to have read the *Golden Words* of Pythagoras nightly—he wrote extensively on ethics. He advocated a self-control brought about by an extensive philosophical training although he acknowledged that this might be doubly difficult for those who had been badly trained or whose psychic genetic makeup predisposed them to evil. He advocated a very strong interaction between body and soul, for just as overeating and drinking or pleasurable and painful sensations have an obvious effect on behavior, so, in turn, anger or grief can lead to physical illness and even death. Galen contrasts his own equanimity at the loss of most of his library in a fire with his mother's shocking irascibility and with the timorousness of a patient who worried himself to death after dreaming that he had replaced Atlas as

the upholder of the world. Doctor and philosopher should cooperate in the search for health and wholeness.

Anatomy also helped to resolve some philosophical disputes about intentionality. Some actions, Galen showed, were under the direct control of the brain via the nerves and muscles; others were "natural," the result of our genetic makeup, and beyond rational control; others were more complex, such as speech, which required both the will and the modification of "natural" patterns of breathing. Others, such as winking and blinking, appeared to indicate the coexistence of voluntary and involuntary activity in the same organ whereas others, such as a penile erection, he explained by other notions such as sympathy. Only laughter defeated his attempts at explanation. Throughout, Galen sought to use his medical experience to illuminate contemporary philosophical debate, just as he used philosophical debates on physics or causation to explain his decisions as a practitioner.

Contemporary reactions to his philosophy were mixed. A sect of Christians attempted to recast their Christianity to take account of his logical objections to miracles, but others were less polite. Skeptics objected to his reliance on sensory data, and the Aristotelian Alexander of Aphrodisias thought him a great doctor but a poor philosopher, whose profession in *On My Own Opinions* of agnosticism about many philosophical questions was a confession of failure. But his views on creation and some of his Platonic commentaries were cited with respect in the fifth century, and the Christian philosopher Nemesius of Emesa built his Christian anthropology largely on Galen's discoveries. Although much of his philosophy had disappeared in Greek by 1000, the Arabs drew heavily on his work. New fragments of his ethics recovered from Spanish Jewish writers of the twelfth and thirteenth centuries show how much they valued his approach to morality. Renaissance biographers were equally impressed, some even viewing his life as exemplifying the cardinal virtues—a perspective hardly shared by modern scholars. Others hotly debated whether he had become a Christian at the end of his life or not. But after the sixteenth century, Galenic philosophy, like his medicine, was abandoned, not to be studied again in considerable detail until the 1970s.

GALEN [ADDENDUM]

Galen's influence on medieval Islamic thought in general, and on Arabic philosophy in particular, can hardly be overestimated. Galen himself developed a system of philosophical and medical views that gained tremendous authority in Late Antiquity, notably in Alexandria and the Hellenized East. He emphasized the necessity that physicians be conversant in philosophy, and this idea was thoroughly enshrined, for instance, in the Late Antique medical curriculum in Alexandria. To give just one example, physiological and nosological processes were explained in terms of Aristotelian categories and the four causes. This medical tradition, aptly called "Galenism," shaped the Islamic notion of sciences and medicine to a large extent; it is therefore not surprising that many of the most famous Arabic philosophers such as al-Kindī, al-Rāzī (Rhasis), Ibn Sīnā (Avicenna) and Ibn Rushd (Averroes) were also prominent physicians.

Virtually all the works of Galen's medical and philosophical writings were translated into Arabic, and it is in this language that some of the most interesting philosophical works such as *On Medical Experience* survive. The idea of experience was hotly debated among medical authors in the medieval Islamic period, and treatises such as al-Rāzī's *Doubts concerning Galen* show that Arabic authors engaged critically with him. However, many of Galen's ideas, such as concepts about human physiology, which had already entered Late Antique Greek popular intellectual culture, became commonplace in the Islamic world.

GALILEO GALILEI
(1564–1642)

Galileo Galilei, the Italian astronomer and physicist, was born at Pisa. Although he created no systematic philosophy, his influence on the trend of modern philosophical thought is very marked. To it may be traced the definitive separation of physical science from philosophy, the abandonment of authority as a criterion of scientific truth, the distinction between objective and subjective qualities in observable phenomena, and the introduction (or reintroduction) of empirical and skeptical elements into philosophical investigations. The seventeenth-century revival of atomism and the removal of occult qualities from the concept of causation owed much to Galileo. His writings marked the beginning of an antimetaphysical movement in philosophy, exemplified in later times by Positivism and operationalism, and they remained relatively free from such concealed ontological assumptions as are to be found in some ostensibly nonmetaphysical systems; for example, in philosophical empiricism, mechanism, and phenomenalism. The events of Galileo's personal life involved him in an active struggle for freedom of thought, and this in turn underlay those scientific and philosophical convictions for which he became a symbol to his contemporaries and followers.

After a meager, conventional preparatory education, Galileo was enrolled in the school of medicine at the University of Pisa in 1581. His interests turned to mathematics about 1583, and he left the university in 1585 without having received a degree. For a time he continued his studies alone, giving lessons at Siena and Florence, and in 1589 secured the chair of mathematics at Pisa. His early investigations in physics, particularly mechanics, set him in sharp opposition to the views prevailing among professors of philosophy, who, as followers of Aristotle, looked with disfavor upon the introduction of mathematics into physics. In 1591 Galileo left Pisa to become professor of mathematics at the University of Padua. Here he continued his mechanical researches, undertook the manufacture of mathematical instruments for sale, and

composed several useful treatises that were circulated in manuscript among his pupils and friends.

In 1604 he disclosed, in a letter to Fra Paolo Sarpi, the mathematical law of freely falling bodies. He had made substantial progress toward a rational mechanics when, in 1609, his attention was diverted from those studies by the invention of the telescope in Holland. Galileo promptly duplicated and improved the device, producing an instrument suitable for astronomical observation, and early in 1610 he published *Sidereus Nuncius* (The starry messenger), in which he described the mountainous character of the moon, the existence of countless previously unobserved stars, and the discovery of four satellites of Jupiter. These discoveries provoked widespread controversy among philosophers and astronomers. Shortly after *Sidereus Nuncius* was published, Galileo resigned his post and returned to Florence as chief mathematician and philosopher to Cosimo II de' Medici, grand duke of Tuscany. Late in 1610, he detected the curious appearance of Saturn (although he could not account for it) and the phases of Venus, and shortly thereafter he noted the phenomenon of sunspots.

Strong philosophical opposition was aroused by his publication in 1612 of *Discourse on Bodies in Water,* in which he ridiculed the Aristotelian theory of the elements, advocated observation and experiment as the chief criteria of physical truth, and gave some support to the views of Democritus. Publication in 1613 of his *Istoria e dimostrazioni intorno alle macchie solari* (Letters on sunspots) aroused theological opposition by its open support of the Copernican theory, which appeared to contradict the Bible by asserting the motion of Earth and the stability of the sun. Toward the end of that year certain philosophers and priests, in the presence of members of the ruling family, attacked Galileo and Copernicanism on religious grounds. Galileo replied in a long letter addressed to his former pupil Benedetto Castelli, who had defended him in his absence. In this letter Galileo contended that biblical passages had no authority in scientific controversies, and that the language of the Bible should instead be interpreted in the light of man's knowledge of natural phenomena, gained through reason and observation.

Early in 1615, Galileo was violently attacked from the pulpit in Florence, and a copy of his earlier letter, together with a denunciation of the Galileists, was sent to the Inquisition at Rome. Rumors spread that the Catholic Church would soon officially condemn the Copernican theory and silence Galileo. He countered by greatly expanding the arguments of his previous letter to Castelli,

and widely circulated the new version in manuscript copies ostensibly addressed to Grand Duchess Christina, the mother of Cosimo de' Medici. At the end of the same year Galileo went personally to Rome in an attempt to stem the anti-Copernican tide. In this he was unsuccessful, for the church officially moved to condemn the views of the motion of Earth and stability of the sun as contrary to the Scriptures. Galileo was instructed not to hold or defend these views, but no action was taken against his person or his previously published books.

After a period of silence, Galileo entered into a polemic with a Jesuit professor at Rome over the nature of comets, and in 1623 he published *The Assayer* (*Il saggiatore*), ridiculing the Aristotelian philosophy and expounding his methodological ideas. This book was dedicated to the new pope, Urban VIII, who as cardinal had been very friendly toward Galileo. In 1624, Galileo visited Rome and obtained permission to write on the Copernican and Ptolemaic systems, provided that the treatment was impartial. The composition of his next book, *Dialogue concerning the Two Chief World Systems,* occupied Galileo intermittently for several years. After great difficulty in getting a license to publish it, he brought it out at Florence in 1632. Five months later the printer was ordered to issue no more copies, and Galileo was summoned to Rome to face the Inquisition. Despite remonstrances of the Tuscan ambassador and of Grand Duke Ferdinand II, he was eventually compelled to appear and stand trial. In June 1633 the book was condemned, and Galileo was sentenced to life imprisonment. He was, however, permitted to reside first at Siena with the archbishop, his friend and former pupil, and then under house arrest at his own villa near Florence. There he managed to compose and smuggle out his most mature work, a treatise on physics known as *Two New Sciences,* which was printed in Holland in 1638. Galileo died four years later.

PHILOSOPHICAL ROOTS

The conditions of Galileo's education and career led to his intimate familiarity with the works of Aristotle. There is little evidence, however, that he ever preferred to read the works of any particular philosopher. His personal library was scanty, and his correspondence is devoid of philosophical references or discussions. In polemic works he refers often to Aristotle, usually with disfavor. His occasional references to Democritus, Socrates, Plato, and Seneca are more favorable but superficial, and appear to express general anti-Aristotelianism rather than allegiance to any other philosopher. Near contemporaries

such as Girolamo Cardano and Bernardino Telesio were dismissed by Galileo with the remark that he had read but little of their work. Although there is extant a Latin treatise in Galileo's handwriting that contains references to scores of ancient and medieval philosophers, this dates from his student days (1584) and is not demonstrably original or representative of his own views.

It is evident that during most of his life Galileo's favorite reading was literary rather than philosophical. He is said to have known Ludovico Ariosto by heart; he lectured on Dante Alighieri, annotated Torquato Tasso, delighted in the rustic dialect writings of Ruzzante (Angelo Beolco), and frequently cited Homer, Vergil, Pulci, and other poets in his works. Nowhere in his writings is there an overt expression of allegiance to any of his philosophical predecessors. However, the question of Galileo's true metaphysical position has been much debated in recent decades. His emphasis on the mathematical element in physics has induced many excellent scholars, led by Alexandre Koyré, to classify him unequivocally as a Platonist. On the other hand, Galileo's insistence on the power of observation to refute any reasoned conclusion has caused others, notably Ludovico Geymonat, to resist this conclusion and even to stress a strong Aristotelian element in Galileo's own work. In opposition to both these views, Edward Strong has questioned the propriety of reading any metaphysical position into Galileo's work and emphasizes his evident preoccupation with methodological considerations, to the exclusion of dogmatic philosophy. Finally, Alistair Crombie has aptly remarked that it is precisely the absence of systematic philosophy in Galileo that has made it possible for adherents of nearly every philosophical school to find some support for their views in his works.

Galileo's anti-Aristotelianism makes its first appearance in his early studies of motion. In order to defend a theory of motion (later abandoned) founded on Archimedean conceptions, he was obliged to demolish several prevailing Aristotelian assertions: that the speed of free fall is proportional to the weight of the falling body and inversely proportional to the density of the medium; that the motion of projectiles depends on some action of the medium; and that motion is impossible in the void. Galileo's attack on Aristotle widened with his adoption of the Copernican astronomy and his abandonment of the distinction between elemental and celestial matter, so essential to Aristotle's world view. In the end he questioned the reliability of Aristotelian logic and asserted that rigorous demonstration was to be found only in mathematics. Thus, it may be argued that Aristotle's physical errors led

Galileo to distrust logical deduction as a basis for physics, and his famous dictum that "the book of nature is written in mathematical characters, without a knowledge of which men cannot understand it" probably represents a methodological canon rather than a metaphysical position.

Galileo's opposition to Aristotle was also to some degree a literary pose rather than a true philosophical position. In later years he often declared himself a better Aristotelian than his contemporary Peripatetic adversaries, and in the opening sections of the *Dialogue* he made extensive use of Aristotelian arguments to secure assent to essential points in the Copernican theory. Perhaps the chief significance of Galileo's anti-Aristotelianism is its intimate relation to his consistent rejection of authority of any kind in matters of science. His unwillingness to accept any intermediary between himself and nature was the motivation of his bold warning to the church against the utilization of scriptural authority in scientific disputes. In short, Aristotle was not so much the philosophical opponent as the historical symbol in Galileo's unremitting battle against authority as a criterion of truth.

SEPARATION OF PHYSICS FROM PHILOSOPHY. Until Galileo's time, physical science (including theoretical astronomy) was regarded as a proper part of philosophy and was so taught in the universities. Aristotle's principles of motion supplied the axioms, and the science was purely deductive. Several of Galileo's predecessors had questioned those principles as being in apparent contradiction with experience; Galileo continued these attacks and undertook experimental investigations of the actual phenomena of motion. In this way he came upon some new results and sought principles from which both the old and new phenomena might be deductively established. If he was not entirely successful in this quest, that was not a matter of deep concern to him. René Descartes later criticized Galileo sharply for his investigation of physical effects without a prior knowledge of their causes, and Cartesian physics was made an integral part of Descartes's systematic philosophy. In the end, however, the example of Galileo, and not that of Descartes, was followed by scientists. Physics became first a distinct branch (the "natural philosophy" of Isaac Newton) and ultimately a separate discipline from philosophy. The philosophical effects of this separation have been enormous. The emphasis on physics that prevailed in philosophy at Galileo's time has vanished; in its place, the theory of knowledge has risen to preeminence in modern philosophy, where from time to time it has threatened to subordinate or even to expel metaphysics. It is very doubtful that this would have come about without the separation of physical researches from philosophical investigations, in which separation Galileo was the pioneer.

Nor was Galileo content merely to remove terrestrial physical phenomena from the realm of speculative philosophy. Telescopic observation suggested to him a direct analogy between terrestrial and celestial matter, a conception that was antagonistic to Aristotle's entire scheme. The mountainous character of the moon's surface refuted the axiom of perfect sphericity of celestial bodies; the appearance and disappearance of sunspots destroyed the axiom of celestial immutability and perfection. Galileo did not hesitate to attribute terrestrial qualities to all celestial bodies, thus laying the basis for physical astronomy, even though this had grave religious implications and challenged the traditional cosmological and cosmogonical assumptions of the Peripatetics, who dominated the philosophical thought of the time.

ABANDONMENT OF AUTHORITY

The age into which Galileo was born was one in which the power of authority was uppermost in every sphere of activity—political, religious, and philosophical. It was therefore virtually impossible to attack that power in one sphere without disturbing it in others. To Galileo it was clear that in matters of scientific investigation, authority as such could not be allowed any weight; observation, experiment, and reason alone could establish physical truth. Accordingly, he disputed the right of philosophers and theologians to exercise control over scientific investigations or even scientific theories. Confronted with almost overwhelming opposition in this dispute, he was compelled to adopt, if not to formulate systematically, an alternative criterion of truth that might have some hope of acceptance. In so doing he avoided the error of such philosophers as Bernardino Telesio and Francis Bacon, who in effect had called for reliance solely upon sensory evidence, for Galileo was well aware of the possibility of illusion or of misinterpretation. It appeared to Galileo that mathematics alone had the kind of certainty that could be completely trusted, and he took the position that only to the extent to which men can detect mathematical regularities in phenomena can they be certain they have reached the truth in physical matters: "Without mathematics, one wanders about in a dark labyrinth."

This dictum of Galileo's is often taken today as the expression of a fundamentally Platonic viewpoint, but there is no evidence that Galileo believed in a world of Platonic forms as distinguished from that of events. He appears to have been concerned with relationships rather

than essences, and it is in this sense that his mathematical conception of the world is to be taken. He expressly stated that the failure of a physicist to describe the real world was not the fault either of that world or of mathematics, but was merely a result of the limited competence of the physicist, analogous to the shortcomings of a merchant or an accountant who had failed to take into account the weights of the containers in computing the value of his merchandise. Galileo held that although we must be satisfied with limited objectives, we may achieve complete certainty with regard to them.

Galileo's battle for free inquiry, independent of the interference of authority, was, in his own time, doomed to defeat. Nevertheless, the practicability of his alternative criterion of truth gained him a substantial number of followers whose intelligent application of his suggestions was eventually beneficial not only to physical science, but to philosophy as well. The systematic search for solutions to physical problems within preestablished limits of inquiry, under the rule that the demands of sense data, reason, and mathematical interpretation must be simultaneously satisfied, led to the development of a body of dependable knowledge of the physical world that philosophers could no longer ignore in their speculations about underlying reality. At the same time, this complex criterion of physical truth gave rise to a more serious examination of epistemological problems that had been relatively neglected in previous ages of untrammeled speculative philosophy. "We must deal with the real world, and not one on paper," Galileo proclaimed in his *Dialogue.*

It should be noted that Galileo did not extend his demands beyond the domain of physical science. In order to reconcile his scientific position with his acceptance of religious authority, he distinguished sharply between the two uses of language, or even the two languages, of faith and science. This position was expounded at length in his *Letter to Christina* (1615, published 1636). Wherever natural phenomena are involved, the language of the Bible is to be interpreted by the findings of science, while the exposition of supernatural texts is to be left to theologians. This concept of duality of language was given an interesting extension in his *Two New Sciences*; the purely mathematical sections are written in Latin, while the physical and more general sections are in Italian. It is reasonable to assume that Galileo's attitude toward the difficult question of why mathematical relations prevail in physics, and indeed toward metaphysical questions in general, was similar to his expressed opinion with regard to supernatural assertions of any kind: that they were outside the domain of science.

OBJECTIVE AND SUBJECTIVE QUALITIES

It is well known that Galileo clearly set forth the distinction, later made into a fundamental principle by the philosophical empiricists, between primary and secondary qualities. In accordance with his conception that only mathematics afforded complete certainty, he believed that to the fundamental particles of matter one must attribute size, shape, number, and rate of motion; but that one is under no compulsion to invest them with color, sound, odor, and the like. This separation of subjective qualities from those capable of mathematical treatment was a decisive step in the removal of man from his traditionally central place in the entire scheme of things. It is also noteworthy that Galileo showed no interest whatever in pursuing an analysis of subjective (or secondary) qualities; he did not (as did Aristotle and Descartes) compose books on the mind, the spirit, or man in general. Thus, Galileo's treatment of this fundamental principle of empiricism is by no means indicative that he subscribed to an empiricist philosophy in the technical sense. His distinction of objective-subjective was simply an integral part of his separation of physics from philosophy; and if it had any metaphysical implications, they were lost to Galileo. The source of inspiration for this fundamental notion was certainly Greek atomism; but if any classifiable system of philosophy is to be found in Galileo's own writings, it is that of naive realism—a recurrent theme in physical science and the philosophy of science from Galileo's time through the nineteenth century.

Highly important philosophically in Galileo's physical investigations was his insistence on the doctrine of relativity of motion. On the one hand, this removed Earth from its privileged position in astronomy, and in this regard was little more than an extension of the Copernican revolution. On the other hand, it began a new revolutionary movement in which the investigation of natural laws as mathematical relationships was to replace traditional inquiries into the natures or essences of physical entities. Thus, the way was opened to a coherent science of dynamics, while the accepted world view based on the doctrine of "natural places" was rendered untenable.

SKEPTICISM AND THE SCIENTIFIC METHOD

It is worth noting briefly that Galileo introduced (or rather reintroduced) into Western philosophy certain traditions of skepticism which had lapsed during the reign of authority. He often said that it was easier for him to determine that something was false than to discover the

truth of any matter, and he openly contended that it was less shameful to be ignorant than to argue on the wrong side. He was accustomed to advise his pupils freely and candidly to confess "I do not know" rather than to offer merely verbal explanations. Thus, among his followers it became once more respectable for a philosopher to acknowledge ignorance. The effects of this were very noticeable in the activities of his disciples and in the Galilean school they created. Establishment of the first great experimental scientific society, the Academy of the Cimento, with its motto of "Test and test again," would scarcely have been possible before Galileo. It was his habit to stress the infinite amount that must remain unknown, no matter how deeply one might penetrate into any subject of inquiry.

METHODOLOGICAL VIEWS. Galileo's philosophical importance is nowhere clearer than in his contributions to the method of scientific investigation. His suggestions and his example in this field laid the basis for procedures in physical science that have enriched epistemology as much as science itself. Yet Galileo's conceptions of scientific method, like his other philosophic views, make their appearance in his books only implicitly and incidentally to other considerations. They are first apparent in his polemic work on floating bodies (1612), in which experiments are designed for and applied to the refutation of verbal explanations and arguments. This book marked a definite epoch in the philosophy of science, inasmuch as it is perhaps the first systematic exposition of physical experiments specifically designed to refute a philosophical position. In classical form, it presents the Peripatetic theory and Galileo's countertheory, with a set of experimental tests to show the falsity of the former and the truth of the latter. Although methodological considerations are not discussed in the abstract, the work is a model of the "experimental philosophy" carried on by the school of Galileo.

The work on sunspots published in the following year is also rich in methodological material; here Galileo destroyed the arguments of his anonymous Jesuit adversary by establishing the analogy of terrestrial phenomena to solar phenomena and by applying mathematical reasoning to the problem of the location of the spots. In this instance the use of experiment was precluded by inaccessibility of the phenomena, but observational data were correctly applied in its stead. It thus constituted a methodological continuation of the book on floating bodies, although the points at issue were in this case strictly scientific and not philosophical, at least in modern terms. Particularly noteworthy are certain semantic critiques directed against arguments based upon purely verbal deductions made by Galileo's adversary in this controversy.

Because of the prohibition against discussion of Copernicanism, ten years elapsed before the publication of Galileo's next acknowledged work, *The Assayer,* which differed markedly from his earlier works. Ostensibly a polemic over the nature of comets, it was in reality a detailed critique of the then prevailing treatment of astronomical phenomena. Instead of adopting a specific theory of comets, Galileo undertook to refute his opponent by showing that all his arguments depended upon assumptions that could not be demonstrated or upon confusions of a linguistic character. It is probable that he was motivated at least in part by a desire to place in the hands of his readers a method by which they might themselves arrive at conclusions that he had been forbidden to advocate. Among the principal themes of this work are the proper and improper use of observation and experiment, the distinction between primary and secondary qualities, the necessity for clarification of language in dealing with physical concepts, and the infinite scope of natural phenomena.

In his ill-fated *Dialogue* of 1632, Galileo developed the last-named theme at length. It was his view that physical truths are boundless in number but perfectly consistent; that human knowledge at any time can comprise but a finite part of this infinite whole; that sense experience, indispensable though it is to a knowledge of the world, can be deceptive or misleading in any given instance. Thus, the concept of physical science as essentially a process of successive approximations is already implicit in the teachings of Galileo. At each stage of inquiry, sense experience must be combined with reasoning and with mathematics to afford a sound basis of deduction. Galileo noted that the method used in proof is rarely the same as that used in making a discovery, and held that unless the proof is mathematical, it lacks absolute certainty.

The *Two New Sciences* of 1638, Galileo's chief contribution to physics, was of less direct philosophical importance. Its indirect importance lies in the fact that it definitively established physics as a distinct discipline on the basis of its own methods of investigation, methods that have persisted virtually unchanged. Of particular importance to later philosophical developments were the introduction in this work of the concept of one-to-one correspondence in the analysis of the arithmetical infinite and Galileo's suggestions relating to the roles of physical and mathematical indivisibles in the explanation of observable phenomena.

In conclusion, it should be observed that a profound difference existed between the methods by which Galileo and his contemporary, Johannes Kepler, applied mathematical reasoning to physical science, particularly to astronomy. Kepler's thought was pervaded by the conviction that numerical relationships determined the structure of the universe in the sense of Pythagorean mysticism. Accordingly he attempted, repeatedly, to deduce that structure from a priori numerical hypotheses. As a result, he was early led into fantastic speculations from which he was sometimes able to extricate himself only after years of labor. Galileo, on the other hand, regarded mathematics as an indispensable practical tool and as the definitive test in the quest for physical certainty; but he was not inclined to follow wherever mathematical deduction might lead. His errors, unlike Kepler's, are usually to be found in attempts to create mathematical proofs for physical laws of which he had previously made certain, in the desire to achieve the unique degree of certainty that he ascribed to mathematical demonstration.

GALLUPPI, PASQUALE
(1770–1846)

Pasquale Galluppi, the Italian epistemologist and moral philosopher, was born in Tropea, Calabria. He began the study of law in Naples but soon switched to theology and philosophy. At first Galluppi was strongly influenced by Christian Wolff. In 1800 he began to read Étienne Bonnot de Condillac and John Locke, and his first published work, *Sull'analisi e sulla sintesi* (On analysis and synthesis; Naples, 1807), was an attack on sensationalism. From 1807 until 1815 Galluppi studied Immanuel Kant. Although he was strongly attracted by Kantianism, he finally rejected it as "skepticism," and, through an exami-

nation of René Descartes and Locke, he arrived at a position strongly resembling that of the Scottish commonsense school as it had been interpreted by the French eclectics.

The publication in 1819 of the first volume of his *Saggio filosofico sulla critica della conoscenza* (Philosophical essay on the critique of knowledge; 6 vols., Naples, 1819–1823) brought Galluppi widespread recognition. Between 1820 and 1827 he published his best-known works: the *Elementi di filosofia* (4 vols., Messina, 1820–1827), in which he expounded his theories, and the *Lettere filosofiche sulle vicende della filosofia relativamente ai principî delle conoscenze umane da Cartesio sino a Kant inclusivamente* (Philosophical letters on the events in philosophy concerning the principles of human knowledge from Descartes to Kant inclusive; Naples, 1838), a remarkable history of human thought. In October 1831 Galluppi was named professor of philosophy at the University of Naples. He corresponded with Victor Cousin, whose *Fragments philosophiques* he translated into Italian (2 vols., Naples, 1831–1832), and in 1838 he was named foreign correspondent of the Academie des Sciences Morales et Politiques.

Galluppi held that the only method of philosophy is analysis, a regressive movement in which reflective thought goes back over its own development. The starting point is consciousness: The existence of the conscious ego is "an original experimental truth" and an immediate intuition. The conscious ego consists in the immediate apprehension which the existing ego has of itself. This apprehension simultaneously produces apprehension of the object (which is sensation) and apprehension of the subject that perceives the object (which is feeling). Galluppi expressed this originating act in the formula "I feel (*sento*) a me which senses (*sente*) something" outside of me. Consciousness, in other words, is the awareness that the ego has of itself and of a separate, independently existing reality. On the basis of this indisputable testimony of consciousness Galluppi proclaimed the reality of both the ego and things, in opposition to George Berkeley's idealism and David Hume's analyses.

Using the same procedure, and by means of the evidence provided by internal consciousness, Galluppi found in the ego the universal ideas which had been denied by the empiricists: these ideas are proved by inner experience, which affirms the existence of God and, by revealing that the conscious ego can only be the effect of a divine intelligent cause, invariable and absolute, also attests the validity of causal relations. True knowledge, knowledge that is adequate to reality, consists in rear-ranging, by a real synthesis, the objective unities of beings just as they are. The existence of God, proved in the same way that Descartes did, by means of consciousness ("I think, therefore I am; therefore God exists"), proves that the self-evident relationships are valid. (This last argument differs from the Cartesian principle of divine truth.)

Galluppi adhered to the same theory in moral philosophy. In moral philosophy also it is the testimony of consciousness that tells us we are free and that makes us feel the necessity of moral good and thus the presence of a natural moral law: Our duty is affirmed to us by our innermost sense.

GAME THEORY

GAMES OF COMPLETE INFORMATION

A game is an abstract, formal description of a strategic interaction. Any strategic interaction involves two or more decision makers (players), each with two or more

ways of acting (strategies), such that the outcome depends on the strategy choices of all the players. Each player has well-defined preferences among all the possible outcomes, enabling corresponding utilities (payoffs) to be assigned. A game makes explicit the rules governing players' interaction, the players' feasible strategies, and their preferences over outcomes. Game theory describes games by means of mathematical concepts (e.g., sets, functions, and relations).

NORMAL FORM. A possible representation of a game is in normal form. A normal form game is completely defined by three elements that constitute the structure of the game: a list of players $i = 1, \dots , n$; for each player i; a finite set of pure strategies S_i; and a payoff function u_i that gives player i's payoff $u_i(s)$ for each n-tuple of strategies $(s_1, \dots , s_n)$, where u_i: $\underset{j=1}{X} S_j \rightarrow R$. A player may choose to play a pure strategy or instead to randomize over his or her pure strategies; a probability distribution over pure strategies is called a mixed strategy and is denoted by σ_i. Each player's randomization is assumed to be statistically independent of that of his or her opponents, and the payoffs to a mixed strategy are the expected values of the corresponding pure strategy payoffs. A different interpretation of mixed strategies, based on the idea that players do not always randomize over their feasible actions, is that the probability distribution σ_i represents other players' uncertainty about what player will do. A mixed strategy is thus thought of as other players' conjecture about a player's plans of action. The conjectures depend on the player's private information, which is left unspecified in the model. A problem with this interpretation is that if there are reasons behind the choices a player makes, they should be included in the model, since they are likely to be payoff relevant.

The two-by-two matrix in Figure 1 depicts the two-player normal form representation of the famous Prisoner's dilemma game, where C stands for *cooperate* and D for *defect*. The numbers in the cell of the matrix denote players' payoffs: the first number is the payoff for the row player, the second for the column player. Each player picks a strategy independently, and the outcome, represented in terms of players' payoffs, is the joint product of these two strategies. Notice that in the game of Figure 1, each player is better off defecting no matter what the other player does. For example, if the column player cooperates, the row player gets a payoff of 3 by defecting and a payoff of 2 by cooperating, while if the column player defects, the row player gains a payoff of 1 by defecting and of 0 by cooperating. When, regardless of what other players do, a strategy yields a player a (strictly) infe-

rior payoff than some other strategy, it is called a *dominated strategy*. When a strategy yields the same payoff of another undominated strategy, but it has an inferior payoff against at least one opponent's strategy, it is called a *weakly dominated strategy*.

The game of Figure 1 is one of complete information, in that the players are assumed to know the rules of the game (which include players' strategies) and other players' payoffs. If players are allowed to enter into binding agreements before the game is played, one can say that the game is cooperative. Noncooperative games instead make no allowance for the existence of an enforcement mechanism that would make the terms of the agreement binding on the players. What strategies should rational players choose? What could be rightly called the central dogma of game theory states that rational players will always jointly maximize their expected utilities, or play a Nash equilibrium (compare Nash 1996). Informally, a Nash equilibrium specifies players' actions and beliefs such that (1) each player's action is optimal given his or her beliefs about other players' choices; (2) players' beliefs are correct. Thus, an outcome that is not a Nash equilibrium requires either that a player chooses a suboptimal strategy or that some players misperceive the situation.

More formally, a Nash equilibrium is a vector of strategies $(\sigma^*_1, \dots , \sigma^*_n)$, one for each of the n players in the game, such that each σ^*_i is optimal given (or is a best reply to) σ^*_{-i}. That is

$$u_i(\sigma^*_i, \sigma^*_{-i}) \geq u_i(\sigma_i, \sigma^*_{-i}) \text{ for all mixed strategies of player } i \ \sigma_i$$

Note that optimality is only conditional on a fixed? σ_{-i}, not on all possible σ_{-i}. A strategy that is a best reply to a

given combination of the opponents' strategies may fare poorly vis-à-vis another strategy combination.

In a game like the one depicted in Figure 2 the row player gains a payoff of 1 if the toss of two coins results in two heads or two tails and loses 1 otherwise, and vice versa for the column player.

This game has no Nash equilibrium in pure strategies. Nash proved that—provided certain restrictions are imposed on strategy sets and payoff functions—every game has at least one equilibrium in mixed strategies. In a mixed strategy equilibrium, the equilibrium strategy of each player makes the other indifferent between the strategies on which he or she is randomizing. In particular, the game in Figure 2 has a unique Nash equilibrium in which both players randomize between their strategies with probability ½. Then, if the first player plays $\sigma_1 = (\frac{1}{2}$ H, ½ T), his or her expected payoff is $\frac{1}{2} \cdot 1 + \frac{1}{2} \cdot -1 = 0$ regardless of the strategy of the second player.

The players (and the game theorist) can predict that a specific equilibrium will be played just in case they have enough information to infer players' choices. The standard assumptions in game theory are:

CK1. The structure of the game is common knowledge

CK2. The players are rational (i.e., they are expected utility maximizers) and this is common knowledge

The concept of common knowledge was introduced by David K. Lewis (1969) in his study on convention, which is arguably the first major philosophical work in which game theory plays a central role as a modeling tool. Simply put, the idea of common knowledge is that a certain proposition p is common knowledge among two players if both of them know p, both of them know that they know p, and so on ad infinitum. The previous assumptions may allow the players to predict an opponent's strategy. For example, in the prisoner's dilemma

game of Figure 1 rational players would never choose the strictly dominated strategy C. CK1 and CK2, then, allow the players to predict that the opponent will play D. However (compare Bicchieri 1993), the previous CK assumptions do not always guarantee that a prediction of play can be made. For one, even if the game has a unique equilibrium, the set of strategies that, under the assumptions CK1 and CK2, players may choose need not contain the equilibrium strategies only. Moreover, predictability is hampered by another common problem encountered in game theory: multiple Nash equilibria.

Suppose two players have to divide $100 among them. They must restrict their proposals to integers, and each has to independently propose a way to split the sum. If the total proposed by both is equal or less than $100, each gets what he or she proposed, otherwise they get nothing. This game has 101 Nash equilibria. Is there a way to predict which one will be chosen? In real life, many people would go for the fifty-fifty split. It is simple and it seems equitable. In Thomas C. Schelling's (1960) words, it is a focal point. Unfortunately, mere salience is not enough to provide a player with a reason for choice. In this example, only if it is common knowledge that the fifty-fifty split is the salient outcome does it become rational to propose $50. Game theory, however, filters out any social or cultural information regarding strategies, leaving players with the task of coordinating their actions on the sole basis of common knowledge of rationality (and of the structure of the game).

A different approach to the problem of indeterminacy is to start by considering the set of Nash equilibria and ask whether some of them should be eliminated because they are in some sense unreasonable. This is the approach taken by the refinement program (Kohlberg 1990, van Damme 1987). Consider the game in Figure 3:

The game has two Nash equilibria in pure strategies: (*a,c*) and (*b,d*). The equilibrium (*a,c*) is *Pareto dominant*,

since it gives both players a higher payoff than any other equilibrium in the game. However, common knowledge of rationality and of the structure of the game does not force the column player to expect the row player to eliminate the weakly dominated strategy *b*, nor is the row player forced to conclude that the column player will discard *d*. Prudence, however, may suggest that one should never be too sure of the opponents' choices. Even if the players have agreed to play a given equilibrium, some uncertainty remains. If so, one should try to model this uncertainty in the game. R. Selten's (1965) insight was to treat perfect rationality as a limit case. His "trembling hand" metaphor presupposes that deciding and acting are two separate processes, in that even if one decides to take a particular action, one may end up doing something else by mistake. An equilibrium strategy should be optimal not only against the opponents' strategies but also against some small probability $\epsilon > 0$ that the opponents make mistakes. Such an equilibrium is *trembling-hand perfect*.

Is the equilibrium (*b,d*) perfect? If so, *b* must be optimal against *c* being played with probability ϵ and *d* being played with probability $1 - \epsilon$ for some small $\epsilon > 0$. But in this case the expected payoff to *a* is 2ϵ whereas the payoff to *b* is?. Hence for all $\epsilon > 0$, *a* is a better strategy choice. The equilibrium (*b,d*) is not perfect, but (*a,c*) is. Therefore, a prudent player would discard (*b,d*). In this simple game, checking perfection is easy, since only one mistake is possible. With many strategies, there usually are many more possible mistakes to take into account. Similarly, with many players one may need to worry about who is more likely to make a mistake.

EXTENSIVE FORM. A different representation of a game is the *extensive form*. It specifies the following information: a finite set of players $i = 1, \ldots , n$; the order of moves; the players' choices at each move; and what each player knows when he or she has to choose. The order of play is represented by a game tree *T*, which is a finite set of partially ordered nodes $t \in T$ satisfying a precedence relation $<$. A *subgame* is a collection of branches of a game such that they start from the same node and the branches and the node together form a game tree by itself. A tree representation is sequential, because it shows the order in which actions are taken by the players. It is natural to think of sequential-move games as being ones in which players choose their strategies one after the other, and of simultaneous-move games as ones in which players choose their strategies at the same time. What is important, however, is not the temporal order of events per se, but whether players know about other players' actions when they have to choose their own. In the normal form representation, players' information about other players' choices is not represented. This is the reason a normal form game could represent any one of several extensive form games. When the order of play is irrelevant to a game's outcome, then restricting oneself to the normal form is justifiable. When the order of play is relevant, however, the extensive form must be specified.

In an extensive form game the information a player has when he or she is choosing an action is explicitly represented using information sets, which partition the nodes of the tree. If an information set contains more than one node, the player who has to make a choice at that information set will be uncertain as to which node he or she is at. Not knowing at which node one is means that the player does not know which action was chosen by the preceding player. If a game contains information sets that are not singletons, the game is one of *imperfect information*.

A strategy for player *i* is a complete plan of action that specifies an action at every node at which it is *i*'s turn to move. Note that a strategy specifies actions even at nodes that will never be reached if that strategy is played. Consider the game in Figure 4. It is a finite game of perfect information in which player 1 moves first. If he chooses *D* at his first node, the game ends and player 1 nets a payoff of 1, whereas player 2 gets 0. But choosing *D* at the first node is only part of a strategy for player 1. For example, it can be part of a strategy that recommends "play *D* at your first node, and *x* at your last node." Another strategy may instead recommend playing *D* at his first node, and *y* at his last decision node. Though it may seem surprising that a strategy specifies actions even at nodes that will not be reached if that strategy is played, one must remember that a strategy is a full contingent plan of action. For example, the strategy *Dx* recommends playing *D* at the first node, thus effectively ending the game. It is important, however, to be able to have a plan of action in case *D* is not played. Player 1 may, after all, make a mistake and, because of player 2's response, find himself called to play at his last node. In that case, having a plan helps. Note that a strategy cannot be changed during the course of the game. Though a player may conjecture about several scenarios of moves and countermoves before playing the game, at the end of deliberation a strategy must be chosen and followed throughout the game.

The game of Figure 4 has two Nash equilibria in pure strategies:(*Dx,d*) and (*Dy,d*). Is there a way to solve the indeterminacy?

Suppose player 1 were to reach his last node. Since he is by assumption rational, he will choose *x*, which guar-

FIGURE 4
antees him a payoff of 4. Knowing (by assumption) that player 1 is rational, player 2—if she were to reach her decision node—would play *d*, since by playing *a* she would net a lower payoff. Finally, since (by assumption) player 1 knows that player 2 is rational and that she knows that player 1 is rational, he will choose *D* at his first decision node. The equilibrium (*Dy,d*) should therefore be ruled out, since it recommends an irrational move at the last node. In the normal form, both equilibria survive. The reason is simple: Nash equilibrium does not constrain behavior out of equilibrium. In this example, if player 1 plans to choose *D* and player 2 plans to choose *d*, it does not matter what player 1 would do at his last node, since that node will never be reached.

The sequential procedure one has used to conclude that only (*Dx,d*) is a reasonable solution is known as backward induction. In finite games of perfect information with no ties in payoffs, backward induction always identifies a unique equilibrium. The premise of the backward induction argument is that mutual rationality and the structure of the game are common knowledge among the players. It has been argued by Ken Binmore (1987), Cristina Bicchieri (1989, 1993), and Philip J. Reny (1992) that under certain conditions common knowledge of rationality leads to inconsistencies. For example, if player 2 were to reach her decision node, would she keep thinking that player 1 is rational? How would she explain player 1's move? If player 1's move is inconsistent with common knowledge of rationality, player 2 will be unable to predict future play; as a corollary, what constitutes an optimal choice at her node remains undefined. As a consequence of the previous criticisms, the usual premises of backward induction arguments have come to be questioned (compare Pettit and Sugden 1989, Basu 1990, Bonanno 1991). There are a number of further equilibrium refinements for games in extensive form. Their multiplicity makes it impossible to delve into details here. The interested reader can consult Bicchieri (1993, chapter 3).

In games of incomplete information certain elements of the game are not common knowledge among the players. The knowledge and beliefs of the players have to be incorporated into the game-theoretic model, as one usually does in extensive form games, and an appropriate equilibrium concept has to be devised. The approach is based on the seminal work of John C. Harsanyi (1968). In the Bayesian approach adopted by Harsanyi, a player's uncertainty about variables that are relevant for his or her decision ought to be made explicit by means of probability distributions representing his or her beliefs. Moreover, second-order beliefs (beliefs about other players' beliefs) can be represented by further probability distributions, and third-order beliefs about second-order ones, and so on. The flexibility of Harsanyi's model allows one to incorporate all such infinite sequence of higher-order beliefs without an explicit representation of it.

The main idea is that the payoffs associated to each strategy profile depend on certain parameters $\theta_1, \ldots, \theta_n$, one for each player $1, \ldots, n$. Each parameter is drawn from a set $\Theta_i = (a_i, b_i, \ldots)$ associated with each player i. The composition of the sets Θ_i is known, yet the true value of the parameter θ_i is not (at least for one of the players). The parameter θ_i is called *i*'s type and the set Θ_i represents, intuitively, the other player's ignorance about *i*'s characteristics. A type amounts to a specification of certain variables: a player's strategy set, a player's preferences and payoff function, and so on, that make up the private information of a player. Although it is convenient to refer to "the type a_i of player *i*" as if it was a separate individual, one should keep in mind that types represent players' knowledge (and uncertainty about others) only. As mentioned earlier, in a Bayesian approach uncertainties are represented by probability distributions. Hence, each player has an initial probability distribution $\mu_i = (\mu_i (a_{-i}), \mu_i (b_{-i}), \ldots)$ over the types of any other player other than i. Since in a Bayesian game the choices of a player depend on his or her type, the concept of Nash equilibrium has to be generalized accordingly.

Note that all that a player knows, except from the game itself (and the priors), is his own type, and the fact that the other players do not know his own type as well. As their best responses depend on the players' actual types, a player must see himself through his opponents' eyes and plan a best reply against the possible strategies of his opponents for each potential type of his own. Thus, a strategy in a Bayesian game of incomplete information must map each possible type of each player into a plan of

actions. Then, since the other players' types are unknown, each player forms a best reply against the expected strategy of each opponent, where he averages over the (well-specified) reactions of all possible types of an opponent, using his prior probability measure on the type space. Such a profile of type-dependent strategies which are unilaterally unimprovable in expectations over the competing types' strategies forms a Bayesian Nash equilibrium. In other words, a Bayesian Nash equilibrium is a Nash equilibrium "at the interim stage" where each player selects a best response against the average best responses of the competing players.

In the framework provided by Harsanyi (1968) it is possible to reduce a game of incomplete information to one of imperfect information. "Nature" is called to make the first move of the game, as if it was an actual player. Nature's random moves determine the type of each player, with a fixed probability that represents the prior probability attached to the events that player i is of type θ_i. Priors are assumed to be common knowledge, and players observe their own type only. Players then pick their strategies in this extended game, and it is possible to show that the equilibrium of such a game corresponds to the Bayesian Nash equilibrium of the game with incomplete information. In particular, the choice function s_i yields the action $\sigma_i(\theta_i)$ if and only if (iff) that is the action that player i chooses in the game with Nature when she observes her type θ_i.

EPISTEMIC FOUNDATIONS OF GAME THEORY

An important development of game theory is the so-called epistemic approach. In the epistemic approach to game theory strategic reasoning is analyzed on the basis of hypothesis about what players know about the game, about other players' knowledge, and about other players' rationality. Since Robert J. Aumann's (1976) formalization, the idea of common knowledge, and the analysis of what players choose depending on what their beliefs about each other are, began to play an increasingly important role in game theory. In particular, one can evaluate solution concepts by examining the epistemic assumptions and hypotheses from which they can be derived (compare Battigalli and Bonanno 1999). Such epistemic hypotheses are treated formally using the tools provided by interactive epistemology (compare Aumann 1999).

To formalize players' knowledge states, one considers a space set Ω whose elements are possible worlds. An event is then represented by a subset of Ω. For example,

the proposition "it is sunny in Philadelphia" is represented by the set of all possible worlds in which it is sunny in Philadelphia. For each player, there exists an information function that partitions the space set. Intuitively, a player cannot distinguish among worlds belonging to the same cell of his or her information partition. Thus, in a possible world ω, player i knows an event E iff the set E (of possible worlds in which E obtains) includes the cell of his or her information partition containing ω. The intuition behind this is that if a player cannot distinguish among all the worlds in which E is true, then he or she knows that E is the case. It is possible to define a knowledge function K_i for each player i so that, when given E as an argument, it returns as a value the set of those worlds such that, for each one of them, the cell of i's information partition that contains it is a subset of E. That is to say, K_iE is the event that i knows E.

By imposing certain conditions on the K_i's, one can force the epistemic functions to possess certain properties. For example, by requiring that K_iE be a subset of E, one requires that what players know is true, since in every possible world in which K_iE obtains, E obtains as well; similarly, by requiring that K_iK_iE be a subset of K_iE, one establishes that players know what they know, and by requiring that $Ki–KiE$ be a subset of $–K_iE$ that they know what they do not know (where – is the usual set-theoretical operation of complementation). The first condition is often referred to as the truth axiom, the second as the positive introspection axiom, and the third as the negative introspection axiom. Note that this setup has an equivalent formulation in terms of modal logics (compare Fagin et al. 1995, Meyer and van der Hoek 2004). To see the equivalence of the two approaches, consider that modal formulas express propositions whose semantic interpretation is given in terms of Kripke structures of possible worlds. It is then possible to establish a correspondence between formulas of the modal logic and events in the approach described earlier. In a Kripke model, then, an event corresponds to the set of those possible worlds that satisfy the formula expressing the proposition associated to that event.

Knowledge functions can be iterated, thus they can represent mutual and higher-order knowledge, and Aumann (1976) provides a mathematical definition of the idea of common knowledge in the setup sketched earlier. A proposition p is common knowledge between, say, two players i and j iff the set of worlds representing p includes the cells of i's and j's partitions meet that contain p, where the meet of two partitions is the finest common coarsening of them. An application of the definition is the

theorem proved in the same article, in which it is shown that if players have common priors, and their posteriors are common knowledge, then the posteriors are equal, even if the players derived them by conditioning on different information. Or, in other words, that one cannot "agree to disagree." As mentioned earlier, Aumann formalized Lewis's (1969) definition of common knowledge. However, it is currently debated whether Aumann's seminal definition is a faithful rendition of Lewis's informal characterization of common knowledge (compare Vanderschraaf 1998, Cubitt and Sugden 2003, Sillari 2005).

In such a framework it is possible to investigate which strategy profiles are compatible with certain epistemic assumptions about the players. For example, CK1 and CK2 imply that players would never choose strictly dominated strategies. The first contributions in this sense are David G. Pearce (1984) and B. Douglas Bernheim (1984), in which a procedure is devised to eliminate all the players' strategies that are not rationalizable, that is, not supported by internally consistent beliefs about other players' choices and beliefs. In general, it can be proved that certain epistemic conditions are only compatible with the strategy profiles yielded by a certain solution concept, hence providing an epistemic foundation for that solution concept. For example, Aumann and Adam Brandenburger (1995) proved that, for two-person games, mutual knowledge (i.e., first-order knowledge among all the players) of the structure of the game, of rationality, and of the players' chosen strategies implies.

CORRELATED EQUILIBRIUM. So far it has been assumed that players' strategies are independent, as though each player receives a private, independent signal and chooses a (mixed) strategy after having observed his or her own signal. However, signals need not be independent. For example, players can agree to play a certain strategy according to the outcome of some external jointly observed event, for example, a coin toss. If the agreement is self-fulfilling, in that players have no incentive to deviate from it, the resulting strategy profile is an equilibrium in correlated strategies or, in short, a correlated equilibrium (compare Aumann 1974, 1987). For any Nash equilibrium in mixed strategies, a correlation device can be set such that it generates a probability distribution over the possible outcomes of the game yielding such an equilibrium profile. Note, however, that the set of correlated equilibria of a game is much larger than the corresponding set of Nash equilibria. If the correlation signal is common knowledge among the players, one speaks of perfect correlation. However, players may correlate their strategies according to different signals (less

than perfect correlation). The idea is that players have information partitions whose cells include more than one possible outcome, since they ignore which signals are received by other players. To represent the fact that players receive different signals (i.e., they ignore which strategies will be chosen by other players), it is required that in every cell of the information partition of player i his or her strategy does not change. It is then possible to calculate the expected payoff of playing the strategy indicated by the correlation device versus the expected payoff obtained by playing a different strategy. If the players have no incentive to deviate from the indicated strategy, the profile yielded by the correlation device is an equilibrium. Correlation by means of private signals may generate outcomes more efficient than those obtained by playing a Nash equilibrium. An important philosophical application of correlated equilibrium is found by Peter Vanderschraaf (1998, 2001), in which conventions as defined by Lewis (1969) are shown to be correlated equilibria of coordination games.

EVOLUTIONARY GAME THEORY

A Nash equilibrium need not be interpreted as a unique event. If one thinks of it as an observed regularity, one wants to know by what process such an equilibrium is reached and what accounts for its stability. When multiple equilibria are possible, one wants to know why players converged to one in particular and then stayed there. An alternative way of dealing with multiple equilibria is to suppose that the selection process is made by nature.

Evolutionary theories are inspired by population biology (e.g., see Maynard Smith 1982). These theories dispense with the notion of the decision maker, as well as with best responses/optimization, and use in their place a natural selection, a "survival of the fittest" process (with mutations) to model the frequencies with which various strategies are represented in the population over time. In a typical evolutionary model players are preprogrammed for certain strategies and are randomly matched with other players in pairwise repeated encounters. The relative frequency of a strategy in a population is simply the proportion of players in that population who adopt it. The theory focuses on how the strategy profiles of populations of such agents evolve over time, given that the outcomes of current games determine the frequency of different strategies in the future.

As an example, consider the game in Figure 5 and suppose that there are only two possible behavioral types: hawk and dove.

A hawk always fights and escalates contests until it wins or is badly hurt. A dove sticks to displays and retreats if the opponent escalates the conflict; if it fights with another dove, they will settle the contest after a long time. Payoffs are expected changes in fitness due to the outcome of the game. Fitness here means just reproductive success (e.g., the expected number of offspring per time unit).

Suppose injury has a payoff in terms of loss of fitness equal to C, and victory corresponds to a gain in fitness B. If hawk meets hawk, or dove meets dove, each has a 50 percent chance of victory. If a dove meets another dove, the winner gets B and the loser gets nothing, so the average increase in fitness for a dove meeting another dove is $B/2$. A dove meeting a hawk retreats, so his or her fitness is unchanged, whereas the hawk gets a gain in fitness B. If a hawk meets another hawk, they escalate until one wins. The winner has a fitness gain B, the loser a fitness loss C. So the average increase in fitness is $(B − C)/2$. The latter payoff is negative, since one assumes the cost of injury is greater than the gain in fitness obtained by winning the contest. One can also assume that players will be randomly paired in repeated encounters, and in each encounter they will play the stage game of Figure 5.

If the population were to consist predominantly of hawks, selection would favor the few doves, since hawks would meet mostly hawks and end up fighting with an average loss in fitness of $(B − C)/2$, and $0 > (B − C/2)$. In a population dominated by doves, hawks would spread, since every time they meet a dove (which would be most of the time) they would have a fitness gain of B, whereas doves on average would only get $B/2$. Evolutionary game theory wants to know how strategies do on average when games are played repeatedly between individuals who are randomly drawn from a large population. The average payoff to a strategy depends on the composition of the population, so a strategy may do well (in terms of fitness) in an environment and poorly in another. If the frequency of hawks in the population is q and that of doves correspondingly $(1 − q)$, the average increase in fitness for the hawks will be $q(B − C)/2 + (1 − q)B$, and $(1 − q)B/2$ for the doves. The average payoff of a strategy in a given environment determines its future frequency in the population. In this example, the average increase in fitness for the hawks will be equal to that for the doves when the frequency of hawks in the population is $q = B/C$. At that frequency, the proportion of hawks and doves is stable. If the frequency of hawks is less that B/C, then they do better than doves and will consequently spread; if their frequency is larger than B/C, they will do worse than doves and will shrink.

FIGURE 5

dove/hawk	D	H
D	B/2, B/2	0, B
H	B, 0	(B-C)/2, (B-C)/2

Note that if $C > B$ then $(B − C)/2 < 0$, so the game in Figure 5 has two pure-strategy Nash equilibria: (H, D) and (D, H). There is also a mixed strategy equilibrium in which hawk is played with probability $q = B/C$ and dove is played with probability $(1 − q) = C − B/C$. If the game of Figure 5 were played by rational agents who choose which behavior to display, one would be at a loss in predicting their choices. From common knowledge of rationality and of the structure of the game, the players cannot infer that a particular equilibrium will be played. In the hawk-dove example, however, players are not rational and do not choose their strategies. So if an equilibrium is attained it must be the outcome of some process very different from rational deliberation. The process at work is natural selection: High-performing strategies increase in frequency whereas low-performing strategies' frequency diminishes and eventually goes to zero.

One has seen that in a population composed mostly of doves, hawks will thrive, and the opposite would occur in a population composed mainly of hawks. So for example, if hawks dominate the population, a mutant displaying dove behavior can invade the population, since individuals bearing the dove trait will do better than hawks. The main solution concept used in evolutionary game theory is the evolutionarily stable strategy (ESS) introduced by John Maynard Smith and George R. Price (1973). A strategy or behavioral trait is evolutionarily stable if, once it dominates in the population, it does strictly better than any mutant strategy, and hence it cannot be invaded. In the hawk-dove game, neither of the two pure behavioral types is evolutionarily stable, since each can be invaded by the other. One knows, however, that a population in which there is a proportion $q = B/C$ of hawks and $(1 − q) = C − B/C$ of doves is stable. This means that the type of behavior that consists in escalating fights with

probability $q = B/C$ cannot be invaded by any other type, hence it is an ESS. An ESS is a strategy that, when it dominates the population, is a best reply against itself. Therefore, an evolutionarily stable strategy such as $(B/C, C − B/C)$ is a Nash equilibrium. Though every ESS is a Nash equilibrium, the reverse does not hold; in our stage game, there are three Nash equilibria, but only the mixed strategy equilibrium $(B/C, C − B/C)$ is an ESS.

Evolutionary games provide one with a way of explaining how agents that may or may not be rational and—if so—subject to severe information and calculation restrictions, achieve and sustain a Nash equilibrium. Philosophical implications and applications can be found in the works of Brian Skyrms (1990, 1996, 2004). When there exist evolutionarily stable strategies (or states), one knows which equilibrium will obtain, without the need to postulate refinements in the way players interpret off-equilibrium moves. Yet we need to know much more about processes of cultural transmission and to develop adequate ways to represent payoffs, so that the promise of evolutionary games is actually fulfilled.

GARRIGOU-LAGRANGE, RÉGINALD MARIE
(1877–1964)

Réginald Marie Garrigou-Lagrange notably influenced the revival of Thomism in some European and American philosophical circles. He was born Gontran-Marie Garrigou-Lagrange at Auch, France. His first university studies were in the faculty of medicine at the University of Bordeaux. After two years, however, he chose to embrace the priesthood and on May 20, 1900, made his profession as a Dominican, receiving the name Réginald Marie.

In addition to the regular course of philosophy as a Dominican, he pursued graduate studies at the Sorbonne, where he had the opportunity to attend the lectures of Henri Bergson. In 1909 Garrigou-Lagrange entered into what proved to be a long career as professor at the international university of philosophical and theological studies in Rome, now called the Universitas Studiorum Pontificia S. Thomae Aquinatis in Urbe. He remained in this position until 1959. Although his courses were primarily in the theological faculty, it is significant that throughout his teaching life he lectured each week on the metaphysics of Thomas Aquinas. Garrigou-Lagrange was also a founding member of the Academia Pontificia Academia Romanae S. Thomae Aquinatis.

An accurate view of the philosophical thought of Garrigou-Lagrange must take into account the fact that he was not simply a philosopher; his professional labors as well as his writings are preponderantly theological. However, because his concern was with the teachings of Thomas Aquinas, his work has a philosophical import on two counts. First of all, the Thomistic theological synthesis is characterized by its employment of the speculative resources of human intelligence. In this concentration on theology, then, Garrigou-Lagrange necessarily devoted himself to the exposition of the basic Thomistic philosophical positions. Second, from the beginning of his career Garrigou-Lagrange was faced with a challenge to the relevance and the validity of Thomism, or indeed of any metempirical assertions of the human mind. It is to this challenge that his purely philosophical labors and writings are principally addressed.

His first book, *Le sens commun, la philosophie de l'être et les formules dogmatiques,* is a rejoinder to the position taken by Édouard Le Roy in a series of articles (*Revue de métaphysique et morale,* 1899–1901). Le Roy alleged all expressions of truth by the human mind to be totally relative, mutable, and conditioned. Human thought is simply the expression of de facto acceptations, significant according to that natural and subjective orientation of the human mind which for Le Roy is the *sens commun.* Against this Bergsonian usage, Garrigou-Lagrange used the term *sens commun* to designate the commonly assumed character of the human mind, namely, its extramental orientation toward objectively existent and intelligible reality. He set himself the task of vindicating this realism, of defending the objective validity and transcendental range of human thought.

The basic themes of his position are readily discernible. The human intelligence has "being" as its connatural object. In its attainment of being the human mind surpasses sense knowledge, goes beyond mere phenomena. The first principles of human reason—identity, contradiction, causality, and finality—are not mere subjective thought patterns; they are grounded in being. The human evaluation of the data of experience in virtue of such principles, then, has an ontological validity; the human mind is capable of assertions concerning the real that are objectively true and absolute. Because in its attainment of being the mind goes beyond mere phenomena, the principles of philosophical inquiry have a transcendental validity. Man is able, consequently, to achieve true judgments, not only about the entitative structure of experienced reality, but also about the nonexperienced but necessarily affirmed primary cause of the beings of experience. The connaturally realistic orientation of human intelligence, therefore, provides the capacity for objectively valid metaphysical evaluations of reality and even for a true natural theology.

Garrigou-Lagrange maintained that Thomas presented a philosophy of being that was an effectively enunciated and developed expression of the natural metaphysical orientation of human intelligence in which the *sens commun* has its scientifically articulated realization. Garrigou-Lagrange's principal philosophical contribution, then, was a forceful and clear exposition of the basic Thomistic insights. In his writings there is a clear and honest confrontation of Thomistic realism with both nominalist empiricism and Kantian subjectivism.

An evaluation of the work of Garrigou-Lagrange must place it in relation to the so-called Neo-Scholastic movement. Since his career began well after the early attempts to reassert Thomism, his writings are free of the alien influences present in the work of the restoration's pioneers. His chief concern, the basic critical problem of the validity of human intelligence, is a central issue in all Neo-Scholastic philosophy. In the light of subsequent developments among Neo-Scholastic philosophers, and even among Thomists, concerning the critical problem,

the approach of Garrigou-Lagrange may be designated as somewhat simplified. He strove to set forth directly the positive statements of a philosophy of being against a philosophy of becoming, to manifest the human mind as a faculty of truth, not an amasser or coordinator of data. Later Thomists have sought by more reflective methods to show how being manifests itself in the very process of cognition as the evidential justification of human knowledge. Their efforts are a refinement of the task to which the efforts of Garrigou-Lagrange were directed. His work, then, was a necessary stage in a vital development. Because of his dedication to the thought of Thomas, he directed that development to a more fruitful use of Thomas's understanding of the problems of being and intelligence.

GARVE, CHRISTIAN
(1742–1798)

Christian Garve, the German "popular philosopher," was born in Breslau. After studying at Frankfurt an der Oder, Halle, and Leipzig, he became extraordinary professor of philosophy at Leipzig in 1770, but in 1772 he resigned on account of ill health and moved to Breslau. In 1779 Frederick II called him to Charlottenburg, where he remained until his death.

Garve's interests were mainly in practical morality and empirical psychology. He sought useful knowledge and was averse to abstract speculation. He drew inspiration from Duc François de La Rochefoucauld and Claude-Adrien Helvétius, and especially from the British moralists. His translations of Adam Ferguson, Edmund Burke, Alexander Gerard, Adam Smith, and other British authors were important in popularizing British moral philosophy and aesthetics in Germany. He also translated and commented on the moral and political works of Aristotle and Cicero.

In his own writings Garve studied the individual characteristics and inclinations of different men, and their interrelation in society. He explained their differences by a difference in the degree of clarity and vividness of the ideas they possessed. Interest—the participation of an individual in the feelings, ideas, and actions of another—was a central notion in his psychology. It was derived from the "benevolence" and "sympathy" then current in British thought. In Garve's works psychology, sociology, and ethics were interwoven. His goal was that of a social psychologist, moralist, and educator. Immanuel Kant drew from Garve some elements of his moral and religious philosophy.

GASSENDI, PIERRE
(1592–1655)

Pierre Gassendi, the leading French seventeenth-century skeptical and Epicurean philosopher and scientist, was born at Champtercier, a Provençal village in France. He studied at Digne and Aix-en-Provence and was appointed professor of rhetoric at Digne at the age of twenty-one. In 1614 he received his doctorate in theology at Avignon. He was ordained a priest in 1616 and was appointed professor of philosophy at Aix. From 1617 to 1623 he lectured on Aristotle's philosophy, developing a forceful critique of it. His first published work, *Exercitationes Paradoxica Adversus Aristoteleos* (1624), was intended to be followed by six more parts, of which only the second part, published posthumously, was written. It contains both an attack on Aristotle's thought and portions of Gassendi's mitigated skepticism.

After a year in Digne, during which he performed various ecclesiastical duties, Gassendi visited Paris for a brief period in 1625 and became friendly with such avant-garde thinkers as Francois de La Mothe le Vayer and Marin Mersenne. He continued the astronomical researches that he had begun in Provence, and, with the mathematician Claude Mydorge (1585–1647), observed a lunar eclipse. Gassendi's careful astronomical records from 1618 to 1655 were published after his death. He also engaged in many scientific studies with his patron, Nicolas-Claude Fabri de Pieresc (1580–1637). His discovery of the perihelion of Mercury was an important support for the Copernican theory at the time.

Gassendi returned to Paris in 1628, remained there until August 1629, and then spent nine months in Flanders and Holland, where he met many leading scientists and scholars. He spent the next years partly in Paris and partly in Provence, publishing scientific works on astronomy and physics and presenting skeptical attacks on Herbert of Cherbury and the Rosicrucian Robert Fludd. He undertook an intensive study of Epicurean atomism, a subject in which he had been interested for some time. The results of this study were to form a basic part of his later writings.

In 1634 Gassendi was elected provost of the Cathedral of Digne. In 1641 he was sent to the assembly of the French clergy in Paris and during this visit taught philosophy to the young Molière (1622–1673). Gassendi was appointed to the chair of mathematics at the Royal College (now the Collège de France) in 1645, but because of ill health he was away from his post from 1648 to 1653. He fell ill in 1654 and died the following year.

Except for his early attacks on Aristotelianism, Fludd's Rosicrucianism, and Herbert of Cherbury, Gassendi's philosophical works date from the 1640s onward. In 1641, at the request of Mersenne, Gassendi wrote his objections to René Descartes's *Méditations* ("Fifth Set of Objections"). Descartes's testy answer led Gassendi to expand his criticism into the bulky *Disquisitio Metaphysica*, finished in 1642 and published in Amsterdam in 1644. He published three works on Epicurus and his philosophy between 1647 and 1649: *De Vita et Moribus Epicuri* (1647), *Animadversiones in Decimum Libri Diogenis Laertii, qui est de Vita, Moribus Plascitisque Epicuri* (1649), and *Syntagma Philosophiae Epicuri, cum Refutationibus Dogmatum, Quae Contra Fidem Christianum ab eo Asserta Sunt* (1649). His most important philosophical writings appeared only posthumously, in the 1658 edition of his complete works. His overall treatment of philosophical problems appears in *Syntagma Philosophicum* (*Opera*, volumes 1 and 2) and in the second part of his first work, the *Exercitationes*, which presents his constructive or mitigated skepticism.

EXERCITATIONES

Gassendi's thought developed from a fairly thoroughgoing skepticism, strongly influenced by Sextus Empiricus, Michel Eyquem de Montaigne, Pierre Charron, and Francisco Sanches, to what he called a *via media* between skepticism and dogmatism. The *via media* involved both a fundamental epistemological skepticism and a hypothetical form of Epicurean atomism that was modified to eliminate those aspects of Epicurus's thought that conflicted with Christian doctrine. In the first part of the *Exercitationes* Gassendi, following in the tradition of Francesco Patrizi and Peter Ramus, tried to show all the erroneous or dubious aspects of Aristotelianism. The second part set forth an attack on all those who claimed to have discovered necessary and indubitable knowledge of the real nature of things. Our knowledge of the world, Gassendi insisted, comes only from sensory experience. We are unable to arrive at absolutely true first principles and real or essential definitions, since inductions from experience can never yield certain universal prepositions. No matter how much data are gathered, a negative instance may still turn up in the future. Even if we somehow managed to discover some genuine definitions and first principles, no further scientific knowledge about nature could be gained by employing syllogistic reasoning, since, as the Greek Pyrrhonists had shown, the truth of the premises of a syllogism depends on antecedent knowledge that the conclusion is true. Either the conclu-

sion is part of the evidence of the premises or the syllogism establishes nothing, since it is not known whether the premises are true.

In the concluding section Gassendi launched his strongest attack on the possibility of gaining necessary knowledge about the world. Using the arguments of the ancient skeptics, he tried to show that all that we can know is how things appear, not how they really are in themselves. We can know that honey seems sweet, but we cannot find out if it really is sweet. On the basis of appearances we cannot tell what the real nature of things must be that produces such effects on us. Sense experience varies too much to provide any means for determining what reality is like on the basis of what is perceived. We lack any means of reasoning from experience to what has caused it. We are not even able to establish any criterion of true knowledge. Hence, we can only conclude that nothing can be known about reality. However, in this early work Gassendi insisted that we can develop useful sciences about appearances. As long as we restrict our conclusions to the world of experience, we will neither come in conflict with divine truth, nor accept any dubious dogmatic theory about unperceived reality. Such theories, whether metaphysical or mathematical, are presumptuous conjectures that have no value whatsoever.

OBJECTIONS TO DESCARTES

In his middle period Gassendi challenged those who claimed to have discovered some means of knowing the real nature of things. He employed various skeptical arguments against Renaissance naturalists and against such leading "new philosophers" as Herbert of Cherbury and Descartes. Gassendi's two letters against Herbert's *De Veritate* (in which the latter claimed to have refuted skepticism) used arguments about diversity of experience and disagreements among individuals to counter Herbert's common notions and common consent theory. In the "Fifth Set of Objections" and the *Disquisitio Metaphysica*, Gassendi turned skeptical argumentation against Cartesianism. He tried to show that Descartes's method of doubt illustrated what the skeptics had claimed for centuries. Then Gassendi challenged Descartes's positive dogmatic conclusions. Gassendi contended that the vaunted Cartesian criterion of true knowledge (that of clarity and distinctness) was useless, since people often think that they clearly and distinctly perceive something and then turn out to be wrong. Hence, to employ this criterion, another criterion would be needed to determine when something really is clear and distinct and does not merely appear to be so. In addition, another criterion would be necessary to employ this second criterion, and so forth.

The culmination of Gassendi's attack, which Descartes called the objections of objections, was his posing the possibility that all knowledge, even if it were clear and distinct, might not be about anything outside of our minds. If this could be the case, then all the knowledge purported to be found by Descartes might be imaginary or fictitious. Descartes saw this suggestion as a fundamental challenge to his system and as a denial of the possibility of gaining knowledge about any reality other than our own thoughts. His reply consisted in refusing to take the objection seriously, since if one did, "it follows that there is nothing that we can in any way comprehend, conceive or imagine, that should be accepted as true, that is to say that we have to shut the door completely on reason, and be content to be monkeys, or parrots, and no longer men" (Descartes, *Oeuvres*, C. Adam and P. Tannery, eds. vol. IXA, 212).

MITIGATED SKEPTICISM

In his later writings Gassendi attempted to develop a mitigated skepticism that would show how we could possess worthwhile knowledge about the world of appearances and how a science of this world could be developed, using Epicurean atomism as a hypothetical model.

Gassendi's mature theory about our knowledge of the world appears in his *Syntagma Philosophicum*, published in 1658 after his death. The work is enormous, containing 1,600 folio pages, printed in double columns. It is divided into three general sections, the first dealing with logic and theory of knowledge, the second with the natural world, and the third with ethics. Because of his skepticism, Gassendi did not regard metaphysics as a serious subject and so he omitted it entirely from his book.

At the outset, Gassendi seeks to establish a way to knowledge that is between the doubts of the skeptics and the complete assurances of the dogmatists. Neither the view that we can know nothing nor the view that we can know everything is tenable. The skeptics admit that we can know how nature appears to us. But they deny that we can know more than this. On the contrary, the dogmatists claim that we can know the real nature of things, which are not apparent to us. This, Gassendi contends, is exaggerating the power of the human mind. However, between skepticism and dogmatism there is a third possibility, which has been called constructive or mitigated skepticism, an acceptance of the thesis that although in a fundamental sense we cannot gain certain knowledge of the nature of reality, we can nevertheless gain a type of

knowledge that we need have no reason to doubt and that will suffice to enable us to understand the world.

This limited knowledge is obtained first by accepting what is obvious to us, our sense experience, plus certain obvious conclusions from it, such as that things exist. Signs found in sense experience enable us to know about other matters not immediately obvious to the senses. The ancient Greek skeptics had admitted that, on the basis of the constant conjunctions found in experience, we could judge that certain things temporarily not apparent to us were the case, such as when we see smoke, we can judge that there is a fire. In addition, we are also able to judge, by means of our reasoning ability, that particular sense experiences indicate that the world has certain features, even though we are never able to perceive these features. Thus, we can judge from the appearance of sweat on the skin that it has pores.

Long before the invention of the telescope, Democritus was able to judge from the white color of the Milky Way that it is composed of an innumerable quantity of stars. This type of reasoning, which leads us to knowledge about the world, is based on a careful and cautious evaluation of our sense information by our reason, plus inferences, made from this information, based on careful reasoning and on certain general principles that we have learned from experience. The conclusions we reach in this way about the nature of the world are beyond doubt and are ultimately evaluated in terms of future information gained from experience (as in the case of the Milky Way) and from these conclusions in explaining the course of our experience. We do not discover the absolute truth in this way, but only a faint shadow of it. This faint shadow will turn out to be the most satisfactory scientific explanation that can be given of experience in terms of the hypothesis (confirmed by experience and reasoning) that the world is composed of atoms in motion.

In terms of this theory of knowledge Gassendi examines various logical systems, ancient and modern, to state the best method for attaining limited knowledge. Many of the classical devices, Gassendi finds, are practically useless. The philosophies of Francis Bacon and Descartes have serious defects, Gassendi claims. Our senses can err, and we cannot, no matter what we do, attain real knowledge of the inner nature of things. But a logical method that is based on sense information carefully analyzed on general, unquestionable principles gained from experience and careful reasoning, and constantly checked and verified, can serve as the instrument for attaining what truth is possible.

ATOMISM

According to Gassendi what we can know about the world consists of a modified form of the atomism of Epicurus, modified in terms of the science of the time and the religious principles Gassendi maintained that he accepted. (Whether Gassendi was a sincere Christian has been, and still is, debated among scholars.) After surveying and criticizing the views of various philosophers about the nature of the world, Gassendi offers as the most probable theory (but not as the necessarily true one) the view that the actual components of the universe are indivisible atoms, moving in empty space. The supposed atoms are assumed to have been eternally created by God, to have different shapes, and to be moving at different rates of speed. Gassendi did not want mathematically describable atoms, since he feared this would lead to some sort of mathematical metaphysics. His atoms had features like those of ordinary experience. The atoms collided and presumably the result of all the collisions is the world that we perceive. A mechanical model related to our experience can then allow us to find empirical laws, make predictions, and explain relationships between different kinds of phenomena. In so relating the phenomenal world to the atomic world, there is no longer any need for Aristotelian purposes.

Appealing to the recent findings of scientists such as Evangelista Torricelli (1608–1647) and Blaise Pascal, Gassendi insists that the essential feature of atoms is solidity. In addition, they have the properties of extension, figure, and weight. They are conceived of as having the kinds of configurations found in ordinary experience, like those of wagon wheels and houses, rather than mathematically describable sizes and shapes. Gassendi had a distrust of those who maintained that nature was to be described in mathematical terms, since he felt that they were probably advocating some type of Platonic metaphysical theory about the nature of reality.

God has created the atoms and given them an impulse to move downward. They move at different rates of speed, and for this reason they collide with one another. The collisions change the courses of the atoms, causing still further collisions, and so on. The various changes that take place in the world, both on the apparent and on the nonapparent level, can be accounted for by the movements of the atoms, their collisions, and their combinations. Thus, the real world is conceived as a mechanism made up of small moving parts, the atoms. The qualities and movements of the atoms suffice to account for changes in the real world and the way in which the world appears to us. The qualities that we per-

ceive, the colors, sounds, tastes, smells, and so on (the so-called secondary qualities), are not actually properties of real objects. Instead, they are the ways we perceive various atomic movements when they affect our sense organs.

Gassendi begins to modify his Epicurean theory when he discusses the cause of the movement of the atoms. He accepts the Scholastic thesis that the primary cause of motion is God. The evidence that God exists is the almost universal natural belief in a deity and the conclusion drawn from observing the order in the universe, namely, that there must be an orderer or designer of the world. That there are some atheists is dismissed by Gassendi as similar to the existence of blind people. That a few people lack the normal, natural human faculties and beliefs is no reason to doubt the reliability of the faculties and beliefs of the rest of humankind. Both the senses and our reasoning ability give us an adequate basis for accepting the view that there is a God.

One's conception of God is that of an omniscient and omnipotent being who is all-wise and all-good. He is the author and providential guide and cause of everything that exists and everything that happens in the world. Gassendi specifically rejects Epicurus's view that everything can be explained and accounted for solely in terms of the atoms and their motions. Where, he asks, do the atoms come from, and what makes them move? Furthermore, if the world were produced only by "the fortuitous concourse of atoms," why is it that the atoms never, by themselves, make a house, or a temple, or a book? Each of these seems to require a designer to organize the atoms in a specific way, and so does the universe in general.

Turning from physical events to mental ones, Gassendi attempts to give an atomic explanation of the nature of the soul. First, he exhibits his vast erudition by examining the opinions of many different ancient philosophers on the subject. Then he offers the theory that seemed most probable to him; namely, that the animal soul is a material object. Though we cannot see the soul, reason convinces us that it must exist. The various processes that occur in living beings, such as nutrition, sensation, and movement, could not take place were there not a soul. But what is the soul like? It is a tenuous material substance existing in the body. It is like a subtle fire, giving life to corporeal things somewhat as fire warms objects.

The human soul, however, is more complex than the animal soul, being composed of two parts. The first is the irrational soul, which is material and is like the soul of any other living thing. It accounts for the vegetative and sensitive processes that exist in man. This part of the

human soul comes to us from our parents. Besides this, we possess another feature of our souls, the rational element that, Gassendi insists, contrary to Epicurus's view, is not corporeal and is not derived from other human beings, but only from God. The rational part of our souls, which is responsible for our higher intellectual activities, is also immortal. Epicurus had argued for the mortality of the soul, but Gassendi strongly insists that only the animal soul is mortal. As evidence for his belief in the immortality of the rational soul, Gassendi contends that the fact that it is immaterial suffices to show that it is immortal. Furthermore, the universal agreement of humankind on this point is offered as another proof, as well as the view that the divine and just government of the world would seem to require human immortality for a proper system of rewards and punishments to function.

Gassendi apparently believed that there was no conflict between his atomism and his views about man and God. Hence, Catholicism could be compatible with a strictly material account of the natural world. And although Gassendi was a heliocentrist he tried to present his astronomical views in such a way that they did not conflict with those of the church in its condemnation of Galileo Galilei.

Gassendi's atomism was as complete a scientific theory as any other offered in the first half of the seventeenth century. It rivaled Descartes's. However, as science developed later on, Gassendi's picture was replaced by that of Isaac Newton and others. No important discoveries are attributed to Gassendi's great scientific program.

HUMAN PSYCHOLOGY

In his discussion of human psychology Gassendi presents a theory to explain how the various mental processes take place. This section culminates with an examination of the sources of all of our knowledge, which, to some extent, anticipates the views that appear in John Locke's *An Essay concerning Human Understanding* (1690).

The faculties of sensation and imagination are common to humans and animals. Gassendi even asserts that sensation occurs to some extent in plants and minerals. Sensation occurs by means of a physical process involving material particles affecting a sense organ and causing a sensation, which is a physical event in the brain. The faculty of the imagination, which includes the memory as well, operates on traces or remains of the physical sense impressions. These traces are conceived of as waves in the brain that are actuated by other motions in the body and then cause further movements in the brain, giving rise to sensations or feelings similar to the original sensation

that caused the wave. Much of the account offered by Gassendi is close to that presented by his contemporary, the materialistic philosopher Thomas Hobbes.

The imagination has three functions: apprehension, judgment, and reasoning. We can apprehend, as a result of the wave motions, the exact experiences and sensations that have occurred. Because of movements inside and outside us, the various waves can be agitated at later times, so that we can now be aware of what we experienced yesterday. Also, different features of different experiences can be apprehended at the same time, giving rise to apprehensions of objects that have never, as such, been experienced. Thus, for example, our apprehension of a centaur results from our previous sense experience of a horse and a man, plus the simultaneous activation of part of the remaining wave that came from each of them. Judging and reasoning, which Gassendi insists takes place in both humans and beasts, involves comparing apprehensions and associating them together according to their relations in actual experience. The faculties of judgment and reasoning put various apprehensions into an ordered sequence based on the experienced sequences of sensations, plus the natural instinct that makes us expect certain consequences to follow from what we have experienced.

Up to this point the detailed psychological theory that Gassendi presents is much like that later developed by the British empiricists from Locke to John Stuart Mill. But Gassendi also insists that there is another mental faculty that exists in humans, but not in other animals, that of intelligence or understanding, which belongs to our rational souls. By means of intelligence we are able to know things that cannot be experienced in sensation, such as God, space, and time. By this faculty we are also able to know the abstract essences of things, which transcend the powers of the imagination. Thus, for example, the imagination can know what "man" is, in terms of the sensations received. But, the essence of man, what it is that makes him what he is, can be known only by the intelligence. Lastly, this highest mental faculty is capable of self-consciousness. It can reflect on its operations and those of the imagination and make us aware that we see, we think, and so on.

In terms of this theory of the nature of the soul Gassendi next offers his opinion about the origin of our ideas. He repudiates completely the theory of Descartes and of Herbert of Cherbury that we possess innate ideas. Instead, Gassendi insists on the principle accepted by Aristotle and Epicurus, that there is nothing in the understanding that was not first in the senses. At the outset, the mind is a tabula rasa, a blank tablet. All the particular ideas that the mind ever knows, such as that of the sun, either come directly from sense experience or result from combinations of elements furnished by the senses. General or abstract ideas are formed by the intelligence from the collection of sense materials. In this case the sense information is necessary, but not sufficient to account for general ideas, such as that of "man." The intelligence goes beyond the actual sense-data in forming a unique idea from all the particular sensations. With regard to ideas of incorporeal things, which cannot be known by the senses, sense experience and the imagination furnish the occasion for the understanding to gain this knowledge. Because of certain experiences the understanding thinks, reflects, abstracts, and arrives at ideas, such as that of God. The senses provide some of the basic materials for these ideas and provide the context in which the understanding reasons to reach a conception of an incorporeal being.

Thus, all ideas either come from the senses or result from intellectual activities that are either caused or occasioned by sense information. However, in the cases of abstract ideas and ideas of incorporeal things, the actual content does not derive from any particular sense experiences. General principles, such as "The whole is greater than the part," are formed by induction from various particular experiences. When all of our experiences exhibit the same characteristics, we reach a general conclusion, which then becomes the basis of all further reasoning.

ETHICS AND RELIGION

The last part of *Syntagma* deals with ethics. Gassendi's theory is only a slightly modified version of Epicurus's hedonism. Gassendi holds that every pleasure, considered in itself, is a good and that all things that are considered good have value only in terms of the pleasure they produce. A completely pleasurable life is one without pains and troubles. Ultimately, for Gassendi, such a life can be achieved only by God. We can mitigate the pains in our lives as much as possible and thus attain a relatively good life.

A major problem in interpreting Gassendi's contribution is that of assessing his intentions and actual beliefs. There has been great debate whether Gassendi was really a Christian. He has been seen both as the founder of modern materialism, a leading skeptic and libertine, and as a serious Christian trying to find a *via media* between his faith and the new science. There have been long debates, especially in French literature, about the so-called Le cas Gassendi. He was a close associate of

some of the leading French freethinkers and took part in retreats with them where they boasted of being able to speak freely on all subjects. Gassendi was also a close friend of some leading church figures such as Mersenne. Gassendi and Mersenne shared similar views about science and its foundations. They agreed that science could not refute skepticism and each offered a form of mitigated skepticism as a way of carrying on useful science without metaphysics. Nobody ever questioned Mersenne's religious sincerity, and he remained in closest touch with Gassendi. No charges were ever made at the time about any heretical opinion or activity on the part of Gassendi.

Arguments about how to evaluate Gassendi still go on. Researches into his few theological writings go one direction, his materialism points another way, and his associations with leading figures of the time, ranging from Hobbes to Pascal, allow for many interpretations. Gassendi was a priest all his life and he was friendly with the most orthodox and the most unorthodox figures of his time. His philosophical system represented a cautious and careful attempt to explain the world in keeping with both the results of the new science and the official views of the Catholic Church. He may have seen, as few others of his time did, the importance of the values of his religious tradition, of the classical heritage, and of the new science, and at the same time fully appreciated what the skeptics had shown about man's fallible nature. Unlike Montaigne, Charron, and La Mothe Le Vayer (all of whom he admired), he did not wish to destroy the fruits of human efforts along with man's presumptuous and dubious claims. More like Sanches, he wanted to find a constructive resolution to the skeptical crisis of the Renaissance, but not in the form of the new dogmatisms of Herbert of Cherbury or Descartes. Living within a major religious tradition, he tried to show that by discarding Aristotelianism and by accepting the wisdom of the skeptics along with certain elements of Epicureanism, faith and the new scientific discoveries could coexist.

Gassendi adapted various features of the philosophy of Epicurus to the state of knowledge of his day, and he modified certain portions of Epicurus's theory that were not in keeping with the Christian religion. The result was a semiskeptical, semiempirical theory that portrayed the world in terms of an atomic structure. Gassendi's philosophy remained important throughout the seventeenth century and was the chief modern alternative to Descartes's. It began to lose its appeal and importance after the development of Newton's scientific theories. Many of the basic elements of later English philosophy

appear in Gassendi's views, and he probably had great influence on such thinkers as Hobbes and Locke.

INFLUENCE AND SIGNIFICANCE

Gassendi was one of the foremost philosophers and scientists of the early seventeenth century. He was the most important rival and critic of Descartes, and he had a crucial role in the revival of the ideas of the ancient Greek skeptics and atomists. Gassendi began his intellectual career as a skeptic; a staunch follower of Sextus Empiricus and Montaigne. Gradually, he mitigated his skepticism in the face of the scientific revolution of the time, in which he played a major role, and he adopted more and more of a materialistic explanation of the world based on the ancient theory of Epicurus. Though a prominent Catholic priest of his day, Gassendi developed one of the first completely mechanistic and materialistic theories of modern times.

Gassendi's ideas had much influence in the seventeenth century. Although he published his work in huge Latin tomes, a French abridgement was made in the latter part of the century and many portions of his work appeared in English. His ideas were being taught in Jesuit schools in France, English universities, and even newly founded institutions in North America. Because of the close similarity between Gassendi's skeptical empiricism and some of the major portions of Locke's *Essay concerning Human Understanding*, there has been a good deal of discussion about whether Locke was influenced by Gassendi or used some of his works. It has been discovered that one of Gassendi's main works on Epicurus appeared in English in 1659 in Thomas Stanley's *History of Philosophy*, a work that Locke knew. Locke had also met a few of Gassendi's disciples in France, so it is possible that some influence occurred.

Gassendi's atomism never connected itself with basic scientific findings, so that modern atomism had to start elsewhere. There has been more interest in Gassendi in recent years. Many conferences were held for his 400th birthday in 1992, with explorations of many aspects of his thought and activities, and his scientific researches are proving important in the history of botany, geology, and other fields. There is growing interest in his critique of Cartesian philosophy and he is now being seen as a genuinely original thinker of the first rank.

Rochot, Bernard. *Les travaux de Gassendi sur Epicure et sur l'atomisme, 1619–1658.* Paris: J. Vrin, 1944. Important study of Gassendi's development. Contains a critical bibliography.

Turner, Anthony, and Nadine Gomez. *Pierre Gassendi: Explorateur des sciences.* Catalogue from the exhibit on Gassendi at the Musée de Digne, Digne-les-Bains, France, May 19–October 18, 1992. Portrays the many scientific interests Gassendi had.

Richard Popkin (1967, 2005)

GAUGE THEORY

Gauge theory is concerned with the problem of comparing physical states at different space-time locations. To get a feel for the problem, it is best to begin with a simple example. Quantum chromodynamics is the theory of the force that binds quarks together. An initial presentation of the theory might begin by stating that the *color force* (a fanciful name having nothing to do with visual colors) comes in three *color charges*—red, blue, and green, and their *anticharges*—anti-red, anti-blue, and anti-green. Every quark has one of these charges, and a stable collection of quarks must have no net color. Thus, a stable three-quark object, such as a proton, can be formed from a red, a blue, and a green quark (red + green + blue = white, which is colorless), or a stable two-quark object, such as a pion, can be formed from a red quark and an anti-red quark. This would explain why quarks are never seen in isolation. Just as electric charge comes in two forms, positive and negative, color charges come in six species. The interaction between any pair of quarks will depend on their charges.

Note an immediate consequence of the little story just told. It suggests that given any two arbitrarily specified quarks, no matter where they happen to be, there is a fact about what color charge they have, and, a fortiori, a

fact about whether their color charges are the same or different. Most metaphysical accounts of properties have the same consequence. If there is a universal corresponding to the color charge red, for example, then there is a fundamental fact about any pair of quarks whether they both instantiate this universal or not. Or if one prefers a theory of tropes, then there is still a fundamental metaphysical fact about whether the trope that is part of one quark is qualitatively identical to the trope that is part of the other. These metaphysical facts would obtain no matter where the two quarks were located even if they were located in different space-times.

Gauge theory rejects this metaphysics. It is correct, according to gauge theory, that there is a variety of color charges possible for each quark and that the structure of these physical possibilities is that of a genus with six species (speaking roughly). But there is no natural identification between the particular color states available to one quark and the particular color states available to a distantly located quark. Here an analogy will help.

Consider the surface of a sphere. At any point on the sphere, there is a set of directions one can move in. And the generic structure of that set at any one point is exactly the same as the structure of the set at any other point: Wherever you are, you have a full 360 degrees of different directions available. But there is no fact about whether a particular direction at one point on the sphere is *the same* or *different* from a particular direction at another point on the sphere. One could, for example, lay down a circle with degree markings from zero to 360 at the North Pole and lay down an identical circle somewhere on the equator. But there is no further sensible constraint that the two circles be *oriented the same way* or that the zero-degree direction at the North Pole *point the same way* as the zero-degree direction at the equator. One cannot sensibly ask of two arrows, one at the North Pole and the other at the equator, whether they point the same way or not.

Having placed the circle of degrees at the North Pole in one orientation, one is still free to place the circle at the equator at any orientation one likes. Such an arbitrary choice of orientation for the degree numbers is called *picking a gauge*, that is, fixing on a convention for assigning numbers to different directions at different points. Once one has picked a gauge, one can talk about an arrow at the North Pole and one at the equator pointing the same way (e.g., both pointing at thirty-seven degrees), but since the gauge itself was an arbitrary choice, the *sameness* carries no ontological weight.

When considering distant points on the sphere, it is obvious that there is no sameness or difference of direction: The set of directions one can go in at one point are, as it were, specifically different from the set of directions one can go at another. And one might then be tempted to simply index any direction by the point it is attached to: There are a set of North Pole directions and a set of Eiffel Tower directions, and so on, with none of these being intrinsically comparable to any other. But the situation is not so simple. Suppose a person is standing at the North Pole holding a rod out in a certain direction and is told to walk forward *keeping the rod pointed the same way*, that is, the person is to walk forward *without letting the rod twist*. This is a sensible demand, and a physically meaningful one: If the rod is allowed to twist as the person walks, the force will be felt in the hands. But *twisting* is just *changing direction*. So if there is a fact about whether the rod is twisting, there must be a fact about whether it is changing direction even though at every moment the person is located at a different point on the surface of the earth.

There is a nice mathematical object that handles this situation. The set of directions one can go in at any given point of the sphere is called its *tangent space*. The tangent spaces are all generically identical (360 degrees around) but specifically different: Each tangent space is *glued to* a point on the surface of the sphere. The mathematical object that will now be introduced is called a *connection* on the tangent spaces, and what it allows, intuitively, is for one to make comparisons between directions in the tangent space at one point with directions in tangents spaces at points infinitesimally nearby. So, as one moves continuously from one point to another on the sphere, the connection will determine whether the direction of the rod is changing or not. There are no absolute comparisons of *distant* directions, but there are comparisons of *nearby* ones mediated by the connection. More precisely, the connection provides a notion of *parallel transport*, that is, of *carrying* a direction from one tangent space to another without twisting *along a specified path*. It does not underwrite any absolute comparison of directions in different tangent spaces.

This is the sort of structure used in the gauge theories of physics. There are various charge states available to a quark at one location, and a similarly structured set of charge states available to a quark at another location, but no absolute comparison between the two: There is no fact about whether the states of the quarks are the same or different. How, then, can there be any *forces* associated with the color charges? In the case of the electric force, it is critical to know whether two particles have the same or different charge: Like charges repel and unlike charges attract. How can one say, as was said above, that a stable

collection of quarks must have no net color if there is no fact about exactly which color charge each quark has?

It is not enough to say that in a proton or a pion the quarks are nearby so there is a way of comparing their charges: Nearby is evidently not a mathematically precise term. The story is rather this. In modern particle theory, every force is mediated by a set of particles. The electromagnetic force is mediated by the photon, and the color force is mediated by particles called *gluons*. Furthermore, unlike the case of the photon, which carries no electric charge, the gluons themselves carry the color charge. And the very same remarks about the impossibility of absolute judgments about *which* charge a quark carries can be made about which charge a gluon carries. For heuristic purposes, it helps to think of gluons as carrying two charges: a color and an anticolor.

Now, suppose there is a bound state of two quarks, as in a pion. The quarks are only bound to each other through the mediating effect of a gluon. Originally, it was said that the pion as a whole must have no color, so the quarks can be, for example, one red and the other anti-red. But the gauge freedom, the freedom to identify different states at different points as the red state or the blue state means that there must be an equally valid description according to which the one quark is blue and the other anti-red. This seems to violate the demand that the pion have no net color.

Here, the gluon comes to the rescue. When gauge is changed, it must be done in a locally smooth way, and this means that not only do the color charges ascribed to the quarks change, but the color charges ascribed to the mediating gluon will change, too. So, while in one choice of gauge the pion will be described as a red quark bound to an anti-red quark by (say) a mediating blue/anti-blue gluon, in another choice of gauge, the very same pion will be described as a blue quark bound to an anti-red quark by a mediating red/anti-blue gluon. In each case there is no net color charge even though the particular charges ascribed to the constituents change. Evidently, while there is a *gauge freedom* involved in ascribing charges to particles—free enough so that any particle can be ascribed any charge—there are global constraints on the choice of gauge, and changing the gauge for one particle will have to have consequences for the charges ascribed to others. Because the gauge can be changed in different ways at different points, this is called a *local gauge freedom*.

The key point is this: The gauge freedom is wide enough that there is no objective, gauge-independent fact even about whether two particles have either same or different color charge. So no metaphysics that tries to asso-

ciate the color charges with universals or tropes in the usual way can succeed. This result is of particular significance for David Armstrong's project of justifying belief in universals by appeal to scientific accounts of the world. The fundamental structures employed by the best scientific theories simply do not correspond to the ontology of substance/universal that Armstrong proposes.

Gauge theories provide a novel approach to the fundamental ontological problem of sameness and difference. A metaphysics of universals or tropes entails that there be certain absolute facts about whether two individuals have similar or different qualities or properties, facts that obtain independently of where the individuals are located or even whether they are located in the same space-time at all. According to gauge theories, comparisons of *properties* are always mediated by a gauge connection. This means both that comparisons between individuals that inhabit disconnected space-time cannot be made at all and that even within a single space-time, ascription of charges to individuals always requires a somewhat arbitrary global choice of a gauge. The gauge connection itself is objective, but the particular charges assigned to individuals are not. This is an ontological structure that does not fit neatly in any traditional metaphysical category.

GAUNILO
(fl. 11th century)

Soon after St. Anselm circulated his *Proslogion*, it was the target of a vigorous rejoinder by an otherwise unknown Benedictine monk named Gaunilo. Although Guanilo's "Reply on Behalf of the Fool" raises a number of objections to the ontological argument, by far the best known is the Lost Island *reductio*, an argument intended to be exactly parallel to Anselm's that generates an obviously absurd conclusion. Gaunilo proposes that instead of "that than which nothing greater can be thought" we consider "that island than which no greater can be thought" (2001, p. 31). We understand what that expression means, so

(following Anselm's reasoning in the ontological argument) the greatest conceivable island exists in our understanding. But (again following Anselm's reasoning) that island must exist in reality as well; for if it did not, we could imagine a greater island—namely, one that existed in reality—and the greatest conceivable island would not be the greatest conceivable island after all. Surely, though, it is absurd to suppose that the greatest conceivable island actually exists in reality.

In order to defend himself against Gaunilo's criticism, Anselm would have to show why Gaunilo's argument about the island is not in fact analogous to his own argument about that than which nothing greater can be thought. Yet although his "reply to Guanilo" asserts more than once that the island example fails, he does not explain why it fails. The usual reply given on Anselm's behalf (and indeed often attributed to Anselm himself) is that the notion of a greatest conceivable island is incoherent; however great an island might be, one could always conceive of a greater. (For a reading of the argument that endorses a response of this sort, see Klima 2000.)

Gaunilo's reply does have its defenders, however, most notably Nicholas Wolterstorff, who argues that Anselm "realized the 'tellingness' of [Gaunilo's] points. … The sign of his realization, however, is not concession; Anselm does not concede. The sign is rather bluster" (Wolterstorff 1993, 87).

GAY, JOHN
(1699–1745)

John Gay, the English moral philosopher, was a fellow of Sidney Sussex College, Cambridge, and later vicar of Wilshampstead, Bedfordshire. His short "Dissertation concerning the Fundamental Principle of Virtue or Morality" was first published as a preface to Edmund Law's translation of William King's Latin *Essay on the Origin of Evil* (1731). (Law was bishop of Carlisle and King was archbishop of Dublin.) The "Dissertation" is one of the seminal works in the history of English utilitarianism. In the eighteenth century its influence may be found in the works of the theological utilitarians, Abraham Tucker (*The Light of Nature Pursued,* 7 vols., 1768–1778) and William Paley (*Principles of Moral and Political Philosophy,* 1785). David Hartley said that Gay's assertion of the importance of psychological association in human nature was the origin of his *Observations on Man* (1749).

Gay hoped to eradicate confusion in moral philosophy and to harmonize the competing theories about the criterion of virtue. In his survey of candidates for the criterion of virtue, Gay noticed acting agreeably to nature; acting agreeably to reason; conformity to the fitness of things; conformity with truth; promoting the common good; and conformity to the will of God. In opposition to the claim that a criterion of virtue can be stated, Gay noticed the protagonists of the moral sense who claim that our judgments of virtue and vice are but the instinctive determinations of a moral sense. Gay set himself the task of showing that all of the above-mentioned criteria of virtue are compatible and not inconsistent with our having a moral sense.

Gay insisted upon the difference between a definition and a criterion, claiming that one must know what a thing is before one can measure it. Therefore, he first defined virtue as conformity to a rule of life. He expanded on the concept of "rule of life" by saying that it is a rule directing the actions of all rational creatures with respect to each other's happiness and that the rule must be understood to be obligatory for everyone in all cases.

Gay next turned to the question, What is it that can oblige everyone in all cases to follow a rule of life? He argued that a full and complete obligation can only arise from the authority of God, because only God can in all cases make a man happy or miserable. Gay then said that the criterion of virtue is the will of God. But what rule of life does God will that we follow? Attending to God's nature, we find him supremely happy. From God's goodness we infer that he has designed men to be happy and that he has willed the means to human happiness. Therefore, a person should always behave so as to be a means to the happiness of humankind. Arguing from the will of

God, Gay thus arrived at a criterion of virtue once removed.

The above account covers what might be called the first part of Gay's system. In it he found the clues for harmonizing the several criteria of virtue he had collected from earlier writers. He found conformity to the will of God to be the fundamental criterion of virtue, but the other criteria are necessary to explicate this one. Thus the criterion of the will of God with respect to virtue is whatever promotes the happiness of humankind or the common good. Gay defined things that are fitting and agreeable to nature as those things or actions which may be used to bring about the happiness of humankind. He complained about earlier writers who left the phrases "fitness of things" or "agreeableness to nature" empty of meaning by not seeing that they must be used in relation to some end, namely, the happiness of humankind.

To account for agreeableness to reason as a criterion of virtue, Gay included under his notion of reason not only reason—that is, the foreseeing of the inconveniences of certain things and actions by contemplating their natures—but also experience, or the perceiving of these inconveniences when they happen. Reason in this extended sense is the criterion of the fitness and unfitness of things and actions, as they contribute to human happiness. Gay added that when reason conforms to things as they really are, we say that we have the "reason" of things, or the "truth" of things. Thus, he fit in conformity with truth as yet another criterion of virtue. But while he succeeded in fitting all these criteria into an account of virtue, he also warned that some are more remote criteria than others.

Gay brought the moral sense into his account of virtue by denying that it is innate, or that it operates instinctively. Men must acquire the moral sense, notably by learning to be pleased by those actions which promote human happiness and to be displeased by those which do the contrary. Gay allowed that once it is learned, the operation of the moral sense may be habitual. He also allowed that much of humankind may learn what virtue is by example and observation, without being able to reason out their judgments.

Gay also explained why a person may be virtuous. Curiously enough, he made little of man's obligation to obey the will of God. Rather he appealed to the universality of man's inclination to seek pleasure and to avoid pain; and he equated a person's happiness with his being pleased. There are two motives, then, for virtuous behavior. First, when I see that my own happiness depends on the happiness of others, I will seek to promote their happiness in the hope that they will in turn promote mine. Second, since esteem and merit are associated with virtue, I may behave virtuously in order to enjoy the pleasure of being esteemed. Similarly, I will esteem those who promote my happiness, in order to encourage them.

GEHLEN, ARNOLD
(1904–1976)

The German social psychologist Arnold Gehlen was born in Leipzig. In 1934 he succeeded his teacher Hans Driesch as professor of philosophy at the University of Leipzig. He went to Königsberg in 1938 and from 1940 to 1944 was at the University of Vienna. In 1948 he became professor of sociology and psychology at the Hochschule für Verwaltungswissenschaften at Speyer. After 1962 he was at the Technische Hochschule in Aachen. He died in Hamburg.

Gehlen, a leading representative of the movement known as philosophical anthropology, sought to reinterpret the concepts of mind and intelligence in biological and sociological terms. His eclectic thought has partial affinities with the pragmatism of G. H. Mead and F. C. S. Schiller, with the integrationalism of Rudolf von Ihering, Maurice Hauriou, and Carl Schmitt, and with the cultural criticism of Oswald Spengler, Hans Freyer, and Martin Heidegger. At the same time, he rejects ontology and metaphysics. He rejects the traditional dualisms of soul and body, mind and matter, theory and practice. He emphasizes the predominant role of collective, or institutional, values as against those of individuals. He discards rationalism and regards present-day civilization as one of late-period decline.

METHOD AND TASK OF PHILOSOPHY

Gehlen rejects the experimental methods of the natural sciences as leading to materialism and rejects the "understanding" approach of the advocates of the *Geisteswis-*

senschaften, because it employs contemporary intellectual standards in the analysis of heterogeneous situations. The method of philosophy, Gehlen claims, is the intuitive or phenomenological method that he himself uses to interpret the significance of sociocultural institutions. According to Gehlen the task of philosophy differs from that of science. Disregarding the factual inferences of the sciences as irrelevant, philosophers should "unravel" (*freilegen*) the realities that are their proper concern. These realities, or "categories," are the basic qualities of man and of institutions that remain intact after the fullest cultural, social, and historical analyses. Gehlen conceives of such a study of reality as empirical and thus envisages no complete system of categories.

MAN'S NATURE AND POWER

Gehlen defines man as an "acting, anticipatory, nondetermined, self-delimiting being—a product of culture." Like other philosophical anthropologists, Gehlen views man, compared with other animals, as a vulnerable, deficient being, lacking the powerful instincts and natural weapons of survival of other animals. Man's fabled power of thought is an artificial substitute for his weak instincts. He is reduced to dependence on technical means for his survival. For survival and to liberate himself from anxiety he has had to develop tools and techniques including language, myth, and magic, and has had to create a common, habitual, and stable cultural environment.

This cultural environment is perpetuated in institutions, the historically evolved realities of state, family, law, economy, and so forth. To be "legitimate" an institution need not be useful but must be derived from man's nature as expressed in the cultic, nonutilitarian experiences of ecstasy, trance, and asceticism. Institutions are comprehensive and abstract structures that, through their principle of order, impart autonomy to the individuals participating in the collective *entente secrète*. The utility of social and cultural institutions is a secondary by-product of their development. Gehlen contrasts unreflective, spontaneous, self-sacrificing action, which he describes as noble (*vornehm und edel*), with self-interested and utilitarian action (including its sublimated forms in art, philosophy, and literature), which he designates as base (*gemein*).

THEORY OF TRUTH

Like certain pragmatists, Gehlen stressed action as the determinant of valid thought. While defining truth in terms of inner coherence and correspondence with facts, Gehlen also distinguished another aspect of truth, which he calls "inner truth." "Essentially irrational, non-scien-

tific and not directly controllable experience has *its* truth: that is certainty. And it has *its* form of acting: non-experimental action based on tradition, instinct, habit and conviction" (*Der Mensch*, p. 330). These illogical, ethical certainties are valid without rational or experimental justification—as a matter of mere "appositeness" or inner sanity. Rational knowledge (*Wissenschaft*) cannot take over the function of the *idées directrices* of society that are the product of *Urphantasie*, the divinity and energy of the animal component of man.

PESSIMISM

Gehlen's analysis of his age was unrelievedly somber. His times, according to Gehlen, were marked both by the dissolution of institutions and a shift in individual and social consciousness from irrational certainty to an anarchic intellectualization. This change took place against a historical background in which organic agrarian society was giving way to organized industrial society. The cultural rupture transforms social organisms into "colonies of parasites" riddled with subjectivism, mechanization, a turn toward abstract and mathematical methods in art and science (desensualization), and experimental thinking.

Rising living standards, far from representing progress, create new urges for limitless satisfactions. Such changes lead away from ethical obligation deriving from man's nature to goal-directed efficiency deriving from man's method. These changes entail making the spiritual sphere political and robbing the political sphere of its religious aura. Since science is esoteric, the mass of the people are condemned to be primitive. The eclipse of the nation-state and the trend toward supranational organization and peace will leave a legacy of unresolved conflicts that may lead to a complete loss of individual freedom. Only two very unlikely circumstances could reverse the trend: an unexpected return to legitimate, nonrational values that are not amenable to conscious volition or the rise of a creative personality to provide a new kind of institutional leadership.

According to Gehlen, the philosopher's task in such a world situation is to point to signs of decline and to emphasize the "legitimate" elements in national heritages as expressed in the institutions of state, church, and law. Although present-day society is increasingly alienated from these heritages, they alone represent society's legitimate "reality." Reality has therefore to be sought in the archaic forms of the past.

GEISTESWISSENSCHAFTEN

Geisteswissenschaften, a term commonly used in German to denote disciplines referred to as "the humanities" in English, emerged in the course of a nineteenth-centry discussion about the proper designation for those disciplines whose topics and methodologies were different from those of the newly predominant natural sciences (*Naturwissenschaften*) such as physics, biology, and chemistry. A compound word, its second component— "the word *Wissenschaften*" or "sciences"—indicates that these disciplines are indeed legitimate sciences, but sciences of a different kind than the natural sciences. The assumption underlying the discussion out of which the term emerged is that there are valid scientific methods for studying topics such as literature, art, and history, but that the objects of these disciplines and their appropriate methods were significantly different from the objects and quantitative methods appropriate of modern natural science. Originally conceived as one side of a binary opposition between the realms of "nature" and those things that could not be subsumed under that heading, it uses the term "*Geist*" to provide a positive description of the general domain that is the proper field of study for those disciplines.

Many scholars have noted that the plural form of the term was used in 1849 in J. Schiel's German translation of John Stuart Mill's *Logic* as a translation for Mill's phrase "the moral sciences" and count that as the origin of the term *Geisteswissenschaften*. However, earlier uses of similar terms have been documented (see, e.g., Diemer) and the term *Geist* as a central term for historical and cultural manifestations of human mentality had become common in German romantic philosophy (Herder and Hamann), and German Idealism (especially Hegel) well before 1850.

The clearest formulation of the notion of *Geisteswissenschaften* as a group of disciplines united by a common method was presented by Wilhelm Dilthey in his *Einleitung in die Geisteswissenschaften* (1883). In this work, he identifies the common topic of these sciences as historical social reality that cannot be captured through the natural sciences. They find their ultimate basis in the structures of human experience, which is essentially historically and contextually situated. Hence the *Geisteswissenschaften* seek to do more than merely to explain, instead they seek to understand the expressions of human experience by situating them into broader personal, social, and historical contexts that provide insight into their "sense." For Dilthey, then, the fundamental disci-

plines for all of these others were anthropology and psychology, with psychology understood as a descriptive science aimed at understanding the structures of human experience.

During the late nineteenth and the first half of the twentieth centuries these fields included not only what would traditionally fall under the concept of the humanities in English, such as philosophy, history, philology, and the histories of art and music, but also traditional faculties such as law and theology whose methodologies were not consistent with those of the natural sciences. It also came to include areas that were just beginning to emerge as special disciplines such as political science and sociology, which at the time were paradigms of the *Geisteswissenschaften*. Hence in the second half of the nineteenth century and the beginning of the twentieth century, the term *Geisteswissenschaften* was in competition with the term "*Kulturwissenschaften*" or "cultural sciences" as another way of capturing the difference between all of the fields that were distinct from natural sciences, a term that was championed above all by members of the Southwest German school of Neokantianism such as Wilhelm Windelband (1915) and Heinrich Rickert (1986) for all of the areas Dilthey called *Geisteswissenschaften*. They stressed the unique and specific nature of the objects that these (idiographic) sciences seek to understand as opposed to the general laws that were the object of the (nomothetic) natural sciences.

During the first half of the twentieth century, Dilthey's preferred terminology predominated, but toward the end of the twentieth century, the social sciences have come to be generally grouped together under the heading of "*Sozialwissenschaften*" or "*Gesellschaftswissenschaften*," two different German words for "social sciences," as they have increasingly adopted the quantitative methodologies associated with the natural sciences. From the outset, questions about the status of psychology as a scientific discipline have played a pivotal role in the discussion of the nature and limits of the *Geisteswissenschaften*. At the end of the twentieth century, however, it too was increasingly grouped together with social sciences based on shared quantitative research methods; the notion of the *Geisteswissenschaften* became closer once again to what in English would be called the humanities. Law, economics, and the social sciences are becoming less commonly subsumed under the heading of the *Geisteswissenschaften* and an increasing number of departments concentrating on history, literature, art, and related fields often choose to refer to themselves as *Kulturwissenschaften* instead of as *Geisteswissenschaften* as

they combine methodologies from both the humanities and the social sciences into their studies.

GENERAL WILL, THE

The idea of the general will (*volonté générale*) forms the core of Jean-Jacques Rousseau's political philosophy. Others had introduced the term before him, and his use influenced many others, including Immanuel Kant and Georg Wilhelm Friedrich Hegel, but the general will is most closely associated with Rousseau's *Social Contract* (1762/1997). In that work, Rousseau argued that "the general will alone can direct the forces of the State according to … the common good" (II.1.1, p. 57) and that political rule is only legitimate when based on a social contract that establishes the general will as sovereign. This led Rousseau to hold that laws must be authorized by the people as a whole, since "only the general will obligates particulars, and there can never be any assurance

that a particular will conforms to the general will until it has been submitted to the free suffrage of the people" (II.7.7, p. 70). The general will, as Rousseau understood it, is impartial in that it "must issue from all in order to apply to all" (II.4.5, p. 62).

Prior to Rousseau, the term "general will" was introduced into seventeenth-century theological disputes by Antoine Arnauld and then discussed by Blaise Pascal and Nicolas Malebranche, among others. The issue was whether God has a *general will* to grant all people salvation, and if so, how it is possible and just for particular individuals to be condemned to hell. In the early eighteenth century, authors such as Pierre Bayle and the Baron de Montesquieu began to use the term in a secular context. In defending the separation of governmental powers, Montesquieu associated the legislative function with the general will and judicial power with a particular will. When Denis Diderot published an entry on "natural law" in his *Encyclopédie* in 1755, the general will held a central place. He wrote that only humanity, and not any individual, can "determine the nature of justice and injustice. … Private wills are suspect; they may be either good or bad. But the general will is always good" (1755/1992, pp. 19–20). He continued, "The general will is in each person a pure expression of the understanding, which in the silence of the passions calculates what every individual may demand from his fellow-man, and what his fellow-man has a right to demand of him" (pp. 20–21).

While clearly influenced by Diderot, Rousseau rejected his colleague's cosmopolitanism and focused instead on the general will of a society. Rousseau held that "each individual may, as a man, have a particular will contrary to or different from the general will he has as a Citizen" (I.7.7, p. 52). A person's private will directs him toward his own particular interests, while the general will aims at the common good of society. In addition, Rousseau introduced the crucial contrast between the general will and the will of all: "From the preceding it follows that the general will is always upright and always tends to the public utility: but it does not follow from it that the people's deliberations are always equally upright. … There is often a considerable difference between the will of all and the general will" (II.3.1–2, pp. 59–60). A simple aggregation of private wills may generate the will of all, but the general will requires a mutual adjustment of interests in light of what individuals can reasonably demand of one another.

There is no infallible procedure by which to determine the general will. Rousseau argued that the general will can only act when all the people are gathered together in the "people's assembly" to vote on whether a proposed law "does or does not conform to the general will, which is theirs" (IV.2.8, p. 124). However, when their private wills distort their assessment of the common good, individuals may be mistaken about the content of the general will. It is even possible for the majority to be mistaken, and Rousseau was especially concerned about two sources of corruption, not to the general will itself, but to a society's ability to identify it. The first was the existence of factions, which Rousseau believed would lead individuals to elevate their shared private interests above the general will. The second was large inequalities in wealth, which could allow the wealthy to replace the judgment of the poor with their own: "No citizen [should] be so very rich that he can buy another, and none so poor that he is compelled to sell himself" (II.11.2, p. 78).

Rousseau held that outside of society, individuals have "natural freedom," since they need not limit their ability to act on their private wills. However, because private wills may conflict, individuals may still be dependent on the private wills of others and therefore lack freedom. It is only when a society is guided by the general will that individuals are freed from their dependence on private wills and are able to achieve "civic freedom." Their natural freedom is then limited, since they may no longer act on their private wills when these conflict with the general will. However, since others are similarly constrained, no one is dependent on anyone's private will.

For example, it is only under the general will that mere possession is transformed into property, with the result that no one may take what is not theirs. Furthermore, in a passage that strongly prefigured the work of Kant, Rousseau wrote that being freed from the dictates of one's own private will also represents a kind of moral freedom, "which alone makes man truly the master of himself; for the impulsion of mere appetite is slavery, and obedience to the law one has prescribed to oneself is freedom" (I.8.3, p. 54). Understanding that freedom involves independence from arbitrary private wills and that such dependency can only be avoided by the general will helps to explain Rousseau's comment "Whoever refuses to obey the general will shall be constrained to do so by the entire body: which means nothing other than that he shall be forced to be free" (I.7.8, p. 53). For Rousseau, this merely meant that individuals should be constrained in their unconditional pursuit of self-interest by principles of justice, which make them independent of anyone's private will.

Beginning with Hegel, but especially in the twentieth century, many critics saw in Rousseau the origins of the

Reign of Terror of the French Revolution or an endorsement of unconstrained majority rule. For example, in 1945 Bertrand Russell wrote that Rousseau was "the inventor of the political philosophy of pseudo-democratic dictatorships" and that "Hitler is an outcome of Rousseau" (pp. 684, 685). Such interpretations, because they neglect the contrast between the general will and the will of all, typically reveal more about the ideological fears and commitments of the commentators than about Rousseau. In contrast, the final decades of the twentieth century brought a revitalization of liberal political philosophy, much of it under the influence of John Rawls, and with it came a renewed interest in the general will. Rawls's project can be understood as an attempt to reconcile the two elements that Rousseau identified as the central commitments of the general will: "If one inquires into precisely what the greatest good of all consists in, which ought to be the end of every system of legislation, one will find that it comes down to these two principal objects, *freedom* and *equality*" (II.11.1, p. 78).

Jon Mandle (2005)

GENERICS

Generics are noun phrases (NPs) and sentences of certain types; the phenomena exhibited by these NPs and sentences are known as "genericity." Two rather different phenomena are embraced by this term, and they both are of interest to philosophers.

THE FIRST PHENOMENON: REFERENCE TO A GENUS (OR KIND)

An example of the first phenomenon, reference to a genus, is the sentence *The black-capped chickadee winters in central Alberta*, which refers to the genus, or kind, *The Black-Capped Chickadee*. The sentence may also do other things, such as make claims concerning individual black-capped chickadees and the things they do. But the way it accomplishes these other tasks is to employ its NP subject term to refer to the kind and then make a predication about this kind. There are various tests that one might employ to show that NPs like this really do refer to kinds. For instance, note that predicates like *is (not) extinct* are true only of kinds and not of individual instances of a kind. It makes no sense to assert that *Tweety is extinct* (as opposed to being dead). But it does make sense to say *The black-capped chickadee is not extinct*, thereby showing that in this sentence at least, *the black-capped chickadee* refers to a genus. Of course, not every occurrence of *the black-capped chickadee* refers to a kind. For example, it does not do so in *The black-capped chickadee in the far cage needs more seed*; here *the black-capped chickadee* refers to an individual instance.

A fundamental question concerning this type of genericity is the following: What types of expressions can refer to genera? As the previous example shows, definite NPs can do this in certain sentences. And since the sentence *Black-capped chickadees winter in central Alberta* has the same force as the previous example, most theorists take these "bare plural" NPs also to refer to kinds, at least in this sort of sentence. Another type of NP that is of the same nature contains mass terms ("bare singular" NPs they are sometimes called) such as *gold, furniture*, and *information*. The subjects of sentences like *Gold is a yellowish metal* refer to a kind. There is at least one case in English of a bare singular count NP that designates a kind: In *Man evolved from the great apes*, the NP *man* (as opposed to the common noun *man*, as it occurs in … *is a man*) refers to a kind. And there are some proper names of kinds also, such as *Ursa arctos horribilis is common in the mountains of Alberta*. On the other hand, indefinite NPs do not refer to kinds (with an exception to be men-

tioned just below): *A grizzly bear is common in the mountains of Alberta* seems nonsensical; the indefinite NP in *A black-capped chickadee winters in central Alberta* refers to some individual instance of the kind. The same is true for quantified NPs: The subject NPs in *Every/Most/Some/All/Each/Few black-capped chickadee(s) winter(s) in central Alberta* quantify over individual instances of the kind, and do not designate the kind. (Actually, there can be reference to kinds using indefinite NPs and quantified NPs, but then these NPs are given a *taxonomic* interpretation. We can say *All dinosaurs are extinct*, meaning thereby that every species of dinosaur is extinct; similarly, we can say *A whale has been labeled as endangered*, meaning thereby that a species of whale, perhaps the Blue Whale, has been labeled as endangered.)

Another fundamental question concerning this type of genericity is the following: What are the truth makers for such sentences? Some of these predications seem clearly to predicate a property *directly* of a kind—in cases such as *The dodo is extinct*. But consider the (true) generic sentence *Man landed on the moon in 1969*. In such cases the truth maker would seem to be the initial person who satisfies the predicate; then this property is attributed or projected to the kind. But of course not every property that is true of an individual person becomes true of mankind. For this type of *indirect reference to a kind*, it seems that the property in question must be "important" enough: For sentences like *Man pole-vaulted 6 meters in 1985* do not seem true, even though Sergey Bubka of Ukraine did so in Paris in 1985 (and he was the first person to have done so).

We can also sometimes use an individual exemplar of a kind as the truth-maker for things we (or other agents) do, as in *We photographed the grizzly in Alberta last summer*, when in fact it was only a few of the instances of *Ursa arctos horribilis* that were photographed. These and other types of indirect reference to kinds are discussed by Krifka et al. (1995). The fact that predicates that are primarily true of ordinary individuals are somehow projected to be true of kinds raises questions of both a logical nature (about the resulting "type mismatch") and a metaphysical nature (about the relation between kinds and their exemplars).

Yet a further fundamental question concerns what kinds there are. The examples thus far surveyed have been of "natural kinds," but clearly there are kinds of artifacts: *Schockley invented the transistor in 1957* employs *the transistor* as designating a kind. And *The Coke bottle has a narrow neck* employs *The Coke bottle* in this way also; yet *The green bottle has a narrow neck* seems not so much false as

nonsensical, unless *the green bottle* is taken to designate a particular bottle. Intuitively, there just is no such kind as The Green Bottle. Of course, with sufficient background contextual buildup one can make *The green bottle* be, for instance, the salvation of all those stricken with some new disease. Considerations like these have suggested to some that the notion of kind that is relevant to genericity in this first sense is "conventional" or "social."

THE SECOND PHENOMENON: GENERIC CHARACTERIZATION

An example of the second phenomenon, generic characterization, is the sentence *Lions have manes*, which predicates the property of having a mane "generically" to lions. By this it is meant that it is *generally* true (plus some qualifications to be discussed below) that lions have manes. As we know, only male lions have manes, so this predication is not universally true of lions. This feature is usually described by saying that generic characterizations *allow for exceptions* while they nonetheless remain true. It is this feature of genericity that has aroused the interest of logically oriented philosophers of language; for, given this portrayal of generic characterization, some radically new logical techniques will be required in order to employ these sentences in arguments.

Note that this second notion of genericity is a feature of entire sentences, whereas the first notion was a feature of NPs. But to complicate matters, the two phenomena can occur together, as in *The rutabaga contains vitamins A and C*, where *The rutabaga* exemplifies genericity of the first sort and the sentence as a whole exemplifies genericity of the second sort. (There might be some rutabagas that are missing either vitamin A or C, yet the original sentence would be true.)

Generic characterizing sentences express regularities about specimens of a kind: some regularities concern properties that are exemplified by the typical member (such as in the rutabaga sentence), whereas others express regularities of action that an object engages in (such as in "habitual" sentences like *Mary plays tennis after lunch*, which again is true despite the existence of days where Mary must work after lunch). It is this ability to express regularities in the face of exceptions that explains why all languages allow the expression of generic characterization. People notice regularities in nature and form "folk laws" to codify these regularities and predict what the future might bring. Despite the existence of exceptions, they are intellectually satisfying and practically useful because the objects *typically* or *usually* or *normally* or

nomically perform those actions. And such regularities commonly have exceptions.

Most writers in the genericity literature have argued that it is wrong to view these characterizing generic sentences as "really false but acceptable despite the exceptions because they are close enough to being universally true." For, they claim, most of our knowledge of the world is encoded in these generic sentences, so this is not a useful attitude. And if it were correct, then we would expect that sentences with fewer exceptions are more acceptable. But this is not borne out by examples, as we will see shortly.

These writers also have tended to shun the view that generics are *neither* true nor false but are instead directions or rules. For, this would make most of our knowledge become neither true nor false but instead directions to guide our belief formation ability. Further, since generics would not have a truth value, they could not be embedded inside propositional attitudes or joined into longer generic statements. But *John knows that rutabagas contain vitamin A* and *It is common that countries that do not honor women's rights also do not honor general human rights* are in fact either true or false.

Consider this list of (true) characterizing generic sentences:

1. Snakes are reptiles.

2. Telephone books are thick books.

3. Guppies give live birth.

4. Italians are good skiers.

5. Crocodiles live to an old age.

6. Frenchmen eat horsemeat.

7. Unicorns have one horn.

Obviously these call for different proportions of the subject terms satisfying the predicate. In (1) it is all; in (2) most; in (3) some subset of the females; in (4) some small percentage, but a greater percentage than in other countries (or maybe the very best of the Italian skiers are often better than the very best from other countries); in (5) it is strikingly few, since of the hundreds born to one female at a time, most are eaten within a few weeks of birth; in (6) there need be only a very small percentage—somehow the culturally determined views of North America make it striking that it happens at all; and in (7) no unicorns have one horn. Such examples show that there is no univocal quantifier that will serve in all characterizing sentences.

Even attempts to employ vague, probabilistic quantifiers such as *most* or *generally* or *in a significant number of cases* are misguided. Consider such false characterizing sentences as the following:

8. Leukemia patients are children

9. Prime numbers are odd.

These false sentences would become true if prefixed by *In a significant number of cases*. Indeed, the actual number of cases has nothing to do with the truth of the characterizing generic sentence as opposed to what evidence we might have for the sentence's truth. We might use the preponderance of thick telephone books in the world as our evidence for the truth of (2); but we will be prepared to retract it when we discover other relevant background facts, as perhaps happens with (9). This is often put as "characterizing sentences are inherently intensional." A sentence like *Members of this club help one another in emergencies* can be true despite there never having been any emergency. What is required for its truth is intensional: the preparedness to act in certain ways in certain situations. This intensionality is often claimed to thwart any attempt to use an extensional quantifier in the analysis of characterizing generics.

TWO RELATED AREAS

The feature of allowing for exceptions while nonetheless remaining true raises interesting issues in logic. This general topic is called *nonmonotonic reasoning* in the artificial-intelligence literature. Although these researchers do not explicitly aim to provide a semantics for characterizing generic sentences, nonetheless results of their research might be pressed into service for this purpose (Pelletier and Asher, 1997).

The issue of how children can learn that some occurrences of NPs are universal, others existential, and still others generic has been investigated both from the point of view of English-speaking children learning language (Hollinger et al. 2002) and comparatively between English-speaking children and Mandarin-speaking children (Gelman and Tardif 1998). It seems that children learn the difference by the age of four and that there is a difference in the frequency of generic vs. nongeneric NPs and sentences encountered by English and Mandarin children.

PHILOSOPHICAL CONSIDERATIONS

Genericity has been seen by some as requiring an ontology of (abstract?) kinds, individuals, and (momentary) stages of individuals. Furthermore, it seems to some that the semantics of generics presumes that these kinds are

conventional in some way. And the issues surrounding natural laws that admit of exceptions has been seen by some as endorsing a kind of scientific antirealism. All of these considerations raise deep questions of the relation between semantic models of natural language and reality. Some have claimed that the relationship should be modest and that these ontological conclusions pertain only to the metaphysical presuppositions of natural language— a natural-language metaphysics, in the phrase of Bach (1986)—but not necessarily to reality. This is the deepest issue in philosophy of language.

GENETICS AND REPRODUCTIVE TECHNOLOGIES

Modern genetics and technological aids to human reproduction, like other advances in science and technology, have created ethical problems heretofore unencountered. Biomedical developments have also posed new conceptual, epistemological, and metaphysical problems. This entry addresses these philosophical concerns as well as the more widely discussed ethical implications of contemporary genetics and reproductive technologies. One conceptual and ethical link between these two fields is the prospect of "designing our descendants." This prospect has been viewed by some as a boon to humankind (Fletcher 1974) and by others as a fearsome possibility to be avoided at all costs (Ramsey 1970).

The Human Genome Initiative, a "big science" project launched by the U.S. government to map and sequence the entire human genome, has heightened concerns about the privacy and confidentiality of genetic information, the uses to which such information might be put, and the possibility of stigmatizing individuals or groups because of their genetic constitution. The knowledge the Human Genome Project can yield is massive in contrast to previous efforts to acquire information about human genetics.

The contemporary science of genetics provides, not only an understanding of heritable traits, but also the capability to diagnose the probability or certainty of transmitting to offspring genetic conditions such as sickle-cell anemia. Tay-Sachs disease, or cystic fibrosis. The ability to identify and locate specific genes that render a person likely to manifest heritable conditions, such as Huntington's disease and certain forms of cancer, raises profound questions about the wisdom and desirability of learning about future contingencies when no cure exists and preventive measures are of uncertain efficacy.

A conceptual question is prompted by the rapid advances in genetics: What constitutes genetic disease? The traditional concept of disease relies on the ability of medical scientists to identify deviations from the normal physiological functioning of an organism. Asymptomatic diseases, such as hypertension, can be detected by diagnostic instruments even though the individual feels no symptoms of illness. With the discovery of genes that render an individual with a family history highly likely to develop a particular disease later in life, how should the

individual who carries the gene be characterized? Does the person in whom the gene is found have a genetic disease or not? The individual has no symptoms and the disease may never express itself. Yet merely being susceptible opens the possibility of harm to the interests of such individuals, making them vulnerable to actions by others such as insurance companies who seek to deny insurance on grounds of a preexisting condition or employers who refuse to hire workers with a known propensity for illness.

Beyond the problems posed by diagnosis and prediction in genetics are those of intervention: Is gene therapy intrinsically different from traditional medical therapy? Even if gene therapy by means of manipulating somatic cells poses no special problem, what about altering germline cells, a procedure that would affect future generations? If genetic manipulation to correct defects is ethically permissible, what, if anything, would be wrong with alterations intended to provide genetic enhancement? Are efforts to improve human intelligence, appearance, or other attributes by genetic means essentially different from the traditional methods of education, physical or mental training, or behavior modification (President's Commission for the Study of Ethical Problems 1982)?

Attempts to improve the quality of the human gene pool, or "positive eugenics," have generally been viewed with disfavor, especially after the policies in Nazi Germany promoting racial hygiene (Proctor 1988). Yet eugenic practices remain at the level of individual choice. The recipients of donated sperm are typically given information about physical and other personal characteristics of donors, allowing them to choose sperm from a donor whose traits they hope to replicate in the child. The prospect of genetic enhancement using the techniques of recombinant DNA manipulation can allow for more precision and wider applications than older approaches such as selective sperm banking.

Knowledge that one carries a gene for a heritable disease can pose a profound dilemma for the individual. An early form of this dilemma arose when carrier screening was the only way to determine whether a couple would pass on a genetic disease to their offspring. A couple then had to decide whether to take the chance that a child would be born with the heritable condition. With the advent of various forms of prenatal diagnosis (amniocentesis, chorionic villus sampling, blood tests), the presence of some genetic diseases in a fetus can be detected. The ethical question in such cases is whether to abort an afflicted fetus. In the case of both carrier screening and prenatal diagnosis, trained genetics counselors have uni-

formly taken a nondirective approach. The norm in genetics counseling has generally been to provide unbiased information to enable individuals or couples to make an informed decision whether to initiate a pregnancy or to abort a fetus found to have a genetic disease (Lappe 1971, President's Commission for the Study of Ethical Problems 1983).

As the science of genetics yields an increasing amount of information, individuals are faced with making decisions about prophylactic medical interventions. For example, a woman who learns that she carries a gene for an inherited form of breast cancer may contemplate bilateral mastectomy before any clinical signs appear. The epistemological problem posed by such scenarios is a familiar philosophical one: decision making under risk and uncertainty. If the woman decides to undergo a major, disfiguring operation, she does so with the knowledge that she might escape the disease entirely. But if she forgoes the preventive step, she runs the risk of developing a dread disease that may be curable if detected early but that also has a high mortality rate.

The knowledge by individuals or couples that they are at risk for transmitting a genetic disease to offspring is one indication for embarking on the use of reproductive technologies. The couple may elect to use donated sperm or ova. A far more common indication for the use of reproductive technologies, however, is infertility or subfertility on the part of one or both members of a couple. Methods include in vitro fertilization (IVF)—fertilizing a human ovum outside the womb—the use of sperm or ova contributed by third parties or the womb of a woman not intended to be the rearing parent (surrogacy); cryopreservation (freezing) of fertilized ova, which are termed *preembryos*; and embryo splitting.

Frequently discussed ethical issues include concerns about destruction of the traditional family when third parties are used as gamete donors or surrogates (Macklin 1991); worries about the effect on children who learn that they were born as a result of these techniques; and the opposite worry about harmful effects of struggling to maintain family secrets. Prior to the first IVF birth in 1978, fears were expressed that IVF would produce a higher than normal incidence of birth defects, but scientific evidence gathered over the years has shown this concern to be unwarranted. The objection that being created with the aid of gametes from a third party can harm the interests of children is countered by the metaphysical observation that these are children who would never have existed but for the use of these techniques.

Different religions are opposed to the use of some or all of these reproductive technologies. The Roman Catholic Church has urged prohibition of virtually all forms of assisted reproduction (Congregation for the Doctrine of the Faith 1987). The church's opposition is based on the fact that these techniques separate the procreative and unitive functions of marriage. Some authorities in Orthodox Judaism allow insemination from non-Jewish sperm donors but prohibit donation from Jews, in order to prevent consanguinity; others oppose all third-party donations out of fear of consanguinity and also by analogy with adultery. Islamic law prohibits the use of sperm or eggs from anyone other than the married couple on grounds that the results are similar to adultery (Serour 1992). Since the identity of gamete donors is normally kept confidential, a secular concern is that a brother and sister may unwittingly mate or marry, unaware that they have a genetic parent in common.

Possibly the most intriguing philosophical issues posed by reproductive technologies are those that arise from the newfound ability to separate the genetic from the gestational procreative functions. IVF permits an ovum from one woman to be fertilized and the resulting embryo implanted in a different woman. This creates the entirely novel situation of two different "mothers": the genetic mother, who supplies the egg; and the gestational mother, who undergoes pregnancy and childbirth. Apart from the emotional or other psychological consequences that may result from such arrangements, the separation of the woman's procreative role into two distinct biological functions requires a conceptual decision of whether the individual who performs each function properly deserves the appellation "mother" (Macklin 1991).

A variation on this conceptual theme stems from research that demonstrates the capability of transplanting ovaries from an aborted fetus into an adult woman who lacks ovaries of her own. The woman into whom the ovaries are transplanted is a mother in the traditional sense of one who is pregnant and gives birth to the child. Is it appropriate to construe the aborted fetus as the "genetic mother"? The conceptual oddity of this construal suggests that "mother" is a concept laden with connotations that do not permit its expansion to include aborted fetuses. Although the aborted fetus is without question the source of the genetic material from which the new life was created, it is semantically odd to conclude that the aborted fetus is the genetic mother.

A persistent quandary relates to the status of extracorporeal embryos. The product of IVF is termed a *preembryo,* partly because of its early developmental stage but also because it is unimplanted. The ability to freeze embryos indefinitely and thaw them for use later poses both conceptual and ethical questions. When disputes arise concerning the ownership of embryos, should the embryos be construed as "people" or as "property" (Annas 1989, Robertson 1990)? Should anyone other than the couple who contributed the gametes have the authority to destroy frozen embryos? If it is permissible to destroy embryos that are not intended for implantation, is it permissible to do experiments on the embryos? Controversy exists over the splitting of embryos, a technique sometimes called cloning (Robertson 1994). One objection holds that such deliberate duplication destroys genetic individuality and thus devalues the uniqueness of each individual.

Genetics and reproductive technologies pose new philosophical questions about the scope and limits of such familiar concepts as disease, individuality, parent, mother, and the family. The importance accorded to human reproduction and lineage throughout history is a reminder that such questions are not merely abstract concerns of philosophers but deeply rooted in the lives of individuals and communities.

GENETICS AND REPRODUCTIVE TECHNOLOGIES [ADDENDUM]

Philosophical scholarship on genetics and reproductive technologies typically follows the development of these scientific fields closely, providing critical analysis of the major assumptions and implications of their emerging claims, often in advance of their realization. This addendum reviews three discussions that have become particularly prominent in the literature since Ruth Macklin's original entry appeared in 1996: debates over the design and interpretation of human genetic variation research, the prospect of human reproductive cloning, and the potential limits of human genetic modification.

HUMAN GENETIC VARIATION RESEARCH

The principal outcome of the Human Genome Project was a set of research tools for human genetic variation research. With improved genomic maps and DNA sequencing technologies, geneticists have been able to launch a new generation of projects comparing human genomes to better understand our similarities, differences, and patterns of relationship at the molecular level. These comparisons are critical to the development of successful medical applications of genomic research, as well as to the interests of anthropologists and paleontologists interested in the evolution, differentiation, and global migrations of our species (Risch et. al. 2002). On the other hand, these comparisons also raise two sets of important philosophical issues:

First, how should scientists define and identify the relevant comparison groups within our species? The initial attempt to use genomic tools in a large scale study of human variation, the so-called Human Genome Diversity Project, followed the accepted practice of physical anthropologists and epidemiologists of describing its target groups in ethnic, linguistic, and geographical terms, and was called to task by both biologists and social scientists for using socially constructed categories that would obfuscate rather than illuminate underlying patterns of gene flow within our species (Gannet 2001, Reardon 2005). Rather than reifying various human political histories by looking for "ethnic-affiliation markers" in human DNA, some suggested a random global sampling strategy blinded to social identifiers (National Research Council 1998). The U.S. National Institutes of Health followed this approach in developing a major genetic variation research resource—a databank of known single nucleotide variants in human DNA—and was in turn called to task by public health and pharmacogenomic researchers for omitting "phenotypic data" about the distribution of the DNA variants across different populations (Altshuler and Clark 2005).

As a result, the subsequent international effort to a variation-measuring "haplotype map" of the human genome intentionally collected samples from groups defined by their "continents of origin" (International Hapmap Consortium 2003). Critics charge that this strategy returns population genomics to a set of outmoded racial categories that human scientists of all stripes have repudiated as biomedically meaningless and socially pernicious (Duster 2005). Claims that, nevertheless, research framed in this way has identified patterns of genetic variation that cluster along racial lines, and that these variations may be the key to "population specific" public health interventions or even "race-based medicine," have only lent fuel to this conceptual debate.

The second issue follows from the first. Assuming that, for the foreseeable future, the definition of comparison groups in population genomics will be informed by socially constructed criteria at some level of resolution (either familial, tribal, ethnic, racial, or regional), how should the interests of group members be protected? Outside of groups with clear political sovereignty, like Native American nations, most targets of genetic analysis have ambiguous moral standing. Is it ethically important for scientists to attempt to discuss their plans with groups at the collective level before recruiting individual group members into genetic variation studies? Some argue strongly that a principle of "respect for community" needs to supplement our traditionally individualistic principles of research ethics in these contexts, if only

because individuals gain so much of their identity through their community memberships and their genetic lineages (Weijer 1999). Others argue that, at least for genetic studies, extensive efforts at community engagement are disingenuous and guaranteed to fail, given the mismatch between genetic populations and the politically defined communities available for consultation (Juengst 1998).

HUMAN REPRODUCTIVE CLONING

Philosophical questions about the nature of human identity have been raised from quite another angle, meanwhile, by the successful cloning of a sheep in 1997 (McGee 2000). In that case, the nucleus of a mammary gland cell from an adult ewe was transplanted into an enucleated egg, and, after 280 attempts, coaxed into developing into a genomic twin of the gland cell's donor. If the technique that produced Dolly, the ewe, could be used effectively with humans, it would open up the prospect of adding reproductive cloning to the repertoire of techniques available to those seeking to procreative assistance. This prospect has prompted questions about the personal identity and moral status of the resulting "delayed twin," but these seem easily answered by our experience with natural twins who also have identical genomes: Clearly, the cloned individual would be a distinct person with full moral standing, due full protection against exploitation or abuse by his or her progenitors.

However, anticipating parental expectations for cloned offspring raises more difficult questions. How similar might the cloned offspring be to the progenitor, and what impact should the foreknowledge (or assumption) of such similarities have on the rearing of the offspring? Should progenitors of clones assume special responsibilities to anticipate the health and behavioral challenges their delayed twins may face, or do they, instead, acquire unusual obligations to refrain as much as possible from prejudicing the life experience of their offspring? These questions are animating new work on the nature and ethics of parenting, procreative liberty, and the limits of genetic determinism. They have also given new energy to "natural law" arguments against reproductive technologies in general, by providing a case in which the slippery technological slope seems to lead us to a form of reproduction—asexual reproduction—that contradicts an element of human nature that has been fundamental to our species' identity to date (Lauritzen 2001).

Behind all of these concerns looms a follow-up question that links this discussion to back to the role of genetic lineage in human identity. Given the psychologi-

cal complexities of cloning and their potential impact on the offspring, is the value of sheer genetic continuity important enough to ever warrant the inclusion of this option on the menus of fertility medicine? Some argue that prospective parents who feel the need for genetic connections with their offspring simply mistakenly essentialistic, and should be re-educated accordingly (Post 1997). Others, however, suggest that the interest in extending the limits of procreative liberty to defend technologies like cloning reflects something important about the role of lineage in human identity which philosophy has yet to fully unravel (Roberts 1995).

HUMAN GENETIC MODIFICATION

The philosophical status of intergenerational genetic connections also lies at the heart of a new generation of attempts to define the appropriate limits of human genetic modification. The provisional boundaries of such a practice were established in the 1980s to provide a window for human gene therapy research. On one axis, a line was drawn between using genetic interventions to treat disease, and using it to attempt to "enhance" human traits to achieve nonmedical goals. On the other genetic interventions that only affected somatic cells were distinguished from those that might lead to intergenerational transmission of modifications, through the "germ-line." Both distinctions have come under recent philosophical critique. The line between treatment and enhancement appears difficult to maintain as a conceptual matter and its moral implications diverge significantly between its personal, parental, professional and public policy applications (Parens 1998). Meanwhile, it begins to appear that the price to pay for successful somatic cell gene therapy will be the development of tools for safe and effective germ-line interventions, and in that light the arguments in favor of abandoning that boundary in the service of medicine are gaining strength (Chapman and Frankel 2003).

Animating these debates is another argument over the importance of our genetic inheritance. Those who strive to preserve the "common genetic heritage of humankind" and protect the rights of future generations to "inherit an untampered genome" argue that our genetic inheritance forms the limits of our "species integrity", the violation of which risks literally de-humanizing ourselves and our offspring (Annas, Andrews, Isasi 2002; Fukuyama 2002). On this view, the contours of human nature, and thus the foundations of human moral status, are defined by the pool of genes—and their variants—that humans have collected over the course of our

evolution, and any manipulation of that legacy risks distorting or corrupting the human identity of our offspring.

This view is difficult to reconcile with what population genetics, developmental biology and gene transfer research itself teach us about the fluidity of the human genome and its relatively remote role in the human traits we prize most (Robert and Baylis 2003, DeGrazia 2005). Like the interest in race-based genomic medicine and concerns about the moral status of clones, it accepts a level of genetic essentialism that seems more indebted to Aristotle than to James Watson and Francis Crick. Nevertheless, all these views enjoy wide acceptance in both academic and public circles, which is intriguing. Perhaps this convergence signals the next challenge that genetics offers philosophy: to help clarify the role of genetic histories—the genes we inherit, the lineages we belong to, the peoples we spring from—in our identities as human beings and our experience of the human condition. If philosophical anthropology examines what it means to be a human individual, what genetics seems to call for now is a *philosophical genealogy*: the study of what it means to be a human descendant (Juengst 2004).

GENOVESI, ANTONIO
(1713–1769)

The Italian philosopher and economist Antonio Genovesi (the name was originally Genovese), was born in Castiglione, Salerno. After studying literature and rhetoric and then philosophy, he attended the lectures of the aged Giambattista Vico. In 1741 he began to teach metaphysics at the University of Naples as extraordinary professor. In 1743 he published the first volume of his *Elementa Metaphysicae Mathematicum in Modum Adornata* (5 vols., Naples, 1743–1745), for which he was accused of rationalism and atheism. In 1745 he began to teach ethics. In that year he published his *Elementa Artis Logico-criticae* and an important historical introduction to the Neapolitan edition of Pieter van Musschenbroek's *Elementa Physicae*. In the same year his *Universae Christianae Theologiae Elementa* was accused of heterodoxy; it was not published until after his death (Venice, 1771). Discouraged, Genovesi turned to other, less philosophical studies. He was offered the new chair of civil economy

(economics), the first in Europe, by the University of Naples and began his lectures in 1754 (*Delle lezioni di commercio ossia di economia civile,* Naples, 1765–1767). The problems of practical philosophy which occupied his final years are discussed in *Diceosina o sia filosofia del giusto e dell'onesto* (2 vols., Naples, 1766–1777).

In Genovesi's judgment, modern philosophy began when Francis Bacon and Galileo Galilei freed Europe from abstract and sterile inquiry. "Dialectics and metaphysics," he proclaimed, "are the Don Quixote of the Republic of Letters." According to him, it is impossible to know true reality, substance, that which "underlies" the phenomena that we can observe. (He asked, "Who lifts the skirt of nature to see that which ὑπάρχει [underlies]?") Although his thought had some similarities to George Berkeley's idealism and Gottfried Wilhelm Leibniz's monadism, as time went on his interest turned from logic and metaphysics and was oriented toward the moral disciplines, particularly toward economics, which he considered as affecting "our present comfort and tranquility." He sought to determine in a rational system "the primary, simple, and universal laws" of economics. He arranged in a similar framework the *Discorso sopra il vero fine delle lettere e delle scienze* (Naples, 1753), in which he argued against all inquiries "that remain exclusively in the shadow of the school, and never transgress into the acquisition of something useful for mankind."

GENTILE, GIOVANNI
(1875–1944)

Giovanni Gentile was one of the major figures in the resurgence of Hegelian idealism in Italy at the beginning of the twentieth century. His "actual idealism," or "actualism," represents the subjective extreme of the idealist tradition in that the present activity of reflective awareness (*l'atto del pensiero, pensiero pensante*) is regarded as the absolute foundation on which all else depends. The act of thinking is the "pure act" that creates the world of human experience.

LIFE AND WORKS

Gentile was born on May 30, 1875, at Castelvetrano in Sicily. He began his university education as a student of Italian literature under Alessandro d'Ancona at Pisa in 1893, but was quickly drawn into the study of philosophy by Donato Jaja, a pupil of the Neapolitan Hegelian, Bertrando Spaventa. Of the two main threads that run through all of Gentile's work, one—his concern with the theory and practice of education—is rooted directly in his own temperament and his strongly felt vocation as a teacher; but the other—his almost chauvinistic interest in the Italian philosophical tradition and its relation to the general European tradition—reflects the lifelong influence of Spaventa on his mind. His degree thesis, *Rosmini e Gioberti* (Pisa, 1898), in which he emphasized points of contact and agreement between the native Catholic thinkers and the German Idealists, was meant to illustrate Spaventa's thesis regarding "the circulation of European philosophy."

His second book was a critical examination of Karl Marx (*La filosofia di Marx,* Pisa, 1899) from an orthodox Hegelian standpoint. While writing it, Gentile became acquainted with Benedetto Croce, who was similarly occupied at the time. Thus began a friendly alliance that lasted more than twenty years. Gentile was the younger by nine years, but it seems clear that in these early formative years it was he who influenced the development of Croce's philosophy rather than vice versa, as most of their contemporaries assumed. Gentile was always more of a Hegelian than Croce ever became, and was more exclusively interested in the traditional problems of philosophy.

In 1900 Gentile wrote his important essay "The Concept of Education" ("Il concetto scientifico della pedagogia") and began his long campaign for the reform of the Italian school system. He became *Privatdocent* at Naples in 1903 and professor of the history of philosophy at Palermo in 1906. But the "reform of the Hegelian dialectic" and the "method of immanence" that led to actual idealism (in a paper of 1912) were worked out amid controversies with Modernists and polemics for religious instruction in elementary schools; and Gentile's philosophy was first fully expounded in the two-volume work *Sommario di pedagogia come scienza filosofica* (Summary of Educational Theory; 2 vols., Bari, 1913–1914).

In 1914 Gentile succeeded to Jaja's chair at Pisa, where he wrote the one book through which he is internationally known, *Teoria generale della spirito come atto puro* (The General Theory of the Spirit as Pure Act; Pisa, 1916). In 1917 he moved to the University of Rome; and the first volume of his *Sistema di logica come teoria del conoscere* (System of Logic as Theory of Knowing; Pisa, 1917), the most systematic statement of his view, appeared. The second volume followed at Bari in 1923.

In 1922 Gentile became minister of education in Benito Mussolini's first Cabinet, and in this capacity he reformed and reorganized the whole Italian school system. After his resignation in 1924 he became the first president of the National Fascist Institute of Culture; he remained for the rest of his life the most prominent publicist of the regime and the self-styled "philosopher of fascism." Gentile continued until his death to lecture at Rome, but in the fascist period his only important philosophical work was the *Filosofia dell'arte* (Milan, 1931). He was directing editor of the *Enciclopedia italiana* from its inception in 1925 to its completion in 1937. After the fall of Mussolini in 1943, Gentile went into retirement and wrote a short but important book on the genesis and structure of society that was published only after his death (*Genesi e struttura della società,* Florence, 1946). Subsequently persuaded to return to public life as a supporter of the Fascist Social Republic set up by the Germans, Gentile was assassinated by Italian communist partisans at Florence on April 15, 1944.

CONCEPTION OF PHILOSOPHY

Gentile justifies his "theory of the spirit as pure act" in two ways. First, he strives to show that it is the logical outcome of the whole movement of Western philosophical thought since René Descartes; and, second, that the "method of pure immanence," when we arrive at it, pro-

vides an adequate and coherent way of explicating our actual experience. It is impossible to give more than the briefest indication of the line of his historical argument, although it bulks very large in most of his systematic works.

In any case, the significance of his theory emerges more clearly through an examination of his analysis of actual experience. The claim that actual idealism is the logical outcome of the main tradition of modern philosophy is interesting chiefly because it throws light on Gentile's conception of the essential problem of philosophy and the conditions for its solution. Philosophy for him, as for Johann Gottlieb Fichte, was *Wissenschaftslehre,* the science of knowledge, the science that, without presupposing anything itself, provides an a priori ground for the presuppositions actually made in other sciences. Descartes's method of universal doubt can quite naturally be viewed as the first approach to this problem, and George Berkeley's doctrine that *esse est percipi* is a vital step toward its solution. However, the genesis of actual idealism begins with Immanuel Kant; and although Gentile arrived at his view through the progressive elaboration of a "reform of the Hegelian dialectic" that had been initiated by Spaventa, he remains fundamentally a Kantian in his determination to confine philosophical speculation to the task of exhibiting the logical structure of actual experience. He is at one with Kant and Fichte in his resolute rejection of any "dogmatic metaphysics" that posits or presupposes a reality transcending actual consciousness.

THEORY OF SELF-CONSTITUTION

There is a temptation to say at once that it is a mistake to conceive of the task of philosophy in this way, as the exhibition of the logical structure of actual experience, and that the ideal of a "philosophy without presuppositions" is a chimera. The most primitive postulate of ordinary common sense is that a physical world exists prior to and independent of our consciousness of it. However, Gentile's theory is not meant to be taken as a denial of this assumption, but as a thesis about logical priority. The temporal preexistence of the object of awareness is itself something that we take ourselves to be aware of, and in this sense the commonsense assumption is a product of our attempt to organize our experience in thought. Actual idealism must properly be judged as a theory about this process of rational organization or "concrete logic."

The most primitive level of the process for which we have ordinary words is sensation. We normally distin-

guish the objective cause of a sensation from the subjective feeling (pleasant or unpleasant) that it arouses in us. According to Gentile, this is a mistake. The sensation as a whole is our act of self-awareness, and the pleasure or pain is an aspect of this whole, not a reaction of the self to an object. He agrees emphatically that there cannot be any actual consciousness without the distinction of the subject of the awareness from the object of which it is aware. But he holds that since what has to be understood is the integral unity of the self, it is a mistake to look for the cause of experience within the content of experience. At the ideal limit, pure sensation can be thought of as an encounter with something absolutely other than the self; but it can also be thought of as a spontaneous activity of self-affirmation. Gentile does in fact employ "sensation" in both ways. Spontaneous self-affirmation is in his view the ideal aim of the artist, and loss of self in the contemplation of an absolute object is the typical concern of religious experience. But actual experience is always a synthesis, so that pure art and pure religion are nowhere to be found; and the actual understanding of any type of artistic or religious experience will involve restoring the suppressed aspects of the synthesis, that is to say, discovering the philosophy behind it.

Actual sensation is a process of self-constitution (*autoctisi*) in which the subject preserves its own past and relates it to present sensation. Language is abstractly the instrument and concretely the form through which this is done. It is neither the clothing nor the vehicle, but the embodiment of our thought. But we are able to think of it abstractly, as an inheritance shared by all who are able to use it, because the thought embodied in it has universal import. Thus the self that comes to consciousness when we express our thoughts in language is a spiritual universe, a system of meanings in which all other thinking beings can share. This is the absolute subject of experience, the transcendental Ego whose being (like the God of Aristotle and St. Thomas Aquinas) is "pure act." The abstract form that Kant called the "transcendental unity of apperception" is given concrete existence, or brought to life, so to speak, in Gentile's conception of the "pure act" of "self-founding." My reflective awareness is on the one hand exactly what is essential to my existence as an independent personality; but on the other hand, so far as I achieve reflective awareness, I enter the world of thought in which nothing belongs, or can belong, to me personally. When I claim to think something, I must be able to communicate my thought; I must be able to show others the path by which I arrived at it so that, insofar as they can follow in my footsteps, they can share it. Reflective awareness is already communication, for my own thought is a dialogue within myself. The obvious fact that humans are social animals and that the peculiarly human institution of language is a collaborative production has its absolute or philosophical ground in the fact that the founding of the self is the founding of a transcendental society.

When we understand the fundamental concept of self-constitution in this way, Gentile's thesis about the unity of thought and action, which was the chief bone of contention between him and Croce, falls naturally into place and is easily understood. There appears to be a contrast between thought and action because in cognitive thinking we presuppose the reality we are concerned about, whereas our action is directed toward the creation of some object. However, all thinking and acting is in reality part of the same activity of self-conquest in which nothing is absolutely presupposed theoretically, and some things must be accepted (or presupposed) practically, if there is to be a line between the self and the not-self, the conquering subject and the nature or world that is to be conquered: "the spiritual act is never a self-creation that must be contemplated and watched over afterward; it is always simultaneously a self-creation that is self-awareness and vice versa" (*Opere* I, 84). The establishment of truth is the self-establishment of the transcendental Ego; and the establishment of the Ego is the establishment of an ideal community that Gentile, like G. W. F. Hegel, calls "the State."

The State is on the one side that complex of social institutions, cultural traditions, and ethical values that appears to the individual as the actual fabric of his own moral personality; on the other side it is all the ideals that have still to be striven for and achieved in the actual world in which he lives. Gentile often insists on this latter Mazzinian side of his doctrine, but in practice he tended to subordinate it to his conservative Hegelian faith in the rationality of the actual social structure. In his fascist apologias it often seems as if whatever is done in the name of the existing State must be patiently, even joyfully, accepted and endured as a condition for any further advance—an attitude that is more reminiscent of Thomas Hobbes than of Giuseppe Mazzini. There can be no question that this attitude is false to the spirit of his doctrine.

GENTILE'S LOGIC AND THE FORMS OF VALUE

The unity of theory and practice means that in Gentile's work "logic"—the concrete logic of the self-concept—becomes inseparable if not indistinguishable from ethics,

and philosophy itself is seen as the critical self-awareness of actual political life. His major theoretical problem was to show how the nonpolitical values of human experience could be integrated into his view. This problem came to Gentile in the form that Hegel gave it when he made art and religion the moments of the final triad of the Absolute Idea, subordinate only to philosophy itself. Gentile solved it by regarding art and religion as the moments of his own Absolute, the act of thought. Thus art and religion, instead of being ultimate, become primitive; they are the essential moments of all experience. They have their joint origin, as has been shown, in the opposite aspects of the sensation or "self-feeling" in which consciousness originates. As distinct modes of experience they are attempts to achieve the impossible by aesthetically recapturing or mystically losing oneself in that ideal point of origin.

Thus the seeming independence of aesthetic and religious values arises from the one-sided consciousness of the artist or worshiper. In reality the self-willed artist is dedicated to the production of an object of universal value and significance; art is not just the release of feeling, but the disciplined expression of it. And the proclaiming of the glory of God or the doing of his will is the work of a human voice or the task of a human hand. The "private" world of the artist and the "other" world of the believer get their meaning and fulfill their function in the actual society of the transcendental Ego. When we view the artist's work, we must strive to comprehend the ideal to which he has devoted his skill; and when we seek to interpret a religious doctrine, we must express its meaning for humanity and in terms of our own actual lives. It thus becomes the task of the critic to interpret the work of art or the religious doctrine philosophically. Gentile wrote a number of books and essays—mainly but not exclusively about literary artists—in which he endeavored to do just this; and on the religious side he maintained that his "humanistic conception of the world" was a philosophical expression of the Christian revelation.

In the concrete logic of the act of thought, the moment of spontaneous self-expression is prior to the consciousness of the object, which necessarily appears as a limit upon the self. Hence, in the progressive development of consciousness, which is the subject of Gentile's philosophy of education, an aesthetic phase of free, spontaneous play is succeeded by a religious phase that it is the main task of the elementary school to establish and govern. On this basis a properly philosophical conception of the world, a sense of the autonomous moral responsibil-

ity of the self-conscious citizen, should then be built up in secondary education.

ABSTRACT LOGIC. It should by now be clear that actual idealism can be interpreted as primarily a theory about the logical structure of our experience of values. But this theory does contain within it a theory about the ordinary logic of factual propositions. Formal logic, whether mathematical or conceptual, is the logic of presupposition, the logic of "nature," the abstract logic of any object that any actual concrete consciousness may assume as its content. Gentile thought of this *logo astratto* as being essentially static and unchanging. Benedict de Spinoza's system was for him the perfect philosophical expression and reductio ad absurdum of it; and his own conception of natural science was strictly Kantian. "Nature" was for him an a priori concept with a fixed logical structure, not an idea that evolves in the dialectic of actual research. But this is only a reflection of his own personal background and interests. The "idea of nature" has a history, and a full development of the theory of mind as pure act would seem to require that the history of science be incorporated as an essential aspect or complement of the history of theoretical philosophy.

Gentile's own use of the category of the *logo astratto* in the sphere of practical philosophy was quite fluid and dialectical. In ethics, for example, it appears as the nature that we must conquer and subdue, but it appears also as the abstract law to which we must submit. When we remember that the transcendental Ego itself, the *logo concreto,* is both the organic unity of all prior achievement and the ideal of a perfect harmony still to be achieved, this becomes quite easy to understand. The concrete self-concept has its abstract content under each aspect—there is sinful nature and there is the law in virtue of which we are aware of it as sinful; the act of self-constitution is the resolution of the conflict that produced the two opposed abstractions.

NEGATIVE VALUES. Finally, Gentile holds that error, pain, and sin are in some sense "unreal." This doctrine follows logically from the fact that they belong to the category of the *logo astratto.* They are things that we are conscious of, and they have already been overcome or surpassed in the very consciousness of them. It is quite easy to exhibit, as a mere matter of logic, how "truth" is the concrete category of which "error" is only the abstract content. For to be actually aware that some proposition is or may be an error is to hold that a proposition about that proposition is true—namely, the proposition that it is or may be an error.

In the case of sin, something more than a logical relationship of propositions is involved. If I say, "I am a sinner," I am setting myself up as a supposedly just judge of my own conduct; but I do not thereby cease to be a sinner. Rather, the question is posed of how a single self is to be constituted out of this divided consciousness. This is the key to the only defensible interpretation of Gentile's doctrine, which then asserts that when I truly say, "I am a sinner," I must be on the road to redemption and that the test of whether I do actually think I am a sinner is my consciousness of repentance.

Gentile's view that "pleasure" is the concrete and "pain" or "grief" the abstract category is more difficult to interpret. If I am conscious of being in pain, I have certainly "overcome" the pain; that is, isolated it and objectified it as a fact. But to argue that because of this it is not really I who am in pain is sheer sophistry. It is certainly true that the consciousness of pain is a complex activity (including, for example, the active seeking of a remedy or a distraction), while the pain in itself is an abstract element. But pain is "unreal" only in the sense in which art and religion are unreal. That is to say, there cannot be a pure pain-consciousness, for this is just the point at which consciousness disappears.

GENTILE'S INFLUENCE

Actual Idealism was the dominant philosophy in Italian state schools and universities throughout the last twenty years of Gentile's life. In this period his students, like Hegel's, split into two main parties. There was first the "right," led by Armando Carlini, who emphasized the Christian origin and Augustinian character of much of Gentile's thought, and identified the transcendental Ego with the God of Catholic theology. After Gentile's death this group joined with the religious existentialists to form the contemporary movement known as Christian Spiritualism.

On the other side, a group of younger disciples, led by Ugo Spirito, formed the Gentilian "left," which from the first devoted itself to social problems and provided much of the economic and political theory of the fascist corporate state. Since World War II this group has been aligned with the political left and has shown some affinities with orthodox Marxism. But in the current work of both groups it is the mystical spirit of Gentile's philosophy rather than the logical structure that has survived. Outside of Italy, Gentile's influence can be seen most notably in the work of R. G. Collingwood.

Bibliography

The Gentile Foundation was established in Rome in 1947, with the *Giornale critico della filosofia italiana* (founded by Gentile in 1920) as its official organ. The foundation is issuing the definitive edition of Gentile's *Complete Works* in 55 volumes. Three of his books have been translated into English: *The Theory of Mind as Pure Act* (London: Macmillan, 1922); *The Reform of Education,* lectures to the schoolteachers of Trieste (New York: Harcourt Brace, 1922); and *Genesis and Structure of Society* (Urbana: University of Illinois Press, 1960). This last includes a complete bibliography and critical survey of everything by or about Gentile in English.

For critical studies of Gentile, see the following: H. S. Harris, *The Social Philosophy of Giovanni Gentile* (Urbana: University of Illinois Press, 1960) surveys the whole range of Gentile's practical philosophy, including his "philosophy of fascism," which has been largely ignored above. R. W. Holmes, *The Idealism of Giovanni Gentile* (New York: Macmillan, 1937) is a detailed and critical study of the *System of Logic* and a work of fundamental importance. P. Romanell, *The Philosophy of Giovanni Gentile* (New York: S.F. Vanni, 1938) provides a general survey.

H. S. Harris (1967)

GEOMETRY

Until 1800, mathematics was divided into two great branches: *geometry* and *arithmetic.* Both were commonly regarded as the more obviously secure repositories of human knowledge. At this stage, geometry could be suitably defined as "the science which investigates the properties and relations of magnitudes in space, as lines, surfaces, and solids" (*Oxford English Dictionary*). However, with the enormous enrichment of mathematics in the nineteenth century, the scope of geometry was greatly expanded and diversified, its content disrupted, and its epistemic standing called into question.

The word "geometry" comes from a Greek word that literally means measurement of the earth and was originally applied to the art of land surveying. But around 500 BCE or even earlier, the spatial properties and relations

that had been codified by land surveyors in Mesopotamia and Egypt became in Greece the starting-point of inquiries of a more abstract sort that soon took leave of their down-to-earth origins. In this guise, geometry appeared to Plato as a testimony of the other-worldly origin of the human soul (*Meno*) and was included by him as a compulsory item in the curriculum for would-be philosopher-kings (*Republic*, VII, 526c–528d). For more than twenty centuries, philosophers regarded the geometry created by Greek mathematicians from Eudoxus, through Euclid, to Archimedes and Apollonius as the standard of indubitable truth and cogent reasoning. As a result of later developments, geometry, with the rest of mathematics, came to be seen as a capital example of the loss of certainty that currently pervades most areas of civilized life (Kline 1980). In more than one sense, this enhances, rather than diminishes its philosophical significance.

This entry is divided into three sections. The first section touches on some philosophically noteworthy aspects of ancient geometry. The second section deals briefly with geometry and philosophy from 1600 to 1800. And the third section describes those episodes in the history of geometry since 1800 that had the greatest impact on twentieth-century philosophy.

TOPICS IN ANCIENT GEOMETRY

GEOMETRY IN THE MIDDLE EAST. According to Herodotus (2.109), the Greeks learned land surveying (*geōmētriē*) from the Egyptians, who used it to reassess taxes on properties partially washed away by the Nile. It appears that this art was first cultivated in the Middle East to cope with the consequences of floods in southern Mesopotamia. Archaeological evidence from both regions displays applications of the so-called theorem of Pythagoras, and a clay tablet now at Yale University (YBC 7289) gives the length of the diagonal of a unit square as 1.41421296, the same approximation to $\sqrt{2}$ that Ptolemy used some 2,000 years later. The Old Babylonian scribe who calculated it probably knew that he could improve on this figure, but it is highly unlikely that he suspected that no algorithm could ever yield a perfectly accurate one. No extant document from ancient Egypt or Mesopotamia contains the general statement of a geometric theorem or anything that even remotely resembles a geometric proof.

PYTHAGOREANS AND IRRATIONALS. Thales of Miletus, "the first to philosophize," supposedly was also the first to prove a geometric theorem (namely, that a trian-

gle with two equal sides also has two equal angles). The earliest proofs probably consisted of diagrams that plainly displayed the relations they were meant to prove (see Plato, *Meno*, 80d–86c). But Greek geometers soon produced purely discursive proofs (like the one given later in this paragraph). The Pythagoreans, intellectually and politically active in southern Italy throughout the fifth century BCE, worked intensely on mathematical problems, as they thought that numbers (i.e., the positive integers) are the principles of everything. This suggestive belief was supported by their discovery that musical chords are associated with simple numerical proportions. It broke down, however, when a member of the school, possibly Hippasus of Metapontum, showed that there are geometric magnitudes of the same kind whose relative sizes cannot be conveyed by numbers. Presumably, this was first demonstrated for the diagonal and the side of the regular pentagon; but it is proved more easily for the diagonal and the side of a square by the following argument transmitted in an appendix to Euclid's *Elements*.

Take the side of the square as the unit of length. Then, by Pythagoras's theorem, the length of the diagonal equals $\sqrt{2}$. But there are no two integers a and b such that $(a/b)^2 = 2$. For suppose there are. Then, by simplification of the fraction a/b we should find two integers p and q, with no common divisor, such that $(p/q)^2 = 2$. Then $p^2 = 2q^2$ and p is an even number, equal to $2n$, say. (For the square of an odd number, say $2n + 1$, is always odd, that is, $4n^2 + 4n + 1$). But then $2q^2 = p^2 = 4n^2$, and $q^2 = 2n^2$, so that q is also even. But this is impossible, for we assumed that p and q do not have a common divisor. Therefore, one cannot find two integers a and b, no matter how large, such that the diagonal of a square exactly equals $a \times 1/b$ of its side. Awareness of the existence of incommensurable lengths cut short dreams of grasping nature through numbers and opened a chasm between arithmetic and geometry.

EUDOXUS'S THEORY OF PROPORTIONS. Eudoxus of Cnidos (c. 390–c. 337 BCE) invented a method for representing the visible motion of each planet in the sky (including Sun and Moon) as the resultant of the combined uniform rotations of several geocentric spheres. Eudoxus's planetary models are the earliest extant example of geometrical representation of natural processes for the sake of predicting their future evolution. Their moderate predictive success may have motivated Plato's change of mind from his early view that real planetary motions are essentially irregular and unpredictable (*Republic* VII, 529d7–530b4) to his later commendation of mathematical astronomy as an efficient servant of

theology (*Laws* VII, 822a4–c5; X, 897c4–9; XII, 966d6–967d2) and his endorsement of Eudoxus's program as the proper way of "saving the phenomena" of the sky (Simplicius, 7.492.30–35). Eudoxus also originated the method of exhaustion employed by Archimedes for calculating volumes enclosed by curved surfaces, which was the first step toward the creation of the integral calculus. But Eudoxus's chief contribution to geometry was his theory of proportions, preserved in book 5 of Euclid's *Elements*. With it, geometry recovered the computational powers it had lost when separated from arithmetic, and the road was opened for rigorously conceiving and handling physical quantities of all sorts.

Two magnitudes *a* and *b* are said to have a ratio *a:b* to one another if there are integers *m* and *n* such that $m \times a > b$ and $n \times b > a$. (The assumption that any two lengths have a ratio to one another is known as the Archimedean postulate.) Eudoxus produced definitions by virtue of which ratios can be added and multiplied, yielding new ratios, and any two ratios *a:b* and *c:d* satisfy *trichotomy*, that is, either *a:b = c:d*, or *a:b > c:d*, or *c:d > a:b*. In this last case, there will always be an integer *n* such that *n(a:b) > c:d*. Thus, it is natural to regard all Eudoxean ratios as magnitudes that have ratios to one another. This paves the way for setting up equations that combine magnitudes of very different kinds, for example, masses, distances, and times, or volumes, temperatures, and pressures (as represented by their respective ratios with the appropriate units). However, it is not apparent that anyone saw this before the seventeenth century.

EUCLID'S *ELEMENTS*. In this, the most famous of mathematical textbooks, Euclid (c. 325–c. 265 BCE) organized the results and displayed the methods of fourth-century-BCE Greek geometry. It is usually taken for granted that the book is patterned after Aristotle's conception of a true science (*epistēmē*). This must consist of a collection of universal statements (theorems) obtained by deductive inference from self-evident premises (axioms) and definitions using a few self-explanatory terms (primitives). However, Euclid's book, though prima facie it may seem to prove every theorem from five postulates and a short list of so-called common notions, often resorts to unspoken assumptions. Moreover, Euclid's deductions do not all fit into the narrow frame of Aristotle's logic, and use forms of inference first codified by George Boole (1815–1864), Augustus De Morgan (1806–1871), and Charles Sanders Peirce (1839–1914). Also, his primary definitions (e.g., "A *straight* is a line which lies evenly with the points in itself") would have to be further supplemented by axioms to be of use in deductions. It seems

more likely, therefore, that Aristotle based his idea of a true science on his own grasp of what contemporary geometricians were doing (textbooks similar to Euclid's had been around since Aristotle was a student in Plato's Academy) but did not set a paradigm that they or their successors actually followed.

EUCLID'S POSTULATES. The first three postulates are not statements, but requests to allow certain constructions. The third—"to describe a circle with any center and any radius"—would require an infinite drawing board, which is not self-evidently available. The fifth is a conditional existential statement: "If a straight line falling on two straight lines makes the interior angles on the same side less than two right angles, the two straight lines, *if produced indefinitely*, intersect on that side on which are the angles less than the two right angles." Obviously, the condition here printed in italics can only be met on an endless plane. So in the finite world of Aristotelian and medieval cosmology, this postulate is vacuously true, and its existential consequent may be false (there may well not be any such intersection). Still, if Euclid's other postulates and the Archimedean postulate are true, denial of the consequent implies that a quadrangle with three right angles has an acute angle at the remaining corner, so there can be no rectangles. It also implies that polygons with the same shape also have the same size, in which case Aristotle's suggestion (*Physics* 207b29–34) that all geometrical theorems can be demonstrated in his bounded cosmos by suitably scaling down the diagrams employed would simply be wrong.

These seemingly counterintuitive implications kept geometers throughout the centuries trying to prove the fifth postulate from other principles until, shortly after 1820, Nikolay Lobachevsky and Janos Bolyai dared to deny it and independently published essentially the same system of non-Euclidean geometry. It might be a sign of Euclid's genius that he did not gloss over the fact that this assumption (without which the theorem of Pythagoras will not stand) is not self-evident.

GEOMETRY AND PHILOSOPHY AT THE ONSET OF MODERNITY

NATURE GEOMETRIZED. Aristotle taught that natural science, to adequately grasp its proper subject, must employ terms that connote the peculiar matter of each thing, for example, "snub," which only applies to fleshy noses, rather than "concave," which connotes merely a geometric shape (*Metaphysics* E, 1, 1025b30–1026a7; *Physics* II, 2, 194a2–27). Still, he agreed (*Metaphysics* Λ, 8)

with the purely geometric description of astronomical phenomena proposed by Eudoxus, presumably because he believed that ether, the stuff that the heavens are made of, can change only by rotation about the center of the Earth, and this is properly described in geometric terms. Anyway, Aristotle's strictures on science did not deter Archimedes (c. 287–212 BCE) from dealing mathematically with the equilibrium and the flotation of bodies. In the meantime, astronomers from Apollonius (third cent. BCE) and Hipparchus (second cent. BCE), through Ptolemy (second cent. CE), to Copernicus (1473–1543) developed ever more complex geometric models of planetary motion, involving diverse circular motions about different centers (none of which coincides with that of the Earth).

After Galileo Galilei's telescope showed that there are mountains on the Moon and fleeting spots on the Sun, the distinction between celestial and terrestrial physics became pointless, and each took cues from the other. Thus Johannes Kepler (1571–1630) sought to explain the motion of planets (including the Earth) by *forces* exerted on them from the Sun, while Galileo (1564–1642) proposed a chronogeometrical model of free fall on the surface of the Earth, which he conceived as uniformly accelerated rectilinear motion. Lasting success was finally achieved by Isaac Newton (1642–1727), by dint of his mathematical genius and his consummate command of geometry. In the course of these efforts, Kepler (1609) had the words "God is always doing geometry" printed on the front page of his masterpiece, and Galileo wrote that the book of nature "is written in mathematical language, and its characters are triangles, circles and other geometrical figures, without which we cannot understand a word of it" (1623, sec. 6). René Descartes's contention that extension is the one and only clearly and distinctly conceivable attribute of bodies surely called for a comprehensive and thoroughgoing geometrization of physics and might have led to it had geometry been ripe enough to deal with its strenuous demands.

DESCARTES'S REVOLUTION IN GEOMETRY. Except for his first law of motion (the principle of inertia) and his work on the refraction of light, Descartes's direct contribution to physics, subjected to unsparing criticism by Christian Huygens, Gottfried Wilhelm Leibniz, and Isaac Newton, failed to gain admission into the classical canon. But modern mathematical physics would not have been possible without Descartes's *indirect* contribution to it, through his two great inventions in geometry: *coordinates* (independently introduced also by Pierre Fermat) and the *algebra of lengths*.

Coordinates are quantitative labels employed for identifying points in space. By means of them the relations among the points can be quantitatively represented and investigated. Nowadays geometric coordinates are drawn from the field of real numbers $\mathbb{R}$, which we regard as a natural extension of $\mathbb{Q}$, the field of rationals, which, in turn, is constructed from the familiar integers. But this understanding of these matters was still far off in Descartes's time (although his geometric algebra was a decisive step toward it). To avoid anachronism, one must regard Descartes's original coordinates as oriented lengths or, more exactly, as Eudoxean ratios between such lengths and a conventionally chosen unit length. To assign so-called Cartesian coordinates to a point P in space, one takes the three distances x, y, and z from P to three mutually perpendicular planes (listed in a conventional order, the same for all points), and prefixes to each a plus sign or a minus sign, according to the side of the respective plane that faces P (again by convention). The Cartesian coordinates of P then form an ordered triple of oriented lengths, say $\langle +x, -y, -z \rangle$. (There are other ways of defining coordinates: Oblique coordinates depend on three planes not at right angles to each other. Polar coordinates label a point P by its absolute distance from a fixed point O, the angle made by OP with a fixed plane Γ through O, and the angle made by the perpendicular projection of OP on Γ with a fixed line through O on that same plane.)

In Euclid's *Elements* (1956), segments are added to segments in an obvious way to obtain new segments; multiplying a segment s by an integer n amounts to adding n copies of s end to end; a straight segment or a length is never multiplied by another one. Until not too long ago, it was usually understood that such multiplications do occur in Euclid's book, but then the product of such a multiplication had to be an *area*. Descartes followed Euclid on the addition of lengths and defined the multiplication of a length a by a length b so as to yield still another length ab. Here is how. Draw two straight lines from a point O. Mark points F and H on one line so that OF has unit length and OH has length a. Mark point G on the second line so that OG has length b. Draw the straight line segment FG. Let the parallel to FG through H cut the second line at K. Clearly, then, $OH/OF = OK/OG$. Therefore, $OG \times OH = OK \times OF$; in other words, OK has length ab (Figure 1).

By this procedure, entirely based on elementary geometrical knowledge available to Euclid, Descartes and his successors were able to represent all geometrical relations by equations or inequalities between given and unknown

FIGURE 1
quantities, and to solve geometrical problems algebraically. In the algebra all such quantities were handled in the same way as the positive integers and they were therefore called *numbers*. Newton explains: "By a number we do not understand a multitude of units, but rather the abstract ratio of any quantity to another quantity of the same kind, which is taken as a unit. There are three varieties of number: integers, rationals and irrationals" (1707, p. 2). Eventually, they were called *real* numbers, to distinguish them from the imaginary ones, that is, the multiples of $\sqrt{-1}$, which also turned up as solutions of algebraic equations.

The method of coordinates soon suggested the idea of a space with *n* dimensions, whose points would be labeled by *n* quantities. In particular, if $\langle x, y \rangle$ denotes an arbitrary point on a plane, a straight line on that plane can now be defined as the set of points satisfying the linear equation $y = ax + b$, and a circle with radius *r* and center at $\langle 0, 0 \rangle$ as the set of points satisfying the quadratic equation $x^2 + y^2 = r^2$. These two equations take care of all points on the plane that can be constructed with a ruler and a compass, which were the only points contemplated by Euclid. But after Descartes, mathematicians felt free to consider any curve defined by an algebraic equation or indeed by a convergent series, such as $y = \sin x$, or $y = e^x$ (where *e* is the base of the natural logarithms). Even though Euclid never countenanced the plethora of points obtainable in such ways and it does not follow from his postulates, what we normally call "Euclidean space" comprises them all.

KANT'S PHILOSOPHY OF GEOMETRY. The overwhelming success of geometry in physics and astronomy induced some seventeenth-century philosophers to fol-low its example in ethics and metaphysics. The foremost instance of this is Benedict de Spinoza's *Ethica ordine geometrico demonstrata* (Ethics demonstrated in geometric order; 1677), but John Locke too believed that "if men would in the same method, and with the same indifferency, search after moral as they do mathematical truths," then "a great part of morality might be made out with that clearness, that could leave, to a considering man, no more reason to doubt, than he could have to doubt of the truth of propositions in mathematics, which have been demonstrated to him" (1690, IV.iii.20, xii.8).

Immanuel Kant, however, thought otherwise. Invidiously comparing geometry, as a science that "excels all others in certainty and distinctness," with metaphysics, which "has only just started out on the path to these goals" (1902–, 2: 168), he recommended, in 1763, that the latter stop imitating the former, in order to progress along that path. He soon went further. In his Latin dissertation of 1770, Kant taught that confusion and stagnation in metaphysics were due to the contamination of the human intellect with the sensuous notions of time and space. By thoroughly avoiding them, metaphysics will escape the temptations of materialism and determinism and become a secure science of God, freedom, and immortality. Yet in the *Critique of Pure Reason* (1781), Kant likened the purified understanding he advocated in 1770 to a bird that, tired by the resistance of the air, sets out to fly in a vacuum. In his mature view, the basic concepts of human thought—one and many, reality and negation, substance and cause—are not obtained from sensuous experience, but they can refer to objects only when applied to it, under the conditions of human sensibility, namely, space and time.

This decisive turnabout in the history of philosophy is closely related to Kant's reflections on geometry and its use in physics. In 1746 Kant spoke of a general or "supreme" geometry, adapted to a space with any number of dimensions. That the space we live in has only three dimensions is due to the empirical fact that all material particles are linked by forces governed by Newton's inverse-square law (1902–, 1: 34). But in 1768 he made a discovery that, he thought, put an end to all such explanations of space and spatial structure from the physical relations between bodies in space. No description of a shoe in terms of its different parts and the relations between them will allow us to tell a left shoe from the matching right shoe; the difference between the two shoes can be grasped only by considering their respective orientation in the space that embraces them. Kant understood this to imply that the bodily structure of bodies

depends on that of space as a whole, which therefore is presupposed by them, rather than being only an expression of their interactions.

Kant was then faced with the following dilemma: Either (a) space itself is a substance, of which bodies are modes (a position that, according to Kant, results in Spinoza's unchristian and immoral deification of space), or (b) space must be thought of as possessing a novel, hitherto unheard of manner of existence (which implies a corresponding adjustment of the ontological standing of bodies as such). About 1769 Kant lighted on alternative (b), which he described around 1791 as one of the two hinges on which metaphysics must turn (the other one being the reality of freedom). He claims that "*space is not something objective and real*, neither a substance, nor an accident, nor a relation; it is rather a subjective and ideal scheme, so to speak—which issues from the nature of the mind according to a stable law—for coordinating everything that is sensed externally" (1902–, 2: 403). Or, in mantra form, *space is one of the forms of human sensibility* (time is the other one). As a consequence of this, things are bodies only insofar as they are actual or potential objects of our sense perception, but not as they are in themselves. (Indeed, Kant figured out in the early 1770s that the standard assumption that things in themselves are spatial would make it impossible to solve the contradictions regarding the limit of the physical world and the divisibility of its content, which he later set forth in the first two items of the Antinomy of pure reason.)

Kant's conception of space is the key to his philosophy of geometry (and is in turn reinforced by it). The epistemological problem of geometry lies in explaining how it can furnish us with precise quantitative information about things we have never met in real life and which anyway we could not measure accurately, for example, the exact size of the angles of a trillion-sided regular polygon. Plato proposed that this knowledge is remembered from another life in which we had direct access to the intelligible "form" of things. The fact that geometry contains such knowledge nourished similar hopes for metaphysics and ethics, which, however, were crushed by Kant's approach. In his view, geometry rests on our natural awareness of the conditions under which alone the manifold appearances displayed through our external senses "can be ordered into certain relations" (1787, B 34) and thus shaped into corporeal phenomena. Such awareness is not intellectual but intuitive, as we may gather from the example of the pair of shoes, described above, and also from the fact that geometrical proofs proceed by the "construction of concepts." Kant explains this expression

somewhat intriguingly as follows: "To *construct* a concept means to exhibit a priori the intuition that corresponds to it: the construction of a concept therefore requires a *non-empirical* intuition which … as intuition is a *particular* object, but nevertheless, as the construction of a concept (a general idea), must convey universal validity for all possible intuitions that belong under the same concept" (1781/1787, A 713/B 742).

Anyone not put off by these opaque notions could well regard them as a proper explanation of the amazing success of geometry in physics. For, if geometry spells out the ordering that is required for us to grasp external phenomena, then it is no wonder that all external phenomena comply in every detail with the teachings of geometry. Soon, however, innovations in geometry moved the ground from under Kant's position and made it untenable. Before we turn to them, it should be emphasized that among these innovations, the best known one—the derivation of a consistent geometry from the denial of Euclid's fifth postulate—does not challenge Kant's view but somehow corroborates it. For Kant, geometry provides information, conveyed by what he called *synthetic* propositions, and this implies that any of its unproven principles can be denied without self-contradiction.

FROM GAUSS TO HILBERT AND BEYOND

NON-EUCLIDEAN GEOMETRY. The fact that Euclid's fifth postulate is not self-evident prompted several mathematicians to try to prove it. John Wallis (1616–1703) succeeded in inferring it from the assumption that for any given figure there is another one, similar to it, of any arbitrary size. This assumption is neither necessarily true nor empirically obvious, but it does provide a perspicuous characterization of Euclidean space.

Girolamo Saccheri (1733[1986]) sought to prove the postulate indirectly. He devised a quadrilateral thus constructed on a plane: Draw straight lines *m* and *n* through points *P* and *Q*, making right angles with the segment *PQ*. Mark points *A* and *B* on *m* so that *AP* = *PB*. Mark points *C* and *D* on *n* so that *CA* and *DB* are both perpendicular to *m* (See Figure 2).

If one assumes the Archimedean postulate (which Saccheri tacitly does), the fifth postulate will hold if and only if ∠ACQ and ∠BDQ are right angles. Saccheri assumed that these angles are obtuse and easily proved that, if so, two points can be joined by more than one line, which he considered absurd. He then assumed that both

FIGURE 2
angles are acute and derived from this hypothesis many surprising propositions that did not appear to be contradictory, until at last he reached one he pronounced "repugnant to the nature of the straight line."

The consequences that Saccheri drew from the acute-angle hypothesis reappeared in the nineteenth century in the private papers of Carl F. Gauss (1777–1855) and in independent publications by Nikolay I. Lobachevsky (1793–1856) and Janos Bolyai (1802–1860). These authors treated these consequences as theorems of an alternative system of geometry, based on the straightforward denial of Euclid's fifth postulate (with the others retained). This system has received various names, but by priority of publication, it should be called *Lobachevskian geometry*. In this geometry, the three interior angles of a triangle add up to less than two right angles, the difference being proportional to the area of the triangle. Therefore, similar triangles are congruent. Consider again the segment *PQ* perpendicular to straight line *m* at *P*. By the denial of the fifth postulate, there is a set *S* of straight lines through *Q* that form an acute angle with *PQ* on one or the other side of it and yet do not meet *m* on that side (let alone on the side where they form an obtuse angle with *PQ*). Let α be the smallest of these angles. By symmetry, there are two lines in *S* that form angle α on either side of *PQ*. In Lobachevsky's terminology (independently adopted also by both Gauss and Bolyai), these two lines are called the *parallels* of *m* through *Q*, and α is the *angle of parallelism* for *PQ*. The size of α decreases as *PQ* grows. On any Lobachevskian plane, there is a unique length *h* such that the angle of parallelism for any segment of length *h* equals 45°. The length *h* provides an absolute standard of length for that plane. Kant's friend Johann Heinrich Lambert, who around 1766 worked on this sub-

ject along lines similar to Saccheri's, said there was "something alluring about this consequence which readily arouses the desire that the [acute angle] hypothesis be true!" (1786/1895, p. 162). Note that if, in the case discussed, *PQ* = *h*, the two parallels to *m* through *Q* are mutually perpendicular. Lambert thought this was an intolerable paradox.

The absence of contradiction in a long series of theorems inferred from the denial of the fifth postulate does not, of course, imply that Lobachevskian geometry is consistent. Lobachevsky proposed an argument for proving that his geometry is at least as tenable as Euclidean geometry. He showed that there is a logically formal correspondence between the equations of Lobachevskian trigonometry and the familiar equations of spherical trigonometry. By virtue of it, any contradiction derived from the former will be matched by one flowing from the latter. Such a contradiction would entail that the said standard trigonometric equations are false, and this in turn would entail the falsehood of the Euclidean principles from which these equations follow.

Lobachevsky also tried to ascertain whether his own geometry or Euclid's is true of physical space. He used astronomical data to calculate the sum of the internal angles of the triangle formed by three stars and concluded that the difference between the result obtained in a Lobachevskian space and the Euclidean value was well within the margin of observational error. Decades would pass before Hermann Lotze (1879, p. 774) pointed out that all such attempts are vain, for if astronomical measurements do not agree with Euclidean geometry, the disagreement can still be accounted for by a deviation of stellar light from its supposedly rectilinear trajectory.

GROUPS AND INVARIANTS. Shortly before Lobachevsky's earliest publication on his geometry, Jean-Victor Poncelet's *Treatise on the Projective Properties of Figures* (1822) started a way of doing geometry that seemed more intuitive and tame but which ultimately was much more radical and would have deeper consequences than the denial of Euclid's fifth postulate. It is based on adding to each straight line *m* a "point at infinity" that *m* shares with every straight line parallel to it and treating all such "points" as belonging to a single "plane." This assumption enormously simplified the statement and the proof of geometric theorems concerning relations of incidence, collinearity, and coplanarity among points, lines, and planes. Metric features like distance and metric relations like congruence were totally ignored. Natural (initially tacit) assumptions regarding the neighborhood relations

between the points at infinity and the standard points implied that ordinary space differed drastically from the new *projective space* in which it was now embedded. For example, a left shoe traveling indefinitely in a fixed direction would, after crossing the plane at infinity, return to its original location from the opposite side, in the guise of a right shoe. In this way, projective geometry disposed of Kant's claim about the irreducible difference between the two kinds of shoes, its ontological implications, and its intuitive roots.

Projective geometry grew in scope and sophistication at the hands of August Moebius (1790–1868), Julius Plücker (1801–1868), Karl Georg Christian von Staudt (1798–1867), Arthur Cayley (1821–1895), and others. Different sorts of numerical coordinates were introduced as sheer labeling devices, for in this metric-free context they plainly did not represent distances. The use of coordinates consisting of complex numbers made it possible to introduce more points, in addition to the familiar real points (those labeled by real numbers). These "complex points" are linked to real points and among themselves by relations of collinearity (if their coordinates satisfy the same linear equations) and vicinity (by dint of the neighborhood relations between real and nonreal numbers on the complex plane). The beautiful vistas opened by such developments inspired further flights of mathematical freedom leading to the creation of still other branches of geometry.

Moved by the confusing variety of geometrical methods and approaches, Felix Klein formulated his celebrated Erlangen Program, in which he seeks to unify all forms of geometry under a single overarching point of view. This is provided by the notion of *transformation group* and the related notion of *invariant*.

Let S be a set of points. A *transformation* (or *permutation*) T of S assigns to each point p of S one and only one point $T(p)$ of S, in such a way that every point of S equals $T(p)$ for some p. In other words, a transformation of S is a one-to-one mapping of S onto itself. We say that $T(p)$ is the *value* of T at p. T is said to *send p to $T(p)$*. If M is a subset of S, T is said to *send M to the set* $T(M) = \{T(p): p \in M\}$. For every transformation T, there is an *inverse transformation* T^{-1} that, for each p in S, sends $T(p)$ back to p. The identity transformation Id_S sends every p in S to itself. Given two transformations T_1 and T_2, their *product* T_2T_1 is the transformation that sends each p in S to the value of T_2 at $T_1(p)$. The product of transformations is clearly *associative*, that is, $(T_3T_2)T_1 = T_3(T_2T_1)$ for any three transformations T_1, T_2, and T_3. A set G is a *group of transformations* of S if every element of G is a transfor-

mation of S and G contains (1) the product of any two of its elements, (2) the inverse of every one of its elements, and (3) the identity transformation Id_S. Any subset of G that meets conditions (1) through (3) is said to be a *subgroup* of G.

Given a group G of transformations of a set S, let R be an *n*-adic predicate ($n \geq 1$) such that, for any points p_1, … , p_n in S and any transformation T in G, $R(p_1, … , p_n)$ implies that $R(T(p_1), … , T(p_n))$. We say then that R is an *invariant* of group G or that R is *G-invariant*. Likewise, a function f on S^n is said to be *G-invariant* if, for every *n*-tuple $\langle p_1, … , p_n \rangle$ of elements of S, $f(p_1, … , p_n) = f(T(p_1), … , T(p_n))$. G is said to *preserve* its invariants.

Klein's Erlangen Program for systematically ordering geometries is based on the following simple idea: Each geometry is the study of the invariants of a group, and the relations of inclusion between groups and their subgroups determine a hierarchy of geometries. Starting from the group of all possible transformations of an arbitrary set, whose sole invariant is the cardinality of the set, one descends, through multiple branches, right down to the trivial group, which is a subgroup of every group and preserves every property and relation, for it only comprises the identity transformation. In particular, projective geometry studies the invariants of the group of collineations, that is, the set of transformations that send straight lines to straight lines. This is a subgroup of the group of continuous transformations, whose invariants are the *topological* properties of projective space. Drawing on work by Arthur Cayley (1859), Klein (1871, 1873) found a way of defining different real-valued functions on point pairs that behaved, on well-defined regions of projective space, precisely like the distance functions of, respectively, Lobachevskian geometry (which he called *hyperbolic*), Euclidean geometry (which he called *parabolic*), and a third geometry (which he called *elliptic*). Each of these functions was an invariant of a certain subgroup of the said group, comprising the collineations that map a specific quadric surface onto itself.

Klein's result led Russell (1897) to assert that the general "form of externality" is disclosed to us a priori in projective geometry, but its metric structure—which Russell wrongheadedly claimed can *only* be Lobachevskian, Euclidean, or elliptic—must be determined a posteriori by experiment. Poincaré took another view of this matter: If geometry is nothing but the study of a group, "one may say that the truth of the geometry of Euclid is not incompatible with the truth of the geometry of Lobachevsky, for the existence of a group is not incompatible with that of another group" (1887, p. 290). Euclidean geometry has

seemed preferable only because the rotations and translations of the Euclidean group reflect, to a comfortable approximation, the motions of ordinary hard bodies in our environment.

RIEMANNIAN MANIFOLDS. In his lecture "On the Hypotheses Which Lie at the Foundation of Geometry" (1867), Bernhard Riemann took an approach to geometry that did not fit into Klein's Erlangen Program. He noted that traditional geometry rested on assumptions summed up in Pythagoras's theorem (by which the distance between a point with Cartesian coordinates $\langle x, y, z \rangle$ and the origin $\langle 0, 0, 0 \rangle$ equals the positive square root of $x^2 + y^2 + z^2$). These assumptions had been corroborated by using light rays to line up things and rigid bodies to measure the length of lines, and therefore were bound to break down on very small scales, where such physical objects are not available, and perhaps also on very large scales, where the errors of observation generated by using such instruments might become intolerable.

Riemann therefore proposed to proceed from more general assumptions toward a more flexible geometry that physicists could later resort to when they needed it. He took his cue from Carl Friedrich Gauss's work on the intrinsic geometry of surfaces (1828), which he extended to general spaces of n-dimensions (*n-manifolds*, for short). Though Riemann supposedly addressed his lecture to humanists (hence its meager use of mathematical symbolism), the meaning and reach of the lecture first became clear through its further elaboration by other outstanding mathematicians (e.g., Elwin Bruno Christoffel, Friedrich Schur, Wilhelm Killing, Élie Cartan, Hermann Weyl), and a whole century would pass before it was satisfactorily explained to undergraduate students (Spivak 1979). The following rough sketch of Riemann's breakthrough owes much to the light shed on it by such later developments.

An n-manifold M is furnished with coordinate systems or *charts*, by which different regions or *patches* of M are mapped continuously and one-to-one onto subsets of $\mathbb{R}^n$ (the set of all n-tuples of real numbers, endowed with the neighborhood relations it inherits from the real-number field $\mathbb{R}$). Two charts defined on overlapping patches are said to be *compatible* if the coordinate transformation between them is a smooth function from one open subset of $\mathbb{R}^n$ onto another (possibly the same) one. An *atlas* of M is a collection of compatible charts for M such that every point of M lies on the patch of at least one chart. Any atlas A of M determines a corresponding maximal atlas A_{max} comprising every conceivable chart of M

compatible with those in A. The way the charts of A_{max} combine with each other in coordinate transformations reflects the overlapping and intertwining of the patches on which they are defined and thus specifies the global topology, the shape, of M. (In the realm of 2-manifolds, or surfaces, the atlas of a pretzel differs from that of a donut or a bun.) The lengths of curves drawn in M (which are best thought of as continuous mappings of an open interval of $\mathbb{R}$ into M) can then be defined in an endless variety of ways by rules that assign to each point p of M an appropriate function on the coordinate differentials at p, in a manner that varies smoothly from point to point.

Riemann was aware that this approach gave the mathematician enormous freedom, and he proposed restricting the admissible functions, for the time being, to quadratic functions on coordinate differentials, which, on a small neighborhood of each point of M, would yield a definition of length in optimal agreement with the n-dimensional version of the Pythagorean theorem. To conform to the standard concept of length, he also required his quadratic functions to be positive-definite, that is, to take their values only among the nonnegative real numbers. This requirement was subsequently relaxed in the spacetime geometries of the theory of relativity, which, for this reason, are often called *semi-Riemannian*.

From the standpoint of twentieth-century mathematics, the characterization of an n-manifold M by means of an atlas of the kind described makes it possible to assign an n-dimensional real vector space to each point p of M, the *tangent space* at p (thus called by analogy with the plane tangent to a smooth surface at any point of it). A Riemannian metric on M assigns to each p of M a tensor of rank 2, that is, a bilinear function on its tangent space, that varies smoothly from point to point. Riemann's quadratic functions on the coordinate differentials at each point can be naturally obtained as appropriate representations, relative to one or another locally defined coordinate system, of such coordinate independent objects.

A given Riemannian metric μ on M determines a smoothly varying assignment, to each p of M, of a tensor of rank 4, that is, a quadrilinear function on its tangent space. Such an assignment is in effect a *field of tensors* (one at each point), but, for short, this assignment is called the *Riemann tensor* of the Riemannian manifold $\langle M, \mu \rangle$. This is a natural generalization to n-manifolds of the analytically defined yet fairly intuitive concept of the Gaussian curvature of a surface (a real-valued function that is positive and constant on a sphere, variable but

always positive on an ovoid, alternatively positive and negative on the surface of a saddle, and equal to 0 on a plane or a cylinder), and is therefore also called the *curvature tensor*, a term that mathematicians wield nonchalantly but that among philosophers has been a source of endless worries.

On this same analogy, *n*-manifolds of constant 0 curvature are said to be *flat*. In particular, Euclidean space is a flat 3-manifold, while Lobachevskian space is a 3-manifold of constant negative curvature, and Klein's elliptic space is a 3-manifold of constant positive curvature. But a generic Riemannian manifold ⟨*M*, μ⟩ has variable curvature, and therefore the only group of transformations of *M* that will preserve the metric μ is the trivial group consisting only of the identity transformation. Already for this reason, Riemannian geometry obviously cannot fall under the Erlangen Program. Another excluding reason is the fact that a geometric inquiry that considers general spaces of endlessly different shapes cannot be characterized by a group of transformations of one of these spaces onto itself. Still, there are Riemannian manifolds endowed with interesting symmetries, and group theory has been the tool of choice for studying them.

HILBERT'S *FOUNDATIONS*. Euclid's putative program for logically inferring the truths of geometry from a sufficient list of unproven premises was fondly imitated by scientists and philosophers in the seventeenth century, but it was first properly carried out by Moritz Pasch (1882). He gathered what he regarded as the empirical foundation of geometry into a few undefined concepts concerning the shape, size, and reciprocal position of bodies and a few axioms that linked these concepts among themselves and with other concepts defined in terms of them. Pasch's axioms "state what has been observed in certain very simple diagrams" (p. 43). All other geometric statements should be proved from the axioms by the strictest deductive methods.

Pasch dealt with projective geometry. The first rigorous axiomatization of Euclidean geometry was given in David Hilbert's *Foundations of Geometry* (1899), a book that had a major influence on twentieth-century mathematics and philosophy. Hilbert invited the reader to consider three arbitrary sets of objects, which he called points, straights, and planes; three undefined relations of *incidence* between a point and a straight line, between a straight line and a plane, and among three points; and two undefined relations of *congruence* between two pairs of points (*segments*,) and between two equivalence classes of point triples (*angles*). Hilbert linked these objects and

relations through nineteen axioms, which—when supplemented with the "axiom of completeness" added in the second edition—are sufficient for characterizing the said objects and relations up to isomorphism. This means that if we have two threefold collections of points, straights, and planes having the prescribed relations of incidence and congruence in agreement with Hilbert's twenty axioms, there will always be a one-one mapping of the points, straights, and planes of one collection respectively onto the points, straights, and planes of the second that preserves all five sorts of relations. Such a structure-preserving mapping between structured sets is called an *isomorphism*. Evidently it can hold between two systems of intuitively very dissimilar objects.

Hilbert availed himself of this feature of axiomatic theories for studying the independence of some axioms from the rest. To prove such independence, he proposed actual instances (*models*) of the structure determined by all the axioms but one, plus the negation of the omitted one. Gottlob Frege complained that the geometric axioms retained in these exercises could be applied to Hilbert's far-fetched models only by tampering with the natural meaning of words. Hilbert replied, on December 29, 1899, "Every theory is only a scaffolding or schema of concepts together with their necessary mutual relations, and the basic elements can be conceived in any way you wish. If I take for my points any system of things, for example, the system *love*, *law*, *chimney-sweep*, … and I just assume all my axioms as relations between these things, my theorems, for example, the theorem of Pythagoras, also hold of these things.… This feature of theories can never be a shortcoming and is in any case inevitable" (Frege 1967, p. 412). Hilbert's declaration of independence from sense experience and ordinary usage concisely expresses the modern view of mathematics as a universal "science of patterns" (Resnik 1997), in which geometry is barely distinguishable from its other branches, except on historical grounds.

THE GEOMETRY OF THE UNIVERSE. This approach to pure geometry and mathematics gives physicists enormous freedom to choose the abstract structures they judge most suitable for representing (modeling) the phenomena under inquiry. Yet, as Albert Einstein (1921) pointed out, so long as physics remains unable to provide, from microphysical principles, an exact theoretical construction of the instruments it uses for measuring distances and times, it will continue to need a practical geometry, which must be suggested and corroborated by experience.

According to Einstein, the stability of sharp spectral lines justifies the postulate that any two ideal clocks, once running beside each other at the same rate, will always do so, no matter where and when they are brought together again for comparison. Under this postulate, and for spatiotemporal regions sufficiently small that gravity is practically homogeneous in them, experience has amply vindicated the validity of the flat semi-Riemannian geometry that Hermann Minkowski (1909) initially proposed for the whole world. For broader regions, Einstein's theory of general relativity assumes a semi-Riemannian spacetime geometry whose variable curvature reflects the variations in gravity.

By solving Einstein's equations of the gravitational field under cosmologically plausible special symmetry requirements, Alexander Friedmann (1922, 1924) produced big-bang models of the universe. These big-bang models were ready at hand to explain the systematic recession of the galaxies away from us when discovered by Vesto Slipher and Edwin Hubble before 1930 and the current low temperature of the background thermal radiation when discovered by Arno Penzias and Robert Wilson in 1964. It is worth emphasizing that the explanation of these phenomena from the Einstein field equations is purely geometrical—a consequence of the shape of the universe under the postulated symmetry requirements. Purely geometric arguments also support the proof by Stephen Hawking and Roger Penrose (1970) that, under physically very plausible assumptions, a generic relativistic space-time most likely contains black holes.

GERARD, ALEXANDER
(1728–1795)

Alexander Gerard was professor of moral philosophy and divinity at the University of Aberdeen and a leading member of the Aberdeen Philosophical Club along with James Beattie and, most importantly, Thomas Reid. He is known primarily for his *Essay on Taste* (1759/1963), which was awarded a prize by the Edinburgh Society for the Encouragement of Arts, Sciences, Manufacture, and Agriculture. Gerard returned to the subject with *An Essay on Genius* (1774/1966). In addition to the primary influence of Reid, the work of David Hume is a principal influence, though, like Reid, Gerard disagrees fundamentally with what he takes to be Hume's skepticism.

Although Gerard writes in the tradition of eighteenth-century theories of taste, it is questionable whether he should be regarded as a taste theorist in a

strict sense. Gerard is responding to the theories of criticism of Francis Hutcheson and Hume who set the context of discussion in terms of taste and sentiment, but Gerard follows Reid in taking a more realist position regarding the qualities that produce a perception of beauty and relies more directly on rules and principles that are derived by induction. Thus, Gerard defends a position that is moving rapidly away from an essential dependence on taste.

Gerard depends on two fundamental principles. The first is a faculty of imagination. Imagination combines reflective ideas supplied by fancy. Gerard's faculty psychology posits internal senses that are "*reflexive,*" that is, they refer to the workings of the mind rather than to external objects. However, whereas for Hutcheson an internal, reflexive sense is a direct intuition of beauty and virtue, Gerard, following Reid, treats internal senses as active principles of perception. Internal senses correspond to the qualities that they respond to. For example, there are senses of novelty, sublimity, beauty, imitation, harmony, ridicule, and virtue. The second fundamental principle, following Joseph Addison's *Spectator* essays (particularly no. 418), identifies the pleasures of the imagination as depending on mental activity. The faculty of imagination exercises the mind; and, when that exercise falls within a moderate range, it is experienced as pleasurable. If it is either too languid and easy or too excited and difficult, discomfort (or simply indifference) results. These two principles combine to explain judgments of taste.

The subordination of taste to imagination seems clear; for example in *Essay on Taste*, Gerard writes "Taste, therefore, though itself a species of sensation, is in respect of its principles, justly reduced to imagination" (1759/1963, p. 144); and later, "Taste, in most of its forms at least, [is] a derivative and secondary power. We can trace it up to simpler principles, by pointing out the mental process that produces it, or enumerating the qualities by the combination of which it is formed. These are found, on inquiry, to be no other than certain exertions of *imagination*" (1759/1963, p. 151). Gerard goes on to explain each of the aesthetic predicates in terms of the kind of pleasurable mental activity that they produce: "The sources of all the sentiments of taste ly [sic] in the mind. The qualities of objects affect, in a certain manner, some principles of human nature, which by their operation, either singly or several in conjunction, produce gratification or disgust. … Simplicity, for instance, occasions easiness of conception; novelty or variety, an effort to conceive; amplitude, an expansion of soul" (1759/1963, p. 260).

Gerard holds that sentiment can be judged false because the qualities of taste can be figured out empirically. If I perceive something as grand that lacks the necessary qualities of extensiveness and amplitude, I am mistaken in my sentiment just as I would be if I experienced motion in violation of its actual occurrence. Therefore, for Gerard, there can be only a limited appeal to sentiment: "the qualities of an object, which gratify us, are more fixed and definite than the sensation which they excite" (1759/1963, p. 288). Gerard is clearly committed to what he understands as a "scientific"—that is, Newtonian—model, but at bottom he is siding with Reid against Hume by holding that aesthetic properties must be really in the object and that principles of common sense are sufficient to provide standards of judgment when disagreement arises.

For both Reid and Gerard, active judgment is logically prior to sensory experience in the aesthetic process. The function of sensory experience is to supply the material; the aesthetic operation comes about only when the mind is actively engaged. For example, Gerard writes, "For all the objects that affect taste, and excite its sentiments, are certain forms or pictures made by fancy, certain parts or qualities of things which it combines into complex modes" (1759/1963, p. 157). "In order, therefore, to form an able critic, taste must be attended with a philosophical genius, which may subject these materials to a regular induction, reduce them into classes, and determine the general rules which govern them" (1759/1963, p. 171). That engagement is critical and judgmental. Gerard's theory points toward Archibald Alison's *Essay on the Nature and Principles of Taste* (1790) in that Alison, too, reduces taste to a form of mental activity. But when Gerard says that "The sources of all the sentiments of taste lie in the mind" (1759/1963, p. 290), his purpose is to deny Hume's division between external sense and passions and to side with Reid's dualism between mind and body. Gerard's theory of taste marks the beginning, therefore, of a break with the theories of taste that run from The Third Earl of Shaftesbury (Anthony Ashley Cooper) through Addison and Hutcheson to Hume.

GERBERT OF AURILLAC
(c. 938–1003)

Gerbert of Aurillac, an educational reformer and pope (Silvester II) of the eleventh century, was born in Auvergne about 938, became a monk of St. Gérard d'Aurillac, and was educated there and in Catalonia. He later visited Rome, where Pope John XIII (965–972) introduced him to Emperor Otto I. Gerbert shortly left Otto's court to study at Rheims, where he later became master of the schools. His fame led Otto II to make him abbot of Bobbio about 980, but in 983 Gerbert returned to Rheims, where he engaged in political and antipapal controversies. In 991 he became archbishop, and after many vicissitudes he was transferred to Ravenna in 998. His old friend and patron Otto III secured his election as Pope Silvester II in 999; as pope he established the church in Hungary and strongly asserted papal claims. He died in 1003.

Despite the intrigues and restlessness of his later public life, Gerbert was—and was recognized as—the most learned, versatile, and influential master of his age. Rheims during his first stay (c. 966–980) became a principal center of the educational revival that was beginning to inspire the cathedral schools of France and that from them passed to the universities. Fulbert, founder of the school of Chartres, was Gerbert's pupil.

Gerbert's greatest achievement was to give new life to the skeleton of the ancient *trivium* and *quadrivium*. In rhetoric he restored the careful study of Terence and Vergil, the satirists Horace and Persius, Lucan, and the critics Seneca and Quintilian; in dialectic, which he reestablished as the goal of a literary education, he developed what was to become the classical syllabus of the *Isagoge* of Porphyry, the *Categories* and *De Interpretatione* of Aristotle, the *Topics* of Cicero, and the whole dialectical corpus of Boethius. He rescued the *quadrivium* from its bookish decadence and injected a real, practical orientation. In mathematics, his forte, Gerbert revived the ancient Greek tradition and replaced clumsy Roman numerals with the Indian numerals 1 through 9; he produced a simplified abacus, with instructions for its use; and he wrote at length on methods of multiplication and division. In astronomy he taught by means of a sphere showing the movements of the planets.

It is uncertain how much these innovations were the result of his early experiences in Spain and his contacts there with Arabic science and thought. Save for a short disputation on human reason, in which he showed an attraction toward the Platonic Ideas, he wrote no philosophical work. His only authentic scientific writings are mathematical. His letters, some of which contain discussions of mathematics, illustrate his political activity and the events of his age. In his later life he had little influence on the intellectual and spiritual life of his age. His earlier work as a teacher, however, marked an epoch.

GERSHON, LEVI BEN

See *Gersonides*

GERSON, JEAN DE
(1363–1429)

Jean de Gerson was one of the most influential French intellectuals of the early fifteenth century. He studied under Pierre d'Ailly and received his doctorate in theology in 1392. He was elected the chancellor of the University of Paris in 1395. He used this key position for intense intellectual involvement in ecclesiastical politics. He was part of the University of Paris delegation to the Council of Constance and played an important role in the discussions there. After the council, he fell from political favor. Returning to France in 1419, he lived in Lyon for the rest of his life in relative obscurity. He was then engaged mainly in literary work, producing, for example, the well-known defense of Joan d'Arc.

During Gerson's lifetime, the emphasis in university work turned from research to teaching and social influence. The saying "everything necessary has already been written" was often used at the time, and accordingly university teaching was often directly based on canonical sources. Gerson was an active figure in developing the university away from "idle speculations" and toward applying learning for the larger world. His own philosophical work cannot be described as highly original. But he was very productive and very influential through his writings on popular topics.

In political philosophy, Gerson was close to his master Pierre d'Ailly. They worked in close cooperation on many issues. As *conciliarists*, they understood the church as a political society. Thus, they thought that a general council of the church would have the power to solve the papal schism, like in any political society the ruler may rightly be deposed if he fails to promote the welfare of the society. Gerson cannot be said to have promoted individual rights because he did not understand the welfare of society in terms of the welfare of the individual.

Gerson has been called both an opponent and a proponent of the nominalist movement of his time. In many contexts, he relied on nominalist positions. He was, however, an opponent of the idea that natural reason could solve metaphysical problems. Also, he acted with the Renaissance humanists against the increasing role of logic and natural reason in the theological faculties. This was a time in which the English tradition in nominalist logico-semantical work was gaining ground in continental universities, especially among the Scotists and the Ockhamists. Later on, achievements in this field were to prove crucial in the formation of what is today known as modern science. Gerson's opposition to this increasing emphasis on logico-semantical analysis in the theological faculties was not so much due to a disagreement about philosophical issues so much as a preference for what he saw as more applicable and experientially grounded knowledge.

Instead of speculative theology, Gerson encouraged mystical theology, and indeed many of his best known writings are from this field. His approach is that it is the duty of every person to acquire experiential knowledge of God. This did not mean a rejection of philosophical learning. Rather, Gerson sought for mutual support between devotion and learning. In his anthropological writings, he presents a threefold division both of cognitive potencies—simple understanding, reason, and sensitivity (*intelligentia simplex*, *ratio*, and *sensualitas*)—and of affective potencies—conscience, rational desire, sensitive desire (*synderesis*, *appetitus rationalis*, and *appetitus sensualis*). These divisions accord with neoplatonic models, but Gerson's special emphasis is upon the reciprocal relations between the affective and the cognitive powers. They must work together so that knowledge and love both contribute to the approach to God. In this way, the *unio mystica* can be achieved. Gerson says very little about that experience itself, claiming that it is known only through experience and cannot be described.

Gerson was a typical fifteenth-century Renaissance intellectual. He was deeply religious and committed his efforts to public affairs, concentrating on the papal schism and his duties at the University of Paris. Apart from the writings on mysticism, his philosophical views

are best understood in terms of the ecclesiastical situation and his position in the university politics of the time.

GERSONIDES

(1288–1344)

Gersonides, or Levi ben Gershon, also known by his acronym, "RaLBaG," was a French Jewish philosopher, biblical exegete, mathematician, and astronomer. He was born at Bagnols and died at Perpignan. He was the inventor of two astronomical instruments, the Jacob's staff ("baculus") and an improved camera obscura. Gersonides' literary contributions include biblical commentaries of a philosophical and moral tone, supercommentaries to Averroes's treatises on Aristotle, and his philosophical masterwork, *Milhamot Adonai* (Wars of the lord). Because of his knowledge of Averroes, Gersonides was exposed to a more authentic version of Aristotle than was available to his predecessors and was thus motivated to reexamine certain problems that he felt had previously been treated inadequately or incorrectly. These problems, corresponding to the six sections of the "Wars," are (1) the nature and immortality of the soul, (2) prophecy, (3) the nature of God's knowledge, (4) divine providence, (5) miracles and the structure of the universe, and (6) the creation of the world. Methodologically, he recognized the authority of the four roots of knowledge (as first formulated by Saadya Gaon), namely, reason, sensory perception, divine revelation, and rabbinic tradition, in that order of priority, although he seldom cited the last specifically.

The work begins with a detailed analysis of Aristotle's doctrine of the soul according to the interpretations of Alexander of Aphrodisias, Themistius, and Averroes. In agreement with Alexander, Gersonides maintained that the material or hylic intellect is a capacity inherent in the sensitive soul. Under the agency of the Active Intellect, the last of the separate intelligences, the material intellect is transformed, through the acquisition of ideas, into an actual or acquired intellect. Opposing the nominalism of Alexander and Maimonides, Gersonides maintained the reality of the ideational content of the acquired intellect. It is this acquired intellect that survives independently after the death of the individual.

Gersonides' account of the nature of God's knowledge is related to his theory of divine attributes. Maimonides' theory of homonymy, according to which attributes in general and the term *knowing* in particular refer to entirely different concepts when applied to God and man, allowed Maimonides to maintain both God's absolute omniscience and human free will. Rejecting this as absurd, Gersonides reaffirmed, in agreement with the Muslim philosophers Avicenna and Averroes, that attributes are to be treated as ambiguous terms, applied in a primary sense to God but in a derivative sense to man. Furthermore, the attributes imply no plurality in God's nature since they are subjects of discourse and not of essence, just as the terms *redness* and *color* imply no plurality in the concept "red."

Since God's knowledge is similar in nature to man's, he cannot know the contingent and consequently knows the particulars only insofar as they are ordered. This amounts to a virtual restriction of divine knowledge to the universals. Since men are endowed with free will, this restriction normally precludes special providence for individuals. However, some individuals enjoy special providence; this consists in a knowledge, received from the Active Intellect, of stellar configurations that determine events on earth. Modern scholarship has not generally noted that this explanation of special providence for the intellectual elite was foreshadowed in one of the two discussions of the problem in Maimonides' *Guide for the Perplexed* (III.51).

The communication of astrological information to the human intellect by the Active Intellect is known as prophecy. The prophet, to the extent of his ability, interprets the general information received, in the light of the particular circumstances with which he is concerned,

Gersonides' tendency to deny God's direct involvement in terrestrial affairs is further illustrated by his theory that the capacity for miracles was implanted in nature so that miracles do not represent any specific divine concern.

In his discussion of the origin of the world, Gersonides agreed with Maimonides that it was indeed created but, in opposition to him, maintained that *ex nihilo nihil fit.* Rather, he posited an absolutely formless matter (not eternal in time since time did not exist before the creation of the world) out of which the world was formed. Gersonides found this dualism useful in ascribing the origin of evil to matter.

Bibliography

Gersonides' *Milhamot Adonai* (Wars of the lord) was first printed at Riva di Trenta (1560) and reprinted at Leipzig (1866). The editions omit the rather technical astronomical treatise in the fifth book which is extant in manuscript and which was translated into Latin by order of Clement VI. The partial German translation by Benzion Kellerman, *Die Kämpfe Gottes von Lewi ben Gerson* (Berlin, 1914), should be read in conjunction with Isaac Husik's review, "Studies in Gersonides," in *Jewish Quarterly Review,* n.s., 8 (1917–1918): 113ff. and 231ff. For a complete bibliography, see *Encyclopedia Judaica* (Berlin, 1929), Vol. IV, p. 656; Vol. VII, pp. 328ff. and 338, to which may be added H. Wolfson, "Maimonides and Gersonides on Divine Attributes as Ambiguous Terms," in *Mordecai Kaplan Jubilee Volume,* edited by M. Davis, 515–530. (New York: Jewish Theological Society, 1953).

GERSONIDES [ADDENDUM]

The intensive and fruitful research conducted on Gersonides since the 1960s has increasingly led to a recognition of his exceptional stature as a philosopher-scientist. It is also appreciated now that the multifarious aspects of Gersonides' thought constitute a coherent unity that must be studied as such. Contrary to Maimonides, whom he venerated, Gersonides believed in the human power to discover God's blueprint for creation, namely through empirical study of nature and through the interpretation of God's revelation (the Scriptures). This belief triggered his various scientific activities, most of which have been the subject of recent research.

Following notably Charles Touati's French monograph on Gersonides' philosophy, many detailed studies have been devoted to specific issues. Several parts of the *Wars of the Lord* have been translated into English and French, followed by a full English translation by Seymour Feldman. The great significance and originality of the largely unpublished astronomical part of Gersonides' *Wars* (often referred to as his *Astronomy*) have been brought to light, notably by Bernard R. Goldstein. In addition, J. L. Mancha has shown that the Latin translation of the *Astronomy* had been realized with the collaboration of Gersonides himself at the papal court in Avignon, testifying to the importance ascribed to it there. (For these and all other bibliographical references see Kellner's "Bibliographia gersonideana.")

Scholars realize now that Gersonides' numerous super-commentaries on Averroes's commentaries on Aristotle's treatises are crucial for an adequate understanding of Gersonides' thought and its evolution. Recent scholarship (R. Glasner) established that Gersonides was the first to teach Averroes's commentaries—in their Hebrew versions—in the Jewish community of southern France. Recent editions of Gersonides' commentary of the Pentateuch unearthed new material, revealing that Gersonides was more interested in Jewish law than had previously been thought. More generally, the great importance of the biblical commentaries for the understanding of Gersonides' thought has become better appreciated.

Scholars—notably Ruth Glasner—point to the originality of Gersonides' thinking about natural philosophy and its central place in his work. The originality of Gersonides' work in logic has also been highlighted, notably by Charles Manekin. Other studies, especially by Sara Klein-Braslavy, emphasize the importance of Gersonides' scientific methodology. Gersonides depended essentially on literature available in Hebrew; the question why his work bears next to no trace of a familiarity with Latin philosophy—even though Gersonides is known to have had contacts with Christians—has been much, albeit inconclusively, discussed in recent research.

GESTALT THEORY

The Gestalt movement in psychology began early in the twentieth century; its founders were the German psychologists Max Wertheimer, Wolfgang Köhler, and Kurt Koffka. A Gestalt is essentially an organized whole whose parts belong together, as opposed to being simply juxtaposed or randomly distributed. As Wertheimer put it, "What happens to a part of the whole is determined by intrinsic laws inherent in this whole." The Gestalt theorists believed this principle to be of wide application and to be relevant to the psychology of perception in particular.

HISTORY

As early as 1890 Christian von Ehrenfels had pointed out that to appreciate a melody we need to be aware not of single tones in isolation but of a succession of tones

FIGURE 1
which combine in a particular way. If notes of the same pitch as those of the original melody are presented in a different temporal order, there will be a completely different effect, whereas the same melody played in a different key is immediately recognizable, even though the notes are different in pitch from the original ones. The melody as a whole was said by von Ehrenfels to have a *Gestaltqualität* independent of the qualities of the separate notes. Wertheimer, Köhler, and Koffka were concerned to apply the concept of Gestalt over a wide area and thus give a new direction to psychological research.

A central feature in their view was the doctrine of isomorphism, which asserts that our experiences have the same structure as the brain processes which underlie them. Thus, if the stimulus is a nearly complete circle which the subject sees as a complete circle the doctrine of isomorphism would assert that there must be some pattern in the brain that is isomorphic with the complete circle, as opposed to the incomplete one. The detailed neurological hypotheses which they put forward are of questionable value, but the general principle is still of interest, as is Köhler's demonstration that there are Gestalten in physical nature, for example, the soap bubble, whose spherical shape is the necessary result of the total forces in operation at any one time (see Koffka, *Principles of Gestalt Psychology,* p. 14).

The following are some typical examples of the Gestalt principle as applied to vision: Figure 1 appears as a cross; if, however, we consider the effect on the retina of

FIGURE 2A

FIGURE 2B
the eye of each of the dots in isolation, there is nothing to account for the way in which they are organized. Implicit in traditional thinking, according to Köhler and Koffka, is the so-called constancy hypothesis—the hypothesis that stimulation of a particular point on the retina has a constant effect regardless of the total pattern of stimulation. Yet if the constancy hypothesis were true, it would be hard to explain the obvious recognizability of the "4" in Figure 2a and its camouflage in Figure 2b, since the same retinal points are being stimulated in both cases. Similarly one cannot explain how a person who moves from twenty yards away to ten yards away continues to look approximately the same size, since the retinal stimulation must by the laws of optics be quite different. Indeed there are many characteristics of the perceived world (what Koffka terms the "behavioral," as opposed to the "geographical," environment) which do not bear a one-one relationship to anything in the pattern of stimulation. Thus, in Figure 3 we see the lines as four pairs, but the "togetherness" of each pair has no direct counterpart in the system of stimuli; and in Edgar Rubin's famous example (Figure 4), whether we see the white as "figure" and the black as "ground" or vice versa, there is no direct counterpart to the "thinglike" character of the figure and the absence of this character in the ground.

This thinglike character, the character of "productivity," which occurs in some causal transactions, the character of "being mine," which belongs to, say, my hand in contrast to an object on which my hand is resting, the character of anger present in someone's face—these are some of the many features which are present in the behavioral environment, even though they are necessarily absent from the world of physics because there is nothing in the stimulus situation directly corresponding to them.
On the Gestalt view what is all-important is the way in which the immediate, or "proximal," stimuli (for example, light waves or sound waves) combine in space and time; when these combinations are of a certain kind, certain perceptual organizations will arise (for example, two parts of a diagram will be seen as belonging together), and laws can be framed in terms of which such organizations can be predicted. Details of these laws have been set out by David Katz; they include the law of proximity, which states that, other things being equal, in a total stimulus situation those elements which are closest to each other tend to form groups, and the law of closed forms, which states that, other things being equal, lines which enclose a surface tend to be seen as a unit.

A law of a more general kind is that of *Prägnanz.* As formulated by Koffka (*Principles of Gestalt Psychology*, p. 110), this law states: "Psychological organisation will always be as 'good' as the prevailing conditions allow. In this definition the term 'good' is undefined. It embraces such properties as regularity and symmetry, simplicity and others." In other words, when the stimuli are of a certain kind, there are forces within the organism that operate in the direction of maximum simplicity; hence, we tend to see "good" figures—squares and circles, for example—rather than less regular ones. The word *Prägnanz* is of course ultimately connected with the Latin *impregnare.* The suggestion here, however, is not that of something being fertilized or made pregnant but rather of something being stamped or pressed into a particular shape (compare the word *prägen,* which is used primarily to refer to the minting of coins). Certain types of configurations, one might say, are particularly impressive; they carry a certain stamp or they strike us in particular ways.

Contrary to what has sometimes been said, the Gestalt psychologists did not dispute that past experience can influence perception; this is made plain by Katz in *Gestalt Psychology* (pp. 28–29). Their criticism was

FIGURE 3

FIGURE 4
directed against the view of perception that invoked past experience as a deus ex machina when observed results did not fit the constancy hypothesis. Thus a penny, unless its flat surface is directly in front of us, might be expected from the laws of optics to look elliptical. Since it does not, one can preserve the view that the "basic datum" is an ellipse by postulating a rapid process of inference based on past experience. On this view we *infer* that the penny is round because of our alleged previous experience of round pennies. According to the Gestalt psychologists, however, not only is there nothing in introspection to suggest such an inference; they would also have questioned whether in fact it is particularly common in ordinary life for pennies to have their flat surfaces directly in front of the observer—a condition that their opponents' theory seems to require. In contrast, their view was that when the proximal stimuli combine in a certain way a particular perceptual organization is forced upon us; thus a circle is a "good" figure, and hence the "internal forces" will operate in the direction of a circle rather than an ellipse.

Interesting experimental studies include those of Wertheimer ("Experimentelle Studien über das Sehen von Bewegung," in *Zeitschrift für Psychologie*) on the perception of movement, those of Köhler (*The Mentality of Apes*) on problem solving in apes, those of Wertheimer (*Productive Thinking*) and K. Duncker ("On Problem Solving") on problem solving in humans, that of Katz (*The World of Colour*) on the perception of color, that of Rubin (*Synsoplevede Figurer*) on the figure-ground distinction, those of Kurt Lewin (*Principles of Topological Psychology*), who has attempted to apply Gestalt principles to the study of social situations, and those of Albert Michotte (*La perception de la causalité*)—although he was not a member of the original group—on the conditions in which we receive an impression of causality. A recent interesting development is the attempt to relate figural goodness to the amount of information (in the mathe-

matical sense) needed to specify a particular pattern or figure (see especially Fred Attneave, *Applications of Information Theory to Psychology,* p. 82). The problem of perceptual Gestalten has arisen in an acute form in the programming of computers to carry out pattern recognition (see, for instance, Kirsch, "Computer Interpretation of English Text and Picture Patterns").
SCIENCE AND COMMON SENSE

The advance of science continually brings in its train a challenge to our commonsense beliefs about the world. At one time or another in the history of scientific thought it has been held, for example, that sense perception is unreliable, that the things around us are not really colored, that the floor on which we walk is not really solid, and that no two events are ever exactly simultaneous. In contrast with many other scientific systems, Gestalt theory involves the attempt to call us away from such paradoxes back to common sense; it invites us to consider the world as we in fact experience it, not as we might expect to experience it in the light of the latest scientific developments.

It does not, of course, follow, that philosophical paradoxes can be disposed of simply by pointing out that experience is in fact of such-and-such a kind. Thus, it is no argument against John Locke's account of substance or David Hume's account of causality to point out that

the behavioral environment is found by experience to consist of things in causal interaction, any more than it is an argument against the distinction between primary and secondary qualities to point out that we are aware of greenness as being in the grass and not in our heads. Similarly, a philosopher who wishes to defend the sense-datum terminology cannot be refuted simply by an appeal to Rubin's claim that what we perceive is organized into figure and ground and is not just "a mosaic of sense data." As a corrective against those who mistake the point of philosophical arguments, it may be helpful on occasions to make explicit exactly what we are aware of at the commonsense level, but this does not prove the philosophical arguments to be wrong.

Despite the emphasis on naive judgment, however, the Gestalt program does not involve an uncritical return to naive realism. Rather, its claim is that the gulf between what common sense tells us and what science tells us is not, after all, as great as might be supposed; the world of nature is *gestaltet* no less than are our experiences. Moreover, although in some of their discussions Köhler and Koffka speak in traditional terms about "the relation between mind and matter," their views do not fit easily into the traditional categories of interactionism, epiphenomenalism, and parallelism; indeed, like many modern philosophers, they are critical of a starting point which forces us to decide between theories couched in these terms.

POSITIVISM AND BEHAVIORISM

The prevailing scientific attitude of the time, which Koffka called "positivism," was mistaken, on the Gestalt view, because it allowed no place for the categories of meaning and value. The important fact for psychology is that the behavioral environment is organized—it is intelligible. Thus we are making *sense* out of a person's facial expression when we say that he is angry. Similarly, if a person listens to music, he is sometimes aware that a chord with the leading note (the seventh of the scale) at the top *requires* to be followed by the tonic chord of the original key; the cadence has its special meaning only if the second chord follows the first. This remains true even though such "requiredness," as Köhler terms it in *The Place of Value in a World of Facts,* can play no part in the world of physics. As physical science advances we are enabled to make continually more refined statements about the geographical environment; but in so doing, on the Gestalt view, we are in danger of losing sight of facts—those of the behavioral environment—which for the psychologist are of special interest. Koffka agreed that vitalism is "no

solution but a mere re-naming of the problem"; but by taking seriously the concept of Gestalt one can, he held, be antimechanistic without being obscurantist.

There is also an attack on the allegedly "scientific" creed of behaviorism, whose development was almost contemporary with that of Gestalt theory. The term *behaviorism,* as Köhler understands it, implies a denial that there can be "a science of direct experience," either because there is no such thing as direct experience or because if it exists, it is not accessible to public scrutiny. In reply Köhler points out that no scientist can even begin to experiment unless he starts from his own experienced world. He also points out that one has as little or as much justification to be skeptical about the world of experience as one has to be skeptical about the world of physics; there is no good reason why the behaviorist should choose to ignore the world of experience while taking the world of physics on trust.

ISOMORPHISM

It is far from clear whether the doctrine of isomorphism constitutes a radically new discovery, as the Gestalt theorists supposed, or whether it is a somewhat high-sounding way of asserting the obvious. Most modern psychologists, if asked, would doubtless express the hope that complete explanations of perception and learning will eventually be found in terms of brain processes. If, therefore, the contribution of Gestalt theory is to be distinctive, clearly some more far-reaching claim must be involved.

Koffka expressly pointed out that Gestalt theory does not stand or fall with the correctness of a particular theory about perceived movement. According to Koffka its more general objective is to contribute to "the integration of value, life, and mind. … The Gestalt concept … cuts across the division of realms of existence, being applicable in each of them." That is, there are Gestalten in nature (for example, the soap bubble); there are Gestalten in the living brain; and there are Gestalten in our conscious experience. In traditional discussions about the relation between mind and body, according to Köhler, it was "tacitly assumed that only *microscopic* events in the cortex can be the correlates of mental life." In contrast, the doctrine of isomorphism invites us, in Koffka's words, to "think of the physiological processes not as molecular but as molar phenomena. … If they are molar, their molar properties will be the same as those of the conscious processes which they are supposed to underlie." As has already been pointed out, this is not just an answer within the context

of traditional mind-body dualism; it is an attempt to look at this whole family of problems afresh.

The distinction between the geographical and behavioral environments gives rise to difficulties of its own. One very reasonably asks, in the first place, what kind of duality is involved. Clearly, there are not two environments in the same sense that there are—or might be—two rooms in a country cottage. If a child specialist recommended a change of environment for a child, it would make no sense to reply "very well; we will change him from the geographical to the behavioral environment." One is reminded in this connection of Arthur Eddington's claim—which in fact involves the same kind of difficulty—that he is writing simultaneously at two tables. Second, if we take the idea of two environments at its face value, we are tempted to ascribe some kind of superior status or "reality" to one or the other. It is the geographical environment, according to Koffka, whose contents are "real": "The pen with which I am writing is a unit in my behavioural environment and so is the *real* pen in the geographical" (italics added). What is "real," however, does not apparently coincide with what is "given"; "every *datum* is a behavioural datum; physical reality is not a datum but a constructum." The suggestion that each of us somehow "constructs" a physical world out of his immediate experiences implies a phenomenalist view which in the last resort leads inevitably to solipsism. Clearly this was not Koffka's intention, but he gave no indication how such a conclusion can be avoided.

The important point, according to Köhler and Koffka, is that the concept of Gestalt cuts across these two different kinds of reality. In the words of Köhler, "Any actual consciousness is in every case not only blindly coupled to its corresponding psychophysical processes, but is akin to it in essential structural properties." The difficulty here is that *anything* can be regarded as "structurally akin" to anything else, provided enough rules are given. Many maps are structurally akin to landscapes in that they involve the same geometrical shapes; but if one is allowed sufficient rules for specifying what represents what, a map of England (as we now call it) could function without any misrepresentation as a map of France. What Köhler needs to argue for is some relatively clear-cut and uncomplicated structural relationship. Thus, it may well be that the shape of the areas stimulated in the cortex has something in common with the shape which we observe in an object, although it is hard to see how there can be any close parallel in the case of color, since, when *X* is looking at a green object, *Y* does not find anything green in *X*'s cortex. One must suppose that the use of the term

psychophysical (instead of *physical*) to describe processes in the brain is intended to emphasize these relatively close structural similarities.

KNOWLEDGE OF OTHER MINDS

In reply to the charge of solipsism, Köhler and Koffka could point out that they both discuss the problem of knowledge of other minds at some length. The main feature of philosophical interest in these discussions is that structural similarities are pointed out between behavior which is noticed by others and so-called inner states, which are discriminated only by the person himself. A person's wincing may have precisely the same temporal properties as his twinges of pain, and the sound of his rising voice may have the same movement properties as his inner feelings of rising anger. Koffka pointed out that a character in a Mickey Mouse cartoon can quite well look exuberant or dejected; and if we can directly observe such exuberance or dejection in these cases, there seems to be no reason why we should not directly observe it in our friends. Similarly, Michotte has argued that visual experiences of live movement are structurally similar to kinesthetic and other experiences that we have when we make an effort. These considerations are not, of course, sufficient to remove all possible skeptical doubts; but they at least make clear the conditions in which we can justifiably say of a person that, for example, he is angry, dejected, or making an effort.

"SEEING" AND INFERENCE

Koffka suggested that the word *see* should be used in a "purely phenomenological" sense, that is, in such a way that the words which follow are a simple description of our experience. Thus, if we look at a table that is partly covered by a book, we are not aware of any gap or hole in the table in the area where the book is; and Koffka therefore wanted to say that what we *see* is a complete table. On his view it is necessary to describe our experience without being influenced by considerations of what we might expect to see on the basis of scientific knowledge—in this case, by our knowledge about the characteristics of the light waves striking the retina.

In ordinary usage, when we say that we or someone else saw something, this is normally not just the report of a visual experience; there is also an implicit claim to correctness. If the person is in fact deceived, then one is wrong to use the word *saw*, just as one would be wrong to say that a person has "proved" something if his argument contains a fallacy. One might therefore express Koffka's difficulty by saying that, as our knowledge of physics

increases, claims to *correctness* will force us further and further away from naive description. "Why," he asked rhetorically, "are we so hopelessly stupid as to call the colour of our table-cloth on the candle-lit dinner table white, when Helmholtz told us that it was yellow?" According to Koffka's proposed usage we actually see a white tablecloth, the evidence of the physicists notwithstanding.

This "purely phenomenological" sense of "see," however, is unnecessary. We already possess the expression "seeing-as" for situations where we do not wish to make claims to correctness. On this usage, we *see* the tablecloth *as* white even though we might have expected to see it as yellow. Similarly, a person who is exposed to an ambiguous diagram may *see* it *as* two-dimensional, even though on another occasion he sees it as three-dimensional. Unless one is an extreme skeptic and asserts that claims to correctness are never appropriate when visual perception is involved, it is surely useful to have a terminology which enables us to make such claims on some occasions and to withhold them on others.

Moreover, Koffka's proposed usage, if adopted consistently, carries the paradoxical consequence that we can never be sure or unsure about what we see, nor can we be right or wrong. If we look more carefully at something, or if others give us a verbal description or point to a contour line, we may, of course, see something new; but we were still neither right nor wrong about what we saw before.

There is the further paradoxical consequence that no two people can ever see the same thing. Köhler is apparently prepared to accept this, since he expressly tells us that no two scientific investigators ever see the same galvanometer. Moreover, if everything that we see (in Koffka's sense) is, by definition, part of the behavioral environment, this has the effect of turning the behavioral environment into a home for every erroneous perception which has been made. It is as bad as having to postulate false facts to ensure that false propositions refer to something. In general, the distinction between the geographical and behavioral environments involves many points of interest, but in philosophizing in this area, Koffka in particular was not successful in avoiding paradoxical consequences.

As far as psychology is concerned, the work of the Gestalt theorists has led to the discovery of a large number of new facts, particularly in the sphere of perception, and to a reinterpretation of facts which were already known. On the basis of the laws of structural organization, predictions can be made about what will be perceived when the proximal stimuli are of a particular kind,

and these predictions normally work. The neurological explanations are inadequate by present standards, but even in this area the Gestalt theorists have at least called attention to problems which require to be solved, and, in particular, they have taken seriously the challenge presented by our ability to perceive spatial and temporal relationships.

On the broader theoretical issues, traditionally the province of philosophy, their main contribution has been to indicate the need for a change of emphasis. In the light of advancing scientific knowledge, it appeared to be the case that what we thought we were perceiving was not what we were really perceiving at all ("the grass is not really green," "the white tablecloth seen in candlelight is really yellow," and so on). For the Gestalt theorists, however, as for some modern philosophers, such claims were paradoxical and confused. Whatever physics tells us, the starting point, on the Gestalt theorists' view, must necessarily be the world as perceived by common sense; this is the world to which organisms respond, and it is therefore of special importance for the psychologist; moreover, if we ourselves did not perceive it in certain ways, physics could not even begin. This is to say, in effect, that language descriptive of ordinary experience can never be reduced to the language of physics—a thesis that has been held in many forms but which has seldom been defended in such a sustained and systematic way.

GEULINCX, ARNOLD
(1624–1669)

Arnold (or Aernout) Geulincx, the Flemish metaphysician and moralist, was born in Antwerp. He studied philosophy and theology at Louvain and in 1646 was made professor of philosophy, a position he held for twelve years. Although information about his life at Louvain is limited and his important works date from a later period, it appears that as a student he was influenced by the Cartesian Guillaume Philippi, that in his teaching, as later, he attacked scholastic physics from a Cartesian point of view, and that he was also attracted by the doctrines of Cornelis Jansen.

In 1658, on charges that were not made public but that may have been prompted by his criticisms of scholasticism and accepted religious practices, he was deprived of his professorship and left Louvain for Leiden. At the same time, he renounced Roman Catholicism and became a Calvinist. Arriving in Leiden in distressed circumstances, he was assisted by the Cartesian Abraham van der Heyden (Heidanus) and set to work on a study of fevers, which he presented for the doctorate in medicine. Despite his precarious situation at first, Geulincx succeeded in publishing treatises on logic and method (*Logica Fundamentis Suis … Restituta,* Leiden, 1662, and *Methodus Inveniendi Argumenta,* Leiden, 1663) and the first part of his most accomplished work, the "Ethics" (*De Virtute et Primis Ejus Proprietatibus,* Leiden, 1665). He was appointed professor extraordinary of philosophy at

the university in 1665 and remained in Leiden until his untimely death, in 1669. Six years later the complete "Ethics" was published, under the title *Γνωθι σεαυτον, Sive … Ethica* (Leiden, 1675). His "Physics," taken from manuscripts used in his classes, appeared in 1688 (*Physica Vera,* Leiden); commentaries on René Descartes's *Principles of Philosophy* in 1690 and 1691 (*Annotata Praecurrentia, Annotata Majora,* Dordrecht); and the very important "Metaphysics," published apparently from a student's copy, in 1691 (*Metaphysica Vera et ad Mentem Peripateticam,* Amsterdam).

OCCASIONALISM

Geulincx is best known for his occasionalist theory of causation and his denial of the substantiality of particular created things. Following Descartes's order of procedure in his "Metaphysics," he considered at the outset the possibility and the limits of doubt and found that our first knowledge is of the self as a thinking thing. Consideration of the various states of the self or mind led him to formulate a principle, which he took to be self-evident though obscured by prejudices, that expresses a necessary condition implicit in our conception of an action: that something cannot be done unless there is knowledge of how it is done, or, as specifically related to activities of the self, that a person does not do what he does not know how to do (*impossibile est, ut is faciat, qui nescit quomodo fiat; quod nescis quomodo fiat, id non facis*).

The principle had far-reaching consequences in Geulincx's moral philosophy as well as in his metaphysics. Concerning the self, he contended that actions involving movements of the body cannot in truth be attributed to the self and that the mind or soul is not, as it is often supposed to be, the true cause of movements of the body. Not only are we unaware of changes in the brain, nerves, and muscles requisite for, say, moving the arm, but even if we know of these changes from a study of physiology, our knowledge is based on ex post facto observation of sequences of volitions and physiological happenings, not on awareness of a supposed mental activity producing these movements. Though we have, Geulincx maintained, immediate knowledge and understanding of internal actions—that is, of acts not involving bodily movements and consisting solely of changes in a state of mind—we are not in like manner cognizant of how movements are initiated in the body or how external actions come about. Accordingly the influence of the human mind is limited to its own states, and the mind is not the master of—that is, the true cause of movements in—the body.

The principle was also invoked against the assumption that bodies, or corporeal things, are capable of acting, either on minds or on other corporeal things. It is assumed, for instance, that a fire acts on a man's body and, affecting sense organs, nerves, and brain, produces sensations of light and heat in his mind. It is also assumed that in cases of impact one body striking another sets the second body in motion. But how, Geulincx asked, can a body produce these effects? To bring them about, according to his principle, it would have to know how. Yet admittedly a body is inanimate and, lacking consciousness, lacks the knowledge that on reflection we see is a necessary condition of acting. Bodies are *res brutae.* To suppose that they have the distinctively spiritual characteristic of acting is a signal instance of confusion involving the self-contradictory notion of corporeal action or causation. Arguing against the possibility of genuine corporeal causation as such, Geulincx, like the occasionalists Géraud de Cordemoy and Nicolas Malebranche, took it to be true a fortiori that bodies cannot act on minds. (There is no evidence that Geulincx was influenced by, or that he in turn influenced, the other occasionalists.)

Though the human mind does not act on the body and bodies do not act on the mind or on other bodies, changes obviously do take place, and in these changes we discern patterns or constant conjunctions of events. According to Geulincx, the agent responsible for these changes is God, and the patterns we observe are due to laws that God enacts and in accordance with which he operates. Explicating his theory of supernatural causation in the case of volitions and bodily movements, Geulincx iterated two analogies, the second of which was the subject of an important controversy among German historians in the nineteenth century. (1) When a child wants his cradle to move, it often happens that the cradle moves, not as a result of his willing it, but because the mother or nurse in attendance wills that it move. (2) Two clocks that are synchronized sound the hour in unison, not because one influences the other, but because they are fashioned in such a way that they keep the same time. The second illustration has been cited to show that Geulincx, like Gottfried Wilhelm Leibniz, conceived of a preestablished harmony between mind and body and that he was the unacknowledged source of Leibniz's famous analogy of concurrent clocks and, by implication, of Leibniz's view of the relation between mind and body.

Against this interpretation it can be argued convincingly (as was done by Eduard Zeller) that in Geulincx's view, God's actions, though in accordance with rules, are immediate or direct in the sense that there is nothing in

mind or body comparable to the internal natures which, according to Leibniz, account for their successive states and mediate the will of God and the course of events. It is not the case, however, that the actions of Geulincx's God are ad hoc or, as Leibniz accused the occasionalists, that Geulincx's God is a deus ex machina. The rules of his action are fixed, and he simply applies them, with no special volitions required, in particular circumstances.

SUBSTANCE

Geulincx's views about substance were roughly midway between Descartes's and Benedict (Baruch) de Spinoza's. In the Synopsis of the *Meditations,* Descartes, drawing a distinction between body taken generally (*in genere sumptum*) and the human body, suggested that the former, like a person's mind, is a substance or pure substance (*puram … substantiam*), whereas the latter, insofar as it is a particular body differing from other bodies, is not. Following Descartes's lead, Geulincx contrasted body in itself (*corpus ipsum, corpus simpliciter dictum*), which he identified with extension, and particular bodies, which he claimed are modes of body (*aliquid ipsius corporis simpliciter dicti, modi corporis*). Body in itself is simple, unique, individual, infinite, and indivisible. Particular bodies are limitations of, or abstractions from, body in itself. They are not, he explained, constituent parts, nor are they figments of the mind (*entia rationis*); rather, they are related to body in itself as the superficies, or surface, of a particular body is related to that particular body. In another analogy, as the country is not a collection of fields, orchards, and meadows but the land on which these divisions are imposed, so corporeal nature is not an aggregate of particular bodies but the matter or extension common to them all and specified in various ways. The analogy also explains Geulincx's conception of mind. Like Spinoza (though independently), he held that individual minds are themselves not substances but modes of mind (*modi mentis*) or of infinite thinking substance, which he identified with God. We are, he said, both from God and in God (*ex Deo et in Deo*). To the extent to which we can transcend the distorting forms of our limited understandings and see the eternal truths in ourselves as they are in the mind of God, we lose our status as limited beings and are one with God. Geulincx's reflections on problems about substance paralleled Spinoza's. However, he preserved the Cartesian distinction between thinking substance and extended substance, or matter.

ETHICS

In the letter prefaced to the first part of his "Ethics," Geulincx implied that his moral philosophy rounds out the system conceived by Descartes, who, though he proposed a provisional code of morality in the *Discourse,* did not bring this branch of the tree of knowledge to fruition. In Geulincx's view the subject matter of ethics is virtue, and virtue is located not in deeds but in a determination of the will—that is, in love of right reason or, since reason as prescriptive comprises laws imposed by God, in devotion to divine law. Though virtue is one and simple, there are four aspects, and these cardinal virtues are distinguished from and contrasted with the traditional cardinal virtues, which refer to actions or accomplishments, not to the locus of morality—namely, the condition of the will. (1) *Diligence* is attention to the voice of reason. Its issue is wisdom and prudence in conduct. (2) *Obedience* involves compliance with the dictates of reason. Though we are free to will in conformity to divine law or not, in the end we cannot but do what God wills. By obeying his prescriptions we attain freedom in the highest degree: We will what we can do and do not will what we cannot do, and our volitions are effective. (3) *Justice,* also, is a determination of the will: to will no more and no less than reason dictates. (4) *Humility* consists in knowledge, and denial, of self (*contemptio sui*) in the love of reason and of God. Contrasted with the virtuous man is the egoist, whose end in life is happiness. He is the slave of his passions and the creature of circumstance, whereas the virtuous man, not seeking happiness and resigned to what happens to him, is in a position to attain it.

GEULINCX, ARNOLD [ADDENDUM]

LIFE AND WORKS

Arnold Geulincx was born in Antwerp, Belgium, in 1624. In 1641 he matriculated at University of Louvain, where he became a professor of philosophy in 1646. For reasons that never became clear but were probably of a religious nature (at Louvain there was much sensitivity over Jansenism), he was suspended from his duties and consequently dismissed in 1657/1658. He moved to Leiden, The Netherlands, and converted to Calvinism. After taking a degree in medicine he obtained permission to lecture on philosophy, but his position was regularized only in 1662, when he was appointed reader in logic. He became professor *extra ordinem* in 1665. In 1667 he died from the plague. Most of his works, dealing with logic, moral philosophy, physics, and metaphysics, were published posthumously.

LOGIC

Although the main merits of Geulincx's works on logic seem to be their elegance and precision, Karl Dürr (1939–1940, 1965) and Gabriël Nuchelmans (1983, 1984, 1986) show that he made some important steps toward a logic of propositions. According to him words like *est* and *non* are signs (*notæ*) by which to indicate the mental act performed with respect to a particular content. Every denial is the negation of an affirmative claim, and that means that an affirmation has been present to the mind (*affirmatio inclusa*). Accordingly, "Peter is not learned" must be interpreted as "It is not the case that Peter is learned" or also as "The sentence 'Peter is learned' is false."

Speaking of compound conditional sentences, Geulincx defines an antecedent as a statement that says that the whole of that which some other statement (the consequent) says to be the case, is indeed the case. Consequence is a form of containment (*continentia*): Between two statements A and B there obtains a relation of consequence if A says the dictum of B. Both the theory of containment and the theorem that every A implies the statement "A is true" are corollaries of Geulincx's idea that by making a statement one commits oneself to the truth of that statement and of everything entailed by that statement. For example, if one says "I am standing," this must be taken as an affirmation of whatever is entailed by that statement, such as, for example, "I am capable of standing." Accordingly, "I am standing" serves as the antecedent of any number of other statements to the truth of which one commits oneself.

METAPHYSICS

According to Geulincx metaphysics is first philosophy or first science. It deals with the human subject, body, and God, each of which is the basis of a separate science: *autologia*, *somatologia* and *theologia*. The autologia basically consists in an exploration of the Cartesian *cogito*, which, however, Geulincx does not see as the basic principle of his philosophy but rather as a way to gain access to the realm of necessary truths. In fact, the more fundamental principle is the axiom that one can truly be said to make or do something only if one knows how it is made or done (*quod nescis quomodo fiat, id non facis*). This axiom allows Geulincx to claim that one is a passive spectator of the world, one's only activities being to will and think, albeit in a purely immanent way. Indeed, the world cannot be the cause of one's seeing and perceiving, given the fact that, since it can neither think nor know anything, it cannot be active. The only true cause is God and the only truly causal relation is that between God and the world. In fact, all philosophy should start with the concept of God, and the only reason why one has to start with the cogito is that the Fall has obscured one's faculties.

The result of Geulincx's analysis is that God is Being *simpliciter* as well as Mind *simpliciter*. This implies not only that all reality is ultimately mental but also that whatever is neither God nor part of God is nothing but an appearance. In fact, there are only two things that really exist, namely, Mind, which is the creator, and Body, which is the created. One's mind is part of the Divine mind (*mentis quid*). One's body is part of a phenomenal world. Particular three-dimensional bodies can be understood as limitations of the archetypal Extension that was produced in the act of creation. However, that there is a world, extended in three dimensions, can be known through the sensations God causes one to have. Finally, since contingent facts cannot be accounted for by principles of metaphysics (which explain only what is necessary), physics makes use of hypotheses, which must consist of clear and distinct ideas that together with the principles of metaphysics must be sufficient to explain all phenomena.

MORAL PHILOSOPHY

Like his metaphysics, Geulincx's moral philosophy is based on a corollary of his fundamental axiom, namely, that where there is no possibility to act there can be no will either (*ubi nihil vales, ibi etiam nihil velis*). In whatever way one acts, it is God that makes one act in that particular way. Accordingly, virtue is not to act in a particular way but to internally yield to God's will. Morality lies in the intention, not in the act. As a result, the cardinal virtues are dispositions: diligence, obedience, justice, and above all humility. On the contrary, passions are like sense impressions. Although they belong to human nature, they are relevant only insofar as they prevent one from developing the right attitude toward God's will. The most dangerous passion in this respect is self-love. In any case, the reward of virtue is that, freed from self-love, one enjoys peace and tranquility in this life.

RELATIONS TO OTHER THINKERS

Although much in Geulincx's philosophy goes back to René Descartes, it would probably be wrong to call him a Cartesian. For not only are the various parts of his philosophy differently connected (his metaphysics is crowned by his moral philosophy, not by his physics, which is comparatively independent), his metaphysics is, as has been shown by Brian Cooney (1972, 1978), basically an attempt to provide a metaphysical account of Divine Creation.

Accordingly, his philosophy has more affinity with Nicolas Malebranche's, with whom Geulincx shares a basically occasionalist interpretation of causality. Also, there is some similarity (although no affinity at all) with Benedict (Baruch) de Spinoza's philosophy, except, of course, that Spinoza rejects the idea of creation. In fact, Geulincx's starting point is fundamentally different. Whereas Spinoza argues that on the basis of Cartesian metaphysics it is impossible to account for creation, Geulincx takes creation to be a fact and attempts to make sense of it in terms of Cartesian metaphysics. However, the only way to do this is, he believes, to assume that creation consists in producing a world of appearance.

Not only Geulincx's metaphysics but also his physics is different from Descartes's, not because it would involve different concepts but because the status of their concepts is interpreted in a different way: Geulincx's concepts are hypotheses that, even if they are clear and distinct, are not automatically and necessarily true. This doctrine, which involves an interplay of empirical and metaphysical principles, has often been associated with Immanuel Kant's theory of judgment (Cassirer 1971–1973), but this is a bit far fetched. The best characterization seems to be that he is a Christian philosopher trying to find his way in the world of post-Aristotelian philosophy and availing himself of the language and concepts of his contemporaries to provide an intelligible account of the mysteries of faith.

GEWIRTH, ALAN
(1912–2004)

Alan Gewirth was a twentieth-century moral philosopher best known for his attempt to complete the Kantian project and show that rationality requires morality. Gewirth took his BA at Columbia University in 1934, studying with John Herman Randall and Richard McKeon. After two years of graduate study at Columbia, he spend the academic year 1936–1937 on a Sage Fellowship at Cornell University and then followed McKeon to the University of Chicago as his research and teaching assistant. In June 1942 Gewirth was drafted into the army, and, without seeing combat, moved up the ranks from private to captain in four years. After World War II, he returned to Columbia and received his PhD in philosophy in 1948. From 1947 on, he was a regular member of the faculty at the University of Chicago, eventually becoming the Edward Carson Waller Distinguished Service Professor in the Philosophy Department in a career that lasted more than sixty years. He also taught as visiting professor at Harvard University, the University of Michigan, John Hopkins University, and the University of Santa Barbara.

Early in his career Gewirth did important work on Descartes's theory of knowledge; later he did notable scholarly studies of the medieval political philosopher, Marsilius of Padua, published as his *Marsilius of Padua and Medieval Political Philosophy* (1951) and a published a translation from the Latin of Marsilius's *Defensor Pacis* (1956) with a lengthy introduction. Gewirth is best known, however, for his attempt to develop a stringently rational foundation for morality in his *Reason and Moral-*

ity (1978). The central argument of this book begins with a claim that every rational agent must accept, which is that he or she prudentially ought to have freedom and well-being. Gewirth argues that when the logical implications of this claim are fully worked out, particularly when the claim is universalized, it follows that every rational agent must also accept the claim that all prospective, purposive agents *morally* ought to have freedom and well-being, although, of course, purposive agents may not act on this claim—that is, they may not act morally.

Most of the critical reaction to Gewirth's work has focused on this particular argument. Two book of critical responses, along with replies from Gewirth, have been published. key issue concerns whether the universalization of a rationally inescapable claim that "I prudentially ought to have freedom and well-being" leads to the claim that "we all morally ought to have freedom and well-being" or to the claim of universal ethical egoism that "we all prudentially ought to have (or pursue) freedom and well-being." Gewirth claims the former; many of his critics claim the latter. Yet even some of those who reject Gewirth's argument for morality, for example, Christine Korsgaard and myself have been inspired by him to develop somewhat different arguments that attempt to establish just the same conclusion that Gewirth wanted to establish—that morality is rationally required.

In *The Community of Rights* (1996), Gewirth hoped to add to enhance his defense of morality by establishing against libertarians that rights—especially the human rights that equally belong to all humans as such—are positive as well as negative, and that they therefore warrant serious and active governmental concern for protecting and promoting the freedom and well-being of all humans, especially those who are most deprived. To this end, Gewirth employs two independent arguments. The first appeals to a definition of freedom, but, unfortunately, not to a definition of freedom that libertarians are required to endorse. The second is dialectical, but this argument parallels and depends crucially on Gewirth's earlier argument for morality.

In his last completed book, *Self-Fulfillment* (1998), Gewirth develops an interesting notion of self-fulfillment that is either compatible with or required by his conception of morality. A new book manuscript, *Human Rights and Global Justice*, which focused on questions of international justice, remained unfinished at his death.

GEYSER, JOSEPH
(1869–1948)

Joseph Geyser, the German critical realist philosopher, was born in Erkelenz, in the Rhineland. He received a doctorate in philosophy from the University of Bonn in 1898. He became an extraordinary professor at the University of Münster in 1904 and a full professor there in 1911. In 1917 Geyser was called to Freiburg, and in 1924 he succeeded Clemens Baeumker, the distinguished historian of ancient and medieval philosophy, at the University of Munich.

From his youth, Geyser opposed what he regarded as two basic tendencies in recent philosophy, an intellectualism strongly tinged with historical relativism and an overly abstract, idealistic Kantianism. He devoted himself to recalling philosophy to the asking of questions that are largely independent of any temporary situation and to the answering of these questions in an objective, critically realist manner. This attitude, but not Geyser's attachment to Thomistic tradition, was shared by the realist Oswald Külpe and the philosopher of nature Erich Becher. Above all, Geyser was totally devoted to the *philosophia perennis* (Gottfried Wilhelm Leibniz), and through it he related himself to the older European intellectual traditions. Phi-

losophy, he strongly believed, is not a constant new beginning. For Geyser, philosophy, in the words of the early Middle Ages, is like a dwarf perched on the shoulders of a great past in order to see farther. Classical philosophy, in the thought of Plato and Aristotle, was already approaching great truths, insights that have claims on the present as part of a constantly self-renewing stream of thought, a stream that has both enriched and been enriched by the Christian worldview.

Geyser held that answers to philosophical questions must be based on direct contact with a real actuality, understood in the Aristotelian sense, as an entity independent of consciousness, and not on the creative activity of an idealistic, theoretical thought. Only thus can we stand on firm ground. Philosophy is in this view a kind of middle position between the reality of experience and the ideality of a creative reconstruction of the forms of existence. Geyser sensitively expounded this basic attitude in his short but deeply probing book, *Eidologie oder Philosophie als Formerkenntnis* (Eidology, or philosophy as knowledge of form; Münster, 1921). In this programmatic work, whose basic ideas were to guide Geyser's thought from then on, philosophy is presented as a progressive penetration into the realm of possible essences of being insofar as they offer themselves to experience.

Geyser's inclusive *Lehrbuch der allgemeinen Psychologie* (Münster, 1908; 3rd ed., 2 vols., Münster, 1920) had already been written from this point of view, which also formed the basis of Geyser's acute critique of Neo-Kantianism and Edmund Husserl's phenomenology in *Grundlegung der Logik und Erkenntnistheorie* (Foundations of logic and epistemology; Münster, 1919) and *Auf dem Kampffeld der Logik* (On the battlefield of logic; Freiburg, 1926), as well as of his later exposition of ontology and metaphysics. In all of these works we see Geyser as a relentless logician who was honest and strict with himself and an epistemologist capable of critical observations.

We can now examine how Geyser deals with modern problems. Geyser's *Psychologie* combined philosophical and modern empirical psychology, for he found it impossible to separate philosophy from psychology without damage to both disciplines. This open attitude permitted him to develop a method for recording mental life in all its unconscious, organic, and even ontological aspects. Nevertheless, Geyser fought against and tried to refute psychologism, the claim that even logical phenomena depend on psychological structures of experience. He developed an unambiguous distinction between actual psychological events and the logical, objective analysis of

meaning (in the manner of Heinrich Rickert). With equal intellectual vigor he gave a firm basis to his logical objectivism bound to being and distinguished it from both epistemological idealism and the phenomenological theory of constitution.

Objectivism meant for Geyser that logical laws are not only inner relations of thought but that they also have a real ontological character and that they stand the test of analysis. According to Geyser, philosophy should therefore explain how man is capable of grasping the ideal logical order in reality itself. Here we come face to face with ultimate realities, which reveal themselves to the human intellect only after suitable deductive rational preparation. Nevertheless, Geyser attains a knowledge of essence akin to that of phenomenology. But one could say that his phenomenology is Aristotelian and realistic, and Geyser can be credited with showing a connection, through Bernhard Bolzano, between the thought of Husserl and that of Aristotle. Geyser's epistemology is logically rational and tied to reality, and it stresses discursive, genetic methods. Only as a last resort could Geyser justify to his intellectual conscience an encounter with pure immediate insights.

The same rational and empirically bound method is evident in Geyser's views on causation, which provoked a many-sided controversy. These views are of particular relevance to contemporary discussions of the bases of natural science. The principle of universal causation, further seen as the law of causation, has always been considered to be the solid foundation of any given truth that can be discovered by analysis. In this sense it was one of the most essential supports of one of the traditional proofs of the existence of God. It was assumed to be evident and analytically a priori provable that the contingent world must have a supercontingent cause in God. Geyser investigated the distinctions between the ground of knowledge, the principle of contradiction, and the principle of sufficient reason. In *Philosophia Perennis, Festgabe Joseph Geyser,* Kurt Huber gives an exact summary of Geyser's critical investigations. In the same book Aloys Wenzel points out that Geyser was the first philosopher to further develop Arthur Schopenhauer's investigation of the principle of sufficient reason. Geyser showed further, in *Das Prinzip vom zureichenden Grunde* (The principle of sufficient reason; Ratisbon, 1929) and *Das Gesetz der Ursache* (The law of cause; Freiburg, 1933), that only through experience can we discover the meaning of causality. Everything has its sufficient reason, including being: "Everything that comes into being does so through a cause." Such a notion is originally given to us in the mental experience of causation in willing. The notion contains a synthetic feature, but it nevertheless remains completely unconditional although it is not given to intuition as an analytic law of thought. The questions of whether the principle of causation is a priori, and of how it is related to matters of experience, is significant for any possible further epistemological and metaphysical construction that is in accord with experience. Controversy with Thomistic philosophers resulted from this statement.

Geyser's position was also clearly expressed in his metaphysics. He was committed to an inductive metaphysics, not to a purely speculative metaphysics derived from intellectual immediacy. He thus distinguished his own thought from metaphysics as practiced by such Neo-Thomists as Gallus M. Manser and Antonin-Dalmace Sertillanges.

Similarly, when Geyser, like Francisco Suárez, ascribed a concrete, individual spiritual essence to human existence, he did not do so primarily in the Thomistic sense of a universal spiritual essence which achieves individuality by being united with matter. In the foreground of Geyser's thought is the empirically unique real event. It is thus not surprising to learn that Geyser, although he recognized a rational metaphysical knowledge of God by analogy, critically denied any intuitive insight into God's existence. (Here he differentiated his thought from Max Scheler's philosophy of religion, which he criticized in *Max Schelers Phänomenologie der Religion,* Freiburg, 1929). It also shows why Geyser rejected any ontological proof of God, that is, any knowledge of God reached by even the concept of the most perfect being discovered by an a priori encounter with essence. Rather, he felt that the existence of God is to be discovered a posteriori by an interpretation of the "united facts of experience." Geyser's thought found its completion in a rationally founded metaphysical knowledge of God.

Geyser was one of the most inclusive systematic thinkers of modern times. Nicolai Hartmann, another great systematizer, once said that he had learned more from Geyser's criticisms of his ontology than from those of any other contemporary. Few recent philosophers can call such a consistently thought-out and complete worldview their own. Geyser's worldview was developed within and into an inner unity with his Christian conviction; this firmness of attitude toward the world was also expressed in his whole steady personality, which endured the unhappy experience of his homeland during the last years of his life under the perspective of hope.

GIBBON, EDWARD
(1737–1794)

Edward Gibbon, the English historian and man of letters, was born at Putney, Surrey, of a well-to-do family. Frail and constantly ill, the child owed the preservation of his life to an aunt, Miss Catherine Porten, who also acted as his teacher. After instruction by a series of tutors and much reading on his own, he entered Magdalen College, Oxford, at the age of fifteen, with, as he later confessed, "a stock of erudition which might have puzzled a doctor, and a degree of ignorance of which a schoolboy would have been ashamed." Fourteen months at college, "the most idle and unprofitable of my whole life," ended with self-conversion to Roman Catholicism. His irate father immediately packed him off to Lausanne, Switzerland, under the care of Daniel Pavillard, a Calvinist minister who soon led him back to Protestantism. Thereafter, he developed a decidedly skeptical bent. During his five years' stay in Switzerland, Gibbon learned French, Italian, and Greek, and read all the Latin classics. He also fell in love with Suzanne Curchod. When his father refused consent to their marriage, "I sighed as a lover, I obeyed as a son." Mlle. Curchod later married Jacques Necker, distinguished French financier and statesman, and became famous as a *salonnière.* Gibbon never married.

Gibbon's first publication was *Essai sur l'étude de la littérature* (1761). A later manuscript fragment of a "History of the Swiss Revolution," also in French, was shown to David Hume, who approved of the project but chided the author: "Why do you compose in French, and carry faggots into the wood?" Thereafter, Gibbon composed all his major works in English. For more than two years (1759–1762), Gibbon was a captain in the Hampshire militia, and a surprisingly good one. In 1763, with the end of the Seven Years' War, he returned to the Continent, visiting Paris, Lausanne, and finally Rome. He records that it was on October 15, 1764, while musing amid the ruins of the Capitol, that the idea of writing about the decline and fall of the city—later extended to the empire—first occurred to him.

Returning to England in 1765, he became a man of letters and man about town. In 1774 he was elected to Dr. Johnson's Literary Club, where he became the intimate friend of Adam Smith. In the same year he obtained a seat in parliament, where he earned the distinction of never making a speech. He was, however, hard at work on his great history, the first quarto volume of *The History of the Decline and Fall of the Roman Empire,* which appeared in 1776. A letter of congratulation from the dying Hume "overpaid the labour of ten years," but warned that a clamor would arise. It did, and Gibbon responded three years later with a *Vindication.* The sixth and last volume of the history was published in 1788. At least fifty British replies and refutations were published before Gibbon's death, and literally hundreds have been published in many languages since. At his death, Gibbon left behind six drafts of an autobiography, which were pieced together and published in his *Miscellaneous Works* in two volumes by Lord Sheffield (London, 1796).

THE HISTORY OF THE "DECLINE AND FALL OF THE ROMAN EMPIRE"

Received as a masterpiece on first publication, Gibbon's history is still regarded as such, and has never been superseded. Certain misinterpretations of facts, to be sure, have been detected and many additional facts have come to light; some prejudices have been revealed and some misjudgments have become apparent, "but in the main things he is still our master, above and beyond 'date'"—so acknowledged J. B. Bury in the modern standard edition of the work.

It is the famous fifteenth and sixteenth chapters of the first volume, however, that entitle Gibbon to an honored place in the history of philosophy. These are the two chapters that stirred up violent controversy in 1776, and they are still controversial. The problem that Gibbon set himself was to explain the progress of primitive Christianity and its influence upon the ultimate fall of the Roman Empire. Writing *en philosophe,* Gibbon comes to the conclusion that the fall of Rome represents "the triumph of barbarism and religion." He ironically dismisses the most commonly accepted causes of the triumph of Christianity, namely, the convincing historical evidence of the doctrine itself and the ruling providence of its great Author. He notes that through the course of time prejudice and passion have distorted and rendered ambiguous the meaning of the doctrine, while the providence of Deity remains inscrutable to man. The former cause, therefore, is unhistorical, while the latter is unphilosophical. Ruling out supernaturalism as a cause, Gibbon consequently confines himself in the fifteenth chapter to an analysis and discussion of the secondary causes of the rapid growth of the Christian church—causes that can be tested both by historical fact and by philosophical and psychological analysis.

With cool detachment of philosophical and historical inquiry, he examines the early history of the church in the same spirit that he would examine any period of secular history in which no assertions of supernaturalism had been made. He discusses five secondary causes of the rise of Christianity: (1) The inflexible zeal of the Christians was inherited in part from the Jews, who alone had broken the religious harmony of the ancient world, which was based upon mutual toleration of all creeds, and had insisted that theirs was the one and only true religion. The Christians turned this defensive zeal into both the proselytizing of all ranks of people and the persecution of all varieties of idolatry.

(2) Belief in immortality, uncertain and disputed among the ancient philosophers and not to be found in the law of Moses, gradually began to be accepted by the Jews after their servitude to Egyptians and Babylonians. Early Christians, contemptuous of their present existence and convinced of their immortality, believed in the near approach of the end of the world, which was to be preceded by the Second Coming of Christ. At this time, believers and unbelievers alike would receive judgment—the former, eternal bliss; the latter, eternal damnation. As for the tortures which awaited sinners and deluded philosophers, Gibbon finds it proper "to draw a veil over the rest of this infernal description."

(3) The early history of the church is replete with claims to miraculous powers and to divine inspiration. Such forms of superstition and "enthusiasm" made constant progress, until they became part of church tradition. But it remains the scholarly duty of the historian to examine such claims and to reject all pretensions to inspiration that are unacceptable in the light of reason. If the age of miracles once existed, all reasonable men, in contrast to the credulous and the fanatical, agree that at some time it either suddenly or gradually terminated.

(4) The pure and austere morals of the early Christians were enhanced by two laudable human motives: repentance for past sins and the desire for perfection. Converted sinners became saints, disdainfully rejecting the natural human propensities for pleasure and action in favor of the monkish virtues of humility, meekness, and patience. A state of celibacy came to be exalted as the nearest approach to divine perfection, and sensual pleasure was inexorably replaced by spiritual pride. Passive obedience to civil authority led to a refusal to partake in any form of civil administration or military defense of the empire, even when it became evident that such disregard of the public welfare guaranteed the triumph of barbarism. In sum, the morals, and the errors, of the primitive Christians were in reality the excess of their virtues.

(5) Though immune to both the business and the pleasure of the world, the primitive Christians took keen interest in the government of the church, an enthusiasm that gave rise to much religious contention. At first, the bishops were regarded as the equals of the people, but gradually took upon themselves arbitrary power, ultimately proclaiming themselves vice-regents of Christ. Thence arose the rigid distinction between clergy and laity. The early communion of goods among the Christians was soon relaxed, and the clergy adopted the tithe from the original Jewish code. Further clerical controls included excommunication, which involved not only spiritual but also temporal punishment. As to the actual numbers of Christians, nothing definite can be con-

cluded, the figures of the Fathers being at complete variance with those of the pagan historians, and neither providing accuracy. Seneca, the two Plinys, Tacitus, Plutarch, Galen, Epictetus, Marcus Antonius, great sages all, have little or nothing to say about the "perfection" of Christianity. Alleged miracles for the benefit of the church passed unnoticed.

In the sixteenth chapter, Gibbon examines the question of the persecutions of the primitive Christians by some of the Roman emperors. The blame, he indicates, rests chiefly upon the intolerant zeal of the Christians themselves, which drove the emperors reluctantly toward persecution. Even so, there were frequent peaceful intervals, and the detailed accounts of the sufferings of the "martyrs" were largely the inventions of later ecclesiastical writers. Gibbon estimates that no more than two thousand Christians were executed during the period of the most vigorous persecution, and suggests a comparison with the hundreds of thousands of Protestants executed during the relatively brief period of the Reformation, the latter figure far exceeding all martyrdoms over the course of many centuries of early Christian persecution.

GIBBON'S SOURCES

Among the many influences upon Gibbon's method and philosophy, the following should be mentioned: first, John Locke's commonsense approach to philosophy and religion; second, the rationalism of the deists; third, the philosophy of history presented in Baron de Montesquieu's treatise *Considérations sur les causes de la grandeur et de la décadence des Romains* (1734); fourth, the philosophical skepticism of Hume. From Hume he also learned the necessity of investigating the causes of historical events, and from Hume and Voltaire, the importance of cultural, social, and political history. The *Decline and Fall* has gone through multitudinous complete editions and condensations, both in English and in translation, and will continue to be read, not only as a great history, but also as a great piece of literature.

GIBBS, JOSIAH
(1839–1903)

Josiah Gibbs, a theoretical physicist, was born and died in New Haven, Connecticut, and, aside from a few years studying physics in Europe, spent his academic career at Yale. He is one of the few distinguished American theoretical physicists prior to the twentieth century. Gibbs made advances in vector analysis, and he made major contributions to thermodynamics including an insightful diagrammatic method, work on equilibrium and stability, the definition of free energy, and his famous phase rule regarding coexistent phases of a substance. In a vital contribution to thermodynamics Gibbs extended this theory to deal with the rules that describe how chemical interactions are to be integrated with the other thermodynamic processes. He is the inventor of the notion of chemical potential, the key concept of chemical thermodynamics.

For philosophers it is Gibbs's work in statistical mechanics that is of great interest. This work is contained in his elegant *Elementary Principles in Statistical Mechanics* (1902). James Clerk Maxwell and Ludwig Boltzmann had previously developed a method for calculating equilibrium values by taking them to be averages over functions of the microscopic phase of the system using a time invariant probability distribution over a constant energy subspace of the phase space of the system. This technique reappears in Gibbs in the form of his "microcanonical ensembles."

But Gibbs introduced other ensembles as well. Most important of these is the canonical ensemble that intro-

duces a time invariant probability distribution over the phase space that allows for different energies. For systems with a large number of degrees of freedom (a large number of molecules in a gas, for example), this probability distribution is highly concentrated about one specific energy. In these cases, averages calculated using the canonical distribution and those calculated using the microcanonical distribution will converge in the limit of an infinite number of degrees of freedom. Because calculations done using the canonical ensemble are much easier than those using the microcanonical, most practical statistical mechanics is done in the framework of Gibbs's canonical ensembles. Gibbs also developed the grand canonical ensemble whose use becomes necessary when chemical changes are part of the thermodynamic processes.

By showing how these ensembles and the features of them vary as constraints on the system are varied, Gibbs was able to show "analogies" between features of the ensembles and averages of features calculated with their probability distributions and standard thermodynamic quantities such as temperature and entropy. He is cautious in making any explicit "identification" of the latter with the former, possibly in part because of the known difficulties faced by standard statistical-kinetic reasoning at that time in correctly predicting such quantities as specific heats.

With the association of thermodynamic and statistical mechanical quantities, it is easy to understand the microcanonical ensemble as appropriate for a system energetically isolated from the rest of the world, and the canonical as appropriate for a system in perfect thermal contact with an infinite heat bath of constant temperature.

Gibbs's treatment of nonequilibrium is the source of one standard approach to that problem, but remains controversial to this day. Gibbs's ensembles can be thought of as a vast collection of systems identically prepared at the macroscopic level. Find the ensemble for such a collection of systems; now, change a constraint on the system (say by removing a partition in a box of gas): How will the ensemble, appropriate for equilibrium before the change of constraint, evolve? Will it evolve to the ensemble appropriate for equilibrium in the new constraint condition? This is what is most desirable because people want to show that, in some appropriate sense, the systems in the ensemble at a later time will be found, in general, to be ever closer to the equilibrium condition. But provably the Gibbs's ensemble cannot so evolve (Liouville's Theorem).

But, Gibbs argues, the ensemble may evolve in such a way as to approach the new equilibrium ensemble in a "coarse grained" sense. He uses the analogy of a glass mostly filled with water but partly filled with insoluble black ink. Stir the fluid. If one looks closely enough, the fluid always consists of pure water or pure ink, because the ink is insoluble. But looked at "coarsely," the fluid approaches a uniformly gray color. Gibbs was not able to show that such "mixing" would actually occur, but modern extensions of ergodic theory have been able to prove mixing theorems that hold under certain physical conditions. And idealized systems (such as molecules as "hard sphere in a box") have been shown to be mixing. It remains controversial, however, as to whether this model of an ensemble evolving in a coarse-grained sense is the appropriate one for characterizing the actual approach to equilibrium of nonequilibrium systems.

Gibbs is aware that "mixing" ought to be a time symmetric feature of his ensembles, given that it is driven by a time symmetric underlying dynamics of the molecules. But applying mixing in the past time direction would lead, incorrectly, to predict antithermodynamic behavior for systems. His solution is to argue that one ought to apply statistical inferences only into the unknown future, and that applying them to infer the a past that is already known is illegitimate. Paul and Tatiana Ehrenfest, in their important 1910 survey of statistical mechanics, called Gibbs's argument "incomprehensible." But it was later taken up and developed by Satosi Watanabe and Erwin Schrödinger. It also remains a subject of contemporary controversy in discussions of the relationship between the intuitive asymmetry of time and entropic features of the world.

GILBERT OF POITIERS
(c. 1076–1154)

Gilbert of Poitiers (Gilbertus Porreta, Gilbert de la Porrée), the twelfth-century theologian and metaphysician, was born at Poitiers about 1076 and received his first schooling there. Next he went to study under Bernard of Chartres, and later (but before 1117) he devoted himself to theology under Anselm at Laon. He seems to have succeeded Bernard as chancellor at Chartres between 1126 and 1137 and, after a short period as a master in Paris, was elevated in 1142 to the bishopric of Poitiers. He died greatly esteemed in 1154, although in the 1140s he had been made to feel the hostility of other theologians, principally Bernard of Clairvaux, who brought him to trial to account for his opinions at Paris in 1147 and at Rheims in 1148.

Gilbert wrote much and acquired great fame for his scriptural and Boethian commentaries. The former were the fruit of his years at Laon and included major expositions of the Psalms and of the Epistles of St. Paul, as well as other biblical commentaries that have, with greater or lesser certainty, been ascribed to him. But the commentaries upon Boethius's four *opuscula sacra* (and especially that upon the *De Trinitate*) proved controversial. Although Gilbert was never officially condemned for theological error, after his trial in 1148 he appended a new preface to these commentaries professing his orthodoxy. In addition, the treatise *De Discretione Animae, Spiritus et Mentis* is now confidently ascribed to Gilbert. Highly uncertain, however, is Gilbert's authorship of the *Liber Sex Principiorum.* The six *principia* are the last six Aristotelian categories (place, time, situation, habit, action, and passion), which the writer of this treatise considered to be accessory forms (*formae assistentes*) or extrinsic circumstances of a substance. The first four categories, on the other hand, are either substance itself or necessarily inherent forms of a substance. This work enjoyed great authority in the Middle Ages as a completion of Aristotle's own *Categoriae.*

An understanding of Gilbert's authentic philosophical teaching must be based principally upon his Boethian commentaries and upon the literature inspired by his trial. Gilbert's doctrine of being and of the process of knowledge departs from a key distinction between substance and subsistence. A substance is an actually existing individual being that supports (*substat*) a number of accidents. Some beings, however—genera and species, for example—have no need of accidents and are more accurately described as subsistences than as substances. Forms or Ideas in themselves are subsistences and do not come into contact with matter. Only copies (*exempla*) descend into matter. The human mind arrives at the knowledge of the eternal Ideas by first "collecting" from concrete, individual things their substantial similarity, that is, their created or "native" forms (*formae nativae*), to which Gilbert attributed universality. By perceiving the similarity of forms within a group, the mind arrives at the concept of species and then, by the same process, it arrives at the concept of genus. Finally, transcending all created forms, it attains the primary forms, which are in God. Thus, Gilbert inquired why concrete forms agree with one another, and he focused his attention upon the *intellectus* of the universal which is abstracted from singulars. He based his theory of knowledge upon the Platonic doctrine of Ideas but also employed the Boethian-Aristotelian doctrine of abstraction.

The divine work of creation involved the production of forms, which are images of the divine Ideas, and the uniting of these forms to matter. Gilbert described the created being as a compound of the *id quod est* ("what it is") and the *id quo est* ("that by which it is"). Socrates is a man (*id quod est*), but he is what he is by virtue of his humanity and corporeity (*id quo est*). The origin of this distinction is the grammatical rule that, *in naturalibus,* every name signifies both a substance and a quality. But whereas all created being is compound, the divine being is absolutely simple. In God, essence (*id quod est*) and divinity (*id quo est*) coincide. Nonetheless, Gilbert applied the distinction to God, describing divinity as the form in God by which he is God. Gilbert's opponents, such as Bernard of Clairvaux, would not accept this separation of God and his divinity; they maintained that divinity is God, and not that by which he is. Gilbert's position was a difficult one to maintain, but he had no desire to compromise the divine simplicity or unity, and his writings support his claim that he had not established a real distinction between God and his divinity.

In a similar manner, Gilbert's application of logical and grammatical principles to the problem of the Incarnation of Christ aroused suspicions. Gilbert was reluctant to say that the divine nature became flesh, preferring to say that a person, Christ, took a human nature. Other logicians of the day were similarly concerned to test various traditional formulations of the divine Incarnation in the light of Boethian concepts. If Gilbert slipped in his analysis of the person and natures of Christ, he did not intend to deny Christ's divinity or his humanity.

Gilbert's school of disciples survived as a strong force in the twelfth century and included John of Salisbury,

Otto of Freising, Alan of Lille, Nicholas of Amiens, Radulphus Ardens, and John Beleth. It blended at times with the dialectical tradition stemming from Abelard, and, by its investigation of the character of essences, the school of Gilbert perhaps helped to prepare the way for the influx of Avicennian philosophy.

David Luscombe (1967)

GILES OF ROME
(c. 1247–1316)

Giles of Rome, the scholastic philosopher whose real name was Aegidius Colonna Romanus, was born in Rome. Giles entered the Augustinian order of hermits in 1265 and subsequently studied at the University of Paris, where from 1268 to 1272 he was probably the pupil of Thomas Aquinas, who was then lecturing at the university as Dominican regent master. In 1277 the bishop of Paris made his far-reaching condemnation of 219 theses, mainly of Aristotelian origin but also including a number of Thomist propositions. Among these were Thomas's doctrine that each being contains only one substantial form, as opposed to the traditional Augustinian belief in a plurality of forms. Giles, a young scholar, joined in the ensuing controversy with the publication of a sharply worded defense of the Thomist view, the *Liber Contra Gradus et Pluralitatem Formarum.* He attacked the Augustinian doctrine as being contrary to both reason and faith. Upon his refusal of Bishop Tempier's demand for a retraction, Giles left Paris, perhaps for a cooling-off period, but returned in 1285 to take the first Augustinian chair in theology and to receive his license to teach. He remained a professor until 1292, when he was appointed prior general of his order. In 1295 Pope Boniface VIII appointed him archbishop of Bourges, in which office he remained until his death. In 1287 his teachings had become the official doctrine of the Augustinian order, although neither of the other great Augustinian thinkers of the fourteenth century, Thomas of Strasbourg and Gregory of Rimini (each a general of the order) followed his teachings.

METAPHYSICS

Giles's philosophical position still remains something of an enigma. The older view that he was strictly a disciple of Thomas has gradually been modified. While it is true that he reached substantially the same conclusions as Thomas on two of the burning issues of the day, the unity

of the substantial form and the distinction between essence and existence, neither of these seems to have been from Thomist premises and, in the case of the second issue, the conclusion did not even lead to the same doctrine. In particular, Giles seems to have been influenced to a far greater degree than Thomas by Neoplatonism, and especially Proclus, on whose *Liber de Causis* he commented in 1280. This affinity would explain his own treatment of the relation of essence to existence. Thomas had never made a real distinction between the two but had regarded them rather as a composition in which *esse* is the actuality of *essentia,* which is itself the source of a being's actuality; or put another way, a being is what it is in virtue of the actuality (*esse*) that derives from its form (*essentia*). For Giles, on the other hand, *esse* and *essentia* were distinct things (*res*) from the outset. He therefore treated as real what for Thomas were abstractions, an attitude confirmed in his Commentary on the *Liber de Causis,* where he thought in terms of a universe of intelligible beings. To attain intelligible knowledge, it suffices for the image of an object to act directly upon the possible intellect, which under the influence of the active intellect is able to conceive it as an intelligible species. This led Giles to the characteristically Platonic conclusion "that the same quiddity considered in things is particular, considered in the mind is universal."

SCIENTIFIC CONTRIBUTIONS

Although knowledge of Giles's scientific outlook is even less comprehensive than that of his philosophical system, his treatment, often Neoplatonic, of time, movement, gravity, quantity, the intensification and remission of forms, and matter is known to us. Giles made his most original and important contribution to later scholastic scientific discussion concerning the nature of quantity. He posited a twofold quantity (*duplex quantitas*) that corresponds to the modern distinction between mass and volume. On the one hand, a body contains a constant quantity of matter, which limits its possibilities of development; for instance, a barleycorn cannot become a mountain. On the other hand, the same quantity of matter can undergo various changes in dimension, and according to its volume it will be denser or rarer in structure—as with, say, water or air. Giles took this distinction to infer that mass and volume were thus two independent quantities.

Giles also distinguished sharply between form and matter in the structure of a material substance—the so-called problem of the *mixtum.* This raised the question of what happened to the forms of the four material ele-ments—fire, earth, air, and water—which composed any material substance when they were combined with form of that substance, for example, wood. Did they continue to exist separately, or were they absorbed into the substantial form? This was one of the earliest scientific problems to exercise the Scholastics, and while Giles based himself upon what Thomas had already said, he also went further. He accepted Thomas's solution that the forms of the material elements, once included in a material substance, no longer remained formally and actually in being but, rather, virtually as part of the qualities of the substance. To this, however, he added the distinction between the material and formal qualities. The former (*ex parte materiae*) remained the same through all changes in the substance; the forms, on the other hand, could not remain numerically the same. Another aspect of Giles's *mixtum* theory was of a hierarchy (*ordo realis*) among substantial forms, in which each higher form virtually contained the lower forms, the higher form being able to do more perfectly whatever the lower form could do.

Giles was also the first among the high Scholastics to state explicitly the problem of the increased speed of a falling body, namely, that this was not caused by the approach of its destination but rather by the growing distance from its starting point. Again, concerning a falling body in a vacuum, a problem which was to exercise successive generations of fourteenth-century thinkers, Giles was the first to pose it directly, taking a standpoint different from that of Thomas. In his Commentary on Aristotle's *Physics,* Giles posed other original questions about movement: Whether the sole cause of why movement took place in time, and not instantaneously, was resistance to the mover from the medium in which it moved, and whether in a vacuum movement itself would be composed of a succession of instants which in themselves did not constitute time. To both Giles answered in the affirmative. Thus the difference between movement in a medium and movement in a vacuum was that in the first case it was successive as opposed to instantaneous, owing to the resistance encountered; in a vacuum, on the other hand, it was *motus discretus in tempore discreto.* There can be little doubt from what is already known of his scientific speculation that Giles was the forerunner of the scientific inquiry so characteristic of the fourteenth century.

POLITICAL PHILOSOPHY

Giles had been tutor to the future Philip IV (the Fair) of France, to whom he dedicated his *De Regimine Principium.* This work, stressing the Aristotelian view of a ruler, was based upon the *Ethics* and *Politics.* But with the out-

break of the struggle between Philip IV and Pope Boniface VIII in 1296, Giles took the pope's side. His *De Potestate Ecclesiastica* (probably written c. 1302) stated, in the most extreme form yet, the Augustinian view of society, in which the spiritual power is superior to the temporal and only the faithful can possess the just and righteous lordship derived from the universal lordship of the church. Lordship is a gift from God, and justice is submission to God through the church; hence, sin deprives the sinner of all right of lordship. Giles here sowed the seeds of the doctrine of dominion and grace that was to be developed by Richard FitzRalph and then turned against the church by John Wyclyf.

GILSON, ÉTIENNE HENRY
(1884–1978)

Étienne Henry Gilson, the French neo-Thomist philosopher, was born in Paris. His higher education was acquired at the University of Paris. In 1907 he received his agrégé and in 1913, after several years of teaching, his doctorate, publishing both his minor and major theses, *Index scolastico-cartésien* and *La liberté chez Descartes et la théologie.* The years 1914–1916 saw Gilson serving France as an officer on the battlefield. Captured at Verdun, he was a prisoner of war from 1916 to 1918. He spent two years as professor of philosophy at the University of Strasbourg and in 1921 became professor of the history of medieval philosophy at the Sorbonne, in which position he served until 1932, when he accepted the chair of the history of medieval philosophy at the Collège de France, where he taught until 1951. Gilson cooperated with members of the Congregation of Priests of St. Basil of Toronto, at their invitation, to found, in 1929, the Institute of Medieval Studies, in association with Saint Michael's College in the University of Toronto. He was a professor and director of studies at the institute from its foundation until 1956.

Numerous leading universities conferred honorary degrees on Gilson, and many invited him to deliver prominent lectureships, among them the Gifford Lectures at the University of Aberdeen (1930–1931), published as *The Spirit of Medieval Philosophy*; the William James Lectures at Harvard (1936–1937), published as *The Unity of Philosophical Experience*; the Richard Lectures at the University of Virginia (1937), published as *Reason and Revelation in the Middle Ages*; the Mahlon Powell Lectures at the University of Indiana (1940), published as *God and Philosophy*; and the A. W. Mellon Lectures in the fine arts (1955), published as *Painting and Reality*. Gilson founded and directed the famous *Études de philosophie médiévale* and the *Archives d'histoire doctrinale et littéraire du moyen âge* and was a director of *Medieval Studies,* the annual publication of the Pontifical Institute of Medieval Studies. Among the many academies and societies of which he was a member was the select French Academy, to which he was elected in 1947.

PHILOSOPHICAL POSITION

Gilson's main thoughts may best be appreciated in company with two parts of his own intellectual history. (1) The great Jewish scholar Lucien Lévy-Bruhl advised Gilson to study the relation between René Descartes and Scholasticism. From this research Gilson learned to read St. Thomas Aquinas and to recognize that the metaphysical conclusions of Descartes made sense only in the context of Thomas's metaphysics. (2) Further study of Thomas and other medieval thinkers from St. Augustine through William of Ockham proved for Gilson that there was no common philosophy employed within the theologies but, rather, there were different authentic philosophies.

To do the choosing, demonstrating, and judging that he considered one of the proper tasks of philosophy, Gilson gradually developed his personal philosophical position. The only philosopher, Gilson maintained, who made him clearly realize the full metaphysical implications of the major problems was Thomas, a fact that in no way lessened Gilson's intellectual freedom, for he always wanted to be free to agree with somebody when he thought that what was said was right. For him what characterized Thomism is the decision to locate the act of existence in the heart of the real as an act that can be grasped only by or in the essence whose act it is, as an act, therefore, that has primacy not over and above being but within being. Thus, Thomism as an authentic existentialism is opposed equally to the "Thomistic" essentialists, who deposit a dead essence in the mind as a quiddity

without preserving its contact with the act of being, and to such existentialisms as those of Søren Kierkegaard, Martin Heidegger, Karl Jaspers, and Jean-Paul Sartre, which, although divergent from one another, commonly deal with existence only as an object of a possible phenomenology of human existence and are phenomenologies still in search of ontologies.

Gilson's personal commitment to the existentialism of Thomism was related to one of his most central philosophical doctrines—namely, the reality and philosophical validity of what he terms *Christian philosophy.* In *The Spirit of Medieval Philosophy* and in many other books and articles Gilson demonstrated that the Christian religion and its theologies have had the capacity to produce metaphysical conclusions and to transform philosophy itself. Several of its philosophical ideas the Greek philosophers never knew—for example, the existence of a unique God, the infinite, simple, supremely free Creator of the universe, as an all-powerful efficient cause, as well as the existence of man as a substantial composite of soul and body, free, made in God's image. Regarding the philosophical problem of how a speculation can be rational and philosophical if it is connected with religious beliefs, history as such is incompetent to answer, but philosophy provides the answer. History shows that the alliance of the two distinct orders of thought has produced positive philosophical results. Although Gilson recognizes, with Thomas and other medieval theologians, the distinction of philosophy and theology, he opposes their separation as practiced by Descartes and by numerous neo-Scholastics from the sixteenth century to the present day, for whom philosophy became no more than temporary and successively different alliances with any sort of currently fashionable philosophical position that could be reconciled with revelation.

As Gilson saw it, in the medieval theologians what could be philosophically demonstrated received in theological works the full benefit of rational demonstration. Such philosophical demonstrations were part of sacred doctrine and were also philosophy because they were reached by the human intellect through its own light. In the case of Thomas, who represents for Gilson the best in Christian philosophy, the philosophy is that of a theologian with the order of development required for theological ends; hence, one cannot release Thomistic philosophy from its theological moorings without running the risk of not knowing its origin and end, of altering its nature, and even of not grasping its meaning. Apart from the historical fact of the nonseparation of philosophy and theology, Gilson was convinced that the very nature of philosophy

does not demand that the philosophy of Thomas be extracted from the world of faith and the influence of revelation. Philosophy has been and can be authentically philosophy and Christian at one and the same time, for the orientation of Christian philosophy—to knowledge about God and man—entails no a priori exclusion of any area of philosophical research because nothing in the universe is irrelevant to knowledge about God and man.

This central theme in Gilson's philosophy—the nature and validity of Christian philosophy—has exasperated so-called Thomists seeking to develop a Thomism separate from theology; to rationalists it has seemed not to be philosophy at all. Gilson tirelessly represented the historical evidence and philosophical reasons to identify and justify Christian philosophy as the use that the Christian makes of philosophical reason when he associates religious faith and philosophical reflection. Rhetorically, Gilson asked why those who profess the Christian faith and its doctrines should see themselves excluded from philosophy simply because they prefer to philosophize about what they believe.

Other influential aspects of Gilson's philosophical doctrines concern education, social and political philosophy, the philosophy of art, and the history of modern and contemporary philosophy. In *Painting and Reality,* Gilson interprets the evolution of the art of painting, especially its most recent phases, in the light of his existential metaphysics. Because artistic beauty is made, not found, Gilson opposes mere imitation as artistic beauty; the function of any work of art *qua* art is solely to cause in us the contemplative pleasure of enjoying it. In a masterful defense Gilson analyzes the history of art from Leonardo da Vinci to the mid-twentieth century, demonstrates that representation is not of the essence of art, and argues for the legitimacy of abstraction and the necessity to sacrifice all elements of reality that do not contribute to the plastic structure of a work.

GIOBERTI, VINCENZO
(1801–1852)

Vincenzo Gioberti, the Italian philosopher, ecclesiastical polemicist, and statesman, was born in Turin. As a statesman he upheld federalism as the goal of the movement for Italian unity. Gioberti's *Del primato morale e civile degli Italiani* (Brussels, 1843) is one of the great documents of the Risorgimento. His most famous polemical work is *Il gesuita moderno* (5 vols., Lausanne, 1846–1847), attacking the allegedly reactionary influence of the Jesuits on church policy. Throughout his intensely active career, philosophy remained his dominant interest. A long political exile (1833–1845) provided the occasion for the composition of his most important philosophical works: *Teorica del sovrannaturale* (Brussels, 1838), *Introduzione allo studio della filosofia* (Brussels, 1840), and *Degli errori filosofici di Antonio Rosmini* (Brussels, 1841; 2nd enl. ed., 3 vols., 1843–1844).

"PROTOLOGIA"

In 1841 and 1842 Gioberti gave a course of lectures (published as *Cours de philosophie,* Milan, 1947). The second part of these lectures, "Protologie ou science première," was the first sketch of a subject of which many of Gioberti's works can be considered fragmentary studies.

The term *protologia* may derive from the title of a work by Ermenegildo Pini (1739–1825) that was published in 1803. Gioberti envisaged *protologia* as "the science of the creative act and of the ideal formula which expresses it completely." Its complement is *deuterologia,* the theory of the sciences constructed by reflection on the basis of being as it is intuited. *Protologia* has three divisions: theology, logic, and cosmology, which includes psychology. The division arises out of the three elements of the ideal formula, "Being creates the existent." *Protologia* escapes the subject-object dichotomy; it studies neither the subject nor the object but the intelligible principle that relates the two.

ONTOLOGISM

Because of his constant affirmation that being-in-itself is constitutively present to the human intellect, Gioberti's philosophical position is generally described as ontologism. Being is present to the intellect as thought, not as a sensible property of mind itself; that is, the being which is present to the mind is not merely the being of the mind but being itself. Gioberti rejected what he called sensism, by which he meant the view that the being present to the human mind is simply its own being apprehended by the senses. Gioberti asserted that the activity of the human mind "concreates" its object in conjunction with the presence of being. The being constitutively present to the human mind is not merely possible being but real being, and indeed the most real being. This being is indeterminate, not in the sense that it lacks all distinction but in the sense that all distinctions are so related and fused that the human mind does not immediately succeed in discerning them. For this reason the original intuition of being can make known the existent only in conjunction with sensible experience. Sensible experience makes the existent present, but the existent is known by virtue of being. The existent is not, however, a part, determination, or moment of being but a creation of being. Existents are present in being as elements of its creative possibility, not as its modes or qualities (on this point Gioberti thought that he was in disagreement with Benedict Spinoza). The act of thought renders the existent present, and since this act is being and is act only insofar as it is being, it concreates the existent. The act of judgment, which is the pure form of knowledge, has a particular form for thus establishing any particular existent. Its ideal form, or "ideal formula," informs every judgment independently of its particular concern. This ideal formula, "Being creates the existent," is the presence of the pure form of the judgment in its pure possibility.

LANGUAGE

Ontologism shows that thought is a creative act. The object of thought comes into being through the operation of thought in the word. In this view Gioberti was strongly influenced by Giambattista Vico, and like Vico he studied the problem of language as the general theory of the word. Language is the specific manner in which the concreative operation of thought and being is effected in the human matrix. The concreative act, to be actual and effective, must reflect the human condition—it must be psychologized, but not in the manner which Gioberti opposed as "sensism." Gioberti advocated a transcendent psychologism in which the transcendental operation is the transaction of a concrete existent subject. Language is transcendental in that it reflects the constitutive presence of being in accordance with the structure of the human mind while enabling the mind to transcend its own existential limits and achieve universal significance. In this process of transcendence the ideal formula is specified according to the form not only of the object but also of the subject. Language places knowledge beyond the subject-object split. It reduces the being mentioned in the ideal formula to the effective principle of concrete science.

The transcendental operation of language seems to be widely distributed throughout the numerical range of human subjectivity. Gioberti suggested that it is a transaction of particular groups and ultimately of the nation. This view was important in *Del primato morale e civile degli Italiani* and was given an aristocratic cast in the claim that within the nation the transcendental operation is the work only of an elite.

"PALINGENESIS"

Language constitutes the first movement of the life of the spirit, a movement implicit in the ideal formula, "Being creates existence." It is thus at the focus of the genesis of existence and the real as object. The pure form of human thought moves from the immediate givenness of the existent to its ideal ground. In experience we encounter the end product of the movement expressed in the ideal formula. Thought must return the existent thus encountered to its ground in being. Its movement is therefore a *palingenesis*—a return of existence to being.

Mimesis is the mode of existence of that which is encountered in experience. It is a state, but not a radical or irremediable one, of alienation. *Methexis* is the state of the thinking subject, the intelligence whose constitutive principle is the intelligible, that is being. *Methexis* is the

link that ends the alienation between being and existence in *palingenesis.*

Gioberti did not mean by *palingenesis* a dissolution of the distinctions of existence into the indeterminacy of ideal being. Rather, through *palingenesis* the being of the existent qua existent (that is, in its distinctness) is ideally grounded in being. Thus, being itself needs the movement of *mimesis* down into the world in order that it may come into its own actuality, or distinctness, through *methexis.* Hence, being is not absolutely transcendent. It reaches its actuality in the word and thus belongs inalienably to the region of culture and history. Gioberti's theory of language thus contains in germ a theory of culture and history. Culture and cultures are the historical forms of *palingenesis.*

THEOLOGY, POLITICS, AND ETHICS

The *palingenesis* of being is the central operation of the spirit and determines the actual form of the world. The fact that this one process can be studied from two points of view provided Gioberti with a basis for a correlative distinction and unity of theology and philosophy. Theology possesses a certain superiority deriving chiefly from its object, God. Supernatural theology does not, however, take possession of the internal, or constitutive, word of God; it must make use of analogies drawn from philosophy. Supernatural revelation makes use of the "natural revelation" of the word. Philosophy is therefore superior to theology in that it provides the interpretative categories of theology.

Palingenesis takes on deontological status as the supreme norm of action. In this aspect it is the axiological principle of both the moral and the political orders. In both morals and politics, in conscience and in law, the essential process is the return of existence to being. Similarly, Gioberti held that the church is the historical and institutional form of the *palingenesis* of being under the dispensation of revelation.

Gioberti's thought is still influential in two of the leading strands of contemporary Italian thought, Gentilean actual idealism and Christian spiritualism.

GIVEN, THE

GLANVILL, JOSEPH
(1636–1680)

Joseph Glanvill was a skeptic, a prominent defender of the experimental research of the early Royal Society, a liberal rationalistic Anglican theologian and preacher, and a staunch and influential believer in witchcraft. He studied at Cambridge, where he came under the influence of Henry More. On first learning of René Descartes's work Glanvill became an advocate of Cartesianism but was quickly led to cast doubt on it as a metaphysical theory because of More's objections. He then treated Cartesianism as a working hypothesis and began analyzing how much certitude anyone could have about what is going on in the world. He came into contact with John Wilkins, the bishop of Chester, and began developing his case in terms of the categories employed by him.

Glanvill's first work, *The Vanity of Dogmatizing* (1661), was soon revised into the larger *Scepsis Scientifica* (1665), and began with a most laudatory "Address to the Royal Society," which led to Glanvill being elected as a fellow.

GLANVILL AND SKEPTICISM

Glanvill saw the skeptical problem as one that could not be so easily set aside. He saw the reliability of one's faculties as central for avoiding any ultimate and overwhelming skepticism. But Glanvill saw that the kind of certainty one would need to be absolutely sure of one's faculties ("infallible certainty," in which one is assured, "'tis impossible things should be otherwise than we conceive them or affirm them") is unattainable—"for it may not be absolutely impossible, but that our Faculties may be so construed, as always to deceive us in the things we judg most certain and assured."

One may not be able to attain infallible certitude, but one can attain indubitable certitude that one's faculties are true. This is indubitable in two senses: first, that one finds that one has to believe them, and, second, that one has no reason or cause for doubting them. One has to believe one's faculties are reliable if one is to have any rational life at all, even though one has no evidence that one's faculties are, in fact, reliable.

Glanvill carried this on to base acceptance of historical data (and especially that of scripture) on the indubitable principle that "Mankind cannot be supposed to combine to deceive, in things wherein they can have no design or interest to do it." So, skepticism can be set aside in mathematics, science, history, and theology, because one has no actual reason to doubt the results in these areas. One has to believe various findings and act with confidence. But, having said this, Glanvill immediately made clear that he had not offered or provided any way of eliminating ultimate skepticism.

For Glanvill, reasons for doubting had to be reasonable. Descartes's reasons for doubting he dismissed as hyperbolic or metaphysical. No reasonable person would entertain them. On the contrary, there can be reasonable doubts about many things, but this does not prevent one from having a degree of certitude about other matters. Glanvill insisted that human beings are basically in a state of ignorance due to the original Fall. They cannot know the springs and principles by which the world is operating. They can only hypothesize about this and recognize that any hypothesis could be false. There is a reasonable basis for doubting in that one never has sufficient evidence or knowledge and one cannot be sure that things cannot be otherwise than one conceives them.

Glanvill introduced what was to be an important point in later scientific thought, namely, that one can never find necessary connections between events. Any causal hypothesis that one works out is always open to question and doubt, since one does not understand the inner workings of Nature. One can find concomitances of events (what David Hume later called constant conjunctions) but not necessary connections. Because of this analysis of one's causal reason, Glanvill has often been considered a precursor of Hume, although there is no evidence that Hume ever read any of his work.

REASON AND RELIGION

Glanvill's discussion of the relation of reason and religion is perhaps his most original contribution—that of offering a rational-skeptical fideism as a way of living with irremediable skepticism. Glanvill made the acceptance of the reliability of one's faculties a genuine act of faith. "The belief of our Reason is an Exercise of Faith, and Faith is an Act of Reason." He had preceded this by stating that "Reason is certain and infallible," which turns out to be based on one's knowledge "that first Principles are certain, and that our Senses do not deceive us, because God that bestowed them upon us, is True and Good."

Glanvill was not emulating Descartes in making true knowledge depend on the proof that God is not a deceiver. Rather, Glanvill was offering a kind of rational fideism. Faith, and faith alone, is the basis for one's belief in reason. One believes in reason because one believes in God's veracity. One does not try to prove that God is truthful; one believes this. Thus, faith in God gives one faith in reason, which in turn "justifies" one's belief that God is no deceiver.

Glanvill saw that the ultimate guarantee of one's certitude depends not on what one can prove, but on what one can believe. One can believe that God is truthful, and hence believe in the reliability of one's faculties. The first belief is reasonable, since one has no reason to doubt of it. This, then, enables one to avoid ultimate skepticism, by avoiding the fundamental skeptical problem of proving one's first principles.

Glanvill's rational fideism grows out of seeing the conditions requisite for certain and unquestionable reasoning (namely, that God is reliable), and is in sharp contrast to the irrational fideism being offered in the late seventeenth century by Pierre Bayle and Pierre Jurieu. Glanvill posed the possibility that rationality could be based on faith, and in terms of what human beings consider reasonable, accepting such faith is an exercise of reason. Using this rational fideism, Glanvill tried to show the reasonableness of religious belief and of Latitudinarian Christianity.

Glanvill provided an epistemology for a "mitigated" skepticism, which could delineate the kind of certitude that the new scientists could find. Instead of basing the "new science" on dogmatic metaphysical principles, he offered an undogmatic semiskepticism sufficient to encourage the nondogmatic inquiries of the scientists of the Royal Society, while opposing the dogmatism of Descartes, Thomas Hobbes, and Benedict (Baruch) de Spinoza.

Glanvill's belief in witches comes from his critique of the materialism of Hobbes and others. The question of whether evil spirits exist, Glanvill pointed out, is a factual question, not a metaphysical one and has to be answered by examining the empirical evidence. Glanvill compiled ample testimonials to convince any "reasonable" person that (1) it is possible that evil spirits or witches exist, (2) it is probable that they do, and (3) that the acknowledgment of their existence allows for the best explanation of various observed phenomena. Glanvill pointed out that various societies have laws against practicing witchcraft, so it seems likely that there is something of this sort that could be practiced. The possible existence of witches is also part of a larger and more significant question—that of the existence of spirits. If demonic or evil spirits cannot exist, then how can one be sure that good spirits—angels or God—can exist? To deny the possibility of the existence of witches is to deny the possibility of any sort of spiritual or divine world.

GLANVILL'S CARTESIANISM

Glanvill offered a nondogmatic, or deontologized, Cartesianism as the best scientific model of explanation for natural phenomena. In his continuation of Francis Bacon's *New Atlantis* Glanvill had his sage present Cartesianism as "the neatest Mechanical System of things that had appear'd in the world," though it was not certain or all encompassing. The sages could also accept the preexistence of the soul and the existence of spiritual agents, whose manner of operating may not be known or even knowable to one.

Glanvill was an eclectic philosopher, taking his views in part from More, Descartes, Bacon, Anne Conway, and the members of the Royal Society. Glanvill's world of natural science, spirits, and Christianity, based on the "plausible" testimony of historical documents, is one way these kinds of knowledge could be brought into harmony. Glanvill paid the price of having this all rest on a basically ineliminable skepticism. If one could find solace and comfort in a faith in a nondeceiving Deity, then a nice,

harmonious world of science and religion could be accepted.

GNOSTICISM

"Gnosticism" (from the Greek *gnosis*, "knowledge") designates a broad variety of religious teachings that were rife in the Hellenized Near East of the first centuries CE and purported to offer knowledge of the otherwise hidden truth of total reality as the indispensable key to man's salvation. Most of the schools or sects in question were ostensibly Christian by the time our earliest witnesses, the Church Fathers, were familiar with them, and in consequence the whole movement was long regarded as essentially an aberration from Christian doctrine. However, although Gnosticism provided the first chapter in the history of Christian heresies, the Christian veneer of the systems playing that role is often thin to the point of transparency; and clearly non-Christian writings have come to light that by all criteria of content must be classed as Gnostic as well. The details of the literary evidence point to highly syncretistic origins, in which Jew-

ish, Iranian, Babylonian, Egyptian, and other Oriental traditions were blended with one another and with Greek concepts in an extremely free manner. The results were as readily made to represent an alleged esoteric truth of the Christian message as to constitute a superior (Mani) or even hostile (Mandaeans) alternative to it.

This syncretism, pertaining mainly to the outer shell, does not preclude—in fact it tends to mask—a highly original inner unity of thought distinct from all the disparate historical elements employed in its representation. Massively mythological though this representation usually is, the substance thus expressed has philosophical significance as embodying a fundamental choice—the radical antithesis to the classical Greek choice—in the realms of universal theory and human practice at once. The powerful Gnostic impulse to elaborate its basic vision into grandly constructed, quasi-rational systems of thought where everything proceeds from an absolute beginning makes Gnosticism a landmark in the history of the speculative system as such; and it is the identity of that basic vision that defines what is Gnostic and alone justifies the classing of systems of such considerable diversity under one heading.

GNOSTIC TEACHERS AND SCHOOLS

A number of gnostic teachers and writers are known by name (mainly those listed as heresiarchs in the patristic refutations), but much of the surviving literature is anonymous or pseudepigraphic, in keeping with the revelatory style in which it is cast. Historical individuals whose thought is documented by either critical accounts or direct fragments of their works include the Samaritan Simon Magus and his spiritual descendants Menander, Saturninus, Cerinthus, and Cerdon (first and second centuries); the Alexandrians Carpocrates, Basilides and his son Isidore, and, foremost, Valentinus with his illustrious disciples Ptolemaeus, Heracleon, Theodotus, and Marcus (second century); the Pontian Marcion and the Syrian Bardesanes (second century); and the Persian-Babylonian Mani (third century). Major sects whose doctrines are well documented but not identified by individual authors or founders are, in the Christian camp, the Barbeliotes, Sethites, and Ophites (the last actually a cluster of sects); in the Hellenistic-pagan camp, the Hermetic religion (perhaps merely a literature and not an actual sect); in the Semitic East, the anti-Christian Mandaeans. Towering over the known thinkers are Valentinus, Marcion, and Mani; and Valentinianism and Manichaeism respectively represent the culminations of the two main alternative types of Gnostic speculation. The last two are here con-

sidered merely for their part in and exemplification of the wider context.

SOURCES

With the exception of that of the Mandaeans, Gnostic literature was denied direct tradition under the dominion of Christianity and Islam after the eclipse of the Gnostic communities themselves. Thus, until fairly recently, information was supplied almost solely by the abundant indirect sources. These were, in the main, the antiheretical works of the Church Fathers (Greek, Latin, and Syriac, from Irenaeus in the second century to Theodore bar Konai in the eighth century) with their diligent reports, summaries, and excerpts, and still later Islamic histories and compendia. However, for some time an impressive series of manuscript discoveries has been adding vastly to our store of original texts: Coptic-Gnostic papyrus codices from Egypt, belonging to the Christian branch of Gnosticism—the find in 1945 of a whole library at Nag Hammadi is revolutionizing the state of documentation in the area hitherto principally covered by the patristic testimony—Manichaean fragments in Persian, Turkish, and Chinese from Turfan in central Asia and in Coptic from Egypt, and the sacred writings of the Mandaeans of Iraq.

The Mandaeans are the one case of a Gnostic community surviving to the present with an unbroken written tradition of their voluminous Aramaic literature; it came to the attention of Western scholars in the nineteenth century, after it had escaped that of the Church Fathers in antiquity (probably because of the Fathers' predominantly Greek orientation). In all the other cases, the new original sources generally bear out, while greatly enriching, the testimony of the older indirect evidence. The following account, based on the entire, extremely varied material, is synoptic and selective, placing its emphases according to a conception of the whole as a system.

GNOSTIC DUALISM

A radically dualistic mood dominates the Gnostic attitude and unites its widely diversified expressions, whether doctrinal, poetical, or ethical. The dualism is between man and world, and between the world and God. In either case, it is a dualism of antithetical, not complementary, terms; and it is basically one: that of man and world mirrors on the plane of experience the primordial one of God and world and is, in Gnostic theory, deduced from it. The interpreter may hold conversely that the transcendent doctrine of a world-God opposition

sprang from the immanent experience of a disunion of man and world, that is, it reflects a human condition of alienation. In the three-term configuration, man and God belong in essence together against the world but are in fact separated by the world, which in the Gnostic view is the alienating, divisive agency.

The object of Gnostic speculation is to derive these basic polarities—the existing state of things—by way of genetic myths from the first things and through such genealogy to point the way to their eventual resolution. The myth, a conscious symbolical construction, is thus predictive by being genetic, eschatological by being explanatory. Accordingly, the typical Gnostic system starts with a doctrine of divine transcendence in its original purity; traces the genesis of the world from some primordial disruption of this blessed state, a loss of divine integrity that leads to the emergence of lower powers who become the makers and rulers of this world; then, as a crucial episode in the drama, it recounts the creation and early fate of man, in whom the further conflict becomes centered; the final theme—in fact, the implied theme throughout—is man's salvation, which is more than man's, since it involves the overcoming and eventual dissolving of the cosmic system and is thus the instrument of reintegration for the impaired godhead itself, the self-saving of God.

GOD AND THE DIVINE REALM. The transcendence of the supreme deity is stressed to the utmost degree in all Gnostic theology. Topologically, he is transmundane, dwelling in his own realm entirely outside the physical universe, at immeasurable distance from man's terrestrial abode; ontologically, he is acosmic, even anticosmic: To this world and whatever belongs to it he is the essentially "other" and "alien" (Marcion), the "alien Life" (Mandaeans), the "depth" or "abyss" (Valentinians), even "the not-being" (Basilides); epistemologically, because of the transcendence and otherness of his being, and because nature neither reveals nor even indicates him, he is naturally unknown, ineffable, defying predication, surpassing comprehension, and strictly unknowable. Some positive attributes and metaphors do apply to him: Light, Life, Spirit, Father, the Good—but not Creator, Ruler, Judge. Significantly, in some systems one of his secret names is Man. Mainly, the discourse about him must move in negations, and historically Gnosticism is one of the fountainheads of negative theology.

However, the Absolute is not alone but is surrounded by an aura of eternal, graded expressions of his infinitude, partial aspects of his perfection, hypostatized into quasi-personal beings (aeons) with highly abstract names (mostly of mental properties) and together forming the hierarchy of the divine realm, the pleroma (Plenitude). The emanation of this inner manifold from the primal ground, a kind of self-differentiation of the Absolute, is sometimes described in terms of subtle spiritual dialectics, more often in rather naturalistic (for instance, sexual), terms. Among the tenuously mythological entities that thus arise (such as Mind, Grace, Word, Knowledge, Life) are two more concrete ones with definite roles in the further evolution of the transcendental drama: Man as an eternal, divine, precosmic principle (sometimes even identified with the First Being himself) and Wisdom (Sophia), usually the last and youngest of the aeons. Extensive speculation about the diversity within the pleroma is the mark of advanced systems, but some degree of manifold on the upper reaches of being is requisite for all Gnostic metaphysics because it provides the condition for divine fallibility on which the movement into creation and alienation depends.

LOWER POWERS AND THE CREATOR. In the genuine Gnostic systems the downward movement starts from an internal crisis in the divine realm itself, whereas in those under Iranian influence it is occasioned by the action of dark forces from without, thus presupposing the very dualism that the typical speculation lets evolve from the one monistic root. We shall mainly follow this latter, more prevalent type, which is free from Iranian influence. Here, the protagonist of crisis and fall is most often the female aeon Sophia (or such equivalents as Thought and Conception) who, from some overstepping of bounds—assertion of self-will, creative presumption, even excessive desire to know the unknowable Father—is drawn into a history of passion and error that leads her outside the blessed pleroma. (In another family of systems, Primal Man assumes the role of the sinking part of divinity.) Although the upper powers immediately set about healing this breach in the divine order, the downward trend set in motion by the original lapse must take its course, and the counterplay of these two trends henceforth governs the process. There ensues, in a development too complex and too variously elaborated to recount here, a train of ever lower hypostases descended from the erring Sophia, episodically broken by certain archetypal salvations.

The Demiurge. Early in the descending series—and marked with all the deforming effects of the Fall whose fruit he is—appears the Demiurge, the monstrous and benighted archon (lord) of the nether powers. This widespread Gnostic figure, telling symbol of the Gnostic hos-

tility toward the world, is clearly a polemical caricature of the Old Testament God, and the identity is made explicit by frequent transference to him of well-known utterances and actions of God from the biblical text. Pride, ignorance, and malevolence of the Creator are recurring themes in Gnostic tales, as are his humbling and outwitting by the higher powers bent on thwarting his designs. However, over the whole range of Gnostic mythologizing the archon's image varies, and there are milder versions in which he is more misguided than evil and thus open to correction and remorse, even to final redemption. He is always a problematical and never a venerable figure.

Finding himself in the void or chaos outside the pleroma, possessed of the power inherited from his mother but ignorant of the divine worlds above him, he believes himself to be the only God and engages in creations chiefly designed to satisfy his ambition, vanity, and lust for dominion. Prominent among the host of lower powers that issue from him are six further archons whom he installs in six successive heavens; he occupies the seventh above them. Thus originate the cosmic order and its system of rule, the universe of Babylonian astrology with its seven planetary spheres and the almighty planetary deities. An eighth region beyond them (corresponding to the sphere of the fixed stars) is occupied by the mother Sophia, still exiled from the pleroma, who has no part in the creation and government of the world but intervenes in both for the purposes of salvation. The Valentinian version, the subtlest of all, depicts the Demiurge as trying vainly to imitate the perfect order of the aeons with his physical one, and their eternity with the counterfeit substitute of time—thus adding to the parody of the biblical Creator that of the Platonic Demiurge. However, the chief instance of illicit and bungling imitation is the creation of man.

The remaining part of creation is the joint work of the seven archons. Indeed, the early systems (such as that of Simon Magus) simply name the seven as the creators of the world; and the preeminence of one of them, growing into a kind of monotheism of cosmic (lower) divinity, seems to be characteristic of the mature stage of Gnostic speculation. There, an episode, told with almost identical words in the cosmogonies of many different schools, rings in the next act in the drama of creation: The First Archon (the Demiurge), exulting in his works with the Scriptural proclamation "I am God and there is none other than I," draws the retort from on high, "Thou art mistaken! Above thee is First Man."

CREATION OF EARTHLY MAN. Some such divulgence of superior godhead (here meant as no more than a humbling of the Creator's pride, elsewhere serving some other purpose in the divine strategy), and especially the appearance of a divine form with it, inspire the archons with the audacious plan to equal the upper perfection in a work of their own—to create terrestrial man—an effect not foreseen in the divine move. Letting them say on this occasion, "Come, let us make a man after the image we have seen," the Gnostics turned to account the puzzling plural of Genesis 1:26, and the resulting *imago Dei* character of created man, far from being a straight metaphysical honor, assumes an ambiguous, if not sinister, meaning. The motive for the archons' resolve is either simple envy and ambition, or the more calculating one of entrapping divine substance in their lower world by the lure of a seemingly congenial receptacle that will become its most secure bond. The imitation, presumptuous and blundering, is nevertheless effective. Although the mere creature of the archons—the body and a natural soul compounded from their several psychic powers—is not viable by itself, it becomes so through the injection of a spiritual element from beyond.

For this presence of transcendent spirit (pneuma) in psychophysical man—in itself a paradoxical, unnatural fact and the fulcrum of the whole soteriological drama—Gnostic speculation offers various explanations, their chief difference being whether the presence marks a success of the nether powers or a stratagem of the upper ones. In the first alternative, the causality operative on the divine side admits in turn the several variations of being a victim of violence (Mani), of deception, or of its own downward inclination (Poimandres). In the other alternative (the Valentinians), the divine seed is secretly deposited in the creature of the unknowing Demiurge in order to turn his work into an unintended vehicle of salvation. However, this variant is no more optimistic than the first, since the soteriological stratagem merely makes the best of a basic evil, of these divine portions' having become divorced from their source in the first place. In any case, the pneuma's innerworldly existence is a state of exile, the result of primeval divine tragedy; and its immersion in soul and body is the terminal form of that exile. For the archons, on the other hand, the incorporation of this transcendent element into their system is a condition of the system's existence, and its retention therefore becomes to them a matter of survival—their work's and their own. Hence, they must resist at all cost the spirit's extrication from the cosmic involvement, which the upper powers seek for the regaining of divine wholeness. The means of this extrication is knowledge.

HISTORY OF MAN. The process of conveying the saving knowledge to the world-imprisoned hostage of Light begins with Adam himself and runs through the history of humankind in a constant counterplay with the archontic powers. Human history is thus eschatological from the beginning. In the light of this scheme, the Scriptural account of early man, especially the Paradise story, is boldly recast, with all value signs reversed. The most significant of these reversals concerns the serpent, which, as the first bringer of knowledge in defiance of the Creator's mandate of ignorance, becomes the general symbol of the acosmic spiritual principle that works for the awakening of its captive kin in the world. The revelatory line thus started, and continued through the generations, ends in Christ (or may go beyond him to further revelations of the truth). Hence the cult of the serpent in a major group of Gnostic sects, the Ophites (from the Greek *ophis*, serpent). In the same spirit of reversal, Cain, Esau, and other rejected figures of the Old Testament became to certain sects (Cainites, Carpocratians, Perates) bearers of the pneumatic heritage, forming a secret lineage of gnosis and persecuted by the world god for this reason; their opposites, such as Abel and Jacob, his favorites, represent the unenlightened majority. Independently of the intention to scandalize that is evident here, the Gnostic scheme called for a prophetology in succession of the Adamitic revelation, for which Iranian tradition offered the idea of an eternal Messenger who moves through history in ever new incarnations. These messengers were variously identified with names from the religious past; in the final consolidation by Mani we find them reduced to four: Buddha, Zoroaster, Jesus, Mani. The significant omission of Moses from this list requires a comment on the anti-Judaism among the Gnostics.

The this-worldly spirit of the Hebrew religion combined with historical circumstance to make the Old Testament a prominent target of Gnostic dislike, to varying degrees. The extreme of hostility, even contempt, is found in Marcion, for whom this admittedly authentic revelation of the Creator and Lord of this world shares all the blemishes of its source: It is as opposed to the gospel of salvation as its divine author is to the God that saves and as this world, his work, is to the nonmundane realm beyond. Simon Magus and others are hardly less intransigent. A more qualified view is taken by the Valentinians: The law is at least partly prefigurative of the higher truth, and the prophets, although mainly inspired by the Demiurge, are sometimes (and unbeknown to him) used by his mother, Sophia, for her own messages, which thus are interspersed in the inferior bulk. There are other shades of opinion, but rejection of the whole body of Hebrew Scripture, joined with irreverent exegetical use, is by far the rule; and on this issue, and on the related one of the identity or nonidentity of the God of Moses with the Father of Jesus Christ, the main battle was fought between the church and the heretics.

COSMOS AND HUMAN NATURE. The material universe, the domain of the archons, is like a vast prison whose innermost dungeon is the earth, the scene of man's life. Around and above it, the cosmic spheres are ranged like concentric enclosing shells. Their number is usually seven, with a surrounding eighth that does not belong to the archontic realm proper but is intermediate between the cosmos and the upper world of the pleroma. There was, however, a tendency to multiply structures and to make the scheme more and more extensive: Basilides counted no fewer than 365 heavens. The religious significance of this cosmic architecture lies in the idea that everything that intervenes between here and the beyond serves to separate man from God, not merely by spatial distance but through active demonic force. Thus, the vastness and multiplicity of the cosmic system express the degree to which man is removed from God.

The spheres are the seats of the archons, whose ruling set of seven are the planetary gods of the Babylonian pantheon, now significantly renamed with synonyms for the Hebrew God—another sign of the latter's degradation. The archons collectively rule the world that they (or their overlord) made, and each individually in his sphere is a warder of the cosmic prison. Their tyrannical world rule, called Fate (*heimarmene*), is physically the law of nature, morally the law of justice, as exemplified in the Mosaic law, which issued from the Demiurge or the angels and, with its threat of retribution, aims at the enslavement of man as much as the first does with its force of necessity. As guardian of his sphere, each archon bars the passage to the souls that seek to ascend after death, in order to prevent their escape from the world and their return to God.

Man, the main object of these vast dispositions, is composed of flesh, soul, and spirit. Reduced to ultimate principles, his origin is twofold: mundane and extramundane. Both the body and the soul are products of the cosmic powers, who shaped the body in the image of the divine Primal Man and animated it with their own psychical forces: These are the appetites and passions of natural man, each stemming from and corresponding to one of the cosmic spheres, and all together making up the astral soul of man, his psyche. Through his body and his soul man is a part of the world and is subjected to

heimarmene. Enclosed in the soul is the spirit, or pneuma (also called the spark), a portion of the divine substance from beyond that has fallen into the world; the archons created man for the express purpose of keeping it captive here.

Thus, as in the macrocosm man is enclosed by the seven spheres, so in the human microcosm the pneuma is enclosed by the seven soul vestments originating from them. These psychical envelopments are considered impairments and fetters of the transmundane spirit, and its incarnation in the outer, material body merely completes the complex imprisonment. The resulting human constitution is, then, comparable to an onion with so many layers, on the model of the cosmos itself but with the order reversed; what is outermost and uppermost in the cosmos is innermost in man, and the innermost or nethermost stratum of the cosmic order, Earth, is the outer bodily garment of man. Only the innermost or pneumatic man is the true man, and he is not of this world, as his original in the total order, the deity, is external to the cosmos as a whole. In its unredeemed state the spirit, so far from its source and immersed in soul and flesh, is unconscious of itself, benumbed, asleep, or intoxicated by the poison of the world—in brief, it is ignorant. Its awakening and liberation are effected through knowledge.

ESCHATOLOGY: SALVATION THROUGH GNOSIS. The nature of Gnostic dualism determines the general concept of salvation, and the stratifications of cosmos and man condition its details. Its basic premise is that the transcendent God is as alien to this world as the pneumatic self is in the midst of it. The goal of Gnostic striving is the release of the inner man from the bonds of the world and his return to his native realm of light. The necessary condition for this is that he know about the transmundane God and about himself, that is, about his divine origin as well as his present situation, and hence, also about the nature of the world that determines his situation. Such knowledge is withheld from him by precisely the selfsame situation that requires it, for ignorance is the essence of mundane existence, just as it was the principle of the world's coming into being. In particular, the transcendent God is unknown in the world and cannot be discovered from it; therefore, revelation is needed. The necessity for revelation is inherent in the innercosmic condition; and its occurrence alters this condition in its decisive respect, that of ignorance.

Revelation, or the "call," is thus already a part of salvation. Its bringer is a messenger from the world of Light who penetrates the barriers of the spheres, outwits the archons, awakens the spirit from its earthly slumber, and imparts to it the saving knowledge from without. The mission of this transcendent savior begins even before the creation of the world, since the fall of the divine element preceded creation, and the archetypal redemption indeed takes place in the precosmic stage. It is the incompleteness of this initial restoration, whether of Sophia or of Mani's Primal Man, that leads to the genesis of the world and the protraction of the saving process throughout its history. The fact that in the discharge of his task the eternal messenger must himself assume the lot of incarnation and cosmic exile, and the further fact that, at least in the Iranian variety of the myth, he is in a sense identical with those he calls—the once lost parts of his divine self—give rise to the moving idea of the "saved savior" (*salvator salvandus*).

The knowledge revealed by the messengers, for short "knowledge of God," comprises the whole content of the Gnostic myth, with everything it has to teach about God, man, and world, including the history of the beginnings which alone offers the key to the secrets of existence; that is, the revelation contains the elements of a theoretical system. On the practical side, however, it is more particularly "knowledge of the way"—of the soul's way out of the world—comprising the sacramental and magical preparations for its future ascent and the secret names and formulas that force the passage through each sphere. Equipped with this gnosis, the soul after death travels upward, leaving behind at each sphere the psychical vestments contributed by that sphere; thus the spirit, stripped of all foreign accretions, reaches the God beyond the world and reunites with the divine substance. (The most circumstantial description of this ascent is found in the "Poimandres," the first treatise of the Hermetic corpus.) On the scale of the total divine drama, the individual ascent is part of the restoration of the deity's own wholeness, impaired by the events of the beginning. Only through the loss suffered then did the deity become involved in the destiny of the world, and only to retrieve his own does he intervene, through his envoys, in cosmic history. With the completion of this ingathering, the cosmos, deprived of its elements of light, will come to an end.

MORALITY. In this life the pneumatics, as the possessors of gnosis called themselves, are set apart from the mass of humankind. The immediate illumination that makes the individual sovereign in the sphere of knowledge (hence the great variety of Gnostic doctrines) also inspires superior rules of conduct. Generally, the pneumatic morality

is determined by hostility toward the world and contempt for all mundane ties. From this principle, however, two contrary conclusions could be drawn, and both found their extreme partisans: the ascetic and the libertine. The ascetic deduces from the possession of gnosis the obligation to avoid further contamination by the world and therefore to reduce the world's use to a minimum; the libertine derives from the same possession the privilege of unrestrained freedom. The libertine conclusion, more startling and more devious, is argued thus: The law, since it represents the will of the Demiurge and is one form of his tyranny, does not obligate the pneuma, which is "saved in its nature" and can be neither sullied by actions (which in themselves are morally neutral) nor frightened by the threat of archontic retribution which can affect only the body and the psyche).

Thus the pneumatic, since he is free from the power of fate, is also free from the yoke of the moral law, and all things are permitted to him. This freedom, however, is more than merely permissive; its practice is bidden by metaphysical interest. Through intentional violation of the demiurgical norm (for which the mythological vilification of the Demiurge prepares) the pneumatic thwarts the design of the archons and thus paradoxically contributes to the work of salvation. From the motive of defiance it is then only one step further to the teaching of the Cainites and Carpocratians that there is a positive duty to perform every kind of action, to leave no deed undone, no possibility of freedom unrealized, in order to render nature its due and exhaust its powers; only in this way can final release from the cycle of reincarnations be obtained. Gnostic libertinism thus spans the whole scale from mere negative license to positive Faustian obligation—at which point it loses again some of the contrast to its ascetic alternative.

The latter alternative, too, betrays the common root in Gnosticism from which both opposites spring. Although more obvious in the libertine choice, the element of defiance shows in the ascetic one as well; as much as it may serve purification or other perfectionist ends normally associated with asceticism, it often has the declared purpose of obstructing the cause of the Creator, even just to spite him, by refusing to use his works (a kind of metaphysical strike). This obstructive aspect is especially clear in the abstention from sexual intercourse and marriage when, as in Marcion and Mani, its purpose is not to help replenish the world of the Demiurge and further disperse in it the captive light—thereby prolonging its exile and making its ingathering more difficult. Indeed, according to Mani, the reproductive scheme was

instituted by the archons with precisely this end in view. Asceticism is thus a matter less of ethics than of metaphysical alignment, and its common ground with libertinism is the determination not to play the Creator's game. The one repudiates allegiance to nature through abstention; the other, through excess. Both are lives outside the mundane norm. Freedom by use and freedom by nonuse are thus alternative expressions of the same acosmism.

ACOSMISM. Acosmism, the real basis of the Gnostic position, contains the seeds of nihilism; the very extremism of divine transcendence has nihilistic implications. As the totally other, alien, and unknown, the Gnostic God has more of the *nihil* than of the *ens* in his concept. For all purposes of man's relation to the reality that surrounds him, this hidden God is a negative term; no law emanates from him—none for nature, and thus none for human action as a part of the natural order. His only relation to the world is the negative one of saving from the world. Antinomianism follows naturally, even if not inevitably, from these premises.

TWO TYPES OF GNOSTIC DUALISM. This entry has kept mainly to the Syrian-Egyptian stream of Gnostic speculation, to which the majority of systems, especially the Christian ones, belong. There is, however, another, Iranian line of speculation that culminates in Mani.

Both types, being Gnostic, were evolved to explain the same facts of a dislocated metaphysical situation—both are dualistic concerning their common theme: the existing rift between God and world, world and man, spirit and flesh. The Iranian type, in a Gnostic adaptation of Zoroastrian doctrine, starts from a dualism of two opposed principles and then must explain how the original Darkness came to engulf elements of the Light—it describes the world drama as a war with changing fortunes; and the divine fate, of which man's fate is a part and the world an unwilled by-product, is explained in terms of mixing and unmixing, captivity and liberation. Here the knightly male figure of First Man, the warrior, assumes the role of the exposed and suffering part of divinity.

The Syrian speculation, with the female Sophia in that role, undertakes the more ambitious task of deriving dualism itself, and the ensuing predicament of the divine in the system of creation, from the one and undivided source of being. It does this by means of a genealogy of personified divine states evolving from one another that describes the progressive darkening of the original Light

in categories of guilt, error, and failure. This devolution within the divine being ends in the decadence of complete self-alienation that is this world. Both dramas start with a disturbance in the heights; in both, the existence of the world marks a discomfiture of the divine and a necessary, in itself undesirable, means of its eventual restitution; in both, the salvation of man is that of the deity itself. The difference lies in whether the tragedy is forced upon the deity from without by the trespass of an independent Darkness, which thus has the first initiative (the deity itself being in perfect tranquility), or is motivated from within itself, with Darkness and Matter the products of its passion, which they hypostatize in external terms. To divine defeat and sacrifice in the first case correspond divine guilt and error in the second; to compassion for the victimized Light, spiritual contempt for demiurgical blindness; to eventual divine liberation, reformation through enlightenment.

The Manichaean and Valentinian systems respectively exemplify the two types. The Iranian type, with its high-minded story of battle, defeat, and recovery, lends itself to more concrete and gripping dramatization. However, only the subtler Syrian type, by according metaphysical status to knowledge and ignorance as modes of the divine life and therefore as universal, cosmogonic categories, can do full justice to the redemptional claim made on behalf of knowledge in all Gnostic religion. Valentinian speculation inferred that the human individual event of pneumatic knowledge reverses the precosmic universal event of divine ignorance and is in its redeeming effect of the same ontological order. Thus the actualization of knowledge in the person is at the same time an act in the general ground of being.

Bibliography

PRIMARY SOURCES

New Testament Apocrypha are translated in M. R. James, ed., *The Apocryphal New Testament* (Oxford: Clarendon Press, 1953), and in E. Hennecke and W. Schneemelcher, eds., *Neutestamentliche Apokryphen* (Tübingen: Mohr, 1959–1964). Editions of the original texts are listed there. The following Apocrypha are noteworthy for their Gnostic contents: the "Acts of Thomas," containing the Hymn of the Pearl; the pseudo-Clementine "Homilies and Recognitions"; and the "Odes of Solomon." See also the section on Coptic sources, below.

Patristic sources, in standard editions and translations, include Irenaeus of Lyon, *Against the Heresies*; Clement of Alexandria, *Excerpts from Theodotus* and *Stromateis*; Tertullian of Carthage, *Against Marcion, Against the Valentinians, On the Plea of the Heretics*, and *On the Soul*; Hippolytus of Rome, *Philosophoumena*; Origen, *Against Celsus* and *Commentary on the Gospel of John* (containing the fragments of Heracleon); and Epiphanius of Salamis, *Panarion*. Collections of patristic texts (Greek and Latin) may be found in A. Hilgenfeld, *Die Ketzergeschichte des Urchristentums* (Leipzig, 1884), and W. Völker, ed., *Quellen zur Geschichte der christlichen Gnosis* (Tübingen: Mohr, 1932).

Coptic sources include C. Schmidt, *Koptisch-gnostische Schriften* (Leipzig: Hinrichs, 1905) and *Pistis Sophia*, Coptica II (Leipzig, 1925); W. Till, ed., *Die gnostischen Schriften des koptischen Papyrus Berolinensis 8502* (Berlin, 1955). The newly discovered Nag Hammadi texts, so far as published, include the following: M. Malinine, H. C. Puech, and G. Quispel, eds., *Evangelium Veritatis* (Zürich, 1956 and 1961), translated in K. Grobel, *The Gospel of Truth* (New York and Nashville, TN, 1960); H. M. Schenke, "Das Wesen der Archonten," in *Theologische Literaturzeitung* 83 (1958): 661–670; A. Guillaumont, H. C. Puech, and others, eds., *The Gospel according to Thomas* (Leiden, 1959), translated in R. M. Grant and D. N. Freedman, *The Secret Sayings of Jesus* (London: Collins, 1960), and also translated by J. Leipoldt, J. Doresse, T. Säve-Söderbergh, H. Quecke, and R. McL. Wilson; M. Krause and P. Labib, *Die drei Versionen des Apokryphon des Johannes* (Wiesbaden, 1962), also translated by S. Giverson; A. Böhlig and P. Labib, eds., *Die koptisch-gnostische Schrift ohne Titel aus Codex II von Nag Hammadi* (Berlin: Akademie-Verlag, 1962), and *Koptisch-gnostische Apokalypsen aus Codex V von Nag Hammadi* (Halle: Martin-Luther-Universität, 1963); M. Malinine and others, eds., *De Resurrectione Epistula ad Reginum* (Zürich and Stuttgart, 1963); W. Till, *Das Evangelium nach Philippos*, Texte und Studien II (Berlin: De Gruyter, 1963), also translated by R. McL. Wilson. See also H. C. Puech, "Gnostische Evangelien und verwandte Dokumente," in *Neutestamentliche Apokryphen*, Vol. I, edited by E. Hennecke and W. Schneemelcher (Tübingen; Mohr, 1959), pp. 158–271.

Hermetica are collected in A. D. Nock, ed., *Hermès Trismégiste*, translated by A. J. Festugière, 4 vols. (Paris, 1945–1954), which contains text, translation, and notes and supersedes all earlier editions.

Writings of the Mandaeans are in the following editions and/or translations: M. Lidzbarski, *Das Johannesbuch der Mandäer* (Giessen, 1905 and 1915), *Mandäische Liturgien* (Berlin: Weidmannsche, 1920), and *Ginza. Der Schatz oder das grosse Buch der Mandäer* (Göttingen: Vandenhoeck and Ruprecht, 1925); and E. S. Drower, *The Book of the Zodiac* (London: Royal Asiatic Society, 1949), *Diwan Abatur* (Vatican City, 1950, Studi e testi 151), *The Haran Gawaita* (Vatican City, 1953, Studi e testi 176), *The Canonical Prayerbook of the Manaeans* (Leiden, 1959), *The Thousand and Twelve Questions* (Berlin: Akademie-Verlag, 1960), *The Coronation of the Great Šišlam* (Leiden: Brill, 1962), and *A Pair of Nasoraean Commentaries* (Leiden: Brill, 1963).

For writings of the Manichaeans, see the bibliography to the Mani and Manichaeism entry.

A selection of materials from the first four sections of this bibliography can be found in R. M. Grant, *Gnosticism: A Source Book of Heretical Writings* (New York: Harper, 1961).

SECONDARY SOURCES

General studies include F. C. Baur, *Die christliche Gnosis* (Tübingen, 1835); C. W. King, *The Gnostics and Their Remains*, 2nd ed. (London: Nutt, 1887); W. GOBINEAU, COMTE JOSEPH ARTHUR DE
(1816–1882)

Comte Joseph Arthur de Gobineau was a French philosopher, historian, novelist, and diplomat. Gobineau's diplomatic duties during the Second Empire carried him to Switzerland, Persia, Greece, and Brazil, where he produced a number of historical and ethnographic works of considerable merit. He is best known for his *Essai sur l'inégalité des races humaines* (4 vols., Paris, 1853–1855; Vol. 1 translated into English by Adrian Collins as *The Inequality of Human Races,* London, 1915). This work is usually considered an important contribution to nineteenth-century racist thought; but Gobineau's racism was a by-product of his attempt to account for the decline of the European aristocracy in terms of the more general problem of the decline and fall of civilizations.

Gobineau presented his work as an essay in positivistic social theory; in the preface to the second edition (1884), he argued that Henry Thomas Buckle and Charles Darwin had merely proceeded along lines originally marked out by himself. Superficially, then, Gobineau's work resembled those positivistic theories of culture in which his century abounded. However, it differed from them in its categorical rejection of the doctrine of "progress." His work was profoundly pessimistic, and in the end Gobineau predicted the ineluctable decay, not only of Western civilization, but of the whole of humanity. Thus, Gobineau's racism differed from the later racism of the imperialist period. He was neither a nationalist nor a proponent of the idea of "the white man's burden." He was, rather, an apologist for a class that had come to feel that since it no longer had a genuine social role to fill, society itself was no longer possible.

Gobineau held that the human species was originally divided into three races as a result of environmental conditioning. The Negro race is dominated by "desire" and the need to gratify desire, and hence is the natural enemy of civilization. Driven by the need for sensual gratification alone, the Negro lacks both speculative and technical capability. The yellow race is the antitype of the Negroid, lacking in physical vigor but possessing a natural talent for technical accomplishment that allows it to create pseudo civilizations but prohibits it from developing any genuine science. The white race is superior to the other two because it combines energy and intelligence in just the right proportions. The white race has a genuine "love of life," but it is able to control and direct that love to culturally creative ends. The white man is a speculative thinker, which allows him to create both a science of nature and a science of politics. This makes of the white man the natural conqueror of the other two races. Whatever these other races have accomplished in the way of civilizational growth they owe to the superaddition of white blood, Gobineau held.

By the same token, however, racial intermixture results in the debilitation of the white race. Unlike the Darwinists, who saw survival itself as evidence of fitness, Gobineau held that in every racial mixture it is the weaker strain that predominates. In the long run, then, racial intermixture must result not so much in the elevation of inferior breeds as the mongrelization of the entire species. Thus envisaged, the white race is caught on the horns of a dilemma. Its inherent excellence drives it forth to world conquest, but that very conquest leads to its decline. Gobineau's theory of civilization, in short, was not so much an attempt to explain the facts of history as to justify his own overriding sense of *senescens saeculum,* a product of the breakdown of the social class to which he belonged.

Obviously, such a theory could not serve as a rationalization for imperialistic expansion, for if Gobineau were right, it would be better for the white race to cease expanding and seal itself off from contact with all other races. But Gobineau was valuable to the reactionary groups of his time even though he opposed imperialism, for he was an ardent enemy of liberalism. His theory explicitly designated the social egalitarianism of the radicals as an instrument of further mongrelization. The city of Paris, where the races mixed in perfect equality, proved his point, he wrote, because there "tradition is respected not at all."

As for nationalism, Gobineau regarded this phenomenon as another evidence of the breakdown of racial solidarity. He dreamed of an international aristocracy of blood to which the purest elements of all nations belong. His book *La renaissance* (Paris, 1877; translated into English by P. V. Cohen as *The Renaissance,* New York, 1913) was intended to demonstrate that as long as the white race had retained its internationalist sense of caste and eschewed expansion and intermixture, it had remained creative and productive. Neither libertarian nor expansionist, the aristocracy of the Renaissance, as represented by such figures as Cesare Borgia, Michelangelo, and Raphael, was able to produce masterpieces of art and politics. The problem of race did not intrude itself into Gobineau's handling of the Renaissance, because in *La renaissance* he was dealing with a preliberal, amoral, and creative example of the white race's power. But this book

does contain an implicit criticism of his own age, dominated, in his opinion, by weak-willed liberals and traditionless mongrels.

GOD, ARGUMENTS FOR THE EXISTENCE OF

See *Common Consent Arguments for the Existence of God*; *Cosmological Argument for the Existence of God*; *Degrees of Perfection, Argument for the Existence of God*; *Moral Arguments for the Existence of God*; *Ontological Argument for the Existence of God*; *Religious Experience, Argument for the Existence of God*; and *Teleological Argument for the Existence of God*

GOD, CONCEPTS OF

It is very difficult—perhaps impossible—to give a definition of "God" that will cover all usages of the word and of

equivalent words in other languages. Even to define God generally as "a superhuman or supernatural being that controls the world" is inadequate. "Superhuman" is contradicted by the worship of divinized Roman emperors, "supernatural" by Benedict Spinoza's equation of God with Nature, and "control" by the Epicurean denial that the gods influence the lives of men. Therefore, while the above definition satisfies a wide range of usages, it is not universally applicable.

This entry will deal with five problems: the transcendence and immanence of God, his relation to the world, his chief attributes, the extent to which he is "personal," and the ways by which he can be known. In discussing these problems it will be necessary to consult the data provided by both religion and philosophy. But purely religious data (in contrast with theological speculations based on them) will be mentioned only when they are relevant to philosophical understanding.

TRANSCENDENCE AND IMMANENCE

In Judaism and Christianity, God is unquestionably transcendent. He is "wholly other" than the world he made. In Judaism his transcendence was emphasized by, among other things, the prohibition of idols, the explicit teaching of Isaiah 40:12–26, the sacredness of the Tetragrammaton, and the speculations of Philo who, in a typical passage, speaks of God Platonically as "the pure and unsullied Mind of the universe, transcending virtue, transcending knowledge, transcending the good itself." The New Testament, in confirming the Old Testament, repudiates the claims of Hellenistic *gnosis* by affirming that "no one has ever seen God" (John 1:18) and that all our knowledge of him is like a confused reflection in a mirror (1 Cor. 13:12). Among later Christian thinkers this biblical attitude was reinforced partly by the influence of Neoplatonism and partly by the experience of the mystics (especially Dionysius the Pseudo-Areopagite). Hence, in the *Summa Contra Gentiles* (I, 14), Thomas Aquinas says that "the divine substance exceeds by its immensity every form which our intellect attains," so that while we can know *that* God is (*quod sit*) we cannot know his essence or *what* he is (*quid sit*). In recent times divine transcendence has been stressed by Søren Kierkegaard and Karl Barth, as opposed to Hegelian attempts to obtain a rational and synoptic understanding of ultimate reality. From a phenomenological point of view, Rudolf Otto, in his *Das Heilige* (Marburg, 1917), defined the object of worship as a *mysterium tremendum et fascinans* that is revealed to a suprarational faculty of the soul.

Christian theologians claim that this transcendent God can be spoken of either negatively by the *via negativa* or *via remotionis* (the apophatic way) or positively (by the cataphatic way). According to the negative way, we deny qualities to God by the use of such adjectives as "*incorporeal*" and "*uncreated*." Thus we come to know him by knowing what he is not. But we also speak positively of God (for example, by predicating goodness or wisdom of him). Thomas denied that positive predicates are definable in terms of negative ones. He also denied that they simply point to God as an indeterminate cause of finite properties. In his view, they refer to God in a positive manner through an "analogy of proportionality." Thus goodness exists in God in a "supereminent" form, proportionate to his infinite mode of being. Through this theory of analogical predication, Thomas hoped to steer a middle course between the anthropomorphism of univocal predication, on the one hand, and the agnosticism of equivocal predication on the other.

According to the main tradition of Christian thought, God is also immanent. Augustine held that the light of God's presence in the human mind enables it to recognize eternal truth. Thomas, while rejecting the Augustinian theory of illumination, affirmed God's omnipresence unambiguously. "God is in all things, not, indeed, as part of their essence, or as a quality, but in the manner that an efficient cause is present to that on which it acts. Hence God is in all things, and intimately" (*Summa Theologiae* Ia, 8, 1). Similarly, the mystics affirm that the transcendent God is present (even when unrecognized) at the "ground" or "apex" of the soul. But some philosophers have *identified* God's substance either partly or wholly with the world. The clearest exponent of this concept in Western thought is Spinoza, whose identification of God with Nature a paradigm of pantheism. Such later philosophers as Edward Caird and Sir Henry Jones, who equated the Christian God with the Hegelian Absolute, approximated pantheism in varying degrees. Many modern theologians, such as Barth and Rudolf Bultmann, who have followed Kierkegaard in reaffirming God's transcendence, have either denied or ignored his immanence. Paul Tillich is a notable exception. While he spoke of God "existentially" as the transcendent Object of our "ultimate concern," he also held that we could not know God without "participating" in him.

GOD AND THE WORLD

The degree to which God is transcendent or immanent depends on the view that is taken of his relation to the world. At least five views are possible.

GOD AS FINAL CAUSE. God can be viewed as a final, though not efficient, cause of the world. This view was held by Aristotle. According to him, God is the world's "prime mover." God "moves" the world in the sense that he educes form from its material structure by inspiring it, through a series of subordinate movers or "intelligences," to love him as its end or goal. Yet Aristotle expressly denied a creation of the world; he considered matter to be ungenerated and eternal.

WORLD AS EMANATION FROM GOD. The world may be regarded as in some way an emanation from, or self-expression of, God. This view has taken three main forms.

According to Plotinus, the One, or "first god," is beyond all thought and being. The One's simplicity would be violated if the world were a part of it. Its unchangeability would be violated if it were to create the world by an act of will. Therefore Plotinus propounded his theory of "emanation." Mind, Soul, and the material world flow from the One (as rays flow from the sun) without impairing its self-sufficiency.

According to Spinoza, the world *is* God (the only substance) under his attributes of thought and extension. Everything follows from his essence by a logical necessity. "Things could not have been produced by God in any other manner or order than that in which they were produced. All things must have followed of necessity from a given nature of God, and they were determined for existence or action in a certain way by the necessity of the divine nature" (*Ethics* I, prop. 33). Critics of Spinoza have continually pointed out that on these premises it is very hard to account for, first, the individuality which human persons *seem* to have; second, their apparent freedom, which Spinoza elsewhere attempts to analyze; and third, the fact of evil, especially in its moral forms.

The same type of relation between God and the world was posited by G. W. F. Hegel. Unlike Plotinus, he regarded God or the Absolute as in its essence a self-diversifying unity. Unlike Spinoza, he conceived of God's self-expression as a dynamic process that is discoverable in historical events. Hegel's thought is not free from ambiguity. He sometimes speaks of God as an independently existing entity. But his final and distinctive view is that the Absolute Spirit does not exist apart from the human spirits in which it is progressively evolved.

WORLD AS PREEXISTENT MATTER SET IN ORDER. The third way of relating God to the world was stated by Plato in his *Timaeus*. According to this dialogue (29E–30), God is bounded on the one hand by the world of Forms

and on the other by preexistent matter. His task is to impose the Forms on matter, and so construct a rationally ordered whole. Being wholly good, and therefore free from jealousy, he wished everything to be like himself. Since an intelligent being is superior to an unintelligent one, and since intelligence cannot be present in anything that is devoid of soul, "he put intelligence in soul, and soul in body, that he might be the creator of a work which was by nature best." (In the *Republic* 597, Plato implies that God creates the Forms, but this was not his usual view.)

CREATION EX NIHILO. In contrast with all the previous views, Christian theists since Augustine have held the doctrine of creation out of nothing. This phrase is meant to exclude both the idea that the world is a necessary emanation from God's nature and the idea that matter preexists his creative act. God brings the whole world into being by an undetermined choice. He does not need the world to complete his nature, for he is wholly self-sufficient. He is not confronted with an alien Necessity, for he is the efficient cause of all that is.

This conception of the relation between the Creator and the creature can be elucidated through the contrast between necessary and contingent being. God exists necessarily. In him essence and existence are identical. He is self-existent in a unique and incomprehensible way. Creatures, on the other hand, are contingent. Their essence, while preexisting ideally in the mind of God, would not have achieved independent being if he had not chosen to grant it by a free act of love. Therefore, while they participate in him both by nature and by grace, they never lose their created status. They can be deified (as the Greek fathers taught) within their finite limits, but they cannot become divine in the sense of sharing God's aseity.

The full Christian doctrine does not restrict God's creative act to an initial moment in the cosmic process. All things owe their being continuously to his power. He is a first cause in the order of existence, not of time, for he himself is supratemporal. Hence it is irrelevant to theology whether the world did or did not have a temporal beginning. Thomas held that while such a beginning was revealed through Scripture, it could not be rationally proved. All reason knows is that God is the eternal, ever-present, and creative source of anything that does (or can) exist. Creation and preservation are identical.

However, while no creature exists from itself (*a se*), every creature exists by itself (*per se*) or in itself (*in se*). Created substances have a relative independence, or derived autonomy. These paradoxical expressions are required in order to affirm the truth that while creatures owe their being to God as their first cause, they also act according to secondary causes that are appropriate to their natures. The distinction between these two types of cause is necessary for a true assessment of the relation between science and theology. Because finite things exist per se, their secondary causes are discoverable without the aid of faith. But the discovery of secondary causes does not, without a further, nonscientific, act of inference or intuition, either permit or prohibit belief in a first cause, God.

Yet God, as first cause, can suspend or transform secondary causes in order to perform his will. When he does so, his action is called a miracle. A miracle does not violate nature. It is a case of nature behaving in an abnormal way through a special act of the same creative power that is at work in the normal processes which can be subsumed under scientific laws. If the essence of finite being is to be dependent on God's will (and so to possess a *potentia obedientialis* in relation to it), miraculous acts are not less natural than nonmiraculous ones. But while the abnormal character of an event is empirically verifiable, its miraculous character as an act of God can be discerned by faith alone. (Many theologians readily admit that at least some of David Hume's skeptical objections have considerable prima-facie force.)

The relation between divine causality and the human will has been extensively discussed by theologians. The doctrine of predestination, in its rigid Augustinian form, would seem to be obviously incompatible with human freedom. Yet even those theologians who reject the doctrine are obliged to face the problem of the manner in which God acts on men both by nature (through his general providence) and by grace (through the supernatural gift of the Holy Spirit). While various attempts have been made to separate divine and human action so that, for example, the human will is left wholly autonomous in a strictly moral choice, many theologians (more recently, D. M. Baillie and A. M. Farrer) affirm, on grounds of Scripture and experience, that the divine and human wills act simultaneously throughout the Christian life, but that the manner of their interaction is a paradox, or mystery, that cannot be unraveled by the intellect.

GOD AS FINAL STAGE OF COSMIC PROCESS. Samuel Alexander held the eccentric view that God qua deity, so far from being the ground of the cosmic process, is (ideally) its final stage. The world evolves from space time through matter and life to mind. God exists wholly within the world, which is his "body," but he does not yet

exist as deity (that is, as an infinite, transcendent, Being). Moreover, he will never so exist. Deity, as a state of infinite perfection, is a goal to which the world (or God considered as the world) continually strives but which is unattainable.

Some philosophers have combined two or more of these views. Thus A. N. Whitehead, while rejecting the idea that God is the world's efficient cause, held, as did Aristotle, that he is a final cause who (like Plato's God) brings order into the world by ensuring the ingredience of eternal objects (which, however, do not exist independently) in the realm of temporal flux. But Whitehead also shows his affinity with Alexander by asserting that it is as true to say that the world creates God as it is to say that God creates the world.

THE DIVINE ATTRIBUTES

In most systems of religion and philosophy, God is endowed with characteristics that distinguish him from other forms of being.

INFINITY. The infinity of the Christian God was implied above in the accounts of his transcendence and creative power, and in most systems, God's infinity makes him free, in degree, if not in kind, from at least some human limitations. But he is not strictly infinite unless he is limitless throughout the whole range of his existence. He can be wholly limitless, however, only if he is self-existent and thereby self-sufficient. If (as Hegel thought) God needs the world as the sphere of his self-development, or if (as Plato thought) he copies an independent realm of Forms, he is *pro tanto* limited. He is strictly infinite only if his essence is identical with existence, as Thomas held when he said that the most appropriate name for God is the one disclosed to Moses according to the Vulgate text of Exodus—*Qui Est* ("He Who Is"). If God is thus infinite, he must possess all properties in a mode that is free from every limitation. He must be one, simple, incorporeal, immutable, impassible, eternal, good, omniscient, and omnipotent.

UNITY. The Greek philosophers were apt to speak interchangeably of "god" and "the gods" (as may be seen, for example, from Plato's *Laws* 900–905 and the *Discourses* of Epictetus 1,3,1). But in Judaism the belief that Yahweh is the only God became an unquestioned axiom that was inherited by Christians and defended by Thomas on the grounds that if there were two gods, one would possess what the other lacked, so that neither would be absolutely perfect (*Summa Theologiae* Ia, 11, 3). Similarly, Muslims

hold as a primary article of faith that "there is no god but God." But Christians differ from Jews and Muslims in believing that the one God exists in a threefold form as Father, Son, and Holy Spirit. He is one substance (*substantia, ousia*) in three persons (*personae, hypostaseis*).

SIMPLICITY. According to Christianity and Neoplatonism, God is one also in the sense that he is absolutely simple; for the distinctions (such as those between essence and existence, substance and accidents) that make a finite being composite are inapplicable to him. Plotinus interpreted this simplicity as a bare, characterless, self-identity. But Thomas held both that God actually possesses the perfections we ascribe to him and that these coalesce in an unimaginable unity. Each of God's attributes is objectively distinct, but each expresses his whole being.

INCORPOREALITY. Those philosophers who regard the world as an aspect of God or an unfolding of his essence are obliged to think of him materially. Thus the Stoics identified him with nature's basic elements, air and fire. Similarly, Augustine learned from Manichaeism that God is a bright and very subtle substance. But the immateriality of God has constantly been taught by Platonists and Christians on the ground that matter, being a principle of limitation, is incompatible with his perfection.

IMMUTABILITY. That God's nature cannot change (for change implies imperfection) was affirmed by Plato and the Old Testament. It was reaffirmed by Christian theologians, especially Augustine.

IMPASSIBILITY. Impassibility is equivalent to immutability, if it means that God cannot suffer change from either an external or an internal cause. But it has also been taken to mean that God cannot experience pain. While there is an apparent contradiction between this last meaning and Biblical descriptions of God's love, it has been maintained by some theologians (but denied by others) that, although Christ experienced pain in his *human* nature, God cannot experience it in himself, for, being wholly perfect, he is pure Joy.

ETERNITY. In the Bible, God's eternity signifies an everlasting, endless time. In later Christian thought (through the influence of Platonism) it was understood as "timelessness." It is, in the famous definition of Boethius, *interminabilis vitae tota simul et perfecta possessio* ("eternal life possessed perfectly and simultaneously," *De Consolatione Philosophiae* V, vi). God, it is said, would not be perfect unless he possessed his whole being in a simultaneous act.

GOODNESS. The moral order has sometimes been interpreted nontheistically through such abstract ideas as *Rita* (in India), *Dao* (in China), and *Dike* (in Greece). The gods of Greco-Roman polytheism were notoriously immoral. But in Christian thought, Plato's affirmation that God is wholly good (*Republic* 379) was combined with the Hebraic vision of Yahweh's righteousness. Hence Thomas considered it to be axiomatic that "God is sheer goodness, whereas other things are credited with the sort of goodness appropriate to their natures" (*In Boethium de Hebdomadibus* 5).

OMNISCIENCE. Omniscience is entailed by infinity. But a special problem is created by the view that God now knows future *freely chosen* human acts. Those who hold this view urge, first, that since God is timeless it is, strictly speaking, incorrect to say that he "foreknows" events, and second, that even if we say this (speaking from our finite standpoint), we need not assume that a human act, because it is foreknown, is predetermined—by either God or any other factor outside the agent's will. To say that a human act can in principle be predicted is not to say that the agent has no control over it or is not really active and responsible for what he does; this, at any rate, is a view of human action widely held by philosophers at the present time. But other theists (notably James Ward and F. R. Tennant) consider it contradictory to say that a free choice can be known in any sense until it has been made. They affirm that God is ignorant of future human choices and that his ignorance is a "self-limitation" he deliberately incurred in granting man free will.

OMNIPOTENCE. Omnipotence too is entailed by infinity. It is important to note that in the Creeds, *Pantocrator* and *omnipotens* imply that God is ruler of all things, rather than that he can do anything. He cannot act against either reason or morality. But it is extremely difficult to explain the existence of evil in a world created by a God who is both infinitely powerful and infinitely good. Various explanations have been given. Thus, evil has been traced to the fall of a first man or World Soul. Again, it is said that God permits (even if he does not inflict) unmerited suffering as a means of purifying the soul for eternal life. But many theologians would endorse Friedrich Von Hügel's frank admission that no explanation is fully satisfying. It is therefore not surprising that some philosophers (notably J. S. Mill) have tried to relieve God of apparent responsibility for evil by supposing that he is finite both in knowledge and in power. (Christians believe that God displays his omnipotence by *overcoming* evil through the ministry of Christ; but an exposition of

this belief would involve a study in the doctrines of Incarnation and Atonement.)

PERSONALITY

In the preceding sections it has been assumed that God is personal. The assumption is justified by the fact that, while in the primitive stages of religion he has often been conceived subpersonally, philosophers (in the West, at any rate) have nearly always described his nature to some extent by analogy with the human self. Thus, according to Plato, Aristotle, and Spinoza God has mental properties. But two conditions must be fulfilled if God is to be *fully* personal. First, it must be possible to speak of him as loving, or caring for, humankind. Second, it must be possible to speak of him truly through images drawn from human life. The Aristotelian and Spinozistic concepts of him fail to meet the first of these conditions. While Aristotle's First Mover contemplates himself, he does not have any knowledge of the world. Therefore, like Spinoza's God, he cannot return the love that he receives.

The second condition is not universally fulfilled either. Some thinkers have attempted to mediate between philosophy and religion by suggesting that concrete images of God are inadequate attempts to grasp a Reality that is suprapersonal. Thus Hegel held that Absolute Spirit can be adequately known only by the speculative intellect. Consequently, when he speaks of the Absolute as God he means by God (as Aristotle meant) self-thinking Thought. The personal God of theism is a prerational and imperfect representation (*Vorstellung*) of the Absolute. On the ascending scale of truth, religion occupies an intermediate place between art and philosophy.

This contrast between religion and philosophy becomes even more acute when the Absolute is equated with a suprarational Unity. Here there is a striking parallel between Indian monism and the thought of F. H. Bradley. Some Hindu scriptures (notably the *Bhagavad-Gita*) describe God as a personal being, the Lord of the universe, whose "grace" (*prasada*) requires the "loving devotion" (*bhakti*) of his worshipers. The *Gita* is especially significant. Through the theophany in the eleventh chapter, it declares that Krishna (the incarnate God, and friend of Arjuna) is "more to be prized even than Brahman." But Śankara, following the nondualistic strain in the Upanishads, held that the sole reality is the impersonal Absolute (Brahman) with which the soul is numerically identical. Personal concepts of the Absolute belong to the sphere of illusion (maya). They are forms under which the One appears to untutored minds. Likewise F. H. Bradley held that since Reality is nonrelational, a per-

sonal God is "but an aspect, and that must mean but an appearance, of the Absolute" (*Appearance and Reality,* Oxford, 1930, p. 397).

Christians, however, are obliged by revelation to identify the Absolute with a God who is fully personal, both in himself and in his dealings with humankind. Such primary images as Father, King, and Friend mediate a knowledge that cannot be surpassed by abstract speculation. During this century the personal nature of religious conviction has been stressed in varying terms by such writers as William Temple, John Oman, John Baillie, Karl Barth, Emil Brunner, Martin Buber, and the existentialists (especially Kierkegaard, Bultmann, and Gabriel Marcel). Buber's distinction between an "I-Thou" and an "I-It" relationship and Kierkegaard's contrast between subjectivity and objectivity have been widely used to express the difference between a personal and an impersonal attitude to God. At the same time, many theologians are aware that an unqualified application of personal categories to God results in anthropomorphism. Divine personality wholly transcends its finite counterpart. It is unique both because of the fact that essence and existence are identical in it and because of the mystery of its triune character.

THE KNOWLEDGE OF GOD. There are three main routes to God: reason, revelation, and religious experience.

Both Plato and Aristotle claimed that reason can obtain a certain knowledge of God's existence and nature. This claim has been endorsed by many Christian theologians. Thus, St. Augustine, writing from within the Platonic tradition, affirmed that the human intellect by nature participates in eternal Truth. Furthermore, many theologians have held that God's existence can be proved. These proofs may be divided between those which take the form of a priori reasoning from God's essence and those which take the form of a posteriori reasoning from finite experience. The first type of proof is exemplified chiefly by the Ontological Argument, which was first formulated by St. Anselm and restated by René Descartes. In its Anselmic form it runs as follows: The idea of God is the idea of that than which nothing greater can be conceived; a being that exists is greater than a being that does not exist; therefore God exists. In view of the criticisms to which this proof has been subjected (especially by Thomas and Immanuel Kant), it is widely considered to be invalid by both theologians and philosophers today. The main a posteriori arguments received their classical formulation from Thomas.

He constructed five proofs based on the facts of motion, causality, contingency, relative perfection, and design. (The first, second, and third of these Five Ways are different forms of the Cosmological Argument—the argument that the world in all its aspects shows its dependence on self-existent Being.) Kant rejected *all* proofs based on the use of the "speculative reason." But he maintained that the "practical reason" is obliged to postulate both God and immortality. Since World War I, natural theology has been vigorously attacked, on the one hand by Barth and, on the other, by those philosophers who deny the possibility of metaphysics. However, many twentieth-century philosophers (chiefly Roman Catholic Thomists—but also others, such as A. E. Taylor) held that the main a posteriori proofs can be presented cogently.

Thomas affirmed that in addition to a natural knowledge of God there is a supernatural knowledge revealed by Christ and received through faith. Thus, while reason can infer that God is the Creator, it cannot discover that he is Three-in-One. John Locke reproduced this distinction in his *Essay concerning Human Understanding* (Book 4, Ch. 18). But in his *Reasonableness of Christianity* he paved the way for the deists, who held that the Gospel merely "republishes" the basic truths of natural religion and morality. The supernatural character of revelation was also denied later by those Hegelians who regarded Christ as the highest instance of the Absolute's universal presence in humanity.

Religious philosophers from Plato onward have claimed that it is possible to have a *direct* knowledge of divine reality. Among Christian thinkers, some hold that this knowledge is available (even if in a confused form) to everyone; others restrict it to the recipients of biblical revelation. Some regard it as the highest activity of ordinary mental powers; others assign it to a special faculty of the soul. Some describe it intellectually as an insight or intuition; others stress its volitional character by calling it a confrontation or encounter. Apart from these differences, it is necessary to distinguish between an experience that is mediated and one that is immediate. As many recent writers have stressed (notably, William Temple, John Oman, and H. D. Lewis), religious experience is normally mediated through secular experiences, including those which are formulated in the premises of the a posteriori proofs. Thus, we become aware of God as eternal through the contingency of finite things and as holy through the demands of the moral law. (Even the divinity of Christ is experienced, in the first place, through meditation on his human life and on the impact that it made on his disciples.) But there is also an immediate, purely spiritual

experience that is called "mystical." While Christian and non-Christian mystics often use the same terminology, the former (when they are orthodox) differ from many of the latter at two points. First, they affirm that God is transcendent as well as immanent. Second, and as a consequence, they claim, not an absorption into the Godhead, but a union of love and will in which the distinction between the Creator and the creature is permanently retained.

Bibliography
A. E. Taylor's article on theism in *Encyclopedia of Religion and Ethics,* edited by J. Hastings (New York, 1908–1926), is still authoritative. The best single book on Greek thought about God up to and including Plato remains James Adam's *The Religious Teachers of Greece* (Edinburgh: Clark, 1908). On the period from Augustine to Scotus, there are admirable accounts by F. Copleston in Vol. 2 of his *A History of Philosophy* (London: Burns, Oates & Washbourne, 1954). This book also contains an excellent bibliography. Most of the relevant passages in Thomas are assembled in the two anthologies, *Philosophical Texts* and *Theological Texts,* selected and translated by T. Gilby (Oxford: Oxford University Press, 1951 and 1955). On the modern period, there is much useful material in A. S. Pringle-Pattison's *The Idea of God* (Oxford: Oxford University Press, 1920) and in E. L. Mascall's *He Who Is* (London: Longmans, Green, 1943). The latter reexamines the essentials of theism, and contains a full bibliography. See also J. Collins's very comprehensive *God in Modern Philosophy* (Chicago: Regnery, 1959); Illtyd Trethowan's *The Basis of Belief* (London: Burns and Oates, 1960), a concise summary of recent work on natural theology; and F. Ferré's *Language, Logic and God* (London: Eyre and Spottiswoode, 1962), a full account of recent writing on religious subjects from an empiricist point of view. The classical analysis of religious experience remains Rudolf Otto, *Das Heilige* (Marburg, 1917), translated by J. W. Harvey as *The Idea of the Holy* (New York: Oxford University Press, 1925). The best modern defense of the miraculous element in Christianity is C. S. Lewis, *Miracles* (London: G. Bles, 1960). A full survey of recent writing on revelation is contained in John Baillie, *The Idea of Revelation in Recent Thought* (New York: Columbia University Press, 1956).

H. P. Owen (1967)

GOD, CONCEPTS OF [ADDENDUM]

Since H. P. Owen's entry there has been considerable work on Western theism's standard roster of divine attributes. One of the most-discussed, eternity, has its own entry. This entry notes developments on three others.

DIVINE FOREKNOWLEDGE: THE PROBLEM

Many biblical passages ascribe to God knowledge of what we will freely do in the future. But a now-standard argument (derived from Boethius) contends that no future creaturely action can be both foreknown and free. Suppose that for some act A, God believed yesterday that I do A tomorrow.

God is infallible. He cannot make a mistake. That is,

(1) Necessarily, for all P, if God believed yesterday that P, then P. So,

(2) Necessarily, if God believed yesterday that I do A tomorrow, I do A tomorrow.

(3) If God believed yesterday that I do A tomorrow and it is in my power not to do A tomorrow, then it is in my power to make it the case that yesterday God had a false belief, or it is in my power to make it false that God believed yesterday that I do A tomorrow.

(4) It is not in my power to make God have had a false belief (from 2).

(5) It is not in my power to alter the past. So,

(6) It is not in my power not to do A tomorrow. So,

(7) Tomorrow I do not do A freely.

Philosophers have revived approaches to this problem associated with the scholastic thinkers William of Ockham and Luis de Molina.

OCKHAMISM

Ockhamism rejects (4) in favor of

(4a) If it is in my power not to do A tomorrow, and God believed yesterday that I do A tomorrow, then: it is in my power to make it the case that yesterday God had a false belief; it is in my power to make it false that God believed yesterday that I do A tomorrow; or it is in my power to do something such that had I been going to do it, God would always not have believed that I would do A.

If it was the case yesterday that an infallible God had this belief, then I was going to do A. But it was also going to be the case that I have the power not to do A, even though I will not use this power. For Ockhamism, that I was going to do A determines what God believed, not vice versa: My future act constrains the past, rather than God's past belief constraining the future. Had I been going not to do A tomorrow, this would have determined what God believed, and so He would always have believed that I would not do A. Thus, since I have it in my power not to do A, it is in my power to do something such that had I been going to do it, God would always not have believed that I would do A.

But just how does what I do in the future determine what God believed? Ockhamists hold that what makes (1) true is not wholly in the past. Rather, as they see it, what makes a statement about God's past beliefs true is partly in the past and partly in the future. If (1) is true, for Ockhamism, what makes it true is partly God's mental state yesterday and partly my doing A tomorrow. One large question Ockhamism faces is how precisely to understand this. Perhaps God "sees" the future: Had I been not doing A in the future, that is what He would always have seen. Plausibly, when I see a tree, what makes this true is that I am seeing and that the tree is seen. So perhaps future events are part of what make it true that God sees the future.

But when I see a tree, this is because light reflected from the tree enters my eye—the tree sends a signal. So if God "sees" the future, future events send signals back to God in the present—there is backward causation. This is hard to defend.

MOLINISM

Molinism accepts (4a), not (4). For Molinism, God knows our future free actions by knowing "counterfactuals of freedom" (CFs), truths about what we would freely do in various circumstances, and knowing the circumstances we will be in. For Molinists, before all creation, it was true that

(8) were the snake and Eve in the garden, the snake eventually would freely tempt Eve, and

(9) were the snake to tempt Eve in the garden, she would freely fall.

God knew this. God placed Eve and the snake in the garden. As (8) was true, the snake freely tempted her. Since (9) was true, she freely fell. And so on. God decides who is created and what initial and later circumstances they face in light of His knowledge of all CFs. So God sets up the whole future, including the parts we would do freely. God knows the future by knowing the CFs and how He has set things up. But our freedom, say Molinists, is built into the CFs. Eve had it in her power not to fall. Had the CF

(10) were the snake to tempt Eve in the garden, she would not freely fall

been true instead of (9), God would have known that. And since Eve had it in her power not to fall, she had it in her power to do something such that had she been going to do it, God would always not have believed that she would fall.

One problem for Molinism concerns what makes CFs true. It cannot be God. If God determines both that (8) is true and that the snake and Eve are in the garden, God determines that the snake sins: Sin is God's fault. Furthermore, God simply determines all our actions, and so we are not free. Nor can it be our natures. Whatever our having our natures makes true is true necessarily. But CFs cannot be true necessarily. If we suppose that (8) is necessarily true, it is not so much as possible that the snake not tempt Eve, and so the snake does not do so freely—and so (8) turns out false. Nor can it be our actions. They come too late in the game. So there seems to be nothing at all in reality that can make CFs true.

Furthermore, arguably Molinism does not genuinely preserve our freedom. (8) is true from all eternity. It is also true from eternity that God has willed that Eve and the snake be in the garden. So from all eternity it is guaranteed that the snake tempts. It cannot be the case that God has willed that Eve and the snake be in the garden and that (8) is true and yet the snake does not tempt. Given conditions obtaining long before it existed, the snake cannot do otherwise: It is merely the case that it could have done otherwise (had these conditions not obtained). And there is a further worry: Even if God does not will that the snake tempt, does He not in fact initiate the snake's action, albeit indirectly? What initiates an action makes the first difference in the world that guarantees that (barring a miracle) the action is done. On the

Molinist scenario, we do not make this first difference at the moment of choice. God makes it from all eternity. If this is correct, then God removes our responsibility much as He would if He just directly caused our actions. Thus, it is not clear that Ockhamism or Molinism are successful approaches to the Boethian argument.

THE CONCEPT OF OMNIPOTENCE

The claim that God is omnipotent, that is, "all-powerful," concerns the range of God's power—how much He is able to do. At first glance, being all-powerful may seem to be having all powers. But this cannot be right. God has no body (leaving aside the Incarnation). So He cannot walk. He can take on a body. So He is able to walk, and He actually has a conditional power, the power to walk if He acquires a body. But having this conditional power does not entail being able to walk.

St. Thomas Aquinas gave a classic definition, that "God is omnipotent =df. God is able to bring about every absolutely possible state of affairs" (*Summa Theologiae* Ia 25, 3). The thought here is that God can make true any sentence stating something possible, but no sentence stating something impossible, for example, not "there is a square circle." In a sense this does not limit God's power. If a sentence describes something God can bring about, it describes something that can occur, so it states a possibility. So no sentence stating something impossible could describe something God can do. But what can seem to be a limit emerges when we add that some sentences really do state impossibilities, states of affairs God cannot bring about. One may wonder why there are any impossibilities if God is all-powerful. In response, some have wondered whether the sense that there being impossibilities limits God dissipates if we add that God's nature or activity accounts for these states of affairs being possible or impossible.

Discussions of omnipotence suggest that Aquinas's account is too sweeping—that there are some possible states of affairs God cannot bring about. These include

(a) Necessary states of affairs. Necessarily, 2 + 2 = 4. But this, some argue, has nothing to do with God. It is not something He or anyone else could bring about. Still, whatever is necessarily so is possibly so.

(b) Things God is too late to bring about, for example, that the Germans won World War II. It was possible that they do so, and it is now no contradiction to say "the Germans won the war." But it is now (some argue) impossible that anyone bring

this about. Thus, some suggest that we relativize omnipotence to what it is possible to bring about at any given time.

(c) The free actions of creatures. It is possible that I finish writing this entry. But if God makes me finish, some say my doing so is not free. So while it is possible that God makes me finish, some say it is not possible that God makes me freely finish.

(d) States of affairs that would be evil to bring about. Many think that God cannot do evil. If this is so, then if it would be evil to kill you, God cannot do this.

(e) States of affairs that entail that no one brought them about. God can make an atom appear from nowhere. But He cannot make one so appear with absolutely no cause, because if He brings it about that the atom appears, its appearing has a cause.

(f) Molinist CFs.

It is hard to make definition building in all these exceptions seem smooth and natural. But two accounts are worth noting. One could say that God is omnipotent =df. God has the greatest range of power one individual can have. This lets one place outside God's power as many of (a) to (f) as one wants. Suppose that no one can bring about at t states of affairs earlier than t. Then this is not in the range of power of any individual. So if God cannot do this, God can be too late to bring some things about and yet have the greatest range of power one individual can have. Again, it is in my power to kill you when it is evil to do so, and perhaps it is not in God's. Even so, God can still have the greatest range of power one individual can have, because His range of power is overall larger than mine.

Another definition that also allows exceptions (a) to (f) begins from the thought that omnipotence cannot ever be powerful enough to do anything: God is omnipotent =df. there is nothing such that God cannot do because of a lack of power. Anyone other than God cannot do some things because of a lack of power. I cannot run a three-minute mile because my legs are not that powerful. A turtle cannot do mathematics because its mind is not that powerful. On this last definition, the "distinctive" of God's power is that nothing like this is true of Him. God cannot walk because of a lack of a body, not because of a lack of power. There is no power to walk-without-a-body to lack. God cannot sin because of His moral perfection, not because of a lack of any power needed, for example, to tell a lie. If He cannot make the Germans win World War II, this is because it is now too

late, not because of a lack of power. And so on. One may wonder, though, whether having a set of powers with so many limits, even if not because of a lack of power, amounts to being *all*-powerful.

DIVINE SIMPLICITY

Many medieval thinkers held that God is "simple," and this thesis returned to active discussion in the 1980s. The more complicated or complex something is, the more parts it has. The simpler something is, the fewer parts it has, and something is wholly simple if it has no parts at all. The doctrine of divine simplicity (DDS) asserts that God is wholly simple. Most theists think that God is not made of matter, spread out in space, or an event, with earlier and later parts. So they think that God has no material, spatial, or temporal parts. But Aquinas, for instance, also speaks of God as not "composed" of essence, accidents, and existence (*Summa Theologiae* Ia 3, 3–6). The theist mainstream is silent on these. And well it may be, for what Aquinas presupposes here is not at all a matter of common sense.

Parts compose. Wholes are composed. Wholes can consist completely of different sorts of parts at once—our bodies consist completely of both molecules and quarks. When Aquinas speaks of things other than God as "composed" of, for example, essences and accidents, he takes it that concrete things consist completely not only of concrete parts but also of abstract ones—essences, accidents, and so on This claim stretches the sense of "part." For the part-whole relation is transitive. If a bolt is part of a wheel and the wheel is part of a car, it follows that the bolt is part of the car. The subject-attribute relation (that between things and their accidents) is not transitive. Being an attribute is an attribute of my accidents but not an attribute of mine.

If DDS is true, then while what makes it true that Brownie is a donkey is that Brownie has an essential property, donkeyhood, what makes it true that God is divine is simply God. Again, while what makes it true that Brownie is brown is that Brownie has an accidental property, brownness, what makes it true that God is just is simply God. We could put this a bit crudely by saying that given DDS, all God's properties are identical with God.

This courts two obvious objections. One is that if all God's attributes are identical with God, then they are all identical: God has just one attribute. But that does not seem true. God is wise and omnipotent. These seem to be two attributes.

Still, this is a bit quick. *Wise* and *omnipotent* are two predicates. But it is not obvious that real attributes pair 1:1 with (almost all) predicates. And even if predicates usually apply in virtue of a thing's having distinct attributes, it would take some argument to show that they can never apply in virtue of the same thing. Perhaps what made it true at one time that someone was king of England was that he rightfully wore one crown, and what made it true at one time that someone was king of Scotland was that he rightfully wore another crown. When the monarchies united, both became true in virtue of rightfully wearing a single crown.

A second obvious objection is that if God is identical with His properties, then He is a property, yet surely He is not. This objection takes it that the result of identifying God with His properties is to eliminate God. But why think that? Perhaps the identification gets rid of the properties, leaving God to make it true that He is wise, good, and so on. If an identity-statement A = B is true, then where one could have thought there to be two items, A and B, there is only one. This one has all attributes A really has and all attributes B really has, but may have only some attributes A has been thought to have and some B has been thought to have. It may even have none of either. (Here's a partial analogy: Suppose a spy is also a bigamist. He is discovered, and his wives meet. Each wife may learn that the husband's real life story includes nothing he has told her about himself. In fact, by pooling clues that previously only one had possessed, the wives may eventually learn that he is not even human, but really a robot. So the wives may well wind up learning that almost nothing either had believed about the husband was true.) Given that A = B, which of the attributes we thought A and B had this one thing has remains to be determined. If God = justice, why think that God has only attributes we thought justice had? Some might reply that the property has to be there regardless—there has to be such a thing as justice, because others than God are just. But actually one can use God in place of the property in other metaphysical contexts, though this is a story too complex to tell here.

GÖDEL, KURT
(1906–1978)

Kurt Gödel, a logician, was born in Brno, in what is now the Czech Republic, and educated at the University of Vienna, where he became privatdozent in 1933. In 1940 he joined the Institute for Advanced Study in Princeton, New Jersey, where he remained for the rest of his career. Following David Hilbert, Gödel was instrumental in establishing mathematical logic as a fundamental branch of mathematics, achieving results such as the incompleteness theorems that have had a profound impact on twentieth-century thought. In philosophy, by contrast, he represents the path not taken. Of his few writings in this area, including posthumous publications, those that focus on the more immediate ramifications of his own (and closely related) mathematical work have had the greatest impact.

GÖDEL'S INFLUENCE

A close student of the history of philosophy, Gödel follows Plato, Gottfried Wilhelm Leibniz, and Edmund Husserl as opposed to the more fashionable Aristotle, Immanual Kant, and Ludwig Wittgenstein. (On Kant, however, see Gödel 1946/9 and 1961.) Methodologically, two patterns in his thinking stand out. First, a tendency to move from the possible to the actual is reflected in his Leibnizian ontological argument for the existence of god (Gödel 1970). He relies here on the S5 modal principle,

(possibly necessarily P ⊃ necessarily P). It can also, arguably, be discerned in his mathematical Platonism—because the distinction between the possible and the actual, relevant to material being, collapses in the formal realm of mathematics (see Yourgrau 1999). Finally, in relativistic cosmology (Gödel 1949, 1946/9) he concludes from the possible existence of rotating universes, where time is merely ideal, to its ideality in the actual world.

Second, he is preoccupied with probing mathematically the limits of formal methods in representing intuitive concepts. In his first incompleteness theorem, for example, by applying an ingenious arithmetization of metamathematics to a formal system of arithmetic, Gödel was able to construct a formula expressing its own unprovability, and thus to prove (as he made explicit later) the indefinability within the system of the intuitive concept of arithmetic truth (see Feferman 1984). Along the same lines one may view his results in cosmology as demonstrating the limits of the theory of relativistic space-time in representing the intuitive concept of time, although here, interestingly, his response was to abandon the intuitive concept (see Yourgrau 1999).

From a broader perspective Gödel isolates two basic philosophical worldviews: one with a "leftward" direction, toward skepticism, materialism, and positivism, the other inclined toward "the right," toward spiritualism, idealism, and theology (or metaphysics; Gödel 1961). He puts empiricism on the left and a priorism on the right and points out that although mathematics, qua a priori science, belongs "by its nature" on the right; it too has followed the spirit of the times in moving toward the left—as witnessed by the rise of Hilbert's formalism. With Gottlob Frege, Gödel resists this trend, pointing to his incompleteness theorems as evidence that "the Hilbertian combination of materialism and aspects of classical mathematics … proves to be impossible" (1961, p. 381).

FREGE AND GÖDEL

Frege's mathematical philosophy is held together by two strands that may appear to be in tension with one another: on one side his Platonism and conceptual realism, on the other his conception of arithmetic as analytic (that is, as resting on definitions and the laws of logic) and his "context principle" (which seems to put our sentences—hence language—at the center of his philosophy). This second aspect of Frege's thought, via Bertrand Russell and Wittgenstein, helped persuade the positivists of the Vienna Circle (whose meetings Gödel attended) that mathematics is without content, a mere matter of (more or less arbitrary) linguistic conventions concern-

ing the syntax of (formal) language. This conclusion was, however, rejected by both Frege and Gödel (1944, 1951, 1953–59), Frege hoping, contra Kant, "to put an end to the widespread contempt for analytic judgments and to the legend of the sterility of pure logic" (1884, p. 24; see also 1879, p. 55). Gödel, for his part, insists that "'analytic' does not mean 'true owing to our definitions,' but rather 'true owing to the nature of the concepts occurring therein'" (1951, p. 321). (See Parsons, 1994.)

Frege and Gödel are in further agreement against the spirit of the times, that the fundamental axioms of mathematics should be not simply mutually consistent but (nonhypothetically) true. They also reject Hilbert's conception of axiom systems as "implicit definitions," with Gödel insisting that a formal axiomatic system only partially characterizes the concepts expressed therein. Indeed, his Incompleteness Theorem makes the point dramatically: "Continued appeals to mathematical intuition are necessary … for the solution of the problems of finitary number theory.… This follows from the fact that for every axiomatic system there are infinitely many undecidable propositions of this type" (1947 [1964], p. 269). And it is in human ability—if indeed humans possess it—to intuit new axioms in an open-ended way that Gödel sees a possible argument to the effect that minds are not (Turing) machines (Gödel 1951; Wang 1996).

What kind of intuitions, however, are these? Gödel does, it is true, employ a Kantian term here, but he does not mean concrete immediate individual representations, and on just this point he faults Hilbert: "What Hilbert means by '*Anschauung*' is substantially Kant's space-time intuition.… Note that it is Hilbert's insistence on *concrete* knowledge that makes finitary mathematics so surprisingly weak and excludes many things that are just as incontrovertibly evident to everybody as finitary number theory" (1958 [1972], p. 272, n. b). (See also 1947 [1964], p. 258.) Note, further, that mathematical intuition, though a form of a priori knowledge, does not ensure absolute certainty, which Gödel rejects (Wang 1996); rather, as with its humbler cousin, sense perception, it too may attain various degrees of clarity and reliability (see Gödel 1951, his remarks on Husserl in 1961, and Parsons 1995, 1995a).

THE GÖDEL PHILOSOPHY

Frege and Hilbert, then, serve as useful coordinates in mapping Gödel's philosophy, in its tendency to "the right." What if one chooses Albert Einstein as a third coordinate? Note first that "idealistic" in the title of Gödel (1949) is not a gesture toward a subjective philosophy

such as George Berkeley's. (In his final years, he became sympathetic with Husserl's later idealism, which does not exclude objectivism. See van Atten and Kennedy 2003.) Rather, Gödel is pointing to the classic Platonic distinction between appearance and reality. Though the world may appear (to the senses) as if temporal, this is in fact an illusion. Only reason—here, mathematical physics—can provide a more adequate cognition of reality (i.e., of Einstein-Minkowski space-time). Gödel makes a sharp distinction between intuitive time, which lapses, and the temporal component of space-time. By his lights, already in the special theory of relativity (STR) intuitive time has disappeared, because "the existence of an objective lapse of time means … that reality consists of an infinity of layers of 'now' which come into existence successively" (Gödel 1949, pp. 202–203), whereas the relativity of simultaneity in the STR implies that "each observer has his own set of 'nows,' and none of these various systems of layers can claim the prerogative of representing the objective lapse of time" (p. 203).

These observations, however, rely on the equivalence of all "observers" or reference frames in the STR, whereas in the general theory of relativity (GTR), of which the STR is an idealized special case, the presence of matter and the consequent curvature of space-time permit the introduction of privileged observers, in relation to which one can define a "world time" (which, one may say, objectively lapses). Gödel's discovery is that there exist models of the GTR—the rotating universes—where, provably, no such definition of a world time is possible. In particular, these worlds permit time travel, in the sense that, "for *every* possible definition of a world time one could travel into regions of the universe which are past according to that definition," and "this again shows that to assume an objective lapse of time would lose every justification in these worlds" (1949 p. 205). The idea here is clearly that if a time has "objectively lapsed," it no longer exists and so is not *there* to be revisited (in the future). Hence, by contraposition, if it can be revisited, it never did objectively lapse in the first place.

To describe the Gödel universe as static, however, as opposed to our own, would be misleading. The time traveler's rocket ship, for example, would move at a speed of at least $1/\sqrt{2}$ of the velocity of light! It would seem to observers, just as in this world, to be moving at great speed, and in general the denizens of Gödel's universe may well experience time much as we do in the actual world. Indeed, that is why Gödel moves from the mere possible existence of the Gödel universe to the ideality of time in the actual world, because "if the experience of the

lapse of time can exist without an objective lapse of time, no reason can be given why an objective lapse of time should be assumed at all" (p. 206; see Yourgrau 1999).

Here, then, is another example of the Janus-faced quality of Gödel's thinking, presaged already in his arithmetization of metamathematics—contributing mathematically to "the left" while at the same time, as he sees it, pointing to "the right."

GÖDEL'S INCOMPLETENESS THEOREMS

The axiomatic method is at the heart of mathematics. The work of mathematicians is to derive the consequences of axioms. According to Euclid, axioms are evidently true, and deduction from them is a powerful method of learning new truths. The rise of non-Euclidean geometry disrupted the carefree connection between truth and proof and led many modern thinkers to adopt the formalistic attitude that the mathematician's sole endeavor is to work out the consequences of axioms, taking no professional interest in inquiring what, if anything, the axioms are true of.

In 1931 Kurt Gödel proved a deep theorem that showed that deduction from axioms cannot be all there is to mathematical understanding. Gödel showed that, for whatever system of truths of number theory we choose to regard as axiomatic, there will be statements of basic arithmetic that we can recognize as true even though they are not consequences of the axioms. That there are truths not derivable from our axioms is hardly surprising; nobody ever promised us omniscience. What is surprising is that there are arithmetical statements *we can recognize as true* even though they are not derivable, so that no system of axioms we can write down fully captures our arithmetical understanding. Moreover this situation holds not only for systems of axioms we are capable of producing today but also for whatever systems we may devise in the future.

Gödel's true, unprovable sentence is obtained by using strings of numbers to encode strings of symbols, thereby reducing statements about language to statements about numbers. Under such a coding Gödel's sentence says that the system of axioms is consistent. Of course if we accept the axioms, we regard the axioms as true, so we certainly regard them as consistent. But even though adopting the axioms means accepting their consistency, the statement that the axioms are consistent cannot be proved from the axioms. We could adopt the thesis that the axioms are consistent as a new axiom. This would give us a new, larger system of axioms that can prove the consistency of the old system but not the consistency of the new system. We can continue the process of adding consistency statements repeatedly, but however far we go we shall never catch up with Gödel. No consistent system that includes basic arithmetic can prove its own consistency.

Gödel's result has important corollaries, notably, Church's theorem (1936) that there is no algorithm for testing whether a sentence is logically valid and Tarski's theorem (1935) that the set of true sentences of a language cannot be defined within the language itself.

THE LANGUAGE OF ARITHMETIC

Gödel's results apply to the language of arithmetic, which is an artificial language for formalizing reasoning about the natural numbers, and to other languages into which the language of arithmetic can be translated. To state his results we need to specify the language exactly. As numerals, the language uses "0" and expressions obtained from "0" by repeatedly prefixing "S," which stands for the successor function. The numeral for 3 is "$SSS0$," which we abbreviate "$\underline{3}$." The language also contains function signs "+" "$\times$" and "E," for addition, multiplication, and exponentiation, so that the *terms* of the language make up the smallest class that contains the numeral "0" and the variables $v_0, v_1, v_2, v_3, \ldots$, and that contains $S\tau$, $(\tau{+}\rho)$, $(\tau{\times}\rho)$, and $(\tau E\rho)$ whenever it contains τ and ρ. In the exposition here we shall sometimes use other letters as variables in place of the official v_is, so as to reduce the proliferation of subscripts. Including "E" as a primitive operation is not strictly necessary, as we shall see below, but it enables us to get off to a fast start.

A term without variables is *closed*. Rules that we learned in elementary school enable us to calculate the numerical value of each closed term. A term with n variables represents an n-ary function, calculable by a grade-school algorithm.

The *atomic formulas* take the form $\tau = \rho$ or $\tau \leq \rho$, where τ and ρ are terms, and the *formulas* constitute the smallest class containing the atomic formulas and containing $\sim \phi$, $(\phi \vee \psi)$, and $(\exists v_i)\phi$, whenever it contains ϕ and ψ. An occurrence within a formula of the variable v_i is *bound* if it occurs within some subformula that begins with $(\exists v_i)$, and it is *free* otherwise. A formula without free variables is a *sentence*; it is sentences that are either true or false. The symbols for conjunction ("$\wedge$"), the conditional ("$\rightarrow$"), the biconditional ("$\leftrightarrow$"), universal quantification ("$(\forall v_i)$"), and the less-than relation ("$<$") are treated as defined.

Where v_i does not occur within the term τ, we use $(\exists v_i \leq \tau)\phi$ and $(\forall v_i \leq \tau)\phi$ to abbreviate $(\exists v_i)(v_i \leq \tau \wedge \phi)$ and $(\forall v_i)(v_i \leq \tau \rightarrow \phi)$. These are *bounded quantifiers*, and a formula with no quantifiers that are not bounded is a *bounded formula*. For example 'v_0 is prime' is formalized by the bounded formula '$(SS0 \leq v_0 \wedge (\forall v_1 \leq v_0)(\forall v_2 \leq v_0)(v_0 = (v_1 \times v_2) \rightarrow (v_1 = S0 \vee v_2 = S0)))$'. A set or relation is said to be *bounded* if it is the extension of a bounded formula.

We can test whether an atomic sentence is true by grade-school algorithms; "true," that is, in the standard model consisting of the natural numbers 0,1,2,3, … Any bounded sentence is demonstrably equivalent to a truth-functional combination of atomic sentences, since bounded quantifiers can be cashed out as long but finite disjunctions and conjunctions. Thus we have an algorithm for determining the truth value of a bounded sentence. It follows that every bounded set or relation is decidable; that is, there is an algorithm for testing membership in the set or relation. If S is the extension of the bounded formula $\sigma(x_0)$, we can test whether $n \in S$ by asking whether $\sigma(\underline{n})$ is true.

The Σ *formulas* are obtained by prefixing a block of existential quantifiers to a bounded formula, and their extensions are *recursively enumerable* sets and relations. Any recursively enumerable set is the extension of a formula obtained by prefixing a single existential quantifier to a bounded formula, since $(\exists x_1)(\exists x_2) \ldots (\exists x_n)\phi$ is equivalent to $(\exists x_0)(\exists x_1 \leq x_0)(\exists x_1 \leq x_0) \ldots (\exists x_n \leq x_0)\phi$. (The same goes for recursively enumerable relations; in the future we shall let this go without comment.) The union and intersection of recursively enumerable sets are recursively enumerable, since $((\exists y)\phi(x,y) \vee (\exists z)\psi(x,z))$ and $((\exists y)\phi(x,y) \wedge (\exists z)\psi(x,z))$ are, respectively, logically equivalent to $(\exists y)(\exists z)(\phi(x,y) \vee (\psi(x,z))$ and $(\exists y)(\exists z)(\phi(x,y) \wedge (\psi(x,z))$ (assuming bound variables have been chosen so as to avoid conflicts). If $\chi(x,y,z)$ is bounded and τ is a term, $\{x:(\exists y \leq \tau)(\exists z)\chi(x,y,z)\}$ and $\{x:(\forall y \leq \tau)(\exists z)\chi(x,y,z)\}$ are both recursively enumerable since they are the extensions of $(\exists z)(\exists y \leq \tau)\chi(x,y,z)$ and $(\exists w)(\forall y \leq \tau)(\exists z \leq w)\chi(x,y,z)$, re-

spectively. If a Σ sentence is true, we can show it is true by providing an appropriate witness.

Σ FORMULAS AND DECIDABILITY

A set of numbers is *effectively enumerable* if there is a mechanical procedure for listing the set, so that every member of the set turns up on the list eventually and nothing appears on the list that is not in the set. Every recursively enumerable set is effectively enumerable. To see this, we introduce the pairing function. $Pair(x,y) = \frac{1}{2}(x^2 + 2xy + y^2 + 3x + y)$ is a one-one correspondence between $\mathbb{N} \times \mathbb{N}$ and $\mathbb{N}$ (where $\mathbb{N}$ is the set of natural numbers). Define the functions 1st and 2nd so that $Pair(1st(z), 2nd(z)) = z$. Given a recursively enumerable function $S = \{x_0: (\exists x_1)\sigma(x_0,x_1)\}$, with σ bounded, we can list S by the following algorithm: At stage n, test whether the sentence $\sigma(\underline{1st(n)}, \underline{2nd(n)})$ is true; if it is, add $1st(n)$ to the list.

Every set that is known to be effectively enumerable is recursively enumerable. This striking fact, together with a large body of evidence obtained by examining idealized models of computation and examining structural properties of effectively enumerable and recursively enumerable sets, has led to the general acceptance of the *Church-Turing thesis*: A set of natural numbers is effectively enumerable if and only if it is recursively enumerable.

A set of natural numbers is *decidable* if and only if there is an algorithm for testing membership in the set. A set can be effectively enumerable without being decidable, since, if we have a procedure for listing an infinite set, there will be no stage at which, from the fact that a given number has not yet turned up on the list, we can conclude that the number will never appear on the list. On the other hand if a set and its complement are both effectively enumerable then the set is decidable, and conversely. Defining a set to be *recursive* if it and its complement are both recursively enumerable, the Church-Turing thesis tells us that a set is decidable if and only if it is recursive.

An *unary partial function* is a set of ordered pairs f with the property that, whenever $<i,j>$ and $<i,k>$ are both in f, we have $j = k$. If $<i,j> \in f$, for some j, we say that i is in the *domain* of f, and we write $f(i) = j$. (Partial functions of more than one variable are defined similarly.) f is said to be *calculable* if there is an algorithm that, for given input i, gives the output $f(i)$ if i is in the domain of f, and yields no output at all if i is outside the domain of f. A unary partial function is calculable if and only if, *qua* binary relation, it is effectively enumerable. It follows according to the Church-Turing thesis that f is calculable

if and only if it is recursively enumerable. If so, f is said to be a *partial recursive function*. (The notation is confusing—a collection of ordered pairs can be a partial recursive function without being a recursive relation—but entrenched.) A *total recursive function*—a partial recursive function whose domain is all of $\mathbb{N}$—will be a recursive relation, since if f is $\{<i,j>: (\exists x)\theta(i,j,x)\}$, with θ bounded, the complement of f is $\{<i,j>:(\exists x)(\exists y)(\sim y = j \wedge \theta(i,y,x))\}$.

ARITHMETIZATION OF METAMATHEMATICS

The set-theoretic paradoxes, particularly Russell's paradox, had on David Hilbert much the same effect that Zeno's paradoxes had on Aristotle. Both thinkers came to realize that the idea of the infinite held great intellectual peril with the risk of contradiction at every turn. Unlike Aristotle, however, Hilbert was unwilling to banish the actual infinite from mathematical reasoning. Instead he proposed to develop the theory of infinite sets in such a way that we could be assured that no contradiction would ensue, by treating mathematical proofs as the objects of mathematical study, in the same way that earlier mathematicians had treated curves, planes, and numbers as objects of mathematical study. A mathematical proof is, after all, a finite object, even if the sentences that appear in the proof talk about infinite objects, and Hilbert proposed that a new science of *metamathematics* could show by finite means that set theory was free of contradiction, by showing that there is no finite path that leads from the axioms to "$\sim 0=0$."

The great breakthrough in metamathematics was Gödel's proof, which showed that it was not necessary to go outside set theory or even outside arithmetic to carry out metamathematical investigations. By assigning numerical codes to formulas and finite strings of formulas, and by reducing properties of proofs to properties of their code numbers, it was possible to develop proof theory as a branch of number theory. This technique led to a great flowering of metamathematics even though as we shall see, it derailed Hilbert's plan.

The arithmetization of metamathematics proceeded in two stages. In the first stage numerical codes are assigned to simple symbols more-or-less arbitrarily, so that a formula, which is a string of simple symbols, can be coded as a sequence of numbers. Second we devise a method for encoding a finite sequence of numbers as a single number. This enables us to encode a formula as a single number. In this way a proof, which is a sequence of formulas, is encoded as a sequence of numbers, which is, in turn, coded as a single number.

We attack the second stage first. We already know how to use the function *Pair* to code a pair of natural numbers by a single number. We can encode a finite set of natural numbers by a single number by setting the code number of the finite set F, *Code*(F), equal to $\sum_{i \in F} (2Ei)$ *Code* provides a one-one correspondence between the set of finite sets of natural numbers and $\mathbb{N}$. The number n is the image under *Code* of the set of places in the binary decimal expansion of n in which "1"s appear. Finally, we encode the finite sequence $<k_0, k_1, \ldots, k_m>$ as the number *Code*($\{Pair(0,k_0), Pair(1,k_1), \ldots, Pair(m,k_m)\}$). Here we shall use an expression like "$<3,2,1>$" ambiguously to denote a sequence of length three and to denote the code number for that sequence, which is 448.

The relation that holds between k and n if k is an element of the set coded by n is defined by a bounded formula; abusing notation, we write "$\underline{k} \in \underline{n}$" to represent the statement that $(\exists i < (\underline{2E\underline{k}}))(\exists j < \underline{n})\underline{n} = (i + ((\underline{2} \text{ E } \underline{k}) + (j \times (\underline{2}E(S\underline{k})))))$. The set of all code numbers of finite sequences is the extension of a bounded formula, as are the concatenation operation and the partial function that takes i and n to the ith member of the sequence coded by n (provided n codes a sequence of i or more elements). The simplicity of this technique for encoding a finite sequence of numbers by a single number is the motive for including exponentiation as a primitive operation.

The details of the assignment of numerical codes to terms and formulas are highly arbitrary. A motive for the particular choices here is to avoid fretting over parentheses. With each term τ, we associate a number $\ulcorner\tau\urcorner$, as follows: The numeral "0" is assigned $<0,0>$, and the variable x_i is assigned $<1,i>$. $\ulcorner S\tau\urcorner$ is $<2,\ulcorner\tau\urcorner>$, and $\ulcorner(\tau+\rho)\urcorner$, $\ulcorner(\tau\times\rho)\urcorner$, and $\ulcorner(\tau E\rho z)\urcorner$ are $<3,\ulcorner\tau\urcorner,\ulcorner\rho\urcorner>$, $<4,\ulcorner\tau\urcorner,\ulcorner\rho\urcorner>$, and $<5,\ulcorner\tau\urcorner,\ulcorner\rho\urcorner>$, respectively.

A number x is a the code of a term just in case it is an element of a finite set s with the following property: For any element y of s, either $y = <0,0>$; or $y = <1,i>$, for some $i \leq y$; or $y = <2,z>$, for some z in s; or y is equal to one of $<3,z,w>$, $<4,z,w>$, and $<5,z,w>$, for some z and w in s. s represents a finite tree, with each node labeled by the code of a term, so that when a node is labeled by a complex term, nodes beneath it are labeled by the term's constituents and so that each leaf of the tree is labeled either by the code of "0" or by the code for a variable. This characterization is naturally written out as a Σ formula, showing that the set of (code numbers of) terms is recursively enumerable.

The set of terms is, in fact, recursive. To see this, we note that, if x is not a term, then the attempt to construct a labeled tree with x at its trunk winds up with at least one branch that does not terminate in either $\ulcorner0\urcorner$ or a variable. More precisely, x does not encode a term if and only if there is a sequence $<x_0, x_1, \ldots, x_n>$ of numbers $\leq x$ with the following properties:

$x_0 = x$.

If x_i has the form $<2,y>$, then $i < n$ and $x_{i+1} = y$.

If x_i has one of the forms $<3,y,z>$, $<4,y,z>$, or $<5,y,z>$, then $i < n$ and either $x_{i+1} = y$ or $x_{i+1} = z$.

If $i < n$, x_i has one of the forms $<2,y>$, $<3,y,z>$, $<4,y,z>$, or $<5,y,z>$.

x_n does not have either of the forms $<0,0>$ or $<1,k>$.

This can readily be written out as a Σ formula, showing that the complement of the set of terms is recursively enumerable.

The function Z that takes a number n to the code number for the numeral $\underline{n}$ can be described by a recursive definition:

$$Z(0) = <0,0> = 5.$$
$$Z(m+1) = <2,Z(m)> = 8 + (2E(Pair(1,Z(m)))).$$

We can convert this recursive definition into an explicit definition, using a quite general technique that Gödel obtained by refining an idea from Gottlob Frege's *Begriffsschrift*. $Z(n) = k$ if and only if there is a sequence $<x_0, x_1, \ldots, x_n>$ with the following features:

$x_0 = <0,0>$.

For $m < n$, $x_{m+1} = <2,x_m>$.

$x_n = k$.

This characterization shows that Z is a total recursive function.

The function that associates a code $\ulcorner\phi\urcorner$ with each formula ϕ is again highly arbitrary. For τ and ρ terms, we let $<6,\ulcorner\tau\urcorner,\ulcorner\rho\urcorner>$ and $<7,\ulcorner\tau\urcorner,\ulcorner\rho\urcorner>$ be the codes of $\tau = \rho$ and $\tau \leq \rho$. For ϕ and ψ formulas, we let $<8,\ulcorner\phi\urcorner>$ be $\ulcorner\sim\phi\urcorner$, $<9,\ulcorner\phi\urcorner,\ulcorner\psi\urcorner>$ be $\ulcorner(\phi \vee \psi)\urcorner$, and $<10,i,\ulcorner\phi\urcorner>$ be $\ulcorner(\exists v_i)\psi\urcorner$. The proof that the set of codes of formulas is recursive is just like the corresponding argument for terms.

It is straightforward if somewhat laborious to verify, just by writing down an appropriate formula, that, for example, the arithmetical operations corresponding to forming the disjunction and the conjunction of two formulas, to prefixing a quantifier to a formula, and to substituting a given term for free occurrences of a variable in a formula are partial recursive functions. Also, for example, that the set of terms in which the variable v_{17} appears

and the set of formulas in which v_{123} appears free are recursive sets.

PROOFS AND COMPUTATIONS

Euclid's *Elements* deduces highly sophisticated geometric theorems as consequences of simple, intuitively obvious axioms. Aristotle, the father of logic, investigated the methods by which consequences are derived from axioms, identifying simple patterns of valid reasoning like the following so-called *syllogism*: "All men are animals. No stone is an animal. Therefore, no stone is a man." The methods of reasoning Euclid actually employed were far more sophisticated than the mere production of chains of syllogisms, however, and the ancients were generally content to take it as obvious that Euclid's deductions were legitimate, without demanding a detailed survey of deductive methods.

Meticulous nineteenth-century investigations revealed the surprising fact that, despite having been accepted by generations of scholars as the exemplar of deductive rigor, Euclid's proofs were often invalid. In proving a theorem he sometimes imported information from the accompanying diagram that was not justified by either the hypotheses of the theorem or the axioms. These investigations led to a search for fully precise methods of deduction in which one could have complete confidence. This search culminated in the widespread acceptance of a system of precise rules for the first-order predicate calculus—the logic governing the operators "∨," "~," (∃v_i), and "="—within which the deductions of classical mathematics can be formalized with scrupulous rigor.

With these rules in hand, we can capture the notion of logical consequence precisely, by pressing it from below and from above. It is clear that, if a sentence ϕ is a logical consequence of a theory (set of sentences) Γ, then it cannot be possible to choose a domain of discourse and semantic values for the nonlogical terms so as to make the members of Γ all true and ϕ false. Thus a necessary condition for a ϕ to be a logical consequence of Γ is that ϕ be true in every model of Γ. It is also clear, from examining the rules (for whichever of the standard textbook systems is convenient), that if ϕ derivable from Γ, ϕ is a logical consequence of Γ; this gives us a sufficient condition for logical consequence. Gödel's 1930 *Completeness Theorem* shows that these two conditions meet, so that if ϕ is true in every model of Γ then ϕ is derivable from Γ.

The Completeness Theorem applies equally well to any of many different logical calculi for first-order predicate logic. W.V. Quine developed a particularly convenient system with the following two properties: The (codes of the) axioms of logic form a recursive set; and each logical consequence of a theory Γ can be found at the end of a sequence of sentences, each member of which is either an axiom of logic, an element of Γ, or obtained from earlier members of the sequence by *modus ponens*, the rule that permits the deduction of ψ from ϕ and ($\phi \rightarrow \psi$). (Such a sequence is a *proof* of the sentence from Γ.) Quine's axioms will not be written out here.

If Γ is recursive, the set of pairs $<s, \ulcorner\phi\urcorner>$ such that s is a proof of ϕ from Γ is a recursive relation, represented by a Σ formula we shall abbreviate "$s\, B_\Gamma \ulcorner\phi\urcorner$." (In terminology introduced below, "B_Γ" "binumerates" the relation.) We write "$Bew_\Gamma(\ulcorner\phi\urcorner)$" to abbreviate "$(\exists s)s\, B_\Gamma\ulcorner\phi\urcorner$." Since "$Bew_\Gamma$," is Σ, the set of logical consequences of Γ is recursively enumerable.

William Craig noted a converse result: If the set of consequences of the theory Γ is recursively enumerable then Γ has the same consequences as some recursive set to axioms; Γ is, as they say, *recursively axiomatizable*. To see this, note that there is a bounded formula $\psi(x,y)$ such that the consequences of Γ constitute the set of sentences whose code numbers satisfy $(\exists y)\psi(x,y)$. Let Γ_{Craig} be the set of all sentences of the form ($\underline{m} = \underline{m} \wedge \theta$), for which the pair $<\ulcorner\theta\urcorner,m>$ satisfies $\psi(x,y)$. Then Γ_{Craig} is recursive (bounded, in fact), and Γ_{Craig} and Γ are logically equivalent.

We would now like to see how any numerical computation by algorithm can be simulated by a logical deduction from basic arithmetical axioms. Q_E, a variant of *Robinson's arithmetic*, is the conjunction of the following nine statements:

$$(\forall x)(x = 0 \leftrightarrow \sim (\exists y)x = Sy).$$

$$(\forall x)(\forall y)(Sx = Sy \rightarrow x = y)$$

$$(\forall x)(x + 0) = x.$$

$$(\forall x)(\forall y)(x + Sy) = S(x + y).$$

$$(\forall x)(x \times 0) = 0.$$

$$(\forall x)(\forall y)(x \times Sy) = ((x \times y) + x)$$

$$(\forall x)(x \, E \, 0) = S0.$$

$$(\forall x)(\forall y)(x \, E \, Sy) = ((x \, E \, y) \times x)$$

$$(\forall x)(\forall y)(x \leq y \leftrightarrow (\exists z)(x + z) = y).$$

Q, which we shall talk about later on, is obtained from Q_E by deleting the two clauses involving exponentiation.

A straightforward induction on the complexity of terms shows that, for every closed term τ, there is a number m such that the sentence $\tau = \underline{m}$ is a theorem of Q_E.

Another induction shows that every bounded sentence is decidable (either provable or refutable) in Q_E. Since every true bounded sentence is provable in Q_E, it follows that every true Σ sentence is provable in Q_E, since we can prove an existential sentence by providing a witness. If S is a recursively enumerable set, it is the extension of some Σ formula σ. Because every true Σ sentence is provable in Q_E and (because Q_E is true) no false Σ sentence is provable, we have (where "⊢" is provability):

For any n, $n \in S$ if and only if $Q_E \vdash \sigma(\underline{n})$.

We shall say that σ *enumerates* S in Q_E. (The same observation holds for recursively enumerable relations.)

We shall say a formula ϕ *binumerates* a set S in Q_E if and only if, for each n, we have:

$n \in S$ if and only if $Q_E \vdash \phi(\underline{n})$.

$n \notin S$ if and only if $Q_E \vdash \sim \phi(\underline{n})$.

If S is recursive then there is a bounded formula $\chi(x,y)$ such that $(\exists y)\chi(x,y)$ enumerates S in Q_E, and there is a bounded formula $\theta(x,y)$ such that $(\exists y)\theta(x,y)$ enumerates the complement of S in Q_E. To show that S is binumerable in Q_E, we need to show that S is enumerable by a formula whose negation enumerates the complement of S. Developing an idea of J. Barclay Rosser, Tarski, Mostowski, and Robinson showed that the following Σ formula does the job:

$$(\exists y)(\chi(x,y) \wedge \sim (\exists z < y)\theta(x,z)).$$

Clearly if ϕ binumerates S in Q_E, it binumerates S in any consistent theory that entails Q_E.

A formula $\psi(x,y)$ *functionally represents* a total function f in a theory if and only if, for each k, the following sentence is a consequence of the theory:

$$(\forall y)(\psi(\underline{k},y) \leftrightarrow y = f(\underline{k})).$$

If f is a total recursive function, we know that there is a formula $\phi(x,y)$ that binumerates f in Q_E. Tarski, Mostowski, and Robinson showed that the following formula functionally represents f in Q_E (and hence in any theory that entails Q_E):

$$(\phi(x,y) \wedge (\forall z < y)\sim \phi(x,z)).$$

THE FIRST INCOMPLETENESS THEOREM

We are now ready to see how to construct, for any recursively axiomatizable, true theory that includes Q_E, a true sentence that is not a consequence of the theory. The key to the construction is to see how to produce sentences that can talk about themselves so that we can construct a

sentence that asserts its own unprovability. Such a sentence cannot be provable since if it were provable it would be a false consequence of the axioms. So the sentence must be true. To carry out this plan we use the following result, one of the masterpieces of modern mathematics:

GÖDEL'S SELF-REFERENCE LEMMA. For any formula $\psi(y)$, one can construct a sentence ϕ such that $Q_E \vdash (\phi \leftrightarrow \psi(\ulcorner \phi \urcorner))$.

The hard part, the part that requires true genius, is to figure out what sentence to write down. The easy part is to verify that the sentence works. Here we shall only attempt the easy part.

Define a function f as follows: If m is the code of a formula $\chi(x,y)$ with only "x" and "y" free, let $f(m)$ be the code of the formula

$$(\exists x)(\exists y)((x = \underline{m} \wedge \chi(x,y)) \wedge \psi(y)).$$

Otherwise, $f(m) = 0$.

This definition can easily be written as a Σ formula, showing that f is a total recursive function. Consequently, there is a formula $\theta(x,y)$ that functionally represents f in Q_E. Let m be $\ulcorner(\theta(x,y)\urcorner$, and ϕ be the following sentence:

$$(\exists x)(\exists y)((x = \underline{m} \wedge \theta(x,y)) \wedge \psi(y)).$$

Then $\ulcorner \phi \urcorner = f(m)$, and so the following sentences are consequences of Q_E:

$(\forall y)(\theta(\underline{m},y) \leftrightarrow y = \ulcorner \phi \urcorner)$.

$((\exists x)(\exists y)((x = \underline{m} \wedge \theta(x,y)) \wedge \psi(y)) \leftrightarrow \psi(\ulcorner \phi \urcorner))$.

$(\phi \leftrightarrow \psi(\ulcorner \phi \urcorner))$.

Let Γ be a consistent, recursive set of sentences that entails Q_E. Using the Self-reference Lemma, we can find a sentence γ so that $(\gamma \leftrightarrow \sim Bew_\Gamma \ulcorner \gamma \urcorner)$ is a consequence of Q_E; γ is called the *Gödel sentence* for Γ. If γ were a consequence of Γ, $\sim Bew_\Gamma(\ulcorner \gamma \urcorner)$ would be a consequence of Γ, and also $Bew_\Gamma(\ulcorner \gamma \urcorner)$ would be a true Σ sentence, hence a consequence of Q_E, hence a consequence of Γ. This contradicts the consistency of Γ. So γ is unprovable, so that $Bew_\Gamma(\ulcorner \gamma \urcorner)$ is false, and γ is true. Thus γ is our example of a true, unprovable sentences.

If Γ is true then Γ does not prove $\sim\gamma$ because $\sim\gamma$ is false, so that γ is undecidable in Γ. Let us say that a theory Δ is *ω-inconsistent* if there is a formula $\chi(x)$ such that $(\exists x)\chi(x)$ is a consequence of Δ, and yet, for each n, $\sim \chi(\underline{n})$ is a consequence of Δ. Every ω-consistent theory is consistent, so if Δ is a recursive, ω-consistent theory that entails Q_E, the Gödel sentence γ for Δ is a true sentence not provable in Δ. Hence, for each m, the sentence

~ $\underline{m}$ B_Δ $\ulcorner\gamma\urcorner$ is true, hence provable in Q_E, hence provable in Δ. It follows by ω-consistency that Bew_Δ $\ulcorner\underline{\gamma}\urcorner$ is not a consequence of Δ, and so ~γ is not a consequence of Δ. Thus the assumption of ω-consistency, rather than truth, is enough to ensure that γ is undecidable in Δ. Because γ is unprovable in Δ, $\Delta \cup \{\sim\gamma\}$ is consistent, although ω-inconsistent. So consistency does not imply ω-consistency.

Gödel used γ to show that every ω-consistent, recursively axiomatizable theory that entails Q_E is incomplete, that is, that there are sentences that the theory cannot decide; this is the *First Incompleteness Theorem*. Rosser went a step farther, showing that the assumption of ω-consistency can be weakened to consistency. Rather than examine Rosser's proof, we shall derive his conclusion from a stronger result, one due, in essentials, to Tarski, Mostowski, and Robinson:

RECURSIVE INSEPARABILITY THEOREM. There is no recursive set that includes the consequences of Q_E and excludes all the sentences refutable in Q_E.

Suppose C were such a recursive set, and take a formula $\mu(x)$ that binumerates C in Q_E. The Self-reference Lemma gives a sentence ν such that $(\nu \leftrightarrow \sim \mu(\ulcorner\underline{\nu}\urcorner))$ is a consequence of Q_E. We derive a contradiction by examining two cases:

Case 1. $\nu \in C$. Then $Q_E \vdash \mu(\ulcorner\underline{\nu}\urcorner)$, and so $Q_E \vdash \sim \nu$. Thus υ is a sentence refutable in Q_E, and so it is excluded from C. Contradiction.

Case 2. $\upsilon \notin C$. Then $Q_E \vdash \sim \mu(\ulcorner\underline{\nu}\urcorner)$, and so $Q_E \vdash \nu$. Thus υ is a consequence of Q_E, and so an element of C. Contradiction.

Corollary. No consistent theory that entails Q_E has a recursive set of consequences.

This follows from the fact that, if a consistent theory entails Q_E, it excludes the sentences refutable in Q_E.

Corollary (*Rosser's Theorem*). No consistent, recursively axiomatized theory that entails Q_E is complete.

If Γ is consistent, recursively axiomatized, and complete, then the complement of Γ is recursively enumerable, since it is the union of the set of non-sentences with the set of sentences whose negations are provable in Γ.

Corollary. No theory consistent with Q_E has a recursive set of consequences.

If Δ were such a theory then the set of sentences ψ such that $(Q_E \rightarrow \psi)$ is a consequence of Δ would be a consistent,

recursive set of sentences, closed under consequence, that included Q_E.

Corollary (*Church's Theorem*). The set of logically valid sentences in not recursive.

The valid sentences are the consequences of the empty theory, which is consistent with Q_E.

MATHEMATICAL INDUCTION

Q_E is a weak axiom system. It cannot prove the associative law of addition or multiplication, nor can it prove the commutative law of addition or multiplication. The system is weak because it leaves out the essential feature of the natural number system, the principle of mathematical induction, according to which any collection of natural numbers that includes 0 and is closed under the successor operation has to include all the natural numbers. *Modulo* Q_E, the principle is equivalent to the thesis that the natural numbers are well-founded, that is, that any nonempty collection of natural numbers has a least element.

Richard Dedekind showed that the system one gets from Q_E by adding the principle of mathematical induction completely characterizes the natural numbers. The system is *categorical*, that is, there is an isomorphism—a one-one correspondence that preserves mathematical structure—between any two models of the system. Thus if $\mathfrak{A}$ and $\mathfrak{B}$ are models of Q_E plus the principle of induction, let f be the smallest class that includes the pair $<0^{\mathfrak{A}}$, $0^{\mathfrak{B}}>$ and includes $<S^{\mathfrak{A}}(x), S^{\mathfrak{B}}(y)>$ whenever it contains $<x,y>$. It is easy to verify, using induction several times, that f is an isomorphism. It follows that the system is complete, since if it left ϕ undecided, it would have a model $\mathfrak{A}$ in which ϕ is true and a model $\mathfrak{B}$ in which ϕ is false; but then $\mathfrak{A}$ and $\mathfrak{B}$ could not be isomorphic.

Peano Arithmetic (PA), is the system used to formalize the principle of induction into a precise system of axioms. Its axioms are Q_E together with all instances of the *induction axiom schema*:

$$((R(0) \land (\forall x)(R(x) \rightarrow R(Sx))) \rightarrow (\forall x)R(x)).$$

An *induction axiom* is a sentence of the language of arithmetic obtained from the schema by substituting a formula of the language of arithmetic for "R," then prefixing universal quantifiers to bind all the variables other than "x" that appear free in the substituted formula.

In view of Dedekind's categoricity theorem, it is surprising to realize that PA is incomplete. But incomplete it must be, since it is a true, recursively axiomatized theory that entails Q_E. The explanation is that the induction axiom schema does not fully capture the principle of

mathematical induction. It tries to assure us that every nonempty collection has a least element, but only succeeds in telling us that every nonempty collection that is the extension of a predicate (with parameters) of the language of arithmetic has a least element.

Let γ be the Gödel sentence for PA. We know that γ isn't a consequence of PA, so that, by the Completeness Theorem, there is a model $\mathfrak{A}$ in which all the axioms of PA $+ \sim \gamma$ are true. In $\mathfrak{A}$ there is an element g that satisfies "$x\mathrm{B}_{\mathrm{PA}}$ $\ulcorner\gamma\urcorner$." For each n, "$\sim \underline{n}\mathrm{B}_{\mathrm{PA}}$ $\ulcorner\gamma\urcorner$." is a theorem of PA, so g must be different from the referents of all the numerals $\underline{0}, \underline{1}, \underline{2}, ...$ Instead, g is one of the *nonstandard numbers* that lie above all the standard numbers in the relation $\mathfrak{A}$ assigns to "$\leq$."

It is worth emphasizing because there has been some confusion on this score that the existence of nonstandard models of PA does not depend on the First Incompleteness Theorem. Their existence follows from the Compactness Theorem, according to which an infinite set of sentences has a model if every finite subset does, which Gödel derived from the Completeness Theorem. Let Γ be a consistent theory that entails Q_E. Add a new constant "c" to the language, and let Γ^c be the union of Γ with the set of sentences "$\sim c = \underline{n}$," for n natural number. Any finite subset of Γ^c has a model, obtained by taking a model of Γ and letting "c" denote a sufficiently large standard number. The Compactness Theorem gives us a model of Γ^c, which means we have a nonstandard model of Γ. This construction works even if we take Γ to be *true arithmetic*, the set of sentences true in the standard model, even though true arithmetic is complete. Because it is complete, the First Incompleteness Theorem tells us that true arithmetic is not recursively axiomatizable.

THE SECOND INCOMPLETENESS THEOREM

The proof of the First Incompleteness Theorem showed that, if Γ, a recursively axiomatized theory that entails Q_E, is consistent, then the Gödel sentence γ for Γ is unprovable in Γ. Using "$Con(\Gamma)$" as an abbreviation for

$$\text{"} \sim Bew_\Gamma(\ulcorner\underline{\sim \underline{0}=\underline{0}}\urcorner),\text{"}$$

we can formalize this result in a sentence of the language of arithmetic:

$$(Con(\Gamma) \rightarrow \sim Bew_\Gamma(\ulcorner\gamma\urcorner)).$$

If we were able to prove this conditional in Γ, we could conclude that, if $Con(\Gamma)$ were provable in Γ, $\sim Bew_\Gamma(\ulcorner\gamma\urcorner)$ would be provable in Γ. Since we already know that $\sim Bew_\Gamma(\ulcorner\gamma\urcorner)$ is only provable in Γ if Γ is inconsistent, we

could conclude that $Con(\Gamma)$ is only provable in Γ if Γ is inconsistent.

Can we prove the conditional in Γ? We certainly cannot do so if we take Γ to be Q_E, for we can scarcely prove any significant generalizations in Q_E. We can, however, prove the conditional if we take Γ to be PA. This is hardly surprising, since nearly all our reasoning about natural numbers can be formalized in PA. The details are, nonetheless, burdensome; so we only present a faint sketch here.

Let Γ be a recursively axiomatized theory that entails PA. M. H. Löb singled out the following three principles as central to Gödel's proof that, if Γ is consistent, it does not prove $Con(\Gamma)$:

(L1) If $\Gamma \vdash \phi$, then $\Gamma \vdash Bew_\Gamma(\ulcorner\phi\urcorner)$.

(L2) $\Gamma \vdash (Bew_\Gamma(\ulcorner\phi\urcorner) \rightarrow Bew_\Gamma(\ulcorner\underline{Bew_\Gamma(\ulcorner\phi\urcorner)}\urcorner))$.

(L3) $\Gamma \vdash (Bew_\Gamma(\ulcorner(\phi \rightarrow \Psi)\urcorner) \rightarrow (Bew_\Gamma(\ulcorner\phi\urcorner) \rightarrow Bew_\Gamma(\ulcorner\Psi\urcorner)))$.

We have already seen why (L1) has to hold. If ϕ is a consequence of Γ, $Bew_\Gamma(\ulcorner\phi\urcorner)$ is a true Σ sentence, hence provable in Q_E, hence provable in Γ. (L2) is obtained, laboriously, by formalizing the proof of (L1). In fact, Γ proves $(\theta \rightarrow Bew_\Gamma(\ulcorner\theta\urcorner))$, for each Σ sentence θ. (L3) is easy. If we have proofs of $(\phi \rightarrow \psi)$ and ϕ, we get a proof of ψ by concatenating the two proofs and tacking ψ on the end.

Given the Löb conditions, the proof of the *Second Incompleteness Theorem*, according to which, if Γ is a consistent, recursively axiomatized theory that entails PA, then Γ does not prove its own consistency, is straightforward. Let γ be the Gödel sentence for Γ. Because of the way γ was constructed, we have:

$$\Gamma \vdash (\gamma \rightarrow \sim Bew_\Gamma(\ulcorner\gamma\urcorner)),$$

which is logically equivalent to:

$$\Gamma \vdash (\gamma \rightarrow (Bew_\Gamma(\ulcorner\gamma\urcorner) \rightarrow \sim \underline{0}=\underline{0})).$$

One application of (L1) and two applications of (L3) give us this:

$$\Gamma \vdash (Bew_\Gamma(\ulcorner\gamma\urcorner) \rightarrow (Bew_\Gamma(\ulcorner\underline{Bew_\Gamma(\ulcorner\gamma\urcorner)}\urcorner) \rightarrow Bew_\Gamma(\ulcorner\underline{\sim \underline{0}=\underline{0}}\urcorner))).$$

(L2) gives us this:

$$\Gamma \vdash (Bew_\Gamma(\ulcorner\gamma\urcorner) \rightarrow Bew_\Gamma(\ulcorner\underline{Bew_\Gamma(\ulcorner\gamma\urcorner)}\urcorner)),$$

and these two results together give us:

$$\Gamma \vdash (Bew_\Gamma(\ulcorner\gamma\urcorner) \rightarrow Bew_\Gamma(\ulcorner\underline{\sim \underline{0}=\underline{0}}\urcorner)).$$

By contraposition,

$$\Gamma \vdash (\sim Bew_\Gamma \ulcorner\underline{\sim \underline{0}=\underline{0}}\urcorner) \rightarrow \sim Bew_\Gamma (\ulcorner\gamma\urcorner)),$$

that is,

$$\Gamma \vdash (Con(\Gamma) \rightarrow \sim Bew_\Gamma (\ulcorner\gamma\urcorner))$$

Now assume

$$\Gamma \vdash Con(\Gamma).$$

Then

$$\Gamma \vdash \sim Bew_\Gamma (\ulcorner \gamma \urcorner).$$

By the way γ was constructed,

$$\Gamma \vdash \gamma.$$

Hence, by (L1),

$$\Gamma \vdash Bew_\Gamma (\ulcorner \gamma \urcorner),$$

and so Γ is inconsistent.

In accepting PA, we recognize that the axioms of PA are all true. If the axioms are all true then the theory is certainly consistent, and if the theory is consistent its Gödel sentence is true. So we have good reason to accept the Gödel sentence for PA, even though it is not a consequence of PA. If in this argument we replace PA with our total arithmetical theory—the (admittedly, vaguely defined) totality of arithmetical sentences we are willing to accept as true—we seem to get the curious result that, assuming that our total theory is recursively enumerable, we accept the Gödel sentence for our total theory even though it is not a consequence of the theory. But this contradicts the characterization of our total theory.

J. R. Lucas (1961) and Roger Penrose (1989) took this puzzling situation as reason to believe that the cognitive processes of the human mind cannot be simulated by any purely mechanical device, and that this conclusion undermines the prospects for a naturalistic conception of mind, according to which the human mind is a product of the orderly operation of the laws of nature, not in principle any more mysterious or less constrained by physical law than a player piano or a personal computer. Adherents to the computational theory of mind hold that the operations of the mind are usefully understood on the model of a sophisticated electronic computer, and even naturalists who are not advocates of the computational model will be inclined to say that the facts that the human body is produced by natural selection rather than conscious design and that its central processing unit is carbon-based rather than silicon-based will not affect its capabilities in any fundamental way, so that, according to a naturalistic conception, the cognitive activities of a human being can, in principle, be simulated by a purely mechanical device.

The connection between mechanism and recursive enumerability is given by a variant of the Church-Turing Thesis, supported by similar evidence, that declares that the set of numbers accepted by a mechanical input-output device is invariably recursively enumerable. This includes nondeterministic machines, whose operation is to some extent a matter of random chance, so that the set S is accepted by the machine just in case, for any n, n is in S if and only if there is some possible computation of the machine on input n that yields a positive outcome, as well as deterministic machines for which the course of a computation is uniquely determined by its input.

The argument that our total arithmetical theory is not recursively enumerable proceeds by *reductio ad absurdum*. If the theory were recursively enumerable, it would be recursively axiomatizable, so it would have a Gödel sentence. But we can see that the Gödel sentence is true, even though it is not part of the total theory.

The Lucas-Penrose argument is vulnerable to two criticisms. First, for naturalism to be correct, there has to exist a recursive axiomatization of our total theory. In order to construct the Gödel sentence, we have to be able to specify a recursive axiomatization by writing down a formula that binumerates it. However it is perfectly possible for a recursive axiomatization to exist without our being able to specify it.

Second, even if we were able to specify a recursive axiomatization, perhaps by analyzing a futuristic brain scan, it is hard to see how we could be justified in being completely confident that our total theory is consistent. If we decide to be strict about what arithmetical sentences we are willing to count as "accepted," so that we only regard a sentence as part of our total theory if we arrive at it by unimpeachably lucid reasoning, we shall increase our confidence that our total theory is consistent, but raising the bar this way will also heighten the hurdle that the Gödel sentence has to pass in order to count as "accepted." There are different standards we might use for when we are willing to count a sentence as proven, and each standard has a different Gödel sentence, but however high we set the standard the Gödel sentence corresponding to that standard cannot pass it, on pain of inconsistency.

THE LOGIC OF PROVABILTY

If we explicitly embrace a theory Γ, so that we are willing consciously to acknowledge that the axioms of Γ are all statements we regard as true then we surely ought to regard Γ as consistent. Yet (assuming that Γ implies PA and is recursively axiomatizable and consistent) the statement that Γ is consistent is not provable in Γ. Thus the arithmetical statements that we commit ourselves to in embracing Γ go beyond what Γ itself entails.

The disparity between what consciously accepting Γ commits us to and what Γ entails is even wider than the Second Incompleteness Theorem indicates. Accepting Γ means acknowledging that all the consequences of Γ are true. For a given sentence ϕ, we may not know whether ϕ is a consequence of Γ—there is after all no algorithm to tell us—but at least we accept that, if ϕ is a consequence of Γ, ϕ is true. Consciously accepting Γ commits us to the conditionals $Bew_\Gamma(\ulcorner\phi\urcorner) \to \phi)$, but they are not in general consequences of Γ. In fact such a conditional is a consequence of Γ only if its consequent is a consequence of Γ.

> **Löb's Theorem.** Let Γ be a recursively axiomatized theory that entails PA. If $Bew_\Gamma(\ulcorner\phi\urcorner) \to \phi)$ is a consequence of Γ, so is ϕ.

We can regard the Second Incompleteness Theorem as the special case of Löb's Theorem in which ϕ is taken to be the sentence "$\sim 0{=}0$." Conversely we can derive Löb's Theorem from the Second Incompleteness Theorem. The argument, which is due to Saul Kripke, utilizes the observation that, for any ψ and θ, $\Gamma \vdash (\psi \to \theta)$ if and only if $\Gamma \cup \{\psi\} \vdash \theta$, and the fact that this observation is provable in PA.

Suppose that ϕ is not a consequence of Γ. Then $\Gamma \cup \{\sim \phi\}$ is consistent, which implies, by the Second Incompleteness Theorem, that $Con(\Gamma \cup \{\sim \phi\})$ is not a consequence of $\Gamma \cup \{\sim \phi\}$. Thus we have:

$\Gamma \cup \{\sim \phi\} \not\vdash \sim Bew_{\Gamma \cup \{\sim\phi\}}(\ulcorner\sim 0{=}0\urcorner)$

$\Gamma \cup \{\sim \phi\} \not\vdash \sim Bew_\Gamma(\ulcorner(\sim \phi \to \sim 0{=}0\urcorner)$

$\Gamma \cup \{\sim \phi\} \not\vdash \sim Bew_\Gamma(\ulcorner\phi\urcorner)$

$\Gamma \not\vdash (\sim \phi \to \sim Bew_\Gamma(\ulcorner\phi\urcorner))$

$\Gamma \not\vdash Bew_\Gamma(\ulcorner\phi\urcorner) \to \phi)$

Conditionals of the form $Bew_\Gamma(\ulcorner\phi\urcorner) \to \phi)$ are called *reflection principles*. We cannot obtain them by working within Γ. We get them from the outside by reflecting on the fact that Γ is a theory we accept.

We can describe the logic of provability precisely by utilizing the methods of modal logic. Modal sentential calculus has, in addition to formulas built up from atomic formulas by the familiar connectives "$\lor$" and "$\sim$," a new connective "$\square$." "$\square\phi$," usually read "It is necessary that ϕ," is here understood to mean, "It is provable in Γ that ϕ," where Γ is a consistent, recursively axiomatizable theory that implies PA. An *interpretation* of the modal sentential calculus is a function i that associates an arithmetical sentence with each modal formula, subject to the conditions that $i(\phi \lor \psi)$ be equal to $(i(\phi) \lor i(\psi))$, $i(\sim\phi)$ be equal to $\sim i(\phi)$, and $i(\square\phi)$ be equal to $Bew_\Gamma\ulcorner i(\phi)\urcorner$. A modal formula

ϕ is *always provable* if, for each interpretation i, $i(\phi)$ is provable in Γ. ϕ is *always true* if, for each ϕ, $i(\phi)$ is true.

(L1) tells us, if $i(P)$ is provable, $i(\square P)$ is provable, so that the set of always-provable formulas is closed under necessitation, the rule of modal logic that infers $\square\theta$ from θ. (L2) tells us that $(\square P \to \square\square P)$ is always true, and the formalization of (L2) tells us that it is always provable. (L3) tells us that $(\square(P \to Q) \to (\square P \to \square Q))$ is always true; it is easily seen to be always provable as well. Löb's Theorem tells us that whenever $i(\square P \to P)$ is a theorem, $i(P)$ is a theorem. Formalizing his proof, we see that the formula $(\square(\square P \to P) \to \square P)$ is always provable and always true.

Robert Solovay deployed an ingenious application of the Self-referential Lemma within the possible-world semantics for modal logic to show that, provided Γ does not prove any false Σ sentences, a formula is always provable if and only if it is derivable by *modus ponens* and necessitation from sentential-calculus tautologies (formulas that are assigned the value "true" by every function assigning truth-values to formulas that respects the meanings of "$\lor$" and "$\sim$") and instances of the following schemata:

$(\square(\phi \to \psi) \to (\square\phi \to \square\psi))$

$(\square(\square\phi \to \phi) \to \square\phi)$

Assuming Γ is true, a formula is always true if and only if it is derivable by *modus ponens* from always-provable formulas and instances of the reflection principle $(\square\phi \to \phi)$.

BEYOND THE LANGUAGE OF ARITHMETIC

Gödel's results apply not only to the language of arithmetic but to any language into which the language of arithmetic can be translated. Thus any recursively axiomatized, consistent theory into which one can translate Q_E is incomplete. The appropriate notion of translation was made precise by Tarski, Mostowski, and Robinson. An *interpretation* (what they call a "relative interpretation") of an arithmetical theory Γ into a language $\mathcal{L}$ is obtained by doing the following: First, having rewritten all the sentences in Γ so that the "$+$" sign only appears in the canonical form "$(v_i + v_j) = v_k$," pick a formula "$A(x,y,z)$" of $\mathcal{L}$ and replace "$(v_i + v_j) = v_k$" by "$A(v_i,v_j,v_k)$," changing bound variables to avoid conflicts. Do the same thing for the other function signs and "0" and pick a formula $L(x,y)$ to replace "$\leq$." Next pick a formula "$N(x)$" of $\mathcal{L}$ to represent the members of the domain of $\mathcal{L}$ that are to play the role of natural numbers, and restrict the quantifiers, writing "$(\exists v_i)(N(v_i \land \ldots$" in place of $(\exists v_i)$. Finally add an axiom ensuring that "$A(x,y,z)$" represents a function on

the set of things that satisfy "$N(x)$," writing " $(\forall x)(N(x) \to (\forall y)(N(y) \to (\exists z)(N(z) \land (\forall w)(N(w) \to (A(x,y,w) \leftrightarrow w = z))))$)." Do the same thing for the other function signs and "0." If the theory thus obtained is a consequence of the theory Δ of $\mathcal{L}$, Δ is said to *interpret* Γ.

We can translate the language of arithmetic into the language of set theory, identifying a number with the set of its predecessors, so that 0 corresponds to $\emptyset$, 1 corresponds to $\{\emptyset\}$, 2 corresponds to $\{\emptyset, \{\emptyset\}\}$, and so on, and defining set-theoretic analogues of "+," "×," "E," "S," and "≤" accordingly. The axioms of set theory, in any of its normal versions, interpret PA. We can arithmetize proofs in set theory just as we artimeticized proofs in PA, proving the Second Incompleteness Theorem for set theory. The axioms of set theory, if consistent, cannot prove their own consistency.

This result devastates the Hilbert program. Hilbert wanted to prove the consistency of set theory in a finitistic theory much weaker than set theory, and it turns out that proving the consistency of set theory requires a theory even stronger than set theory.

The standard way to prove that there is no algorithm for testing whether a given sentence is a consequence of a theory Γ—that is, for showing that Γ is *undecidable*—is to interpret an arithmetical theory strong enough to prove the First Incompleteness Theorem into Γ. As far as what we have looked at so far, we would need to take our arithmetical theory to be Q_E, but we can actually do much better. We can define exponentiation in terms of "0," "S," "+," and "×," and we can prove the First Incompleteness Theorem in the dialect of the language of arithmetic without "E," with Q in place of Q_E. In trying to prove undecidability results, this improvement (which is due to Gödel) is an enormous practical advantage.

Let us define $\beta(u,v,w)$ to be the remainder obtained on dividing u by $(v \times w) + 1$. β can be defined by a bounded formula in the language of arithmetic. For $x > 0$, we have $(xEy) = z$ if and only if the following formula is satisfied:

$$(\exists u)(\exists v)((\beta(u,v,0) = 1 \land (\forall w < y)\beta(u,v,Sw) = (\beta(u,v,w) \times x)) \land \beta(u,v,y) = z).$$

The right-to-left direction of this characterization is obvious. What is hard is to verify the left-to-right direction by finding an appropriate u and v. We make use of the Chinese Remainder Theorem, which says that, given $p_0, p_1, \ldots, p_n$ relatively prime (that is, no two of the p_is have a common divisor other than 1), and given a sequence $a_0, a_1, \ldots, a_n$, with each $a_i < p_i$, we can find a number b such that a_i is the remainder on dividing b by

p_i, for each i. A proof of the theorem can be found in any number-theory textbook or in George Boolos's *The Logic of Provability* (1993).

Given x, y, and z with $(xEy) = z$, let $v = z!$, the product of the positive integers $\leq z$. If $s < t \leq z$, then $(s \times v) + 1$ and $(t \times v) + 1$ are relatively prime, since if p were a prime that divided both of them, p would divide $(t - s) \times v$, and so, since $(t - s)$ is one of the factors of v, p would divide v. But this enables us to conclude that the remainder on dividing $(t \times v) + 1$ by p is one, contrary to our assumption that p divides $(t \times v) + 1$. Use the Chinese Remainder Theorem to find u so that, for each $t \leq y$, xEt is the remainder on dividing u by $(t \times v) + 1$.

Now that we have our Σ definition of exponentiation—Σ, that is, in the restricted language—we can apply our standard tricks for pulling quantifiers to the fronts of formulas to convert a Σ formula of the language with exponentiation to a Σ formula of the language without exponentiation. With this emendation, all the proofs go through.

The use of interpretations originates with Beltrami's proof of the consistency of non-Euclidean geometry. By interpreting non-Euclidean geometry (Euclid's axioms with the axiom of parallels replaced by its negation) into Euclidean geometry, Beltrami showed that if the latter is consistent then so is the the former. Beltrami's strategy was exploited by Alex Wilkie and Samuel Buss to obtain a dramatic strengthening of the Second Incompleteness Theorem, applying it to theories that merely contain Q rather than PA. The details are complicated, but the idea is to interpret into Q a theory that, while weaker than PA (the induction axiom schema being restricted), is just strong enough to provide the Löb conditions (L1)-(L3). The interpretation leaves the arithmetical symbols unchanged but restricts the domain of quantification to an initial segment, replacing "$(\exists x)$" by "$(\exists x)(J(x) \land \ldots$," for artfully chosen "$J(x)$;" call the sentence thus obtained from ϕ "ϕ^J."

Where Γ is a recursively axiomatized theory that includes Q, let Γ^{-J} be the set of sentences ϕ for which Γ entails ϕ^J. Suppose that Γ entails Con(Γ). Con(Γ) entails Con(Γ)^J, so that Con(Γ) is in Γ^{-J}. The argument Beltrami used tells us that if Γ is consistent then Γ^{-J} is too. This proof can be formalized in Γ^{-J}, so that Γ^{-J} entails Con(Γ^{-J}). Because (L1)-(L3) yield the Second Incompleteness Theorem for Γ^{-J}, Γ^{-J} must be inconsistent. Consequently Γ is inconsistent.

TRUTH

There is a bounded formula of the language of arithmetic that defines the set of prime numbers, and there is a Σ for-

mula that defines the set of consequences of PA. Tarski proved that there is no formula of the language of arithmetic that defines the set of codes of true sentences. The difficult part of his argument was to say precisely what would be required for a formula to define truth; the easy part is to show that there is no such formula.

A proposed definition of truth is a formula of the form $(Tr(x) \leftrightarrow \tau(x))$, where $\tau(x)$ is a formula of the language of arithmetic. A proposed definition is *materially adequate*, Tarski tells us, if and only if it lets us derive all sentences of the form:

(T) $Tr(\ulcorner\phi\urcorner) \leftrightarrow \phi.$

To see that there is no materially adequate definition, apply the Self-reference Lemma to find a sentence λ so that $(\lambda \leftrightarrow \sim\tau(\ulcorner\lambda\urcorner))$ is a consequence of Q. The argument here is a formalization of the paradox posed by Eubulides, who asked whether a man who says "I am lying" speaks truthfully.

We can define the set of true sentences of the language of arithmetic within, say, the language of set theory, but we cannot define it within the language of arithmetic. This negative result obtains for any language into which we can translate the language of arithmetic.

The question of what moral, if any, these formal results have for the notion of truth as applied to natural languages is deeply troubling. Tarski showed that there is no formula of the language of arithmetic that means (or even has the same extension as) "true sentence of the language of arithmetic." Manifestly there is a phrase of English that means "true sentence of English," and Tarski and Eubulides' reasoning would appear to apply to that phrase just as to the formal language. Is there in spite of this a coherent way to talk about the truth of an English sentence?

Vann McGee (2005)

GODFREY OF FONTAINES

Godfrey of Fontaines, the scholastic philosopher and theologian, was a native of Fontaines-les-Hozémont in the principality of Liège. He was born of a noble family about the middle of the thirteenth century, the exact date unknown. About 1270 he began studies at the University of Paris and became a *magister regens* in the faculty of theology there in 1285, having studied under Henry of Ghent and Gervais of Mt. St. Elias. His regency lasted until 1297, and during this period he produced fourteen of his *Quodlibets,* his most important works. There is evidence that he resumed teaching at Paris about 1303 or 1304, composing *Quodlibet* XV at this time. Canon of Liège, probably also of Paris, and provost of Cologne (1287–1298), Godfrey was chosen bishop of Tournai in 1300 but renounced his rights when the election was contested. He is cited among the senior members of the Sorbonne until 1306 and probably died about that time. The obituary at the Sorbonne dates his death October 29, but does not give the year.

Godfrey's doctrinal preferences generally favor the positions of St. Thomas Aquinas, but he manifests a marked independence of judgment on certain points and sometimes works out the logic of Thomas's principles to different conclusions. Some historians (M. De Wulf, E. Gilson) see Godfrey as an opponent of Thomas's distinction between essence and existence in finite being, and attribute Godfrey's stand to a hard-and-fast Aristotelianism that refused to admit an act of the form. Others see Godfrey as opposing the realism of Giles of Rome rather than Thomas. Godfrey held that in the divine mind there is no proper idea of individuals distinct from their species. On the hotly debated issue of the oneness or plurality of substantial forms in composite beings, Godfrey always remained hesitant. He would have favored the doctrine of the unicity of form were it not for the fact that it seemed to contradict theological truths.

Godfrey showed particular acumen in his treatment of psychological problems. Under the influence of Averroes, probably through Siger of Brabant, he espoused an Aristotelianism stricter than that of most of his contemporaries. Godfrey criticized and rejected the so-called Augustinian theory on the genesis of ideas, insisting on the close dependence of human concepts on sense experience. He insisted strongly on the passive nature of the human intellect—the abstractive function of the agent intellect does not consist in the production of any positive disposition in the sensible image upon which it works, but in disregarding in a merely negative way the concrete particularizations characteristic of the image. This outlook is intimately connected with an Avicennan realism of abstract essence, so that Godfrey held that the intellect does not produce intelligibility or universality either in things or in images, but that the agent intellect places the images under an illumination such that the quiddity or essence of the object can appear alone and act on the possible intellect and become known to us.

In his explanation of human free will Godfrey adhered closely to the Thomistic doctrine, but he insisted more than Thomas upon the freedom of the intellect as its foundation. Against the voluntarism of Henry of Ghent, Godfrey stressed the formal influence of the intellect upon the will to the point of making it an efficient cause, whereas Thomas, in different historical circumstances against the Averroists, minimized the formal influence of the object upon the will. In other respects Godfrey did not break cleanly with the Augustinian tradition. For example, he made an interesting equivalence of the active and passive intellects with Augustine's "memory," the passive intellect inasmuch as it conserves species and is a *habitus,* the active intellect inasmuch as it contributes to actual knowledge.

Godfrey was a lively controversialist, combating at length the opinions of his contemporaries, particularly Henry of Ghent, Giles of Rome, and James of Viterbo. Not only did he engage in an active dialogue with his contemporaries, but he also occupied himself with pressing problems—moral, legal, social, and political—arising from daily life. Among his admirers can be listed John the Wise, Peter of Auvergne, and Gerard of Bologna; among his critics, Bernard of Auvergne, Gonsalvus of Spain, and John Duns Scotus. His influence was widespread and lasted well into the fourteenth century but waned thereafter.

GOD/ISVARA IN INDIAN PHILOSOPHY

This entry deals briefly with the Isvara concept in the six schools of philosophy in Hinduism, usually called the orthodox schools because they were thought to believe in the authority of the Vedas. The schools are Nyaya, Vaisesika, Samkhya, Yoga, Purvamimamsa, and Uttaramimamsa, also called Vedanta. This article is not a philosophical discussion of the nature of Isvara but is a description of how Isvara is viewed in these schools.

Each of the main schools has a foundational text called *sutras*. The word *sutra* means "a thread" and is usually a brief sentence of a few words that convey the basic philosophy of the respective school. As these *sutras* are difficult to follow without some explanation, commentaries called *bhasyas* emerged from erudite commentators, which in turn spawned commentaries on commentaries that went on for a long time up until the present day. One could generally assign the period between the second century to the fifth century CE as the point of origin for these schools of philosophy. The authors of the first *sutras* of Nyaya was Gautama, of Vaisesika Kanada, of Samkhya Kapila, of Yoga Patanjali, of Purvamimamsa Jaimini and of Vedanta Badarayana, also called Vyasa. These *sutras* are all written in the oldest lan-

guage of the world, Sanskrit, which was the language of religion and philosophy for most of Hinduism's history. Each of these schools has a unique approach to the understanding of Isvara.

It is useful to remember that in Hinduism, within which one has to view the six schools, Isvara cannot be equated with the concept of God as it is understood in the Abrahamic religions. Isvara does not have the role of creator because Isvara does not create the world and the selves from "nothing." The theory of karma and the cyclical evolution and dissolution of the universe in periodic cycles, in keeping with karma, does not allow Isvara the same role that is assigned to God in the Abrahamic religions. Hindu schools of philosophical thought have liberation or *moksa* as their highest value, and each school develops its ontology and epistemology in order to realize this eschatological value.

All the orthodox schools share in the belief that the self (also called variously as *atman, jiva, purusa*, and so on) is an eternal entity born into the world and associated with a body and other faculties in accordance with the karma that belongs to it from the past. The ego or sense of "I" that one normally associates with notions of one's identity is not the real self in these schools. The real self is the *atman*, which is the inner essence, and it is the quest for this inner self and its realization that constitutes ultimate freedom or *moksa*, which, in an extended sense, also means breaking the chain of subsequent births and deaths in the world. This quest for the true self is also situated within the inner efforts of individual earthly selves and so, on the surface at least, there is no role for Isvara in the way these *sutras* were initially formulated. As Isvara does not also have a role in the direct evolution of living beings in the world, the concept of Isvara is something that is sneaked into the *sutras* sometimes by later commentators in order to serve other needs. Since there is no uniformity of approach in the methodology followed for this purpose in the different schools, our task is to examine how this is done in the different schools and how the Isvara concept is made to fit into the general philosophy of the different systems.

NYAYA-VAISESIKA

Although *Nyayasutras* and *Vaisesikasutras* were composed by different authors, because of certain similarities in the way they viewed ontology and epistemology, they gradually came to be discussed jointly in all discussions of the philosophical schools. I shall also deal with them together in this entry.

Nyaya and Vaisesika are realistic schools and trace the origin of the real from basic atomistic principles. They have minor disagreements in the number of metaphysical categories and also in the emphasis that each brings into the discussion. Whereas Vaisesika concentrates on discussing in detail the metaphysical categories and the ultimate realistic principles, Nyaya is more concerned with developing the epistemology of gaining right knowledge of reality, which is to realize the true nature of *atman*.

The ultimate realities that explain the whole universe are the atoms of earth, water, fire, air, ether (*akasa*), space, time, mind, and self (*atman*). As can be seen from the above, the system is not purely materialistic. The self is considered to be eternal and many. Though omnipresent, it is confined to the body to which it is associated. The theory of causation is teleological; the karma called *adrsta* (unseen potential of past *dharma* and *adharma*) is sufficient to determine the coming together of the eternal atoms to form bodies for the selves to continue their cycle of lives until they attain liberation through a discrimination between the true nature of *atman* and the false identity it has with the body and other material substances. Thus the initial *sutras* of Gautama and Kanada did not really have a place for Isvara though Gautama refers to Isvara in a weak sense in one place (*Nyayasutras* IV 1.21)

Later commentators, however, found a place for Isvara in both Nyaya and Vaisesika by using various arguments. The eternal atoms and the eternal selves (*jivas*) are not created by Isvara. However, there was a need to bring together the *jivas* and their future embodied lives in consonance with past karma. Since karma itself was not a conscious category, there was room for the introduction of an intelligent, superconscious *atman* who could fulfill this task. Thus, some of the reasons for the existence of Isvara in Nyaya-Vaisesika are: (1) because the world as an effect needs an agent as an efficient cause equal to the task of coordinating the different phenomena of the world; (2) the atoms being basically inactive, Isvara enables them to combine in accordance with the past karma (*adrsta*) of *jivas*; (3) the manifestation and destruction of the world in cyclical rhythm is due to Isvara.

Liberation called *apavarga* in these two schools is, however, still an individual effort, and Isvara has no role to play in the achievement of the highest value of liberation (*moksa*) for the *atman*. It comes about by correct knowledge of things of which Isvara is also just one more thing.

SAMKHYA-YOGA

The *Samkhyakarika* of Isvarakrsna and the *Yogasutra* of Patanjali are used for this discussion. Like Nyaya and Vaisesika, Samkhya and Yoga also share some metaphysical ideas; they both believe in two ultimate realities—one called *prakrti*, the material reality and the building block of the world—and the other the spiritual reality called *purusa*, which is another word for *atman*. Even though there are many *purusas* in these two schools, they are not different from one another in essence. Whereas in Nyaya-Vaisesika *atman* only has knowledge as an adventitious property, in these schools it is also characterized as being pure consciousness.

The coming into being of the world and its properties in both the schools is from *prakrti* alone without the assistance of any outside agency. The proximity of *purusa* and *prakrti* is a sufficient condition for the evolution and involution of the world. *Prakrti* is viewed as constituted of the three *gunas* (characteristics) of *sattva, rajas,* and *tamas*. These *gunas* are not properties of *prakrti* but its very nature. *Prakrti* as constituted by the *gunas* is in constant motion. When the *gunas* are in equilibrium, there is no evolution of the world, and the world evolves when there is disequilibrium of the *gunas*. Thus evolution and involution is a teleological process governed by the past karma associated with *purusas*. The evolution is also explained as serving the twin purposes of *purusa*: experience in the world and gaining liberation or *kaivalya*.

Philosophically there are many difficulties, among them (1) the conception of many *purusas* who are all of the same nature of pure consciousness, (2) an insentient *prakrti* sufficient to explain the evolution of the world, (3) the problem of what initiates the disequilibrium in the first place, and so on. This article, however, confines itself to Isvara in the system. Thus, as seen above, it is clear that there is no role for Isvara in the *Samkhyakarika*. The final goal of liberation or *kaivalya* also comes through discrimination between the true nature of *purusa* and *prakrti* gained by correct knowledge. Thus Isvara does not figure either in the coming into being of the world or in the attainment of *kaivalya* for *purusa*.

Although Yoga shares with Samkhya the belief in the ultimate two realities of *prakrti* and *purusa*, there is a weak introduction of Isvara in the system, described as an excellent *purusa*. The excellent *purusa* (Isvara) is unaffected by karma in the past, present, and the future. By arguing from experience that there is a graded scale of knowledge, wisdom, power and so on, Patanjali describes Isvara as the one who represents the utmost excellence and who is also an aid to the practice of yoga by being an object of support (*alambana*) in meditation. But, at the same time, Isvara is only one among many supports in meditation. He is also called the first guru who teaches the Vedas to the sages. His symbol is Om, and he is one that brings the association and disassociation of *purusa* and *prakrti* to start the evolution and involution of the universe. Though philosophically these are weak arguments, Isvara has been accommodated in a backhanded manner into Yoga philosophy by Patanjali. However, because Isvara does not play any role in the manifestation of the world, in the evolution of individual *purusas*, or in the granting of liberation, one can conclude that Yoga also does not accommodate Isvara in the usual sense of the term.

PURVAMIMAMSA AND UTTARAMIMAMSA

The earlier sections (*purva*) of the Veda, the *mantra* and ritualistic or *brahmana* sections, deal with rituals and are therefore called the *karmakanda* (sections dealing with rituals) while the latter sections (*uttara*), the Upanisads, deal with knowledge of reality and so are called the *jnanakanda* (sections dealing with knowledge). Both the schools believe implicitly in their respective sections of the Veda. I shall first consider Purvamimamsa (PM) and then talk about Uttaramimamsa (UM) or Vedanta.

PM is a realistic school and considers the Vedas as an infallible authority. This discussion is based on Jaimini's PM *sutras* and on some later commentaries. PM primarily focuses on the right interpretation of Vedic statements and in the correct performance of rituals or karma. It differs from all other schools in not believing in the periodic evolution and involution of the world. According to PM, there never was a time when the world was different from what it is now. PM believes in the law of karma as an unseen power, in the individual selves that are ruled by the law of karma, and in *moksa* which, though initially the attainment of *svarga* (heaven), gradually changed to the attainment of the true nature of *atman* in later commentaries. It is attained by the exhaustion of *dharma* and *adharma* by the disinterested performance of one's own karma. The ultimate authority being the Veda, there was no need of an Isvara in the system. Karma classified in various ways was sufficient to explain the coming into being of the individual selves and their ultimate achievement of *moksa*.

Uttaramimamsa or Vedanta is based primarily on the Upanisads, which are the basis of Badarayana's Brahmasutras (BS), also called the Vedantasutras. Although there are many Vedanta schools based on differing interpreta-

tions of the BS and the Upanisads, this entry shall be dealing only with Advaita Vedanta and very briefly with Visistadvaita and Dvaita philosophies. Samkara (c. eighth century CE), Ramanuja (c. eleventh/twelfth century CE) and Madhva (c. thirteenth/fourteenth century CE) are the important commentators on the BS for Advaita (nondualism), Visistadvaita (qualified nondualism), and Dvaita (dualism), respectively.

Samkara declares the ultimate ontological reality as Brahman and identifies the individual self called *atman* with this Brahman. Because there is only one Absolute Reality, the so-called reality of the world and all other things is only an appearance, according to Advaita (nondual)Vedanta. Brahman is described as *nirguna* (without any qualities) and cannot be viewed in a personal way. However, because the world appears to be real, in order to reconcile this world-reality with the ultimate reality, Advaita views reality as a threefold entity that includes the illusory (*pratibhasika*, such as dreams), worldly experience (*vyavaharika*), and absolute reality (*paramarthikasatta*). Because Brahman is also without any properties, it cannot be an agent of manifestation. Therefore, the necessity of explaining the world forces Samkara to introduce *maya* (cosmic ignorance), which, when associated with Brahman, is called *saguna*-Brahman (Brahman with qualities) or Isvara, which is then considered to be both the efficient and material cause of the universe. There are many ways in which *maya* and its association with Brahman are explained in order to maintain the nondual nature of Advaita, but that need not concern us here. Because this Isvara is not free to manifest the world and the selves but is bound by the karma of the individual selves in the manifestation of the world, and because Isvara does not have a role to play in the attainment of *moksa* of the selves, it is only a device to explain the so-called reality of the world. Liberation is achieved when, through correct knowledge, the *atman* realizes its identity with Brahman.

By the times of Ramanuja and Madhva, a fundamental change has taken place in the religious sphere. Devotion (*bhakti*) has come to be valued as higher than knowledge in the attainment of *moksa*, and the highest entity Brahman is also now viewed in a personal manner. Brahman—variously called Narayana, Visnu, Gopala-Krsna, Vasudeva-Krsna, and so on—is capable of responding to the devotion of individual selves and even to mitigate the evil effects of karma, enabling the devotee to attain *moksa*. *Moksa* is also defined differently in a dualistic manner whereby the self retains its separation from the Supreme Brahman it worships. There are differ-

ences in the way in which the nature of the individual selves, the world, and the nature of Brahman are understood in Ramanuja's and Madhva's interpretation of the BS. But those are in the details. In both *bhakti* is a sufficient condition for *moksa*.

As long as the philosophical schools depended only on correct knowledge to attain the true nature of *atman*, there was no need for dependence on an outside agent called Isvara to enable *atman* to achieve its highest value. But when the religious atmosphere changed with the introduction of devotion as the paramount means for achieving liberation, it was possible for Isvara to play a role in many ways—like the reduction of karma, bestowing grace, and so on—for the *atman* to attain *moksa*.

GODWIN, WILLIAM
(1756–1836)

William Godwin, English political philosopher, novelist, and essayist, was born at Wisbech, in Cambridgeshire, where his father was a dissenting minister. He was educated at Hoxton, one of the dissenting colleges that had been founded because of the refusal of the established universities to admit nonconformists, and himself entered the ministry in 1778. By 1783, apparently as the result of reading Claude-Adrien Helvétius and Baron d'Holbach, he had lost his faith, and instead took to literature as a means of livelihood. Much that he wrote at this time was hackwork, including three novels, none of

which have survived. He did, however, gain some reputation as a political journalist, contributing regularly to such Whig publications as *The Political Herald* and *The New Annual Register.*

In 1791 Godwin managed to free himself from hackwork by persuading a publisher to subsidize him while he settled down to a serious treatise on political theory. The *Enquiry concerning Political Justice* (London, 1793) was the kind of book the intellectual radicals of the day had been waiting for, and Godwin soon became a celebrity. In this work, he set down, with passionate sincerity and a complete absence of compromise, the radical beliefs that were emerging from the French Revolution and the intellectual ferment that had preceded it. The book went through three editions (2nd ed., 1796; 3rd ed., 1798).

For a few years Godwin was happy and successful. His novel *Things as They Are; or, the Adventures of Caleb Williams* (London, 1794) was widely acclaimed as a masterpiece. In the same year, his *Cursory Strictures on the charge delivered by Lord Chief Justice Eyre to the Grand Jury* (London, 1794), which protested against the committal on charges of treason of twelve leading radicals, may have been partly responsible for the acquittal of three of the defendants and the dropping of the charges against the others. He also published a volume of essays, *The Enquirer* (London, 1797).

In 1797 Godwin married Mary Wollstonecraft, the author of *A Vindication of the Rights of Woman.* She died in the same year, a few days after the birth of their daughter Mary, who was to become the wife of Percy Bysshe Shelley. In 1798 Godwin wrote a memoir of his wife (*Memoirs of the Author of A Vindication of the Rights of Woman,* London, 1798), and in the following year another novel, *St. Leon* (London, 1799).

From then on his fortunes declined. Radicalism came into disfavor, and Godwin was fiercely attacked, sometimes by his former friends. One of these preached a sermon against him, to which he replied in *Thoughts Occasioned by Dr. Parr's Spital Sermon* (London, 1801).

In the same year, 1801, he married a widow, Mary Jane Clairmont. His second marriage was less happy than his first. Before long he was back at hackwork, and the last years of his life were spent in poverty.

Though he continued writing until his death, many of his later books were potboilers. The most important of these works (all of which, with one exception, were published in London) are his novels *Fleetwood* (1805), *Mandeville* (Edinburgh, 1817), *Cloudesley* (1830), and *Deloraine* (1833); his *Life of Chaucer* (1803); *An Essay on*

Sepulchres (1809); *Of Population* (1820), a reply to Thomas Robert Malthus; and *Thoughts on Man* (1821). He had expressed his views on religion in a book that he called *The Genius of Christianity Unveiled,* but it was not published until long after his death, when it appeared under the title of *Essays Never before Published* (London, 1873).

ANARCHISM

Godwin's political theory is uncompromisingly anarchist. He was opposed to all kinds of coercion, including punishment, partly because of his determinism. "The assassin," he said in *Political Justice,* "can no more help the murder he commits than the knife in his hand." Such a view might be thought to lead to an authoritarianism based on the need to condition men rigidly so that their actions will not be antisocial. Godwin did indeed believe that it is society that molds men's characters and actions. He was one of the earliest proponents of what is now called cultural determinism, but he combined this view with a quite extreme liberalism and individualism.

TYPES OF SOCIETY. Before Godwin, Baron de Montesquieu (and indeed Plato) had already maintained that each type of government developed not only its own characteristic type of institution, but also its own characteristic attitudes and value judgments within the minds of its citizens. Montesquieu distinguished three main types of government, each with its own characteristic "spirit": despotism, whose spirit is fear; monarchy (the aristocratic semifeudal type of society still current in most of eighteenth-century Europe), whose spirit is honor; and the republic (which for Montesquieu suggested Sparta, oddly idealized in the eighteenth century, as much as the actual contemporary example), whose spirit is virtue, used not quite in its modern sense but rather to mean public-spiritedness.

Where Godwin differed from the modern anthropologist and, to some extent at least, from Montesquieu, was that he saw all three types of society as corrupting their citizens—even monarchy, with its ideal of honor, so much admired in Godwin's time. Honor demands that one shall do what is fitting to one's rank; this was thought a sufficient motive to keep the wheels of society turning and to ensure decent and at times even noble behavior. Falkland, in *Caleb Williams,* is a portrait of the Man of Honor. He is a thoroughly charming, accomplished, and benevolent man, but at the moment of crisis he is prepared to commit murder and further crime rather than see his good name disgraced. The moral is clear enough:

Honor is not enough to make men behave benevolently. Only benevolence will do that.

In some ways Godwin was more sympathetic to the republican ideal than to any other. Montesquieu's Republic is a state like Sparta, in which there is equality, frugality, and complete submission of the individual to the state. Godwin was strongly in favor of equality; he shared the republican objection to ostentation and luxury; and he agreed that it was the supreme duty of the individual to merge his own welfare with that of his neighbor. Nevertheless, Godwin rejected the republican ideal quite as decisively as the monarchic one—first, because it turns men's attention away from human beings toward a quite mythical entity called the State, and second, because it teaches men to merge their own judgment in that of the majority.

CORRUPTING INFLUENCE OF GOVERNMENTS. Behind these objections, there is a quite general criticism that would apply to any type of government. Godwin believed that social institutions corrupt because they create prejudice; they prevent men from seeing things as they are. Men in society see themselves and one another through a mist of preconceived ideas—as members of this or that social class, as fellow countrymen or foreigners, but never as the unique individuals they really are. To some extent this is inevitable, in society or out of it: All generalizations, according to Godwin, distort the particulars that are subsumed under them; and yet it is impossible to think at all without generalizing. Nevertheless, to see things as they are, though difficult, is not impossible. However, it is peculiarly difficult to see ourselves and our fellow men as they are unless we can get close enough to them to sympathize with them and to realize the true complexity of their motives.

Government perverts our judgment in three main ways. First, it creates artificial barriers between men, as the result of social inequality and of the insincerity that results from the perpetual effort to keep up with the Joneses.

Second, it encourages us to do the right things for the wrong reasons. Patriotism and social prestige are both wrong reasons for treating other men benevolently. Punishment, which leads men to keep the law from fear and not because they understand the reasons for keeping it, acts in the same way. The objection to doing the right thing for the wrong reason is that, since it results in the muddling of men's minds, they will become quite incapable of adapting their actions intelligently to changed circumstances; and consequently the things they do will not for long be the right ones.

Third, government encourages us to acquiesce in the opinions of others, whether of the majority or some minority of rulers. This means that we accept conclusions without really understanding the evidence upon which they are based. Consequently we are acting from prejudice, without any real understanding. Once again, this can only make us unfit to cope with a complex and changing world. "The history of mankind," Godwin said, "is little else than a record of crimes" (*Political Justice,* I, ii), crimes that are caused ultimately by man's inability to see things as they are and to think clearly about them.

THE IDEAL SOCIETY. For these reasons, Godwin rejected all three of Montesquieu's forms of society. Godwin did not, however, merely want to put a fourth type of government in place of the other three. He believed not merely that all existing governments have corrupted society, but also that government as such is necessarily corrupting.

In what kind of society, then, can one hope to escape prejudice? Obviously not in a large society, because every individual is unique, and one can avoid prejudice only by an intimate and sympathetic understanding of one's fellows. Indeed, it is rare enough to know even one person well enough not to misjudge him. In this connection, it is worth noticing that Godwin had an almost morbid obsession with friendship. In all his novels the central figure complains of being without a friend, and is cut off from the rest of his fellows—usually as the result of his own prejudices. This loneliness is, for Godwin, the central tragedy of the human situation.

The ideal community, then, must not be large and must not be highly organized. The citizen must never be a cog in a machine, unable to see the significance of his everyday activities. There must be no class distinctions that prevent us from seeing individuals as individuals. And there must be no formal rules and regulations, because these are rules of thumb that demand the acquiescence of the individual in propositions he does not really understand. For the same reason, there is to be no punishment. For Godwin, the ideal society is one in which individuals cooperate without any kind of compulsion because they like and understand each other and wish each other well.

THE NEED FOR GRADUAL CHANGE. Godwin's ideal society is usually criticized as absurdly unpractical and utopian. The truth is that he was not really a political

reformer in the ordinary sense. He was not very interested in blueprints for a "brave new world"; he did not believe in political organizations, and he had no program. He was primarily a moralist concerned with analyzing the causes of prejudice; once we understand these, according to him, the cure may very well be left to look after itself. We need to have some vague idea of the direction in which we wish to move, but we need have no more than that, because change can be brought about only very slowly and gradually. Godwin insisted again and again upon the folly of violent change. We can do nothing here and now but try to make a few small breaches in the wall of prejudice. If enough people can be brought to see what is wrong with society, society will right itself—but only by slow and gradual changes that will take generations. There is no question of a political program; political organizations are themselves a cause of prejudice. We are not even to point the way to the new society by setting an example of a better way of life. It is by reasoning and discussion that we must break down existing prejudice. The immediate task is to destroy the current ideals of honor and virtue. These ideologies have been created by existing institutions. They can be destroyed without destroying these institutions, however, because though prejudice is strong, it cannot entirely blind men to the facts. When supported by existing institutions, opinion can only be changed slowly—but it can be changed, and as it changes, the institutions will gradually be transformed.

MORAL THEORY

Society is to be transformed, then (even if only slowly and gradually), by means of a change in men's opinions—chief among them their opinions about what is desirable. But here a major difficulty presents itself. Even if men can be brought to see things as they are, how can their moral beliefs be changed thereby, since, as David Hume had pointed out, it is impossible to derive any conclusion about what ought to be the case from knowledge about what is the case? Godwin knew of Hume's views and agreed with them, at least in part. In a certain sense, Godwin believed that virtue is knowledge; but he also insisted quite emphatically that "moral reasoning is nothing but the awakening of certain feelings" (*Political Justice*). It is in order to reconcile these two positions that he introduced his concept of natural goodness.

GODWIN'S UTILITARIANISM. Godwin was a thoroughgoing utilitarian. For him, the right action is the one that makes for the greatest happiness of the greatest number. His utilitarianism, however, is unusual in two respects. First, it is not derived from egoism: The "greatest happiness" principle is ultimate, and cannot be derived from self-interest. Second, Godwin was quite prepared to push utilitarianism to its logical conclusion and openly embrace the consequences that many critics have regarded as fatal to it. He repudiated as immoral any obligations that cannot be derived from the general obligation to promote the general happiness—such obligations, for example, as promises and other contractual obligations, or the domestic obligation to prefer the happiness of one's friends and family to the greater happiness of others. He caused considerable scandal by the passage in *Political Justice* in which he said that one ought to save François Fénelon from a burning building rather than his chambermaid (supposing that the archbishop has more to contribute to the general happiness), even if the chambermaid is one's own mother.

KNOWLEDGE AND VIRTUE. For Godwin, then, our belief that X is desirable is true only when X is something that will make for the general happiness. Since "moral reasoning is nothing but the awakening of certain feelings," the virtuous man is the one who does desire whatever makes for the general happiness. How will seeing things as they are awaken this desire? The following may serve as an example: If someone says that it is a bad thing that millions of people in a distant part of the world are starving, I may very well agree, but the chances are that I won't do anything about it. But now suppose that one of them comes and starves on my doorstep. Almost certainly I shall be moved to feed him. When I see a man starving before my eyes, the proposition "starvation ought to be relieved" takes on a new meaning for me. I can now see in detail precisely how and why starvation is evil; I can see exactly how the generalization applies to the particular instance. It is not a question of perfect knowledge being reinforced by emotion, since my knowledge before was imperfect. When it becomes perfect, it necessarily brings the emotion with it. Thus, if I *know* in this sense that X is desirable, and if I not only accept this as a rule of thumb but also fully understand the evidence on which it is based, then I cannot but desire it.

THE CAUSES OF IMPERFECTION. Because he held that men are "perfectible" and "naturally good," Godwin has been accused of excessive optimism. He did not mean, however, that men are, or are likely to become, perfect. He was merely saying that imperfection has causes (usually social causes) that may be removed. To talk about original sin is to give up the search for the causes of sin. It is as if we were to say "disease is a natural phenomenon" and turn our backs on medicine. In general, no doubt,

wickedness, like disease, is always with us; but any particular piece of wickedness, like any particular disease, has specific causes, and it may be possible to remove them. That the causes are far-reaching and difficult to remove, Godwin did not deny. He was even prepared to grant that there may be "something in the nature of man incompatible with absolute perfection." Men can never fully understand the principle of universal benevolence, simply because they cannot hope to know all their fellows intimately. But this is an ideal toward which we can strive and which, even if it can never be reached, can always be brought a little closer.

RIGHTS. As a thoroughgoing utilitarian, Godwin, like Jeremy Bentham, denied that there are any natural rights. The only right, which is also a duty, is to do whatever makes for the general happiness. He would not concede the rights to life and liberty. Nevertheless, the individual has one right—the right of private judgment. The reason for this is simply that, in the final analysis, nothing will be gained if men do not understand the reasons for acting as we wish them to act. When men see things as they are, they will quite freely and without any kind of coercion do what makes for the general happiness. Any attempt to coerce them will hinder them from seeing things as they are and will therefore do more harm than good. In this way, Godwin was able to reconcile utilitarianism with the utmost insistence on individual freedom, and especially on freedom of thought and opinion.

THE BASIS OF GODWIN'S ETHICS. Godwin's basic beliefs may be summarized in three propositions—one about ethics, one about logic, and one about social psychology.

The nature of virtue. The ethical proposition is that to be virtuous is to feel the right emotions. The right emotions are those that men feel when they see all the facts clearly. When we analyze these emotions, we find that they are all consistent with the "greatest happiness" principle.

In the last analysis, statements about morals are expressions of feeling. But this does not mean that we cannot reason about morals. There are good and bad reasons for feeling frightened or angry. Fear is appropriate in a situation of danger. We do not doubt that if once we make a man see the full facts of the situation, the emotion of fear will come of its own accord. In the same way, if we want men to feel the appropriate emotions of benevo-

lence, pity, affection, and so on, we can do it by making them realize the full facts about human beings. It is in this sense that men are naturally good.

Generalizations. The logical proposition is that true knowledge is of particulars and all generalizations are, if not false, at least seriously misleading. It is possible to know in a sense that a situation is dangerous without feeling the appropriate emotion. A man may ignore the danger out of bravado, but in that case we may say that he does not fully appreciate the danger. He knows, as a generalization, that the situation is dangerous, but he does not know the particulars that the generalization expresses—which is to say that he does not really know the generalization at all.

But we cannot, of course, do without generalizations. It is impossible to know every particular in all its particularity. Here, then, is an inescapable source of error. It is particularly likely to mislead us in our judgments of human beings and of human actions, for every human being is unique. Since we cannot know everyone intimately, we have to rely on generalizations, any one of which may be seriously misleading when applied to a given individual. Such generalizations form, as it were, a distorting glass through which we look at the world. And, since virtue depends on feeling the appropriate emotions toward other human beings, emotions that depend on a clear perception of all particulars, the logical proposition is an adequate explanation of human frailty. It also explains what Godwin meant by prejudice.

Political institutions influence beliefs. The proposition about social psychology is that the generalizations men believe depend on the political institutions under which they live. In practice, the particular distorting glasses we use are, so to speak, handed out to us by the governments under which we live. Our opinions about how human beings actually behave are influenced by concepts derived from legal institutions, like "thief" or "murderer," or concepts derived from social institutions, like "lord" or "pauper." These stereotypes come between us and the actual human beings around us. Our opinions about how human beings ought to behave are distorted by such concepts as "honor" and "virtue," which stem directly from political institutions, as Montesquieu had clearly demonstrated. This is what Godwin meant by the corrupting effect of government.

GODWIN'S SOLUTION. Two main conclusions follow from these three basic beliefs: First, that if we want to improve human beings, we must help them to see things, and particularly each other, as they are; and second, that

this can be done by simplifying society, by sweeping away social categories like rank and the legal categories that depend on punishment, and by encouraging individual judgment so that men will no longer trust to rules of thumb.

GOETHE, JOHANN WOLFGANG VON
(1749–1832)

Johann Wolfgang von Goethe, the German poet, pantheist, novelist, and scientist, was born in Frankfurt am Main and died in Weimar. Goethe's literary genius disclosed itself early. He wrote numerous lyric poems, invariably inspired by love affairs, while still in his teens. University studies in Leipzig and Strasbourg were less important to his development than were his extracurricular interests: occult philosophy, astrology, and religious mysticism while in Leipzig; and his friendship with Herder at Strasbourg, a friendship that evoked Goethe's passion for William Shakespeare, nature, and German folk poetry. The historical drama *Götz von Berlichingen,* written while Goethe was a law student in Strasbourg, marks the start of his *Sturm und Drang* ("storm and stress") period. *Die Leiden des jungen Werthers* (The sorrows of young Werther, 1774), written to purge himself of the despair engendered by his love for Charlotte Buff, who married another man, marks the high point of this phase of Goethe's career. *Werther,* translated into numerous languages, made Goethe famous throughout Europe. Other works belonging to this period were the dramas *Stella, Egmont,* and the "Gretchen" episodes of *Faust.*

In 1775, at the invitation of Karl August, Duke of Saxe-Weimar, Goethe moved to the court at Weimar. Here, in addition to his work as chief of state and his continued literary activity, Goethe's interest in the sciences developed: His official duties involved such diverse matters as horticulture, mining, road inspection, and later the management of the state theater. In Weimar, Goethe's involvement with Frau Charlotte von Stein, an intellectual lady of refined tastes in the arts, lasted for twelve years. His writings during those years included some of his greatest lyrics. It is said that Stein exercised a humanizing, moral influence on Goethe.

Goethe's trip to Italy in 1786 was to his own mind the climax of his life. In his thinking about art and literature, the classical ideal of calm beauty replaced the representation of tempestuous emotion and rebelliousness characteristic of the *Sturm und Drang* movement. *Iphigenie auf Tauris* (1787), a verse reworking of an earlier play, and *Torquato Tasso* (1789) exemplify the new style.

Returning to Weimar, Goethe took a new mistress, Christiane Vulpius, who bore him a son in 1789 and whom he married in 1806. Many of Goethe's scientific studies were published in this period: *Versuch, die Metamorphose der Pflanzen zu erklären* (Essay on the meta-

morphosis of plants, 1790), *Beiträge zur Optik* (Contributions to optics; 1791 and 1792). Earlier he had published his discovery that a part of the human jawbone is analogous to the intermaxillary bone in apes (1784). Goethe returned to Italy in 1790 but did not find the excitement and inspiration of his earlier travels. In 1792 he accompanied Karl August in a battle against the French revolutionaries. In 1794 began Goethe's friendship—more literary and intellectual than personal—with Friedrich Schiller, which lasted until Schiller's death in 1805. Schiller was a sympathetic critic and he encouraged Goethe's work on *Faust*. It has been thought that Schiller's Kantian background stimulated Goethe's interest in Immanuel Kant, but Goethe was familiar with Kant's writings even before 1794.

While the political and social tumult of the Napoleonic era dominated the minds of his contemporaries, Goethe calmly concentrated his attention on optics and plant morphology. Perhaps as a result of Goethe's indifference to the popular causes of nationalism and democracy, his reputation declined somewhat, but the appearance of *Faust* (Part I) in 1808 and the psychological novel *Die Wahlverwandtschaften* (Elective affinities) in 1809 served to restore his stature. Some of Goethe's subsequent works were *Zur Farbenlehre* (Toward the theory of colors; 1810), which contains an extended attack on Isaac Newton's theory of light; *Dichtung und Wahrheit* (Poetry and truth, 1811, 1812, 1814, and, posthumously, 1833), a series of autobiographical essays; *Italienische Reise* (1816–1817), the record of his Italian travels; *Zur Morphologie* (1817–1824); and the second part of *Faust*, completed in 1831, just before his death. Goethe was buried in Weimar beside Schiller.

PHILOSOPHY

Although Goethe was not a systematic thinker and even asserted that philosophy only ruined him for poetry, he was aware of the philosophical and scientific tendencies and controversies of his time; and while he admitted his lack of a "proper organ for philosophy," he did not hesitate to express himself on numerous philosophical and scientific questions. In addition to specific essays and pronouncements, his poems and novels were often vehicles for expressing his intellectual convictions concerning God, man, and nature.

SPINOZA AND GOETHE. The influence of Benedict Spinoza on Goethe's overall *Weltanschauung* was considerable, although the importance of Kant, Gottfried Wilhelm Leibniz, and Friedrich Schelling is also evident.

Goethe first became slightly acquainted with Spinoza's philosophy while in Strasbourg, but it was in 1774 that his acquaintance with Friedrich Jacobi (who regarded Spinoza's views as the only rational philosophy) drew his full attention to Spinoza. Goethe's commitment to pantheism is often cited to show his agreement with Spinoza. Yet when Goethe himself spoke of his relation to Spinoza, he emphasized the ethical as much as the metaphysical doctrines of Spinoza and Spinoza's "all-harmonizing peace," which contrasted with his own restlessness. Spinoza's rejection of final causes and his defense of determinism and of the view that praise, condemnation, and regret are attitudes reflecting an inadequate understanding of inexorable natural processes were accepted by Goethe and given expression in *Faust* (especially in the opening scene of Part II). Goethe said that Spinoza's mathematical method was the opposite of his own poetic way of feeling and expressing, and that Spinoza's orderly treatment of moral questions made Goethe his passionate disciple and convinced admirer. He defended Spinoza against the charge of atheism and claimed (without slavish regard for accuracy) that Spinoza was the most theistic and Christian of philosophers, since for him all existence is God and thus no proof of God's existence is needed.

The central thesis of Spinoza's system, Goethe thought, was that the universe contains and expresses a creative force which appears as a duality (*Zweiheit*) but is in fact a unity. God is not simply the cause but the indwelling spirit of the world, the all-embracing actuality. Goethe, however, questioned Spinoza's contention that reason can attain an adequate knowledge of God-nature. We cannot comprehend this infinite whole, and when we attempt to do so, even in a limited way, we must use imagination and intuition, not the method of mathematics.

LEIBNIZ AND GOETHE. While Goethe's view of nature was, like Spinoza's, deterministic and nonteleological, his mystical feeling for nature was more akin to Schelling, and he resembled Leibniz in maintaining that everything in nature is in some sense animate (*Beseelt*). The universe consists of an infinite number of unique beings—Leibnizian monads—each alive and harmonious with all others. The essence of these individuals is activity and creativity. Goethe's knowledge of Leibniz was probably derived from Goethe's friend Johann Kaspar Lavater, the Swiss theologian who linked his theory of phrenology with the theory of Leibniz's monadology, and from the Earl of Shaftesbury, whose presentation of Leibnizian optimism involved the belief, so congenial to Goethe, that nature's physical beauty expresses the divine harmony.

KANT AND GOETHE. Goethe was inclined to take from philosophers whatever elements or fragments fitted his intuitions and feelings. Thus, while he found Leibniz's confident optimism appealing, he also praised Kant for destroying the popular optimistic teleology of common-sense philosophers who with Philistine wisdom sought to demonstrate that everything in nature exists to satisfy some human purpose. Goethe's enthusiasm for Kant was mainly based on Kant's *Critique of Judgment.* He was pleased with Kant's claim that nature and art both resemble purposive agents but pursue no external goal. He maintained also that art mediates between nature and freedom, since it is produced by the artist in conformity with principles that operate in nature as well.

Goethe, like many of Kant's contemporaries (including Moses Mendelssohn and Johann Gottfried Herder), had little understanding of the *Critique of Pure Reason*; and while he praised Kant's ethics, he rejected most of Kant's central claims. In particular, he denied the opposition of duty and inclination, reason and sensuality, and regarded Kant's Calvinistic notion of a radical evil in human nature as a sad regression toward Christian orthodoxy. Goethe also took exception to Kant's view of knowledge. He insisted that imagination (*Phantasie*) was an avenue to knowledge distinct from and supplementary to Kant's faculties of reason, understanding, and sensibility. Furthermore, Goethe held, men are capable of intellectual intuitions, and with such nonsensuous insights they may hope to penetrate the heart of nature.

SCIENTIFIC THEORIES

Goethe thought his scientific theories were as important as his literary works. The concepts of primal phenomena (*Urphänomen*) and primal polarity (*Urpolarität*) were central to his conception of the world and were the foundations for both his scientific studies and his conception of man and existence.

PRIMAL PHENOMENA. Nature's secrets can only be understood by discovering, through intellectual intuitions, her ideal: ground phenomena. In optics the primal phenomenon is the opposition or antipathy of light and darkness. This *Urphänomen* (which in this instance is also an example of polarity) is the goal and limit of a scientific investigation of light. In mineralogy and geology the *Urphänomen* is granite, which Goethe believed to be the base of Earth's crust.

In the organic realm there are primal shapes and modes of development that nature repeatedly uses, like a theme and variations in music. The same organ is trans-

formed manifoldly through metamorphosis. In plants the leaf is the organ that is varied to form all the parts of the plant. The study of the basic formations, morphology (*Gestalten*), would disclose the secret principles according to which nature operates. Seeking the primal image or idea by observing and comparing the metamorphosis of organisms, Goethe conjectured that a primal plant (*Urpflanze*), might be the basic model according to which all plants are patterned. This theory has sometimes been cited to show Goethe as a forerunner of the theory of evolution, but it is not at all clear that he believed in the historical evolution of species from a common ancestor. The doctrine of the *Urpflanze* is more Platonistic and, perhaps, mythical than Darwinian, Charles Darwin's reference to Goethe as a "path-maker" notwithstanding.

POLARITY. Goethe's distrust of mathematics and experimental instruments (such as prisms) was, unfortunately, great. He believed that numbers and equations only distort our vision of nature. Isaac Newton's physics was repellent to him; Newton's theory that white light contained the spectrum seemed to him absurd because light was an elemental entity, an inscrutable attribute of the world that could not be analyzed. Goethe attempted to explain the origin of color phenomena out of an original polar opposition of light and dark. If light and dark are mixed directly, the result is gray; but a "murky medium" (such as a prism, according to Goethe) produces a cooperation of the polar opposites, and this cooperation produces colors. The activity of the eye in color perception is explained by the rule that brightness is "demanded" when the eye encounters darkness. The perception of every color produces a "demand" for the complementary color.

Goethe used extensively the idea of polarity, of attraction and repulsion as basic cosmic forces. He explained the metamorphosis of plants in terms of the periodic alternation of contraction and expansion. Contraction (*systole*) produces specific differentiation; expansion (*diastole*) produces an "advance into the infinite." The importance of polarity is seen also in magnetism—another *Urphänomen*—and in the activity of the heart, the rhythm of life, and in man's moral activity where the good is brought into play by its contrary, evil. Schelling had said that there is no life without opposites, and Kant had claimed attraction and repulsion to be the only essential forces of matter. Goethe adopted these principles in both his science and his art. The whole of existence is "an eternal parting and uniting."

STRIVING. Polarity is one of the driving wheels of nature, and while Goethe's use of this idea may suggest a

cyclical view of life and history, his concept of gradation (*Steigerung*) is that of a constantly striving ascent. This upward striving Goethe believed to be a universal characteristic of nature. It discloses itself in the "higher intention" of every heavenly body and in the variations of similar organisms developing from a basic form. What Goethe meant by this is not very clear, but in *Faust* the idea is applied to man. Every man, said Goethe, innately feels an urge to strive upwards. This striving involves all his capacities, his creativity in every sort of action and experience. Faust's insatiable love of life and hunger for new experience are expressive of this natural longing.

RELIGION

Goethe early rejected positive religion. With Spinoza, he came to regard creeds and dogmas as irrelevant to the veneration of God-nature. Although Goethe was on friendly terms with many ardent Christians and although he even spoke at times of a providential God, he opposed the dogmatism of churches and theologians and regarded the idea of miracles as a "blasphemy against the great God and his revelation in nature." Since Goethe maintained that no set of concepts could be adequate to the unfathomable infinity of the divine, it is not surprising that his pronouncements concerning God are somewhat ambiguous and inconsistent. While the remark on miracles seems to imply a distinction between God and nature, this is, of course, not Goethe's usual position.

Goethe rejected asceticism and the tendency to devalue the physical in favor of a supernatural world. To Johann Kaspar Lavater he wrote that he could find a thousand pages of various books as lovely, useful, and indispensable to humankind as the Gospels. He claimed that he was unchristian rather than anti-Christian but declared the crucifix to be "the most repugnant thing under the sun." Although at one time he spoke of the Gospels as messages from God, he clearly did not intend this in the ordinary sense, since he held that God, being the inexorable order of nature, cannot have any personality or be in any sense outside the natural world. Thus God does not cause or control the world in the way that theists have believed. "What sort of God would it be, who only pushed from without?" (*Was wär' ein Gott, der nur von aussen stiesse?*, in *Weltanschauliche Gedichte,* 1815). The ambiguity (or richness) of Goethe's theology may be seen in what is perhaps his most famous remark on this topic: "We are pantheists when we study nature, polytheists when we poetize, monotheists in our morality" (*Wir sind naturforschend Pantheisten, dichtend Polytheisten, sit-*

tlich Monotheisten, in *Maximen und Reflexionen,* No. 807).

Since every man is part of nature and, hence, of the divine, he shares the basic impulses of all natural things—specifically, as already noted, the urge to develop upward and outward, the striving for an ideal. Action and striving are not only means to some static goal but are also ends in themselves. Since there is no goal for man apart from his life, man struggles, like Faust, with the fear of life (*Lebensangst*) and is tempted by care (*Sorge*). Some have argued that Goethe saw man's fulfillment in activity itself, but perhaps it would be more accurate to say that there is no fulfillment—contentment means annihilation—so that man is destined to be dissatisfied, unfulfilled, no matter what he achieves.

Bibliography

Goethe's writings are available in many editions, one of the standard being K. Burdach and others, eds., *Jubiläums-Ausgabe,* 40 vols. (Stuttgart and Berlin, 1902–1907). Goethe's most important works, except *Zur Farbenlehre* and *Beiträge zur Optik,* have been translated into English. Goethe's *Botanical Writings* were translated by Bertha Mueller (Honolulu: University of Hawaii Press, 1952) and by Agnes Arber as *Goethe's Botany; the Metamorphosis of Plants* (Waltham, MA, 1946). Of the dozens of English translations of *Faust,* recent versions by Bertram Jessup (London, 1958) and by Walter Kaufmann (New York: Doubleday, 1961) are sensitive. Kaufmann's version includes sections of Part II and has the German text facing the English.

For an account of *Zur Farbenlehre* and *Beiträge zur Optik,* see Rudolf Magnus, *Goethe als Naturforscher* (Leipzig: Barth, 1906), translated by Heinz Norden as *Goethe as a Scientist* (New York: H. Schuman, 1949), a very sympathetic account. A more critical discussion of Goethe's contributions to science is found in C. S. Sherrington, *Goethe on Nature and on Science* (Cambridge, U.K.: Cambridge University Press, 1942).

Many philosophers have written on Goethe (Wilhelm Dilthey, Georg Simmel, Max Wundt, Heinrich Rickert, and Fritz-Joachim von Rintelen, to name only a few), and some may be read in English: Ernst Cassirer, "Goethe and the Kantian Philosophy," in his *Rousseau, Kant, Goethe,* translated by James Guttmann and others (Princeton, NJ: Princeton University Press, 1945); Benedetto Croce, *Goethe* (Bari:

Laterza, 1919), translated by Emily Anderson (London, 1923); and the beautiful and perceptive chapter on *Faust* in George Santayana, *Three Philosophical Poets* (Cambridge, MA: Harvard University Press, 1922). Thomas Mann's essays on Goethe, which include discussions of Goethe's political views, are in his *Freud, Goethe, Wagner,* translated by H. T. Lowe-Porter (New York: Knopf, 1937) and in his *Essays of Three Decades* (New York: Knopf, 1947). Karl Viëtor, *Goethe the Thinker,* translated by B. Q. Morgan (Cambridge, MA: Harvard University Press, 1950), discusses Goethe's science and philosophy comprehensively. See also Fritz-Joachim von Rintelen, *Der Rang des Geistes* (Tübingen: Niemeyer, 1955).

Arnulf Zweig (1967)

GOGARTEN, FRIEDRICH
(1887–1968)

Friedrich Gogarten, the German theologian, was born in 1887 at Dortmund. After serving as a pastor in Thuringia, in 1927 he became professor of systematic theology at Jena and in 1935 moved to the corresponding chair at Göttingen. He was early associated with the new dialectical theology and its revolt against liberalism and idealism. Within this movement he stands nearer to Rudolf Bultmann than to Karl Barth, but he worked out a distinctive position of his own. His thought shows the influence of existentialist philosophy, but he claimed that it also continues the insights of Martin Luther, on whom Gogarten was a recognized authority.

Gogarten believed that Luther delivered Christian theology from the hold of metaphysics. This achievement was obscured in the period of Protestant orthodoxy following the Reformation, but it is now time to revive his insights, which can be restated in terms of current existentialist philosophy. According to Gogarten, the major Christian doctrines were formulated under the domination of metaphysical categories, in an age when history was understood as a process that takes place within a stationary metaphysical framework and when the course of history was supposed to be determined by metaphysical factors. Deliverance from metaphysics makes it possible to take history with a new seriousness. Man is responsible for history and creates it by his decisions. So far are we from having an obligation to interpret history in the light of metaphysics that we must rather view metaphysical systems themselves as products of history. Christianity is not dependent on any metaphysical system but is rather the summons to a historical self-understanding, in which we accept responsibility for our own historical existence under the word of God, which addresses us in Christ.

These emphases, which Gogarten relates as much to the *sola fide* of Luther as to modern existentialism, are developed into a secular interpretation of the Christian gospel. The Christian faith brings man to maturity and strips the world of every mythical or numinous property. The world is deprived of its religious power and is handed over to man as the son who has come of age, the heir to whom God has entrusted the creation. These views are related by Gogarten especially to the teaching of St. Paul in Galatians 4:1–11.

John Macquarrie (1967)

GOLDEN RULE

One early use of the word *golden* in English is "most excellent, important, or precious." With reference to rules or precepts it was used to mean "of inestimable value," and the expression "the golden rule" was often specifically used with reference to the precept in Matthew: "Therefore all things whatsoever ye would that men should do to you, do ye even so to them: for this is the law and the prophets" (7:12). Thus, the principle that has come to be known as the golden rule has been so called presumably

because it has been regarded as being of inestimable value or importance. This regard was not derived solely from the fact that it was set forth in the sermon on the mount. The golden rule has been widely accepted, in word if not in deed, by vast numbers of greatly differing peoples; it is a basic device of moral education; and it can be found at the core of innumerable moral, religious, and social codes. So far as can be determined from available records, it was probably first formulated by Confucius some five hundred years before Christ—"What you do not like when done to yourself do not do to others"—and the multitude of different formulations testify to its widespread acceptance and influence.

There is probably no principle which has been so widely accepted and remained so controversial. Nonetheless, the golden rule has been the subject of comparatively little philosophical discussion. It is usually mentioned, when it is mentioned at all, only in passing, and it has generally received more attention in theological and inspirational literature. However, there are signs of increasing philosophical interest in it.

One of its commonest formulations today is "Do unto others as you would have them do unto you." It is commonly supposed that there are significant differences between this, the positive formulation, and the negative formulation, "Do not do unto others what you would not have them do unto you," and that the positive formulation "marks a distinct advance" since it "prescribes positive services rather than mere abstinences" and "sets forth an ideal which is higher and therefore more difficult to realize." It can be argued, however, that this is an error resulting from faulty analysis and perhaps also from theological bias. In connection with a specific action or object of desire, there is a considerable difference between a positive desire, a desire to do it or have it done to oneself, and a negative desire, a desire not to do it or not to have it done to oneself. But in the abstract, so the argument runs, there is only a difference in formulation, and a want, wish, or desire formulated in negative terms can always be reformulated in positive terms. For example, there is no difference between not wanting others to lie to oneself and wanting them not to lie to oneself, wanting them to tell one the truth and wanting them not to fail to tell one the truth. In general, "*A* wants *x* to happen" is equivalent to "*A* does not want *x* not to happen," and "*A* does not want *x* to happen" is equivalent to "*A* wants *x* not to happen." Thus, according to this line of argument, every desire formulated negatively, which would come within the scope of the negative golden rule, can be reformulated positively and will then come within the scope of

the positive golden rule. It would follow, then, that there is no logical or moral difference between the negative and positive formulations, only a psychological or rhetorical one.

On either account the negative formulation of the golden rule is to be distinguished from the denial of the golden rule: "Do not do unto others as you would have them do unto you." Obviously, this is not a formulation of the golden rule at all but is, rather, its total rejection. The denial of the golden rule is usually supported by the claim that the golden rule presupposes a uniformity of human nature, in the sense of a uniformity of tastes, interests, needs, and desires, and the attendant claim that there is no such uniformity. One way of meeting this objection is to deny that the golden rule involves any such presupposition. It has been argued that it is necessary to make a distinction between the particular interpretation and the general interpretation of the golden rule. The particular interpretation implies that whatever in particular one would have others do to or for him, he should do to or for them. It is in the particular interpretation that, to take some of the standard objections, the golden rule "authorizes the quarrelsome person who loves to be provoked, to go about provoking others, and the person who hates friendliness and sympathy to be cold and unsympathetic in his dealings with others" (L. J. Russell). But these consequences, it has been claimed, do not follow from the general interpretation. On this interpretation what one has to consider is not what in particular one would have others do to or for oneself but, rather, the general ways in which one would have others act in their treatment of oneself. If one abstracts his general wishes from his particular desires, what one would have others do is to take account of his interests, needs, and desires, which may be quite different from theirs, and either satisfy them or not willfully frustrate them. What the golden rule requires a person to do, then, is to take account of the wishes of others and accord them the respect and consideration he would want them to accord to his. In other words, what the golden rule requires of each of us is that we should treat others in accordance with the same principles or standards that we would have others apply in their treatment of us. Thus, the golden rule, if this argument is sound, is compatible with differences in interests, needs, tastes, wishes, and desires and does not presuppose that human nature is uniform in the sense specified.

Another principle which should be distinguished from the golden rule is what might be called its inversion: "Do unto others as they would have you do unto them." The inversion of the golden rule has received some sup-

port, and it has even been urged that it replace the golden rule as a guide to conduct, mainly as a consequence of the same sort of objection as the distinction just outlined is intended to eliminate. It has been claimed that the inversion of the golden rule has "the merit of stressing the need for an understanding of other people as a basis of our behavior toward them" and does not presuppose any uniformity or identity of nature in the beings it is intended to govern.

One counterargument to this is that the implications of the inversion of the golden rule are more absurd than the alleged implications of the golden rule itself and that it is tantamount to a rule that would require everyone always to do whatever anyone else wants him to do, a rule it is impossible to follow in a world of conflicting interests. Once it is recognized, the argument runs, that the "uniformity of human nature," in the sense of an absolute identity of interests, needs, and desires, is not a presupposition of the golden rule, any temptation to substitute the inversion of the golden rule for the golden rule itself should disappear. For in its general interpretation the golden rule does require us to take account of and accord respect to the differing needs, interests, and desires of others, and it is just this that the inversion of the golden rule is intended to bring about. However, the question remains whether the inversion of the golden rule cannot be rescued from at least some of the more obvious objections to it by means of a distinction similar to that made between the particular and the general interpretation of the golden rule.

In the course of time a number of anomalous interpretations of the golden rule have found strong support. On the one hand, it has been said that the golden rule comprehends all the requirements of morality in a single formula; on the other, it has been said that the golden rule is only a guide, that it is far from complete, that it requires rules, a sense of justice, or even a whole system of morality for its proper interpretation and application. Again, the golden rule has been said to be not only consistent with but actually to comprehend all of utilitarianism; it has also been said to provide just that element, the requirement of justice or fairness, that is alleged to be most lacking in a utilitarian theory. On this interpretation the golden rule is regarded as being the basis of justice, sometimes also the basis or equivalent of Immanuel Kant's categorical imperative. Finally, it has been claimed that the golden rule is a perfect guide to conduct and that the only thing needed to make the world perfect is for everyone to follow it; at the same time it has been claimed

that the golden rule leads to paradoxes and is misleading, false, or absurd.

Each of the points and issues mentioned here is discussed, more or less adequately, in one or more of the sources listed in the bibliography. But no one has yet dealt satisfactorily with the question of why this precept should have appeared in the codes and outlooks of so many diverse peoples and sages. The golden rule, in one version or another, has a prominent place in all the major religions and most minor ones; it has been enunciated by pagan philosophers both before and after Christ and by Sophists (Isocrates) and anti-Sophists (Aristotle). There are no detectable historical traces that could explain this, and the historical diffusion theory is worthless as an explanation here. The nearly universal acceptance of the golden rule and its promulgation by persons of considerable intelligence, though otherwise of divergent outlooks, would therefore seem to provide some evidence for the claim that it is a fundamental ethical truth.

GOLDMAN, ALVIN
(1938–)

Alvin Goldman, an American philosopher, is best known for his contributions to epistemology, philosophy of mind, and related fields. His first paper, "A Causal Theory of Knowing," (1967, reprinted in *Liaisons* 1992), defends the view that an individual S knows a proposition p just in case p is causally related in the right sort of way to the individual's belief that p. Thus, for example, Sam knows that there is a cat on the mat because Sam is looking at the cat, and the fact that the cat is on the mat caused Sam to have that belief. This kind of account of knowledge breaks with the tradition that identifies knowledge with some sort of justified, true belief. While Goldman's account requires that a belief be true if it is to count as knowledge, the requirement of justification is replaced

with a requirement that highlights the importance of the causal ancestry of the belief. Goldman further develops this view in "Discrimination and Perceptual Knowledge" (1976) and "What Is Justified Belief?" (1979) (both reprinted in *Liaisons*), coming to hold, in the latter paper, that knowledge does indeed require justification, where justification is to be identified with reliably produced belief rather than with any kind of ability to produce an argument, as traditional accounts require. This style of account has come to be known as "externalist" (because the factors in virtue of which a belief is justified may be external to the knower's mind), and is opposed to the more traditional "internalist" accounts on which the features in virtue of which a belief is justified are ones to which the knower inevitably has cognitive access. Goldman develops this view in tremendous detail in a series of papers, and ultimately in *Epistemology and Cognition* (1986).

Whereas Goldman's account of knowledge is offered as an analysis of the concept of knowledge, the substance of his account places a great deal of stress on the relevance of empirical work to epistemological issues. Thus, Goldman's approach prompts him to investigate the various psychological mechanisms by which belief is produced because it is upon the reliability of these mechanisms that people's status as knowers depends. This concern with the ways in which empirical work—and especially work in the cognitive sciences—may be brought to bear in advancing human understanding of traditional philosophical issues is characteristic of Goldman's work generally; his work in this area constitutes the most sustained development of naturalistic epistemology available.

Although his early work was concerned with the philosophy and psychology of individual cognition, Goldman has gone on to make seminal contributions to social epistemology. The mechanisms by which beliefs are produced and sustained include not only those inside the knower's head, but features of the social organization of the knower's epistemic community. In *Knowledge in a Social World* (1999), Goldman investigates the ways in which social structures may either contribute to, or interfere with, the discovery and dissemination of truths. This project includes work on the epistemology of testimony and argumentation, the social structure of scientific investigation, and the epistemology of education. Additionally, Goldman addresses questions about democracy, government regulation of speech, the role of truth in legal proceedings, and the economics of communication—all topics illuminated by his epistemological approach.

Goldman has also made important contributions to the philosophy of mind, especially in his elaboration and development of the "simulation" account of mental state attribution. A standard approach to mental state attribution, now known as the "theory-theory," sees human attribution of mental states to others as the product of theory construction. On this view, when one forms the belief that Jack will want the university president to resign, that person's belief about Jack's desire is derived from beliefs held about Jack's other mental states, together with theories the person holds about the laws governing interactions among mental states. On the simulation view, however, attribution of mental states does not derive from theory construction and need not involve any beliefs about psychological laws or regularities. Instead, the processes by which one's own mental states interact are brought to bear on the task of mental state attribution, being used to simulate the workings of the process by which the target mental state was produced. Goldman's *Simulating Minds: The Philosophy of Psychology, and Neuroscience of Mindreading* (forthcoming) develops this view in detail. He assembles evidence from psychology and especially neuroscience of low-level, automatic processes that mimic, mirror, or resonate with those of an observed other. Such processes play a crucial role in the facial mind-reading of emotions, for example. On the topic of the self-attribution of mental states, Goldman defends an introspectionist approach—in contrast with other simulationists. Elsewhere, he defends introspection as the basis for relying on subjects' verbal reports in the science of consciousness.

In his first book, *A Theory of Human Action* (1970), Goldman defended a fine-grained approach to the ontology of action and illuminated the relationship between determinism and fatalism. He has also explored the interface between metaphysics and cognitive science.

GONGSUN LONG
(320–250 BCE)

Gongsun Long was a logician in ancient China and a representative figure of the School of Names (*Ming-Jia*). What distinguishes Gongsun Long's work is his in-depth investigation into the relation between names and reality through conceptual analysis and rational argumentations. His thoughts are delivered in the *Gongsun Longzi*. Three brief essays in the text, "On the White Horse," "On Referring to Things," and "On Hardness and Whiteness," are considered most important in understanding his thoughts. The first one is considered the most philosophically interesting and influential in view of its substantial philosophical points, its articulate character of rational argumentation, and its sophistication.

Gongsun Long's well-known thesis "[the] white horse [is] not [the] horse" (*bai-ma-fei-ma*) is supported by several articulate arguments in the essay "On the White Horse." Modern scholars elaborate their substantial contents and philosophical significance through seemingly competing interpretations. Fung Yu-lan (1952–1953) renders Gongsun Long a Platonic realist; he considers that all of Gongsun Long's arguments are intended to argue that "white horse" and "horse" represent two distinct Platonic universals and thus the universal of white-horseness is not (identical to) the universal of horseness. One criticism is that Fung seems to impose his Platonic realist reading on the thoughts of a figure in the Chinese tradition whose general mentality and language characteristics have not tended to nourish a Platonic outlook of the universe.

Janusz Chmielewski (1962) takes a set-theoretic line: "white" and "horse" are used to denote distinct classes, and "white horse" denotes the intersection of the two classes, which is an empty class, instead of a subclass of either of the two classes. One major difficulty with Chmielewsky's interpretation is that it obviously deviates from the original text in which Gongsun Long clearly indicated that there are white horses.

Chad Hansen (1983) proposes a radical shift of interpretation based on mereology (part-whole logic) and his mass-noun hypothesis: The term "white horse" is a mass noun and refers to a mass *sum* whole of horse-stuff part and white-stuff part, distinguishing it from a mutually pervasive compound, like hard-white, that is a mass *product*; the whole of white part and horse part is not its horse part. Angus C. Graham (1990) endorses Hansen's mereological interpretation though without being committed to the mass-noun hypothesis. The Hansen-Graham radical mereological interpretation is to bypass class-member relation but resorts to whole-part division alone. Nevertheless, an interpretation that renders Chinese thinkers short of conceptual abstraction intrinsically involved in member-class relation is questionable.

The previous interpretations share one feature: Their interpretations of the semantic reference of those common nouns like "white horse" and "horse" seem to variously derivate from the semantic structure as embedded in actual language practice, in which Chinese common nouns are normally used to denote (a collection of) particular things (including particular properties) via their conceptual contents. A modest mereological interpretation with a collective-noun hypothesis might be reasonable for the sake of capturing the semantic structure. That is, (1) the denotational semantics and deep structure of Chinese common nouns are like those of collective nouns; their implicit ontology is a mereological one of collection-of-individuals with both part-whole structure and member-class structure. (2) The denotation of "white horse" is neither a Platonic universal nor a sum of horse stuff and white stuff nor an empty set, but a collection of white horses. (3) The collection of white horses is both a mereological whole and a class; the part-whole relation here is also the relation between subclass and class that accommodates conceptual abstraction and can be specified in terms of Fregean sense. From this point of view Gongsun Long argues for the thesis that what "white horse" denotes (the collection of white horses) is not identical to ("*fei*") or differs from ("*yi*") what "horse" denotes (the collection of horses) in view of their distinct conceptual contents, distinct extensions and ddistinct necessary-identity-contributors.

Although Gongsun Long emphasizes distinct aspects of things, he does not ignore common aspects and connections of things and thus explicitly indicates, "It is when what is pursued is their common aspect that the white horse [as a subclass] is [is included in the class of] the horse" The previously mentioned class-mereological nature of the denotation of collective nouns allows a flex-

ible shift between the identity-relation and the class-inclusion relation between two collections, depending on whether the speaker's focus is on distinct aspects or on common aspects of things: The point of the referring subject's focus shift is related to one central point made in his essay "On Referring to Things": those relevant contributing elements involved in the referring subject's act of referring via a name (such as her purpose or focus) make their intrinsic contributions to the identities of things that are referred to.

In "On Hardness and Whiteness" Gongsun Long investigates the metaphysical status of properties themselves like hardness and whiteness, which are mutually pervasive in the hard white stone, by examining their separability. He thinks that the property itself, say, hardness, can stand alone in the form of *zi-cang* (being self-hidden) but also maintains that "there exists no such hardness in the world [except of its manifestations in particular things]" (the author's translation). The question is this: How could the property per se be self-hidden, in some realist way or in some conceptualist way or in a radical nominalist way? The text of that essay seems to be open to distinctive interpretations. This is a controversial issue that needs to be examined in the context of Gongsun Long's whole thought.

Bo Mou (2005)

GOOD, THE

For many evaluative terms it is useful to distinguish, following John Rawls, between concepts and conceptions of them; for instance, on the one hand there are questions about what it means to be good, on the other there are questions about which specific things actually are good. This distinction helps explain why many evaluative terms allow much more disagreement than other terms; two people can agree about what it means to be good (concept) and still disagree entirely about which concrete things are good (conceptions), whereas people could hardly agree on what it means to be, say, a knife and still widely disagree about which objects are knives.

Although it is not a distinction drawn by all moral philosophers, this split between concept and conception does set its mark on the literature in the sense that there are two main lines of inquiry about the good: inquiry into the meaning of good and inquiry into which things actually are good. Interest in the first question became prominent in the wake of the publication of G. E. Moore's *Principia Ethica* in 1903; with it moral philosophy took a turn toward conceptual analysis. When it comes to conceptions of the good there have been extensive discussions ever since antiquity and there are primarily two types of goodness that have been the focus of most of them, the prudentially good and the morally good (i.e., what constitutes a good life and what it takes to be a good person).

THE MEANING OF GOOD

Moore claimed that good is indefinable, that it is a simple, nonnatural property. He accused several of his predecessors of having committed what he called the naturalistic fallacy in trying to spell out what it meant to be good. His main argument was that of the open question: For any proposed analysis of good, it would seem that one can ask "But is x good?" and the openness of that question shows that the analysis has not succeeded. It is uncertain whether the philosophers discussed by Moore really had proposed analyses of good rather than simply presented conceptions of the good and it is difficult to find unambiguous examples of theories that are naturalistic in Moore's sense of the word. Nevertheless, Moore did set the agenda for the attempts at analyzing good that have since then followed.

Moore himself is not always clear about whether he discusses the concept of good or the property to which this concept refers. This can make an important difference. If one thinks that the reference is determined by the property or properties that a concept causally tracks, then they can see that, even for normative concepts, there is the possibility that they ultimately refer to natural properties even though they cannot a priori be analyzed in such terms. This kind of naturalism, so-called Cornell realism, was developed in the 1980s by David Brink and others and according to it there is nothing peculiar about the open question being open because the identity involved is synthetic, not analytic.

But there are also other alternatives. Around the same time that Moore developed his theory of the good, Franz Brentano (1969) developed an analysis of good that occupied a halfway point between Moore and naturalism. Moore contended that good was a simple, nonnatural quality; Brentano claimed that it was a complex, nonnatural property, that to be good was to be worthy of love. This kind of position was later elaborated in more detail by A. C. Ewing (1947), who claimed that to be good was to be a fitting object of a pro-attitude. He also thought that different types of goodness could be differentiated through kinds of pro-attitudes, so it was a theory that tried to capture an essential unity of good but also make sense of the variety of uses that good is put to. It is however not an analysis without problems; above all, the key notion of fittingness was not given a satisfactory elucidation by Ewing. Later philosophers, such as Thomas Scanlon (1998) with his buck-passing analysis of value, pursue a similar project, albeit framed in terms of reasons for pro-attitudes rather than the fittingness of them.

The largely Moorean approach of focusing on the meaning of particular evaluative notions was however out of fashion from the 1930s through to the 1960s. The dominant approach to ethical language then was instead non-descriptivist. This is an approach according to which the function of ethical language is not to describe a realm of values and norms, but rather to express sentiments or, as in the best worked-out version of this approach, namely that of Richard Hare (1952), to issue prescriptions. Thus, non-descriptivist analyses of evaluative language do not really provide analyses of the meaning of notions like good, rather what they provide is analyses of what it means to say or judge that something is good. And because ethical judgments appear to have a strong connection to action and motivation, one should perhaps doubt whether predications of good really work essentially like predications of round.

However, even if non-descriptivists eschewed talk about objective evaluative properties, it should be made clear that the position was not as such nihilistic. Rather, what these theories often did was to show that ethical

judgments could make sense even if there really were nothing in the world for them to be about. Hare especially argued at length that one could discuss moral matters rationally even though moral discourse was not descriptive. One problem, however, was that non-descriptivists tended to build their accounts on analyses of asserted evaluative judgments, but talk of good and similar notions does not just consist in that. Evaluative notions can also be embedded in nonevaluative claims, for instance, in conditionals such as "If Peter is good, then Mary is also good." When trying to explain how such sentences function even in very simple forms of deductive reasoning, non-descriptivists tend to be driven to suspiciously complex analyses. The popularity of non-descriptivism has waned considerably since its heyday, although new and sophisticated versions of the theory have been presented after that, most notably by Allan Gibbard.

THE UNITY OF GOOD?

When Brentano proposed his analysis of good it was with the intent of showing the essential unity of good. Many other philosophers have simply taken it for granted. However, even if there is one word that is used in a variety of contexts, that does not necessarily mean that a single concept is being dealt with. Some philosophers, such as Peter Geach (1956), have suggested that one needs to distinguish between a predicative and an attributive use of good. Take a sentence such as "X is an A B." If A is used predicatively, then this sentence can be split into "X is A" and "X is a B"; if this is not possible, then A is used attributively. The sentence "Jill is a dark-haired woman" can be split into "Jill is dark-haired" and "Jill is a woman," whereas "Jill is a tall woman" cannot be split that way. The difference is that there is no way of ascertaining whether Jill is tall without taking into account that she is a woman; it is qua woman that she is tall.

When it comes to goodness, judgments such as "that is a good knife" are clearly attributive, whereas judgments such as "that was a good event" seem predicative. Both uses of good have been prominent in the history of ethics, although some (like Aristotle) have leaned toward the attributive and others (like Moore) toward the predicative. Geach himself contended that, when it makes sense, good is always an attributive adjective; nothing is ever simply good. Relatively few philosophers have followed Geach in taking this stance although the distinction still highlights an important disunity of good. This can be seen if one compares good to valuable. The predicative use of good roughly corresponds to valuable, whereas attributive goodness has a much looser connection to

value. For instance, if Jill shoots Jack in the head from a long distance, one might think that it was a good shot without finding the event valuable in any sense.

Although the distinction between the attributive and the predicative concerns good as a concept, it is also the case that when it comes to conceptions of the good, philosophers have tended to take different positions depending on how they have tended to use good. The advantage with attributive uses of good is that they hold the promise of naturalizing the good, thereby rendering its place in the world less mysterious, and this has led some, such as Philippa Foot (2001), to develop ethical theories in terms of the attributive good. The problem with such an approach is just that when it comes to the particular natural kind that is of most interest for ethical matters, namely that of human beings, it is very unclear whether there is any ideal way of leading a human life that one can simply distill from an understanding of what it is to be a human being similar to how one can know what is to be a good knife through an understanding of what is to be a knife.

CONCEPTIONS OF THE PRUDENTIALLY GOOD

The question of what is involved in leading a good life is one of the oldest in philosophy. And although there are many different theories about what is good for people, there are two main traditions of thought on the issue running through the history of ethics. The first is hedonism, the theory that what ultimately makes up a good life is pleasure or enjoyment. The second is perfectionism, that what ultimately is good for a person is to flourish as a human being. Of course, these two traditions do not exhaust the possibilities, but they stand apart in sharing an important strength, namely that they do not simply list a handful of things that are supposed to be good; they also provide an underlying idea about the point of it all. In the case of hedonism there is the appealing thought that if something is to be good for people, then it must feel good to them. In the case of perfectionism, there is another appealing thought, namely that as a human being, one has certain potentials and that it is a waste of one's life if one does not realize them. These two lines of thought do however pull in opposite directions, the first in a subjective one and the second in an objective.

Although there were philosophical schools during antiquity that tended toward hedonism (the Epicureans and, more clearly, the Cyrenaics), perfectionism dominated ethics during that time. As already noted, there was a tendency during antiquity to use good attributively: To

lead a good life is to excel at being a human being. Thus, to understand what the good life consists in, one must understand what lies at the heart of a distinctly human existence. The standard answer was that the exercise of reason was what lifted humans above the level of animals. For instance, Aristotle argued that rational thought was the function, or characteristic activity, of human beings and that, therefore, it must define wherein our good lies.

There are certainly problems with perfectionism having to do with its objectivist slant (what if one really does not want to achieve their potential but do other things instead, where does their good lie?), but the most significant worry is a metaphysical one. Does not perfectionism require a teleological conception of human nature and has not such a conception been put to rest by science? There are modern attempts to address this issue, one of the more interesting being Alasdair MacIntyre's (1984) attempt to understand humans as social beings and partly derive the contents of a good life from the social practices in which humans are embedded; but this remains a difficult issue for perfectionists.

Hedonism, by contrast, had its most prominent exponents in British moral philosophy of the 1700s and the 1800s. Its most emphatic proponent was Jeremy Bentham, although the version that has generated most discussion is that of John Stuart Mill (1998), who argued that there is a qualitative dimension to be considered when judging the value of pleasures: The pleasures of poetry are superior to the pleasures of pushpins. This can thus be seen as an attempt at a hybrid theory, introducing perfectionist elements into hedonism. Hedonism of all forms is however plagued by problems that are rooted in its subjectivist nature.

Say that two people lead lives containing equal amounts of pleasure or enjoyment, but in one of them the pleasures are all based in the subject's delusions; in that case it seems fair to say that the other life is at least somewhat better. So even if pleasure is a very important good, it can reasonably be doubted whether it really is, as hedonists would have it, the only one. Although there are later hedonists, a good example being Fred Feldman (2004), trying to address these problems, the second half of the twentieth century has seen those philosophers who are drawn to subjectivist conceptions of the good life largely abandoning hedonism for theories that emphasize the fulfillment of our preferences instead: One leads a good life when what one wants is realized. This has the advantage of involving the way things really are, but it is accomplished at the cost of moving away from the emphasis on how things feel that provided such an attractive rationale for subjectivist theories to begin with.

CONCEPTIONS OF THE MORALLY GOOD

In antiquity the standard conception of being a good person was to have the four cardinal virtues: wisdom, justice, courage, and temperance. Philosophers tended to conform roughly to this view. Aristotle was a notable exception and presented an extensive list of virtues. His theory is also original in that while many place virtue and vice as opposite poles on a moral spectrum, Aristotle conceived of virtue as a mean lying between two vices, one of deficiency and one of excess. It should, however, be pointed out that even if the ancients tended to list a number of traits as constituents of moral goodness, a common idea among them was that of the unity of the virtues, that one either has all the virtues or none. This is a controversial idea because many would say that it is quite possible, for instance, to be courageous without being just. Adherents of the unity thesis would respond that persons cannot really be deemed courageous if they do not have a fair appreciation of what is at stake—and for that they need to have all the virtues. Terrorists might be prepared to sacrifice their lives, but that alone does not make them courageous.

Although there was a renewed interest in the virtues, particularly in Aristotelian virtue theory, toward the end of the twentieth century, modern philosophers have focused more on the question of which actions are right than on what constitutes a good person. Kantianism is probably the modern moral theory with the best articulated vision of moral goodness. For Kant it is the will rather than character that is the potential bearer of moral goodness. And whereas for Aristotle one cannot be a good person unless acting well comes naturally to them—indeed, he even thinks that it is a mark of good persons that they take pleasure in acting well—for Kant virtue is essentially about self-control, about having moral determination.

This does not preclude that one takes pleasure in acting well, but the true test of virtue occurs when things do not come naturally: Does one then still put morality above their own inclinations? Kant also sharply distinguished between the moral and the prudential. This is very common among modern philosophers, whereas ancient philosophers often saw the virtues as constitutive parts of the good life. This tendency has led some philosophers, such as Bernard Williams (1985), to question whether the idea of a sui generis category of the

moral is not a modern artifice, thus partially echoing Friedrich Nietzsche's complaints about how the evolution of morality has involved a turn from a positive striving after excellence to a negative, prohibitive ethic of self-diminishment.

ETHICAL THEORIES AND THE GOOD

A common way of distinguishing ethical theories (i.e., theories of what one ought to do) with respect to the role played by the good in them is into teleological and deontological. This distinction was introduced by J. H. Muirhead (1932). In teleological theories actions are right because of the way that they contribute to the good, either, as is the case in utilitarianism, because it contributes to the common good or, as is the case in self-realization theories like those of ancient virtue theorists or Hegelians such as F. H. Bradley (1927), because it contributes, or is at least ultimately connected to, the agent's flourishing. Deontologists reject this direct link between the right and the good. In its simplest form, exemplified by W. D. Ross (1930), a deontological theory simply consists in a set of moral rules that are to be obeyed. Indeed, one main worry, voiced by Muirhead as well as others such as J. J. C. Smart (1973), about deontological theories is precisely that they inculcate almost a form of blind rule worship: One just obeys certain rules because they are the rules one should obey.

As a general charge against deontological theories, this is unfair. There can still be an underlying rationale in terms of the good; it is just that it does not take such a direct form. The most sophisticated form of deontology is probably Kantian ethics and while it is true that moral rules are given another kind of justification in Kant (in terms of what reason demands of one as an agent), he does still provide a picture of the place of morality in the life of a human agent, namely that it is a condition of the value of one's well-being: If one is not moral, one cannot reasonably view one's self as worthy of happiness. And in liberal rights theory it is a common idea that the rationale for the basic principles of right is provided at least in part by the fact that there is such widespread disagreement about the good: In the face of such disagreement certain principles of right make sense because they enable people to live together and pursue their own private conceptions of the good. It might even be seen as a weakness of teleological theories that they require that a conception of the good be spelled out in order to make it possible to tell right actions from wrong ones. A variety of teleologists, especially in the utilitarian tradition, have of course proposed a number of such conceptions, but none of

them have won wide assent and there seems to be little reason to see such assent as forthcoming. In light of that, some might see deontology as a more viable approach.

GOODMAN, NELSON
(1906–1998)

Nelson Goodman, the distinguished American philosopher of science and language, was born in Massachusetts in 1906. He received a bachelor of science degree from Harvard in 1928 and took his Ph.D. in philosophy there in 1941. After an instructorship at Tufts College (1945–1946), he was appointed associate professor at the University of Pennsylvania (1946–1951) and then professor (1951–1964). From 1964 to 1967 Goodman was the Harry Austryn Wolfson professor of philosophy at Brandeis University. In 1967 he became a professor of philosophy at Harvard. He died in 1998.

Goodman's delineations of certain strategic problems in epistemology, philosophy of science, and constructional methods, as well as the results of his own inquiries, are fundamental in the areas in which he worked. Specifically, these include theories of inductive logic or confirmation, problems concerning the nature of causal or lawlike regularity, theories of the structural or logical simplicity of theories, and constructions of linguistic systems within which philosophical problems may be solved, as well as theories of the adequacy or accuracy of such systems. Because of his achievements any further significant contributions to these areas may be expected to rest, in some measure, upon his work.

In this brief compass no attempt will be made either to give a comprehensive account of Goodman's ramified views or to rehearse in full detail any one of his major achievements. Instead, we will give an account of a few aspects of his major contributions in just sufficient detail to make their general import intelligible and to show something of their interconnections.

Our order of presentation of topics is quite independent of their chronology in Goodman's philosophical development. We begin with those of his important studies with which there appears to be widest familiarity.

INDUCTIVE THEORY

One of Goodman's characterizations of the task of inductive theory is that it consists in "formulating rules that define the difference between valid and invalid inductive inferences." On this usage a set of rules for discriminating valid acceptances or nonacceptances of hypotheses from those which are invalid constitutes an inductive theory, or, alternatively, a theory of confirmation or a theory of projection.

Goodman's contribution to the provision of such inductive canons has been threefold. First, he provided an analysis of the character of philosophical problems about induction. Second, he furnished a critique of the problems still to be solved and of the versions of confirmation theory which have been at all fully elaborated (notably those of Rudolf Carnap and Carl Gustav Hempel; see *Fact, Fiction and Forecast,* especially pp. 24–34, 48–51, and 68–86, and also the published exchanges between Carnap and Goodman to which reference is made on p. 86). Third, he made advances, explicitly in the form of a discussion of a *theory of projection,* toward the solution of some of the problems thus delineated. Where *induction* is construed narrowly as inference about future cases on the basis of examined cases, *projection* is, by contrast, inference about any unexamined cases on the basis of examined ones. We will consider each of these three aspects of his contribution in turn.

THE "PROBLEM OF INDUCTION." Goodman argues that the so-called problem of induction, when it is construed as the problem of *justifying* induction, is one that may be "dissolved" as soon as we see what is at issue. Moreover, this "dissolution" highlights all the more clearly the bona fide problem that he calls the new riddle of induction. As he sees it the problem is not to justify induction but to be able to distinguish valid from invalid inductions. On Goodman's view the dissolution of the *old* problem of induction, that is, of the problem of justifying induction, is accomplished when we come to understand that a genetic or descriptive account of our inductive behavior, such as the one that David Hume *almost* brought off, furnishes the basis of such a justification. That this is a cogent view, he points out, can be seen when we raise the question of justifying *deduction.* How do we justify a deductive inference? By showing that it conforms to specific logical rules of deduction. By the same token, an inductive inference can be justified by showing that it conforms to a specific rule of induction.

One may immediately ask, however, what justification we have for adopting a set of rules of induction as valid. Of course, the same question might be asked concerning a set of deductive rules. The answer may be indicated by furnishing a parable.

Consider the situation of an imaginary philosopher to whom we may give the name "Aristotle." Aristotle has a keen interest in the area of deductive inference. In this area, he finds that although there is *already* an established practice among humans of making deductive inferences and although there is *already* a practice of discriminating,

among ostensible inferences of this type, those that are correct from those that are not, nevertheless no one has yet made explicit or systematically codified the implicit rules upon which such discriminations appear to be based.

Our imaginary philosopher decides to undertake this task and eventually comes forward with such a codification. Using his codification people are enabled to make explicit their reasons for discriminating valid from invalid deductions by referring to the explicit rules that Aristotle has placed conveniently at hand. Of course no one would have paid any attention at all to these rules if they did not, with fair accuracy, reflect established practice—this is indeed what constitutes their validity as a set of rules. In the course of many years, however, other philosophers come forward to point out anomalies in Aristotle's set of rules. They point out that in certain cases some of his rules yield unacceptable inferences, and these philosophers suggest amendments which will remove the anomalies. When the amendments are incorporated they, in turn, have the effect of modifying practice. As Goodman puts it:

> [Deductive] inferences are justified by their conformity to valid general rules, and … general rules are justified by their conformity to valid inferences. But this circle is a virtuous one. The point is that rules and particular inferences alike are justified by being brought into agreement with each other. A rule is amended if it yields an inference we are unwilling to accept; an inference is rejected if it violates a rule we are unwilling to amend. The process of justification is the delicate one of making mutual adjustments between rules and accepted inferences." (*Fact, Fiction and Forecast,* p. 67)

If we return our attention to induction we see that an analogous situation obtains. Particular inductive inferences are justified by reference to rules of induction, and rules of induction are justified by reference to particular practices of inducing. Hume was on the right track in giving a descriptive account of inductive practice and in explicating rules of causal inference that he held to be in conformity with this practice. Those who have criticized him for this have been wrong.

We are thus quits with the old problem of induction, but the new, very formidable "riddle of induction" still remains. For although Hume was right in turning to description of actual practice, his description was insufficiently precise. He pointed out that observed regularities give rise to habits of expectation and that predictions based on such regularities are "normal or valid." But the defect in Hume's account, Goodman shows, lies in his failure to note "that some regularities do and some do not establish such habits; that predictions based on some regularities are valid while predictions based on other regularities are not. … To say that valid predictions are those based on past regularities is thus quite pointless" (ibid., pp. 81–82). Accordingly, the new riddle of induction consists in finding a set of rules of inductive logic that will do for us what Hume failed to do. Thus, the problem is not to justify induction but adequately to codify it. An adequate codification would presumably stand to inductive practice very much as the codification of deduction, accomplished by our mythical Aristotle, stood to deductive practice as described in our parable above. In particular, it would presumably consist of a set of rules the appeal to which would serve to validate specific acceptances or rejections of scientific hypotheses or theories.

CRITIQUE OF CONFIRMATION THEORY. In "The Problem of Counterfactual Conditionals" (reprinted without major change as Chapter 1 of *Fact, Fiction and Forecast*) Goodman was able to show that a solution to the problem of achieving an adequate interpretation of counterfactuals is intimately connected with many of the other crucial questions of the philosophy of science and that such a solution could be achieved only if various critical questions about the nature of scientific laws and of confirmation theory could be answered.

He shows, in particular, that the problem of furnishing adequate criteria for distinguishing true from false counterfactual conditionals has as a constituent the problem of adequately defining "scientific law," that this requires us to distinguish those hypotheses which are *confirmed* by their instances from those which are not, and that this, in turn, requires the fashioning of an adequate theory of confirmation. It is together the burden of the last part of "The Problem of Counterfactual Conditionals," of two brief articles on confirmation theory and of several passages in Chapter 3 of *Fact, Fiction and Forecast* that extant confirmation theories are defective, for they provide no means (except such as vitiate the theories through question-begging stipulations about what primitive predicates may be comprised in confirmable hypotheses) to distinguish the hypotheses to which such theories may be applied. Goodman, for example, points out that extant provisions of criteria for what constitutes a confirming instance in such defective theories either have the consequence that "any statement will confirm any statement" (ibid., p. 81) or make question-begging assumptions, mentioned before, about the recognizability

of "purely qualitative predicates" which are held to be the only permissible ones that may occur in (thus distinguishable) confirmable hypotheses. He shows, in short, that a desideratum of theories of confirmation is a definition of "confirmable hypothesis." In the final chapter of *Fact, Fiction and Forecast* he attempts to fill this need through advances on the problem of defining "projectible" as a predicate of hypotheses.

THEORY OF PROJECTION. In earlier discussions Goodman had shown that certain dispositional terms (other than *projectible*) may be adequately defined by *projecting* them over the extensions of (that is, by defining them in terms of) certain carefully specified nondispositional or *manifest* predicates. Such earlier successes provide important paradigms. If on their model the meaning of the term *projectible* can be clarified, it will be feasible to decide to which hypotheses the term applies, and a crucial desideratum of heretofore defective theories of confirmation will have been taken care of.

Inasmuch as the term *projectible* is itself a dispositional predicate we may expect that among the manifest predicates that will occur in any candidate definiens will be the *corresponding* manifest predicate: "projected." However, defining *projectible* in terms of "projected" offers some very special difficulties which do not arise in the case of many dispositional predicates. The predicate "projectible" is like "desirable." It is not the case that every hypothesis that has been actually projected ought to have been or ought to be projected. (A hypothesis is characterized as having been *actually projected* if "it is adopted after some of its instances have been examined and determined to be true, and before the rest have been examined"; ibid., p. 90.)

Goodman, perhaps unlike J. S. Mill in confronting "desirable" is explicitly aware of the trap, and although his task is thereby enormously complicated, he avoids falling into it. He proposes, eventually, an explication of "projectibility" that provides criteria for discriminating projectible hypotheses based on past projections and certain other characteristics of our actual linguistic habits. In particular, attention to actual projections of hypotheses enables Goodman to explicate a relevant sense of *projected predicate* (a predicate occurring in an actually projected hypothesis). This, in turn, leads to his explication of a concept that becomes pivotal to his theory of projection: the concept of "entrenchment"—more specifically, the concept "is a much better entrenched predicate than."

One predicate, *P,* is said by Goodman to be much better entrenched than another predicate, *Q,* if *P* and all

predicates coextensive with it have actually been projected much more often than *Q* and all predicates coextensive with it. Thus, take the predicate "grue" (which applies to any blue thing not examined before some time, *t,* and also to any thing examined before time *t* and found to be green). This "highly artificial" predicate, occurring in the hypothesis "The next emerald to be examined (after time *t*) will be grue" allows that hypothesis to be *equally highly evidenced* with the more usual "The next emerald to be examined (after time *t*) will be green." But hypotheses employing "grue" (or any term applicable to exactly the things "grue" is applicable to) have, nevertheless, been much less frequently projected (for example, used in making predictions) than have hypotheses using "green" (or any term applicable to exactly the things "green" is applicable to). This is part of the basis upon which "green" is judged a much better-entrenched predicate than is "grue"; and Goodman's theory attempts to show how, although they are equally well evidenced, hypotheses containing much better-entrenched predicates are to be preferred to ones that contain much less well-entrenched predicates. Goodman points out that when we speak of the entrenchment of predicates we are really speaking of the entrenchment of habits of classification. This is to say that talk of the entrenchment of predicates is, in effect, talk of the entrenchment of their extensions. And, a little later on, still referring to his elucidation of entrenchment, he says:

> Like Hume, we are appealing here to past recurrences, but to recurrences in the explicit use of terms as well as to recurrent features of what is observed. Somewhat like Kant, we are saying that inductive validity depends not only upon what is presented but also upon how it is organized; but the organization we point to is effected by the use of language and is not attributed to anything inevitable or immutable in the nature of human cognition. To speak very loosely, I might say that in answer to the question what distinguishes those recurrent features of experience that underlie valid projections from those that do not, I am suggesting that the former are those features for which we have adopted predicates that we have habitually projected. (Ibid., pp. 96–97)

The import of these considerations is that what constitutes a valid projection, and consequently what comes to constitute a projectible hypothesis, is a result of how we have, as a matter of fact, come to classify.

If Goodman's attempt to define "projectible" is successful, we have at hand the means of solving the problem of distinguishing confirmable from nonconfirmable hypotheses and thereby of surmounting a major obstacle in the way of providing a logic of induction.

These results of Goodman's—both the critique of extant theories and the positive proposals put forward in 1955 (ibid.)—are clearly still being digested by people in the field, if one may judge by the discussions of them that (ten years later) appeared in print with increasing frequency.

THEORY OF STRUCTURAL SIMPLICITY

An early version of Goodman's calculus of simplicity (later extensively modified) occurs in Part I, "On the Theory of Systems," of his first book, *The Structure of Appearance.* There the calculus is exclusively connected with considerations somewhat more general than those involved in, for example, assessing the simplicity of scientific theories. In *The Structure of Appearance* interest in simplicity is interest in the simplicity of the primitive predicate basis of *any* constructional system; that is, any constructed linguistic system or axiomatic system which makes explicit what are the primitive (that is, the undefined) terms of the system. The main general problem that Goodman addresses is that of delineating criteria of adequacy for constructional systems generally, rather than for scientific theories in particular. For the constructor of such systems this problem is often posed—in part, at least—as the problem of choice among alternative primitive predicate bases. In choosing a primitive basis such considerations as antecedent clarity and "defining power" are obviously to be taken into account, but Goodman shows that the simplicity—the structural or logical simplicity—of such bases, is also an at least equally important consideration.

In his later writings on the subject (particularly in "The Test of Simplicity" and *Fact, Fiction and Forecast*) Goodman also made clear the relationship of measures of simplicity to the philosophy of science. He maintains that simplicity is a primary consideration guiding choices among scientific theories or systems of hypotheses. It is a mistake to believe that simplicity becomes a factor only after we have first sought a true system and then turn to matters of elegance. He maintains that, on the contrary, our concern with simplicity is an inevitable concomitant of our concern with system. For, he points out, we achieve systematization only to the extent that the basic vocabulary and principles we employ in dealing with some subject matter come to be simplified. The important thing to note is that "when simplicity of basis vanishes to zero—that is, when no term or principle is derived from any of the others—system also vanishes to zero. Systematization is the same thing as simplification of basis" ("The Test of Simplicity," p. 1064).

Goodman finds the key to the problem of measuring the structural simplicity of predicate bases in a "meagre and negative" but highly plausible principle: "If every basis like a given one can always be replaced by some basis like a second, then the first is not more complex than the second" (ibid., p. 1066). The relation "always replaceable by" between predicate bases holds in cases where the replacement is a matter of a purely routine procedure that can always be applied (presumably, for example, in case there is available some *decision procedure* for determining replaceability). Employing this key principle and some results in the theory of relations. Goodman provides a means of effecting the requisite measures. The *calculus of simplicity* is applicable only to theories that have been at least sufficiently formalized to enable discrimination of their primitive predicates. Its applicability (for example, as a factor in assessing the acceptability of some scientific theory) is thus severely limited for the present by the paucity of scientific theories that have reached this stage of formalization. On the other hand, this situation would be importantly alleviated if some means could be found either to bring more such theories to the requisite stage of formalization or to modify the calculus in such a way that useful applications of it may be made even to less fully formalized systems.

For the time being, applications of the simplicity measures may, however, be made to constructional systems devised for purposes of philosophical explication (for example, see Goodman's own system in *The Structure of Appearance*).

CONSTRUCTIONALISM

Whatever its importance for both philosophy of science and constructional methods, furnishing a way of measuring the simplicity of bases of any constructed systems by no means represents Goodman's only contribution to constructional methods. The first three chapters of *The Structure of Appearance* (for example) provide also a discussion of the problem of assessing the adequacy and the accuracy of definitional systems. Here an especially significant discussion (for example, in Ch. 1) provides both an illuminating critique of criteria which in the past have been adduced for assessing such systems and a newly developed criterion, *extensional isomorphism,* for assessing the *accuracy* of such systems. The development of this

criterion throws new light on the entire program of philosophical or logical analysis.

Although full elucidation of the criterion is beyond the scope of the present entry, some general inkling of its import may perhaps be conveyed by pointing out some of its differences from some of the criteria which have been previously offered for the adequacy of philosophical analyses. It has long been recognized that full synonymy of analysandum (the concept or term being subjected to philosophical analysis) and analysans (the concept or term constituting the product of the analysis) is too strong a requirement. Accordingly, weaker criteria (for example, *intensional identity* or *extensional identity* of analysandum and analysans) have been proposed. In *The Structure of Appearance* Goodman argues that even the weakest of these—extensional identity—is too strong a requirement to place on tasks of analysis, for none can totally fulfill such a condition. He proposes instead a criterion that does not "square" an analysandum with its analysans in any one-to-one fashion but rather tests the whole *system* of concepts to which the analysandum belongs against the whole newly constructed system to which the analysans belongs. The meeting of specified and relatively weak extensional correspondences between two such systems is sufficient—and indeed is the most that can cogently be required—to warrant the accuracy of the analysis.

The discussions of new constructional methods in the first chapter of *The Structure of Appearance* and the presentation of a version of the calculus of individuals which had been developed by H. S. Leonard and Goodman (in "The Calculus of Individuals and Its Uses") are well supplemented by the specific application of these and other devices to a detailed critique of Carnap's *Der logische Aufbau der Welt* (in Ch. 5). An important application is also provided by the construction (in Chs. 6–11) of his own systematic explication of phenomenal concepts or predicates.

PHENOMENALISM AND NOMINALISM

Goodman's actual work upon, and his defenses of work upon, phenomenalistic systems lead many observers to conclude that he subscribes to phenomenalism as a philosophical position. The fact is, however, that he wrote in full and explicit detail about the relative unimportance and the opacity of questions about the epistemological priority of the phenomenal (and "rival," for example, physicalistic) systems, and there seems to be no good reason to doubt the sincerity of his disavowals of that kind of philosophical commitment. (See *The Structure of Appearance,* Ch. 4 and passim, and "The Revision of Philosophy.") All of this is notwithstanding the fact that he made contributions to the solution of many very complex problems that are involved in the construction of a phenomenalistic system.

If phenomenalism represented, for him, no particular philosophical commitment, *nominalism,* on the other hand, surely did. His major writings on this topic (in his and W. V. Quine's "Steps Toward a Constructive Nominalism" and in his *The Structure of Appearance; Fact, Fiction and Forecast;* and "A World of Individuals") obviously constitute a fundamental philosophical conviction. Although Goodman's and Quine's nominalism coincide importantly (for example, in their mutual rejection of classes, see "Steps toward a Constructive Nominalism"—but note, however, that in later writings Quine appears no longer to embrace such views) it should nevertheless be observed that their nominalistic positions are quite disparate. Thus, Quine apparently rejects, so to speak, classes on account of their being abstract entities; whereas Goodman rejects, so to speak, classes not on account of their being abstract entities (his system in *Structure,* indeed, refers to abstract entities categorematically) but rather on account of their being *nonindividuals.* It is the notion of a *nonindividual* that Goodman finds unintelligible, and he is conscientious in avoiding any philosophical or logical method which presupposes or extorts the claim that there exist any nonindividuals. The consequent austerity in bases chosen and logical tools available to him have had, in fact, fruitful results in eliciting complex, ingenious, and far-reaching techniques or methods of constructional analysis.

We have indicated that there are differences between what might be called G-nominalism (Goodman's position)—the view, on the one hand, that there are no nonindividuals—and the position that might be called Q-nominalism—the view that there are no abstract entities, on the other. While it would, again, be beyond the scope of this entry to give a detailed account of G-nominalism, it may yet be illuminating to remind the reader that Goodman himself characterized his position as a sort of "super-extensionalism." The usual or classical extensionalist position prohibited some otherwise indiscriminate multiplication of entities by imposing a principle to the effect that two entities (say, two classes) that have, so to speak, the same proximate constituents are identical. G-nominalism goes further; it imposes the condition that any two things which have the same systematically *ultimate* constituents are identical.

Thus, consider the systematic atoms (things not having anything else in the system as possible constituents) *a, b, c,* and *d.* Suppose in a (classically) extensional system *A* we discriminated the classes of pairs {*a,c*} and {*b,d*}, and suppose in system *B* we discriminated the classes {*a,b*} and {*c,d*}. For classical extensionalism, systems *A* and *B* would *not* be identical; that is, the proximate constituents—the two classes of pairs—are different, and hence the world's population on this account is increased by two more classes. The G-nominalist, however, has a stronger condition for diversity. For him there are not, say, the eight different entities consisting of the four atoms and the four classes of pairs of them. Rather, there are only four entities—the ultimate atoms of the system themselves. The cogency of this view is argued with great vigor and clarity in "A World of Individuals."

WORK IN PROGRESS

Goodman's interest appears to be an analysis of representationalism in a very broad sense of this concept taken presystematically. Thus, the focus of his attention is not only upon representation as a phenomenon involving, for example, paintings in aesthetics but also upon the representational aspects or functions of maps, graphs, musical scores, and choreographic notations, and, in addition, theories and other descriptions. His deep and abiding interest in this topic is evidenced too as a recurrent thread in many of his works, from very early ones on. The articles in which this concern is most obviously expressed are "On Likeness of Meaning," "Sense and Certainty," "The Way the World Is," and "About." The concern is also dominantly present in his John Locke lectures (given at Oxford in 1962), published as *The Languages of Art.*

Richard S. Rudner (1967)

GOODMAN, NELSON [ADDENDUM]

Nelson Goodman (1906–1998) was one of the foremost philosophers of the twentieth century. His works reshaped epistemology, metaphysics, and the philosophy of art. *The Structure of Appearance* (1977), which grew out of his PhD dissertation, shows how to construct interpreted formal systems that solve or dissolve long-standing epistemological and metaphysical problems. *Fact, Fiction, and Forecast* (1983) poses the new riddle of induction and proposes a solution to it, arguing that to block the inference to "All emeralds are grue," one must consider the ways terms have been inductively used in the past. *Languages of Art* (1976) reconceives aesthetics, construing it as a branch of epistemology. It is tempting to say that Goodman worked in diverse branches of philosophy. A more accurate claim would be that he focused on issues that cut across philosophy, showing that the branches are not so diverse as they sometimes seem.

Goodman attended Harvard University both as an undergraduate and as a graduate student. During graduate school, he supported himself by running an art gallery in Boston. He spent most of his academic life as professor

of philosophy at the University of Pennsylvania. For the final decade of his teaching career he was professor of philosophy at Harvard, where he founded Project Zero, an ongoing research program in arts education, and the Harvard Summer Dance Program. He was an avid, eclectic collector of art.

MEANING

In the late 1940s, Goodman, W. V. Quine, and Morton White wrote a series of papers repudiating the analytic/synthetic distinction. Goodman's target is synonymy. He contends that synonymy requires that terms agree in primary extension and all parallel secondary extensions, where the secondary extension of a term is the extension of a compound containing that term. Although "unicorn" and "centaur" have the same (null) primary extension, because compounds such as "unicorn picture" and "centaur picture" differ in extension—because, that is, not all unicorn pictures are centaur pictures—"unicorn" and "centaur" differ in meaning. This fits human intuitions. But even seemingly synonymous terms differ in meaning according to Goodman's criterion. Although "spine" and "backbone" seem synonymous, one can readily contrive a spine description that is not a backbone description—for example, "spine that is not a backbone." In general, "*p* that is not a *q*" is a *p*-description but not a *q*-description. Such an all-purpose device for generating differences in meaning might seem illegitimate. Even if a person were to exclude its deliverances, the pictures and descriptions that belong to a secondary extension of one but not both of a pair of coextensive terms are easily found. The vast majority of apparently synonymous terms fail to satisfy Goodman's criterion. Although Goodman does not argue for his criterion, its justification is evident. Synonymous terms should be intersubstitutable in fiction and in statements of fact. Because nothing should count as a representation of the referent of the one that is not a representation of the referent of the other, divergence in the classifications of the descriptions or pictures marks a divergence in meaning.

Secondary extensions do more than discredit synonymy; they provide resources for recognizing degrees and kinds of likeness of meaning. To do this, one must limit focus. If, within a restricted range, all parallel compounds of a pair of coextensive terms are coextensive, the meanings of the coextensive terms agree within that range. The terms then may be alike enough in meaning to be intersubstitutable within that range, even if their meanings diverge elsewhere. If in medical discourse all and only instances of "spine representation" are instances

of "backbone representation," then "spine" and "backbone" may be sufficiently similar in meaning to be intersubstitutable in purely medical contexts. If most parallel compounds are coextensive, or most important parallel compounds are coextensive, terms may be sufficiently similar in meaning to justify substituting one for the other. In place of a rigid, context-indifferent criterion of synonymy, Goodman provides a flexible, context-sensitive criterion of likeness of meaning (Goodman 1972, pp. 221–238).

The analytic/synthetic distinction is not unique. Other familiar dualisms—essence/accident, scheme/content, necessity/contingency, and the like—are vulnerable to similar objections. All must be rejected, Goodman, Quine, and White believe. Unlike Quine, Goodman devotes little subsequent effort to arguing against the dualisms. He simply jettisons them and does philosophy without them. He considers the demise of the dualisms not to deprive philosophy of resources, but to liberate it from unwarranted restrictions. Perhaps surprisingly, he finds that the rejection of the dualisms fosters progress in aesthetics.

ART

Goodman's trailblazing *Languages of Art* reorients aesthetics. Active engagement, rather than passive contemplation, marks the aesthetic attitude. Goodman believes that the arts function cognitively. He thus construes aesthetics as a branch of epistemology whose task is to explain how and what the arts contribute to cognition. The plausibility of such a position obviously depends both on the nature of art and the nature of cognition. If the cognitive function of art is simply to transfer information to passive receivers, resemblance might be the mechanism. Then works resemble their subjects and convey information about how their subjects appear.

There are, however, seemingly insuperable objections to such a position. At best it works only for representational art. Music, abstract painting, and architecture would not be accommodated under such an account. Nor can it feasibly accommodate anything except realistic works. Neither cartoons nor cubist portraits much resemble their subjects. Indeed, Goodman argues that the account does not even accommodate realistic works. The cognitive contribution of a painting could be to convey the way its subject looks only if there were such a thing to convey. Any thing looks many ways, and looks different ways to different people. A subject then has no canonical look that its painting, to be accurate, ought to convey. Moreover, some realistic pictures have fictive subjects—

unicorns, griffins, and the like. Clearly they do not resemble their subjects, because there are no unicorns or griffins to resemble. Nonetheless, one can readily interpret such pictures, recognize what they are of, and gain insights from them.

The problem, Goodman believes, is that the proposal rests on misunderstandings both of art and of cognition. Contrary to what classical empiricists thought, the mind is not passive in the reception of sensations. It actively searches, seeks, selects, and finds. Nor should works of art be construed as mere sensory surfaces. Rather, Goodman maintains, they are symbols with determinate syntactic and semantic properties. Art advances understanding and affords insight in much the way language does. Like linguistic symbols, the symbols that constitute a work of art require interpretation, and the symbol systems to which the works belong need to be learned. In *Languages of Art* Goodman develops a taxonomy of symbol systems used in the arts and elsewhere, detailing their powers and limitations.

Two modes of reference are basic. Denotation links names to bearers, predicates to instances, representations to the things they represent. "George Washington," "the first U.S. president," the figure on the U.S. dollar bill, and the Gilbert Stuart portrait all denote Washington. In exemplification, a symbol points up—hence refers to—properties it serves as a sample of. A fabric swatch exemplifies its pattern; a Mondrian painting, squareness; a blood test, the presence of antibodies. Ubiquitous in art, exemplification is also widespread in science, advertising … indeed anywhere people adduce samples and examples (Goodman 1976).

Reference need not be literal. Metaphorical reference, Goodman maintains, is real reference; metaphorical truth, real truth. "Bulldog" genuinely, albeit metaphorically, denotes Churchill. "Churchill is a bulldog" is genuinely, although not literally, true. Michelangelo's *Moses* genuinely, albeit metaphorically, exemplifies rage. Expression is metaphorical exemplification by a work of art functioning as such. *Moses* thus expresses the rage it metaphorically exemplifies (Goodman 1976, 1984).

Some reference is complex. In allusion, a referential chain composed of denotational and exemplificational links connects a symbol to its referent (Goodman 1984). Two chains figure in variation, one exemplifying features a variation shares with its theme, the other exemplifying features that contrast with the theme (Goodman and Elgin 1988).

Scientific symbols, Goodman maintains, are relatively attenuated, aesthetic symbols relatively replete. A scientific symbol is normally univocal, its full referential import readily apparent. An aesthetic symbol may bear multiple correct interpretations and symbolize along several dimensions simultaneously. Exactly what it symbolizes may never be settled. The same item may qualify as a symbol of either kind, depending on how it functions. So "When is art?" not "What is art?" is the crucial question. When, how, and to what effect does a symbol function aesthetically (Goodman 1978)?

Art advances understanding, not only because interpretation is a cognitive process. Encounters with art afford insights that extend beyond the aesthetic realm; discoveries made, orientations adopted, and patterns discerned in aesthetic contexts transfer and make sense of other aspects of experience; emotion transform from ends to means. The emotional reactions a work evokes are not ends in themselves but means of understanding the work and the light it sheds on other aspects of human experience.

WORLDMAKING

In *Ways of Worldmaking* (1978), Goodman returns to constructionalist themes first explored in *The Structure of Appearance*. Worlds, he contends, are made, not found. Because the elements of any group are alike in some respects and different in others, mere examination will not reveal whether two manifestations are of the same thing, or two things of the same kind. To settle such matters requires criteria of individuation and classification. Category schemes supply them. But category schemes are human constructs. In devising them, people demarcate the individuals and kinds that make up a world. Different demarcations yield divergent, but equally tenable world versions. One might characterize light as a stream of particles; another, as a sequence of waves. Each may be right relative to its own world-version, wrong relative to its rival's. Neither is right or wrong absolutely.

If overlapping world-versions all supervened on a single base, such differences would be ontologically innocuous. But world-versions do not supervene on a single basis. A physicalist version, for example, neither supervenes on nor underlies a phenomenalist version. Nor does any neutral version underlie them both. Because people can and do construct multiple, individually adequate but irreconcilable world-versions, there are, Goodman concludes many worlds, if any (Goodman 1978).

Worldmaking is not always deliberate. In *Ways of Worldmaking*, Goodman analyzes a series of psychological experiments and shows how, with only sparse cues, the visual system constructs the apparent motion it detects (Goodman 1978). Nor is worldmaking always discursive. Nonverbal schemes structure things in ways no description precisely captures. The arts as well as the sciences construct viable world-versions.

Despite Goodman's recognition of multiple ways of worldmaking and multiple worlds made, he does not contend that every version makes a world. Only right versions do. Rightness does not reduce to truth, for some truths are wrong, some falsehoods right, and some symbols right though neither true nor false. Rightness involves fitting and working—fitting with past cognitive practice and working to promote cognitive ends. Consistency, cogency, projectibility, and fairness of sample figure in the rightness of tenable world versions (Goodman 1978, Goodman and Elgin 1988).

GORGIAS OF LEONTINI
(c. 485–c. 380 BCE)

Gorgias of Leontini (in Sicily) was a leading Greek rhetorician and Sophist of the fifth century BCE. He came to Athens on an diplomatic mission on behalf of Leontini in 427 B.C.E. and made an enormous personal success, delivering public orations as well as his official speech. He also toured the Greek cities as a celebrated teacher and public speaker, giving orations at the Olympic and Pythian games. Ancient sources associate him with the philosopher Empedocles (who may have been his teacher) and the rhetorician Isocrates (possibly his pupil). In addition to various sayings and fragments, three complete works by Gorgias have survived: *Encomium of Helen*, *Defense of Palamedes*, and *On Not Being or On Nature*. Gorgias is also depicted as a character in Plato's *Gorgias*, though how much evidence we can extract from this for his ideas or character is unclear. Whether Gorgias should be counted as a sophist is debatable. He was first and foremost a rhetorician, a teacher of public speaking, whereas the central subject of sophistic teaching was virtue. But the distinction was somewhat blurred, and Gorgias's ideas clearly belong to the sophistic movement, broadly construed.

Gorgias was not the first professional rhetorician; but his style was novel, and he was later seen as the real founder of the discipline. His language was notoriously elaborate, with a heavy use of antithesis and alliteration (see especially the *Helen* and the fragmentary *Funeral Oration*). At the same time, he specialized in improvisation: he would offer to answer any question posed by his audience or to speak extemporaneously on a suggested topic. He seems to have understood rhetoric as an all-powerful, value-neutral art (*technē*), consisting in a set of verbal techniques for the manipulation of an audience. As Plato reports it, he claimed that the art of persuasion was superior to all others because it enslaves all the rest—not by force, but with their own consent (*Philebus* 58a–b). Plato's *Gorgias* presents Gorgias as a genial, self-satisfied old gentleman, basically unreflective and blind to the morally problematic nature of such a craft. Plato's *Meno* also provides some intriguing scraps of information about Gorgias (who was Meno's teacher): he (a) disclaimed the teaching of virtue (95c), (b) held scientific

views, including a theory of how vision takes place (76c–d), and (c) held that the virtue of each kind of person (man, woman, child, slave, and so on) is different (71c–2b), suggesting that he may have advocated definition by an enumeration of species, in opposition to the Socratic search for a common denominator.

Of Gorgias's surviving works, the *Palamedes* is notable as an example of the rhetorical genre of *epideixis*: a set-piece speech presented as an advertisement, and perhaps used as a template for students to study. It argues on the basis of probability (*to eikos*), a characteristic rhetorical form of argument. Gorgias's other two surviving speeches might also have served as *epideixeis*: the sophists were traditionally described (for example, in Aristophanes' *Clouds*) as "making the weaker argument the stronger," and it is hard to think of a better way to display that skill than by proving that Helen of Troy was blameless (the *Helen*) or that nothing exists (*On Not Being*). But these texts are also more ambitious and philosophically interesting.

Gorgias's *Encomium of Helen* undertakes to free Helen of Troy from blame for having abandoned her husband for the Trojan prince Paris, triggering the Trojan War. His method is argument by the exhaustion of alternatives. Helen's action must have been caused either by fate, necessity and the will of the Gods, by force, by persuasion, or by erotic love. That an action caused by the force of another person cannot be blamed is hard to deny; Gorgias's strategy is to assimilate the other possible causes to cases of force. Divine forces are stronger than human will, so if Helen's action was caused by them she cannot be blamed. As for persuasion, Gorgias here launches into a hymn to the powers of speech (*logos*)—a passage that is outsized relative to the whole and may well give away the real purpose of the *Encomium*. *Logos*, he says, is a "mighty ruler," and though a small body it controls the actions of many larger ones. (Gorgias seems to assume a scientific account of speech as composed of tiny sound particles that physically enter the audience's body through sensory pores—as in Plato, *Meno* 76c–d.) Speech is to souls as drugs are to bodies, causing involuntary reactions: So persuasion is a kind of compulsion. What gives *logos* this power is, somehow, the reliance of the human mind on fallible opinion (*doxa*), which is necessitated by our limited access to the truth. Finally, *eros* is assimilated to involuntary perceptual reactions. We cannot help the way things appear to us: some sights terrify, others seduce, and actions driven by such reflexes are again compulsory.

The quality of argumentation in the *Helen* is inevitably uneven, but its ingenuity is remarkable. The upshot of the argument as a whole is much debated. The causes of action itemized by Gorgias, such as fate and the way things appear to us, are extremely general and able to cause a wide range of our actions. So the upshot seems to be that any one of our actions would appear as involuntary, if only its causal origins were known in full—a claim that still figures in arguments about determinism and free will.

But this claim is far from explicit in Gorgias's text. To complicate matters, Gorgias opens the speech by saying that the "adornment" (the virtue or best state) of a speech is truth; but he closes by describing the encomium as "a plaything for myself." This playful, self-subverting presentation leaves us to judge the arguments and their implications for ourselves. If anything about the *Helen* is unequivocally serious, it is the miniencomium to *logos*, with its conception of language as an instrument of manipulation, a conception the *Helen* itself aims to display.

The *On Not Being* has a complex structure, comprising three parts: Part I argues that nothing exists, Part II that if anything did exist we could not know it, and Part III that even if something existed and we could know it, we could not communicate it to one another. (In summarizing, I will freely combine points from the two somewhat garbled versions of the text that have come down to us: One is in the pseudo-Aristotelian *On Melissus, Xenophanes and Gorgias (MXG)*, the other in Sextus Empiricus, *Adversus Mathematicos* VII. The two differ substantially in places and neither can be exactly what Gorgias wrote.) Part I argues by the exhaustion of alternatives: for instance, Being (or "what is" or "the existent") must be eternal or generated or both, but each option leads to an impossibility; similarly, if Being exists, it must be either one or many, but each is argued to be impossible. Part II argues that things thought are not existent, and that, therefore, Being is not thought. Here Gorgias raises the perennial philosophical problem of reference to nonexistent objects: We can think of a man flying or chariots running over the sea, but it does not follow that any such things exist. Gorgias seems to infer, fallaciously, that existent things and objects of thought differ in the sense that nothing can be both. But perhaps his real point is just that thoughts and their objects are different in kind, and the connections between them are unreliable: contra both Parmenides and Protagoras, we can and do think what is not (Caston 2002). (The very obscure fragmentary saying

of Gorgias on being and seeming, DKB26, must be relevant here, but it is difficult to say what it adds.)

Part III of the *ONB* deals with language, and as with the *Helen*, we may here approach the real point of the exercise. Gorgias argues that just as sight and hearing have their own proper contents (colors, sounds), so speech is of words, which are different from sensory contents and from the things themselves. So how can speech make clear things different from itself? How can it reveal objects or sensations we are not already familiar with? And how can the same thought be shared by two different people?

The *ONB* has often been read as a parody of Parmenidean philosophy. There are clear echoes of certain arguments made by Parmenides and the other Eleatics, particularly in Part I. And the overall upshot of the *ONB* is, as Kerferd (1981) has noted, to sunder three things that Parmenides had argued must coincide: what is, what can be thought, and what can be spoken. The question, then, is whether the *ONB* is merely satirical, both satirical and serious (cf. DK82B12) but purely negative and critical, or intended as positive doctrine in its own right. As positive doctrine it seems to be self-refuting. Nevertheless, scholars have attempted to find interpretations of its conclusions which lend them some plausibility. Mourelatos (1987) has noted that Part III can be read as arguing for conclusions that complement those of the *Helen*. Language cannot communicate either the natures of things or the thoughts of the speaker; the remaining possibility is that it is to be understood not as a system of representations but simply as an instrument of behavioral manipulation. Alternatively, Parts II and III could perhaps be read as arguing only that mental and linguistic items are by nature distinct and different in kind from their referents (and from each other), and, therefore, are inherently fallible and defective in representing them.

Parts II and III are also often likened to Protagorean relativism as presented in Plato's *Theaetetus*, our other most important source for sophistic epistemology. However, the two positions are very different. There is nothing relativistic about Gorgias's conclusions; moreover Gorgias in effect denies the possibility of *true* opinion and speech, whereas for Protagoras their *falsity* is impossible. Nevertheless, there is a family resemblance insofar as both can be read as essentially critical positions. They repudiate the metaphysical ambitions of philosophers like Parmenides, denying the possibility of a knowledge distinct from opinion and a reality distinct from appearance.

GOTTSCHED, JOHANN CHRISTOPH
(1700–1766)

Philosopher, literary critic, and theoretician, Johann Christoph Gottsched was Christian Wolff's disciple and one of the architects of the German Aufklärung. Particularly conscious of Germany's cultural shortcomings, compared to France and England, Gottsched worked vigorously to reform German theater and poetry. Taking the ancients (Aristotle, Horace) as models, but also the French "Grand Siècle" (Racine, Molière, Boileau) and some few national examples (such as Martin Opitz), he wrote his *Versuch einer Critischen Dichtkunst* (1729, but often reedited until 1751) as a normative poetic theory destined to help form the taste of German writers and public alike. Gottsched's project, however, did not reduce

itself to this pedagogical goal: His poetics was meant to ground the rules of poetic taste on systematic philosophical foundations inherited for the most part from Gottfried Leibniz and Christian von Wolff. He saw it as imperative for both the philosopher and the serious poet that they know not merely the rules inherited from antiquity and French classicism, but that they also understand the reason underlying these rules. For Gottsched, criticism was a philosophical task, a part of Wolffian rationalism. In this sense, the *Critische Dichtkunst* prefigured the new aesthetical science set forth by Baumgarten a few years later.

Gottsched's theoretical positions are utterly rationalist. In keeping with Wolff and Leibniz, he conceives beauty as the clear yet conceptually indistinct representation of a perfection in an object—whether this object is natural, technical, or the result of poetic imagination. Being the perception of a perfection, the apprehension of beauty is accompanied by pleasure. Gottsched therefore rejects the subjective account of beauty: Aesthetic pleasure reduces itself to the perception of a perfection, the components of which could be made explicit. In other words, this perception could lead to rational knowledge and could thus be reduced to knowable rules. Every category of beauty, and every type of poetic or artistic beauty, rests on specific rules (those of architecture, of music, of painting, of tragedy, of epic) that nonetheless share some common fundamentals, namely, the notions of order, proportion, correlation between the parts and the whole, and the appropriateness of the rules to the specific function of the object.

The rules of poetry and liberal arts are therefore neither subjective nor variable; they are brought out by the best specialists of each domain and confirmed by experience and reflection. In this context, aesthetic taste depends on understanding as it judges the sensation of a beautiful thing. Good taste (that is, correct taste) consists, according to Gottsched, of "judging adequately, from a simple sensation, of the beauty of a thing for which we lack clear and distinct knowledge." This knowledge is "indistinct" because the person for whom this thing is pleasing is incapable of explaining the causes of the pleasure. Here, Gottsched's rationalism almost forces him into a contradiction: If taste is an indistinct judgment, does its improvement—which is the avowed goal of Gottsched's normative poetics—lead to the development and enrichment of aesthetic sensibility or does it rather perfect judgment and, hence, dissolve taste into knowledge? Only with Baumgarten's *Aesthetica*, and its notion of sensible

knowledge, will this problem, inherent to any aesthetic rationalism, find a credible answer.

In his analysis of the "poet's character," Gottsched applies the Wolffian theory of the mind's faculties to Boileau's classic conception of poetic production. For Gottsched, the "divine gift" traditionally attributed to the poet comes down to having a natural disposition for poetic imitation. Among the faculties the poet must have, wit (*ingenium, Witz*), or the capacity to easily perceive similarities between things, is the most important. But the mind must also be supported by a strong power of imagination, which Gottsched understands as the power to reproduce concepts we have already had on the occasion of present sensations and on the basis of the principle of resemblance, and perspicacity, which consists in perceiving nuances and differences within things.

Merely having these faculties, however, is insufficient: They must be the object of education. Moreover, imagination, perspicacity, and wit are not the poet's or the artist's only requisite talents; art (all the disciplines pertaining to the practice of a particular art), erudition (mythology, history, geography) and a profound knowledge of human psychology are also necessary to the artist's character. He must also develop his judgment (*Beurteilungskraft*), which serves reason as an instrument to control an overheated imagination; judgment keeps wit within the limits of verisimilitude and the natural. Finally, the poet's character rests on an honest and virtuous disposition of the mind that depicts morally wrong actions as ugly and revolting. On this issue, Gottsched's aesthetics concurs with one of the central tenets of the *Aufklärung*, which holds, drawing from a conception leading back to Horace, that poetry's mission is to please while providing moral instruction.

Even if imitation is the essence of poetry, the fable constitutes its "soul." There are three degrees of poetic imitation: the vivid portrayal of natural things, the imitation of characters, sentiments, and human passions, and the plot or "fable" (*Fabel*). Referring to Leibnizian metaphysics, Gottsched describes the fable as the tale of an event, rich in moral truth, that did not really happen but that could have taken place in some possible world. Poetic fiction is the "history of another world" that must nonetheless be submitted to the principle of verisimilitude, which Gottsched defines as concordance with the general order of nature. Ensues a tension between two principles, that of the fabulous (which satisfies the taste for novelty, strangeness, and remarkableness, but risks lapsing into the unconceivable and extravagant) and of

verisimilitude, on which rests poetry's credibility and its capacity to serve a morally edifying function.

Attempting to give more importance to the freedom of creative imagination, Swiss critics Johann Jakob Bodmer (*Critische Abhandlung von dem Wunderbaren in der Poesie*, 1740) and Johann Jakob Breitinger (*Critische Dichtkunst*, 1740) distanced themselves from Gottsched on this issue. Mobilizing Milton's *Paradise Lost* and Pseudo-Longinus' treatise on the sublime as guides for their reflection, they aimed to encourage the fabulous in poetry and to grant a certain autonomy to the "truth of imagination" vis-à-vis the "truth of understanding."

GOURNAY, MARIE LE JARS DE
(1565–1645)

Marie le Jars de Gournay was the editor of the first complete text of Michel Eyquem de Montaigne's *Essais*; author of feminist, moral, and religious tracts; and a literary writer and theorist. Born into an aristocratic family in Paris, she mastered Latin and translated Diogenes Laertius's *Life of Socrates* in her youth. At eighteen or nineteen, having read with enthusiasm Montaigne's *Essais,* books 1 and 2, she met with the author, which inspired her novel. Their friendship led to her becoming his "adopted daughter," which, in the sixteenth century, implied a literary partnership. Thus, in 1594, Montaigne's widow sent her the final manuscript of his *Essais,* which Gournay edited, later annotated, and published, together with a long "Préface," in 1595.

The "Préface" attempts to defend Montaigne against the main criticisms advanced by his contemporaries: (1) Against the charge that his Latinisms and neologisms did harm to the French language, Gournay stressed the importance of Montaigne's usages. Gournay would later make a name for herself as the protectoress of ancient French words and would defend the innovative, metaphorical use of language against Malherbe and other moderns. (2) In response to Dominique Baudius's and Étienne Pasquier's claim that Montaigne's frank discussion of love was indecent, a point Blaise Pascal would later take up, Gournay argued that the ancients rightly took such discussion as a prerequisite for the self-knowledge needed for virtue. (3) The charge of philosophical obscurity was countered with a skeptical attack against the critics' capacity for judgment: "The gift of judgment is the thing in the world that men possess in more varied proportion." (4) Gournay defended Montaigne's digressive style against the objection that it precluded treating a topic thoroughly and evidenced a lack of method. Since Gournay and Montaigne were steeped in skepticism, Gournay could hardly imagine Montaigne producing rigorous, linear proofs. (5) The accusation of heresy, leveled especially at the "Apologie de Raymond Sebond," was the criticism Gournay was most anxious to refute. Her defense of Montaigne's religious orthodoxy is of particular interest, since it rests on one of the clearer statements that we have of his fideism—a doctrine that she shared: "Who, likewise, could tolerate these new Titans of our century, these scalers of the heavens, who think that they will manage to know God by their own means?" "Judgment alone puts us in direct possession of God: which is to know nothing of Him and to worship Him on the basis of faith." (6) Montaigne's focus on the self and use of confessional autobiography had been attacked as vain and pointless. Gournay argued that Montaigne was instructing us in the Platonic art of self-examination; she was one of the first to see the epistemic and moral significance of the first-person philosophical voice, which would play such an important role in the works of René Descartes and Jean-Jacques Rousseau. (7) Beginning with the 1625 edition, Gournay countered the charge that Montaigne was ignorant of the sciences by providing a skeptical, humanist understanding of a "true science": That which aids us in conducting ourselves as "honnêtes hommes" and in leading a good life. The sub-

jects of which Montaigne might have been ignorant were "pure scholastic amusements."

After defending the Jesuits in a pamphlet, for which she was attacked in print, Gournay published a collection of classical translations, and a feminist tract, *Egalité des hommes et des femmes* (The Equality of Men and Women; 1622). *Egalité* is arguably the first modern philosophical response to the *querelle des femmes,* or "woman question." Gournay's innovative contribution was to combine (1) skeptical attacks, including the use of *reductio* arguments, against traditional views on the intellectual and moral inferiority of women with (2) evidence on behalf of the thesis of equality based on the authority of holy scripture, the early church fathers, and the ancient philosophers whom the church has recognized. As a Christian skeptic and fideist, Gournay saw (1) and (2) as consistent.

Gournay's moral essays reflect not only Pyrrhonism and fideism but the Christian stoicism that made up part of her *morale provisoire.* They appear in her collected works: *L'ombre de la Damoiselle de Gournay* (The Shadow of Mademoiselle de Gournay, 1626) and *Les advis ou Les presens de la Demoiselle de Gournay* (The Advice and Presents of Mademoiselle de Gournay, 1634; 1641).

She corresponded with Anna Maria van Schurman, Justus Lipsius, Saint Francis de Sales, La Mothe le Vayer. Abbé de Marolles, and Cardinal Richelieu. In her final years Gournay participated in the salons of the Duchesse de Longueville and the Comtesse de Soissons; her own salon was, arguably, the seed from which the French Academy grew.

GRACIÁN Y MORALES, BALTASAR
(1601–1658)

Baltasar Gracián y Morales was a Spanish Jesuit and author of several baroque, obscure, laboriously polished books in which he expounded and illustrated conceptism, or metaphysical wit. Conceptism (from *concepto,* thought) is the quest for fine, brilliant, subtle thoughts expressed in antitheses, ambiguities, new words, and elaborate conceits.

Gracián published only one book under his real name, *El Comulgatorio* (Sanctuary meditations for priests and frequent communicants; 1655). A book of devotion, it enjoyed great success in several languages until the nineteenth century but is little used today. All his other books were published under pseudonyms without the permission of his superiors, for which offense he was disciplined because their subjects were thought too worldly for a priest, especially at a time when the Society of Jesus was struggling against Jansenism. The first was *El héroe* (1637), a portrait of a Christian political superman, similar to scores of books printed in Europe in the sixteenth and seventeenth centuries in answer to Niccolò Machiavelli's *The Prince.* Governance, then in the hands of absolutist rulers, was thought to be an art that could be taught in analytical character studies of the "exceptional man." Unfortunately, Gracián's model was Philip IV of Spain. However, in *El político* (1640) he took Ferdinand the Catholic as a more plausible subject for another panegyric on the Great Man. Such works fell from favor as government came to be conceived more democratically, but romanticism revived the cult of the hero, and Gracián's books were annotated by Napoleon Bonaparte and admired by Friedrich Nietzsche.

In *El discreto* (1646) Gracián continued his portraits of perfect types, descending to the level of the man of the world to describe the perfect gentleman as seen by provincial Spanish society. This book is remembered for its formula for the ideal life: First converse with the dead, then with the living, finally with oneself. In other words, first book learning, then travel and worldly experience, and last, meditation and preparation for death. From these three books, and others like them that remained unpublished, Gracián extracted an anthology of 300 aphorisms, published as *El Oráculo manual* (1647), or *Art of Worldly Wisdom.* These wise sayings have enjoyed constant success. La Rochefoucauld echoed many of them in his *Maximes,* and Arthur Schopenhauer translated them into German.

La agudeza y arte de ingenio (1642–1648) is a treatise on rhetoric and aesthetics that codifies the taste of the baroque age with its thirst for conceits, subtlety, eloquence, and artifice. Composed in a tortured hermetic style—the style Gracián praised as literary perfection—the book has never been translated into English. Literary historians consider it the beginning of the decadence of Spanish literature.

Gracián then wrote a quite unexpected book, for which his uneventful, sheltered existence offers no explanation but on which his fame rests. After extolling heroism, kingliness, savoir-faire, and poetic beauty in the works so far mentioned, he composed *El criticón* (1651–1657), a bitterly critical satire of the very society he had been exploring so complacently. It is a long philosophical novel, painstakingly allegorical and overadorned to the point of obscurity, which has been compared with the paintings of Hieronymus Bosch. A noble savage, Adrenio, is brought to Europe and shown all the inventions and refinements of civilization. Critilo, a man of the world, directs an "experiment" that becomes an inventory of human knowledge at that date, reviewing most of the questions that then interested moralists, scholars, and statesmen. The idea, later used by Blaise Pascal and Voltaire, was not new; such didactic allegories were already known in Spain, perhaps because Indians really had been taken on "conducted tours" of civilization there. What was striking was the extent to which Gracián's characters came to pessimistic conclusions; their judgments on civilization were uniformly unfavorable.

Long before Jean-Jacques Rousseau, Gracián said that, although man was created pure in the state of nature and left God's hands perfect, civilization corrupted and debased him. Yet, he added, as man grows older, he can acquire wisdom to free himself from slavery to worldly illusions, to begin the hard apprenticeship of renunciation and preparation for death. Gracián's pessimism was redeemed by faith in salvation beyond life. The world is not wholly bad; it is a mixture of true and false values, of misleading images and authentic shadows of eternal life. This world is a profoundly ambiguous tragicomic farce, with a concealed sense that is to be sought in another world of eternal being. This combination of extreme pessimism and a confident religious faith introduced a curious ambivalence into Gracián's view of the world, notably of the things that he most admired: social success, worldly glory, and political power. Perhaps on only one subject was he utterly pessimistic—woman, whom he called "a Satanic creature, vile, inferior." Schopenhauer agreed with him here, but on other matters the German misrepre-

sented the Spanish Jesuit's pessimism by taking it out of its religious context. To be sure, some critics have argued that Gracián's piety was pretense, designed to get his work past the Inquisition's censorship. Voltaire knew *El criticón,* so resemblances to *Candide* might not be accidental; but Gracián's clearest philosophical influence was over Schopenhauer and Nietzsche.

GRAMSCI, ANTONIO
(1891–1937)

Antonio Gramsci, the Italian socialist born in Sardinia, founded the Italian Communist Party in 1921. He turned from political action to philosophical study when the Fascists jailed him in 1926 in order, said the public prosecutor, "to stop that brain working for twenty years." That brain, one of the most gifted that communism has produced, could not be stopped even by the inhuman conditions of Benito Mussolini's prisons: Gramsci filled three thousand pages with writing on a vast range of philosophical and political subjects. His frail health undermined by ill treatment, he died in Rome a week after his commuted term ended.

From the thirty-two prison notebooks, devoted editors have extracted "books" by grouping fragments on connected topics. In addition, *L'ordine nuovo* (1954) is a collection of articles from a socialist newspaper of that name, *Letteratura e vita nazionale* (1950) contains book and drama reviews, and *Lettere dal carcere* (1947) are his letters from jail. The heroic conditions under which he worked, and his founding role in Italian communism, may be responsible for overestimation of Gramsci's contribution to philosophy, but there is no doubt of his erudition and critical powers.

His philosophical notes (they seldom attain essay length) go beyond defense of Marxist doctrine; they mean to be a refutation of the idealism of two eminent ex-Marxists, Benedetto Croce and Georges Sorel. His criticism of them is seldom hostile, and in fact implies a disparaging opinion of orthodox Marxist-Leninist thought. Gramsci's central thesis is that Karl Marx's "materialist" overturning of G. W. F. Hegel was not a once-for-all affair that left communism, in Friedrich Engels's phrase, the secure "heir of the classical German philosophy." It had to be a continuing effort, to be repeated by each generation. Better, it was a Giambattista Vico-style cycle in which the same work of philosophical synthesis recurred at ever-higher levels. Gramsci saw that official Marxist thought in his day was in danger of relapsing into that vulgar materialism from which Marx's Hegelian training had rescued socialism a century before. Thus, it needed a new blood transfusion from speculative philosophy, a synthesis with neo-Hegelian idealism, notably with Croce and Giovanni Gentile.

This diagnosis entailed departure from the standard Marxist view on how philosophy "culminated" in revolutionary action. The last of Marx's Theses on Ludwig Feuerbach—"the philosophers have only *interpreted* the world in various ways; the point however is to *change* it"—had been taken to mean that philosophy would be realized in, and replaced by, revolutionary action. The postrevolutionary world would have no room for mere speculation, and philosophy would become the ideological branch of the administration. Gramsci replied that

philosophy could not be realized in, and even less supplanted by, political action. If the proletariat were to be "the heir of the classical German philosophy" (and if it were not, the revolution would be a cultural failure), it would have to pursue some recognizably philosophical activity. Specifically, it would be bound to go on reckoning with speculative idealism, putting it back on its feet as Marx did with Hegel and as Gramsci hoped to do with Croce.

Any one philosophy or system could indeed "culminate," or be realized. In fact, if it were a significant cultural product and not reverie, it surely would be. Yet that realization, the passage from speculation to action, from theory to practice, was not the "end" of philosophy foreseen by many Marxists. Rather, it was the transposition of private thinking into historically effective mass beliefs and a new ethic. Thus, Gramsci's program was to synthesize V. I. Lenin and Croce, to produce a reinvigorated Marxist philosophy that could be translated into a mass faith "like the Protestant Reform or the French Enlightenment."

The victory of such a new ethic was the essence of revolution, which meant above all "a moral and intellectual reform" and the "creation of a new integral culture." In all this, Gramsci explicitly followed Sorel but, against him, he denied that a "revolution of ideas" could do without politics, as Lenin practices it. His defense of Leninism, and of political organization generally, was a genuine contribution to political theory. Incidentally, it involved a fresh assessment of Niccolò Machiavelli. Gramsci wanted to be "both Robespierre and Kant," and indeed he succeeded in combining—at least on paper and in jail—the tough-minded political practicality of communism with a liberal attachment to classical education and philosophical culture.

GRAY, ASA
(1810–1888)

Asa Gray was a leading American interpreter of Charles Darwin's theory of evolution. Born in Sanquoit, in central New York, he became deeply interested in botany as a youth. Although he received a medical degree from Fairfield Medical School in 1831, he decided to devote his life to botanical studies, in which field he soon gained an international reputation. Harvard University appointed him Fisher professor of natural history in 1841, a post he held for over forty years. His writings both popularized the subject of botany and advanced it scientifically. Through his correspondence with Charles Darwin in 1856 and 1857, Gray obtained a preview of the theory of evolution by natural selection. When the *Origin of Species* was published, Gray wrote one of the first reviews, in the *American Journal of Science and Arts* (March 1860). This review, with several other essays on evolution, was reprinted under the title *Darwiniana* (1876).

Gray's attitude to Darwin's theory was open-minded but cautious. He regarded it as a plausible scientific hypothesis, although far from conclusively proved. As an explanation of the diversification of species, it was markedly superior to the doctrine of special creation. However, it did not really explain the origin of species because it failed to give a satisfactory account of the cause of variations. Gray thought that Darwin was often rash in drawing conclusions that outran the evidence, as when he asserted that all species must have descended from "four

or five primordial forms" and when he contended that man's mental powers must have had an evolutionary origin. This last contention "accumulates improbabilities beyond belief."

Against those who said that the Darwinian theory implied atheism, Gray argued that "it is neither atheistical in statement nor in intent." The theory could be given a nontheistic interpretation, but it could equally be given a theistic one. A central question was the presence or absence of design in nature as a whole, and this question was one for the natural theologian or the philosopher, not for the biologist. Gray himself favored a theistic interpretation, since the idea of a Designer of the universe "is most natural to the mind." It was not even true to say that Darwin's theory was mechanistic. It assumed that adaptations produced by natural selection are useful to organisms, enabling them to achieve certain ends, and this assumption clearly reintroduced purpose or teleology into natural history. "If purpose in this sense does not itself imply design, it is certainly compatible with it and suggestive of it."

Gray's cool analysis of Darwinism coupled with his espousal of theism irked some of Darwin's militantly agnostic supporters, though not Darwin himself, who valued Gray as a friend and searching critic.

GREEK ACADEMY

Academeca was the name of a public park, equipped with a gymnasium and lecture facilities, located about a mile northwest of the Dipylon Gate of ancient Athens. There, probably shortly after 387 BCE, Plato bought a house and estate and began to teach, so successfully that his school dominated the facilities of the area, was named after the park, and continued until Justinian's closure of the pagan schools of philosophy in 529.

CLASSIFICATION

The main philosophical contributions of the Academy had been made by the time of Antiochus's death (c. 68 BCE); the different phases in this period were classified into Old Academy and New Academy or, by some ancients, as Old (Plato and his immediate successors), Middle (marked by Arcesilaus in the middle of the third century BCE) and New (dominated by Carneades in the second century BCE). To this were sometimes added a Fourth Academy (Philo of Larissa, head 110/109–80 BCE) and a Fifth Academy (under his successor, Antiochus). Broadly speaking, the Old Academy was occupied with problems posed by Plato, Middle and New with aspects of skepticism, and the Fifth with the eclecticism introduced by Antiochus. The history of Middle Platonism and Neoplatonism is distinct from that of the Academy, which was, however, a notable Neoplatonic center under Proclus in the fifth century.

EVIDENCE

Plato is the only leading Academic whose published works have survived, and they are not primarily internal documents of the school; our knowledge of the doctrines of his successors and of the functioning of the Academy is tantalizingly limited to fragmentary references, opponents' criticisms, and later summaries.

ORGANIZATION

At first the organization may have been informal and fluid, with Plato's personality and interests forming the center of gravity. At some point this fused into a nonfee-paying (fees were instituted by Speusippus), nonresidential corporate society, possibly in the form of a religious guild (*thiasos*), joined in the common worship of the Muses and in pursuit of truth at their shrine of learning (*Mouseion*), which Plato built on his estate. There were regular dining and other formal ceremonies. Plato appointed his successor; thereafter, the members elected their head, who held the original estate for the society and who governed until his death.

TEACHING

Apparently the teaching varied to some extent among the junior and senior members of the society. Plato's own

writings indicated that he had a practical aim in training young men and inspiring them with his political ideals, but he also suggested that the process required much time and study; thus, we find that the most important members remained within the school, researching and teaching, for years or for a lifetime (for instance, Aristotle and Speusippus). Practical political contributions of the Academy therefore came from senior members who were advising rulers or drafting legal codes rather than from former students who had chosen political careers. See, for example, the details given by Plutarch in *Moralia* (1126 CD); however, the extent of Academic influence is in dispute (see E. Zeller, *Die Philosophie der Griechen* II, 420, n. 1). The *Republic* declares mathematics and dialectic to be the fundamental studies, thereby placing the Academy in opposition both to the literary education of the rival school of Isocrates and to the training in techniques characteristic of some professional sophists. These subjects were chosen not only because their object was real Being, as Plato thought, but also because their method forced students into a Socratic self-learning and willingness to follow a communal discussion wherever the rational argument led.

What is certain is that instruction did not consist in the propagation of orthodox doctrine. There is a hostility to the lecture system in Plato's dialogues, which, together with the notorious failure of his public lecture on the Good, suggests that the main activity of the Old Academy lay in discussions and seminars (of which there is also some contemporary evidence in a comic fragment of Epicrates). Aristotle's mention of unwritten tenets and ascription to Plato of certain doctrines which do not appear in the dialogues (such as the equation of Forms and Numbers, the principles of Unity and Indeterminate Duality, mathematical entities of intermediate status between Forms and phenomena) have led some scholars to posit an esoteric oral teaching of Plato's, and others to suggest that Plato did no oral teaching at all in the Academy.

Both extremes, however, run counter to evidence. Aristotle may be reflecting Plato's part in some exploratory debates with senior members, for while the young and inexperienced had to be nursed and stimulated along educational paths by Plato, it is clear that no consideration of orthodoxy froze research. For such stimulation Plato posed problems, such as accounting for the movements of the planets, which produced a variety of answers including, according to Simplicius, Eudoxus's famous hypothesis of concentric heavenly spheres. We have evidence of equally lively and uninhibited debate in the Old Academy on the theory of Forms, mathematical metaphysics, classification, soul, good, and pleasure. It was at this higher level that the Academy was most successful and influential; in the conflict of educational ideals for schooling the young, the literary education of Isocrates and the rhetorical schools completely defeated in the elementary and state schools the philosophical, scientifically based Academy. However, the latter throughout its history preserved the high ideals of a society dedicated to the disinterested and independent inquiry after knowledge, ideals that succeeding ages—from the Lyceum of Aristotle to the present day—have recognized as models and standards for their own institutes of advanced study.

OLD ACADEMY

The head of the society naturally influenced all members, so the history of the Old Academy is largely an account of Plato's pupils. The most brilliant was Aristotle, a member from his eighteenth year until Plato's death in 347 BCE; his philosophy stems from the Academy, where his earliest works were written. There is some evidence that he was still being considered for the headship at Speusippus's death in 339 BCE and that he finally broke away to found his own school four years later.

Mathematical research was particularly distinguished in the Old Academy. Theaetetus of Athens, tragically killed in battle in 369 BCE, succeeded in generalizing the theory of irrationals and in constructing and circumscribing the five regular solids, thereby laying the foundations of Euclid's solid geometry in Books 10 and 13. Still more important was Eudoxus of Cnidus, who with his pupils joined forces with Plato (c. 367 BCE) for a few years. Apart from the influential astronomical theory of concentric spheres, he is credited with a general theory of proportion and a method of exhaustion fundamental to Greek geometry. He criticized Plato's theory of Forms, arguing that Form, to be a cause, must be immanent in phenomena, as white is the cause of whiteness of that in which it is mixed. He apparently regarded Form as a kind of substance. This seems to have drawn reactions from Plato and Aristotle. Eudoxus's championship of hedonism likewise produced opposing arguments from Plato and Speusippus. Another astronomer, Philippus of Opus, is reported to have edited Plato's *Laws* and to have written its appendix, the *Epinomis*; whether written by him or by Plato, the latter is an important document of a stage in the Academy at which mathematical astronomy advanced from a propaedeutic science to the central science of Being and theology.

Heraclides of Pontus (c. 390–c. 310 BCE), temporary head of the Academy during Plato's third Sicilian journey, unsuccessful candidate in the election of 339 BCE, and later associated with the Lyceum, had a Pythagorean bias and was a prolific, learned, and elegant writer on a wide variety of subjects rather than an original thinker. He appears to have responded to the problem of the planets' motion, but it remains uncertain whether he partially anticipated Aristarchus's heliocentric system and posited the rotation of Earth on its axis, as was thought. He posited an atomic theory of irregular units of mass but attacked the mechanical atomic theory of his day, holding that matter was subject to a divine teleology.

Speusippus, who succeeded his uncle Plato in 347 BCE, may well have been the senior member or even a founder of the society. He and the third head, Xenocrates of Chalcedon (c. 396–314 BCE, head 339–314 BCE), another pupil of Plato's from his earliest years, were thought by Aristotle and others to be concerned with similar problems. Although neither was a great philosopher, a study of fragments of their writings reveals a development of trends apparent in Plato's later work, some positions between Plato and Aristotle, and some foreshadowing of later Platonism. Both, but especially Speusippus, were strongly influenced by the current Pythagorean fashions in the Academy. In the school debate over the division of Being into the three spheres of Forms, Mathematicals, and Physicals, Speusippus replaced Plato's Forms with mathematical entities and Xenocrates identified Forms and Mathematicals. Both were preoccupied with the derivation of a hierarchy of substances from mathematical first principles—Speusippus disjointedly, according to Aristotle, in that he abandoned the uniform interdependence of the whole universe on one set of first principles and assumed different principles for different kinds of substance in series. Xenocrates posited the Platonic Unity and Indeterminate Dyad (or continuum of opposites such as great and small). Good, which was derivative for Speusippus (coming at the end of becoming), was distinguished from both Unity and Being. Soul fell into the mathematical classification—as self-moving number for Xenocrates and seemingly as a form of extension for Speusippus, a theory of great importance for the later Stoic, Posidonius.

Another Pythagorean trait was the strong theological interpretation of their mathematical cosmology, also hierarchical in treatment, Xenocrates advocating the influential doctrine of *daimones,* animate beings between gods and men. In dealing with the Academic problem of real definition by *diaeresis* (division) and classification,

Speusippus suggested in an important work, *Homoia* (Resemblances), that definition by division was impossible without knowing all existing things, the essential nature of any one concept being constituted solely in its relation of likeness and difference to every other concept. Xenocrates foreshadowed Aristotle by asserting the logical and ontological priority of species over genus. In epistemology both continued the trend of allowing more cognitive importance to perception; Xenocrates, who had a weakness for triadic systematization, worked out spheres of the universe corresponding to cognitive powers: the sphere within the heavens as perceptible, that outside the heavens as intelligible, the heavens themselves as a mixture of both and thus objects of opinion. Both men were prolific writers on practical ethics; they held that happiness can come into being from virtue alone but that virtue is not the only good. Speusippus campaigned against pleasure as being contrary to both pain and good.

The next head, Polemon of Athens (elected 314 BCE), concentrated on conduct, elaborating Xenocrates's conception of happiness as life "in accordance with nature," a phrase which, especially through the Stoa, became the center of ethical debate. Polemon had more personal influence than philosophical originality, but he is of some importance for the Academy of the first century BCE. His friend, Crantor of Soli in Cilicia (c. 335–c. 275 BCE), wrote a famous work, *Peri Penthous* (On grief), a prototype of an ethical genre later popular, directed against the extreme views of the Stoics on pain and the affections.

MIDDLE AND NEW ACADEMIES

Crantor's reaction to the Stoa heralded a major change in the school. Until Crates of Athens (elected head 270 BCE), the main topics of inquiry were Platonic questions and developments. The next head, Arcesilaus of Pitane (316–241 BCE), is reputed to have concentrated on an attack on the Stoic theory of knowledge. He was probably reacting not only to an ontology and epistemology inimical to the Platonic tradition but even more to the dogmatic character of Stoicism, which he countered by an exaggerated form of Socratic skepticism: Not only did he know, like Socrates, that he knew nothing, but he is also said to have doubted whether he could ever know that he knew the truth. He imitated Socrates in writing nothing and taught mainly in open debate, introducing to the school the system of arguing on both sides of a question. Nevertheless, he saw to it that Plato's works were studied; and in the controversy with the Stoa, the Academy maintained that by "suspension of judgment" (*epoche*) they

were not inhibited in their main philosophic task of a continual search for truth, however unattainable, or from moral action, as a guide for which Arcesilaus recommended "the reasonable." The dialectical influence of Arcesilaus set the Academy firmly in the main stream of Greek skepticism, but it was an age of formalization through controversy. Arcesilaus helped to produce Chrysippus, the great fortifier of Stoicism; Chrysippus was in turn the whetstone of the most brilliant figure of the second century BCE, Carneades of Cyrene (214–129 BCE), who systematized a comprehensive and devastating skeptical attack against the whole philosophy of the dogmatic schools. But while Carneades had penetrating observations on sense perception, probability, causation, fatalism, and anthropocentric theology, he seems, both in method and content, to have drifted some way from the original Socratic-Platonic tradition.

Reaction began with Philo of Larissa (160/159–80 BCE, head from 110/109), Cicero's teacher, who, while maintaining skepticism against Stoic epistemology, reclaimed his Platonic ancestry. It was completed with Philo's pupil and opponent, Antiochus of Ascalon (c. 130–c. 68 BCE, head from c. 79 BCE), who came to think that the representatives of the New Academy had perverted the teaching of the Old Academy by maintaining that no truth could be grasped, thereby destroying any criterion of true and false and, in Antiochus's opinion, inhibiting action through denial of certainty. Antiochus reinstated a dogmatism whereby a criterion of truth arising from but not contained in the senses was grasped by the mind as self-evident. His reinterpretation of Platonism was marked by an eclecticism in ethics that enabled him to propose that the Stoa and Peripatos had merely followed the lead of the Old Academy, differing from it in terms rather than in substance.

In fact, the theories of morals of the three schools were all naturalist, and Antiochus's distorted arguments were facilitated by certain shared areas of discussion, covered by Polemo and the early Peripatos and Stoa, based on "the things according to nature" (*ta kata physin*) to which human beings had a natural affinity (*oikeiosis*). Doubtless there had been interchange of ideas, which was fostered even by the New Academy's insistence on arguing on both sides of the question, but Antiochus blurred the quite different approaches of the schools to a common area of dispute.

His thesis may have been further encouraged by the early "Platonic" works of Aristotle which were then popular, and influenced by the Stoic Panaetius, who had admired Plato and who gave greater prominence in his teaching than had earlier Stoics to the "intermediate natural things" (health, wealth, etc.), which, although the material of ethics, were held by Stoics to be in themselves of only relative value and morally neutral compared with the absolute value of the rational operation of virtue. Antiochus, however, maintained that the end of action, the happy life (*beata vita*), although possible through virtue alone, was completed (*beatissima*) by bodily and external goods. Thus Antiochus shared a graded axiology with the Old Academy and Peripatos; for him the difference between virtue and other goods was one of degree, for the Stoa there was a difference of kind. In a manner similar to some Stoic arguments, he held that the chief good was based on natural instincts for self-preservation and self-development, so that from the germ of virtues in the impulses of childhood man gradually attained knowledge of his own nature; but for Antiochus the perfection of human nature involved all parts of it, not only the highest, and also man's relationship to others and to the community.

This attempted dogmatic synthesis of the three great schools was of minor philosophical interest in itself, but of major importance for subsequent Greek thought. Apart from professional Academics, Antiochus profoundly influenced the popular expositor Cicero, some Stoics with doxographic interests like Arius Didymus, who taught at the court of Augustus, and Middle Platonists such as Albinus of Smyrna, whose lectures Galen attended in 151/152. Albinus's markedly eclectic epitome of Platonism (the *Didaskalikos*) still survives. Indeed, without the growth of syncretism initiated by Antiochus, the fusion that created the final explosion of ancient thought in Neoplatonism would not have been possible.

Throughout the long history of the Academy, the founder's works were studied and his birthday revered with celebrations. It is a remarkable tribute to his personality, philosophy, and educational ideals that through the very different phases of the school all members considered themselves his true heirs, so that one man's ideas stimulated his pupils over nine hundred years without in any way rigidifying their thought.

GREEK DRAMA

When Plato spoke of an ancient quarrel between poetry and philosophy, and when Aristotle said that poetry is more serious and more philosophical than history, they were both thinking primarily of epic and dramatic poetry, especially of tragedy. The reason why the two great Greek philosophers paid so much attention to dramatic poetry is closely connected with the reasons why Greek tragedy continues to deserve the interest of philosophers today. An account of philosophical ideas in "Greek drama" can usefully begin with some consideration of ancient philosophical ideas about Greek drama.

PLATO AND ARISTOTLE

It is well known that Plato was hostile to what he regarded as the inflated pretensions of the poets as moral and religious teachers and to the arrogant claims made on their behalf by rhapsodes and expositors. In numerous dialogues (notably in *Apology, Ion,* and *Republic*) he reiterated the complaint that poets lack the knowledge that, he believed, can be achieved only by rigorous philosophizing and that is necessary for the understanding of the human situation and the ordering of human life. The poets pronounce on life's problems without being able to "give an account" (λόγον διδόναι) of themselves and their ideas. Plato might ironically allow that, like conventional statesmen, they have some divinely inspired glimpses of moral and political truth, but he insisted that they lack the true knowledge that is achieved by the philosopher after strenuous dialectical thought.

Tragedy is essentially a kind of rhetoric (*Gorgias* 502D), and Plato reviled it with all the passion that he displayed in his attacks on forensic and political oratory. All these are the arts of mere persuasion, and they are customarily used to persuade men of what is false. Plato explicitly held that most orators, politicians, and poets are dishonest or ignorant, or both, and even the most famous of them would be refused admission to the ideal republic.

One of Plato's most important grounds for despising literature was based on the theory of Forms. The poet deals in the concrete and particular; dialectic, like its mathematical archetype, is concerned with the abstract

and universal. It follows that even an honest poet must inevitably fail to achieve and convey knowledge and understanding, since he is operating at entirely the wrong level. He presents images of images; he and his audience are at two removes from the world of reality and truth (*Republic* 597E).

Aristotle, the philosopher of the concrete particular substance, with his keen interest in the actual particular specimen, was more sympathetic to poetry and literature. Poetry is philosophical because it portrays the nature of man in general by presenting particular individual men in such a way that each portrait throws light on other individuals, just as the biologist studies the genus or the species by attending in detail to actual particular specimens. A chronicle of "what Alcibiades did or suffered" tells us only about Alcibiades. Oedipus or Agamemnon is Man as well as *a* man. Aristotle regarded the poets as contributors to thought, knowledge, and understanding, not as mere entertainers.

The opposite views of Plato and Aristotle on the value of literature must not be allowed to hide the importance of a point on which they agreed. Plato's attack on poetry, like Aristotle's more sympathetic treatment, presupposes that there is an overlapping of function between philosophy and literature. Plato thought that the poets gave wrong answers to the questions and problems that he dealt with in his dialogues, but the very form of his attack implies his recognition that the poets are also concerned with those questions and problems. The old battle between philosophy and poetry could not take place at all unless the two parties shared at least a battleground.

This point is confirmed, and its importance is underlined, by further knowledge of the history of ancient literature and philosophy. It was only in the time of Plato and Aristotle themselves that there began to appear any very clear distinctions between philosophy, history, science, and imaginative literature. Homer had fulfilled all the functions that were later divided among historians, tragic and comic poets, philosophers, theologians, moralists, and scientists. Parmenides and Empedocles were poets as well as philosophers; they did not write both poetry and philosophy—their poetry was their philosophy. Heraclitus wrote in prose but in an oracular, literary manner. Hesiod is part of the history of philosophical and cosmological speculation as well as of the history of literature. Plato himself wrote philosophy that is also literature and, in spite of his own strictures, imaginative and dramatic literature.

MODERN VIEWS

Modern controversy about Greek tragedy has followed similar lines. Many scholars and critics have praised the Attic tragedians as religious and moral thinkers and prophets, thus accepting Plato's view of the nature of the aims and themes of the ancient plays while often strongly dissenting from his valuation of them. Others, by contrast, have denied that the tragedians either showed or meant to show any moral or religious depth or originality, and have presented them as "mere" poets and playwrights whose purpose was purely literary and dramatic and who used traditional mythological and religious material simply because it was traditional.

This dispute is misconceived and is based on a false dichotomy. It not only ignores the artificiality of any attempt to draw a sharp distinction between literature and philosophy in Greek times but also involves drawing a distinction between them that is too sharp to be faithful to the nature and function of literature and philosophy in any age, including our own. Both parties to the dispute share Plato's mistaken assumption that nothing can count as philosophical, religious, or moral thought unless it is explicitly and formally general and systematic. Aristotle's recognition that fifth-century tragedy illuminated morality and religion by a dramatic presentation of particular events and characters needs to be extended to literature in general. The themes of Greek tragedy are the themes of literature: Man, God, Nature, Chance, Freedom, Will, Fate, Necessity, and Good and Evil. Most, if not all, of these themes are also themes of great and permanent philosophical interest, and philosophers should not despise the contributions of dramatists, poets, and novelists to our understanding of them.

TRAGEDY

Aeschylus, Sophocles, and Euripides had much in common: they all drew their characters and plots from a common stock of religious mythology and historical legend inherited from Homer, and they all used their plays as means of presenting the relations between men and gods. The stories of the Trojan War, of Agamemnon and the House of Tantalus, of Oedipus and the House of Cadmus recur in the works of all three. (A "history play," such as *The Persians* of Aeschylus, is exceptional, although commentators have found historical and political allusions in many of the plays that are based on mythical themes.)

Aeschylus and Sophocles were relatively orthodox in their treatment of the traditional themes. The *Oresteia* of Aeschylus presents, through the story of the working out of a family curse, a study of the conflict between man's

efforts to choose and guide his own life and the almost irresistible weight of past events and external influences. Agamemnon "puts on the yoke of necessity" when he chose to sacrifice his daughter Iphigeneia rather than to risk the ruin of the Greek expedition against Troy. In that phrase and in that incident Aeschylus combines an awareness of the force of circumstance with a consciousness of the responsibility that a man bears for his own actions, however circumscribed they are by what lies outside his control. The yoke is a yoke of necessity; but it is Agamemnon who puts it on. In the same trilogy Aeschylus portrays the growth of revenge ("a kind of wild justice," as Bacon called it) into the cultivated plant of civil law. His *Prometheus Bound* is also concerned with conflict. The struggle between Prometheus and Zeus is also the struggle between man's aspiration after knowledge and power and the forces of nature and environment represented by the gods. Men pay in suffering for every step in understanding.

The *Oedipus Tyrannus* of Sophocles also shows the price that must be paid for knowledge and self-knowledge. The man who answered the riddle of the Sphinx finds, when he knows his own nature and his own circumstances, that not all knowledge is sweet, and blinds his eyes that have seen too much. And yet it was ignorance that led him to his tragic end. If he had known more and had known it sooner, he would have done better and fared better. In the *Antigone* we find the "conflict of right with right" that led to G. W. F. Hegel's definition of tragedy; the legitimate claims of Creon, the civil power, are set against Antigone's ardent loyalty to holy and unwritten laws.

Euripides used the same stock of mythical material but in a different spirit. He was a friend of Anaxagoras and a student of the sophists and orators, whose influence is seen in his set debates and rhetorical speeches. The sophistry of Hippolytus ("my tongue it was that swore; my heart is not forsworn") and the atheism of Bellerophon are only two examples of the "free thought" of some of his characters that shocked Aristophanes and other conventional Athenians. It was debated, and is still debated, whether Euripides was himself an atheist or a modernistic theologian. To the modern reader of the plays the question is of merely academic interest. In the *Hippolytus* and the *Bacchae* he vividly presents conflicts between Aphrodite and Artemis and between Dionysus and the forces of order and restraint. The impact of these conflicts on a modern reader is not much affected by questions about whether Euripides literally believed in the gods of the Greek pantheon or merely used them as personifications of forces in human nature that are as familiar to us as they were to his original audience.

In reading Greek tragedy, as in reading any work of imaginative literature, we must beware of attributing to the author the opinions and attitudes expressed by his characters. The best Greek tragedies are as dialectical as the works of Plato. The issues they deal with are too complex and subtle to allow a neat answer to be given to them in the speeches of any one character. The dramatist presents and portrays; he does not argue and declaim.

COMEDY

Attic comedy is of little more than historical interest from the philosophical point of view. The *Clouds* of Aristophanes pillories and parodies a "Socrates" who is made to represent all that was new and disturbing in contemporary Greek thought. Aristophanes shows here and in several other plays (especially in the *parabasis,* or address of the chorus to the audience on current topics) that he was a conservative who looked back to the golden days of Aeschylus and the other "men of Marathon." His satirical purpose could best be served by ignoring the great diversity in the movements of thought that he disliked: Pythagorean and Orphic mysticism, natural speculation, sophistic attacks on conventional morality and religion, and the revolutionary theology of Euripides.

Comedy, like tragedy, was religious in its origin, and Aristophanes, if read with caution, can contribute to our knowledge of the history of Greek religious thought. But no comic writer can be trusted very far as a source of information on philosophical or scientific thought, and in particular Aristophanes' account of Socrates needs more delicate handling than it has received from scholars preoccupied with the "Socratic question." What the *Clouds* does show is that philosophical speculation was of some interest to the general public in Athens, even if only as a butt of jokes and gibes. Socrates testifies in Plato's *Apology* that attacks by comic poets helped to foster prejudice against him.

The contest between Aeschylus and Euripides in the *Frogs* of Aristophanes is one of the earliest examples of literary criticism, and it preaches, as Plato did, that the poet's function is to edify and instruct his audience.

GREEN, THOMAS HILL
(1836–1882)

Thomas Hill Green, the English idealist philosopher, was born the fourth son of a Church of England clergyman at Birkin in Yorkshire. His mother died when he was only a year old. Green received his early education from his father before going at the age of fourteen to Rugby School, which had been reorganized on distinctive lines by Thomas Arnold a few years earlier. The corporate side of life at Rugby had little appeal for Green, but his fellow scholars were already impressed by his seriousness and independence of mind. Academically, he was able but not outstanding. In 1855 he entered Balliol College, Oxford, where he was an undergraduate for the next four years. Green was only a moderate classical scholar, but he got first-class honors when he took the final examinations in

Literae Humaniores, preparation for which gave him his first serious work in philosophy. He was elected a fellow of Balliol in November 1860 but did not get a regular teaching post there for several years. In 1863 he refused an offer of the editorship of the *Times of India,* then being started in Bombay; in 1864 he was an unsuccessful candidate for a philosophy chair at the University of St. Andrews. In 1865 and 1866 he served as assistant to a Royal Commission investigating school education in England and Wales, working mainly in and around Birmingham. From 1866 onward he was heavily engaged at Balliol, where he became the first nonclerical tutor; by 1870, the year in which Benjamin Jowett became master, much of the administration of the college had fallen on his shoulders. He continued to serve as a tutor until 1878, when he was elected Whyte's professor of moral philosophy at the university.

By this time Green had married Charlotte Symonds (1871) and had published his first major philosophical work, the long critique of empiricism which constitutes the introduction to the edition of David Hume's works, which he produced with T. H. Grose. He had also begun to take an active part in social work and in local politics. From 1872 on he was prominent in the temperance movement (one of his brothers was a hopeless drunkard), and in 1876 he became a member of the Oxford town council, being the first active teacher in the university to hold such an office. He also played a major part in a movement to found a new high school in Oxford. Unfortunately, however, his health deteriorated sharply during these years, and matters were not improved by the added lecturing duties of the professorship, which Green undertook with characteristic thoroughness, writing out his lectures in full. He had long planned a major work on moral philosophy, but his *Prolegomena to Ethics* was still incomplete when he died in 1882. It was published by A. C. Bradley the following year. Green's other philosophical and miscellaneous writings were collected in three volumes by R. L. Nettleship, who also wrote the long memoir printed in Volume III.

Green has been described as the first professional philosopher in the modern sense; he was certainly one of the first specialized teachers of the subject in Oxford. But he exercised influence in many spheres outside philosophy. His work as a Balliol tutor did much to produce a distinctive type of Oxford graduate, unknown in the mid-nineteenth century: hardworking, intensely serious, aware to a surprising degree of social problems and realities. In politics he was important not only because of what he did to ease relations between "town and gown" in

Oxford but also for his pronounced radicalism: He was a strong supporter of John Bright against Lord Palmerston and of the cause of the North in the American Civil War. His essay "Liberal Legislation and Freedom of Contract" (1881) is important for its criticisms of pure laissez-faire liberalism and can be seen as anticipating the doctrine of the welfare state. Theologically, Green was not strikingly original, but the low value he set on dogma and historical tradition was certainly not without its effect. By insisting on the independent authority of philosophy he may well have persuaded many intending ordinands to take up other careers. Although very different in his philosophical views and immediate disciples from his contemporary Henry Sidgwick, he made much the same contribution to the secularization of Oxford as Sidgwick made to the secularization of Cambridge.

CRITIQUE OF "POPULAR PHILOSOPHY"

A useful point of entry into Green's philosophical thought is to be found in his early essay "Popular Philosophy in its Relation to Life," originally published in 1868. The "popular philosophy" of the title was that professed by the advanced thinkers of the time, whom Green explicitly compared with the ancient Sophists. Like the Sophists they were superficially clear and rhetorically persuasive; again like them, they owed their apparent success to a refusal to examine their basic notions. Yet these notions, when applied in the concrete, turned out to be wholly inadequate; they could not successfully be brought to bear on life, as understood in art or religion or moral practice. In "Popular Philosophy" Green set himself to demonstrate this conclusion only in the case of ethics, reviewing for this purpose the doctrines of Joseph Butler, David Hume, and Jean-Jacques Rousseau, but it was obvious that he had wider considerations in mind. When he spoke of the need for an "adequate theory," of which the philosophy of G. W. F. Hegel might offer a foretaste, he was implying that the philosophers he was considering were wrong not only in their ethical distinctions but also in their whole method and metaphysical outlook. Following John Locke, they assumed that truth could be arrived at by simple introspection; they had no notion of the difference between image and concept and hence no tenable theory of thinking. The statement of their theories presupposed a continuing self-identical subject, but the theories themselves had no room for any such thing. Nor, in practice, had they anything like an adequate grasp of the workings of the human mind, which they looked on as an isolated automaton mechan-

ically pursuing pleasure and seeking to avoid pain, instead of as an active agent whose interest and welfare were intimately bound up with those of others.

The corrective to popular philosophy, Green said at this stage, was to be found in "the deeper views of life which the contemplative poets originated" and in the notions of "evangelical religion," as well as in some of the better insights of Rousseau. It was not "'within his own breast'" that Wordsworth had looked to "read what he was," but to "the open scroll of the world, of the world, however, as written within and without by a self-conscious and self-determining spirit" (*Works,* Vol. III, p. 119). Similarly, the evangelical insistence on the sense of sin showed the superficiality of the moral philosophy of the Enlightenment, which could represent vice as an object of regret or distaste but never as an object of abomination. Much of Green's mature philosophy becomes intelligible if we bear these remarks in mind. He took neither poetry nor religion to be a substitute for philosophy, but nonetheless he felt deeply that both had important lessons to teach the philosopher.

CRITIQUES OF HUME AND NATURALISM

The more academic criticisms sketched in Green's early essay were elaborated in the introduction to his edition of Hume's works (1874). Green's view was that Hume was a major philosopher who had taken Locke's ill-thought-out assumptions to their logical conclusion and, in so doing, had revealed their absurdity. Hume's first principle was that nothing is real save feeling; Green attacked this view with the argument that to say that something is real is to relate it to other things and that relations are not given in feeling but are the work of the mind. Hume's attempt to ground "philosophical" in "natural" relations, that is, in what is given to sense, was a failure. So was his theory of the self as a succession of perceptions, for relating clearly demands an unchanging subject that relates. The argument of this passage was carried further in the first book of the *Prolegomena to Ethics,* where Green claimed that not only our consciousness of nature but also nature itself presuppose an "eternal," self-identical, and self-differentiating subject which is the source not only of the connections in thought but also of its material. A halfway position, such as Immanuel Kant had taken, was not intellectually defensible: The thing-in-itself and its empiricist counterpart, the sheerly given, remain unintelligible on this type of view.

Green's object in metaphysics was plainly to state an alternative to materialism, which struck him as both

insidiously attractive and intellectually preposterous. Much the same ambition informs his writings on ethics, in which field he again saw himself as developing an anti-naturalist position. In his critique of moral sense theories, which forms part of his general criticism of Hume, he represented the supporters of those views as one and all hedonists, on the ground that they made the passions the only spring of action and thought of reason as practically inert. Hence, his own first aim in the *Prolegomena* was to establish that human actions spring from *motives* and to show that motives are not "natural phenomena." He defined a motive (Sec. 87) as "an idea of an end, which a self-conscious subject presents to itself, and which it strives and tends to realise." The vital point here was the connection between motives and a continuing subject consciously pursuing good; human action, for Green, was entirely different from animal behavior, for although much of it had animal impulses as its basis, these impulses were transformed in being brought into consciousness and thought of in relation to long-term aims. As for the good with which action is concerned, Green said (ibid., Sec. 92) that "anything conceived in such a way that the agent acts for the sake of it, must be conceived as *his own* good, though he may conceive it as his own good only on account of his interest in others, and in spite of any amount of suffering on his own part incidental in its attainment." But in practice he had little to say about the connection of good with the satisfaction of the agent: The moral ideal must be realized in persons, but one person's claims to moral self-expression were as good as those of another, and moral progress came about with the realization that more and more persons and types of person were entitled to have their claims considered. Green made much use of the phrase "the common good" in speaking of the ultimate aim of moral action, but his alternative description of the end as the attainment of "human perfection" is in some ways more appropriate, provided it is added that he wanted to see human perfection realized without distinction of persons.

POLITICAL PHILOSOPHY

In ethics Green had clearly learned a lot from Hegel, although his general outlook remained more Kantian than Hegelian—both in theory and in practice he must be counted as a liberal moralist. His political philosophy also is in the liberal tradition, despite its rejection of such elements of older liberal political theory as the doctrine of the contract. The state, according to Green, is the product of will, not of force, insofar as the system of rights and duties it operates rests on a moral as opposed to a merely natural basis. Green was as emphatic in his political as in his ethical theory that rights cannot be created out of nothing, in the way Thomas Hobbes and Benedict Spinoza supposed. But although he thus saw the state as, in a sense, a moral organism, Green had no inclination to endow it with positive moral authority. The state might sometimes have to inhibit the freedom of particular men to enable others to be free at all, but the end of political action could only be to put citizens in a position to lead the good life. The liberalism he favored was thus in the end a negative liberalism, concerned with creating the minimum conditions in which people could exercise moral choice and, for the rest, leaving matters to their voluntary efforts.

Compared with that of his younger contemporary F. H. Bradley, Green's literary style was flat and uninteresting. The moral earnestness that is apparent in so much of his writing also has had much to do with its neglect by more recent philosophers. But however earnest he was, he was at the least estimate an influential thinker; to describe him, as C. D. Broad did, as "thoroughly second-rate" is to forget the extent to which his articulation of problems is still accepted, for example in political philosophy. Nor are his solutions entirely without interest, if only we can divest them of the stiff Victorian garments in which he chose to clothe them.

GREGORY OF NAZIANZUS
(329/330–c. 390)

Gregory of Nazianzus, the poet, theologian, and bishop, was born at Arianzum in Cappadocia. Although his parents were Christians, he enjoyed an excellent classical education at Caesarea in Palestine and at the universities of Alexandria and Athens. He was from his earliest years a close friend of the other two Cappadocians, Gregory of Nyssa and Basil the Great. Baptized at about the age of thirty, he was ordained by his father, the local bishop—apparently against his will—and immediately fled. After his penitent return, Basil appointed him bishop of the isolated town of Sasima. However, Gregory refused to go and remained with his father at Nazianzus, staying on after his father's death in 374. After a period of monastic living he was approved as bishop of Constantinople under Emperor Theodosius, but distrust of his own administrative ability once again forced him to resign after a year. After a few years at Nazianzus, he finally retired to his estate at Arianzum and devoted his last years to writing; it was here, between 384 and 390, that he wrote his greatest poems.

Adequate study of Gregory is still hampered by the lack of a full critical edition of his works. The bulk is poetic (more than 16,000 lines). There are also 44 orations, including the important dogmatic ones (numbers 27–31, delivered in 380), and 244 authentic letters.

Gregory Nazianzen is the most literate, self-conscious stylist of the three Cappadocian Fathers, although perhaps not as profound as Gregory of Nyssa nor so immersed in ecclesiastical affairs as Basil the Great. Although he once compared philosophy to "the plagues of Egypt," his poetry shows the wide influences of all the Greek schools, and especially of the Stoic-Cynic. In morals Gregory reflects a sharply critical view of contemporary worldliness and sensuality; and his introspective poetry (especially the autobiographical "De Vita Sua") marks a new era in Christian self-awareness and is comparable to Augustine's *Confessions.* The bulk of his verse, however, is coldly classical and heavily didactic.

Gregory was fully aware (see *Oration* 20.17) of the role of speculation in theology. He contributed to Trini-

tarian theology by clearly defining the relations and properties of the three Persons of the Trinity. In Christology he insisted on the two distinct natures in Christ bound by a "union according to essence," copresent to each other by "circumincession"—a term later applied to the Persons of the Trinity. In developing traditional dogma, Gregory's discussion is sometimes sharper than either Basil's or Gregory of Nyssa's, although he is vague on the doctrines of hell and original sin.

GREGORY OF NYSSA
(c. 330–c. 394)

Gregory of Nyssa, the Christian theologian and Father of the Eastern church, was born in Cappadocia. Resisting the invitation of his brother, Basil the Great, to join his monastic community at Annesis, Gregory married and became a teacher of rhetoric. In 372 Basil, bishop of Caesarea, had Gregory appointed bishop of Nyssa; but Gregory was deposed in 374 by a local synod dominated by the Emperor Valens and the Arian party. Restored to his see in 377, Gregory began to grow closer to Basil's monas-

tic and theological ideals. After Basil's death in 379, Gregory engaged more and more in writing and in the vigorous administration of his diocese; he was an important figure at the councils convoked at Constantinople in 381, 383, and, just before his death, in 394. An ardent defender of the orthodox Trinitarian doctrine of Nicaea against the Arians and semi-Arians, he was also popular in court circles at Constantinople. Toward the end of his life, when his influence began to wane, he devoted himself to the deepening of the traditional Christian heritage of mystical theology; during this period, from about 390 until his death, he composed some of his most profound works, the *Commentary on the Song of Songs* and the *Life of Moses*, which represent the culmination of the process inaugurated in his earliest work, the *Treatise on Virginity* (c. 370).

Gregory's originality lay chiefly in the depth and mystical awareness he brought to the problem of human's knowledge of the Transcendent. Many of his works, such as the *Life of Moses*, can be understood on three levels: Moses represents the life of the true believer, the Christian philosopher, and the mystic attempting to find God in the universe. In his exposition of the Trinity and his discussion of God's nature, Gregory penetrated deeper than any other Eastern Father. The core of his theology is the historical perfection of humankind through the restoration of the divine image, regained by the Atonement and communicated through the church. In his doctrine of the *Apokatastasis*—the restoration of all people, even the damned, to the vision of God at the end of time—Gregory reveals his loyalty to Origen as well as his own attempt to create a harmonious structure of salvation history. Throughout his work we see the development of the doctrine of the spiritual or mystical senses (implying a direct intuition of God's presence) and an analysis of ecstasy that prepared the way for Dionysius the Areopagite, Maximus the Confessor, and later Byzantine mysticism.

In his epistemology Gregory is derivatively Neoplatonic, and his allegorical exegesis reflects the anthropology of Origen and Philo of Alexandria as well as the eclectic philosophy of Hellenistic Asia Minor. But Gregory never slavishly followed any master, and scholars like H. F. Cherniss go too far when they suggest that Gregory's theology was merely a question of giving Christian names to Plato's doctrines. Rather, the opposite view of Jean Daniélou and others seems closer to the truth: Gregory's theology represents a subtle transformation of Neoplatonism into authentic Christianity, whereby the intuitive vision and ethical achievement of the Christian mystic (in Daniélou's terminology, *epektasis*) was the culmination of the pagan philosopher's quest.

GREGORY OF RIMINI
(c. 1300–1358)

Gregory of Rimini, a member of the Augustinian friars and one of the foremost thinkers of the fourteenth century, was born in Italy and died in Vienna, where he spent the last eighteen months of his life as general of the Augustinian order. A large part of his active career was spent at Paris, where he studied from 1323 to 1329. After teaching in Italy, he returned to Paris in 1341 and remained there for ten years. During this second sojourn in Paris he wrote his main work, a *Commentary on the Sentences.* None of the other writings ascribed to him, ranging from biblical commentaries to a treatise on the remission and intensification of forms, has survived.

Gregory's system was a reassertion of St. Augustine's teachings in fourteenth-century terms. He shared the contemporary awareness of the radical contingency of the created order and the unbridgeable gulf between God and his creatures that it entailed. He thereby followed William of Ockham and his confreres in rigorously confining natural knowledge to what could be verified and in excluding theological truths and evidence for God's existence from ratiocination. On the one hand, God was sovereignly free and man had no means of knowing what He might do; on the other, the knowledge accessible to man dealt only with contingencies and was ever liable to be superseded if God so willed. In consequence, there was no guarantee that the world was not infinite or eternal or that there was only one world; and even if its finiteness was accepted, God could still transform it. Gregory parted from the Ockhamists, however, in his refusal to allow this distinction between natural experience and God's will to undermine the traditional certainties. Even if natural knowledge was confined to practical experience, there still remained an inner realm of knowledge that was the source of all necessary truths and nonsensory principles. Similarly, although God was unconstrained

and his ways inscrutable, he still acted in accordance with his perfections.

Thus Gregory rebutted the Ockhamist assertions that God could cause a man to sin, or mislead him, or command a man to hate him: God's freedom could not violate his own nature as revealed in the Scriptures. Although Gregory subscribed to the current distinction between God's ordained power (*potentia ordinata*) and his absolute power (*potentia absoluta*), by which he could do anything without qualification, he never—unlike the Ockhamists—employed the latter to override dogma. Gregory accordingly adhered to the accepted dogmatic tenets whether they concerned God's foreknowledge, man's fallen state, or the theological virtues. Only in the case of the physical world did he acknowledge the possibility, both on epistemological and theological grounds, that the world could be other than it was: that it might be infinite or eternal. Gregory joined in the current reversion to the earlier view that theology was *sapientia* (wisdom) rather than *scientia* (scientific knowledge). It was distinguished by its inaccessibility to the nonbeliever, and faith, far from being communicable, was the barrier that divided the Christian from the infidel. In this, as in other ways, Gregory shared in the changed outlook of the time, while remaining true to the tradition of St. Augustine.

GRICE, HERBERT PAUL

(1913–1988)

Herbert Paul Grice was born and educated in England. He taught at St. John's College Oxford until 1968, when he moved to the University of California–Berkeley. He taught there until his death. He published little until near the end of his life, but had a great influence through students and the wide circulation of unpublished manuscripts. His earliest work dealt with perception, but he subsequently moved to problems in language, ethics, and metaphysics. A concern with reason and rationality is a subtle thread which unites these investigations. His historical idols were Aristotle and Kant.

One early topic was a defense of the causal theory of perception. This defense required separating the scientific or specialist's part of the task of analyzing perception from that of the philosopher. This distinction relies on an underlying notion of analysis closely related to the analytic–synthetic distinction for which Grice and Strawson provided a brief spirited defense. Three subsequent papers represent intricate attempts to define meaning using only common sense psychological concepts such as intention, belief, and desire. If this program is successful it would provide a more elaborate defense of the analytic synthetic distinction.

Grice's best known and most influential contribution is the concept of a conversational implicature. A conversational implicature of an assertion is something that is conveyed to a thoughtful listener by the mode of expression rather than by the meanings of the words. These arise from the fact that conversation is normally governed by principles including cooperation, truthfulness, and informativeness, and that both parties are aware of these. The two best known applications of this concept are to perception and logic. Grice was concerned to provide an account of sense data discourse in terms of how things seemed to the perceiver. A common objection to this is that it is odd to say in a normal case of the perception of a table that it *seems* to the subject that a table is present. Grice's concept of conversational implicature can be invoked to explain the oddity as a result of the fact that a

stronger statement can be made, thus leaving room for the *seems* statement to be true.

The concept of conversational implication has been widely deployed in linguistics and artificial intelligence as well as in philosophy and is a continuing topic of research and debate. One major focus of discussion is the adequacy of the account when applied to quantitative statements, such as "John has two children." It is controversial whether this statement means that John has exactly two children, or whether it means that John has at least two children. In the latter case, interpreting an assertion of the statement as conveying that John has exactly two children is a matter of conversational implication.

Grice also scouts the possibility of defending the claim that the logician's material conditional is an adequate representation of the indicative conditional of English by explaining the apparent divergence as a matter of conversational implicatures. If one knows the truth values of P and Q then one can make a more informative statement than P⊃Q, so the only conversationally appropriate use of P⊃Q is when the speaker does not know the truth of either component, but only that they are so connected that the truth of P guarantees the truth of Q. The appropriate conversational use of P⊃Q requires a connection that is not part of the truth condition of the compound. The main objection to Grice's approach concedes that his account squares fairly well with the assertion of conditionals, but points out that it does nothing to ameliorate the implausible fact that on the material conditional account, to deny "if P then Q" implies both P and ~Q.

Part of the definition of a conversational implicature requires that the hearer should be able to reason out the intentions of the speaker and in conjunction with the conversational principles to discern the implicit message. This places an important role on reasoning, especially inasmuch as in typical cases the reasoning is not conscious in the hearer.

Grice devotes considerable energy to investigating rationality, reasoning, and reasons. Grice emphasizes that reasoning is typically directed to the goal of producing reasons relevant to some end in view. This intentional activity involves the ability to make reason-preserving transitions. Grice defines "reason preserving" analogous to the concept of "truth preserving" in deductive logic. A transition is reason-preserving just in case, for if one has reasons for the initial set of thoughts, beliefs, actions or intentions, then one does for the subsequent set as well.

Grice uses this general account of reasoning to investigate moral reasoning and moral reasons. He emphasizes the connections between reasons, actions, and freedom. Strong rational evaluation—which Grice sees as essential to freedom—involves the rational evaluation and selection of ends, including ultimate ends.

How do people choose ultimate ends? Grice answers that people should choose ends that have unrelativized value. Grice grants that the concept of unrelativized value requires defense. Typically, things have value only relative to ends and beneficiaries. A concern for the focus of relativization gives the value-concept a *bite* on a person; it ensures that the value-concept carries weight for that person. So how are people to understand unrelativized value?

Grice turns to final causation for a special kind of value. A tiger is a good tiger to the degree that it realizes the final end of tigers. Grice defines a good person as one who has, as part of their essential nature, an autonomous finality consisting in the exercise of rationality. Grice's philosophical psychology supports this conception of persons as end-setters. Freedom intimately involves the ability to adopt and eliminate ends. One does not (ideally) arbitrarily select and conform to ends; one does so for reasons. This makes being an end-setter an instance of unrelativized value; for to take a consideration as an ultimate justification of action is to see it as having value. Grice defines unrelativized value "in Aristotelian style [as] whatever would seem to possess such value in the eyes of a duly accredited judge; and a duly accredited judge might be identifiable as a good person operating in conditions of freedom." (*Aspects of Reason* 2001, p. 119) Of course, we are still talking about what is of value for and to persons. But the point was not to avoid this *relativization*; the point was to avoid relativization to this or that kind of person.

GROSSETESTE, PSEUDO-

See *Pseudo-Grosseteste*

GROSSETESTE, ROBERT
(c. 1168–1253)

Robert Grosseteste was one of the most influential Englishmen of his day—initiator of the English scientific tradition, one of the first chancellors of Oxford University, a famous teacher and commentator on the newly discovered works of Aristotle, an important translator from the Greek, friend to the mendicant orders, first lecturer to the Oxford Franciscans, and zealous bishop of England's largest diocese. However, his life is imperfectly known and much of his work remains unpublished. He was born of humble parents in the county of Suffolk between 1168 and 1175 and by 1190 had become *magister in artibus* at either Oxford or Paris. Sometime between 1190 and 1198 he was a member of the household of William de Vere, bishop of Hereford, and may have taught in the Hereford schools. After the bishop's death in 1198, Grosseteste was a member of the arts faculty at Oxford or possibly at Cambridge. He probably studied theology at Paris during the *suspendium clericorum,* 1209–1214. At some time between 1214 and 1221 he became chancellor of Oxford University. In 1229 he became the first lecturer to the Oxford Franciscans, leaving this post only on his elevation to the see of Lincoln in 1235. He was bishop of Lincoln until his death eighteen years later.

Grosseteste lived at a crucial period in intellectual history: The scientific and philosophical writings of the Muslims were just becoming known in Latin Europe and the works of the Hellenistic writers and the recently rediscovered works of Aristotle were being translated, disseminated, and lectured upon. As teacher, commentator, and translator, he took an active part in this movement. Basically Augustinian in outlook and relying heavily on the standard authors, he was nevertheless deeply influenced by Muslim learning, especially Avicenna and the astronomers, by the Jew Solomon ben Judah ibn Gabirol (Avicebrón), and by the newly found Aristotelian works. He never wrote a comprehensive philosophical work or devised a system, but he developed many characteristic views that have had a profound influence on the later development of both philosophy and science. The most important of his many philosophical works are *De Luce* (Light), *De Motu Corporali et Luce* (Corporal Motion and Light), *Hexameron,* and commentaries on Aristotle's *Posterior Analytics* and *Physics.*

LIGHT METAPHYSICS

Basic to Grosseteste's view of the universe is his metaphysics of light. He held that in the beginning God created the first corporeal form (*lux*), which had the property of instantaneously multiplying itself infinitely in every direction, and simple matter, an unextended substance. The original point of light was joined to unextended matter (since matter and form never exist separately) and in its expansion drew matter out into spatial dimensions. The resulting universe was a sphere extremely rare at the periphery but dense and opaque near the center. It was finite because a simple substance multiplied an infinite number of times would result in a finite quantity, and the matter of the periphery (the firmament) was completely actualized and capable of no further change.

When this perfect first body, containing only first matter and first form, had been created, it diffused its reflected light (*lumen*) back to the center, where the *lumen* gathered together the mass existing below the first body, again rarefying the outermost parts and making the center more dense. The second sphere was thus formed, as were, by a similar process, all thirteen spheres, including the four elements. On the outside of our universe, matter is completely actualized and capable of no further change, while at the center the degree of actualization is less and matter remains susceptible of taking on a variety of forms. From first form (light) every subsequent form is generated, both substantial and accidental, and every privation derives from the privation of light.

Since all things have in common first form and first matter, they are, in a sense, one. But each thing includes a hierarchy of form superadded to the original form of corporeity, making it the individual thing it is. Most of Grosseteste's other views were either derived from or imply his light metaphysics. He considered light the cause of local motion, the means by which the soul operates on the body (he denied that the soul is the form or perfection of the body), and the principle of intelligibility in the created universe.

THEORIES OF KNOWLEDGE

Grosseteste had two distinct theories of knowledge. The first, in the Augustinian tradition and strongly influenced by Avicenna, held that men may acquire knowledge by virtue of the intellect alone, without recourse to sense. The second held that certain knowledge may also be gained through sense perception. Although sense turns toward matter and is therefore unstable, imperfect, and subject to imaginative embellishments, it also follows reason, even though confusedly, and does not obscure the species it provides. Reason, which understands the principles of nature in a single manner, either corrects or completes whatever was lacking in the senses.

Both these ways of knowing involve another of Grosseteste's key concepts, the purgation of the mind. It is not until the desires of one's mind (*affectus mentis*) are purged of error that the gaze of one's mind (*aspectus mentis*) can be raised to the eternal and true and can overcome the delusions caused by corporeal phantasms. "Many men," Grosseteste said, "can prove by sure reasons that the Intelligences exist and that God exists but they do not understand the Divine Essence or the non-corporeity of the Intelligences.… Aristotle and others, who firmly knew by discursive reasoning that eternity was simple but saw it under the phantasms of temporal extension, have affirmed many improper things such as the perpetuity of time and motion and consequently the eternity of the world." In this quotation from the *Commentary on the Physics,* we see Grosseteste at once as one of the foremost critics of the dangers latent in the works of Aristotle and yet also among the leaders in introducing Aristotle's natural philosophy into western Europe.

INFINITY

One of Grosseteste's most original and influential teachings concerns infinite aggregates. He believed that "one infinite number can be related in any proportion,

numeral or non-numeral, to another infinite number." To God, infinite numbers are finite, and he determines the primary cubit (and every other measure) by a certain infinite number and a half-cubit by another infinite number half (to him) that of the cubit, and so on. But such a manner of measuring is possible only to one to whom the infinite is finite. Being finite, we must necessarily adopt a different manner of measuring, that is, by commensurable magnitudes as accidents of matter.

SCIENTIFIC METHOD

It is as a scientist and innovator in scientific method, however, that Grosseteste attracted the interest of the twentieth century. In his most important scientific writings he progressively developed a characteristic method of investigating nature that employed analysis (*resolutio*) and synthesis (*compositio*) in physical inquiries, first breaking down a problem into its simplest parts, then framing a hypothesis that would show how these elements are to be combined in order to produce the phenomenon under investigation. He also held that an experimental universal of provisional truth might be obtained by observing that a given effect always results from a particular cause, if one controlled his observation by eliminating any other possible cause of the effect.

In addition to this framework, Grosseteste used experiments as an integral part of his investigation: as aids in accomplishing his analysis, as suggestions in framing his explanatory hypothesis, and most important, as tests of the truth or falsity of a hypothesis. He also employed mathematics in his researches, holding that since light is the cause of local motion and the means by which superior bodies act on inferior ones, and that since light behaves according to geometric rules, therefore all local motion can be described mathematically. He denied, however, that mathematical entities have any objective being and insisted that they are simply abstractions from physical bodies and exist only in the minds of mathematicians.

Another of his basic principles was that of the subordination of sciences. A superior science, he said, may provide the cause for which the inferior science provides the effect. In the study of heavenly bodies, for instance, the sciences of mathematics, astronomy, and physics are concerned. Mathematicians abstract magnitudes from motion and matter and demonstrate the accidents per se with respect to magnitudes. Physicists, on the other hand, demonstrate the figured magnitudes in the sense that they belong to physical bodies. Astronomers have much in common with physicists, but whereas they might both be studying the same body—for instance, the moon—the physicist demonstrates that the predicate belongs to the subject by nature, while the astronomer does not care whether it belongs to it by nature or not.

Grosseteste wrote four works on astronomy. His work *De Sphaera* (On the Sphere) is a theoretical treatise. The other three works are primarily concerned with reforming the Julian calendar, which was nearly four days in error at that time. Using the works of Ptolemy, al-Battani, and Ibn Thebit, he worked out a program for calendar reform that continued to find supporters until it was largely incorporated into the Gregorian reform of 1582.

Grosseteste was in many ways the hinge between the early and late Middle Ages. He had at his disposal the standard late Roman authors and the recently introduced Greek and Arabic sources. His powerful, resourceful, and disciplined mind assimilated and transformed this material. He left many loose ends and sometimes failed to think through his positions; and in his scientific works, despite his methodological triumphs, he was not a notable experimenter. Still, so powerful was his thought that he influenced an uninterrupted succession of philosophers and scientists throughout Europe for 300 years after his death.

GROSSETESTE, ROBERT [ADDENDUM]

Since the mid-1970s, further research into Grosseteste's biography has produced more uncertainty than any new detail. His putative birth date and his humble beginnings are unquestioned, but the first twenty years of his life remain obscure. How he became learned in the liberal arts is open to speculation. Doubtless he was a *magister in artibus* by 1190, but there is no evidence that he studied (or taught) at either Oxford or Paris during this time. His association with Hereford may explain his lifelong interest in natural philosophy, although no evidence has emerged supporting a subsequent teaching career there, nor anywhere else, between 1198 and 1225. The scholarship is divided as to whether Grosseteste actually studied theology at Paris between 1209 and 1214 because of a compelling case made recently that he may have studied there between 1225 and 1229.

This latter dating would certainly explain how Grosseteste gained access to the commentaries of Averroes that were disseminated in Paris soon after 1225. It has been well-established that the 1220s was a highly productive period when he began to engage seriously the writings of Aristotle and his Arabic commentators. Some scholars have also called his Oxford chancellorship into question: The documentary evidence is open to interpretation and can be read as if he never were chancellor; or if he were, he was not the first. After 1229 or 1230, the first documented date of Grosseteste as a teacher, the biographical evidence is more abundant and the chronology from this point until his death is unchallenged.

GROTE, JOHN
(1813–1866)

John Grote, the English moral philosopher and epistemologist, was born at Beckenham in Kent. He was a younger brother of George Grote, the historian. Grote studied classics at Cambridge and became a fellow of Trinity College in 1837. He took orders in the Church of England and eventually obtained a church living at Trumpington, where he resided until his death. In 1855 he succeeded William Whewell as Knightbridge professor of moral philosophy at Cambridge. For a number of years an informal group, sometimes called the Grote Club, met regularly with him for philosophical discussion; Henry Sidgwick and John Venn were among its members.

Grote's writings were concerned primarily with ethics and theory of knowledge. He thought the former the more important study and intended the epistemological discussions in his *Exploratio Philosophica* to serve as prolegomena to his moral theory. Throughout his work he criticized the claim that only science or the "positive standpoint" could give us truth. Science treats perception simply as the action of one body on another, and it investigates the antecedents and concomitants of all thoughts and feelings indifferently. Hence it can give no adequate account of truth or falsity in thought. Philosophy, which is the study of thought and feelings as we are directly aware of them from within, can deal with truth and falsity, but it cannot give causal explanations. Hence the positive and the philosophical standpoints can lead us to truths that supplement each other. Grote argued with considerable acuteness that confusion of these standpoints was responsible for many of the difficulties of traditional theories of perception and knowledge, but he confessed himself unclear as to how they were related.

In ethics, Grote argued that utilitarianism overlooked the fact that man is essentially as active a creature as he is a sentient one. Concentrating only on human sentience, utilitarianism provides a theory of the good in feeling, but since it says little about right acting, it is unable to give an adequate account of the right distribution of good. The attempt to construct a positive science of morality is misguided and hopeless, since it omits the "ideal" element, or conception of what ought to be, which is central to morality. An ethical principle cannot be derived from facts alone, nor can it usefully be made true by definition; hence a basic intuition is required. There is, however, an important utilitarian element in morality, and that element provides a necessary check on possibly spurious intuitions. Grote suggested that the old conflict between utilitarianism and intuitionism should be seen as a conflict between partial views of a whole truth.

Grote held that the philosophical standpoint was more fundamental than the scientific. He gave a number of reasons for this. Underlying them is the view that the attempt to come to a rational understanding of the world implies the belief that the world is already rational, which implies in turn the belief that it is the creation of a mind. But mind, Grote held, can be understood as such only from the philosophical standpoint. The attempt to act morally in the world presupposes, similarly, a belief that the world is morally ordered, and this implies a belief in a moral governor. Grote interpreted these beliefs theistically. His development of them anticipated in many ways the absolute idealism of the generation after him. He argued that all truth is systematically interconnected; that truth is ultimately to be understood as coherence, rather than correspondence; and that the distinctions of perception and conception and of necessity and contingency are relative. In ethics he worked toward a view emphasizing self-development and man's duty in his station.

It has been said that Grote should be viewed as the first of the Cambridge analytic philosophers, and certainly his great respect for ordinary language and ordinary thought, his persistent attempts to find and remove logical confusions, his insistence on the importance of clarity, and his pursuit of it in detailed and painstaking criticism have obvious affinities with the work of that group. There is, however, little evidence to show that he had much direct influence on anyone, and his writing, which is difficult and prolix, has been very little studied despite its acuteness and considerable originality.

Bibliography

With the exception of *Exploratio Philosophica*, Vol. 1 (Cambridge, U.K.: Deighton, Bell, 1865), Grote's main writings were edited from his papers and published posthumously by his literary executor, J. B. Mayor. They are: *Examination of the Utilitarian Philosophy* (Cambridge, U.K., 1870); *Sermons* (Cambridge, U.K., 1872); *Treatise on the Moral Ideals* (Cambridge, U.K.: Deighton, Bell, 1876); and *Exploratio Philosophica*, Vol. 2 (Cambridge, U.K., 1900). There are also some papers, of which the most interesting is a series called "Glossology" in the *Journal of Philology,* 1872 and 1874. Further details may be found in Mayor's prefaces to the volumes he edited. There are no detailed secondary studies, but G. Watts Cunningham, *The Idealistic Argument* (New York: Century, 1933) has a chapter on Grote.

J. B. Schneewind (1967)

GROTIUS, HUGO
(1583–1645)

The Dutch jurist and statesman Hugo Grotius, or Huig de Groot, was born at Delft, of a distinguished Calvinist family. He entered the University of Leiden when he was eleven, graduating with great distinction at the age of fourteen. At fifteen he served as a member of a Dutch mission to France and obtained the degree of doctor of law at the University of Orléans. In 1601 Grotius was asked for a legal opinion by the Dutch East India Company in an international case, which appears to have spurred the writing of his pamphlet in defense of freedom of the seas (*Mare Liberum,* 1609) and generally stimulated his enduring interest in international law. In 1607 Grotius was appointed advocate general of the fisc of the provinces of Holland, Zeeland, and Friesland. In 1613 he became the pensionary for Rotterdam and went to Eng-

land as a member of a Dutch diplomatic mission. A bitter theological dispute, in which Grotius sided with the estates of Holland against orthodox Calvinism (supported by Prince Maurice of Holland) led to a special trial and the condemnation of Grotius to life imprisonment. During his imprisonment he wrote the famous pamphlet, *De Veritate Religionis Christianae* (Leiden, 1627). In 1621 Grotius escaped from prison and fled to France, where he wrote his great work *De Jure Belli ac Pacis* (1620–1625), dedicated to Louis XIII. Grotius later returned to Holland. From 1634 to 1644 he was Swedish ambassador to France. He was recalled to Sweden in 1644 and died in Rostock on his way back from Sweden to Holland shortly after.

Grotius's enduring influence upon legal science and, in particular, on the science of international law may be attributed to qualities somewhat comparable to those of John Locke. Both men formulated, articulated, and systematized, at a critical point in history, certain ideas and principles that suited the needs of a changing society.

But whereas Locke articulated the rights of the individual in a rapidly expanding, acquisitive, and increasingly antiabsolutist society, Grotius understood that the international society of burgeoning sovereign states had to find and abide by certain rules of conduct in war and peace, formalizing diplomatic relations and mutual respect for sovereignty. Since modern international society is still dominated by the legal and political supremacy of the national state, Grotius's classical treatise, *De Jure Belli ac Pacis,* is still an essential foundation for international law. The international order of the Middle Ages, based on the twin foundations of the ecclesiastical authority of the Church of Rome and the political authority of the emperors, had crumbled together with the social, economic, and spiritual conditions on which it was based. New kingdoms, dukedoms, principalities, and cities had emerged from the debris. Europe was torn by wars, big and small, motivated by religious, dynastic, political, and social conflicts. While Grotius wrote his principal work, the Thirty Years' War was raging in much of Europe, demonstrating the destructive effects of the lawlessness of a society that had not yet developed new rules of intercourse appropriate to the emerging society of sovereign nations. There was no prospect of reestablishing the international authority exercised by popes and emperors. There was no hope of abolishing or outlawing war. But there was an urgent need to establish a new code of behavior, and, more than that, a need to humanize the conduct of war even within modest limits. To lay the foundations for such a development was a gigantic task, a

task only for someone who could combine the qualities of philosopher, political scientist, jurist, humanist, and diplomat. That man was Hugo Grotius, a man of prodigious learning—theologian, philologist, historian, and poet, as well as jurist—who was also an active diplomat.

All his various interests are reflected in his great treatise, a rambling work ranging over many fields of human knowledge, studded with quotations and references to innumerable scholars and sources. *De Jure Belli ac Pacis* established a partially legalized system of international relations by blending certain general principles of political and moral philosophy with state practice. It is this combination that gives to Grotius's work the flexibility and durability that enabled subsequent generations to make use of it by emphasizing the one or the other aspect.

NATURAL LAW

Grotius was first a major exponent of the philosophy of natural law and of social contract. Second, he was an Aristotelian whose deepest and most abiding belief was in the power of reason and the rationality of man. Third, Grotius was a pragmatic diplomat who, through the observation and practice of diplomacy in a singularly disturbed and savage period, was fully aware of the practices of states in peace and war—and it was war that dominated both the life of the people and the thought of Grotius. But fourth, Grotius was a humanist in the spirit and tradition of his master, Erasmus of Rotterdam, a man who abhorred the brutality and lawlessness of war and violence, and whose principal purpose, therefore, was not only to civilize the conduct of war but also to place certain limitations upon its legality. He combined this last objective with his belief in reason and in natural order in the formulation of his famous theory of the *bellum iustum* (the just war).

As a natural law philosopher, Grotius was much closer to the Stoics than to the Scholastics. Like the former, he derived the postulates of natural law from principles of reason rather than of divine order. Such reason was founded in the human intellect. "Natural law is so immutable that it cannot be changed by God himself."

The natural law doctrine provided Grotius with the theoretical foundation for certain overriding principles of order in the relations between states. It also gave him faith in the rationality of man and in man's potentialities for developing a better society in accordance with the needs of social and international life. Grotius was, of course, well aware that there was in his time no law-giving authority superior to the will of the states. It was, therefore, necessary for him to find some principle that could bind the nations to a common standard of behavior. He found this principle in *pacta sunt servanda,* the respect for promises given and treaties signed. In the absence of an international sovereign authority, modern international lawyers, such as Dionisio Anzilotti and Hans Kelsen, have reaffirmed the same principle as the metalegal foundation of international law.

Grotius formulated a large number of other principles of natural law that inevitably share the weakness of all natural law teachings—that is, the sublimation of certain political postulates into immutable principles of order. Among Grotius's rules of natural law were respect for other people's property and the restitution of gain made from it, the reparation of any damage caused by a person's (or nation's) fault, as well as certain elementary principles of punishment. The political coloration of natural law is more evident in Grotius's postulate of the freedom of the seas. This postulate corresponded to the interests of the Netherlands as the world's leading maritime nation. It was opposed by the Englishman, John Selden (*Mare Clausum,* London, 1635), at a time when England was still struggling against stronger maritime nations.

SOCIAL CONTRACT

The other pillar of Grotius's legal philosophy was the theory of social contract, which also led him to emphasize the supremacy of the compact as the highest binding principle of law. Unlike later theorists of social contract, Grotius considered the contract as an actual fact of human history. In his view, the constitution of each state had been preceded by a social contract, by means of which each people had chosen the form of government they considered most suitable for themselves. While each people had the right to choose their own form of government, they forfeited the right to control or punish the ruler, however bad his government, once they had transferred their right of government to him. Generally, Grotius, like Thomas Hobbes, reflected not only the need of a disturbed society for strong governmental authority, but also the essentially absolutist and predemocratic character of government of that period. In his own official and diplomatic career Grotius represented autocratic governments.

INTERNATIONAL LAW

Aware of the insufficiency of natural law to supply more than certain general guiding principles, Grotius based the principal body of international law on *ius voluntarium* (the body of treaties and other engagements that form the

bulk of international state practice). Although a realist, Grotius was not a cynic. He believed not only in the essential rationality of man and peoples, but also in the necessity of progress from war to peace, from international anarchy to international order. His principal contribution in this respect was his theory of the *bellum iustum*. A major part of the second book of his treatise was devoted to the problems of the legality of war. For a war to be just, there must exist a legal cause for it. Essentially, there are only three types of just wars: Those that are conducted in defense against an actual or immediately threatening injury; those aimed at the recovery of what is legally due; and those inflicting punishment for a wrong done. Each of these categories allows for a great degree of latitude, especially in the absence of an impartial international judicial authority that can decide between conflicting claims.

Nevertheless, this emphasis on the need to justify war, and the limitation of its justification to causes that even today would be regarded as essentially defensive against wrongful injury, was a remarkable contribution to international order. It became obscured and forgotten during subsequent centuries of absolute national sovereignty, particularly during the nineteenth century when the aggressive national state celebrated its greatest triumphs, in practice as in theory. In modern time, the League of Nations Covenant and the United Nations Charter have attempted once again to distinguish between just and unjust wars. The future of humankind may well depend on the elaboration of an authoritative method of finding reliable and enforceable criteria for distinguishing between wars of aggression and wars of defense and on the establishment of an impartial forum to decide on claims for the reparation of wrongs alleged to be inflicted by one state on another.

International law in our own day is still essentially based on state practice as recorded in custom, treaties, and other international agreements; but these practices allow for the evolution of international law, not so much in the terminology of natural law as in the similarly conceived evocation of "general principles of law recognized by civilized nations." Some of these principles were applied, with dubious theoretical justification, in the Nuremberg and Tokyo trials of German and Japanese war criminals.

Grotius's doctrines were inevitably a mixture of reactionary and progressive principles. On the one hand he felt compelled to justify many barbarous practices of war, subsequently condemned in modern rules of warfare (yet surpassed in cruelty by modern war). Again, Grotius con-

curred with the great majority of legal and political philosophers in denying to the individual the right of resistance to an oppressive sovereign, although he affirmed the right of passive resistance of an individual against unjust wars. On the other hand, Grotius anticipated by centuries some of the principles of the Nuremberg Charter by regarding as justified a war waged to prevent the maltreatment by a state of its own subjects. And Grotius's concern with the individual stands in noble contrast to subsequent absolutist political theories.

In working and thinking within the limitations of his time, Grotius did not differ from any other philosopher, jurist, or political scientist. What is remarkable is that, in the midst of a war that threatened to undermine the whole fabric of European society, he developed principles and standards that can still serve as the basic themes for the struggle for international order in our time.

GUILT

There are two main forms of the idea of "guilt"—moral guilt and legal or quasi-legal guilt. Originally these were not sharply distinguished, but enlightened thought requires that they should be. In outward substance the two often coincide. In committing a crime one is usually morally at fault, but the degree of one's guilt is not likely to be the same in the two respects in such instances. We may in any case be morally guilty and legally innocent—and vice versa. Few who consult this book have committed a crime, but who is there who has never done anything for which he may be morally reproached? Some of the most vicious things men do are well within the law. Nor would it be wise to legislate against all forms of moral evil—much of that would defeat the purpose of morality. One may also break the law and incur no moral blame. This might be because of unavoidable ignorance (of the law or of some matter of fact), but we could be blameless even in committing a crime deliberately. That would come about if we broke the law on conscientious grounds. Some of the people we admire most (religious or political martyrs, for example) have put religious or moral scruples before the claims of the law. They were not in all cases outwardly justified. The outward justification of resistance to the law is greatest under oppressive government. The duty to conform is very great where there are constitutional means of seeking redress or reform. Upholding constitutional procedure is normally much more important than righting a particular wrong. Resistance (but not of course normal opposition) is very extreme medicine in a democracy, and it is not always justified under tyranny. Persuasion is the best means of reform. But whether outwardly justified or not, a person is free from moral blame (and perhaps worthy of much praise) if he breaks the law in obedience to his own conscience.

MORAL GUILT AND DETERMINISM

Legal responsibility means liability to punishment, and legal guilt thus means that one has merited some punishment. This may be understood in a retributive, reformative, or deterrent sense. On the latter view, the commonest today where strictly legal or social issues are concerned, absolute freedom of choice is not presupposed. It is of course pointless to seek by punishment to deter someone who in no sense controls what he does—or to make him an example for others. We restrain the insane or the delirious. We do not punish them, and it is absurd to punish people for what they do by accident. But punishment is not made pointless when we act in character and wittingly do certain things even though, being the persons we are, we could not help doing them. Punishment as deterrence is consistent with determinism, for our conduct on other occasions—and the conduct of other persons—could be affected by punishment or the threat of it. But in moral matters punishment is a secondary issue. To be morally guilty is to have incurred moral disvalue or to be morally blameworthy. This may call for punishment or some other outward censure, but that is a further question.

Moral guilt is a more basic notion than punishability. It is a unique moral concept not to be merged in associated social and legal notions. Moral guilt presupposes freedom of a more radical kind than legal guilt and is hard to reconcile with any form of determinism. The moral evil it involves must be distinguished sharply from nonmoral evils like sickness, pain, error, and stupidity. I am not to blame for being ill or for failing to win a race, compose a poem, or solve a mathematical problem. I am to blame for moral failure. I cannot help the former failures, provided I try, if it is my duty. But it is hard to see how there could be moral failure if there is any sense in which I could not help it.

THE ASSUMPTION OF ABSOLUTE FREEDOM. But how strictly are these last words to be understood in the case of moral guilt? Is absolute freedom presupposed? If it is, are we ever guilty in the strictly moral sense? Is there not some continuity of character and conduct? Plainly there is such a continuity, and advocates of absolute freedom of choice as a moral requirement have therefore argued that moral praise or blame only apply on the occasions where there is a conflict between "duty and interest"—that is, between what we most want to do and what we think we ought to do. During much of one's life there is no such conflict, and we can therefore anticipate one another's actions with much confidence: we know what to expect of

people we have come to know. But character and duty will sometimes draw apart. To that extent, it is maintained, nothing affects the outcome but the act of choice itself. If we fail to make the effort of will—an absolutely free one in this case—to overcome some weakness of character, and if we thus follow the line of least resistance rather than the call of duty, we incur moral guilt. The degree of the guilt depends not on the outward features of the situation and the magnitude of the ill we do, or at least not directly so, but on the effort of will that would have been required to do right. But it should be noted well that the more outwardly vicious an act may be, the less is the effort needed to resist a temptation to do it, for one can normally presuppose much natural resistance to the act in one's own character. The less the effort required, the more we are to blame for not making it; the greater the effort we do make, the greater our moral worth.

It follows from this view that while we may, for practical and kindred purposes, censure misdeeds in their outward form, we need to be very chary of passing strictly moral judgments on other persons. If we have reason to believe (as is often the case) that someone has acted contrary to his moral convictions, we can impute to him some measure of blame, but how much is much harder to assess than the outwardly objectionable features of a situation. It is also much harder to assess the positive moral worth of another person than to assess his moral guilt. For we know in the latter case that the effort required was not forthcoming; in the former case it is harder to know how much to ascribe to natural good qualities of character, a benevolent or naturally plucky nature, and so on, and how much to free effort. Only the agent himself and God can know the full inner story.

THE FEELING OF GUILT

We must, however, distinguish "guilt" in the strict moral meaning from the sense of guilt. The latter is the feeling that accompanies the consciousness of being guilty. It is appropriate that we should feel remorse for wrongdoing, the proper tone of the feeling being determined by its appropriateness to the situation of guilt. There are kindred feelings appropriate to the wrongdoing we encounter or suspect in others, feelings or attitudes of blame and indignation. The feelings we actually have are not always appropriate to the situation, and there may thus be a sense of guilt out of all proportion to the facts of the case. Some people seem even to enjoy the sense of guilt and to cultivate it. Psychologists have helped us a great deal to understand these deviations and that other

curious aberration by which some people feel guilty for things they have not done at all.

PSYCHOLOGICAL REASONS. Some psychologists go further. They try to account for guilt entirely in terms of psychology. A common form of this attempt is that which ascribes guilt to an alleged "need for punishment." This need comes about through punishment or some other disapproval we suffer in infancy. Coming to expect punishment for certain acts, we feel distress when we wait for it without getting it over, and the strain and anxiety induced in this way is suppressed and operates subconsciously afterwards to produce the sense of guilt in mature experience. There is also the introjection into the "superego" of the relief experienced by those who punish us. These theories no doubt reflect states of mind which psychological investigation uncovers, and the layperson can appreciate much of them from common experience. But they seem nonetheless to be mainly concerned with aberrations and an unhealthy assumption of guilt, or perverse ways of dealing with it. The core of guilt is an ethical one, which psychology does not explain away.

COLLECTIVE VERSUS INDIVIDUAL GUILT

If guilt, in the proper sense, turns on deliberate wrongdoing, it seems that no one can be guilty for the act of another person—there can be no shared or collective or universal guilt. Guilt is incurred by the free choice of the individual. But many have questioned this. Among them are some sociologists who misrepresent in this way the dependence of the individual on society. But the main location of the idea of collective guilt is religion. Many forms of the doctrines of original sin and universal sin regard guilt as a pervasive state of humankind as a whole. It is the guilt of "man," not of this or that person as a whole. Others qualify this and speak of original sin which does not include original guilt. Others hold that while there can be no "great sin" and "little sin," there is inequality of guilt. But it is hard to reconcile the notion of universal sin or guilt, in any form, with elementary ethical convictions. Such notions can also do great harm, both by leading to victimization of the innocent—as in the treatment of Jews by the Nazis—and in undermining the sense of responsibility; for collective guilt is not the guilt of anyone in particular.

SOURCES OF DOCTRINES OF COLLECTIVE GUILT. Why then do such doctrines of collective guilt seem plausible? Mainly through religious confusions like the following. (1) The sense of religious unworthiness, the awe

felt in the presence of God, is mistaken for moral culpability. (2) Certain forms of religious experience are apt to be overwhelming, and the strain is eased at times by encapsulating the divine within the finite media or symbols by which it is known. This is the root of idolatry. The most grievous form of this is that by which the person himself becomes the idol—he aspires to make himself as God. But this distortion of religious experience tends to be conflated, in the heat of prophetic experience, with the expressly moral wickedness of putting one's own wishes before the proper claims of others. This encourages the notion of an unavoidable state of sin and guilt. (3) Guilt is what we seem most disposed to suppress, and at the unconscious level the confusions noted are apt to be intensified. (4) Religious doctrines have often been based on first-order religious utterances taken out of their full context and apart from the experience which prompted them. The figurative character of such utterances is also overlooked—for example, in interpretations of the metaphors of "bondage" or of "sin warring in all my members." (5) Wrongdoing has a cumulative influence that affects the state and the situation of persons irrespective of their own guilty actions; it thus tends to drive men in on themselves and hinder healthy relations with other persons—and with God. This also, or the misrepresentation of it, lies behind misleading doctrines of collective guilt. (6) The idea of universal guilt has often been made the pretext for evading the challenge of high ideals professed by religious people. This seems especially true of much Augustinian theology. (7) Religious confusions are deepened by confusions between the points of view of law—where the idea of corporated guilt has some place—and the point of view of morality.

Recent anthropology has thrown new light on the origin of the idea of guilt. There was at first little distinction between the points of view of law and of morality, both being merged in communal custom. Nor was heed adequately paid to whether the results of an act were those a person intended. The community was also more the bearer of guilt than the individual, and harsh judgments were thus passed on the innocent and bitter feuds perpetuated. But we should not allow this to determine for us how guilt must be understood in enlightened thought. Ethical notions are not jeopardized by having lowly and doubtful origins.

Religious thought today helps us to appreciate what is true and what is false in notions like collective guilt. But much recent sociology and some recent ethics go further and challenge the ultimacy of the ideas of guilt and responsibility. These are thought by some moralists and psychologists to be ideas we ought to have outgrown—"theological anachronisms." A sound ethical theory and better understanding of religion should correct these tendencies.

Bibliography

For a general discussion of the subject, see the symposium on "Guilt" by H. D. Lewis, J. W. Harvey, and G. A. Paul, in *Proceedings of the Aristotelian Society,* Supplementary Volume XXI. See also the papers on Free Will, Responsibility, and Guilt by C. A. Campbell, P. H. Nowell-Smith, and Erich Fromm in *A Modern Introduction to Ethics,* edited by Milton K. Munitz (Glencoe, IL: Free Press, 1958), pp. 356–416. Sir Walter Moberly, *Responsibility* (Oxford: Oxford University Press, 1951) consists of three lectures dealing with the moral and religious aspects of guilt and sin. A classical discussion of the religious and biblical side of the subject is F. R. Tennant, *The Concept of Sin* (Cambridge, U.K.: Cambridge University Press, 1912). N. H. G. Robinson, *Concept of Sin* (New York, 1950) is a first-rate survey of the subject in the work of representative recent theologians like Karl Barth, Emil Brunner, and Reinhold Niebuhr. The liberal approach to this subject may be found in L. Harold DeWolf, *The Religious Revolt against Reason* (New York: Harper, 1949) and in H. D. Lewis, *Morals and the New Theology* (New York: Harper, 1948), Chs. 5–7.

The Freudian view is well presented in J. C. Flügel, *Man, Morals, and Society* (New York: Viking, 1961). This should be considered along with Sigmund Freud's *New Introductory Lectures on Psychoanalysis* (New York: Norton, 1933), pp. 78–106 and Susan Isaacs, *Social Development in Young Children* (London: Routledge, 1933). More recent psychoanalytic works are Melanie Klein and others, *Developments in Psychoanalysis* (New York, 1952); Melanie Klein, *Envy and Gratitude: A Study of Unconscious Sources* (New York: Basic, 1957); and E. Glover, *Technique of Psychoanalysis,* rev. ed. (New York, 1955). There are also helpful references to guilt in Walter J. H. Sprott, *Social Psychology* (London: Methuen, 1952), p. 168ff. The tradition of Ivan Petrovich Pavlov is continued in B. F. Skinner, *Science and Human Behavior* (New York: Macmillan, 1953), in which the conditioning effect of early training is stressed.

There is a short discussion of guilt in T. R. Miles, *Religion and the Scientific Outlook* (London: Allen & Unwin, 1959), Ch. 12.

The sociological approach is well exemplified in Barbara Wootton, *Social Science and Social Pathology* (London: Allen and Unwin, 1959). Criticism of this approach will be found in H. D. Lewis, *Freedom and History* (New York: Macmillan, 1962), and there is further discussion of the religious implications of the sociological approach in Fred Berthold, *The Fear of God* (New York: Harper, 1959).

GUO XIANG
(c. 252–312 CE)

A champion of the Learning of the Mysterious (*Xuanxue*) or neo-Daoism that gained prominence in third-century China, Guo Xiang (c. 252–312 CE) is best known for his commentary to the *Zhuangzi*, which offers to reconcile orthodox teachings (*mingjiao*) with Daoist naturalness (*ziran*).

Like other neo-Daoist philosophers, notably Wang Bi (226–249), Guo recognizes the creative power of Dao; however, contrary to Wang, Guo rejects that "beings originate from nonbeing," which establishes Dao as the metaphysical ground of being (*Zhuangzi* commentary, chs. 2 and 23). The appeal to an anthropomorphic heaven or original substance as the source of creation should, according to Guo, be rejected, for it begs the question of the cause of its own being. Nonbeing, however, is not the answer, because nonbeing remains an abstraction and abstractions cannot bring about creation. Being and nonbeing are mutually exclusive, according to Guo, who writes "nonbeing cannot change into being" (*Zhuangzi* 22). Consequently, the only logical explanation of the origin of being is that "being spontaneously produces itself" (*Zhuangzi* 2).

This explanation introduces Guo's concept of "self-transformation," for which he is particularly famous. Whereas Wang Bi values nonbeing, Guo favors being. At the most basic ontological level, being is "so of itself" (*ziran*), and Guo believes that "we may know the causes of certain things and affairs near to us. But tracing their origin to the ultimate end, we find that without any cause, they of themselves come to be what they are. Being so of themselves, we can no longer question the reason of their being, but should accept them as they are" (*Zhuangzi* 14).

SELF-TRANSFORMATION AFFIRMS THE IMMANENCE OF DAO

Guo explains that the Dao pervades and informs nature as vital energy (*qi*) and that all beings are endowed with a "share" or "allotment" of the inexhaustible energy of Dao, and this defines their nature (*xing*) and capacity. Significantly, "benevolence and rightness" stem from nature (*Zhuangzi* 14); and, moreover, the state of *ziran* depicts an organized regime governed by principles and marked by interdependence and hierarchical order.

Given that individual *qi*-endowment varies, differences in capacity—for example, lifespan and intelligence—should be recognized. This is destiny (*ming*), in that "what one is born with is not something undue or vain" (*Zhuangzi* 5). This, then, begs the question: Is Guo—as many scholars hold—a fatalist?

Destiny dictates that one is born of sagely character or average capacity. Yet, Guo also attempts to distinguish *ming* as fact from value, and to affirm development in human flourishing. Fundamentally, differences in endowment do not constitute any basis for value judgment. Rather, as the *Zhuangzi* urges, what should be recognized is the "equality of things."

Unlike Wang Bi, who emphasizes the "one," Guo embraces the "many." Individuality and authenticity should be cherished (*Zhuangzi* 10). The Daoist goal can be defined as the realization of one's nature, and in particular the optimization of one's inborn capacity. As nature blossoms, "destiny" is fulfilled.

While this may not detract entirely from the charge of fatalism, Guo introduces a dynamic view of nature and destiny. The world of *ziran* is never static; it changes and renews itself constantly. Limits notwithstanding, one's potential should not be underestimated. The sage or person of Dao nourishes his nature and adapts to change, which brings out the meaning of nonaction (*wuwei*). Nonaction "does not mean folding one's arms and keeping quiet" (*Zhuangzi* 11). It is also not a technical skill; rather, nonaction stems from a discernment of *ziran*, which translates into a mode of being and a spirit of action, according to which one performs all functions.

Politically, nonaction means that the ruler enables the people to develop their nature and potential. Artificial restrictions and interference should be minimized, and because needs and circumstances change, sociopolitical practice should not be fossilized—timely adjustments ensure renewal and harmony in a dynamic realm. In this way Guo tries to reconcile the *mingjiao* (orthodox teachings) with *ziran*. Whereas the former refers to doctrines of propriety and government, the latter aspires towards transcendence and freedom from mundane concerns. Conflict arises, then, when orthodox teachings are seen to impinge on nature, or when transcendence is equated with renunciation. For Guo, however—because social and natural phenomena are governed by the same set of principles—*mingjiao* and *ziran* merge into one.

GURWITSCH, ARON
(1901–1973)

Aron Gurwitsch was one of the leading proponents of and contributors to phenomenology in the twentieth century. He was one of a small number of philosophers who brought phenomenology from Europe to the United States and led its growth into a significant presence there. Gurwitsch's main influence came through his expositions of Edmund Husserl's phenomenology and his original contributions that modified and supplemented Husserl's work.

Gurwitsch was born on January 17, in Vilnius, Lithuania (then a part of Russia), of parents who were descended from a long line of Jewish scholars. Following the pogroms of 1905 and 1906, the family moved in 1907 to Danzig where Gurwitsch received his early education. He began his university education at the University of Berlin in 1919, where he studied mathematics, physics, psychology, and philosophy; here he came under the guidance of the philosopher and psychologist Carl Stumpf. On Stumpf's suggestion, Gurwitsch went to the University of Freiburg in 1922 to attend some of Husserl's lectures. Gurwitsch was so influenced by Husserl's style of philosophizing that he decided to devote his life to the continuation and expansion of Husserl's phenomenology.

Gurwitsch left Berlin for the University of Frankfurt, where he studied with the psychiatrist Kurt Goldstein and the Gestalt psychologist Adhemar Gelb, whose studies of psychological pathologies stemming from brain injuries related to human capacity for abstraction, a topic in which Gurwitsch was interested. During this time Gurwitsch realized that Gestalt theory and phenomenology could benefit from one another. This led him to develop in his doctoral dissertation a field theory of sensory per-

ception in which he rejected Husserl's concept that a non-worldly, transcendental ego was at the basis of the human ability to experience a world and developed a nonegological conception of consciousness that was like the one found later in Jean Paul Sartre's work. The dissertation, *Phenomenologie der Thematik und des reinen Ich*, was published in 1929. Husserl was impressed by this work and there were regular contacts between them until 1933.

In 1929 Gurwitsch returned to Berlin, with a Prussian habilitation grant, where he worked on and essentially completed *Die mitmenschlichen Begegungen in der Milieuwelt* (1976). This work concerned basic problems of social phenomenology and contained an original approach to social perception that combined phenomenological and gestaltist insights. Due to the rise of National Socialism that led him to flee Germany and go to France in 1933, Gurwitsch did not publish this book, and it was published posthumously in 1976.

In 1933 and 1934 Gurwitsch began lecturing on Gestalt psychology and phenomenology at L'Institut d'Histoire des Sciences at the Sorbonne in Paris. These lectures were attended by Maurice Merleau-Ponty, whose major work, *Phenomenology of Perception*, incorporates much that he acquired from Gurwitsch. Gurwitsch's posthumously published *Esquisse de la phénoménologie constitutive* (2002) is based on that latter parts of these lectures. In Paris, in 1937, Gurwitsch met the sociologist and philosopher Alfred Schutz. Their correspondence from 1939 to 1959 has been published as *Philosophers in Exile* (1989). In addition to discussing and exploring intellectual topics, the letters contain a fascinating look at the difficulties of the lives of emigré scholars at that time. With the help of Schutz, who preceded him in 1939, Gurwitsch emigrated to the United States in 1940, and took a position at Brandeis University in 1948, first in mathematics and then, in 1951, in philosophy.

In the United States Gurwitsch began work on his magnum opus, *The Field of Consciousness*, published first in French translation in 1957, and then in the original English in 1964. In this work, Gurwitsch related phenomenology to the thought of William James and others, offered a criticism of various dualistic theories of perception, and gave a masterful account of Gestalt theory. This is followed by what became the most influential part of the work, his account of perceptual consciousness wherein the field of what one is aware is articulated into theme, thematic field, and margin. Building on Husserl's work, but abandoning what he took to be a dualism in Husserl's theory where higher level cognitive functions worked on lower level sensations to produce the object as

experienced (what Husserl called the "noema"), Gurwitsch creatively employed Gestalt theoretical concepts to analyze the structure of the focally perceived object (theme) as well as its relationship to the wider experienced context (thematic field) and to other co-conscious items that are not relevant to the theme and thematic field (margin). His account of the object as experienced (noema) was an alternative to Husserl's theory and led to considerable discussion in the secondary literature. A part of the whole manuscript that Gurwitsch wrote that was not published in *The Field of Consciousness* was posthumously published as *Marginal Consciousness* (1985) and contains detailed analyses of human awareness of the margin.

When Alfred Schutz—who held a position at the Graduate Faculty of the New School for Social Research in New York City—died in 1959, Gurwitsch became his successor, joining the phenomenologist Dorian Cairns, and taught there until his retirement in 1972. This was a time when phenomenology attracted much attention in the United States and the New School was a major center for research and study. Gurwitsch, Cairns—and, earlier, Schutz—were major influences on a new generation of phenomenologists. Gurwitsch helped found the Society for Phenomenology and Existential Philosophy (SPEP) in 1962, and later the Husserl Circle, two major forums for the presentation of phenomenological research. During this time he republished eighteen essays in *Studies in Phenomenology and Psychology* (1966). Another group of previously published and unpublished essays dating from 1937 came out posthumously in *Phenomenology and the Theory of Science* (1974). Along with some of Gurwitsch's influential original and critical work these two volumes contain some of the authoritative accounts of Husserl's philosophy that made Gurwitsch such a leading exponent and interpreter of Husserl's philosophy.

Gurwitsch's interests went beyond Husserl and phenomenology. He also wrote and prepared for publication *Leibniz: Philosophie des Panlogismus*, published posthumously in 1974 and wrote what was posthumously published as *Kants Theorie des Verstehens* (1991). Gurwitsch died on June 6, 1973.

William R. McKenna (2005)
HABERMAS, JÜRGEN
(1929–)

Jürgen Habermas, the German philosopher and leading representative of the Frankfurt school of critical theory, was born in Düsseldorf. After World War II he studied in Göttingen, Zürich, and Bonn, where he submitted a dissertation on Friedrich von Schelling in 1954. From 1955 to 1959 he was Theodor Adorno's assistant at the Institute for Social Research in Frankfurt. After habilitating at Marburg University in 1961, he taught philosophy and sociology at the universities of Heidelberg and Frankfurt before becoming codirector of the Max Planck Institute in Starnberg. In 1983 he returned to the University of Frankfurt, where he was professor of philosophy until his retirement in 1994.

Habermas's life and work have remained deeply influenced by the traumatic events of his youth under National Socialism. From the time of his involvement with the German student movement in the 1960s he has been one of Germany's most prominent public intellectuals, speaking out on a wide array of issues, from violations of civil liberties and the attempted "historicizing" of the Holocaust to immigration policy and the manner of German reunification.

Habermas's scholarly work, which aspires to a comprehensive critical theory of contemporary society, ranges across many of the humanities and social sciences. His early and influential *Strukturwandel der Öffentlichkeit* (1962) was a historical, sociological, and philosophical account of the emergence and transformation of the liberal public sphere as a forum for critical public discussion of matters of general concern. While the historical structures of that sphere reflected the particular constellations of interests that gave rise to it, the idea it claimed to embody, the idea of legitimating political authority through rational discussion and reasoned agreement, remains central to democratic theory. Habermas returned to these themes three decades later in *Faktizität und Geltung* (1992), where he applied the idea of justification by appeal to generally acceptable reasons to the deliberations of free and equal citizens in a constitutional democracy. The primary function of the system of basic rights, he argued, is to secure personal and political autonomy; and the key to the latter is the institutionalization of the public use of reason in the legal-political domain.

One might read Habermas's extensive writings in the intervening decades as a protracted examination of the cultural, psychological, and social preconditions of and

barriers to accomplishing this. The essays of the early 1960s, a number of which were collected in *Theorie und Praxis* (1963), introduced the idea of studying society as a historically developing whole for purposes of enlightening political consciousness and guiding political practice. The methodology and epistemology behind this approach were elaborated in the later 1960s in *Zur Logik der Sozialwissenschaften* (1967) and *Erkenntnis und Interesse* (1968). A principal target in both books was the neopositivist thesis of the unity of scientific method, particularly the claim that the logic of inquiry in the human sciences is basically the same as in the natural sciences. The former work started from an examination of the nature and role of *Verstehen* in social inquiry and argued that access to symbolically prestructured object domains calls for interpretive procedures designed to grasp the meanings on which social interactions turn. Intersubjective meanings constitutive of sociocultural lifeworlds can neither be wholly objectified, as positivism supposes, nor simply reappropriated, as hermeneutics proposes. Psychoanalysis suggests an alternative approach, in which explanatory and interpretive procedures are combined with a critique of ideology in a historically oriented theory with practical intent.

In *Erkenntnis und Interesse* Habermas undertook a historical and systematic study of "the prehistory of modern positivism" in an attempt to free the ideas of reason and rationality from what he regarded as a "scientistic misunderstanding." Tracing the development of the critique of knowledge from Immanuel Kant through German idealism to Karl Marx, and its transformation into the methodology of science in early positivism, he elaborated his own position in critical encounters with three classic but flawed attempts to overcome positivism from within methodology: Charles Sanders Peirce's reflections on natural science, Wilhelm Dilthey's on cultural inquiry, and Sigmund Freud's on self-reflection. In each case he examined the roots of cognition in life and argued for an internal connection of knowledge with "anthropologically deep-seated" human interests. A key feature of this "quasi-transcendental" theory of cognitive interests was the basic distinction between the interest in prediction and control of objectified processes and the interests in mutual understanding and distortion-free communication with speaking and acting subjects.

There followed a series of studies of basic structures of communication, organized as a three-tiered research program. The ground level consisted of a general theory of communication in natural languages, a "universal pragmatics," as Habermas called it. This served as the foundation for a general theory of socialization in the form of a developmental account of the acquisition of communicative competence. Building on both of these, Habermas sketched a theory of sociocultural evolution as the historical development of forms of communicative interaction and mutual understanding. These accounts of communication, socialization, and social evolution enabled him to anchor moral theory in the theory of social action. Arguing that our basic moral intuitions spring from something deeper and more universal than contingent features of particular traditions, his discourse ethics sought to reconstruct the intuitive grasp of the normative presuppositions of social interaction possessed by competent social actors generally.

The work of the 1960s and 1970s culminated in the monumental *Theorie des kommunikativen Handelns* (1981), in which Habermas developed a concept of communicative rationality freed from the subjectivistic and individualistic premises of modern social and political theory, together with a two-level concept of society that integrated the competing paradigms of "lifeworld" and "system." On this basis he then sketched a critical theory of modern society that focused on "the colonization of the lifeworld" by forces arising from the economy and the state: systemic mechanisms such as money and power drive processes of social integration and symbolic reproduction out of domains in which they cannot be replaced. The phenomena that Max Weber pointed to in his vision of an "iron cage" and that Marxists have dealt with in terms of "reification" arises from an ever-increasing "monetarization" and "bureaucratization" of lifeworld relations. This relentless attack on the communicative infrastructures of society can be contained, he argued, only by a countervailing expansion of the areas of life coordinated via communication, and in particular by the subordination of economic and administrative subsystems to decisions arrived at in open and critical public debate. Thus, the antidote to colonization is democratization, and the key to the latter is an effectively functioning cultural and political public sphere. What distinguishes this critique of modernity from the welter of counterenlightenment critiques during the last two centuries is Habermas's unflinching defense of enlightenment rationality—a defense, to be sure, that is itself informed by the critique of rationalism and that emphasizes the ongoing, unfinished character of the project of enlightenment.

HAECKEL, ERNST HEINRICH
(1834–1919)

Ernst Heinrich Haeckel, the German zoologist and monist philosopher, was born in Potsdam. He studied medicine and science at Würzburg, Berlin, and Vienna with such authorities as Johannes Müller, Rudolf Virchow, and R. A. Kölliker. After practicing medicine for a short time, he went to the University of Jena in 1862 to teach zoology.

Haeckel was the first noted German biologist to grant enthusiastic acceptance to organic evolution, and Charles Darwin gave him credit for propagating the theory of evolution in Germany. His views were the source of considerable controversy in biology, philosophy, and religion. He battled with his colleagues about their early hostility to Darwin's theory and their reluctance to include man and his consciousness in the evolutionary process. His dislike of the power of the church in social and political matters and his liberal opposition to Otto von Bismarck and other political figures resulted in many controversies; his rejection of free will, immortality, and the personality of God also antagonized many. Haeckel's achievements in zoology brought him academic offers from famous institutions, but he chose to remain at Jena, partly because of the academic freedom he found there.

His interests were broad; he published travel works and illustrated some of his own scientific essays. He founded the Monistic League to propagate his religious views. He had considerable popular success in science and was prominent in the movement to enlighten humankind about scientific developments.

SCIENTIFIC CONTRIBUTIONS

In biology Haeckel helped to publicize and promulgate what he called the "biogenetic law": "*Ontogenesis is a brief and rapid recapitulation of phylogenesis,* determined by the physiological functions of heredity (generation) and adaptation (maintenance)" (*The Riddle of the Universe,* New York, 1900, p. 81). He was a pioneer in drawing up genealogical schemata of the relationships between various orders of animals. Many of his major groupings are still accepted, although the finer divisions have undergone much revision. He was convinced of the essential unity of organic and inorganic nature, and argued that the simplest protoplasmic substances arose from inorganic carbonates through spontaneous generation. Individual primitive organisms, which Haeckel termed "monera," were differentiated out of these protoplasmic compounds. Haeckel believed that to reject this kind of spontaneous generation was tantamount to accepting a miraculous origin of life.

His theory of *gastraea* also received much attention. Haeckel argued that the entire animal world is made up of two groups: primitive unicellular animals, the protozoa, and multicellular animals with complex tissues, the metazoa. Haeckel believed that all the metazoa evolved, in accord with his biogenetic law, from one simple, long-extinct form, the *gastraea.* Although this theory of evolu-

tion from *gastraea* is no longer accepted, it influenced embryological research for nearly half a century.

DOCTRINE OF SUBSTANCE

Haeckel's conviction on the great importance of organic evolution led him into many other fields. His *Die Welträthsel* (Bonn, 1899; English translation by Joseph McCabe, *The Riddle of the Universe*) became a best-seller. The title derived from Emil Du Bois-Reymond's 1880 address to the Berlin Academy of Sciences on seven "world enigmas" (the nature of matter and force, the origin of motion, the origin of life, the order in nature, the origin of simple sensation and consciousness, rational thought and speech, and freedom of the will). Haeckel believed that his monistic outlook could resolve these problems, and others, leaving one "comprehensive riddle," the problem of substance. He insisted upon the essential unity of all substance, but also insisted that the "real character" of substance was as little understood as in the days of Anaximander and Empedocles. Indeed, it became "more mysterious and enigmatic" as more and more became known about its attributes and their evolutionary forms. Haeckel was especially opposed to theological dualism, but he also carefully distinguished his view from both materialistic and idealistic monisms.

Haeckel construed materialism as holding that atoms are "dead," and are moved only by external forces. He maintained instead that both matter and ether possess sensation and will in the lowest grade. They experience a dislike of strain, and struggle against it, and a liking of "condensation," for which they strive. Haeckel denied the existence of empty space and of action at a distance. Those parts of space not occupied with ponderable atoms are filled with ether; action is either the result of immediate contact or occurs through the mediation of ether.

On the other hand, Haeckel rejected any attempt to regard the world as immaterial or nonnatural. Infinitely extended matter and sensitive and thinking spirit, or energy, are two fundamental attributes of the all-embracing universal substance. Every living cell has psychic properties, and multicellular organisms have as their psychic functions the totality of the psychic properties of their parts. Although Haeckel insisted that his view of substance was Spinoza-like rather than materialistic, many of his specific views are similar to those of nineteenth-century materialism. His confidence that "consciousness, thought, and speculation" are "functions of the ganglionic cells of the cortex of the brain," his "hard" determinism, his mechanism, his complete rejection of the supernatural, and his enthusiasm for science all inclined his contemporaries to classify him as a materialist.

Haeckel, then, saw the world as an eternal evolution of substance, and man as part of that evolution. The "law of substance," a law of mechanical causality, established "the eternal persistence of matter and force, their unvarying constancy throughout the entire universe" (*The Riddle of the Universe,* p. 4). He regarded the laws of the conservation of energy and the conservation of matter as inseparable and as parts of his law of substance. Haeckel referred to "great eternal iron laws," and rejected all teleological views. The appearance of design in the world is a consequence of natural selection rather than of the action of a purposive agency.

Although Haeckel often emphasized the tentative nature of scientific conclusions and the necessity for the modification and improvement of hypotheses, on some issues he assumed the finality of certain scientific propositions, including many rejected today. He made this assumption most frequently in his polemics against the philosophic and religious views that he regarded as incompatible with science. Haeckel did not generally consider in detail the technical problems philosophers were debating, but tended rather to attack or to defend the conclusions of technical philosophers on the basis of the scientific results of his day and extrapolations from them.

THEORY OF KNOWLEDGE

Despite his insistence that much of philosophy was far too speculative and a priori, Haeckel held that both empiricism and rationalism are necessary to develop satisfactory knowledge. Although he was hostile to "pure metaphysics," he was also critical of those who advocated a "pure empiricism." The opposition between experimental science and philosophy must and can be overcome.

Haeckel held that the thing-in-itself lying behind knowable phenomena is unknown. He suggested that we need not trouble about this situation; we have no means for investigating the thing-in-itself, and are not even certain it exists. The only genuine knowledge is knowledge of nature, and it consists of "presentations" (combinations of sense impressions in the knowing subject) corresponding to external things. Comparative and critical observation tells us that normally the impressions received by the brain and sense organs from the outer world are the same for all rational people, and that normally the same presentations are formed. Those presentations are true that correspond to the knowable aspects of things, even though things-in-themselves" cannot be reached.

Haeckel's views on knowledge were closely connected to biological findings. He argued that the human sense activity, which forms the beginning of all knowledge, was slowly and gradually evolved from the other primates. The sense organs of all primates are structurally similar, and Haeckel insisted that these organs also function similarly, in a way describable by the same chemico-physical laws. The rod-shaped cells in the retina, the auditory cells in the ear, the olfactory cells in the nose, and the taste cells on the tongue were evolved from simple, undifferentiated cells of the skin. Invoking his biogenetic law, Haeckel concluded that man's higher sense organs were derived from the epidermis of lower animals. Our sense impressions are associated in the cortex of the brain so that isolated elements are united into integrated wholes. Haeckel called these integrated presentations "faith in the broad sense," because they go beyond our sense impressions. In this sense, science requires faith in the construction of both hypotheses and unifying theories. (In the main, Haeckel used "theory" to refer to hypotheses about a common cause for diverse phenomena.) However, he rejected religious faith, which he termed "faith in the narrower sense." He insisted that religious belief always means a belief in miracles and thus contradicts the "natural faith of reason." Even religious liberals, he contended, are forced into the acceptance of superstition, and their faith is no less irrational than the "crude spirit-faith of primitive fetishism."

PSYCHOLOGY

Haeckel attempted a scientific account of the soul. He regarded it as a natural phenomenon, so that psychology was a natural science, a part of physiology. Psychology was the "foundation and the postulate" of all the sciences, since knowledge of nature is "part of the life of the soul." The great difficulty in establishing a naturalistic psychology is that such a science presupposes a thorough knowledge of the human organism, especially the brain. Haeckel deplored the lack of biological training of the psychologists of his time. He insisted that psychic processes, like all others, are subject to the law of substance, and held that the prevalence of mind-body dualisms in psychology has led to a greater confusion of ideas there than in any other department of knowledge. Yet Haeckel did not insist on a nonintrospective psychology; he described the introspective method as "extremely valuable and indispensable." But it had to be supplemented by experimental methods.

Haeckel regarded consciousness as the "central mystery of psychology," and the citadel of all mystical and dualistic errors. He insisted that consciousness is a natural phenomenon, dependent upon a material substratum. He suggested that consciousness can perhaps best be conceived as "internal perception" and can be compared to the action of a mirror. The chief difficulty in the way of a scientific understanding of consciousness is that the subject and the object of knowledge are one and the same; our only source of knowledge of consciousness is consciousness itself. We can therefore only know the consciousness of others by comparing it with our own. This works rather well when the comparison is made between normal people, but the analogy may break down badly when a comparison is made between the normal and the abnormal, or between different evolutionary levels. However, the difference between the consciousness of humans and of other animals is a difference of degree only, not of kind. Haeckel thought it probable that consciousness arises with the centralization of the nervous system, and that the lower classes of animals lack that faculty. The province of unconscious psychic actions, reflex action, for example, is more extensive than that of conscious ones, but the two areas are closely connected.

The consciousness of man and of other mammals biologically close to man is changeable and is modified by both internal and external causes. Consciousness is dependent upon the normal development of certain organs and gradually develops in the child as those organs develop. Despite Haeckel's use of a "faculties" terminology, his views on psychology are often similar to those of recent functionalists.

ATTACK ON TRADITIONAL RELIGION

Haeckel's attack on supernatural religions had many facets. He unequivocally rejected revelation and theological faith. He was outspoken in combating the superstitions associated with the world's great religions. He scathingly attacked the influence of the church as an institution in politics and education. Indeed, he frequently coupled these problems, holding that the German government would not improve until it was free from church influence and its citizens received a better, more scientific, education. Haeckel even claimed that such questions as whether a monarchy is preferable to a republic and whether the constitution should be aristocratic or democratic are subordinate to the "supreme question": Shall the government be secular or dominated by the clergy? Haeckel was no respecter of religious heroes, prominent clerics, sacred myths, or widely held dogma. He tried to show that theological beliefs are

incompatible with scientific data, unreasonable, or merely dogmatic.

Haeckel's admiration for the views of Benedict Spinoza and Johann Wolfgang von Goethe and his belief that humankind's ethical aspirations needed some support led him to advocate a monistic religion. "The ethical craving of our emotion is satisfied by monism no less than the logical demand for causality on the part of reason." He had great respect for the ethical values of primitive Christianity, and felt that Christianity had been so influential in the social and political movements of civilized history that "we must appeal as much as possible to its existing institutions in the establishment of our monistic religion" (*The Riddle of the Universe*, p. 336). He maintained, therefore, that he sought a rational reformation, rather than a revolution, in religion. However, the extent of his criticisms of Christianity appear to be revolutionary.

Haeckel wanted to give rational support to the true, the good, and the beautiful, and he considered the relation of that trinity to prevailing Christian notions. Truth is to be found in the study of nature by means of critical observation and reflection, and hence revelation must be rejected. However, what "we call virtue, in our monistic religion coincides for the most part with the Christian idea of virtue," especially the Christianity of the first three centuries. Charity, toleration, compassion, and assistance are humanistic as well as Christian precepts, and are to be emphasized in the monistic religion.

On the other hand, Haeckel maintained that early Christianity preached the valuelessness of this-worldly things, because this life was merely a preparation for eternity. Hence the beautiful was of little consequence. Haeckel was especially interested in art forms in nature and believed that the microscope had newly aroused our aesthetic sense.

All forms of theism are to be opposed. A pantheism that identifies God and substance is necessarily "the world-system of the modern scientist." All scientists who think theism can be reconciled with science are, in Haeckel's view, either dishonest, or confused, or victims of sophistry. If atheism is construed as a denial of the existence of a personal and extramundane god or gods, then Haeckel agreed with Arthur Schopenhauer's remark that pantheism is only a polite form of atheism. In short, Haeckel's criticism of traditional religions was that their doctrines are often intellectually wrong; that they generate unrealistic hopes; and that the social, political, and educational consequences of supernaturalism are malignant. Haeckel's criticisms, especially of Roman Catholicism, are often strongly worded. Thus he wrote that the

obligatory celibacy of the clergy, auricular confession, and the sale of indulgences were designed for the purposes of strengthening the rule of the church over the "credulous masses and making as much material profit as possible out of them."

ETHICS AND SOCIAL VIEWS

In ethics, Haeckel felt that traditional theories often either emphasize altruism too much (as in the case of many religious views) or emphasize egoism too much (hedonisms). He held that there should be an "equal emphasis" on self-love and love of one's neighbor. The "highest aim of all ethics" is to reestablish a "natural equality" of egoism and altruism. Along with this should go an emphasis on the body as well as the soul; an emphasis on fair treatment of animals as well as humans. Haeckel believed that a recognition of human evolution would incline us to be more sympathetic to animals, and that Christian attitudes easily lead to cruelty toward animals. Haeckel regarded the family as the foundation of society and as a necessity for humanity as well as for the higher social animals, whereas Christianity, he believed, tends to disparage the family as a this-worldly phenomenon. Haeckel also opposed the tendency that he found in Christianity to make woman subordinate to man and to regard sexual intercourse as "unclean." He was especially hostile to the hypocrisy he believed is often found in the church toward sex.

Haeckel was much interested in social reform, holding that progress is a law of nature. He compared the rapid progress made in the natural sciences with the lack of progress in government, the administration of justice, education, and social and moral organization. He gave special attention to justice. He believed that students of jurisprudence need much more education in science than they usually receive, and that their knowledge of human nature is sadly deficient. Politicians too make practical decisions of great import with no scientific grounding in the appropriate areas. He also decried the many impediments to free inquiry, whether they stem from political reaction or from theological superstition. He was highly optimistic about the consequences of an improved system of education.

Many of Haeckel's views that caused violent disputes in the past are today widely accepted by educated people. Much of the antagonism toward him was centered on his insistence that man is a part of nature and in the evolutionary stream. Although large portions of the scientific part of Haeckel's worldview have since been rejected, much is still regarded as sound. His views on religion

would still be challenged by many; some, of course, find them mild.

Rollo Handy (1967)

HÄGERSTRÖM, AXEL
(1868–1939)

Axel Hägerström, the Swedish philosopher, was the son of an orthodox minister of the Swedish Lutheran church and grew up in an intensely religious atmosphere. With the intention of following his father's profession, in 1886 he began theological studies at Uppsala University, which was to remain his academic home throughout his life. His interests, however, were soon diverted from theology to philosophy. From 1893 to 1911 he was docent (roughly, assistant professor), and from 1911 to 1933 professor, of "practical philosophy" (philosophy of morals, law, and religion). During his student days the idealistic metaphysics of C. J. Boström was still influential in Uppsala, although this mode of thought was soon to be swept away by a kind of Neo-Kantianism. Hägerström's publications around the turn of the twentieth century mirror this situation. Under the influence of Immanuel Kant, he came to regard metaphysics as impossible and, going further than Kant, rejected the hypothesis of the *Ding an sich* (especially in *Kants Ethik,* Uppsala, 1902). Like Kant, he considered the pure Ego, the same in all individual minds, as somehow the principle of the reality given to us, as the source of the laws of logic, and also as the source of certain synthetic propositions a priori, such as the principle of causality. Gradually the role played by this pure Ego was taken over, in his thought, by "the concept of reality," which he treated in *Das Prinzip der Wissenschaft* (The principle of science; Uppsala, 1908) and *Botanisten och filosofen* (The botanist and the philosopher; Uppsala, 1910).

Speculation about the concept of reality was to remain a fundamental ingredient in his mature philosophy, but it gradually lost most of its original Kantian flavor. In 1909 Hägerström wrote his *Social teleologi i marxismen* (Social teleology in Marxism; Uppsala). Although this study is a sharp criticism of the Marxist philosophy of history, it seems evident that he was influenced by, or at least in strong sympathy with, certain other aspects of Marxism—its materialism and its views on the functions of ideologies. In his lectures Hägerström soon characterized his own outlook as "enlightened materialism." To give an adequate characterization of his philosophy in a few key words is difficult, for he himself never presented his views in a systematic fashion. His many philosophical writings are mostly devoted to rather special questions, and much of their space is taken by polemics against authors with whom he disagrees. The influences that molded his thought were diverse and seemingly somewhat incompatible. His final philosophi-

cal positions were, on the whole, as far to the left as possible of religion and of any philosophical system, such as that of Boström, that was akin to or gave support to religion. As his motto Hägerström once chose the Catonian paraphrase: "Besides, I think that metaphysics ought to be destroyed."

CRITIQUE OF "METAPHYSICS"

Like so many antimetaphysicians, Hägerström was prone to label any view opposed to his own as metaphysical. The word *metaphysics* as he used it remains somewhat vague as to connotation as well as to denotation. He held, however, that all metaphysical doctrines suffer from a common fundamental fault, that of (implicitly or explicitly) assuming that "reality itself is something real" (or "being is something that there is"). This assumption is as "absurd" as, for example, the assumption that triangularity is something triangular. Hägerström thought it possible to prove positively (1) that the spatiotemporal world of experience exists and (2) that nothing may exist outside this world. In his proof of (1) he made use of an "analysis of the concept of reality" and also of ideas reminiscent of René Descartes's *Cogito.* To deduce (2) from (1) he invoked the principle that two entities cannot exist "outside each other" except as parts of a spatiotemporal context. His materialistic conception of the world of experience does not exclude the existence of consciousness, but consciousness, in his opinion, is a quality of certain material bodies (the psychophysical organisms).

CRITIQUE OF "SUBJECTIVISM"

In an act of consciousness (awareness) we are always conscious of something. If C is a consciousness of O, then C and O are, according to Hägerström, always two distinct entities; and further, the fact that a consciousness of O exists does not imply that O is endowed with any special intrinsic quality (such as being "mental," being a "perception," or being an "idea"). To overlook this is, in his opinion, the fundamental "subjectivist" mistake, which he thinks he can trace in the majority of philosophical epistemologies. This mistake gives rise to a secondary "subjectivist" mistake, the assumption that our knowledge about our own acts of consciousness is the immediate knowledge from which our knowledge of the external world must be derived.

THEORY OF VALUE

Hägerström's first work in value theory was "Kritiska punkter i värdepsykologien" (Critical points in value psychology; in *Festskrift för E. O. Burman,* Uppsala, 1910), in which he raised objections to certain views of the Austrian school of value theory (Alexius Meinong, Christian von Ehrenfels, and others). He rejected especially their distinction between valuating emotive experiences and value judgments as theoretical judgments about the occurrence of such experiences. The value judgment, he claimed, is itself essentially emotive. By the time of his inaugural lecture, published as *Om Moraliska Föreställ-ningars Sanning* (On the truth of moral ideas; Uppsala, 1911), Hägerström had arrived at the "value-nihilistic" doctrine that was to remain one of the most characteristic traits of his philosophic position. Statements of value, such as "To lie is bad," are neither true nor false: They lack truth value. Of the many arguments by which he tried to corroborate this view, the following is typical: A statement is true (or false) if, and only if, the judgment (as a mental phenomenon) expressed by the statement is true (or false); a statement of value, however, does not express any genuine judgment, but an "association" between an "idea" (for instance, the idea of lying) and an emotion. In his work *Till frågan om den objektiva rättens begrepp* (On the question of the notion of law; Uppsala, 1917), he elaborated this view also with respect to deontic statements. A statement such as "I ought not to lie," or "It is my duty not to lie," corresponds, not to a judgment with a truth value, but to an association between an "idea" and a "conative impulse." In this respect deontic statements are closely akin to imperatives. The persistent illusion that value statements and deontic statements have a truth value is caused by the relative stability of the underlying associations, which are built up and supported by the suggestive influence of a number of factors in the social system (such as early education by parents and teachers and the pressure of public opinion).

Hägerström nourished the hope that the spreading of his value-nihilism would contribute to the creation of a more tolerant, more humane, and less vindictive morality. Since he believed that the task of the moral philosopher is to analyze the mental phenomena expressed by, for example, statements of value, and since he took emotions to be an essential constituent in such phenomena, he became deeply interested in the nature of emotion. In order to substantiate his value-nihilism, he thought it important to demonstrate the subjective character of emotions; being "subjective," emotion can not be a source of knowledge—for instance, knowledge of values. Like all mental phenomena, an emotive experience is either an act of being conscious (aware) of something or some combination of such acts. What might commonly be called an emotive experience, such as enjoying the prospect of going to the cinema, is a combination of

intellectual and purely emotive ingredients. The purely emotive experiences, such as a mere feeling of pleasure, consist in being conscious of a certain emotive quality (here a pleasure quality). In his earlier publications, Hägerström seems inclined to regard emotion as "subjective" because emotive qualities are qualities of the Ego. Later he experimented with a variety of explanations. According to one, emotion is "subjective" because the emotive qualities are experienced without "localization." Here, Hägerström invokes his principle that localization in the spatiotemporal context is essential to reality and objectivity, but the form of his argument remains somewhat vague. According to another of his somewhat puzzling explanations, emotion is "subjective" because the emotive qualities inhere in the psychophysical organism that has the emotion, and not in "external" objects.

In some of his works he assumed a "projection of emotive qualities onto external objects." When I look at a painting that pleases me, in his opinion, I project the quality of pleasure experienced by myself onto the painting: I perceive the painting as pleasant, just as I perceive it as square or as dark. On this view, the epistemological distinction that he wished to maintain between emotive qualities and, say, colors, becomes rather problematical. Some Swedish critics of his value theory have taken this view as starting point for their criticism—Einar Tegen, "The Basic Problem in the Theory of Value," in *Theoria* 10 (1944): 28–52; and Søren Halldén, *Emotive Propositions* (Stockholm, 1952).

LEGAL PHILOSOPHY

Hägerström began his mature work in legal philosophy with a criticism of a doctrine, common in nineteenth-century "legal positivism" (*Rechtspositivismus*), according to which "positive law" (as opposed to "natural law," *Naturrecht*) is somehow the expression of a will actually existing in society. His essay "Är gällande rätt uttryck av vilja?" (Is positive law an expression of will?) in *Festkrift tillägnad Vitalis Norström* (Göteborg, 1916) and his previously mentioned book *Till frågan om den objektiva rättens begrepp* are largely devoted to a painstaking criticism of this doctrine in its many varieties. Hägerström devoted much energy to the attempt to clarify the nature of positive law and those factors in "the social machinery" that uphold the law. He maintained that our common view of legal phenomena is blurred by "magical ideas" that can be traced far back in history. In *Der römische Obligationsbegriff im Lichte der allgemeinen römischen Rechtsanschauung* (The Roman notion of obligation in the light of the general Roman view of law; Vol. I, Uppsala, 1927; Vol.

II, Uppsala, 1941), he tried to demonstrate the magical element in ancient Roman law. He believed that such Roman concepts as *ius, dominium,* and *possessio* are magical ideas and that the old Roman legal acts, such as *mancipatio* and *stipulatio* are acts through which magical powers over things or persons are established.

CRITICAL HISTORY OF IDEAS

In his lectures (some of which have been posthumously published) Hägerström discussed, with a wealth of learning, the history of religious, philosophical, political, and legal ideas. The history of ideas appeared to him largely as the history of confusions and errors flowing from certain inborn mechanisms of the human mind. To explain them he used to point especially to certain thought processes that, in his opinion, almost inevitably take place when the emotions and the projection of emotive qualities interfere with intellectual operations.

INFLUENCE

In Sweden, and also in the neighboring Scandinavian countries, Hägerström has exercised great influence. With his pupil and colleague Adolf Phalén he became the founder of the so-called Uppsala school of philosophy, which flourished in the 1920s and 1930s and has had a lasting effect on the whole academic philosophical atmosphere in Sweden. Common to the members of this school—most of whom disagreed with much of Hägerström's own philosophy—were a distrust of metaphysical speculation and of epistemological subjectivism, a realistic (sometimes almost naively realistic) conception of the external world, an interest in the phenomenological analysis of mental acts and their contents, an emotive theory of value (of some kind or another), and an insistence on conceptual analysis as a central task of philosophy. Some of the original members of the Uppsala school became strongly influenced by the Cambridge school of analysis in England and by logical empiricism. Outside philosophy proper, Hägerström gave rise to a school of jurisprudence (Vilhelm Lundstedt, Karl Olivecrona, Alf Ross).

HALEVI, YEHUDA
(c. 1075–1141)

Yehuda Halevi, or Judah ha-Levi, the philosopher of Judaism, was born in Toledo, Spain. In his youth he received an excellent grounding in biblical and rabbinic literature, as well as in the secular, particularly philosophic, disciplines. Halevi early displayed a marked poetic gift, which culminated in a body of Hebrew poetry noted for its adaptation of Arabic poetic forms to the Hebrew idiom and for its religious profundity. He practiced the profession of medicine for most of his life, residing in both Christian and Muslim Spain, a fact that may account for his excellent knowledge of Judaism's two descendant religions. His decision to leave for a perilous pilgrimage to Palestine was the result of his intense longing to see the Holy Land, a longing that is reflected in both his poetry and his philosophic work. Legend has it that he was killed in 1141 by an Arab horseman as he kissed the soil of the Temple Mount in Jerusalem, but there is no historic confirmation of this, since he cannot be traced beyond Egypt on his way to Palestine.

Yehuda Halevi's philosophic work *Kuzari: The Book of Proof and Argument in Defense of the Despised Faith*, written shortly before his departure for Palestine, uses as its framework the historically verified conversion to Judaism of the Khazar King Bulan II and most of his people about the year 740. This event had assumed almost legendary proportions by Yehuda Halevi's time, serving as a source of great religious satisfaction to the otherwise badly suppressed Jewish masses. In his work Yehuda Halevi reconstructed imaginatively the discussions that led to the king's conversion. At the beginning we are told that an angel has appeared to the king in his sleep and has informed him that the Creator was pleased with his intentions but not with his way of acting. In the hope of learning a better way of life the king calls in representatives of Aristotelian philosophy, Christianity, and Islam, but they all fail to satisfy him. The king did not originally plan to call on a representative of Judaism, judging this religion unworthy of serious consideration because of the misery of its adherents, but his dissatisfaction with the other presentations causes him to alter his decision and to

call for a rabbi. The discussion with the rabbi constitutes the rest of the volume.

The rabbi begins his presentation by asserting his belief in the God of Abraham, Isaac, and Jacob, who led the Israelites out of Egypt and whose intervention in the history of Israel has been continuous ever since. By beginning in this way, Yehuda Halevi broke sharply with the tradition of Aristotelian rationalism that characterized the bulk of medieval Jewish philosophy. He was very much aware of the profound abyss separating the God of the philosophers, who is self-contained, unmoved, and nonpersonal, from the personal and historic God of the Bible. For this reason he dispensed entirely with traditional proofs for the existence of God, the usual prolegomena of medieval Aristotelianism—whether Jewish, Christian, or Muslim—to the defense of the faith. For Yehuda Halevi it was history that was decisive. The God who reveals himself in the history of Israel could not have been reached by philosophical speculation but only by revelation. Similarly, Yehuda Halevi's interest in miracles reflected his view of history as the realm in which revelation takes place. The superiority of Judaism over its competitors follows, for Yehuda Halevi, from the public character of the Sinaitic revelation upon which Judaism is based. At Sinai, 600,000 men, women, and children were addressed by God, a mass revelation that no other religion can claim. This precludes the possibility of error or deception, a possibility that cannot be discounted in those instances where the revelation is restricted to one or to a few.

Yehuda Halevi's attitude toward the knotty problem of anthropomorphism also reflected his anti-Aristotelian orientation. Although he was not in sympathy with a literal interpretation of many of the terms applied to God by the biblical authors, realizing that this would lead to a humanization of God even to the extent of attributing corporeality to him, Yehuda Halevi was not willing to go the other extreme and strip God of all attributes, making it all but impossible to speak about him. There are events that can be experienced as proceeding from God directly. When biblical authors, such as the prophets, applied a term like *merciful* to God, they were referring to those actions of God that are experienced by man as merciful and as coming from God. Although the term *merciful* is therefore applicable more to the effects of God's actions than to his essence, to the extent that his actions are his discourse about God becomes possible.

The religious particularism that is fundamental to biblical religion was no source of embarrassment to Yehuda Halevi. The election of the people of Israel and of the land of Israel were fundamental concepts of his religious nationalism. This nationalism was based on the divine election of a people and a land for the proclamation to all humankind of those demands that God makes of all people, but for the special representation of which he has chosen one nation, whose suffering derives from its unfaithfulness to its mission. These themes permeate Yehuda Halevi's poetic works as much as they do his philosophical writings.

Bibliography

WORKS BY YEHUDA HALEVI

The *Kuzari* or *Book of Refutation and Proof on Behalf of the Despised Religion* is Yehuda Halevi's magnum opus on religion, philosophy, and theology in general and Judaism in particular. The first critical edition of this work was based on Yehuda ibn Tibbon's medieval Hebrew translation and published together with a modern German translation and commentary by David Cassel, *Das Buch Kusari des Abū-l-Hasan Jehuda Hallewi*, Zweite verbesserte Auflage (Leipzig: Friedrich Voigt, 1869). A revision of this Hebrew translation with useful notes can be found in A. Zifroni, *Sefer ha-Kuzari* (Tel Aviv: Mahbarot le-Sifrut, 1948). The original Judeo-Arabic text was first edited by Hartwig Hirschfeld and published with Ibn Tibbon's translation as *Das Buch al-Chazari* (Leipzig: Otto Schulze, 1887). A new and much more comprehensive critical edition of the original Judeo-Arabic text has been published by David H. Baneth and Haggai Ben Shammai as *Kitāb al-Radd wa' l-Dalīl fi'l Dīn al-Dhalīl (al-Kitāb al-Khazarī)* (Jerusalem: Magnes Press, 1977); this edition is now the basis of all contemporary scientific translations. Hirschfeld eventually translated his Judeo-Arabic edition into English as the *Book of the Kuzari* (London: Routledge, 1905); this translation has been republished several times. Isaac Heinemann published a much abridged and revised English translation with notes, based on Hirschfeld's work, which originally appeared in *Three Jewish Philosophers*, edited by Hans Lewy, Alexander Altmann, and Isaac Heinemann (New York, 1945); this translation has likewise been republished several times. Modern Hebrew translations with notes include: Yehudah Even-Shmuel, *Sefer ha-Kozari le-R. Yehudah Halevi*, 2nd ed. (Tel Aviv: D'vir, 1972); and R. Joseph Qafih's combined edition and translation, *Sefer ha-Kuzari: Maqor Ve-Tirgum* (Qiryat Ono: Machon Mishnat Ha-Rambam, 1997), which is very close to the original Judeo-Arabic. Equally valuable is Charles Touati's French translation, *Le Kuzari: Apologie de la religion méprisée* (Louvain and Paris: Peeters, 1994). A new English translation of the *Kuzari* with notes, begun by the late Lawrence V. Berman, is being revised, continued, and prepared for publication by Barry S. Kogan under the auspices of the Yale Judaica Series of Yale University Press.

WORKS ON YEHUDA HALEVI

The single most valuable resource on Yehuda Halevi's life is Moshe Gil and Ezra Fleischer's *Yehudah Ha-Levi and His Circle* (in Hebrew; Jerusalem: World Union of Jewish Studies, 2001). A short biographical portrait, in English, reflecting recent research, is S. D. Goitein's "Judah Halevi: Poet Laureate, Religious Thinker, Communal Leader, Physician," in *A Mediterranean Society*, Vol. 5: *The Individual* (Berkeley: University of California Press, 1988). Book-length studies of Halevi's thought include Yochanan Silman, *Philosopher and Prophet: Judah Halevi, the Kuzari, and the Development of His Thought* (Albany: State University of New York Press, 1995); and Diana Lobel, *Between Mysticism and Philosophy: Sufi Language of Religious Experience in Judah Ha-Levi's Kuzari* (Albany: State University of New York Press, 2000). All chapter-length studies of Halevi in standard histories of Jewish philosophy remain useful: Isaac Husik, *A History of Medieval Jewish Philosophy* (New York: Macmillan, 1916); Julius Guttmann, *Philosophies of Judaism*, translated by D. W. Silverman (Philadelphia: Jewish Publication Society, 1964); Colette Sirat, *A History of Jewish Philosophy in the Middle Ages* (Cambridge, U.K.: Cambridge University Press, 1985); and L. E. Goodman, "Judah Halevi," in *History of Jewish Philosophy*, edited by Daniel H. Frank and Oliver Leaman (London: Routledge, 1997). Articles and chapter-length studies on specific topics include: D. H. Baneth, "Judah Halevi and al-Ghazali," in *Studies in Jewish Thought: An Anthology of German Jewish Scholarship*, edited by A. Jospe (Detroit: Wayne State University Press, 1981; original Hebrew version with notes in *Knesset* 7 [1941–1942]: 311–329); Michael S. Berger, "Toward a New Understanding of Judah Halevi's *Kuzari*," in *Journal of Religion* 72 (1992): 210–228; Herbert A. Davidson, "Reverberations [of the Theories of Alfarabi and Avicenna] in Medieval Jewish Philosophy," in *Alfarabi, Avicenna, and Averroës on Intellect: Their Cosmologies, Theories of the Active Intellect, and Theories of Human Intellect* (Oxford: Oxford University Press, 1992); Kenneth H. Green, "Religion, Philosophy, and Morality: How Leo Strauss Read Judah Halevi's *Kuzari*," in *Journal of the American Academy of Religion* 61 (1993): 225–273; Barry S. Kogan, "Al-Ghazali and Halevi on Philosophy and the Philosophers," in *Medieval Philosophy and the Classical Tradition*, edited by John Inglis (Richmond, U.K.: Curzon, 2002); Barry S. Kogan, "Judah Halevi and His Use of Philosophy in the *Kuzari*," in *The Cambridge Companion to Medieval Jewish Philosophy*, edited by Daniel H. Frank and Oliver Leaman (Cambridge, U.K.: Cambridge University Press, 2003); Tsvi Langerman, "Science in the *Kuzari*," *Science in Context* 10 (1997): 495–522; Diana Lobel, "A Dwelling Place for the *Shekhinah*," *Jewish Quarterly Review* 90 (1999): 103–125; Shlomo Pines, "Shiʿite Terms and Conceptions in Judah Halevi's *Kuzari*," *Jerusalem Studies in Arabic and Islam* 2 (1980): 165–251; Eliezer Schweid, "The Artistry of the Dialogue within the *Kuzari* and Its Theoretical Meaning," in *Feeling and Speculation* (in Hebrew; Ramat Gan: Masada, 1970); Leo Strauss, "The Law of Reason in the *Kuzari*," *Persecution and the Art of Writing* (Glencoe, IL: Free Press, 1952); Harry A. Wolfson, "Maimonides and Hallevi: A Study in Typical Jewish Attitudes towards Greek Philosophy in the Middle Ages" and "Maimonides and Hallevi on Prophecy," in *Studies in the History of Philosophy and Religion*, Vol. 2, edited by Isadore Twersky and George H. Williams (Cambridge, MA: Harvard University Press, 1977.

HAMANN, JOHANN GEORG
(1730–1788)

Johann Georg Hamann, the German Protestant thinker and critic of the Enlightenment, was born in Königsberg. In no sense a professional philosopher, and largely self-educated, he made his living as a secretary-translator and later as a government warehouse manager in Königsberg.

WRITINGS

Hamann's originality early caught the eye of such diverse figures as Johann Wolfgang von Goethe, G. W. F. Hegel, and Søren Kierkegaard, but his famous "darkness"—his opaque style—has daunted all but the most persistent investigators. Study of Hamann has long been dominated by Hegel's picture of him as an irrationalist and the paradigm of an individualist and also impeded by discouraging delays in the publication of complete editions of his works and letters. Following World War I, Hamann's influence on Kierkegaard began to be appreciated, but only more recently have scholars been able to expose enough of their subject so that the real dimensions of his thought could be guessed.

MEDITATIONS AND OCCASIONAL PIECES. Hamann's simplest writings were not intended for publication. These consist of his reflections following financial and spiritual crises he underwent on a business trip in 1758—*Biblische Betrachtungen* (Biblical meditations; 1758), *Gedanken über meinen Lebenslauf* (Thoughts on the course of my life; 1758–1759), and *Brocken* (Fragments; 1758). The *Sokratische Denkwürdigkeiten* (Socratic memorabilia; 1759) was his first public attack on the spirit of his century. A meditation on Socrates and his relation to Christ, it adumbrates the central concern of Hamann's intellectual career, the relation of philosophy to Christianity. Hamann saw himself as continuing the work of Martin Luther, under the different conditions of a later age. Whereas for Luther the problem had been the relation of faith to the "law," the established ecclesiastical and religious systems, the problem now concerned faith and philosophy.

Most of Hamann's writings were short occasional pieces. *Die Magi aus Morgenlande* (The Wise Men from the East; 1760), an essay on the symbolic meaning of eighteenth-century astronomical observations, earned him the sobriquet of the "Wise Man of the North." His reputation during his lifetime was largely based on such collections of essays as the *Kreuzzüge des Philologen* (Crusades of the philologian; 1762), which contains the influential "Aesthetica in Nuce" (Aesthetics in a nutshell), and on some political satires—*Lettre néologique et provinciale* (Neological and provincial letter; 1761), *Lettre perdue d'un sauvage du nord à un financier de Pe-kim* (Lost Letter of a savage of the north to a financier at Peking; 1773), and *Le kermes du nord* (The worm of the north; 1774). The sarcasm and irony characteristic of Hamann's style are readily apparent from some of his titles.

PHILOSOPHY AS CRITICISM

In what sense was Hamann a philosopher? Like Augustine, Anselm, Thomas Aquinas, Blaise Pascal, and Kierkegaard, Hamann is difficult to classify. His relation to philosophy was ambivalent and paradoxical. His thought moved between the twin figures of Socrates and the "Philologian." The figure of Socrates, the philosophical hero of the Enlightenment, Hamann adopted for his own purposes, to turn the symbol of the Enlightenment against itself and to call for a philosophical confession of ignorance in place of philosophical pretensions to knowledge. The term *Philologian* was selected for its ambiguity, in that it suggests both a "lover of the word" and a "lover of reason."

Like Socrates, Hamann considered man to be the crucial problem. (Hamann's famous simile compares self-knowledge to a "descent into hell," suggesting later explorations, by existentialism and depth psychology, into the anxieties and subconscious turmoil of the human psyche.) Like Socrates, he called for and practiced a critical and questioning philosophy; he especially appreciated the acid analyses of David Hume's reason. His answer to Immanuel Kant's criticism of metaphysics was a higher level of criticism, not "metaphysics" but "metacriticism." But as the Philologian, Hamann saw Socrates as a forerunner and prophet (although an unwitting one) of the Christ and philosophy as a discipline seen in its true light only in the context of Christianity.

CRITICISM OF THE ENLIGHTENMENT

Hamann's friends included many of the luminaries of the German Enlightenment, but personal relationships did not deter him from mounting the most severe criticism.

(He believed friendship was like Mount Etna, "fire in the bowels" but "snow on the head.")

What were Hamann's objections to the philosophy of the Enlightenment? He viewed as "idealistic vanity" the attempts of leading Enlightenment thinkers to base philosophy upon undeniable rational truths (Moses Mendelssohn), to speak of "pure" reason (Kant), to discover a "natural religion" (the deists), to penetrate the mystery of man's constitution and isolate the origin of man's linguistic capacities (Johann Gottfried Herder and others), and to separate the knowledge of God from its provenance in historical revelation (Gotthold Ephraim Lessing). Hamann valued Hume's skepticism but insisted that it illustrated not the glory but the bankruptcy of reason. Skepticism is a paradigm of the ambiguity of all human powers—reason so conceived and directed is self-destructive. Hume, he felt, performed a service for philosophy in demonstrating what happens when reason is conceived as purely analytical, stripped of its functions of comprehension and intuition and removed from its orientation in religion and its foundations in historical experience.

Hamann's objections to Enlightenment philosophy can be illustrated by two sexual images he employed (such images were characteristic of his style). The rationalism of the age was trying to strip truth of her clothes, or, to change the figure, was trying to divorce what Nature had joined together, to attain reality by removing all excrescences, such as tradition, history, and experiential particulars. For Hamann truth appeared most authentically as "enfleshed" and therefore embodied in a unity of reason, faith, and sensual experience. He was skeptical of abstractions and saw language as the means by which the reason is confused as well as the means by which it expresses itself (the "seducer" as well as the "helpmeet" of man). He insisted on the wisdom and religious depth inherent in the naive vernacular, in imagery, and in myth. A "coincidence of opposites" was to be expected in the present world, even where the opposites seemed to be the most surprising and paradoxical—flesh and spirit, God and man, sensual language and transcendent conceptuality, history and reason. The most radical skepticism conceals a surreptitious credulity, and the most notorious agnosticism a covert religion.

QUARRELS WITH OTHER THINKERS

Hamann's belief that the Enlightenment was sacrificing the concreteness, historicity, and earthiness of reality to the paramount desire of rationalism to systematize initiated his quarrel with such thinkers as Herder,

Mendelssohn, Kant, and Lessing as well as obscure lesser lights. *Philologische Einfälle und Zweifel über eine akademische Preisschrift* (Philological ideas and doubts about a writing which received an academic prize; 1772) attacks Herder's prize-winning essay on the origin of language; *Golgatha und Scheblimini* (1784) is a criticism of Mendelssohn's theory of "natural religion" and its relation to church and state; *KONXOMPAX* (1779) contains a satire on Lessing's dichotomy between the knowledge of God and the knowledge of "accidents" of history.

CRITICISM OF KANT

Hamann's evaluations of Kant's *Critique of Pure Reason* are found in his letters and in several essays, one of which is called "Metacritik über den Purismum der Vernunft" (Metacritique of the purism of the reason; 1784). The issue between these thinkers is the extent to which reason can be "pure" (that is, devoid of experience). Hamann objected not only to Kant's overvaluation of formal knowledge but also to the belief that Kant demonstrated that in some respects reason can be separated from sense experience.

LANGUAGE

To Hamann, demonstration of a separation between reason and sense experience is impossible because it depends on language, or mental symbols, the "purity" of which is ambiguous. This ambiguity cannot be removed (and the old Platonic ideal of knowledge of forms refurbished) by the double maneuver of surrendering knowledge of reality itself and locating the forms of space and time in the knowing ego, known to be emptied of fallible sense experience. The mark of such an "emptiness" (absence of sense experience) would be a synthetic judgment a priori, and according to Kant this would be based on the pure forms of sensible intuition. However, to Hamann these forms of intuition, which he took to be types of *language*, cannot be demonstrated to be pure, because language contains the capacity to create what may be an illusion. "Not only does the entire capacity to think rest upon language … but language is also in the middle of the misunderstanding of reason with itself." The forms of intuition are not simply passive channels for the content of experience, but active forms of language (or of symbols) that have the power to deceive the mind and create the illusion that they are a priori and necessary.

In the new picture of being that Hamann offered as an alternative to his age, man is seen as a creature of flesh and blood ("the heart beats before the head thinks"), history as a living communication of the meaning of man's existence ("a continuing sign"), and the world as the "language" of God ("speech to the creature through the creation"). The metaphor of "language" points to the symbolic nature of the world, which is not to be exhausted in its material significance, deified in a pantheism, or transcended by reason in a Platonic dualism.

INFLUENCE

Scholarly interest in Hamann has focused upon his influence on the Sturm und Drang and Romantic movements and on such figures as F. H. Jacobi, Friedrich von Schelling, Hegel, and Friedrich Schleiermacher; upon his role as a forerunner of existentialism; upon his pioneering exploration of the nature of human sexuality (see his *Versuch einer Sibylle über die Ehe* [Essay of a sibyl on marriage; 1775] and *Schürze von Feigenblättern* [Skirts of fig leaves; 1777]); upon his influence on religious thought, such as the Movement of Awakening (*Erweckungsbewegung*, a revival of intellectual pietism) and neoorthodoxy; upon his contributions to a philosophy of language; and upon his reconception of reason as essentially historical.

HAMELIN, OCTAVE
(1856–1907)

Ernst Heinrich Haeckel, the French idealist philosopher, carried further the neocriticism of Charles Renouvier and Jules Lachelier. Renouvier had criticized the categories of Immanuel Kant, maintaining that the category of relation really included all the others. He had also criticized the fact that Kant had not included personality in the categories, though he should have, since the will determines thought no less than does speculative reason. Thought, according to Renouvier, manifests relation in two ways—in the relations of its elements to each other, and in the relation of judgment to consciousness. The latter relation is always unique because consciousness displays its spontaneity in the synthesis of the objects which it posits.

Hamelin started from a similar position; in fact, he always declared himself a disciple of Renouvier. However, Renouvier had taken account of contingency and discontinuity, and for him the pursuit of truth involved a recurrent dilemma, in which a free choice or wager was presented to the seeker. Hamelin, by contrast, was much more intransigently rationalistic, and in this he was influenced by Lachelier. A priori thinking pervaded Hamelin's system, and he envisaged a reality made entirely transparent and intelligible by a process of rational deduction. "Knowledge will no longer be seen as the invasion of the subject by alien elements, but as a putting into action by the subject of his potentialities."

Such an idealistic system requires some principle that accounts for change yet allows change to remain compatible with the necessity of rational deduction. In Hamelin's system this principle is correlation, and following G. W. F. Hegel, Hamelin pictured a dialectical evolution of reality through the synthesis of complementary opposites. This movement is from abstract elements toward the constitution of concrete reality—toward the constitution, indeed, of conscious personality—and not, as in Hegel, toward the indefinite pursuit of an Absolute. Hamelin's philosophy was a highly ingenious, if perhaps unsuccessful attempt to do away with the dilemma that dogged nineteenth-century French philosophy, the dilemma of a necessary realm of thought and a contingent domain of occurrences. Hamelin brought contingency, freedom, and personal consciousness within his dialectical system, making them the necessary outcome of incomplete, abstract categories that invoke them. They make their appearance, moreover, as the product of the dialectical process and as the coming to fruition of a hitherto inchoate reality.

Hamelin deduced the categories, or elements of representation, according to this dialectical principle. Relation is the synthesis of being and nonbeing, as that which consists in interdependence. The antithesis of relation is what is essentially independent, number. Number and relation are synthesized in time. Space stands in antithesis to time since its parts, though separate, are also simultaneous and reversible. The space-time antithesis is transcended in motion, still a quantitative concept, which finds its opposite in what is unaffected by it, quality. Motion and quality are synthesized in modification (*altération*), which is the movement of quality. Modification is contrasted with a kind of resistance to change that tends to perpetuate the initial state, and this is specification, or the notion of class or species. Out of the interaction of modification and specification comes causality, or change brought about in beings through their sharing the world with other beings. Opposed to causality is a principle of persistence within the self, which is finality. The ultimate synthesis is in independence and self-sufficiency,

which is expressed as free becoming and is an active system, or conscious self.

The characteristic of Hamelin's philosophy is its strictly a priori derivation of the concrete and individual consciousness from general and abstract elements. There is a kind of dynamism of incomplete abstraction working toward its own fulfillment and specification as successive logical demands are met. The element of contingency, which is inescapable in reality, finds its way into the system in the freedom of the individual consciousness: "What provides the explanation of consciousness is the need to choose."

Hamelin proceeded as far as anyone could in the idealistic direction. His no longer fashionable metaphysical deduction of the world through a series of necessary relations has met with some criticism from more recent French philosophers, whose tendency has been rather to see meaningful experiences as involving a compromise between a world of brute facts, which is prereflective, and a mind that almost necessarily orders them, albeit according to its own requirements and in the light of its own tasks.

HAMILTON, WILLIAM
(1788–1856)

William Hamilton, the Scottish philosopher and logician, was born in Glasgow and was educated at Glasgow, at Edinburgh, and at Balliol College, Oxford, where he took his B.A. in 1811. After leaving Oxford he studied law and in 1813 was admitted to the Scottish bar. He was appointed professor of civil history at the University of Edinburgh in 1821 and was elected to the chair of logic and metaphysics in 1836. Hamilton, a man of stupendous erudition, was strongly influenced by Thomas Reid and Immanuel Kant.

PSYCHOLOGY

Hamilton divided "mental modifications, or phenomena" into three classes—the phenomena of knowledge or cognition; the phenomena of feeling, of pleasure and pain; and the phenomena of will or desire, the exertive or connative powers. Knowledge, feeling, and will or desire cannot exist independently of one another. Every state of mind is a combination of all three, although proportions may vary. We can conceive of a being who knows one thing or another but is totally devoid of feeling, desire, and volition; or of a being capable of knowledge and feeling only; but not of a being having the capacity for pleasure and pain and the capacity to will, but lacking the faculty of knowledge.

Mental phenomena are included under the phenomenon of consciousness. When one knows, he knows or is conscious that he knows; when one feels, he knows or is conscious that he feels; and when one desires, he knows or is conscious that he desires. Consciousness is not something in addition to knowledge, feeling, and desire, but the general condition of their existence. It is a relation between a knowing (or conscious, or intelligent) subject and an object of knowledge, in this case a modification of the mind. Although Hamilton sometimes denied the possibility of unconscious mental states, at other times he argued that "the mind exerts energies, and is the subject of modifications, of neither of which it is conscious" (*Lectures on Metaphysics,* Lecture 18).

PERCEPTION

In perception, according to Hamilton, we have an immediate or presentative rather than a mediate or representative knowledge of the object. In presentative cognition a thing is known in itself rather than via something other than itself. When I see a cat I come to know the animal in itself as contrasted with, for example, my knowledge of a past event, which is acquired through testimonials and other means distinct from the event thus cognized. I may have representative knowledge of the past, the future, and the merely possible, as in imagination. Immediate presentative knowledge is of that which exists here and now. Perception is the faculty presentative of the phenomena of the nonego (matter), and self-consciousness is the fac-

ulty presentative of the phenomena of the ego (mind). A thing is known in itself only if it be known as actually existing in its when (now) and its where (here). Perception has for its objects the primary qualities of bodies. Knowledge of secondary qualities is never immediate, in that all we can know of them is that some unknown external cause is responsible for the "present affections of the conscious subject." Thus Hamilton agreed with Thomas Reid that we have a "direct notion" of primary qualities but only relative notions of the secondary qualities of things.

In perception we are intuitively aware of the duality of ego and nonego. This is an immediate, primitive datum of consciousness, to whose existence the natural realist (or natural dualist—both terms were used by Hamilton to designate holders of views like his own) is implicitly committed. Perception is not inference. We do not first become aware of some mode of consciousness and then infer from this awareness the present existence of a physical object as cause of that modification. Nor are we aware of an inner representation or referent from which we conclude the existence of an object referred to or represented. Representative theories of perception presuppose what on their own terms could not be the case. In order to know that *A* refers to or represents or is a sign of *B,* it must be possible to gain knowledge of the existence and nature of *B* independently of our knowledge of the existence and nature of *A.*

RELATIVITY OF KNOWLEDGE

Granting that our senses inform us of the existence and the nature of physical objects, just what information do they provide us with? Hamilton held that our knowledge of mind and of matter is relative and conditioned and that "of existence absolutely and in itself, we know nothing" (*Lectures on Metaphysics,* Lecture 8). Our knowledge of the ego as well as of the nonego is purely phenomenal. The self is known to us only via the phenomena of the immediate introspective awareness of the flow of experience. In external perception we come to know about physical objects only as they appear to us through the senses. A physical object as known is that which appears to us as extended, solid, divisible, figured, colored, hot or cold. Thus, "matter" or "body" is a name for a certain set of appearances or phenomena, but these must be regarded as appearances *of* something. This something, however, is inconceivable apart from its phenomena, absolutely and in itself, out of relation to a knower. By virtue of a "law of thought" we are compelled to think of something absolute, unknown, and unknowable as the

subject, substance, or substratum of the relative, the phenomenal, the known. The same reasoning applies to mind.

That a thing or a quality of a thing is known in itself does not mean that it is known in its "absolute existence" out of relation to the knower, for this is impossible. Hamilton meant, presumably, only that it is not known through a process of inference from signs or representations. All knowledge is relative in that in order to be known a thing must be related to the knower, the relation being precisely that of the knower to the known. But this is trivial. Hamilton pointed out that the way a thing appears to us in perception is relative in another sense— it is a function not only of the objective qualities of the thing, but of the medium and the sense organs as well. When I perceive a book, the phenomena or appearances of the external object are a resultant of the contributions of the book, of the intervening medium, and of the sense organs. Consequently my knowledge of the book is modified through certain intermediate agencies and must be relative. But, as J. S. Mill pointed out in *An Examination,* this conclusion does not follow; rather than entailing the relativity of all knowledge of physical objects, the considerations adduced show at most that that part of the knowledge that is not contributed by the book itself is relative.

PHILOSOPHY OF THE CONDITIONED

To think of a thing is necessarily to think of it as a thing of a certain sort, to classify it, to subsume it under a concept. Thought imposes conditions on its object. Therefore the conditioned is the only possible object of knowledge. The absolute, the nonrelative, the unconditioned is inconceivable; all we can know is *that* it is, not *what* it is. Although many things are inconceivable to us, nonetheless we know that some of them must be true. Hamilton claimed that, given the principles of contradiction and excluded middle, all actual thought lies between two extremes, each of which is inconceivable. The extremes represent that which is absolute or unconditioned. One of these absolutes we know must be true because they are mutually contradictory; but since both are inconceivable we cannot know which is true. "The Conditioned is the mean between two extremes—two unconditionates, exclusive of each other neither of which can be conceived as possible, but of which … one must be admitted as necessary" (*Discussions,* p. 22). The weakness of the human mind thus restricts its objects of positive thought to the mean. As illustration Hamilton argued that space must either be bounded or unbounded. One

alternative must be true, but both cannot be, even though we cannot positively conceive of either one. Similarly we cannot conceive of an absolute beginning of time or of an infinite regress. We cannot conceive of an absolute end of time or of an infinite prolongation, although one or the other must be admitted to be true.

LOGIC

Hamilton regarded his doctrine of the quantification of the predicate as his most important contribution to logic. The doctrine is based on the self-evident truth that we can operate rationally only with what we already understand. This in turn leads to the postulate that we ought to be able to state explicitly what is thought implicitly. When we make a judgment we always implicitly understand the quantity of the predicate as well as the quantity of the subject. Since the predicate is always quantified in thought, and since every quantity is either all or some or none, we always regard the predicate of a judgment as denoting all, some, or none of the objects in its extension. The proposition "All men are animals" must mean either that all men are all animals (all men and only men are animals), or that all men are some animals (all men, but not men only, are animals) "Some animals are carnivorous" becomes "Some animals are some carnivorous," which is to be understood as some and some only, that is, some animals are carnivorous and some are not. Among the advantages of this innovation, according to Hamilton, are the reduction of propositions to equations, the simplification of the doctrine of conversion, the abolition of the figured syllogism and the consequent manifestation of the absurdity of reducing syllogisms of other figures to the first.

Since in Hamilton's view logic is the science of the laws that of necessity govern all valid thought, criticisms of him drawn from psychological considerations are relevant. It comes as something of a surprise to the beginner in logic that conversion of the universal affirmative "All *S* is *P*" is only by limitation to "Some *P* is *S*." But in Hamilton's view this should be obvious to all and should not represent a new idea as in fact it does.

Timothy J. Duggan (1967)

HAMPSHIRE, STUART NEWTON
(1914–2004)

Stuart Newton Hampshire, born in Lincolnshire, England, was a fellow of All Souls College and of New College, Oxford, and then Grote professor of mind and logic at University College, London (1960–1963); he also was professor of philosophy at Princeton University. From 1970 to 1984 he taught at Wadham College, Oxford; in 1984 he joined the faculty of Stanford University, becoming emeritus in 1990. Hampshire's contribution to philosophy, while clearly belonging to the main current of contemporary work in the English language, was highly individual. His work displays a broad and systematic outlook, concerned with bringing together views in the theory of knowledge, metaphysics, the philosophy of mind, ethics, and aesthetics. Among influences outside philosophy itself, it shows a particular awareness of psychoanalysis and of the history and criticism of literature and painting. His philosophical style is distinctive, a sensitive blend of the argumentative and the exploratory, which can be seen as the product of two contrasting influences: a sympathy with the outlook of Friedrich Waismann (himself influenced by Ludwig Wittgenstein) that there can be no proofs in philosophy, together with a respect

for the aim of J. L. Austin and other recent philosophers to reach definite results by definite methods.

Hampshire showed a constant interest in the connections between meaning and confirmation. To this extent, there are links between his concerns and those of logical positivism, and a relatively early paper, "Logical Form," shows a recognizably positivist spirit in explaining differences of form in terms of differences in methods of confirmation. However, Hampshire's views were never positivist. In particular, he was not so much concerned to assign a privileged possibility of certainty to some special class of statements but rather to explore the various certainty conditions of different classes of statement.

The connections between meaning and certainty conditions have been particularly explored with reference to psychological statements. Hampshire rejected the possibility of Cartesian statements of immediate experience, independent of any bodily conditions. He emphasized both the need of communication with other persons for self-knowledge ("The Analogy of Feeling") and the dependence of the subject's sense of his identity on his being a physical agent in a physical environment. This idea is treated in detail in *Thought and Action*, where some influence of Jean-Paul Sartre and of Maurice Merleau-Ponty can be seen. While stressing the connections between mental concepts and physical agency, Hampshire sought at the same time to give an intelligible place to introspection and to the possibility of incorrigible declarations by a speaker of his own mental states, particularly in the case of intentions: Besides *Thought and Action*, see "Self-Knowledge and the Will" and the important article "On Referring and Intending." In line with this is his rejection of any thoroughgoing behaviorist analyses of psychological concepts (review of Gilbert Ryle's *Concept of Mind*) and his interesting account of the notion of a *disposition* as applied to human character ("Dispositions"), an account later elaborated in psychoanalytical terms (in "Disposition and Memory"). Human dispositions must be distinguished logically from merely "dispositional properties," such as are possessed by material objects: Dispositional properties can exist without having been manifested, but ascription of human dispositions implies some actual manifestations of them in the life of the individual. Moreover, the understanding of a human disposition is of a different character, being basically historical or genetical. Psychoanalysis is taken to reveal a basic way of understanding the individual's disposition, as rooted in his early experiences and consisting in the generalization to a class of situations of primitive responses; the influence of the primitive situations is to be seen in terms of unconscious memory. These ideas provide a link between the concept of a disposition and those of rationality and freedom; control over one's dispositions may be increased by self-knowledge, the understanding of how they have come about.

The emphasis on the psychoanalytical type of account of dispositions—that is, a genetical account—is a particular application of the wider view that human activities must be understood historically. This view has had an important influence on Hampshire's outlook on ethics, which rests on two points—that any comprehensible system of ethics must be grounded in a view of human nature and that all views of human nature are historically conditioned and essentially revisable. However, the historical changes in views of human nature or "the powers of the mind" are comprehensible only against a background of something identified, under any view, as essential to human nature, and this Hampshire finds in the possibility of self-conscious intentional action. From this point of view, Hampshire seeks to illuminate two basic (and, he would hold, permanent) distinctions: that between art and other human activities and that between human actions and mere events. Art is connected with the absence of an intentional project (see "Logic and Appreciation"); the appreciation of art is a process of free exploration. The distinction between actions and mere events involves his theory of freedom, which turns on a basic distinction between decision and prediction, and on the claim that there is an ineliminable human power of "standing back" from any prediction of one's future actions, the situation thus being changed (see *Thought and Action* and "Decision, Intention and Certainty"). Whether this has the consequence that determinism is impossible is perhaps not entirely clear; it is notable that Hampshire treated these questions in an illuminating book on Benedict de Spinoza, and his sympathy for a Spinozist connection of freedom and knowledge, rather than a supposed freedom of the will, certainly continued (see "Spinoza and the Idea of Freedom").

HANAFI, HASSAN
(1935–)

Born in Cairo, Hanafi studied first in Egypt but obtained his PhD in Paris (1966), working with Robert Brunschvig on a thesis entitled *Les méthodes de l'exégèse: Essai sur les fondements de la compréhension, 'Ilm usūl al-fiqh*. Hanafi has been a professor of philosophy in Cairo University since 1967 and has written many substantial works, three of which are particularly significant. He produced a study in five volumes on political theory, *From Dogma to Revolution* (in Arabic, 1985), an eight volume inquiry (in Arabic) on the links between religion and revolution in Egypt that focuses also on contemporary Islamic trends (*Religion and Revolution in Egypt*, 1989). The perspective of the foundation of an "Islamic left" leading through religion to a reconstruction of politics is outlined in the book and represents the main political approach of the author. The collected papers of *Islam in the Modern World* (1996) (two volumes) cover a wide range of topics from philosophy and theology to sociology and politics.

Hanafi's philosophical method is grounded in phenomenology and hermeneutics and he is particularly effective in applying this method to Islam. Consciousness and history acquire great importance accordingly. Islam is not merely a religion, according to him, but above all an ideology that connects the temporal and the sacred. Thus the outward (social and practical) and the inner (related to conscience) dimensions of human reality are but two aspects of the same phenomenon. Theology must become anthropology in order to allow humanity to make faith the tool of transformation of economic and social relations. The translation of theology into anthropology needs firstly the Husserlian *epoché* on God's essence; and secondly a new orientation of the object of theology. The center of revelation as the science of God is no longer God but humanity. Revelation is the science of humanity because humans are its objects and interlocutors. In this transformation of theology into anthropology, God keeps his value as telos, the goal of human activity in front of which all are equal. God is not logos, but praxis; not an idea, but a form of practice. Consequently, in Hanafi's view, Islam is a religion of revolution and justice prompting everybody to refuse any subordination to oppressive power and to claim the liberation of the world and its people in the name of God.

Hanafi criticizes Orientalism as a science aimed at colonial submission. He believes that the Third World's peoples have to develop a science of Occidentalism in order to get a fresh cultural, political, and philosophical

stance. Then they will be able to join Europe and North America in its modernity and recover their role in universal history (these ideas are discussed in Hanafi's *Introduction to the Science of Occidentalism*, in Arabic, 1991). From the perspective of intellectual recovery, Hanafi believes a new interpretation of Islamic heritage (turāth) is vitally important, because the reconstruction of a historical consciousness—namely tradition—is the direct path to development. Among the applications of this new reading are an inquiry into the traditional science of *hadith* (the traditional sayings of the Prophet) which Hanafi acknowledges has a historical character, and into Qur'anic exegesis that is envisaged to require an interpretation linked not only to explanation, but also to understanding, and not only to knowledge, but also to awareness.

Massimo Campanini (2005)

HAN FEI
(c. 280?–233 BCE)

Han Fei, the outstanding authority of the Legalist school of Chinese philosophy during the Warring States Period (403–221 BCE), lived some two centuries or more later than Confucius, Laozi, and Mozi. His works consist of fifty-five treatises. He was an aristocrat of the state of Han, in the northwest, where a movement of political reform had arisen. In the rest of the Chinese kingdom, Confucianism, Mohism, and Daoism still maintained the theory of government by customary morality, religious sanctions, and personal virtuous example or even "inaction" (or "nonaction") by the ruler. Since the traditional feudal system had collapsed generally throughout China, new thinkers spoke of government by positive law, exaltation of the state at the expense of the individual, and possession of supreme power by the ruler. Out of these thoughts of his predecessors, Han Fei made a comprehensive synthesis and formed his unique doctrine of legalism. This doctrine was greatly admired by the ruler of the state of Qin, who by its adoption eventually became the first emperor of the unified Qin Empire. Han Fei had been invited to the court of Qin, but he was forced to commit suicide by Li Si, chief minister of Qin and former associate of Han Fei. Although they had studied together under Xunzi, the exponent of a reformed Confucianism, political jealousy overcame Li Si.

Han Fei accepted only one point of Xunzi's philosophy, that human nature is originally evil. He then insisted that all men act from selfish motives and that a system of rewards and punishments can provide an effective control for the government, for there is no one who does not fear punishment and welcome rewards. The ruler can then rule the state through a set of severe laws without his own interference. In economics, too, the government should adopt a laissez-faire policy, leaving people alone to carry on free competition; this will cause them to be more active and frugal, with the result that production will increase. Thus, Han Fei reinterpreted the inaction principle of Laozi in such a way that the sovereign, like the helmsman of a great ship, simply makes slight movements with the "two handles" of reward and punishment, and the whole state follows his desires and dictates.

While "statecraft" serves to keep the sovereign in power, laws are to be obeyed by the people. Han Fei said: "The intelligent ruler sees to it that his subjects do not allow their minds to wander beyond the scope of law; nor perform acts of favoritism within it" (*Works,* Treatise II). He also observed: "In the state of the intelligent ruler there is no literature of books and records, but the laws serve as teachings. There are no sayings of the early kings, but the officials act as teachers." Once laws have been established everyone should obey them; no heterodox doctrines of private individuals and traditional authorities should prevail. This led the first emperor to practice totalitarian regimentation, "burning the books and burying the literati" (*Works,* Treatise XIX).

It was Han Fei who supplied a rational explanation for revolutionary changes from the old order. He

asserted: "Affairs go according to their time and preparations are made in accordance with affairs.… The sage does not aim at practising antiquity and does not model himself upon what is considered to be permanently correct" (ibid.). Indeed, history does not repeat itself. Politics, therefore, must look always to the present and to changing circumstances rather than to any static idea or ideal. In a word, Han Fei can be regarded as a radical positivist or perhaps as the extreme realist of ancient China.

HAN FEI TZU

See *Han Fei*

HAN YU
(768–824)

Han Yu lived in a time when the Chinese Tang empire (618–907) was threatened by military separatism but enjoyed cultural creativity and economic expansion. He became a major writer in his youth and had a successful official career late in his life. He was an innovative poet and essayist and the chief champion of the *guwen* movement that paved the way for a fundamental change of prose style. More unusual for a writer, Han played a leading role in a crucial philosophical redirection.

As a thinker, Han's most important idea was that Confucianism is the sole legitimate teaching for human conduct, to the exclusion of Buddhism and Daoism. This was an extreme position in his own time, but it exerted profound influence throughout later Chinese history. Han presented this view most forcefully in his famous essay "Essentials of the Moral Way" (*Yuan Dao*). This essay asserts that the only Dao is the one based on everyday life, which is the Confucian Way discovered and developed by ancient sage-kings. What are the teachings of these sages? Han declares:

> To love universally, which is called humanity; to apply this in the proper manner, which is called rightness; to act according to these, which is called the Way; to [follow the Way and] become self-sufficient without seeking anything outside, which is called virtue. The *Book of Poetry*, the *Book of History* … are their writings; rites and music, punishments and government, their methods. Their people were the four classes of scholar-officials, farmers, artisans, and merchants; their relationships were those of sovereign and subject, father and son, teacher and friend, guest and host, elder and younger brother, and husband and wife. Their clothing was hemp and silk; their dwellings halls and houses; their food grain and rice, fruit and vegetables, fish and meat (de Bary, et al. 1960, pp. 378–379 with minor changes).

A key point here is the all-embracing and this-worldly nature of the Confucian Way. Han made his point by going so far as to include people's clothing and food as part of the Way.

In his treatise, Han not only rejects all teachings that attempt to find the meaning of life outside or beyond the social order prescribed by Confucian sages, but also asserts that Confucianism values spiritual life as well. However, the Confucian mode of self-cultivation is intrinsically linked to mundane life; spiritual purification should be a basis for bettering, not transcending, the world. In another essay, Han gives his picture of Confucian spirituality. It is essentially a reconfiguration of ideas prevalent mainly during the Han era (206 BCE–220 CE), and failed to win the approval of the later thinkers taking up his program of Confucian renewal.

The chief target of Han's intellectual campaign was Buddhism—the dominant religion of medieval China—which because of its foreign origins conflicted with Confucian values in many fronts. Yet the true significance of his thought shows more clearly in his criticism of Dao-

ism. Han categorically disagreed with the anticivilization attitudes in the *Laozi* and the *Zhuangzi*. He held that in constructing what is now called the Confucian order, ancient sage-kings saved humankind from a state of chaos and savagery; the Daoist calls for a return to the innocent primeval age, he believed, were absurd. Han also accused the religious Daoists, with their search for immortality and a secluded life, of deserting their inviolable duties as members of the human community. By taking an almost unique position against Buddhism, religious Daoism, and philosophical Daoism simultaneously, Han was assailing a view predominant in China since the early third century CE, that Daoism and Buddhism brought to light questions concerning the fundamental essence of the world and the spirituality of individuals whereas Confucianism had practical uses in building a proper sociopolitical order. Han put forward a new vision: that a proper human society can only be built upon Confucian principles in toto.

Han wrote only a few formal essays on philosophical issues, but often expressed his views in other genres and in highly literary manners. He was an original thinker who had effective weapons with which to send his message. Han challenged a fundamental intellectual premise of medieval China, and opened the way for the eventual formation of "the Learning of Principle" (*lixue*)—or neo-Confucianism—in the eleventh century. If the word "pioneer" means anything in historical account, Han was a most significant pioneer.

HAPPINESS

As an object of philosophical inquiry, the concept of happiness is as old as philosophy itself. It was central to the ethical thought of the Greeks, most famously Aristotle, and was restored to this position of prominence by the nineteenth-century utilitarians. Whether a principal theme or not, the pursuit of happiness plays some role in virtually all ethical traditions. Indeed, few would deny that happiness is one of the important goals in life, if not the only one. Through the twentieth century and into the twenty-first, both philosophers and psychologists have continued to ask questions about happiness. These questions fall into two broad categories: (1) The nature of happiness—in what does it consist? (2) The value of happiness—what is its role in a theory of ethics or of the good life?

WHAT HAPPINESS IS

The terms *happy* and *happiness* are used in many different ways, and it is important to identify the precise concept that is of philosophical interest. We often speak about being happy with or about something, where this means roughly regarding it favorably or having a positive attitude toward it. The object of such an attitude can, in principle, be anything: a state of oneself or a state of the world. We also speak about feeling happy, where this is an occurrent state of mind characteristically accompanied by energy, vitality, and buoyancy of spirit. Both of these notions need to be distinguished from that of being happy or having a happy life. When philosophers investigate the nature or value of happiness, it is this concept of a happy life that they have in mind.

Accounts of the nature of happiness can be partitioned initially along a subjective–objective dimension. An analysis is subjective if it makes a person's happiness depend, at least in part, on attitudes or feelings. Conversely, it is objective if happiness is taken to be entirely independent of these subjective states so that someone could be happy even if neither feeling happy nor having a positive attitude toward the conditions of life.

The best-known example of an objective conception of happiness is Aristotle's. According to Aristotle, eudaimonia consists in the excellent functioning of the soul, thus the exercise of virtue. While Aristotle allowed, as does common sense, that a person's happiness could also be affected by external goods and circumstances, the stronger view that virtue is not only necessary for happiness but also sufficient was affirmed by the Stoics. Both views, however, have seemed counterintuitive to many. If virtue is necessary for happiness, how is it possible (as it seems to be) for vicious people to be happy? And if virtue is sufficient, then would we not be compelled to call the virtuous happy even if they are consumed by torment and suffering? The seemingly paradoxical implications of linking virtue and happiness in either of these ways has led some commentators on Aristotle to the conclusion

that what he means by eudaimonia is not adequately captured by our concept of happiness, so that the Greek term he uses should really be translated in some other way, possibly as *well-being*.

However this might be, when the utilitarians revived interest in happiness as an object of ethical inquiry, they assumed a subjective analysis of its nature. For Jeremy Bentham, John Stuart Mill, and Henry Sidgwick, happiness consisted in pleasure and the absence of pain or a surplus of pleasure over pain. The hedonism they espoused represents one of the main options for a subjective analysis of happiness. On the simplest version of it, a person's hedonic state at a particular time is determined by the balance of agreeable and disagreeable feelings at that time. Happiness is then a matter of the longer-term tendencies of these hedonic balances: The greater and more enduring the balance of positive over negative states, the happier the person. In recent years this reduction of happiness to positive and negative affect has been one prominent theme in the emerging field of hedonic or positive psychology. Indeed, a hedonistic or affective state analysis of happiness is now most commonly defended by psychologists such as Daniel Kahneman, though it still has its philosophical advocates as well.

However, many philosophers attracted to the project of a subjective analysis of happiness have found the hedonistic account unsatisfactory. For one thing, the usual sources of pleasure seem too short-term and episodic to tell the whole story of whether a person is happy. The idea that happiness over a lifetime, or a considerable stretch of a life, can be computed simply by adding up episodes of positive and negative affect and finding the balance neglects the role of more global factors, such as the pursuit and achievement of long-term goals or projects. Indeed, there is good empirical evidence that even very intense pleasures on particular occasions add relatively little to a person's overall happiness compared with more stable and enduring sources of fulfillment or satisfaction. Furthermore, there seems to be a cognitive or judgmental aspect to happiness that is not captured by this exclusive focus on occurrent feelings. It seems plausible to think that how happy a person is must have something to do with how well that person thinks life is going, either as a whole or in important sectors (such as work, family, and health). Developing this line of thought has led philosophers and psychologists to develop a conception of happiness as life-satisfaction. This conception is still subjective since it takes someone's happiness to be a matter of how the person thinks life is faring given that person's interests and values. But it makes happiness more a matter of judgment than of feeling. Among psychologists Ed Diener has been the principal exponent of this life-satisfaction view.

So there are two principal subjective analyses of happiness: in terms of affective states or life-satisfaction. Each seems to capture a dimension of the phenomenon that eludes the other. On the one hand we would be reluctant to call anyone happy whose dominant state of mind tended toward the gloomy, dejected, or depressed. Here the affective state account seems to yield the intuitively right result. On the other hand we would be similarly reluctant if the subject were to report that in every important sector, life was failing to measure up to aspirations and expectations for it. This time the life-satisfaction account seems to be on the right track. Perhaps, then, the best theory of the nature of happiness will be a hybrid that takes both dimensions into account, looking for a preponderance of positive affect over time together with an endorsement of the conditions of one's life. Such a theory will not yield a determinate result if these dimensions can come apart, as seems both logically and psychologically possible. But in that case the right response might be to question whether our common notion of happiness is internally unified or whether it looks to both of these factors. If the latter is the case, then the hybrid theory might just be the best fit for it.

WHY HAPPINESS MATTERS: WELL-BEING

Whether construed objectively or subjectively, happiness has been thought to be normatively important either as a part of the good life or as an ethically valuable goal. When inquiring into the role of happiness in the good life, we must be mindful of the multiple ambiguities of this latter notion. A good life is a life high in some particular type of value, but there are many such types (such as aesthetic, perfectionist, and ethical). The dimension of value to which happiness seems most relevant is prudential: the value of a life for the person who is living it. But *prudential value* is a piece of technical philosophical terminology; its ordinary language equivalent is well-being.

Is happiness equivalent to well-being, thus to a good life, in this particular sense? There is some reason to think so. After all, we commonly wish people happiness at critical junctures in their lives, such as birthdays and anniversaries, seeming to imply that this is the best, most optimistic, hope we can have for them. Furthermore, there is much plausibility in the idea that any other of our life's conditions—health, income, job, family—is of little or no value if it does not make us happy. Perhaps then, as

Mill claimed, "happiness is desirable, and the only thing desirable, as an end; all other things being only desirable as a means to that end" (Mill 1969, p. 234).

But there is also reason to doubt the equation of happiness and well-being, especially if we assume a subjective conception of happiness. For one thing, since on either version of a subjective analysis happiness is a state of mind, it can in principle be synthesized in the manner made famous by Robert Nozick's science-fiction example of the experience machine. But we would be reluctant to think that the good life for a person could consist in a thorough-going illusion completely divorced from reality. In addition, people's subjective responses to their lives are notoriously subject to manipulation through such mechanisms as oppression and socialization. As a result, people's self-assessments of happiness will be dependent on their expectations for themselves, which may be artificially lowered through internalized conceptions of their social role or status. In order to correct for these distortions, some philosophers have suggested that self-assessed happiness is a reliable indicator of well-being only under conditions of information and autonomy. Others have taken the further step of suggesting that real or genuine happiness consists in the subject's endorsement of the right kinds of objects or states of affairs—those with independent value. Taking this route will lead to a hybrid subjective/objective theory, not of happiness (which is still interpreted subjectively), but of well-being.

WHY HAPPINESS MATTERS: ETHICS

As noted at the outset, happiness has been a central theme in ethical theories, both ancient and modern. The most natural route to treating happiness as an intrinsic ethical good is through its role in well-being. The argument would then be something like this: Well-being matters in its own right, happiness is at least an essential ingredient in well-being, therefore happiness matters in its own right. Some such argument, in one form or another, seems to have influenced both the Greeks and the utilitarians. However, it is also possible in principle (though perhaps less plausible) to hold that happiness is intrinsically valuable just in its own right, independently of its connection to well-being.

Where well-being is concerned, there is an easy answer to the question *whose* happiness matters: my happiness is central to my well-being, yours to yours, and so on. But the question takes on a more acute importance when we turn to ethics. For the Greeks, and for some contemporary versions of virtue ethics, the primary focus is on showing the agent how to live a good—that is to say,

happy—life. The link to the happiness of others is then through the account of the virtues necessary for the agent's own happiness. This argumentative route, needless to say, is plausible only if we presuppose an objective conception of happiness.

For the utilitarians, by contrast, everyone's happiness is equally valuable: As Mill put it, citing Bentham, "everybody to count for one, nobody for more than one" (Mill 1969, p. 257). Another way of stating this contrast is that for the virtue theorists, happiness provides an agent-relative goal: Everyone has an ultimate reason to pursue their own happiness. For the utilitarians happiness provides an agent-neutral goal: Everyone has an ultimate reason to promote happiness, regardless of whose it is. In this respect Kant's deontological theory occupied the middle ground: We have no duty to pursue our own happiness (since Kant thought that we inevitably did that anyway), but we do have a duty to promote the happiness of others.

HARDING, SANDRA
(1935–)

Sandra Harding is an American philosopher of science whose research interests include feminist and postcolonial theories, epistemology, and science studies. She received her PhD from New York University in 1973 and is a professor in the Graduate School of Education and Information Studies at UCLA. She is a former coeditor of *Signs: Journal of Women in Culture and Society* and former director of the UCLA Center for the Study of Women. Harding has authored four books and numerous articles and edited eight anthologies. She is best known for her work in developing feminist-standpoint theory. Initially focused on illuminating the gendered contexts of science, Harding has gone on to investigate other aspects of the social and cultural contexts of science, including its "racial" and colonialist contexts. Seeking to explore ways in which science can become a more significant force for human well-being, her work has analyzed various social and political contexts of science, including its implication in the exploitation of nature, non-Western cultures, and women.

Harding's work in the 1980s helped shape the landscape of developing feminist epistemology and feminist science. *Discovering Reality*, coedited with Merrill Hintikka (1983), and Harding's *The Science Question in Feminism* (1986) were groundbreaking efforts applying gender to epistemology and the philosophy of science. In *The Science Question*, Harding analyzes then-current feminist epistemologies and their ability to justify feminist science critiques. Although she urges ambivalence toward the frameworks, she suggests that feminist-standpoint theory is the most promising. Standpoint theory traces its roots to Hegel's argument, later developed in Marxist theory, that divisions in power yield corresponding divisions in worldviews: those in dominant positions have a distorted worldview that suggests their privilege is "natural," and those subordinated have the potential to achieve a less distorted view of the relevant social relations. Early feminist-standpoint theory proposed that men and women are, respectively, disadvantaged and potentially advantaged in this sense and stressed the role of the women's movement in helping women achieve a less distorted, feminist standpoint.

In *The Science Question* Harding identifies several problems in then-current versions of feminist-standpoint theory. One is that the theory assumes that there are experiences that are unique to women *qua* women, but Harding argues that is unlikely given differences in race, class, sexuality, and culture, among other factors. Another problem she notes is that there are as many standpoints as there are substantial divisions in power, unbridgeable chasms between the worldviews of those in dominant positions and those subordinated in a social hierarchy.

In *Whose Science? Whose Knowledge? Thinking from Women's Lives* (1991), Harding argues that those politically advantaged can and should come to understand the lives and perspectives of those not. This broadening of the notion of a standpoint has several consequences. It allows Harding to argue not that women as a group have an epistemic advantage over scientists but that, if scientists were to begin to research from the perspective of *women's* lives, new questions would emerge, along with data and theories that would prove more fruitful scientifically and socially. Harding also embraces the implication of multiple standpoints and contends that these are not unbridgeable. Each of us can work to "reinvent ourselves as 'others'" both to understand other standpoints and better understand the partiality and specificity of our own perspectives.

These several lines of argument come together in Harding's account of objectivity. In contrast to a traditional emphasis on a scientist or scholar's detachment from social contexts, Harding advocates what she calls "strong objectivity." To be objective in this sense requires a "robust reflexivity" that would oblige scientists and philosophers of science seek an understanding of the parochialism of the contexts within which their science and culture have coevolved. In *Is Science Multicultural? Postcolonialisms, Feminisms, and Epistemologies* (1998), Harding maintains that such reflexivity requires literacy in the sociology of science and social histories of science literatures, postcolonial and feminist science studies, and other critical science literatures. Only when scientists and science studies scholars achieve such reflexivity, Harding argues, will it be possible for the sciences to change in ways that will enable them to become an unproblematic and significant force for human well-being.

HARE, RICHARD M.
(1919–2002)

Richard M. Hare, the White's Professor of Moral Philosophy at Oxford University from 1966 to 1983, is famous as the inventor of universal prescriptivism. This is a metaethical doctrine, a thesis about what moral words mean. But Hare uses his metaethic to generate an ethic. Anyone who employs the moral concepts consistently in full awareness of the facts must wind up a utilitarian. Hare claims that his utilitarianism is the product of conceptual analysis rather than of moral intuition. To rely on intuitions is a philosophical sin, since it leads to relativism (Hare 1981). His theory is developed in three books, *The Language of Morals* (1952), *Freedom and Reason* (1963), and *Moral Thinking* (1981).

Prescriptivism is a variant of noncognitivism. Moral judgments are action guiding, and the explanation of this is that they are prescriptive: They are not primarily designed to state facts but to prescribe actions. They are more akin to orders than statements or propositions. Nevertheless, moral judgments do have descriptive content, though this will depend upon the moral opinions of the speaker (Hare 1963). Thus, if Captain Bligh says that Burkitt is a scoundrel, we can assume he is disobedient. Indeed, even words such as ought have descriptive content, though this too will vary with the moral opinions of the speaker. Typically, the descriptive content of an ought judgment will consist in the factual considerations—the reasons—that can be advanced in its support. Thus, if Bligh asserts that Burkitt ought to be flogged, this will be because it would be an act of punishing disobedience. That the flogging would be such an act is the descriptive content of "Burkitt ought to be flogged." (Whence it follows that, if Burkitt has not been disobedient, the ought judgment will be factually false.) In Hare's view moral judgments are universalizable. Thus, if Bligh thinks that Burkitt ought to be flogged, he is committed to the view that anyone in relevantly similar circumstances—anyone who has been similarly disobedient to a king's officer—ought to be flogged likewise. He must assent to the imperative "Let me be flogged in the hypothetical case in which I am in Burkitt's position!"—which includes having committed Burkitt's heinous acts of disobedience (Hare 1963). Finally, moral judgments are overriding. They take precedence over any other imperatives the subject may accept. Thus, if Bligh thinks himself morally obliged to have Burkitt flogged, this takes precedence over his aesthetic obligation not to sully the pure air of the Pacific with Burkitt's distasteful groans. Sincere moral commitment entails action. Weakness of the will as traditionally conceived is not a genuine possibility. Thus, Hare reinstates the Socratic paradox that we cannot willingly do wrong (Hare 1952, 1963).

What about utilitarianism? Hare first points out that the metaethic generates a method for refuting moral "conjectures." Bligh considers the maxim "I ought to have Burkitt flogged." He universalizes this to derive the principle that anyone in relevantly similar circumstances ought to be flogged likewise. This in turn entails the imperative "Let me be flogged if I am in Burkitt's position!" But Bligh cannot assent to this unless he is a fanatic—someone who prefers flogging the disobedient to remaining unflogged himself. Thus, Bligh must rescind his original "ought" (Hare 1963). But this is only a method for vetoing moral maxims and a method, moreover, that leads to moral paralysis. As Hare himself points out, a guilty prisoner could challenge the judge to universalize the maxim that the accused ought to be put away and derive the imperative "Let me be imprisoned if I am

in the accused shoes!"—an imperative she could accept only if she had a fanatical preference for imprisoning the guilty rather than staying out of jail herself (Hare 1963). Nonfanatical judges would have to give up sentencing and justice would founder! But Hare offers a utilitarian solution. The correct course is to go the rounds of the affected parties and opt for the action that is subject to the weakest veto[es]. Thus, the judge must take into account the likely depredations of the prisoner and ask herself whether she can accept such imperatives as "Let me be robbed if the prisoner is released and allowed to carry on with his course of crime and I am one of his victims!" If not, and if the vetoes of the prisoner's potential victims outweigh his preference not to go to jail, then to jail he must go. The criminal-justice system can survive without fanaticism, and Hare's method becomes utilitarian. But does Hare derive utilitarianism from his conceptual analysis or assume utilitarianism to rescue that analysis from disaster (Roxbee Cox 1986)?

The fanatic remains a problem. She can consistently subscribe to a persecuting principle if she assents to the imperatives in which she is on the sharp end. In *Moral Thinking* Hare deprives her of this possibility. He claims it is a conceptual truth that if I fully represent to myself what an unpleasant experience is like for someone—an experience that they would prefer to stop—I now acquire an equally strong preference not to have that experience were I in their shoes. Hence, a fanatic who fully represents to herself the sufferings of her potential victims cannot assent to the imperative that she should suffer were she in their position. For she has a preference as strong as theirs that she should not. If, however, Hare's conceptual truth is neither conceptual nor a truth, then fanaticism remains an option (Seanor and Fotion 1991).

Charles R. Pigden (1996)

HARMAN, GILBERT
(1938–)

Gilbert Harman was born in 1938, graduated from Swarthmore College in 1960, and received his PhD from Harvard in 1963, where W. V. Quine was his dissertation advisor. He is distinctive in being a leading contributor across a broad range of subdisciplines of philosophy: epistemology, ethics, philosophy of language, philosophy of mind, and metaphysics. This entry reviews only a few of his many important contributions.

Harman has been perhaps the most significant contemporary defender of moral relativism. According to Harman, moral right and wrong are akin to motion: They are *relative* to a framework and no framework is privileged. Harman appeals effectively to two sorts of consideration in developing his position. First, like J. L. Mackie, he is impressed by the degree of moral diversity across and even within populations. Second, complementarily, Harman defends moral naturalism—the view, roughly, that morality is fundamentally continuous with the natural sciences.

In rejecting moral nonnaturalism, Harman claims that the postulation of nonnatural moral properties is unjustified: They would be explanatorily impotent. Could not a sui generis fact of, say, torture's being bad explain, at least, our belief that torture is bad? Harman argues that there are other better ways of explaining such a belief, in terms of conventions and other social arrange-

ments—arrangements to which we are normally exposed as we develop.

Holding that moral disagreement is widespread, Harman accordingly argues—as a kind of inference to the best explanation—to the conclusion that there are no absolute moral facts, beyond the facts about what holds relative to one or another framework. Different people can, without ignorance (or related independently specifiable failings), find one or another ultimate moral demand inapplicable in their own case. But because a moral demand is said to apply only if the agent either accepts it or rejects it only out of ignorance, then ultimate moral demands may apply only selectively, to some agents and not to others.

A related aspect of Harman's moral relativism is thus his motivational internalism: If morality is understood as the product of a framework constituted by psychological states (and, in particular, by the agreement, plans, and conventions emerging therefrom), then it will be easier to understand how morality could have that motivational force.

It should be noted, too, that, although he distinguishes them, Harman embraces forms of each of *normative moral relativism*, *moral judgment relativism*, and *metaethical relativism*. Normative moral relativism holds, roughly, that people can be subject to different ultimate moral demands. Moral judgment relativism claims, in effect, that moral judgments implicitly refer to a person, group, or set of moral demands. And according to metaethical relativism, conflicting moral judgments about a particular case can in a way both be right.

In epistemology, Harman has long defended a view that has elements of foundationalism and elements of coherentism. Harman's is a kind of "foundations" theory in which everything a person accepts at a given time is foundational and needs no justification except when there are conflicts. Accordingly, knowledge is best understood "when skepticism is turned on its head": starting from what we know, we diagnose what goes wrong with arguments for radical skepticism. For Harman, a key insight is that knowledge is essentially inferential: Inference is a matter of increasing the coherence of one's overall state—reasoning consists in trying to obtain a reflective equilibrium (though he is concerned about possible instabilities in this process)—and coherence is partly a matter of explanation.

If inference to the best explanation is to have the central role in our cognition that it appears to have, it will have to be understood as a sort of explanatory inference.

So Harman defends the adequacy of that sort of inference. In enumerative induction we generalize observed regularities; but according to Harman all such cases of induction are really cases of inference to the best explanation. So, at a minimum, inference to the best explanation is not in general any less legitimate than induction.

This emphasis on the role of inference in knowledge is related to Harman's focus on inference in its own right. He draws a sharp division between logic and inference. For Harman, there is, for example, no such thing as deductive inference and the search for an inductive logic is the product of confusion. Reasoning is change in view; logic is the theory of implication.

Consider *modus ponens*. This exceptionless rule of logic cannot serve as a principle about how to change one's view: sometimes, when one believes *P* and believes that *if P, then Q*, what one should do is to give up one's belief that *P*. Moreover, although according to the rules of logic inconsistent premises *imply* any proposition, it's not the case that inconsistent beliefs permit one to *infer* any proposition. The distinction between inference and logic coheres well with Harman's views about the fundamentally *explanatory* character of inference to the best explanation (see above).

In philosophy of mind, Harman was a seminal proponent of what has come to be known as intentionalism about experiential states. Harman holds that there is no phenomenal difference between such states without an intentional difference. They have accordingly come to be viewed as individuated by their representational or intentional character: what makes the state what it is is that it is about what it is about. That perceptual experience should not be understood as individuated by (what others would call) its *qualitative* character instead is seen as sustained by the *transparency* of experience. Introspection does not seem to reveal the nature of experiences themselves, only that of their external objects.

This brief review cannot do justice to the richness and range of Harman's work. We have not so much as touched on his important discussions of meaning and analyticity (and his brilliant exposition—really, development—of Quine's views on the subject), on his contributions to conceptual-role functionalism in philosophy of mind, or on his more recent argument that work in social psychology supports eliminativism about the central posits of any virtue theory. Still, some sense of the scope and significance of Harman's contributions should have emerged.

HARNACK, CARL GUSTAV ADOLF VON

(1851–1930)

Carl Gustav Adolf von Harnack, the German church historian and theologian, was born at Dorpat (now Tartu) in Estonia, where his father, Theodosius Harnack, was a professor of practical theology at the German-dominated university. Carl Harnack studied at Dorpat and then at Leipzig, becoming a *Privatdozent* there in 1876. He held chairs at Giessen from 1879 and Marburg from 1886 before going, in 1888, to Berlin, where he was a professor until his retirement, in 1924. He died at Heidelberg.

Harnack has come to be regarded as the typical representative of liberal theology. Following Albrecht Ritschl and the members of his school, Harnack stressed the ethical teaching of Christianity and avoided the more speculative flights of theology, but he went further than his predecessors in the direction of an undogmatic, practical statement of the Christian faith. Harnack's appointment to the chair at Berlin was opposed by conservative elements in the Lutheran Church, but by the time he retired he had trained a whole generation of students in the ways of liberal theology and in what he believed to be the unprejudiced pursuit of theological truth. His last years were spent in opposing the nascent "dialectical theology" of the school of Karl Barth, which he saw as threatening the scientific character of the discipline.

THE PROBLEM OF DOGMA

The vigor with which Harnack advocated the cause of liberal theology was matched by his vast erudition. Few Protestant scholars have equaled his knowledge of early Christian history and literature. One of Harnack's major works, the monumental *Lehrbuch der Dogmengeschichte* (3 vols., Freiburg, 1886–1889; many subsequent eds. published at Tübingen; 3rd ed. translated as *History of Dogma,* 7 vols., London, 1894–1899), not only gives a detailed account of the history of Christian dogma, especially in the early formative centuries, but also expounds a definite thesis concerning the nature and development of this dogma.

As Harnack understood it, religion is primarily a practical affair and aims at the right ordering of life. In Christianity, the power of achieving a well-ordered or blessed life had its origin in Jesus Christ and the revelation of God that he brought. But although religion has this practical character, it also implies certain beliefs concerning God, man, and the world; the religious man seeks to make his beliefs explicit and to formulate them in propositions. This happens especially when a religious community comes into being and subscription to the basic beliefs of the community is made the condition of membership—hence the rise of dogma in the early church.

However, Harnack regarded this development as a perversion of the original teaching of Jesus, obscuring its essentially practical character and destroying its spontaneity. On the whole, he saw the history of Christian thought as one of deterioration, a falling away from the original truth rather than an unfolding of it. The process began when the primitive preachers made Jesus himself, as the supernatural Christ, the center of their message, rather than simply repeating Jesus' teaching about the kingdom of God, which Harnack understood as an ethical ideal. The transformation of Christianity into dogma accelerated in the Hellenistic world; the extreme case can be seen in the Gnostic sects, where the supposedly original gospel of Jesus was altogether absorbed into Hellenistic philosophy. With the Reformation an attempt was made to emancipate Christianity from dogma, but it was only partially successful, and dogma persisted into Protestantism.

THE ESSENTIALS OF CHRISTIANITY

In a series of popular lectures, which attracted huge audiences at the university of Berlin in the winter of 1899/1900 and was subsequently published as *Das Wesen des Christentums* (Leipzig, 1900; translated as *What Is Christianity?*, London, 1901), Harnack expounded what he believed to be the core of the Christian religion, set free from the encrustations of dogma that had been laid down through the centuries. The core is to be reached by penetrating back to the teaching of Jesus himself, and Harnack represented this teaching as proclaiming the fatherhood of God, the infinite worth of the human soul, and the ethical ideal of the kingdom of God. The supposedly original gospel of Jesus is also claimed to be the only version of Christianity that can make sense for modern minds, since it is free from theological and metaphysical mystifications.

Harnack's views once commanded a wide following, but this, however, has declined sharply in more recent times, owing to the criticism of such scholars as Alfred Loisy, Albert Schweitzer, and Karl Barth.

HARRINGTON, JAMES
(1611–1677)

The English political philosopher and publicist James Harrington was the eldest son of Sir Sapcote Harrington, of Rand, Lincolnshire. As such, he belonged to a junior branch of a family that had been prominent from the days of Richard I. An erudite man, Harrington must have acquired his great knowledge of languages, literature, and history largely independently, since he spent only two or three years at Oxford and in the Middle Temple and took no degree. During the 1630s he traveled extensively on the Continent and served in an English volunteer regiment in the forces of one of the palatine electors. From these experiences, and especially from a visit to Venice, he gathered much of the data that later formed the raw material for his political theory.

When civil war broke out in England, Harrington took a neutral position, despite his republican sympathies, because of his personal regard for the king, and at one point attempted the role of mediator between royal and parliamentary interests. But after Charles I's execution in 1649 he devoted himself to the construction of a republican political theory, which culminated in 1656 in the publication of his major work, *The Commonwealth of Oceana,* a blueprint for a perfect republic.

He was imprisoned by Charles II in 1661 on a false charge of treason. His mind became deranged while he was in prison, and he never fully recovered his faculties

after his release. He died at his Westminster home in 1677.

Although *Oceana* has the form of a utopia, Harrington stands squarely in the British empiricist tradition. Even Niccolò Machiavelli, whom he admired as "the only Polititian of later Ages," he criticized for violating the canons of empiricism by using such concepts as "virtue" and "corruption," which Harrington held to be meaningless as analytical tools.

Harrington's own concepts are sociological, rather than psychological or ethical. A stable governmental system always represents the dominant property-owning groups of a society. Where political and economic power are held by the same hands, and a single person controls three-fourths of all the property, the political system will be an absolute monarchy. If a few hold three-fourths of the property, it will be a mixed monarchy. If property is so dispersed that no monopoly vests in a single social interest, the system will be a republic, or "commonwealth."

Harrington made no moral ranking of the forms of government. Words such as *tyranny, oligarchy, anarchy* he used descriptively rather than evaluatively, to signify unstable governmental forms that do not match their foundations, those in which power is held incommensurately to the distribution of property. The theoretical question that preoccupied him was stability, and the chief cause of revolution and civil war he identified as an incongruence between social balance and form of government. Conflict he viewed as a mechanism for bringing the two into close proportion. He was not an economic determinist, however, for he thought it just as possible to "frame the foundation unto the Government" as the reverse.

Like Machiavelli, Harrington preferred the republican system to all others. He wrote of "that *Reason* which is the interest of mankind, or of the whole," as "a Law of Nature," and described "the publick interest of a commonwealth" as "nearest that of mankind." Since he espoused a radically hedonic view of human motivation, this must mean he preferred republics because in them the things men enjoy are more widely distributed than in systems with a narrower property base. Not absolute equality but a middle-class order is implied, however. For "leveling" impedes economic growth and the social accumulation of the riches humankind desire.

More sanguine than Machiavelli, Harrington thought it possible to create a perfectly stable and unchanging republic. It could be maintained by an "equal Agrarian" law, fixing forever a middle-class distribution of property, and by arranging a suitable balance of interests in the organization of the government through such devices as separation of powers, division of the legislature, and rotation in office.

HARRIS, WILLIAM TORREY
(1835–1909)

The American philosopher and educator William Torrey Harris was born in North Killingly (now part of Putnam), Connecticut. He attended preparatory schools in his native state and entered Yale College. There he was led to philosophy by Bronson Alcott's "Conversations" on Platonism, which convinced him of "the ideality of the material world" through "insight and reliance on reason." He left Yale in his junior year, dissatisfied with the deficiency of modern science and literature in the curriculum, and went to St. Louis.

In St. Louis, where Harris taught school for eight years and was an administrator for fourteen, he met Henry C. Brokmeyer, a Prussian immigrant who had acquired an enthusiasm for G. W. F. Hegel from reading F.

H. Hedge's *Prose Writers of Germany* (1847) during some disputatious months at Brown University. In 1858, Harris, Brokmeyer, and a few friends began meeting informally as a Kant Club to find the root of Hegel's thought. Harris imported a copy of Hegel's larger *Logic* and encouraged Brokmeyer to undertake a translation, which was never satisfactorily finished but was circulated in manuscript. After the Civil War, adherents of the Kant Club joined the St. Louis Philosophical Society, organized in 1866 with Brokmeyer as president, Harris as secretary, and Denton Snider, G. H. Howison, A. E. Kroeger, and Thomas Davidson among the leading members.

When the editor of the *North American Review* rejected one of Harris's articles as "the mere dry husk of Hegelianism," Harris and the St. Louis Society founded the *Journal of Speculative Philosophy.* Edited by Harris from 1867 to 1893, the *Journal* published numerous translations of German philosophers, particularly Hegel, and original essays by Ralph Waldo Emerson, J. H. Stirling, James Ward, William James, John Dewey, and C. S. Peirce. In defending Hegel's views in America, Harris and Brokmeyer had been preceded by a group of Ohioans that included J. B. Stallo and August Willich, who became "auxiliaries" of the St. Louis Society, as did Emerson, Henry James Sr., Karl Rosenkranz, and Ludwig Feuerbach. But Harris was outstanding among American philosophers up to 1900 as an active public lecturer, a leader of the St. Louis movement and of the Concord School of Philosophy from 1879 to 1887, U.S. commissioner of education from 1889 to 1906, editor of America's first regular journal devoted to philosophy, and author of some five hundred articles and of a book on Hegel's *Phenomenology* and *Logic.*

Like Hegel, Harris saw philosophy as a science concerned with necessary factors in experience related systematically to a first principle. Reflection on sensible objects and their changes, he believed, immediately reveals two necessary factors with which philosophy is concerned, space and time. Both are "infinites" in that they are conditions of all experience. From a parallel analysis he concluded that there are three grades or stages of knowing. The first concentrates on the object and the surface of things as isolated and independent. The second sees how things exist only in relation to other things and thus concentrates on their dependence, on what they are not when taken by themselves as separate and isolated. The third "discovers the independence and self-relation underlying all dependence and relativity"; in discovering what is self-related it discovers "the infinite." These mutually related stages are to be found in every aspect of expe-

rience, and since there are no things-in-themselves behind experience, they characterize all aspects of our world. Harris thus attempted to put into plain English the main features of Hegel's dialectic. Through Brokmeyer, Harris came to believe that such dialectic illuminated the Civil War (legal right would be unified with moral right), American politics, and even problems of school administration—a use of philosophy that pleased the practical, institution-minded members of the St. Louis movement.

Proceeding dialectically from "seeming" to "truth," Harris analyzed causality and concluded that it incorporates space and time in a higher unity but also implies a "self-separation" of energy whereby a cause sends a stream of influence to other things. Without such self-separation a cause could not act upon something to bring about an effect. So conceived, causality must be grounded in "self-activity," which is necessarily self-related and thus independent, free, and creative. Ultimately, in Harris's view, the only authentic self-activity is God, conceived by Harris, following Aristotle and Hegel, as the unmoved motion and self-contained existence of Reason, which, as Reason, is also personal. Like Hegel, Harris believed that philosophy approaches Absolute Reason through conceptual analysis to first principles, whereas religion receives the Absolute "into the heart" through symbols.

As a corollary to the presupposition of relatedness in self-activity, Harris saw education as the self-development of the individual mediated through the salient traditions of civilization. With the self-development of the individual in view, he linked public schools with democracy, conceived of as self-government involving woman's suffrage and separation of religion from the state. With the traditions of civilization in mind, he criticized excessive vocationalism. Along similar lines, his social philosophy viewed civilized freedom as the will of the individual effectuated in such institutions as family, civil society, state, and the Invisible Church, the "absolute institution" uniting all people of all time. In spite of his stress on institutions, Harris apparently gave some kind of precedence to "self-activity" *simpliciter*; he admired the ruthless individualism of the "gilded age" and condemned socialism in all its aspects.

HART, HERBERT LIONEL ADOLPHUS
(1907–1992)

Herbert Lionel Adolphus, professor of jurisprudence at Oxford University (1952–1968), was the most important and influential philosopher of law of the twentieth century. Bringing to bear the linguistic approach to philosophy championed by Wittgenstein and Hart's Oxford colleague, J. L. Austin, Hart transformed jurisprudence into the vibrant discipline it had been at the time of Jeremy Bentham and his student, John Austin. He revealed the law to be a fertile ground for addressing age-old philosophical questions on a wide range of topics, for example, the analysis of causation, human action and intention, responsibility and rights, and the very nature of morality. Ronald Dworkin, who succeeded Hart in the Oxford Chair, nicely expressed this feature of his predecessor's work in a speech delivered at Hart's memorial service: "Herbert showed how philosophy can be tutor to law, how lawyers' questions about punishment and cause and definition have philosophical dimensions that it is irresponsible to ignore. He also showed how law can be tutor to philosophy, how legal problems, discriminations and attitudes can help philosophers in formulating and attacking those same ancient philosophical puzzles." (Hart, Jenifer, p. 213). Although Hart's writings cover a wide range of topics, his most memorable and influential contributions were in four main areas: causation, the the-ory of punishment, the moral limits of the law, and the concept of law.

CAUSATION

Causation in the Law (1959), written with A. M. Honore, is an impressive and original analysis of causation as it figures in Anglo-American legal systems. The authors proceed from the premise that then-extant philosophical analyses of cause and effect were largely inadequate because they focused on causation in science, where the concern is to establish causal laws and generalizations. Within the domain of law (and analogously morals), however, causation is more particularistic in nature, concerned with whether, for example, the defendant caused the death of the victim. Assessing such claims requires appeal to an array of different principles and individuating features, and attention to central or paradigm cases in which causal responsibility is confidently assessed. These factors are all in various complex ways connected with ordinary understandings of causation as these are reflected in our linguistic practices. It is here, perhaps more than anywhere else, that Hart's debt to J. L. Austin's "ordinary language philosophy" is in evidence. This is a method in which, as Hart later said in *The Concept of Law*, "We are using a sharpened awareness of words to sharpen our perception of the phenomena" (Austin 1956–1957, p. 8).

THEORY OF PUNISHMENT

Punishment and Responsibility (1968) is a collection of essays in which Hart develops a distinctive theory of punishment. The account was motivated by two factors. First, there is the potential for abuse seemingly inherent in utilitarian theories of punishment. In the right circumstances, they appear to sanction excessive punishment, as well as punishment of the innocent. Second, there was Hart's utter rejection of Kantian retributivist theories that view punishment as warranted independently of any good that might be brought about through its exercise. In a characteristic effort to seek compromise, Hart sought the middle ground between the two theories. Retributivist principles should influence the distribution of punishment: Only the guilty should be punished and only to the degree that they deserve. But the utilitarian goal of general deterrence remains to justify the overall practice.

THE LAW'S MORAL LIMITS

Law, Liberty and Morality (1963) represents a brilliant statement of Hart's liberal views regarding the role of law in enforcing morality, views that echo those of his distin-

guished liberal predecessor, John Stuart Mill. The book summarizes and extends Hart's contribution to a famous debate with Lord Patrick Devlin who, in response to an official call for legalizing prostitution and homosexuality in England, argued that a society has a right to enforce its morals because a solid moral foundation is as essential to its survival as a firm political structure. In Devlin's view, society has as much a right to enforce its morals through legal means as it has the right to protect itself through laws against sedition and treason. Hart was thoroughly repelled by Devlin's legal moralism. There is little reason, he argued, to believe that failure to enforce widely shared moral beliefs inevitably leads to social disintegration. Devlin also fails to recognize the distinction between positive morality (the morality widely shared within a society) and critical morality (more enlightened, rational standards for assessing both human conduct and, crucially, a society's positive morality). Most importantly, Devlin fails to appreciate the important role of the latter in challenging positive morality and in keeping alive the animating spirit of morality—the belief that certain standards of behavior should be followed, not because they are widely accepted and enforced, but because adhering to them voluntarily is the right thing to do. In Hart's view, critical morality includes a mixture of principles and values, some of which have utilitarian roots, others of which are of a more deontological bent. These standards, he thought, reveal that the coercive hand of the law should be used only to prevent palpable harm to others, or for the sake of a limited set of paternalistic goals.

THE CONCEPT OF LAW

Hart's most memorable work was undoubtedly in the area of general legal theory, where "Positivism and the Separation of Law and Morals" (1957–1958) and *The Concept of Law* (1961) stand as monumental contributions to our understanding of law and legal systems. These works develop a modern version of the legal positivism espoused by Bentham and Austin. Much as those two theorists had done, Hart sought to explain law as it *is*, not as it *ought to be*. In his view, natural law theories confuse these two issues, thus leading not only to philosophical confusion, but to anarchism (this law is not as it ought to be; therefore it is not really law and I am free to disregard it) or reactionary thinking (this is the law; therefore it must be as it ought to be and I must obey). The latter mind-set was of particular concern to Hart because it led, he thought, to a dimming of the vitally important sense that, for all its aura of majesty and

authority, law's demands must always remain open to moral critique and challenge.

Though he shared this overall positivistic approach to law and legal analysis with Bentham and Austin, Hart departed dramatically from them on a number of other fronts. Most importantly, he thoroughly rejected their command theory according to which law is comprised of the general commands of an habitually obeyed sovereign whose directives are backed up with threat of sanction. The command theory reduces law to "the gunman situation writ large" (1994, p. 7), that is, it views our situation under law as analogous to being obliged to surrender our money to a gun-toting robber. But we do not always view laws this way. Many of us take a more "internal point of view" (1994, p. 89) toward them. While we may feel obliged to hand over our money to the gunman, many—especially the officials of the legal system—view laws as imposing legitimate reasons for action. Furthermore, not all laws demand or prohibit conduct. Rather they facilitate our doing certain good things, such as entering into contracts and creating valid wills. As such, they are grossly mischaracterized if conceived as orders backed by threats.

CONCLUSION

So law is not the gunman situation writ large: It is the "union of primary and secondary rules" (1994, p. 99). Unlike the standards of morality and the social mores of etiquette and fashion, legal systems have a formal structure created by the interplay of primary rules (of duty and obligation) and certain fundamental secondary rules (rules about other rules). Every legal system contains a secondary rule of recognition that specifies criteria of validity—for example, parliamentary enactment or conformity with a Charter of Rights—which all other rules of the system must meet if they are to count among its binding laws. There will also be secondary rules of change, through which existing rules are altered or replaced, and secondary rules of adjudication, which regulate the enforcement and application of legal rules, most notably by judges. These fundamental secondary rules are social rules whose existence and content depend crucially on the behavior of the officials who use them in the everyday workings of the system.

Understood in this way, law can be seen to be a human, social creation. Its existence and content are matters of social fact, determined by what is, not by what ought to be. Despite his firm commitment to this positivistic view of law's content, Hart was prepared to concede that there is a kernel of truth in rival natural law

theories. Law is a social institution whose existence depends on its acceptance; but there would be no reason to accept law were it somehow devoid of "minimum forms of protection for persons, property and promises" (1994, p. 199). There is therefore a "natural necessity" (1994, p. 199) that legal systems contain this minimum content. Beyond this humble minimum, however, Hart was not prepared to venture, thus affirming his conviction that the law, by its very nature, may fail to meet our moral expectations of it.

HARTLEY, DAVID
(1705–1757)

David Hartley, the association psychologist and moral philosopher, was born in Luddenden, Halifax, England, and was educated at the Bradford grammar school and Jesus College, Cambridge. He was elected a fellow of Jesus but lost his fellowship when he married. He did not take holy orders, probably because of doctrinal scruples. Although he never received a medical degree either, he became a physician and practiced medicine in, successively, Newark, Bury St. Edmunds, London, and Bath. He was a friend of bishops Butler, Law, and Warburton.

Hartley's contribution to philosophy is his treatise *Observations on Man, His Frame, His Duty and His Expectations* (London, 1749). The first part, called "Observations on the Frame of the Human Body and Mind," is Hartley's exposition of the doctrines of vibration, association, and the seven classes of intellectual pleasures and pains. The second part, called "Observations on the Duty and Expectations of Mankind," consists of arguments for the existence of God, a defense of the truth of Christianity, a set of rules of conduct, and an estimate of our legitimate expectations in this life and hereafter.

Hartley's merit lies not in innovation but in consolidation. Borrowing several doctrines from his predecessors, he offers a comprehensive account of human nature. He treats mind and body as parts of a coordinate system capable of influencing each other. Thus, his work is a mixture of speculative physiology and psychology. While his conclusions may be criticized for their lack of an experimental basis (although he appeals frequently to

experience), he nonetheless deserves credit for supporting the conceptual ideal of a unitary system of mind and body. Hartley's theory of knowledge is John Locke's, offered in a context of religious sentiment. Despite the role that association plays in Hartley's philosophy, there is no mention of David Hume in his pages. By freeing the doctrines of learning by experience and of psychological association from skeptical associations, Hartley gave them a respectability that assured them a general currency.

The three aspects of human nature that Hartley wished to explain are sensation, motion, and the generation of ideas. With regard to sensation, he wanted to account for the way in which impressions on the senses register perceptions in the mind. He postulated, first, that the "white medullary substance" of the brain, the spinal marrow, and nerves is the immediate instrument of sensation. He then claimed that when an external object is impressed on the senses, it occasions, first in the nerves linking the senses and the brain and then in the brain, vibrations of the infinitesimal medullary particles. These vibrations are the means of conveying the sensation to the brain.

From this account of sensation, Hartley moved on to his account of the origin of ideas. Sensations may remain in the mind for a short time after the sensible object has been removed from the vicinity of the senses. By being often repeated, sensations leave in the mind certain vestiges, types, or images of themselves. These images are the simple ideas of sensation, the materials from which complex ideas are made. Once the mind is supplied with simple ideas, the association of sensations and ideas may come into play. The first requirement is that we must have a given set of sensations "a sufficient number of times." These sensations then acquire such a power over their corresponding ideas that when any member of the set is impressed on the senses, it is able to excite in the mind the rest of the corresponding ideas that belong to the set. In this way simple ideas collect and become a complex idea.

In addition to arguing for an association of sensations and corresponding sets of ideas, Hartley also argued for a kind of association that depends on the sensory vibrations. Regularly occurring sensory vibrations leave behind in the nerves miniatures of themselves which he calls "vibratiuncles"; and even as a general sensation is able to call up a corresponding set of ideas in the mind, so a sensory vibration is able to call up a corresponding set of vibratiuncles in the nerves. Similarly, a complex idea may call into being the set of vibratiuncles appropriate to the complex of sensations with which the idea corresponds. Hartley claimed that some of the vibratiuncles

attending upon complex ideas may be as vivid as any of the sensory vibrations excited by the direct action of objects.

In his account of human motion, Hartley again made use of the "white medullary substance" of the brain, spinal marrow, and nerves. He postulated this substance as the immediate instrument of motion. The motor nerves link brain and muscles; motion results as vibrations pass from the brain along the motor nerves and issue in muscular action. Briefly stated, then, Hartley's general theory of motion is that when objects are impressed in the senses, the vibrations excited in the sensory nerves spill over to the motor nerves by way of the brain and the higher ganglia; this process has a consequent effect on the muscles, and a motion results. According to Hartley, there are two sorts of motion, automatic and voluntary. They are distinguished by the fact that automatic motion depends on sensation, and voluntary motion depends on ideas.

Hartley makes "automatic motion" cover a varied class, which includes such motions as the heart's beating, crying, and voluntary actions that have become habitual through repetition. Heartbeats can be fitted into his theory only by the vaguest references to the spillover effect of the vibrations occasioned by sensation and by the additional suggestion that the circulation of the blood may also cause the heart to beat. The "motion" that best conforms to the theory is a fit of crying that results from a frightening experience or from the pain of being injured. In his theory of motion, Hartley did not intend "sensation" always to be the equivalent of "perception." For instance, the motion of breathing is excited in a newborn infant by cold air and the rough handling of the midwife, sensations which, for the infant, are not perceptions of anything.

In contrast to the automatic motions that depend on sensation, there are the voluntary motions which depend on ideas. A person's will consists of one of his ideas associated with sensory and motor vibratiuncles that are strong enough to excite the motor vibrations which, in turn, issue in muscular action. A voluntary action, for Hartley, is one that follows after an idea in the mind and not as a consequence of some outside force. He made it clear that "voluntary" must not mean "uncaused," and he argued that we have no "power of doing different things, the previous circumstances remaining the same." Indeed, he stigmatizes such an account of freedom as "philosophical freedom." He freely acknowledged that he was a mechanist, but he held that practical freedom does exist, in the sense that the causes of actions may sometimes

originate within a person. Nevertheless, he staunchly maintained that human action cannot be exempted from the reasonable and useful belief that everything has a cause. Indeed, he subscribed to this belief even though he knew that many of his readers would think him a greater friend to religion if he had not stated it explicitly.

Hartley distinguished seven different classes of pleasures and pains that may accompany our sensations (and consequently our ideas), and thus reinforce their affective power, namely the following: (1) those of Sensation, as they arise from impressions made on our external senses; (2) those of Imagination, as they arise from natural beauty and deformity; (3) those of Ambition, as they arise from the opinions of others concerning ourselves; (4) those of Self-Interest, as they arise from our possession (or want) of the means of happiness; (5) those of Sympathy, as they arise from the pleasures and pains of our fellow creatures; (6) those of Theopathy, as they arise from affections excited by our contemplation of Deity; and (7) those of the Moral Sense, as they arise from our awareness of moral beauty and deformity.

The classes of pleasures and pains are here arranged in an ascending order of value, from least to most valuable; and from this scale, Hartley derived the rule of life. The pleasures of sensation, imagination, ambition, and self-interest are not in themselves worthy of pursuit. But the pleasures of sympathy are worthy of pursuit in themselves and set a proper limit to our interest in the first four classes of pleasure. Moreover, the pleasures of sympathy are consistent with those of theopathy and the moral sense. Together, these last three classes of pleasure constitute, as a whole, the worthiest object of human pursuit that can be found.

Bibliography

The dissemination of Hartley's doctrines was aided by his enthusiastic admirer and younger contemporary, the scientist Joseph Priestley. Priestley published an abridged version of the *Observations* under the title *Hartley's Theory of the Human Mind on the Principle of Association of Ideas* (London: J. Johnson, 1775). While Priestley omitted the theory of vibrations, it is said that he was inclined to believe in it. Hartley is also the author of an *Enquiry into the Origin of the Human Appetites and Affections* (Lincoln, England, 1747). See also G. S. Brett, *A History of Psychology,* 3 vols. (London: G. Allen, 1912–1921), Vol. II, pp. 278–286, and Howard C. Warren, *A History of the Association Psychology* (New York: Scribners, 1921), pp. 50–64.

Elmer Sprague (1967)

HARTMANN, EDUARD VON
(1842–1906)

The German pessimistic philosopher Karl Robert Eduard von Hartmann was born in Berlin, the son of a Prussian artillery officer. Von Hartmann entered a school for artillery officers, but a knee injury in 1861 that aggravated older rheumatic ailments barred him from a military career and left him a lifelong semi-invalid. After two years devoted to musical composition and painting, he turned to an intensive study of philosophy. By 1867 von Hartmann had nearly finished his *Die Philosophie des Unbewussten* (Berlin, 1869; 9th ed. translated by W. C. Coupland as *The Philosophy of the Unconscious,* 3 vols., London, 1884). This work brought him prompt and widespread recognition, and the rest of his professional life was devoted to a long series of books that amplified and in some details modified its views, and applied them to various fields of philosophy and problems of contemporary culture. Before his death he had published the first volume of an eight-volume *System of Philosophy* (*System der Philosophie im Grundriss,* Bad Sachsa, 1907–1909). Unlike Arthur Schopenhauer's, von Hartmann's pessimism did not keep him from two happy and fruitful marriages.

INFLUENCES OF VON HARTMANN

Although he is generally regarded as a follower of Schopenhauer, von Hartmann found Schopenhauer's intense morbidity and his intuitive procedure temperamentally alien, and he corrected a basic incompatibility between Schopenhauer's Kantian phenomenalism and his Platonism by imposing upon the doctrine of the "will to live" a Hegelian but nondialectical doctrine of an intelligible categorial structure. Von Hartmann also acknowledged an indebtedness to the early Friedrich Schelling for his theory of the unconscious, to the later Schelling for the process in which nature and consciousness emerge from unconscious potencies, and to Gottfried Wilhelm Leibniz for the synthesis of individualism and monism. In *Die Philosophie des Unbewussten* von Hartmann built these influences into a system inductively grounded upon the data provided by the natural and historical sciences.

WILL AND IDEAS

Although Schopenhauer's concept of Will is needed to explain the dynamism of the world process, it cannot, according to von Hartmann, explain the world order. G. W. F. Hegel's dialectic is absurd, but his concept of the notion is required to explain world order, even though it

cannot account for the process by which, according to both Schopenhauer and Hegel, self-consciousness comes into being out of the unconscious. Ideas define the "what" of the world; Will determines its "that." The opposition of Will to the ordering of the Ideas brings about the emergence of consciousness and individuals.

Individuation results from the conflict of purposes into which the universal Will is driven through its resistance to its logical counterpart, the Ideas. Consciousness is required to emancipate the Ideas from bondage to the Will and its torments. Since space and time are the "sole principium individuationis known to us" (*Philosophy of the Unconscious,* Vol. II, p. 230), the result is a phenomenal but real evolutionary process of nature involving the greatest possible emergence of purposes. Consciousness, when it attains its maturity, will "suffice to hurl back the total actual volition into nothingness, by which the *process* and the *world ceases* … without any residuum whatever." (Von Hartmann suggested later, in Volume III, that the undifferentiated, substantial Will might continue to proliferate other orders of consciousness after this destruction.)

In this differentiation between the Unconscious Will and the Ideas, three orders of being must therefore be distinguished: (*a*) the metaphysical order of the unconscious; (*b*) the objective phenomenal-real order of nature; and (*c*) the subjective-ideal order of consciousness. The physiological unconscious in the second order ("the resting molecular predispositions of the central organs of the nervous system," *Die moderne Psychologie,* Bad Sachsa, 1901, p. 76), provides an unconscious ground for the total consciousness of an organism; conscious perception, in turn, is the bond by which knowledge of the transcendent but phenomenal-real order becomes possible.

CATEGORIES

In his *Kategorienlehre* (Berlin, 1896) von Hartmann distinguished between categorial concepts and the categorial functions of which they are the conscious representations. These unconscious rational functions assure that the concepts establish a relationship between phenomena and the thing-in-itself. There are innumerable categories, distinguishable as categories of sense and thought. There are two kinds of sense categories: sensations, which include quality, intensive quantity, extensive quantity (for example, temporality), and perceptions (that is, spatiality). The categories of thought include the primary category of relation, the categories of reflective thought (comparing, distinguishing, measuring, modality, and

others), and the categories of speculative thought (causality, finality, substantiality).

TELEOLOGY

Von Hartmann rejected both the irrational intuitionism of Schopenhauer and the mechanistic and materialistic assumptions of much of the science of his day. His own view of nature was teleological, an interpretation he undertook to demonstrate mathematically by a calculation of probabilities (he estimated the probability of eyesight being produced by mere mechanical processes as less than $15/10^7$) and also by analogies with alleged facts of experience. Instincts are unconsciously purposive, for example, and unconscious ideation in the nerve endings must be assumed to explain the slightest voluntary bodily movements. It is noteworthy that von Hartmann was one of the first to criticize Darwinism, arguing that evolution requires a vitalism and a "heterogeneous generation" of new variations within the germ cells of existing forms of life.

PESSIMISM

Among the factors that account for the great popularity of *The Philosophy of the Unconscious,* the most important is von Hartmann's restatement and justification of philosophical pessimism in the third volume. He regarded Immanuel Kant, not Schopenhauer, as the father of his pessimism: This is not the worst of all possible worlds; indeed, the infinite purposiveness of the particulars in it makes it the best of all possible worlds. Nevertheless, it can be shown that it would be better if there were no world at all, and, paradoxically, the purposiveness of this world is moving to that end.

The argument for pessimism in *The Philosophy of the Unconscious* consists of a remarkable combination of neurological and psychological considerations with commonsense considerations about the misery in the world. Pessimism results from the successive dispelling of three stages of optimistic illusion. The first stage is that happiness has already actually been attained in the present stage of the world; the second is that happiness can be attained in a transcendent life after death; and the third is that happiness will be attained in a future state of this world.

In a later historical and critical essay on pessimism, *Zur Geschichte und Begrundung der Pessimismus* (Berlin, 1888), von Hartmann modified this sweeping argument for the misery of the world by setting up five criteria of value (*Wertmassstäbe*): pleasure, purposiveness, beauty, morality, and religiosity. His pessimistic theory of the

Weltlustbilanz, he now claimed, was based on only the first criterion, and he described his theory as a "eudae-monological pessimism" but a "teleological-evolutionary optimism" in the nonhedonistic fields of value. He still held that efforts to assess values always involve the subjective, hedonistic component, and therefore involve a balance of misery.

Von Hartmann was concerned with showing that, far from making ethics and religion impossible, pessimism is the only foundation for a tenable ethical system and that it provides as well the wider teleological perspective from which religion, including contemporary Christianity, can be evaluated. In his *Phänomenologie des sittlichen Bewusstseins* (Berlin, 1879) he tried to show that all previous efforts to provide a philosophical basis for ethics, whether hedonistic, or built upon formal principles (which, he held, inevitably collapse into an ethics of ends), or socially oriented like utilitarianism and social democracy, had failed because they are untrue of man and the universe. The proper goal, which unites all lesser ethical ends, can only be a cooperative participation in the cultural process contributing to the satisfaction of all particular wills and, therefore, contributing ipso facto to the termination of the universe.

This conclusion anticipates von Hartmann's religious thought. The ethics of pessimism becomes a cosmic drama of redemption. The goal of the absolute religion of the future must be to save God, as Will, from the agony involved in his own inevitable creativity. The essence of vital Christianity, according to von Hartmann, lies in its pessimism about the present world, and liberal Protestantism is the last dying phase of Christian ethics because, by adhering to a faith in social progress, it has lapsed into the first stage of optimism.

Although the unorthodox nature and clear forcefulness of von Hartmann's thought drew a popular following, much critical comment was directed at his paradoxical theory of the unconscious, his criticism of religion, and the incompatibility between his pessimism and his idealistic ethics and philosophy of religion.

Except for a brief attempt to revive interest in von Hartmann's work during the years after his death, it has been largely neglected. He has been hailed as the last of the great speculative idealists, as a philosopher of science who opposed the mechanistic materialism of his time and anticipated the vitalism of the twentieth century, and as a psychologist who introduced the unconscious as a decisive mental factor. His criticism of the human predicament, along with Schopenhauer's, prepared the way for more complete, intensified forms of pessimism and nihilism in the twentieth century.

Two popular but accurate accounts of von Hartmann's thought and influence are contained in G. Stanley Hall, *Founders of Modern Psychology* (New York: Appleton, 1912), pp. 181–246, and Radoslav Tsanoff, *The Nature of Evil* (New York: Macmillan, 1931), Ch. 12.

L. E. Loemker (1967)

HARTMANN, NICOLAI
(1882–1950)

Nicolai Hartmann, the German realist philosopher, was born in Riga, Latvia, and educated at St. Petersburg, Dorpat, and Marburg. He was a professor at Marburg from 1920 to 1925, at Cologne from 1925 to 1931, at Berlin from 1931 to 1945, and at Göttingen from 1945 until his death.

THE WORK AND THE MAN

The typical German philosopher since the mid-1850s gives generous assistance to anyone wishing to become acquainted with his main ideas. He will have published at least one work on a philosopher of the past, who, with the regrettable exception of a few Greeks, turns out to be either German himself or mediocre and, with no exception at all, proves to be someone who could have been the professor's disciple or apostate. By simply observing what the author lauds and damns, stresses and omits, one may gather in concentrated form the materials for a portrait, not of the sitter, to be sure, but of the artist himself. This is true of even so eminently fair a German philosopher as Nicolai Hartmann. In his essays on the history of philosophy, "Zur Methode der Philosophie-geschichte" (1910) and "Der philosophische Gedanke und seine Geschichte" (1936), Hartmann advocated an approach to the history of philosophy in line with that to the history of science (these essays, as well as all others referred to, are reprinted in *Kleinere Schriften*). The history of philosophy is to be presented not as the coming to be and passing away of personal systems but as the progressive accumulation of impersonal insights. Yet many of Hartmann's numerous studies in the history of philosophy show that what he valued as impersonal, objective clarifications and solutions of the past more often than not anticipated views of his own.

In writing his first historical work, *Platos Logik des Seins* (Plato's logic of being; Giessen, 1909), which was his earliest publication as well, Hartmann was so immersed in the neo-Kantianism of Hermann Cohen and Paul Natorp that he viewed Plato's ideas as absolute hypotheses in the neo-Kantian sense of foundational positions taken by thought in its work of constituting reality. His two-volume work on German idealism, on the other hand, particularly the volume on G. W. F. Hegel (1929), bears witness to his accomplished liberation from idealism and the emergence of his main anti–neo-Kantian positions. What he valued in Hegel's philosophy was not its systematic character but its aporetics; not its specula-

tive idealist position but its being, as aporetics, prior to any position; not the Absolute and its self-realization—not even its dialectic, though Hartmann was fascinated and irritated by it, like a skilled craftsman in the presence of genius—but a sort of theory of emergence, describing and exploring, rather than constructing and deducing, basic strata and modes of Being and their interrelations; not the theological and teleological monism of the Spirit, with a capital *S*, but the discovery—or, rather, rediscovery, since Giambattista Vico had been forgotten—of the objective spirit, with a small *s*, that is, superindividual powers such as languages, moral customs, legal systems, into which individual consciousnesses are born and within which they carve their little niches.

Thus, in the end the Hartmannian Hegel is, in method, an aporetician who prefers careful analyses of problems to traditional solutions and, in subject matter, an ontologist engaged in describing a multitude of modes and strata of Being. In brief, what is alive in Hegel is Hartmann, for aporetics, particularly an aporetic epistemology "this side of realism and idealism," an ontological pluralism, and the categorial exploration of the real world, including the spirit as its highest stratum, describe all but one of the major commitments of Hartmann. The exception is his axiology, an exploration of the realm of values, a program that Max Scheler had designed in open battle against the Kantian formalism in ethics but whose execution had to wait for Hartmann's *Ethics*, the only major work of his translated into English.

In his *Grundzüge einer Metaphysik der Erkenntnis* (Outlines of a metaphysic of knowledge; Berlin, 1921), Hartmann presented in book form, for the first time, his aporetic and ontological epistemology. The book, published six years before Martin Heidegger's *Sein und Zeit*, caused quite a stir precisely because it heralded the Continental renaissance of ontology by asserting that epistemology is based on ontology and not the other way around. Almost all of Hartmann's subsequent books are in ontology, with his trilogy *Zur Grundlegung der Ontologie* (Foundations of ontology; Berlin, 1935), *Möglichkeit und Wirklichkeit* (Possibility and reality; Berlin, 1938), and *Der Aufbau der realen Welt* (The structure of the real world; Berlin, 1940) forming his ontological *opus maximum*. To these might be added his *Philosophie der Natur, Abriss der speziellen Kategorienlehre* (Philosophy of nature, outlines of the special doctrine of categories), which he began in 1927 but did not publish until 1950 (Berlin). In fact, his own philosophical work follows the plan he wished the history of philosophy to follow; there is much steady progress and expansion. The germs of his

central ideas—many of them images rather than concepts—can be seen even in his early neo-Kantian writings. For example, so typical an image as that of "the strata" and their hierarchy, basic to his later ontology, is already germinally active in his early *Zur Methode der Philosophiegeschichte* of 1909.

There was only one revolution in Hartmann's thinking. This was the revolution against the neo-Kantian idealism of his philosophical youth. It must have been a matter of profound travail for him, even though he was undoubtedly helped by certain select aspects of Edmund Husserl's phenomenology, in particular its Platonizing intuition of essences and its program for a merely descriptive reappropriation of experience. Whatever one may think of Hartmann's ontology philosophically, one cannot help being awed by his self-liberation from the grand German tradition of transcendental idealism, a liberation much more strenuous to a German than to Anglo-Saxons such as Bertrand Russell and George Edward Moore or Americans such as John Dewey, all of whom, to be sure, had somewhat similar conversions. These other conversions, however, were returns to the main current of their national philosophical traditions, whereas Hartmann's went counter to the main current of his. Indeed, even the severest critic of Hartmann's philosophy will respect the man himself. His philosophy reveals him to have been a careful, disciplined, honest, and sober conservative, kept by his common sense from philosophical extravaganza, but kept also from asking or appreciating radically revolutionary questions of either the existentialist or the new empiricist kind. Though as a person he was unmistakably German, his way of doing and writing philosophy was not at all typical of recent German philosophers. He cherished discussions and admitted to having learned from his students. He wrote not in the attitude of "the reader be damned" but with true courtesy toward his public, not to awe with profundity of learning but to guide with lucidity and thoroughness.

PHILOSOPHICAL POSITIONS

In presenting Hartmann's major positions it is advisable to begin with his conception of aporetics as philosophical method, not only because Hartmann himself put it at the beginning of his "Systematische Selbstdarstellung" (in *Deutsche systematische Philosophie nach ihren Gestaltern*, edited by Hermann Schwarz, Vol. I, Berlin, 1933; reprinted in *Kleinere Schriften*, Vol. I), but also because it is that part of Hartmann's philosophy that philosophers of the English tradition should find the most congenial.

APORETICS AND EPISTEMOLOGY. Aporetics is the unraveling of problems (aporia) into their strands; their presentation as clear-cut issues, preferably in the form of antinomies; and the weighing of the pros and cons of apparent solutions. There are some philosophical problems—the metaphysical problems—that will turn out to be in principle insoluble. Yet their unraveling is still useful, for as some part of the issues may turn out to be soluble, their discussion will contribute to the location and diagnosis of the unmanageable remainder. Aporetics is the central business of philosophy, all too often abandoned in favor of system building. Hartmann did not tire of pointing out that aporetics is what the Platonic dialogues and the best pages of Aristotle exemplify. However, this will hardly suffice in the age of science, when the nature of philosophy and philosophical problems is itself an aporia. Rather, one would wish to know what, if anything, distinguishes philosophical from logical or scientific problems. One would wish to know, besides, what it is that makes some philosophical issues insoluble and what the criteria are in terms of which some answers are solutions and some are not. Hartmann saw philosophical problems as arising from what he took to be the facts and from the contradictions they appear to harbor. His philosophical method, then, consisted really of two parts, a phenomenological presentation of the facts and an aporetic discussion of their implicit contradictions.

A typical example of Hartmann's descriptive-phenomenological and aporetic method may be found in his *Grundzüge einer Metaphysik der Erkenntnis*. No merely descriptive account of experience can plausibly deny that the objects known by a consciousness are experienced as existing independently of their being known. This fact, however, harbors in itself riddles in the form of flagrant contradictions: Consciousness, in knowing an object, transcends itself, yet anything known to consciousness is thereby a content of consciousness—that is, is immanent—and consciousness never transcends itself. The same riddle, but formulated from the side of the object, concerns the influence of the object on the subject. On the one hand, the object must break into a consciousness and produce an image of itself; on the other, the object must remain outside the subject, for it is, as object, something transcendent and indifferent to its being known by a subject.

Hartmann neither questioned the nature of the facts he supposed himself to be describing nor entertained any suspicion that the antinomies he found in those facts might be due to the sort of language he used in describing them. Instead, he proceeded from knowing to being.

The epistemic aporias are essentially ontic aporias, for both the object and the subject are beings (*Ansichseiendes*). The object is not exhausted in its being an object of a subject. Like a nocturnal thief caught in a sudden glare of light, it emerges out of an unredeemably transobjective and metarational background, a background that is in part beyond any human cognition, even beyond any possible sort of cognition. In knowing an object the subject knows "a thing that is," a being. In turn, the consciousness that knows the object is itself something not exhausted by its being a subject. It emerges out of a transsubjective and metarational medium; it is itself "a thing that is, a mode of Being." Hence, the epistemic relation between knower and known is really an ontic relation holding between one being and another, and the problems in epistemology are, or issue in, problems in ontology. As beings, both subject and object are ontologically homogeneous and are members of a context of Being (*Seinszusammenhang*). Within this context their relationship, so puzzling when taken in epistemological abstraction, becomes conceptually manageable, though an insoluble, and hence metaphysical, problem remains. This problem, however, concerns not the fact *that*, but rather how, subject and object stand in relation to each other.

In short, by seeing both subject and object as *Ansichseiendes*, Hartmann believed himself to have discovered that they are ultimately members of one matrix and context of Being. This is supposed to explain that they are related, though the how of their relation remains mysterious. Thus, the Hartmannian turn from epistemology to ontology looks suspiciously like a piece of verbal magic, as if a biologist, puzzled by the relation between males and females, proposed to solve the puzzle by calling both males and females "sexuals" and hence members of the sex context, thus "explaining" that they have sexual relations, though still wondering how they have them. Hartmann's reduction of epistemology to ontology is a piece of philosophical verbal magic if "subject" and "object" have empirical meaning, as "male" and "female" do. But if "subject" and "object" have no empirical meaning, what sort of meaning do they have? This basic question is unasked, and one cannot help wondering if the main use of the terms is not to engender the antinomies without which epistemologists would be out of work. In sum, Hartmann's phenomenological emphasis on descriptive facts seems to bring philosophical problems closer to empirical ones, whereas his aporetic emphasis on antinomies seems to bring them closer to logical ones. It is this basic ambivalence in his conception of philosophical method that cannot but be reflected in his conception of ontology.

ONTOLOGY. If there was anything twentieth- and twenty-first-century ontologists have had in common it is their unquestioning belief that the term *Being* is the name of something or other. What is debated is rather what *Being* is a name of: a quality or feature shared by all beings (and if so, whether this class, as *summum genus*, is distinguished from other classes merely by its higher degree of universality); some relation that any *x*, in order "to be a being," must have to be a subject, or man, or God; or an individual being who is the ground of all beings. Since they have not questioned that "Being" is a name, these ontologists, like their predecessors, have a problem concerning the unity of Being. Protons and principles, nations and numbers, salads and sentences are all said to have some sort of Being, and yet, because they *are* so differently, the ontologist is compelled to admit different kinds of Being. But this would make Being itself the genus of these kinds, just another class concept, albeit more abstract or universal, depriving ontology, in the process, of its metaphysical weight and attraction. In this predicament ontologists have chosen a linguistic escape. Instead of talking of kinds of Being, they prefer to talk of modes of Being. They thus believe themselves to be preserving the unity of Being in the variety of beings without prostituting Being to a mere class name—and a name, of course, it must be.

To a degree, Hartmann shared with the most outspoken ontologists of the mid-twentieth century, the existentialists, both the referential use of "Being" and the preservation of the unity of Being via modes. However, he was at once simpler and more confused than they. Heidegger, for example, made the most of the distinction between Being and beings, between *das Sein* and *das Seiende*, and, correspondingly, between ontological and ontic investigations. But Hartmann, at least in his pre-Heideggerian writings (such as *Grundzüge einer Metaphysik der Erkenntnis*), seems to have been rather uncertain about this difference and to have used the term *ontological* for any investigation concerned with beings. This makes the concept of ontology simpler, as it keeps the white whale of Being from perturbing the Ahab of beings, but it also makes the concept more confused, as one is now at a loss to distinguish between ontology and science, both of which have to do with beings. In his pre-Heideggerian *Grundzüge*, Hartmann was similarly apt to be very cavalier about the problem of the unity of Being, and he spoke of modes and strata of Being as if they were merely basic kinds of beings. Even though in his later works all this appears to have changed, presumably under the influence of Heidegger's *Sein und Zeit*, and Hartmann no longer slid terminologically from "beings" to "Being"

as he had in the *Grundzüge* (p. 182), conceptually the distinction between Being and beings and the problem of the unity of Being remain rather vague and were for him hardly the matter of primary philosophical concern they were for Heidegger.

Hartmann distinguished between two basic modes of Being (*Seinsweisen*), very much as the American new realists distinguished between existence and subsistence twenty years before him. One mode of Being consists of particulars, localizable in time and space, the other of universals—for example, essences, values, numbers. The former are real, the latter ideal; both are equally objective and independent of the subject. The ideals are logically prior to the reals, for a real is what it is only by virtue of an essence present in it (or valuable only by virtue of a value present in it). This apriority of ideal entities, however, does not exclude their being possible objects of experience, ideals being given in intuition just as reals are in perception. (Here "perception" and, it would seem, "intuition" must be used generously enough to include the emotional, for, following Max Scheler, Hartmann asserted valuables, if not values themselves, to be experienced emotionally rather than cognitionally.) Nor does the apriority of ideal entities exclude the possibility that the intuitional acts in which they are experienced are, *in ordo essendi*, grounded on the perceptual acts in which reals are experienced. As in Husserl, then, the a priori is not opposed to, but is rather part of, the empirical.

Within each of the two basic modes of Being, Hartmann distinguished between several strata of Being (*Seinsschichten*). The strata of reality correspond to the distinctions between inorganic nature, organic nature, consciousness, and superindividual culture (*Geist*)—all of them reals, but the last two also agents and carriers of ideals. Each stratum has basic, so-called categorial features, which it is the task of regional ontologies to lay bare. The strata form a hierarchy in which one stratum's dependence on the existence of another and partial freedom (autonomy) from the other's laws mark the higher from the lower. The working out of these regional ontologies through categorial analyses was one of Hartmann's central preoccupations, especially in *Der Aufbau der realen Welt*.

The distinctions between the two modes of Being and between the several strata within each mode were related by Hartmann to the traditional three modalities of possibility, reality, and necessity. Originally these are ontological modalities: It is beings that are possible, real, or necessary (*Seinkönnen, Sein, Seinmüssen*). Only derivatively are they distinctions concerning validity or certainty of knowledge. The many-dimensional relations of the ontological modalities to the modes and strata of Being, on the one hand, and to judgment and knowledge, on the other, are explored in *Möglichkeit und Wirklichkeit*, the most complex and difficult of Hartmann's works.

The revolution of the *Grundzüge einer Metaphysik der Erkenntnis*, making epistemology ontological, revenges itself upon Hartmann's ontology, making it epistemological. A being is primarily understood as that which is *an sich* (in itself), and this *an sich*, the traditional substance of ontology, is defined epistemologically as that which is indifferent to its being known by a subject. Moreover, this *an sich* is either that of reals or that of ideals. Reality and ideality, the two basic modes of Being, become two basic classes of beings. The genus common to both is the *an sich*. Thus, Hartmann appears to have slipped back into class concepts and some sort of taxonomy, half epistemological, half empirical. As with the modes, so with the strata: It is not at all clear what distinguishes strata of Being from kinds of beings. The several strata of reality seem to be related to reality as so many classes are to a genus. Finally, it is not at all clear what distinguishes the concept of a stratum from that of a mode. The two modes of Being, reality and ideality, are themselves related to each other in a multidimensional hierarchical order, very much like the strata, and it would therefore seem that the main difference between mode of Being and stratum of Being is, as with class concepts, the degree of abstractness or universality. In fact, in his *Ethics* Hartmann dealt with ideality as if it were just another stratum and not a mode. If the modes and strata of Being were just kinds of beings, it would follow that ontology is empirical and that the categories are concepts, like any other class concept but more universal. Here lies, as was hinted before, a crucial difficulty of Hartmann's ontology, a difficulty that is shared, mutatis mutandis, by Samuel Alexander's and Alfred North Whitehead's conceptions of categories and that reflects some really basic indecision on their respective conceptions of philosophy. Categories, as Hartmann conceived them, are descriptive of the behavior of different kinds of beings, yet are supposed to be different in kind, not just in the degree of universality, from both the class concepts of ordinary experience—such as "tree" or "rodent"—and the functional concepts of science. At the same time, categories are supposed to be related—and it seems, in some sense, necessarily related—to both. But neither difference nor relation is clearly worked out, and Hartmann's ontology, like Alexander's and Whitehead's cosmologies, continues to hover between the empirical and the a priori as well as between science and ordinary experience.

ETHICS. Indecision of this and other sorts haunts Hartmann's *Ethics*. Moral philosophy must not be casuistry; it must not try to teach what one ought to do in a particular situation. Rather, it should give the general criteria for a universal ethic. This sounds Kantian enough. But whereas Immanuel Kant used it as a steppingstone to philosophically central investigations concerning the logical nature and the transcendental foundation, if any, of these principles, Hartmann veered off in a very different direction. Somewhat like a course in art appreciation, ethics is supposed to make men sensitive to the wealth of values present in the world. This, however, makes Hartmann uncomfortable; it is not academically respectable. The task of moral philosophy is, rather, to present clearly, force into consciousness, and "establish" values, raising to the plane of science what was a mere affair of feeling. How are the two conceptions of moral philosophy—that of making explicit universal principles of what ought to be done and that of raising value feelings to the plane of science—to be united? What one ought to do can be gauged only if one has an insight into what is valuable in life.

In fact, however, this synthesis of the Kantian apriority of moral principles with the manifoldness of values, "which [Friedrich] Nietzsche had discerned only to let it melt away in historical relativism," is only a secondary aim of Hartmann's *Ethics*. Its central task is an analysis of the content of values, an elaborate axiology exploring the multitude of values and their relations to each other, to the ought, and to the real. This is the main body and the core of Hartmann's work in moral philosophy. It fills the second volume of the *Ethics*; the third is devoted to the problem of the freedom of the will. The first volume, besides developing his conception of moral philosophy, is a phenomenology of morality. Typical moral philosophies of the past are discussed with the aim of discovering in each of them a sound insight into some partial aspect of the moral phenomenon. Kant, for example, is said to have seen very clearly that ethical principles do not have the empirical sort of universality. They are a priori. Yet Kant's uncritical use of the Aristotelian form-matter dualism made him equate the a priori with the formal, and his epistemology made him equate the formal with the (transcendentally) subjective. Against this Kantian formalism and subjectivism Hartmann's axiology asserts an a priori of objective content—that is, of values as ideal entities that are intuitable.

It may, of course, be argued against this value objectivism that a judgment like "*x* is valuable" or "*x* is more valuable than *y*" will at some time and by some people be considered true and at some other time and by some other people false without there appearing to be any universal criteria of distinguishing, or any method of testing, the truth or falsity of these rival claims. But Hartmann answers this and other relativistic arguments by comparing the intuitional sense of values with a source of light. Light will penetrate darkness and illumine objects according to the strength of its source and will reveal the below and above of objects according to the position of its source, none of this preventing the objects and their spatial relations from being objective and knowable. This comparison assumes what was to be proved. It assumes that any particular sense of values is able to determine its own weaknesses with respect to all other possible senses of values, quite unlike a particular source of light, whose characteristics could not be objectively determined were it not for the sun and the light of day and the knowledge thus made possible. Hartmann's methodological reliance on an intuitional sense of values leaves his readers without a theoretical basis upon which to check and argue the truth or falsity of his observations in the realm of values. One cannot help being pleased with them as one might be with the descriptions of a foreign though somewhat familiar country, but since the recommended means of transportation is in no public domain, the country might as well be Cockaigne. There is no use arguing with the Baedeker of Cockaigne: Anyone may write his own. However, Hartmann's actual work in describing values is far superior to the account he gives of its method, and it is likely that this second volume of his *Ethics* will be found not only enjoyable but also useful.

Hartmann defined freedom of the will as independence from any determination that is constraint without this independence becoming indetermination. Indetermination is not only ontologically impossible; above all, it has once and for all been overcome in the Kantian conception of freedom as autonomy. Indeed, to Hartmann any determination that is not autonomy is constraint, and therefore autonomy fulfills the requirements of a definition of freedom of will. It is logically impossible for a will, insofar as it determines itself, to be either constrained or undetermined. If this is what freedom of will is, how can there be such a thing?

Hartmann's answer has two parts. The first is general, in terms of the hierarchy of ontological strata. Hartmann had asserted that the mark of a stratum's being higher than another is, in part, its autonomy—that is, the emergence of a new sort of determination or law. Autonomy is, then, a general ontological feature to be found, by definition, in any stratum but the lowest, and the auton-

omy called freedom of will is only a particular type of this general feature. Very much like theories of emergence, such as these of Alexander and Whitehead, which assume the miracle of emergence to be less miraculous if it is repeated, Hartmann's theory explains freedom of will as moral autonomy by making autonomy a universal ontological feature and then describing moral autonomy as a species of it.

The second part of his answer is concerned with this specific nature of moral autonomy. The will, in order to be free, must not be determined by the causal apparatus of nature, nor must it be determined finalistically by values and the corresponding oughts they confront us with. In either case the will would be determined by something outside it; that is, it would be constrained. However, if there were only these two kinds of determination, the causal determination of nature and the finalistic determination of values, then a will independent of nature would be one determined by the ought, and a will independent of the ought would be one determined by nature (indetermination being ontologically impossible); in either case the will would not be free. This is the most basic of Hartmann's aporias connected with the freedom of will. Hartmann proposed to solve it by positing a third kind of determination, whose nature he admitted to be completely inscrutable and metaphysical, a determination that belongs to the person itself, a self-determination through which an agent commits himself to the realization of value. Only such a third kind of determination, above both nature and value, explains the possibility of freedom of will.

Quite apart from the mistaken identification of determination and constraint, what seems particularly objectionable is Hartmann's suggestion of a kind of determination that is in principle inscrutable as a solution to the basic aporia of free will. Postulating an unknowable x as the solution to a problem is like shouting "victory" to undo defeat. In his escape from Kant's conception of autonomy as self-legislation of rational beings Hartmann fell under the spell of a supposed metaphysical ground in which a person and his decision making are taken to be rooted—a romanticism somewhat like Jean-Paul Sartre's "dreadful freedom," which on closer inspection turns out to be mere whim.

The absence of religious thought in Hartmann's philosophy is conspicuous. Value realism offers logical difficulties to theology, and it is, besides, more naturally connected with a life attitude whose religiosity—if this word can here be used—lies in value commitments and not in a personal relation to God. Thus, Hartmann's value

realism, as well as his pro-scientific persuasions and his empirically colored ontology, makes his proximity to atheism quite understandable. Very much unlike his beloved German idealists, who expressed the main existential spring of their philosophical energy in the problem of the "relation of the infinite and the finite," Hartmann was energized by no such preoccupations. His were intellectual aporias, not existential quandaries.

Hartmann's influence on German philosophy, though for a while considerable, was unable to stem the tide of existentialism. With the mid-twentieth-century return of German philosophy to a more sober and rational style, a new esteem for Hartmann began to develop in Germany. In the English-speaking world in the same period his *Ethics* was greeted with respect and then allowed to disappear, leaving hardly a trace. His only notable influence in fields other than ethics seems to have been on W. M. Urban, but as Urban's books have been ignored, Hartmann's effect in English-speaking countries has been limited to such indirect sources as Mario Bunge's somewhat Hartmannian books. Perhaps the sobriety, carefulness, and common sense of his general philosophical style are too much in the English and American tradition to attract our interest, and his logical and analytic naïvetés too numerous to hold it. It will take some time before these naïvetés are overlooked for the sake of his insights in the realm of values.

HARVEY, WILLIAM
(1578–1657)

William Harvey, the English doctor and anatomist, was the demonstrator of the principle of the circulation of the blood. He was born at Folkstone, Kent, and educated at King's School, Canterbury, and Gonville and Caius College, Cambridge. After taking his B.A. in 1597, he left Cambridge for Padua, where he worked with the anatomist Fabrizzi d'Acquapendente (often Latinized as Fabrizio of Aquapendente). Fabrizzi had observed the valves in the veins, although he had not understood their function; Harvey told Robert Boyle that he had developed his theory of the circulation of the blood by reflecting on the operation of these valves, perhaps while still at Padua. In 1602 Harvey graduated from Padua with a medical degree and incorporated as an M.D. of Cambridge. Taking up practice in London, he was married in 1604 to Elizabeth Browne, daughter of the physician to James I. He was elected fellow of the Royal College of Physicians in 1607, and two years later was appointed physician to St. Bartholomew's College, a position he held for thirty-four years. In 1616, when he began to lecture as Lumleian lecturer in surgery of the Royal College of Physicians (a post he assumed in 1615), he was already expounding his theory of the circulation of the blood, although he did not publish his *Exercitatio Anatomica de Motu Cordis et Sanguinis in Animalibus* (An anatomical exercise concerning the motion of the heart and the blood) until 1628. Appointed Physician Extraordinary to James I in 1618, and in 1631 to Charles I, Harvey was identified with the royalist cause during the Civil War. In 1642 his London house was ransacked by Parliamentary troops who destroyed notes and specimens. Charles I appointed him warden of Merton College, Oxford, in 1645.

After the Civil War Harvey lived a secluded life, retiring from practice and devoting himself to embryological research. Pleading age, he declined the presidency of the Royal College of Physicians in 1654, and in 1656 resigned from his Lumleian lectureship. He died at Roehampton.

There has been considerable dispute as to whether the discovery of the circulation of the blood can properly be ascribed to Harvey. As early as 1543, Andreas Vesalius had expressed doubts about the traditional Galenic account, according to which blood was made in the liver, flowed through the veins, and was then excreted, except for a small part that passed through minute channels in the septum to the right ventricle and so into the arteries. Vesalius complained that he could not find the channels through the septum. Michael Servetus (1511–1553), Andrea Cesalpino (1519–1603), and especially Matteo Realdo Colombo (1516–1559) all gave a reasonably accurate picture of the flow of blood through the lungs—the so-called lesser circulation. But none of them recognized that the entire blood supply circulated through the body.

Harvey used the comparative method. Confused by the rapidity of movements within a living human body, he dissected such cold-blooded animals as toads and shrimps, in which movement is slower. Many of his con-

temporaries criticized him on the ground that what was true of the lower animals had no application to man. But for Harvey, as for Aristotle, man formed part of the animal kingdom.

Harvey's great importance lies in the fact that he used the concepts of mechanics in his analysis of physiological processes. He described the working of the heart in the language of pumps; he applied mathematical calculations to show that the body could not possibly manufacture the quantity of blood which, according to Galen's theory, would have to flow through it. The fact that blood still had a quasi-mystical significance made his matter-of-fact approach particularly significant.

Harvey's work greatly influenced many early modern philosophers, including René Descartes and Thomas Hobbes (otherwise so different), who both put Harvey on a level with Galileo Galilei. They saw that Harvey had broken down the barrier between the animal and the human body, and between the processes of the body and the processes of mechanics. Thus Harvey's discovery gave empirical support to their mechanistic hypotheses. Descartes objected, however, that Harvey had not shown from first principles that the blood must necessarily circulate; he had been content to say that the heart is in fact a pump and that the blood does in fact circulate. Harvey replied to Descartes in his letters to the French anatomist Jean Riolan, who had rejected Harvey's theory. These letters were included in *Exercitationes Duae Anatomicae de Circulatione Sanguinis, ad Johannem Riolanum Filium Parisiensem* (Two anatomical exercises concerning the circulation of the blood, addressed to Jean Riolan Jr., of Paris; 1649).

Scientific truth, Harvey argued, is to be discovered by direct observation. "No more certain demonstration or means of gaining faith can be adduced than examination by the senses, than ocular demonstration." In this respect, Harvey compares biology favorably with astronomy. The astronomer, he suggests, argues from appearances. He cannot see what happens in an eclipse; all he actually sees is one disc sliding across another, whereas the biologist can see the heart beating in a shrimp. Observation shows us that the blood circulates, and that is enough for the biologist. This is a classic statement of the attitude of the observational biologist, in opposition to the Cartesian mathematico-physical conception of science. The *Letters to Riolan* also contain Harvey's criticisms of the attempt to explain physiological functioning in terms of "spirits." "Persons of limited information when they are at a loss to assign a cause for anything, very commonly reply that it is done by the spirits."

Harvey's other major work is contained in his *Exercitationes Duae Anatomicae de Generatione Animalium* (Two anatomical exercises concerning the generation of animals; 1651). Although this work was important in developing the view that each living thing is produced from an egg, as opposed to the doctrine of spontaneous generation, it lacks the scientific assurance of the *De Motu Cordis*. The fact that Harvey had to rely upon the unaided eye very much limited his achievement in this area. The first work of any consequence carried out with a microscope was done in 1660 by Marcello Malpighi, who took Harvey's theory as his point of departure.

Bibliography

WORKS BY HARVEY

The collected Latin works of William Harvey were published in London as *Opera Omnia* in 1766; the earliest English texts, dating from 1653, have been reprinted, edited by Geoffrey L. Keynes (London, 1928); a complete English translation was prepared by Robert Willis for the Sydenham Society, London, in 1847. The notes Harvey prepared in 1615 for his Lumleian Lectures were published in facsimile as *Praelectiones Anatomiae Universalis* (London, 1886) and translated by C. D. O'Malley, F. N. L Paynter, and K. F. Russell as *Lectures in the Whole of Anatomy* (Berkeley, CA, 1961). The manuscript *De Motu Locali Animalium* (1627) was first published in Cambridge, U.K., in 1959, edited by Gweneth Whitteridge. See also *De Motu Cordis,* edited and translated by Kenneth James Franklin as *Movement of the Heart and Blood in Animals* (Oxford: Blackwell, 1957); *The Circulation of the Blood,* containing Harvey's reply to Jean Riolan, edited and translated by Kenneth James Franklin (London: Dent, 1963).

HATANO SEIICHI
(1877–1950)

Hatano Seiichi, the Japanese historian of philosophy and philosopher of religion, was born in Nagano and died in Tokyo. He studied at Tokyo University, where his thinking was formed by Raphael von Koeber, a pupil of Eduard von Hartmann. He wrote his doctoral thesis, "A Study of Spinoza" (1904), in German. In 1901 he had published *Seiyo tetsugaku shiyo* (Outline of the history of Western philosophy; Tokyo), a book whose scholarship established his reputation. He went to Germany in 1904 and studied under Carl Gustav Adolf von Harnack and Otto Pfleiderer at Berlin for two years, then under Wilhelm Windelband at Heidelberg. He also developed his studies of Protestant theology (he had been baptized in 1902) under J. Weiss, Ernst Troeltsch, and A. Deissmann. Their lectures prepared him to be a temporary replacement for Anesaki Masaharu, Tokyo University's well-known historian of religion. From his lecture notes he published *Kirisutokyō no kigen* (The origin of Christianity; Tokyo, 1908). In a much later book, *Genshi kirisutokyō* (Primitive Christianity; Tokyo, 1950), he rose above the historico-textual criticism of his early days to present a more thorough study of the essence of Christianity. But at the beginning of the twentieth century this type of work was a novelty in Japan.

In 1917 he resigned from Waseda University, where he had taught for many years, and at the invitation of Nishida Kitarō, the leading philosopher of Japan, he joined the staff of Kyoto University; he taught there until he retired in 1947. Subsequently he became the president of Tamagawa University in Tokyo. At Kyoto he had the chair of science of religion, and from 1922 he held the chair of Christianity. Hatano developed his philosophy of religion in four books (all published in Japanese, in Tokyo): "The Essence and Fundamental Problem of Philosophy of Religion" (1920); "Philosophy of Religion" (1935); "Introduction to Philosophy of Religion" (1940); *Time and Eternity* (Japanese edition, 1943; English edition, 1963). His main idea is that the comparative study of religion presupposes a philosophy of religion because values are a necessary element of that science. As philosophy, religion must start from the reality of the religious experience of God; this experience is first an experience of the God of power, then a quest for the God of truth, and finally an experience of the God of love. Hatano distinguishes three kinds of time: the natural, encompassing the realm of nature; the cultural, characterized by eros; and the eternal, in which agape, or Christian love, triumphs. Original, too, are his observations on the "about-to-come" future (*shōrai*) and the distant future (*mirai*). The first is implicitly part of our present; it is the future we are making, the supplier of being. The second is time that will never be experienced by the subject. Clearly Hatano is much influenced by Christian ideas and takes almost nothing from the Oriental climate of thought; even so this type of philosophy of religion was and still is very influential in Japanese thought.

Bibliography

Hatano's works have been published in Japanese as *Hatano Seiichi zenshū* (The complete works of Hatano Seiichi), 5 vols. (Tokyo, 1949). Vols. III–V include Hatano's works on the philosophy of religion. One of his works on that subject, *Toki to eien* (Tokyo, 1943), has been translated by Ichiro Suzuki as *Time and Eternity* (Tokyo: Japanese Government Bureau, 1963). For a discussion of Hatano's thought see G. K. Piovesana's *Recent Japanese Philosophical Thought, 1862–1962* (Tokyo: Enderle, 1963), pp. 123–131.

Gino K. Piovesana, S.J. (1967)

HAYASHI RAZAN
(1583–1657)

Hayashi Razan, the Japanese Confucianist, helped establish the Zhu Xi (Japanese: Shushi) school as the state doctrine of the Tokugawa government (1603–1867), which played an important role in shaping the national character. Hayashi, who was born in Kyoto, began studying Confucianism at the age of twenty-two, under Fujiwara Seika (1561–1619) and like his teacher abandoned Buddhism for the Neo-Confucianism of the twelfth-century Chinese philosopher Zhu Xi. Fujiwara recommended his talented pupil to Tokugawa Ieyasu as official adviser, a post Hayashi continued to fill under Ieyasu's successors. Through his son Gahō (1618–1680) and grandson Hōkō (1644–1732), both erudite Neo-Confucianists, Hayashi's influence spread. Gahō and Hōkō became hereditary heads of the Confucianist college (Shōheikō) of Edo (Tokyo), center of Japan's orthodox Zhu Xi-ism. Hayashi is credited with an important role in the various codes promulgated by the Tokugawa to reorganize the country under strict military rule. That he also determined educational policy is beyond dispute.

Hayashi, in contrast to his master Fujiwara, was very intolerant toward other doctrines—specifically, Wang Yangming Confucianism, Laozi, Buddhism, Christianity. Thus he is noted more for his negative polemics than for developing Zhu Xi's ideas, which he followed rather faithfully. An instance of deviation from Zhu Xi is Hayashi's almost monistic conception of *ri,* the principle, together with *ki,* the material-force. He came near to identifying these two basic concepts, thus approaching the rival school of Wang Yangming. Nevertheless, he sharply criticized Wang Yangming's "intuitive knowledge" and Kaibara Ekken's views. Hayashi disapproved of Laozi's emphasis on the "Nameless," or the Way understood as the indescribable Great One, intent as he was on stressing social relationships. For Buddhism's escape from society and neglect of loyalty and filial piety he had nothing but scorn, fighting until his death against influential Buddhist monks. His strictures on Christianity were many (Christians were then being persecuted and banished from Japan). He focused, however, on ethical questions and social differences neglected by Christianity. Only with Shintoism did he desire compromise and amalgamation.

HAZLITT, WILLIAM
(1778–1830)

William Hazlitt, the English essayist, journalist, and critic, began his literary career as a "metaphysician," and the principles of his youthful philosophical writing survived to govern his thought during the years when a more brilliant prose style won him fame. Born at Maidstone, Kent, the son of a Dissenting minister, Hazlitt kept faith politically with his Unitarian heritage, but at an early age revolted against his father's rationalistic theology. After trying unsuccessfully to become a painter, he turned in his thirties to journalism and to popular lecturing, and until his death made his living in London as a writer for periodicals. Twice unhappily married, always the fierce defender of both the French Revolution and Napoleon Bonaparte, Hazlitt succeeded in alienating most of his friends and much of his public, although his critical influence on the literature of his time was perhaps second only to Samuel Taylor Coleridge's. Unlike Coleridge, his erstwhile friend and mentor, Hazlitt did not ground his thought in a version of the new Idealism; he stands alone in his age as a romantic thinker who developed a critique of empiricism that nonetheless supported the values and methods of the empiricist tradition.

Hazlitt continued the redefinition of the individual begun by William Godwin in *Political Justice* (1793). Four years before his first meeting with Coleridge in 1798, and while still a student at Hackney College in London, Hazlitt conceived his "metaphysical discovery"—a refutation of necessary egoism. Actually, his position had been anticipated by Joseph Butler and David Hume, but his arguments were original in his insistence on imagination—a power inseparable yet distinct from present sensation and past feeling—as the source of voluntary action, and even of self-consciousness.

His first book—*An Essay on the Principles of Human Action,* to which was added *Some Remarks on the Systems of Hartley and Helvétius* (1805)—argued that ideas of good determine conscious pleasure and self-interest, not the reverse, and that the same "reasoning imagination," which alone can unify sensations from moment to moment, is responsible for all the mind's "associations" except those arising from mere contiguity in experience. In his lectures at the Russell Institution in 1812 on the "Rise and Progress of Modern Philosophy," this line of thought inevitably led Hazlitt to challenge all epistemology, including George Berkeley's and Hume's, that relied on the Lockean premise of "simple" impressions in perception. To perceive the simplest object requires a "general idea," or some act of mind to "comprehend" objects in their sameness or wholeness before qualities can be differentiated. Failure to recognize an activity of mind inhering in sense perception itself had led, he believed, to the vain war between philosophies of "Necessity" and of "Liberty"—between a mechanism or materialism that reduced mind to sensation and an idealism like Immanuel Kant's that mistook man's formative consciousness for a power of will essentially free of sensory experience.

Hazlitt also came to oppose, then, the transcendentalism that Coleridge introduced from Germany. As is clear from a *Prospectus* (1809) for his projected history of English philosophy, Hazlitt saw himself as a loyal reformer of empiricism, although he admittedly left unresolved the central problem of the degree to which ideas are determined by the mind itself, on the one hand, and by "nature" on the other. In part, it was his belief that this dualism must remain intractable to reason which made him forsake formal analysis for the "familiar style" of his literary journalism. Averse to system and always more concerned with the cultural impact of ideas, he began, after 1812, to turn from an analysis of the formal problem to an exploration of the interaction of mind and world in experience as it is known by the self in life or realized by "genius" in the arts. Still affirming that "the mind is one," he made his theme the "everlasting contradiction" of man's nature—the "action and reaction" between the mind and the passional self as dialectical functions of the same unity of consciousness.

From his awareness of this conflict in consciousness Hazlitt forged no metaphysic of his own beyond a vague vitalist belief that "the spirit of life and motion" gave the mind a radical "sympathy" with the physical world. In religion he seems to have remained a modest agnostic, certain only that God is intellectually unknowable. Hazlitt thought that only in the aesthetic mode of imagination could the mind transcend experience, and even then it could attain to no intuition beyond "the soul of nature." The insistence that "passion" is the source both of man's freedom and of his bondage—a bondage to individual "character" that nonetheless implies the freedom of the self to sympathize with other selfhood—underlies Hazlitt's polemic on all fronts; it links his criticism of Thomas Robert Malthus and the utilitarians to his aesthetic theory that organic particularity is the basis of value in the arts.

In the England of 1830, when Hazlitt died impoverished in London, a humanism so darkly paradoxical found little favor; but his powers as a thinker have been increasingly recognized, and he appears today as the versatile Montaigne of his age, often prefiguring in his essays the dynamicist philosophies of Friedrich Nietzsche, Henri Bergson, William James, and Sigmund Freud.

HEAVEN AND HELL, DOCTRINES OF

One of the most basic and existentially engaging of all questions has to do with the possibilities for human happiness and fulfillment on the one hand, and misery and loss on the other. Christian theology has returned the striking answer that the possibilities are truly extreme. According to Christian theology, the world is such that humans can experience perfect happiness, delight, and satisfaction, and do so forever. Indeed, that is just what human beings were created for: an eternal relationship with God that will fulfill humankind's best potentialities and aspirations. But the flip side of this is also possible—namely, that people may fail to achieve this relationship with God and thereby come to utter ruin and misery, a condition that is also believed to be eternal.

So understood, heaven and hell have provided an important moral source for European culture for the better part of two millennia. Not only have they served as moral sanctions that assure people that they are ultimately accountable for their actions, but heaven and hell also have been central to the majestic vision of life and its meaning that flows from belief in a God of perfect character and infinite power.

The fundamental logic of these beliefs is not unique to Christianity and European culture—it is common to Judaism and Islam as well. Of course the details differ in important respects, especially with respect to the crucial issue of the conditions for achieving heaven. In other

words, one's beliefs about the nature and conditions of salvation will be closely connected to one's conception of heaven and hell. But the point for emphasis is that belief in heaven and hell are not peripheral to theology, but are integral to traditional theistic faith, whether Jewish, Christian, or Muslim.

HISTORICAL DEVELOPMENTS OF THE DOCTRINES

Belief in an afterlife is either absent or ambiguous in early Jewish scripture. And even where that belief occurs, it is not always clear that there is a distinction between the fate of the righteous and that of the wicked. *Sheol*, the place of the dead, was conceived to be a place of shadowy existence without clear moral distinctions. A more developed view of the afterlife grew out the Jewish understanding of their covenant with God. While the possibility of punishment for disobedience to the covenant was always recognized, such punishment was understood as confined to this world. Increasing awareness of the injustices of this world led to calls for moral distinctions in the afterlife that would rectify the wrongs of this life, of which the book of Job is perhaps the most famous example. Belief in a double resurrection—of the wicked as well as the righteous, after which the wicked will be punished—emerged later in some Jewish scriptural texts. In extrabiblical literature, heaven and hell have been matters of considerable speculation among rabbis during both the time before the rise of Christianity and Islam, and after.

In the New Testament scriptures there is also significant diversity, and some texts appear to teach that the wicked will be annihilated whereas others appear to teach that all will eventually be reconciled to God. The view that came to predominate in Christian theology—also based on numerous New Testament texts—is that all will be resurrected, but that the wicked, perhaps constituting the majority of humanity, will be banished from the presence of God and forever lost in the misery of hell.

Many notable traditional theologians have conceived of hell as an eternal punishment that is justly imposed on sinners. In the Christian tradition, Augustine, Aquinas, Anselm, and Jonathan Edwards are among those who have formulated influential arguments in favor of this conception of hell. Anselm formulated his version of this argument in his famous account of the purpose of the atonement of Christ. People owe God total and perfect honor, Anselm argued, so any sin against him puts them in infinite debt to him that accordingly deserves infinite punishment. Edwards developed a similar argument by appealing to God's infinite nature. Because God is infinite in his loveliness, honor, and authority, Edward's believes that a person's obligation to love and honor God is likewise infinite. To fail in this obligation is to merit infinite consequences. Moreover, traditional theologians typically held that repentance after death is impossible, and consequently, no one may escape from hell.

In elaborating the punishment view of hell, traditional theologians often distinguished between the "pains of sense" and the "pain of loss." The former of these was typically understood to include literal fire of agonizing intensity, whereas the latter emphasized the unhappiness that naturally results from being separated from God, the true source of all joy and happiness. This picture of hell, along with its corresponding vision of heaven as a place of unbounded delight, has not only haunted the popular imagination but has also been a powerful source of inspiration for classic works of art, both visual and literary.

Despite its important role in both theology and the broader culture, belief in heaven and hell has been in decline in the European and North American world ever since the onset of modernity. The reasons for this decline are complex and are no doubt related to the more general defection from religious belief during this same period. The doctrine of hell, in particular, has lost credibility among believers as well as unbelievers largely because many see it as morally implausible.

CONTEMPORARY ACCOUNTS OF THE DOCTRINE

Both heaven and hell, however, have received renewed attention from contemporary philosophers as part of the revival of interest in philosophy of religion. A number of philosophers have moved beyond issues germane to generic theism to explore issues generated by distinctively Christian belief, including Trinity, incarnation, atonement, and the nature of salvation. Heaven and hell are closely connected to these beliefs, especially those pertaining to salvation. Heaven and hell have also played an important role in discussion of the perennial problem of evil and the project of theodicy. Whereas hell is typically seen as a particularly difficult aspect of the problem because it involves the prospect of eternal recalcitrant evil, heaven is often invoked as an essential component of a satisfactory theodicy. Only the hope of eternal life, it is argued, provides adequate grounds to believe the horrific tragedies of this life may be fully healed and redeemed.

Much of the contemporary discussion of hell has centered on the traditional arguments defending the claim that eternal torment is the just punishment for

human sin. Among those who have subjected these arguments to searching critical scrutiny are Marilyn Adams, Jonathan Kvanvig, and Charles Seymour. This critique begins by contesting the claim that human sin could ever be infinitely serious. Even the most notorious of sinners, such as Hitler, have done only finite evil and caused finite harm, however enormous it is. Next, it is contended that a just punishment should fit the crime. Thus, if God is perfectly just, he cannot punish human sin with infinite punishment. So eternal hell cannot be defended as a just punishment for sins committed in this life. There is a general consensus among contemporary philosophers that this critique is sound, so those who affirm the doctrine of eternal hell have turned to other arguments to make moral sense of it.

The most common strategy is to appeal to libertarian freedom to show how eternal hell can be compatible with God's perfect love and power. That is, it is contended that people have the freedom to reject God, even to the point of being forever separated from him. C. S. Lewis famously summed up the essence of this view in his remark that the doors of hell are locked from the inside. In the same vein, Richard Swinburne has defended the doctrine of hell on the grounds that people may, over time, form the sort of character that can no longer choose God and the good. Those who take this position thus typically affirm the pain of loss, but downplay or deny the pains of sense.

Kvanvig (1993) has defended a variation on this position that he calls the "issuant conception of hell." His position is so called because he believes the doctrine of hell should issue from the same character of God as the doctrine of heaven—namely, his love. It is a mistake, he thinks, to stress love only with reference to heaven, while emphasizing justice in connection with hell. The final choice everyone faces, according to Kvanvig, is either a relationship with God or annihilation, for to choose to live independently of God is in fact to choose annihilation, because living independently of God is actually impossible. Of course, God prefers that all persons accept his love, but he respects the freedom of those who reject a relationship with him.

However, not all who reject God choose annihilation in a clear and settled way. It is precisely because of his love that he allows them to remain in existence. Kvanvig's view is accordingly a "composite" view because it allows for both eternal separation as well as annihilation. God need not force people to choose either a relationship with him or extinction, so this allows the option of everlasting separation from him.

Seymour has focused on human choice in developing a defense of eternal hell that he calls "the freedom view." His fundamental definition of hell is that it is "an eternal existence, all of whose moments are on the whole bad" (Swinburne 1983). For this to be true of hell, he thinks it is not enough for hell to have the pain of loss—it must also include pains of sense. His appeal to freedom is crucial for he rejects the traditional arguments for the claim that sins committed in this life could be sufficiently serious to warrant eternal punishment. Rather, it is the continuing choice to sin that keeps sinners in the perpetual pains of hell.

Seymour believes that sinners can in principle repent and would be accepted by God if they did, so if they remain in hell it is due to their choice to persist in sin.

CONTEMPORARY CHALLENGES TO HEAVEN AND HELL

A growing number of Christian philosophers are challenging the doctrine of eternal hell in favor of a doctrine of universal salvation. Some Muslim thinkers have also advanced the speculation that all may be saved in the end. Not surprisingly, Christian philosophers who challenge eternal hell typically focus on libertarian freedom and the crucial role it plays in the contemporary defense of the doctrine.

Thomas Talbott (2003) has mounted a sustained attack on the doctrine of eternal hell, building his case on both biblical and philosophical grounds. In his biblical arguments, he has attempted to show that the New Testament is best interpreted as affirming that all will eventually be saved. He thereby aims to undermine one of the main pillars of the orthodox view of hell—namely, the contention that scripture requires Christians to believe it. Talbott's philosophical case against eternal hell largely focuses on his claim that the idea of choosing hell is finally incoherent.

His argument for this claim hinges on his account of what is involved in freely choosing an eternal destiny. In short, such a choice must be fully informed, and once the person making the choice gets what he or she wants, then it must be the case that the choice can never be regretted. This means that the person must be free from ignorance and illusion both in the initial choice as well as later. One must fully understand what has been chosen while freely persisting in that choice.

Given these conditions, Talbott thinks there is an obvious and important asymmetry between choosing fellowship with God as an eternal destiny, on the one hand,

and choosing hell as an eternal destiny on the other. Whereas the first of these obviously is possible, the latter is not. The reason for this is because there is no intelligible motive for choosing hell if one is free of ignorance and illusion. One may temporarily choose evil under the illusion that so choosing will make one happy. But God will eventually shatter this illusion by making one ever more miserable until the point is reached that one must repent and turn to God. Thus, Talbott affirms the view that universalism is necessarily true, in contrast to the more common claims that universalism is possibly true or probably true.

Marilyn Adams has also criticized the reliance on libertarian freedom in traditional theodicy, contending that its proponents exaggerate the dignity of human nature as something so sacrosanct that not even God may legitimately interfere with it. She sees this tendency particularly in the doctrine of hell, especially in the mild versions, which hold that hell is simply the natural consequence of freely choosing to reject God and the love he offers. Adams complains that advocates of mild hell tend to assume that God and human adults are moral peers in their insistence that they have the right to resist God and choose evil instead. As she sees it, this is not the appropriate sort of respect for God to pay to the likes of humans.

Indeed, the deeper difficulty here is that free will approaches underestimate what she calls the "size gap" between Divine and created persons. Whereas free will approaches picture the relationship between God and human persons with the analogy of parents and adolescent or adult children, Adams thinks it is better modeled by the relationship between a mother and an infant or a toddler. In the latter relationship, there is little if any sense that the child is free and responsible and that it would be wrong to interfere with his choices. This nicely serves Adams's view that God can save everyone in the end, and relieves her of the worry of how God may accomplish this without violating human freedom. If God needs to causally determine some things in order to prevent the everlasting ruin of some of his children, this should not be seen as an insult to our dignity.

The philosophical credibility of the doctrine of hell will largely depend on one's judgments about the nature and value of freedom as well as one's views of moral psychology. Those who disagree with Adams will argue that freedom is of sufficient value itself—or is the means to other goods of sufficient value—and that God will not override it to save us. In a similar vein, Talbott's critics, including the present writer, have argued that there are,

contrary to his claims, intelligible motives for the choice of eternal damnation. Indeed, an essential component of freedom is people's ability to deceive themselves and turn away from the truth. If so, then God may not be able to shatter people's illusions without destroying their freedom.

Whereas the choice of heaven is easier to grasp from the standpoint of moral psychology because it is the choice of true happiness and fulfillment, some have argued that the notion of eternal joy is a dubious notion. Bernard Williams (1993) has made the case that the notion of eternal joy is incoherent because any life of endless duration would inevitably become boring, no matter how delightful the experiences it offered. Defenders of heaven have responded to this challenge in various ways, depending on how they conceive of the life everlasting. Two broadly different accounts of heaven have been prominent in the Christian tradition. On one end of the spectrum is the theocentric vision, which emphasizes the beatific vision as a timeless experience of contemplating the infinitely fascinating reality of God in all his aspects. On the other end of the spectrum is the anthropocentric view, which pictures heaven in terms familiar to this life, purged of course of the evil and suffering that currently mar human happiness.

However these debates continue and whatever resolutions may be achieved, it is apparent the renewed interest in heaven and hell brings into vivid focus some of the most profound issues that animate the philosophical enterprise. Not only the nature and ground of people's moral commitments, but their understanding of the meaning of their lives and their various configurations of joy and sorrow, hinge on what is believed about heaven and hell.

HEBBEL, CHRISTIAN FRIEDRICH
(1813–1863)

Christian Friedrich Hebbel, the German poet and playwright, was born in Wesselburen in the duchy of Holstein and died in Vienna. His father, an impoverished bricklayer who became destitute as a result of having guaranteed a loan that was defaulted, hated this son who showed no aptitude for earning a living. The boy's mother was more indulgent and protected him from the brutality of the father. It was thus possible for young Hebbel to keep alive his consuming passion for learning. At the age of fourteen he was employed as a clerk by a parish official named Mohr, who allowed him to use his library. Mohr treated Hebbel as a common servant, however, and for this Hebbel never forgave him.

Through the good offices of Amalie Schoppe, the editor of a popular magazine, Hebbel received enough money to go to Hamburg in order to try to complete his fragmentary education. There he met Elise Lensing, a seamstress ten years his senior who cherished an abiding love for him; over the years she gave him clothes, lodging, money, and two sons, both of whom died young. Hebbel, who was ridden by his demon to acquire learning and develop himself as a writer, refused to marry Elise. Instead, he went on to study at the universities of Heidelberg and Munich. In the late winter of 1839, he made the arduous trip from Munich back to Hamburg on foot. In the same year he completed his first play, *Judith,* which he cited as his chief accomplishment when he applied for a travel stipend to King Christian VIII of Denmark. The king granted the stipend, and Hebbel went to Paris and from there to Rome. Because his resources were dwindling, he struck out for Germany by way of Vienna, where he met the talented actress Christine Enghaus, to whom he became engaged after three months. Whether or not Hebbel was largely influenced in this decision by the prospect of financial and social security, the marriage was a happy one and enabled Hebbel to take a place of honor in artistic and intellectual circles. His early death must be attributed in large measure to the hardships he had endured in order to realize his genius.

With the desperate seriousness of the self-educated man, Hebbel dedicated himself to presenting in artistic form his solution, sometimes characterized as "pantragic," of what he considered the ultimate philosophical problem, the incomprehensible escape of the individual from the Absolute or Idea, man's freedom in relation to God.

In Hebbel's dualism individual forms exist only by virtue of having differentiated themselves from the Absolute. Their struggle to maintain themselves as separate entities is a rebellion, the primeval sin of individuation. The sinfulness of the individual consists merely in the fact that he exists, and it is in no way dependent upon the nature or direction of his individual will. For his sinfulness the individual must be punished; he will have to submerge his particular being in the undifferentiated whole. The more splendid, vigorous, and powerful he is, the greater is the threat he poses to the Absolute and the more tragic is the struggle, which can end in only one way. There is only one necessity—that the Absolute maintain itself. However, although the existence of individual forms threatens the Whole, it is precisely the process of individuation that gives life to this closed system. If it were not for the mysterious freedom of the individual forms, the Absolute would become rigid and lifeless. The total life process is dependent on the metabolic flow of individual forms, which may appear at one point; may be submerged forever; or may, whether they retain their identities or their elements enter into new combinations, reappear at another point only to lose individuality again in the never-ending compact flux of history, compact because nothing new enters the universe and nothing leaves it.

It is the common task of philosophy and art, particularly drama and more specifically Hebbel's drama, to describe and make understandable this supreme philosophical problem. Philosophy must fail in its part of the common task, to determine the original cause of individuation, because this ultimate cause is unfathomable. But

the drama is not concerned with this question. It accepts individuation as the prime condition of life and presents the tragic struggle of the All and the one in a way that makes it comprehensible to aesthetic intuition. In the drama the metaphysical breach is closed; the defeat of the tragic hero mirrors the cosmic process.

In order to achieve his aim, Hebbel sets the action of his plays at critical times in history, for at such times the relation of the individual to the Whole is most poignantly manifested. In some plays—for example, *Judith, Maria Magdalene, Herodes und Mariamne*—the prevailing form of the Idea is shown to be on the verge of breaking up. In others—*Genoveva, Agnes Bernauer, Gyges und sein Ring*—the prevailing form of the Idea, although threatened, affirms itself and persists. In both instances, whether the individual is opposed to the Idea or is an instrument of it, the end is tragic, and all individuals meet the same fate—they are crushed and absorbed by the Whole.

Hebbel always insisted that despite obvious parallels he had evolved his metaphysical truths independently of the romantic nature philosophy of German idealism. For a long time, in the absence of specific evidence to the contrary, many literary historians accepted this assertion. Recent research, however, has shown that Hebbel had early steeped himself in certain writings of Gotthilf Heinrich von Schubert, the natural scientist and philosopher, and Ludwig Feuerbach. The ideas he found there he experienced with such intensity that he incorporated them into his own psychic structure although his pride as a self-taught man did not allow him to acknowledge his debt.

HEDONISM

Hedonism (Greek, ἡδονή, "pleasure") is a term that refers to either of two distinct but related views, one a thesis in normative ethics, the other a generalization about human psychology.

ETHICAL HEDONISM

The first view, called "ethical hedonism," affirms that only pleasure is intrinsically desirable and that only displeasure (or pain) is intrinsically undesirable. More fully stated, it is the thesis that only pleasant states of mind are desirable in themselves; that only unpleasant states of mind are undesirable in themselves; and that one state of affairs is more desirable in itself than another state of affairs if and only if it contains more (in some sense) pleasant states of mind than the other (the quantity of value in a state of affairs being measured by the quantity of pleasure in it).

This thesis has been defended by a distinguished line of philosophers from the early Greeks to the present, including Aristippus, Epicurus, John Locke, Thomas Hobbes, David Hume, Jeremy Bentham, J. S. Mill, and Henry Sidgwick. Other philosophers have thought that happiness is the only thing that is intrinsically desirable; and if saying that a man is happy at a given time is the same as saying that he is experiencing pleasure at the time, then their names could be added to this roster. Many philosophers, however, have thought that happiness is different from pleasure, and there has been disagreement and confusion about what "happy" and "pleasant" mean.

The hedonist thesis was a part of traditional utilitarianism, as represented, for instance, by Bentham and Mill, with their "greatest happiness principle." These writers

combined the generic principle of utilitarianism—namely, that an act is morally right if performing it would produce, or could reasonably be expected by the agent to produce, at least as much intrinsic goodness in the world as any other act the agent could perform at the time—with the thesis of hedonism about what is intrinsically good. Traditional utilitarianism is thus a species of utilitarianism that is defined as asserting just the "generic thesis"; other kinds of utilitarianism (for example, that of G. E. Moore) reject hedonism. Unlike utilitarianism, ethical hedonism is not at all a proposal about which acts are morally right; it is only an affirmation about which states of affairs are intrinsically good or desirable.

What is meant by saying that a state of affairs is intrinsically desirable, as opposed to simply desirable, is that it is desirable, good, worthwhile, worthy of choice, when *taken by itself,* viewed abstractly, and in particular considered without reference to consequences. Many things (for example, a visit to the dentist) are worthwhile in view of their consequences, which nobody would say are intrinsically desirable. The hedonist does not deny that other things are desirable; he denies only that they are intrinsically worthwhile. He agrees that something can be desirable instrumentally—as a means to an end—even when it is not intrinsically desirable. (A thing can, of course, be both intrinsically and instrumentally desirable: pleasant experiences can be good in themselves and also instrumentally good, if, for example, they are relaxing and enable one to work better on the following day.) He does add, however, that something is instrumentally desirable only to the extent that it is a means to later pleasure, since a thing can be instrumentally desirable only if it is a means to attaining the intrinsically desirable.

When consequences are taken into account, the hedonist's view about what states of affairs are desirable is apt to differ very little from the view of the nonhedonist. In fact, if one reads various writers' accounts of the "good life," one finds that they are pretty much alike, whether the author professes to be a hedonist or a nonhedonist. Thus, Epicurus, for instance, advocated a simple life devoted to philosophical reflection, with a diet of bread, cheese, and milk, and with its tranquility unendangered by surging bodily passions. And J. S. Mill affirmed that having a good character is "part" of a person's happiness, so that according to him, character is intrinsically good after all by virtue of the fact that it is a part of happiness. Some hedonists, however, have advocated a more distinctive ideal for living: the Greek Aristippus thought that physical enjoyments are the richest source of pleasure and should be fully cultivated.

The meaning of the hedonist's thesis, of course, depends on what is meant by "pleasure." It is true that the associations of the word *pleasure* are such that if an English-speaking person says he favors a "life of pleasure," he is naturally taken to be advocating a life dedicated to the sensory enjoyments—wine, women, and song. Hedonists have not intended the term to carry this implication, however, and the strict meaning of the term does not. It is perfectly correct for a student to say, "I got a great deal of pleasure out of writing that paper." To say that an experience is pleasant (for example, "a pleasant evening"), is, in a strict sense, simply to say that one enjoyed it, or that one enjoyed himself during it. Thus, hedonism is done least injustice if it is taken as simply saying that an intrinsically desirable state of affairs is always a state of consciousness in which the person is enjoying himself in one way or another. Since reflection, reading, and creation are activities that people often enjoy, the hedonist means to include these activities, or states of mind, in the category of "pleasures," just as much as the so-called passive enjoyments, such as eating, drinking, and sex.

Hedonists have often disagreed about the proper analysis of "pleasure" or "enjoyment." Epicurus, for instance, said that pleasure is simply the absence of painful want or longing. Moreover, since the early 1900s, psychologists have also disagreed substantially on this point, some holding that pleasure is a special kind of sensation, others that it is a quality of certain kinds of feeling, and so forth. In recent years a considerable body of philosophical literature has accumulated on the subject of the analysis of "pleasant." While a generally accepted conclusion has not yet been reached, it is plausible to say that a person is enjoying himself (that is, his state of mind is pleasant) if and only if at the time he likes his experience or activity *for itself,* in the sense that, aside from moral considerations or considerations of consequences or of the possibility that something he likes even better could be substituted, he does not wish to change it and in fact would wish to avoid changing it if such a change impended. If this interpretation is accepted, the thesis of hedonism becomes the affirmation that a state of affairs is intrinsically desirable if and only if it is, or contains, an activity or experience which, at the time, the person likes for itself; and one state of affairs is more desirable intrinsically than another if it is, or contains, an experience or activity which, at the time, is liked better for itself. States of affairs which the hedonist thesis apparently rules as being only instrumentally rather than intrinsically desirable, from the point of view of a particular person, are such things as fame after his death and states of knowl-

edge and character (since the latter are not experiences or activities at all, but capacities or dispositions).

PSYCHOLOGICAL HEDONISM

Many (but not all) ethical hedonists have supported their ethical affirmation of hedonism by an appeal to a psychological doctrine known as "psychological hedonism." This theory historically has taken rather different forms; the significance of each for ethical hedonism must be assessed separately. The element common to them is the assertion that actions or desires are determined by pleasures or displeasures, whether prospective, actual, or past. The importance of the theory, however, transcends its relation to ethical hedonism: certain psychologists today are inclined to accept some form of it as a correct account of human motivation.

GOAL IS PLEASURE. The first and historically most important form of the theory of psychological hedonism may be called the "goal is pleasure" theory, according to which a person is motivated to produce one state of affairs in preference to another if and only if he thinks it will be more pleasant, or less unpleasant, for himself. This thesis, of course, is not intended to be a generalization about simple reflex or habitual behavior. The "belief" in question need not be explicit in the sense of having been verbally formulated before action; it may be an unformulated assumption. The theory is not simply about purposive action; it is also a theory about desire: a person is asserted to want one thing more than another if and only if he thinks its occurrence will be more pleasant for him.

The relation of this form of psychological hedonism to ethical hedonism may be explained by the following argument, often used by ethical hedonists. It is assumed as a major premise that something is intrinsically desirable if and only if it is something that people desire for itself. The minor premise is the "goal is pleasure" theory—namely, that people want only pleasure for itself. It is therefore concluded that pleasure is the only thing that is intrinsically desirable. The third-century writer Diogenes Laërtius said of Epicurus that "as proof that pleasure is the end he adduces the fact that living things, so soon as they are born, are well content with pleasure and are at enmity with pain, by the prompting of nature and apart from reason."

Contemporary ethical hedonists seldom appeal to the "goal is pleasure" theory to support their views, partly because the theory seems incompatible with obvious facts. For instance, political figures seem to take a strong interest in securing favorable notice in books on history

that will appear after their death. This motivation obviously does not depend on the belief that the future event will be pleasant for them personally. Again, individuals often appear to risk personal loss for some moral principle or in order not to forsake a friend (this is illustrated by Dean Acheson's famous remark, "I will never turn my back on Alger Hiss"). Adherents of the "goal is pleasure" theory tend to explain such facts by saying that the individual would be unhappy in the future—and knows he would be—if he failed to live by his principle or forsook his friend; hence, the action is motivated by a calculation of personal pleasure after all. What the theory must hold, though, is that a belief to this effect, at least vaguely espoused by the agent, is a necessary condition of the motivation; and this seems implausible. Adherents of the theory may be confusing two things: the agent's belief that a certain future situation will be relatively more pleasant for him, and the agent's thought of that future situation being attractive or repugnant now. A person may say, "I *am unhappy with the idea* of dropping my friendship with *X,* in whose integrity I believe." This statement may be true and also an important clue to understanding his behavior. But this is very different from saying, "I'll continue my friendship with Mr. X *because I think I'll be less happy* if I don't," a kind of statement that would ordinarily be taken as proof that the person did not care about his friend. Adherents of the theory may always argue that the reasoning required by their theory takes place unconsciously, but the postulation of this is ad hoc, the only reason for it being that it saves the theory from conflict with observation.

MOTIVATION BY PLEASANT THOUGHTS. As suggested above, adherents of the "goal is pleasure" form of psychological hedonism sometimes confuse it with a different thesis which we may call the "motivation by pleasant thoughts" theory. This theory is the assertion that a person will choose to do A rather than B or will prefer A to B (whether an action or a situation), if and only if the thought of A (with its expected consequences) is more attractive, or less repugnant, than the thought of B (with its expected consequences). This theory is not obviously false: indeed, as a proposal about preference it could be an analytic proposition that sets forth one test we use to decide whether a person prefers one thing to another. As a proposal about action it is clearly a synthetic proposition. As such, it may not be able to explain the fact (if it is a fact) that sometimes the thought of doing A is not more attractive or less repugnant than the thought of doing B, but the agent simply decides to do A (perhaps he is required to make up his mind between the two).

Even if this form of psychological hedonism is true, however, it gives no support to ethical hedonism, since it sets no restrictions on the *kind* of goal which may be attractive or repulsive to a person. If support of ethical hedonism requires a demonstration that people desire only pleasure, then the present theory does not provide such support. For assuming that desiring a thing *means* finding the idea of it pleasant or attractive, it does not follow that only the idea of pleasure itself is attractive. Hence, it does not follow that only pleasure is desired, and it is therefore no part of the "motivation by pleasant thoughts" theory to assert that only pleasure is desired.

CONDITIONING BY PLEASANT EXPERIENCES. The third form of psychological hedonism, the "conditioning by pleasant experiences" theory, is a theory about the causal conditions of a person's wants or values. Roughly, it asserts that at least one's fundamental values can be correlated with past enjoyments or rewards, that these enjoyments are at least part of the causal explanation of the values, and that a person's values can be controlled by manipulating his enjoyments. If a person values ice cream, it is because in the past he has enjoyed ice cream (and not been made sick by it). The truth of this theory is hardly open to question insofar as it merely affirms that past enjoyments have some influence on likes and values; but its truth can be widely questioned if the theory is claimed to give a complete account of likes and values, which, according to experimental evidence, seem to be influenced by numerous factors. Acceptance of the theory, however, does not commit one to assert that persons desire only pleasure. The theory is consistent with saying that people want and value things such as posthumous fame or being a generous or courageous person. All the theory claims is that *whatever* values one has have been acquired because of past enjoyments or punishments of one sort or another—perhaps the enjoyment of parental praise or the punishment of parental reproaches.

FURTHER ARGUMENTS IN SUPPORT OF ETHICAL HEDONISM

Acceptable psychological theory, as we have seen, does not indicate that people desire only pleasure or things they think will be pleasant for them, or that people prefer *A* to *B* if and only if they think *A* will be more pleasant to them than *B*. Ethical hedonism, therefore, cannot appeal to psychological theory in support of its thesis.

Ethical hedonists sometimes rely on one or more of three other lines of argument in support of their view. The first line of reasoning is simply that ethical hedonism

is an analytic truth that is true by definition. Locke, for instance, defined "good" as that "which is apt to cause or increase pleasure," and Benedict Spinoza defined it as "every kind of pleasure, and all that conduces thereto." The flaw in this contention, however, is that many people have at least thought either that some things other than pleasure are intrinsically good or that some kinds of pleasure are intrinsically bad. In the face of this, it is not easily claimed that "intrinsically good" simply *means* pleasant.

The second line of reasoning, which is more substantial, starts from the premise that it is usually agreed that at least some forms of pleasure are intrinsically good and proceeds by contesting the claim that anything else is intrinsically good. If the claims on behalf of other things are successfully refuted, it is concluded that ethical hedonism is left holding the field. The assessment of this line of reasoning is obviously a complex matter, since it presupposes conclusions about how to adjudicate ethical disputes. There is space here only to mention some examples frequently debated by hedonists and their opponents.

Critics of hedonism often urge that some kinds of pleasure are intrinsically bad—for example, malicious pleasure in the suffering of another person. And, they say, some unpleasant experiences are intrinsically good—for example, the punishment of one who has been cruel to another. Furthermore, it may be claimed that various things in addition to pleasure are intrinsically good: knowledge, certain traits of character, kindly or courageous deeds, life itself (at least the survival of mind with memory) even if it is not positively pleasant, being the object of respect or love on the part of other persons, being remembered after death, achievement, whether intellectual or aesthetic. Anyone who accepts any of these points cannot, strictly speaking, be an ethical hedonist.

A third, more practical, line of reasoning by hedonists has been the contention that their view makes possible scientific and objective evaluations of social planning which other views do not. For instance, if the question arises whether a certain tariff should be raised, the hedonist may say that his theory enables us (in principle at least) to decide objectively whether the tariff will do good, for we have only to decide whether a greater net sum of pleasures will be produced with or without the tariff.

This conception has come in for a great deal of criticism in recent decades, some of it unfair. One criticism, which appears repeatedly in the writings of economists, makes the point that we can know nothing about the

mental states of other persons, since there is no way of observing them directly; hence, the whole idea that theoretically an individual could determine the effects of a tariff on the happiness of anyone but himself is absurd. This criticism probably goes too far, but questions concerning other minds cannot be evaluated here. A more forcible objection is the following. If "is pleasant" is analyzed as meaning "is an experience liked at the time by the person, for itself," then presumably *A*'s experience can be said to be pleasanter than *B*'s, if *A* likes his experience more intensely. In theory, then, we might show that a tariff on bicycles would do more harm than good, if we could match every pleasant experience it would produce with an experience at least equally pleasant (one liked at least equally as intensely) and of at least equal duration, which the tariff prevents, *and* if in addition it costs us pleasures that are not matched with those it produces, or if some of the pleasures it costs us are more intense than the matching pleasures it produces, and the reverse is not the case. So far a decision could be reached, in principle at least. But it is possible that things might be too complex to permit such a simple matching. It might be that we would be forced to compare a more intense but brief pleasure with a less intense pleasure of greater duration; and it is not clear what would be meant by saying that one such experience "contains more pleasure" than the other. Thus, it is not clear that in principle the comparison could be made, except in special favorable situations. In this respect, however, the hedonist seems correct on one point: there is no other theory of the intrinsically desirable which makes such evaluations more scientific or more objective.

HEGEL, GEORG WILHELM FRIEDRICH
(1770–1831)

Georg Wilhelm Friedrich Hegel, the German idealist philosopher, was born at Stuttgart and entered the theological seminary at the University of Tübingen in 1788. Among his fellow students were Friedrich von Schelling and the poet Friedrich Hölderlin. After graduating he became, in 1793, a resident tutor in the home of an aristocratic family at Bern, and in 1796 he took a similar post in Frankfurt. In 1800 he went to Jena, where Schelling had succeeded Johann Gottlieb Fichte as professor of philosophy and was developing an idealist philosophy of nature and metaphysics. Having been accepted as a teacher at Jena on the strength of his dissertation, *De Orbitis Planetarum* (1801), Hegel collaborated with Schelling in editing the philosophical journal *Kritisches Journal der Philosophie* and published his first book, *Differenz des Fichte'schen und Schelling'schen Systems der Philosophie* (1801). Notable articles by Hegel in the *Kritisches Journal* were "Glauben und Wissen" (1802) and "Über die wissenschaftlichen Behandlungsarten des Naturrechts" (1802–1803). At Jena, Hegel wrote his first major work, *Phänomenologie des Geistes* (*Phenomenology of Mind*, Würzburg and Bamberg, 1807). Completed about the time of Napoleon Bonaparte's victory over the Prussians at Jena in 1806, it was not published until 1807, after Hegel had left Jena to become editor of a daily paper at Bamberg in Bavaria.

In 1808, Hegel was appointed headmaster of a school in Nuremberg, a post he held until 1816. While at Nuremberg, Hegel published his *Wissenschaft der Logik* (*Science of Logic*)—Vol. I, *Die objective Logik* (2 vols., Nuremberg, 1812–1813, and Vol. II, *Die subjective Logik oder Lehre vom Begriff* (Nuremberg, 1816). From 1816 to 1818, Hegel was professor of philosophy at Heidelberg. There he published *Encyklopädie der philosophischen Wissenschaften im Grundrisse* (*Encyclopedia of the Philosophical Sciences in Outline*) in 1817. In 1818, Hegel was appointed professor at the University of Berlin, where he became famous and influential. *Naturrecht und Staatswissenschaft im Grundrisse* (*Philosophy of Right*) appeared there in 1821; a second edition, edited by E. Gans as *Grundlinien der Philosophie des Rechts*, was published in Berlin in 1833. In 1827 a second, much enlarged edition of the *Encyclopedia* appeared.

Hegel died during a cholera epidemic in 1831. After his death a group of his friends compiled an edition of his works in eighteen volumes (Berlin, 1832–1840). Several of Hegel's works were published for the first time in this edition: *Vorlesungen über die Aesthetik* (Lectures on aesthetics; translated as *The Philosophy of Fine Art*, edited by H. G. Hotho, 2 vols., 1835–1838); *Vorlesungen über die Philosophie der Geschichte* (*Lectures on the Philosophy of History*, edited by E. Gans, 1837); *Vorlesungen über die Philosophie der Religion* (*Lectures on the Philosophy of Religion*, edited by Philipp Marheineke, 2 vols., 1832); and *Vorlesungen über die Geschichte der Philosophie* (*Lectures on the History of Philosophy*, edited by K. L. Michelet, 2 vols., 1833–1836). This edition also contains notes taken by students of Hegel's comments on the *Encyclopedia* and on *Philosophy of Right*, which he was in the habit of using as textbooks.

In his biography, *Georg Wilhelm Friedrich Hegels Leben* (Berlin, 1844), Karl Rosenkranz referred to and quoted from the manuscripts of works written by Hegel prior to the publication of the *Phenomenology of Mind*. Not all the manuscripts known to Rosenkranz have survived, but toward the end of the nineteenth century Wilhelm Dilthey made a study of those that have and published an account and discussion of them in the *Proceedings of the Berlin Academy* in 1905. This has since received the title *Die Jugendgeschichte Hegels* and is reprinted in the fourth volume of Dilthey's collected works. Dilthey's pupil and editor, Herman Nohl, then published, under the title *Hegels theologische Jugendschriften*, the text of a great part of what Hegel had written while he was at Bern and Frankfurt. The chief of the writings unpublished during Hegel's lifetime are the essay

"Das Leben Jesu" ("Life of Jesus," 1795), *Die Positivität der christlichen Religion* (*The Positivity of the Christian Religion*, 1796), and *Der Geist des Christentums und sein Schicksal* (*Spirit of Christianity and Its Destiny*, 1799). In 1915, Hans Ehrenberg and Herbert Link published, under the title *Hegels erstes System* (Heidelberg, 1915), an early version, written at Jena but never published by Hegel, of what later became the system sketched in the *Encyclopedia*. Since then Georg Lasson (*Hegels Jenenser Logik*, Leipzig, 1923) and Johannes Hoffmeister (*Hegels Jenenser Realphilosophie*, 2 vols., Leipzig, 1932) have published still other writings that Hegel had left unpublished. Thus, much more is now known about Hegel's writings and philosophical development than was generally known in the nineteenth century.

MAIN THEMES OF HEGEL'S PHILOSOPHY

MIND. In the preface to the *Phenomenology*, Hegel wrote that only mind (*Geist*) is real, and he constantly reiterated this view. (I have translated Hegel's *Geist* as "mind," in agreement with William Wallace's view that "to average English ears the word Spiritual would carry us over the medium line into the proper land of religiosity"—*Hegel's Philosophy of Mind*, Oxford, 1894, p. 1.) Thus, he must be regarded as a philosophical idealist. He wrote rather slightingly of George Berkeley, however, whose works he does not seem to have studied closely, and is sometimes described as an objective idealist in order to absolve him from suspicion of the subjective idealism that has often been attributed to Berkeley. Hegel's idealism presupposed the work of Immanuel Kant and was influenced by Fichte and Schelling, but his early unpublished writings show that he had preoccupations of his own, independent of his famous German predecessors.

When Hegel said that only mind is real, he did not mean that material things do not exist and that only minds do. Mind was not, in Hegel's view, a plurality of immaterial substances but a system of individuals actively developing their potentialities by embodying them in increasingly complex forms. A fundamental feature of mind, according to Hegel, is freedom, and nothing that is partial or finite can be wholly free. The mind that is the only reality is therefore infinite. Furthermore, no one is free unless he is conscious of what he is doing, and infinite mind is therefore self-conscious mind. Artists and statesmen, merchants and saints, all busy themselves with their more or less partial tasks without necessarily concerning themselves with what it is that they are doing. According to Hegel, it is the function of the philosopher

to make men conscious of what art and politics, commerce and religion, are, so that mind can exert itself to its utmost range and thus become absolute. Like Pythagoras, Plotinus, and Benedict de Spinoza, Hegel was a philosopher who held that philosophy is an activity that purifies and frees the mind.

DIALECTIC. Hegel is, of course, famous for his dialectical method, but it is enormously difficult to explain this in a brief compass. It should first be noted that Hegel set out his systematic writings in dialectical triads comprising a thesis, antithesis, and synthesis. Thus, he divided his *Encyclopedia*, in which he expounded his system as a whole, into three fundamental division sections—"Logic," "Philosophy of Nature," and "Philosophy of Mind." In the first he expounded the categories as developing forms of thought; in the second, he said "the Idea" is considered in its "otherness" (*Anderssein*) or externality; and in the third, mind is considered as existing "for itself," as conscious of itself and of the institutions it has given rise to. Within these main divisions there are further triadic subdivisions, although a very large number of subdivisions are not of this nature. It is therefore clear that Hegel himself regarded his whole work as a dialectical construction, with thought and nature as opposites united in mind and society, in the artistic and religious products of man, and, ultimately, in the activity of philosophical self-consciousness.

Hegel's system, then, has a dialectical structure, but what is his dialectical method? Hegel, like Spinoza, held that error resides in incompleteness and abstraction, but, unlike Spinoza, he held that the incompleteness and abstraction can be recognized by the contradictions they generate. It is the business of the philosopher, he held, to bring out the contradictions latent in partial or abstract views and to emphasize and elaborate them in such a way that less partial and less abstract views can be constructed that nevertheless retain in themselves what there was of truth in the original views. The same method is to be brought to bear on the less partial and less abstract views in their turn and to be pressed as thoroughly as it can be. This method of pressing and accentuating contradictions is not to be used merely to discard error but also to preserve truth. Because of the happy circumstance that in German *aufheben* means both "to cancel" and "to preserve"—its literal meaning is "to lift up"—Hegel was able to express this aspect of his view with brevity and acuity. The concept or view that is *aufgehoben* is transcended without being wholly discarded. Hegel's *Phenomenology of Mind* was an account of how various human attitudes—reliance on sense experience, the belief in sub-

stance, otherworldliness, strenuous moralism, and so on—all have some point and are yet contradictory, leading to the conclusion that "truth is a bacchanalian revel where not a member is sober," as Hegel put it in the Preface. His *Logic* gave an account of how the categories are related in this way. In his *Lectures on the History of Philosophy* he sought to show that the major philosophical outlooks from that of the Ionians on are, on the one hand, positive contributions that we could not do without and, on the other hand, contradictions that we have to overcome.

HISTORY. Another feature of Hegel's philosophy is its concern with history. Much as Hegel admired Plato's philosophy, he held that it was impossible to be a Platonist in the nineteenth century, when the philosophical context differed so greatly from that of Plato's day. In his *Lectures on the Philosophy of History*, Hegel argued that the history of man in the concrete was as much a progression as the history of his thought. This he deduced from the thesis that mind is of its very nature free. Thus, each historical epoch, according to Hegel, embodied some aspect of or stage in the development of man's free mind, and it would be absurd for an individual to go counter to his time except insofar as he was preparing the way for future epochs. Hegel borrowed this "progressivism," as it may be called, from the philosophers of the Enlightenment. It has greatly influenced Marxism.

CHRISTIANITY. Hegel thought his system provided a defense of Christianity, and both supporters and opponents of his system have taken this view of it. Those known as right Hegelians considered Hegel's apologetic successful, whereas the left Hegelians argued that his Christianity had been only superficial and his Christian terminology a disguise for something very different. In his system Hegel placed philosophy above religion in the dialectical scale, and this may give some support for the interpretations of the left. Yet there is ambiguity in Hegel's view on this, as on other important matters. On one hand, he held that only infinite mind is real; on the other hand, he held that infinite mind cannot be distinct from or beyond the finite and partial. He thought that these views were not incompatible, but it has been argued that the second is a denial of the first and, hence, a denial of any form of theism.

This entry will briefly describe Hegel's early works that were posthumously published in *Hegels theologische Jugendschriften*. It will continue with an account of the *Phenomenology of Mind*, Hegel's first important book,

and conclude with a brief discussion of the Hegelian system based chiefly on the *Encyclopedia*.

EARLY UNPUBLISHED WRITINGS

"LIFE OF JESUS." Even before he wrote his "Life of Jesus," Hegel had written some comments on Christianity in which he criticized it for its belief in the efficacy of prayer and had contrasted it, to its detriment, with the this-worldly, social religion of the Greeks. Jesus, he held, was obscurantist and narrow-minded in comparison with Socrates. In the "Life of Jesus" it almost seems as if Hegel had decided to rewrite the Gospels in the form of a Kantian manifesto. He began by claiming that God is pure reason. He described Jesus as the son of Joseph and Mary. The only miracles Hegel mentioned he interpreted naturalistically, bringing the work to an end with the death and burial of Jesus. The central theme is the conflict between the virtuous Jesus acting dutifully for the sake of the moral law and the Jewish priesthood calling for the meticulous observance of a set of irrational rules said to be commanded by God. Jesus is depicted as saying to the Pharisees, "When you regard your ecclesiastical statutes and positive commands as the supreme law given to mankind, you fail to understand the dignity of man and the power he has of creating out of himself the idea of the divinity and knowledge of his will." This improbable allocution is typical of the way in which this work denudes the Gospel narrative of what is individual and poetical.

THE POSITIVITY OF THE CHRISTIAN RELIGION. The theme of *The Positivity of the Christian Religion*—the place in the Christian religion of the rational, on the one hand, and of the merely factual and historical, on the other—was already raised in the "Life of Jesus." Developing the implications of the then current distinctions between natural law and positive law and between natural religion and positive religion, Hegel argued that the positive element rested on authority and was not wholly based on the dignity of man. In Christianity, according to Hegel, the main positive element was provided by Judaism, a highly authoritarian religion. But Jesus himself brought elements of positivity into the rational morality that it was his prime aim to teach; he could not have obtained a hearing from the Jews of his day if he had not claimed God's authority for his teachings. "Jesus therefore demands attention for his teachings, not because they are adapted to the moral needs of our spirit, but because they are God's will" (*Early Theological Writings*, p. 76). In claiming to be the Messiah, Jesus was using the language his listeners would understand. His followers, from a nat-

ural interest in the details of his life, developed these positive elements into Christianity. They appealed to miracles as proofs of Jesus' divinity and virtue, and instead of revering him for his teaching about virtue, they revered his teaching about virtue because of the miracles he was supposed to have performed.

Hegel asked how it happened that the pagan religion of the Greeks and Romans was overcome by Christianity. His answer was that at the periods of their greatness the Greeks and Romans were free peoples each individual of which regarded his own good as inseparable from the good of his community. When they lost their freedom, they lost the motives that bound them to their fellows; government and authority were now imposed from without, weighing down upon isolated individuals who came to regard their lives as individual possessions to be preserved irrespective of the social whole that alone gave them meaning.

> Thus the despotism of the Roman emperors had chased the human spirit from the earth and spread a misery which compelled men to seek and expect happiness in heaven; robbed of freedom, their spirit, their eternal and absolute element, was forced to take flight to the deity. [The doctrine of] God's objectivity is a counterpart to the corruption and slavery of man. (ibid., pp. 162–163)

THE SPIRIT OF CHRISTIANITY. In *The Spirit of Christianity* Hegel continued and sharpened his attack on Judaism, which he regarded as a religion of domination. He now criticized Kantian ethics as well, however, finding in it elements of the same positivity he had criticized in the Jewish religion and had seen as a contamination in the teachings of Jesus. Kant had contrasted his rational religion with the religion of the Siberian shamans on the ground that these primitive men, as well as some civilized prelates and puritans, irrationally worshiped alien forces that they regarded as exerting domination over men. But according to Hegel, the difference between the believers in these positive creeds and the follower of the religion approved by Kant is "not that the former make themselves slaves, while the latter is free, but that the former have their lord outside themselves, while the latter carries his lord in himself, yet at the same time is his own slave" (ibid., p. 211). Hegel here first used the word *morality* (*Moralität*) as a pejorative description of the Kantian morality, which he now considered to be a submission of man's inclinations, including his impulses and his feelings of love, to a universal reason held to be free from and above all passion. He held that virtue demands more than

this and that in the Sermon on the Mount Jesus made higher demands. "The Sermon does not teach reverence for the laws; on the contrary, it exhibits that which fulfils the law but annuls it as law and so is something higher than obedience to law and makes law superfluous" (ibid., p. 212). Thus, duty takes a lower place than love. "Jesus makes a general demand on his hearers to surrender their rights, to lift themselves above the whole sphere of justice or injustice by love, for in love there vanish not only rights but also the feeling of inequality and the hatred of enemies which this feeling's imperative demand for equality implies" (ibid., p. 218). Hegel here saw in the ethics of the Sermon on the Mount and in the conduct of Jesus something of the "beautiful soul" described by Johann Wolfgang von Goethe in *Wilhelm Meister*. Jesus retained his dignity by refusing to defend himself or to uphold his rights.

Hegel went on to discuss with subtlety the possible consequences for the individual and for other men of resistance to evil, on the one hand, and of withdrawal from conflict, on the other. In this part of the work the beginnings of dialectical method as it was used a few years later in *Phenomenology of Mind* may already be discerned.

PHENOMENOLOGY OF MIND

The *Phenomenology* is the most obscure and the most interesting of Hegel's works. On the title page it is described as a "System of Science, Part I. The Phenomenology of Mind," but this arrangement of Hegel's system was not continued in the *Encyclopedia*, where the section headed "Phenomenology of Mind" is contained in the third part and deals with only some of the topics of the original *Phenomenology*. Hegel put the *Phenomenology* together rather hastily and was uncertain what to call it. Different copies of the first edition have slightly differing titles, and what seems like a new title, "Science of the Experience of Consciousness," is placed after the preface and before the introduction. Insofar as there is a central theme, it consists of an account of the various stages of human consciousness from mere sense awareness to absolute knowledge, but there are many digressions into topics of current interest, such as Goethe's description of the "beautiful soul," the Reign of Terror, and F. J. Gall's phrenology. The difference between the dialectical progression of the *Phenomenology* and of the *Encyclopedia* was cited soon after Hegel's death as evidence of the inadequacy of the dialectical method (C. F. Bachmann, *Über Hegels System und die Nothwendigkeit einer nochmaligen Umgestaltung der Philosophie*, Leipzig, 1833). In the twentieth century Marxists preferred the *Phenomenology* to Hegel's other writings because Karl Marx himself admired it and because of its account of how man develops by transforming the natural world through his labor. Existentialists have preferred it to the later system because of its account of man as maker of himself; no doubt they are also impressed by Hegel's references to death and the fear of death.

The *Phenomenology* begins with a dialectical discussion of sense perception in which it is argued that knowledge of physical things presupposes the view that the physical world consists of forces interacting according to laws. Hegel maintained that knowledge of such a world is really a type of self-knowledge, since in penetrating to the forces behind phenomena we become aware of what we ourselves have devised and put there. "Behind the so-called curtain which is to hide the internal constitution of things, there is nothing to be seen unless *we ourselves* go behind." The physical world of scientific theory presupposes self-conscious beings. When he analyzed self-consciousness, Hegel argued that it presupposed a plurality of living and desiring beings each of whom seeks to subdue the world to his own wishes, to make it part of himself.

MASTER AND SLAVE. No individual will rest satisfied with a conquest that fails to secure the conscious acknowledgment of other men. Hence, there is a struggle for both power and recognition. In this struggle some will take greater risks than their competitors; those who risk the least will become the slaves or bondsmen of those who face death by risking their lives. In order to preserve his life, the slave submits to the master, who regards the slave as nothing but a means to his own designs. The slave is forced to work, whereas the master can enjoy leisure in the knowledge that the slave is reshaping the natural world to provide the products of his labor for the master to consume. Thus, the master's leisure protects him from experience of the negativity of nature, whereas the slave, in struggling with nature's recalcitrance, learns its secrets and puts mind into it. The master, in consuming, destroys; the slave, in working, creates. But the master's consumption depends upon the slave's work and is thus impermanent, whereas the slave's labor passes into things that have a permanent existence. Hegel argued, too, that the slave's work in transforming the natural world is a consequence of his fear of the master, who can kill him. Death is overcome by the works of civilization. The man who risks his life and becomes the first master breaks the bonds of nature and starts the process that will incorporate mind into it.

It is not surprising that this section in the *Phenomenology* has greatly interested Marxists. Both Georg Lukács, in *Der junge Hegel*, and Herbert Marcuse, in *Reason and Revolution* (2nd ed., London and New York, 1955), contrived to discuss it without mentioning Hegel's emphasis on the fear of death. In *Introduction à la lecture de Hegel*, Alexandre Kojève brought out the importance of the fear of death and showed, too, that Hegel was here concerned with the transition from nature to history, from mere life to thought, from animality to freedom.

THE UNHAPPY CONSCIOUSNESS. The next dialectical transition is from mind that is attempting to master nature to mind that seeks freedom and independence in itself, that says, "It is in thinking that I am free because I am not in another but remain completely with myself alone," an attitude exemplified in stoicism. But stoicism passes over into skepticism, for the stoic finds freedom in himself as a rational, thinking being, whereas the skeptic, pushing freedom still further, uses thought to dissipate its own categories. This, according to Hegel, was the state of mind that prevailed when the Roman Empire was dissolving. Christianity was an attempt on the part of men in intellectual despair to find stability in an eternal and infinite God.

Hegel called this frame of mind the unhappy consciousness. The individual is divided within himself, conscious of his own isolation, attributing all that is good to the activity of God. What Hegel said here was elaborated from a passage in *The Positivity of the Christian Religion* describing how the eternal and absolute in man had been "forced to take flight to the Deity." The unhappy consciousness was regarded by Hegel as a characteristic of both Judaism and Christianity and as the condition of all men at all times who believe in a transcendent God before whom they are as nothing. It is a stage on the way to higher forms of self-mastery.

It will be noted that in this part of the *Phenomenology* Hegel passed from epistemology through a sort of speculative sociology to an account of historical stages in human consciousness. According to Rosenkranz, Hegel, in his last years, used to refer to the *Phenomenology* as his philosophical "voyage of discovery," and it does seem that the course of the argument, although arresting, was not altogether foreseen. Josiah Royce was right when he said that in this book Hegel described "in serial order, some varieties of experience which … are at once characteristic of the general evolution of the higher intellectual life, and are examples of the transition from common sense naiveté to philosophical reflection and to the threshold of

an idealistic system" (*Lectures on Modern Idealism*, edited by J. Loewenberg, New Haven, 1919, p. 139).

REASON AS "OBJECTIVITY." After discussing certain scientific theories of his time under the heading "Reason as Observer," Hegel went on to consider some of the ways in which reason becomes practical. He depicted the man who, like Faust, tries to make the passing moment stay. When this attempt fails, as inevitably it must, ideals are sought in a spirit of sentimental disillusionment, but such romantic crusades are never really serious. In reaction to this frivolity there develops a taste for the hard intellectual pursuits of disinterested scholarship, the concern for "objectivity," for facts, for "the thing itself." But these allegedly disinterested researchers actually go into a sort of intellectual jungle (*das geistige Thierreich*) where, deceiving one another and themselves, they tear one another to pieces in the service of truth. It soon emerges that it is not the facts that matter but a certain proprietorship that scholars working in their special fields claim over the facts.

THE DIALECTIC OF MORALITY. In the next part of the *Phenomenology*, titled "Mind," Hegel considered how the mind of man is embodied in his rules and institutions. This part constitutes both an account of the main types of moral attitude and a philosophy of history. These two lines of thought come together insofar as Hegel regarded the historical development from the Greek and Roman civilizations through early and medieval Christianity to Protestantism and the French Revolution as an unfolding of the main aspects and stages of freedom and, hence, as a dialectical actualization of what was merely latent and implicit in the morality of the ancient world. This unfolding is dialectical because it proceeds by oscillations and because it is made possible by conflict, in the ancient world by the conflict between the gods of the family and the laws of the city and in the modern world by the conflict between the claims of the individual and the demands of society.

In this part Hegel gave indications of the doctrine of alienation that attracted Marx in the 1840s. In building his civilization, man creates institutions and rules that are simultaneously his own products and alien constraints upon him. He may not even understand them, so that they appear strange to him. It was Hegel's view, of course, that without these institutions and rules and without the restrictions upon willfulness that they impose, mind could not reach its higher levels.

RELIGION AND ABSOLUTE KNOWLEDGE. In the last two parts of the *Phenomenology*, Hegel presented the dialectic of religion and the passage to absolute knowledge. In the earlier developments of mind the individual has to find his place in the natural world and in society, but in religion he gains consciousness of the Absolute Being. This is first approached in the primitive religions of nature, in which men worship trees, streams, or animals. Next come those forms of religion in which the Absolute Being is approached through such works of art as temples and statues. This type of religion reached a high level in ancient Greece, but when God was represented in human form, he came to be regarded as merely human and hence was lost sight of in the tragic heroes of Greek drama. As the religious element was discarded from tragedy, it gave way to comedy, in which the contingencies of human life were paraded and criticized, and God was completely ignored in favor of human self-knowledge. "The individual self is the negative force through and in which the gods … disappear."

This skeptical and sophisticated humanism is succeeded by Christianity, in which God is revealed to man in Christ. Here the human and the divine are no longer sundered, and God is seen to be present in the world. But it is easy to overemphasize the historical features of Christianity and, as Hegel put it, to neglect the spiritual revelation in the attempt to uncover the often commonplace ideas of the early Christians and to gain knowledge of the mere externality and particularity of Jesus. Thus, no religious experience, not even that of Christianity, can bring absolute knowledge. The historical element in Christianity, although necessary in order to avoid regarding the Absolute Being as apart from the world, is nevertheless inseparable from perception and imagination. The events of the Gospels are, so to speak, pictured or represented. Religion therefore leads on but is subordinate to the supreme form of knowledge, the philosophical, in which human history is "conceived history, the recollection of the Absolute Mind and its graveyard, the actuality, truth and certainty of its throne, without which it would be for ever alone and devoid of life." In these last words of the *Phenomenology*, Hegel made it clear that the course of history, philosophically conceived, was in his view the incarnation of the Absolute Mind. Apart from the history of man God would be alone and lifeless (*das leblose Einsame*). It would seem, indeed, that without the historical development of man and his freedom there would be no God.

THE HEGELIAN SYSTEM

It has already been mentioned that before writing the *Phenomenology*, Hegel had written but had left unpublished some attempts at a complete system of philosophy and that the *Phenomenology* was described on its title page as the first part of a system of science. It turned out that the *Science of Logic* (1812–1816) became the first part of Hegel's final system. A shortened and revised version of the *Science of Logic* appeared in 1817 as the first part of the *Encyclopedia*, a book intended for use at his lectures. A second, very much elaborated edition of the *Encyclopedia* appeared in 1827, and a third in 1830. This last edition was reprinted in the edition of Hegel's collected works published soon after his death, with inserted "additions" taken from the notebooks of students who had attended Hegel's lectures. These additions, which are most frequent in the first and second parts of the *Encyclopedia*, help greatly in the understanding of Hegel's argument but do not have quite the authority of the main text. Such additions are less frequent at the end, since the editors considered that the *Philosophy of Right*, first published in 1821, and some of the sets of lectures, provide commentary of this sort.

THE *ENCYCLOPEDIA*. The *Encyclopedia* starts with a discussion of "Logic"—a revision of *Science of Logic*—and proceeds to the sections "Philosophy of Nature" and "Philosophy of Mind." The transition from the "Logic" to the "Philosophy of Nature" is not easy to understand. There are statements that say that the idea decides to allow nature to go forth freely from itself (Sec. 244), that "Nature has come to pass as the Idea in the form of otherness" (Sec. 247), and that nature is "the unresolved contradiction" (Sec. 248). The last main heading in the "Philosophy of Nature" is "The Animal Organism." Toward the end of this section there is an account of the individual animal as having "an original sickness" and "an innate germ of death" (Sec. 375), which leads to the assertion that with the subjectivity of living organisms the "outside-itself-ness" (*Aussersichsein*) of nature is transcended by the "interiority" (*Insichsein*) of actuality (Sec. 376).

Hegel later claimed (Sec. 381) that mind presupposes nature but is "the truth [of nature] and its absolute ground [*deren absolut Erstes*]." He also stated that the essence of mind is freedom (Sec. 382). A fundamental comment on the dominating triadic division must be made before going further into the details of the system. The revised "Science of Logic" that appeared in the *Encyclopedia* was concerned with the categories of thought,

proceeding from the most inadequate and abstract to the most concrete and adequate, from being to the Absolute Idea. The inadequacies of the abstract categories show themselves through the contradictions they give rise to. Being is more abstract than becoming; becoming, more abstract than being-for-self; these early categories, more abstract than the latter categories of life, and so on.

But Hegel was always concerned with the categories of thought and their relations to one another. When he wrote that the idea decided to allow nature to go forth freely from itself, was he saying that thought is the Divine Being that created nature? The religious overtones that accompany Hegel's major transitions cannot be ignored, but those who wish to interpret him naturalistically—an interpretation his early writings and the *Phenomenology* may well justify—can take the view that the decision and the free going forth are meant to indicate that nature is not deducible from the categories of thought, that there is a contingency about it that no system of logic and no elaboration of concepts can eliminate. In *Subjekt-Objekt* (Berlin, 1951) Ernst Bloch suggested that the free decision of the Absolute Idea is reminiscent of the arbitrary act of an absolute monarch, and he quoted a passage from Schelling's *Philosophie und Religion* (Tübingen, 1804) which held that "the descent of finite things from the Absolute" is a "primal accident [*Urzufall*]."

In the third part of the *Encyclopedia*, Hegel described mind as it develops in the natural world, mind as it transforms the natural world in creating the works of civilization, and mind fully aware of itself in the complete self-consciousness of philosophical thought. The "Logic" culminates in the Absolute Idea, the most adequate category but still a category. In the "Philosophy of Nature," where there is no Absolute, the culminating point consists of mortal individuals belonging to persisting animal species. The "Philosophy of Mind" culminates in Absolute Mind, the consciousness man gains of himself through understanding his own history in a civilization that he has imposed upon the contingencies of nature.

"**LOGIC.**" Like the Hegelian system as a whole, each of its three main sections—"Logic," "Philosophy of Nature," and "Philosophy of Mind"—is again divided into three. The "Logic" is divided into the "Doctrine of Being," the "Doctrine of Essence," and the "Doctrine of the Concept [*Begriff*]." The difficulties in presenting a comprehensible summary of Hegel's views are at their greatest in relation to the "Logic," and all that will be attempted is an indication of a few of Hegel's most characteristic views.

"*Doctrine of Being.*" In the "Doctrine of Being" Hegel was concerned with the most abstract categories. Being itself, the most abstract of all, amounts to the same as nothing. Like Bertrand Russell in his theory of descriptions, Hegel held that nothing can be said to be unless some characteristic is attributed to it; hence, in Hegel's terminology being leads on to determinate being, which involves the notion of quality. On the ground that a quality is something distinct from other qualities, Hegel argued that quality implies the category of a unit (*das Eins*) and that this in turn leads on to quantity. This part of the "Logic" was completed by transitions to degree and measure.

Hegel's object in the "Doctrine of Being" was to show that these categories are not independent of one another but develop from one to the other in an ascending order of adequacy. We know more about something when we know the proportions of its parts than when we know only how many parts it has, that it is, or that it is something or other. An important element in this part of the "Logic" is Hegel's criticism of infinite numerical series as the false infinite and his contrast between the false and the true infinite, which is not an incompletable progression of similar items but a completed, complex whole of supplementary parts. The true infinite is not to be reached by attempting the impossible task of moving from one finite to the next but must comprise the finite.

"*Doctrine of Essence.*" The "Doctrine of Essence" is concerned with such distinctions as that between a thing's nature and its appearances, forces and their manifestations, form and matter. Hegel exploited the difficulties ("contradictions") that arise when these oppositions are so accentuated that we are left with featureless essences, on the one hand, and unattached appearances, on the other. Typical of his treatment of these topics is his claim that "the explanation of an appearance in terms of a force is an empty tautology" (Sec. 136) and his assertion that as a man's outward actions are, so his inner aims and intentions must be (Sec. 140).

"*Doctrine of the Concept.*" A prominent feature in the "Doctrine of the Concept" is Hegel's critical treatment and reorganization of the traditional formal logic. Thus, he classified judgments in terms of his own division of "Logic" into being, essence, and concept. The classification progresses from the mere factual attribution of a quality, through disjunctive and necessary judgments in which the predicate belongs essentially to the subject, to judgments of value that assert that a thing is good or bad just because it is that individual thing. Judgments gain in adequacy as they advance from mere factual attribution

to attribution for reasons contained in the subject. Hence, the more developed forms of judgment are indistinguishable from inferences. In his account of the syllogism Hegel placed inferences in which the terms are only contingently connected at the bottom of a scale leading up to the disjunctive syllogism, in which a genus is exhaustively specified.

Although Hegel retained the terms and distinctions of the traditional formal logic, the use he made of them was highly original. Instead of setting out the types of judgment and the figures and moods of the syllogism as equally valid forms, he regarded judgment as implicit inference and inference as ordered in a scale of ascending rationality. This conception of logic influenced such later writers as Christoff Sigwart and R. H. Lotze and was developed in both F. H. Bradley's *Principles of Logic* (London, 1883) and Bernard Bosanquet's *Logic: The Morphology of Knowledge* (2 vols., Oxford, 1888).

The argument of Hegel's "Logic" can be very briefly summarized. The least that can be said about anything is that it is. More is said about it when it is qualified, numbered, or measured; still more is said about it when it is explained in terms of essences, grounds, or causes. Most is said about it when it is placed in the context of life, purpose, will, and value.

"PHILOSOPHY OF NATURE." At the end of the eighteenth and the beginning of the nineteenth century there was a great deal of philosophizing about nature. Electricity was held to have cosmic significance, and Schelling made much of the opposition between positive and negative poles. Poets as dissimilar as William Blake and Goethe rejected what they regarded as the unduly quantitative physics of Isaac Newton. Spinoza was revived, and among German poets and philosophers much was said about the *έν καί πᾶν*, the one and the all. It is not surprising, therefore, that Hegel's dissertation of 1801, *De Orbitis Planetarum*, was critical of Newton and sought to provide an a priori justification of Johannes Kepler's laws. At the end of the dissertation Hegel mentioned some numerological accounts of the distances and number of the planets and expressed the opinion that if Plato was right in the *Timaeus*, there could be no planet between Mars and Jupiter. Hegel did not then know that Ceres, an asteroid between these two planets, had been discovered at the beginning of the year. However, even after he had heard of this discovery and of the discovery of several other asteroids soon after, he continued to hope that philosophical reasons could be given for the positions of the heavenly bodies. In an addition to Section 270 of the *Encyclopedia*, Hegel tried to show that these asteroids filled a gap that would otherwise have been unreasonable. The addition ends with the words: "Specialists do not think about such matters. But a time will come when in this science there will be a demand for concepts of the Reason."

It should be mentioned here that Hegel accepted and developed Kant's distinction between the reason and the understanding. According to Hegel, the understanding, although a necessary stage of thought, is less philosophical than the reason. To think in terms of the understanding, as is done in mathematics, the natural sciences, and traditional metaphysics, is to think in terms of fixed and uncriticized categories, to think undialectically or in prephilosophical terms. The reason moves dialectically toward completeness in terms of fluid categories that constantly amend themselves. Thus, when Hegel wanted astronomers to pay attention to "concepts of Reason," he wanted astronomy to take its place within a system of philosophy. This place must be a subordinate one, for Hegel wrote in the Introduction to the "Philosophy of Nature" (Sec. 248): "Even if arbitrary will, the contingency of mind, leads on to wickedness, this is nevertheless something infinitely higher than the regular movements of the planets or than the innocence of the plants: for what goes wrong in that way is nevertheless mind." Here Hegel was emphasizing the gulf between mind and nature, even though he held that the understanding does not give a complete knowledge of nature.

Mechanics. The three main divisions of the "Philosophy of Nature" are concerned with mechanics, physics, and organic nature. The astronomical theories expounded in the first part have already been touched upon. This part also contains a brief discussion of space and time. Following Kant, Hegel regarded them both as "forms of sensibility," or, more strikingly, as "the non-sensible sensible." Although he regarded arithmetic and geometry as sciences of the understanding, he considered the possibility of a philosophical mathematics at the level of measure or proportion (mass).

Physics. The second part of the "Philosophy of Nature" moves through various triads from light, the elements, sound, heat, to electricity and chemical combination. Hegel commented upon the philosophical significance of each form of matter. The comment on heat is characteristic:

Heat is the re-establishment of matter in its formlessness, its fluidity, the triumph of its abstract homogeneity over its specific determinations…. Formally, that is in relation to spatial

determinations in general, heat therefore appears expansive, as cancelling the limitations which the specification of the indifferent occupation of space is. (Sec. 303)

That is, when heat spreads out from a heated thing, that thing is not confined to one place, as it would be if it were not heated. Or as Hegel put it in the next section, heat is the "real negation of what is specific and exclusive in body."

Organic nature. In the last main triad of the "Philosophy of Nature," Hegel passed from geological nature through vegetable nature to the animal organism. The most interesting part of this triad is the last, in which Hegel discussed animal species and their relationships. He seems to have thought that violent death is, in the animal world, "the natural fate of the individual" and that because of the contingency of nature animal life is "uncertain, anxious, and unhappy" (Sec. 369). But other members of the same species are not only hostile to the individual; they are also, like him, continuations of the species, and, hence, the individual feels a need to unite himself to the species (*Gattung*) and to continue it by copulation (*Begattung*)—the play on words is, of course, deliberate. Thus, Hegel seems to have held that animal sexual union is not merely a contingent affair. On the other hand, since the new individuals produced in this way only repeat the features of their parents and other ancestors, their constant reproduction is an instance of the false infinite, not of the true infinite in which completeness and perfection are achieved.

"PHILOSOPHY OF MIND." The major triad in the "Philosophy of Mind" consists of "Subjective Mind," "Objective Mind," and "Absolute Mind."

"Subjective Mind." Under the heading "Subjective Mind" and the subheading "Anthropology," Hegel dealt with the soul as a natural entity in the physical world; the soul as a sensitive, feeling being; and the soul as a being that can express itself and act upon the world through its body. The upright body, the hand "as the absolute tool" (Sec. 411), the mouth, and the power of weeping and laughing all enable man to express in nature—to externalize—his thoughts and feelings. Furthermore, the world has effects upon man's body that are internalized by him—Hegel here made a play on the word *Erinnerung*, which means "recollection" but, if taken in the literal sense of its German etymology, can be taken to mean "internalization." When the organism reacts to immediate stimuli in the light of its own experience, mind has

evolved beyond the mere animal level and has reached the stage of consciousness.

Hegel discussed the next moment of subjective mind under the heading of the "Phenomenology of Mind," going through the main phases distinguished in the earlier chapters of his book with that title—namely, sense experience, perception, understanding, desire, the self-consciousness that recognizes others (containing the discussion of master and slave), reason.

The third triad of subjective mind, which is headed "Psychology," contains descriptions of such intellectual functions as intention, representation, recollection, imagination, memory, and thought and descriptions of the practical drives, impulses, and seekings after satisfaction.

This part ends with a brief section headed "Free Mind." Here it is asserted that the unity of theoretical and practical mind is free will. Hegel meant that human freedom is possible only on the dual basis of thought and impulse and consists of the rationalizing and systematizing of the impulses and passions. "This will to freedom," he said, "is no longer an impulse that demands satisfaction, but the character—the mind's consciousness grown into something non-impulsive" (Sec. 482).

"Objective Mind." At the very end of his discussion of subjective mind Hegel wrote that the freedom which is the culmination of subjective mind is only a concept, "a principle of mind and heart destined to develop into the objective phase, into legal, moral, religious and scientific actuality" (Sec. 482). The rest of the system is therefore concerned with the ways in which the human will, in which thought and impulse ("mind and heart") are combined in freedom, becomes effective (this is the idea behind the word *actuality*, which translates *Wirklichkeit*) in the public world, the world in which men act and in which their thoughts and deeds give rise to rules, institutions, and organizations. These rules, institutions, and organizations are independent of each man and thus may be regarded as kinds of objects, though not as physical objects. Men build up in the natural world a world other than the natural world by working on nature and transforming it and by creating systems of property, economic organizations, class differentiations, and the like. The triad that makes up objective mind comprises law (*Recht*), subjective morality (as Wallace translated *Moralität*), and social morality (as Wallace translated *Sittlichkeit*; T. M. Knox translated it as "ethical life"). The first part covers legal rights and duties as exemplified in property, contract, and punishment. The second is concerned largely with the morality of intention and conscience—the term *Moralität* was used by Hegel somewhat

pejoratively to mean a sort of ethics (of which Kant was, in his view, the chief exponent) in which the agent is unduly governed by the subjective and internal aspects of decision and action.

The third part is itself a triad. The first stage of social morality is the family, "the natural or immediate phase" of objective mind (*Philosophy of Right*, Sec. 152). When members of the family have matured, they detach themselves from it and enter the world of independent men who compete in an economic arena free from tribal allegiances. This phase of social life Hegel called "civil society." It is the world of intelligent, responsible individuals in their business relationships, free from irrational tribal loyalties, allowing their connections with one another to be formed by the coincidence of wants in a market of wide extent. Indeed, it is the aspect of human society that the classical economists, whom Hegel admired, had analyzed and justified. But civil society cannot exist as a mere market, for markets need to be policed, whereas trades and industries themselves find common concerns that unite the individuals in corporations of various kinds.

There is thus a double necessity for the state—as the upholder of fair dealing and as the ultimate curb on the selfishness of corporations within civil society. In the *Encyclopedia*, Hegel wrote of "the unification of the family principle with that of Civil Society" and described it as a unification of the love that is essential to the family with the conscious universality that is the mark of civil society (Sec. 535). In the *Philosophy of Right* (Sec. 257) the state was described as "the actuality [*Wirklichkeit*] of the ethical Idea"—that is, as its effective embodiment. In the same section of the *Philosophy of Right*, Hegel wrote that "the mind of a nation (Athene for instance) is the divine, knowing and willing itself," and in an addition to Section 258 is the famous phrase "The march of God in the world, that is what the State is." But this section has been misunderstood. In the sentence before that in which he had written that the state is divine, Hegel had said, with the family in mind, "The *Penates* are inward gods, gods of the underworld," so that it is not only to the state that he attributed divinity. Furthermore, in the same addition as that in which he claimed that the state is "the march of God in the world," he said that the state "stands on earth and so in the sphere of caprice, chance and error, and bad behaviour may disfigure it in many respects." Hegel's main concern was, as he stated, to analyze the state at its best. Although, like Aristotle, he regarded the state as the highest social achievement of man, he also held, again like Aristotle, that within the state there should be guarantees against arbitrariness and despotism. He did not take a

favorable view of "popular suffrage" on the grounds that "in large states it leads inevitably to electoral indifference" and that "election falls into the power of a few, of a caucus" (*Philosophy of Right*, Sec. 311). He strongly believed that all important interests should be represented and thought that there should be a constitutional monarchy with considerable powers advised by an upper and a lower house.

This brings us to the most controversial part of Hegel's account of objective mind, his philosophy of history. Whatever else is involved in his view that the state is man's highest social achievement, it undoubtedly implies that there is no superior body or group by which its claims may be assessed. States are necessarily independent beings. Their relations are regulated to some degree by custom, and there is an international law that regulates dealings between subjects of different states and requires adherence to treaties, as if they were a sort of contract. When the vital interests of states clash, however, there is no alternative except war. War between states, Hegel had said in his "Die Verfassung Deutschlands" ("Constitution of Germany," 1802; first published in *Schriften zur Politik und Rechtsphilosophie*, edited by Georg Lasson, 2nd ed., Leipzig, 1923), does not decide which of the rights of the conflicting states is the true right—for both are—"but which right has to give way to the other." Hegel believed that war performs the function of keeping before the minds of men the realities of death and destruction. He held that states are individuals and that all individuals persist in their existence by ensuring that other individuals recognize them as they recognize the others. The very concept of a state therefore requires that there be a plurality of them, and this makes war a part of the system of states even though war is not their natural condition but an interruption of the normal state of peace. Hegel argued that since war is a relation between states and not a relation of individual men to one another, the rights and interests of noncombatants should be maintained to the utmost. For the same reason he was in favor of professional armies and against conscription or any form of levy en masse.

Each nation is limited by geographical and other accidental features and hence can build up only a particular culture and can have only a particular, not a universal, history. Thus, nations, when they reach the level of statehood, make their contribution to the whole in the part they play in world history (*Encyclopedia*, Sec. 548). World history is not wholly an affair of chance or contingency; as the work of mind it could not be. Therefore, the history of the world has a rational structure, and any his-

torical writing that ignored this "would be only an imbecile mental divagation, not as good as a fairy-tale" (Sec. 549). This rational structure, according to Hegel, is the development of freedom.

"Absolute Mind." The triad that completes the Hegelian system is composed of art, revealed religion, and philosophy. It will be remembered that at the end of the *Phenomenology* Hegel proceeded from the religion of nature to the religion of art and then to the philosophical knowledge of the history of the world. In the *Encyclopedia* art is given what seems to be a more independent status, but the details of the argument hardly bear out the general scheme, since the transitional sections describe a transition from objective mind to religion, as in the *Phenomenology*. Thus, in the concluding sections of the *Encyclopedia* art is regarded as an inadequate form of religion, religion as a more adequate form of art, philosophy as religion freed from picture thinking and wholly rationalized, and all three as manifestations of Absolute Mind. Art is the embodiment of Absolute Mind in material things fashioned by the artist, who, in a sense, is thus "the master of the God" (*Encyclopedia*, Sec. 560). In classical art the embodiment takes place without any antithesis between the embodiment and the mind that is embodied. In the art of the sublime, which preceded classical art, the Absolute Mind is regarded as something that defies embodiment and remains forever beyond and behind the sensible forms that succeed only in symbolizing it. The defect of artistic representation is that the sensible symbols may be taken to refer to another world beyond, which is as limited as this world is falsely taken to be. Thus, men worship idols or even bones, "which point to the unspiritual objectivity of that other world" (ibid., Sec. 562).

God is therefore not something grander and more powerful than the natural world yet fundamentally like it, nor is he something beyond the world that must remain forever inaccessible to man. God is manifested in the world, and this is the truth that revealed religion has expressed most adequately in the Christian doctrine of the Incarnation. Without this doctrine God would still be regarded as beyond the world and, thus, as incomplete and finite. Even with this doctrine he is conceived of through the medium of particular historical events that introduce an element of contingency and irrelevance into our conception of him. In philosophy the artist's external vision and the mystic's internal vision are united in a mode of thought in which there is no further conflict. The philosopher who achieves ultimate self-knowledge is freed from the conflicts that inevitably disturb the infe-

rior levels of knowledge. By philosophizing to the end, he has made himself free (ibid., Sec. 576).

THE DIALECTICAL METHOD

CONTRADICTION. It is now necessary to give more detailed attention to Hegel's dialectical method. There are interpreters of Hegel who say that Hegel denied the principle of contradiction in that he held that contradictories can both exist and that contradictory propositions can therefore both be true. Others deny this interpretation, maintaining, instead that, according to Hegel, since contradiction is a mark of inadequacy and falsehood, contradictions are to be found in the lower categories but are absent from or resolved in the Absolute Idea. This view is summed up in Michael Oakeshott's reference to "the element of self-contradiction inherent in all abstraction" (*Experience and Its Modes*, Cambridge, 1933, p. 328). Those who take the first view can quote some convincing passages from Hegel's *Science of Logic*. For example, there he wrote that "all things are in themselves contradictory," that "movement is existing contradiction itself," and that "only insofar as something has contradiction in itself does it move, have impulse or activity."

If Hegel had rejected the principle of contradiction in the sense that that principle is understood by formal logicians, his case would indeed be serious, for it follows from the rejection of this principle that any proposition can be true and false and that there is thus no means of distinguishing truth from falsehood. It is important, therefore, to see whether Hegel did reject the principle of contradiction in this sense and whether its rejection is part of his dialectical method. That these questions are not easy to answer becomes apparent if we consult some of the commentators on the passages I have just quoted. J. M. E. McTaggart, in his *Commentary on Hegel's Logic*, was dissatisfied with the whole section and claimed that in it Hegel had allowed himself to be too much influenced by Schelling's view on polarity and opposition. "The whole point of the dialectic," McTaggart protested, "is that the perception of a contradiction is a reason for abandoning the category which we find contradictory." Indeed, he found this part of the *Logic* so unsatisfactory that he proposed to amend the sequence of categories by leaving out contradiction altogether.

McTaggart said nothing, however, about Hegel's statement that there are existing contradictions. G. R. G. Mure, in his *A Study of Hegel's Logic*, did not evade this difficulty. Examining Hegel's text more closely than McTaggart had done, he pointed out that on the ground that "the contradictory cannot be imagined or thought"

Hegel rejected the commonsense view that things cannot be self-contradictory but that thought can be. Mure called attention, too, to Hegel's statement that self-contradiction is not a mere disease of thought but something it must pass through on its way to truth. Furthermore, according to Hegel, it is finite things that are self-contradictory, and they are contradictory not in relation to one another but by virtue of their relation to what is infinite: Hegel "is not suggesting that Big Ben can now read both 9 p.m. and not 9 p.m." (p. 105). Although this is an improvement on McTaggart, it left out of account Hegel's statement that for something to move, it must be both here and not here at the same time. What Hegel said about movement is not altogether unlike Mure's example of Big Ben. So the difficulty remains.

In the "Logic" sections of the *Encyclopedia,* which was written later than the *Science of Logic,* contradiction is not a separate category at all. Perhaps the reason for this difference is that Hegel had second thoughts and gave up the idea of contradiction in the nature of things. But although contradiction is no longer a category in the *Encyclopedia*, Hegel still sometimes wrote as if there were contradictions in the nature of things. For example, he stated that although such concepts as "square circle," "many-sided circle," and "straight curve" are self-contradictory, geometers nevertheless regard circles as polygons composed of very short sides and "the center and circumference of a circle as opposite and contradictory to one another" (*Encyclopedia*, Sec. 119). Hegel also suggested that polarity in physics goes against the ordinary logic—but he used the word *opposition* (*Entgegensetzung*) rather than *contradiction* (*Widerspruch*).

In *Geschichte der neueren Philosophie* (Heidelberg, 1901, Vol. VIII, Part 2) Kuno Fischer tried to overcome the difficulty by distinguishing between two sorts of contradiction, "necessary contradiction" and "impossible contradiction." The example of a square circle illustrates the notion of an impossible contradiction, a *contradictio in adjecto*, for it is impossible for the same thing to be both circular and square. When a circle is regarded as a many-sided polygon, however, the contradiction is not *in adjecto* but in *subjecto*, for the circle is then being regarded as in the process of being formed or generated from these many sides. This, Fischer held, is the contradiction involved in all becoming (the first concrete category of the "Logic," the synthesis of being and nothing). Fischer's suggestion is therefore that there is not a vicious or stultifying contradiction involved in becoming or in movement, contradictory though they must in some sense be. But although this may be a correct exposition of

Hegel's view, it is hardly a defense of it, since it merely repeats without explaining his claim that there are contradictions in the objective world.

By drawing this distinction, Fischer has nevertheless raised the question whether Hegel intended the word *contradiction* to be used in the way it is used in formal logic. The answer is clear enough. Hegel did not regard formal logic as a philosophical science, and he therefore rejected any idea that its categories should dominate philosophical thought. Thus, the fact that the word *contradiction* is used in a certain way by formal logicians was not for him a reason for confining himself to that meaning. When Hegel was advocating the dialectical method, he had in mind a method in which oppositions, conflicts, tensions, and refutations were courted rather than avoided or evaded. Hegel was a student of the classical, laissez-faire economists who held that wealth would be maximized by the free play of competition. In this view if traders and producers ceased to compete with one another, the whole level of economic life would be lowered. General prosperity could be reached only at the expense of labor and anxiety. So it is, Hegel believed, with the categories of our thought, the systems of philosophers, and the forms of life and society. There is no tranquillity to be had by withdrawal and isolation. Our categories compete with one another, and out of their competition emerges something better than either of them could have accomplished alone. But it is not possible for the superior category to go into retirement, for without the spur of competition it would fall into decay.

Furthermore, just as competition requires the competitors to continue in business—for if one destroys the others, there is monopoly and stagnation—so the competing categories cannot be swallowed up and lost in the Absolute Idea but must all play their part in maintaining its life and stability. There is nothing fanciful in this comparison. Indeed, it gains support from Hegel's "System der Sittlichkeit" of 1802 ("System of Morality"; in *Schriften zur Politik und Rechtsphilosophie*, edited by Georg Lasson, 2nd ed., Leipzig, 1923), in which it is quite clear that Hegel's systematic thinking was influenced by his understanding of economic theory. For example, in this essay he developed the triad need–labor–enjoyment and described labor as "the destruction of the object … but in such a way that another is put in its place." Here Hegel compared labor with knowledge and undoubtedly had in mind (in accord with his tendency to take German words in the sense of their roots) the element of negation (*nicht*) in the word for destruction (*Vernichtung*). The

destruction of the natural object is the creation of an artificial one.

NEGATION. Negation, indeed, is the vital notion in Hegel's account of the dialectic. In the Preface to the *Phenomenology* Hegel wrote, "The life of God and divine knowledge may, if we wish, be described as love disporting with itself; but this idea is degraded into mere edification and insipidity if it lacks the seriousness, the pain, the patience and the labour of the negative." "Seriousness," "pain," "patience," and "labor" would be strange words to use of the negative symbol of formal logic. Expressed in theological-economic terms Hegel's view is that God cannot be a mere consumer, for there is no consumption without labor, and labor has to face a recalcitrant nature that has to be understood and humored. Thus, there is no God apart from nature. In moral terms there is no good without evil, and in logical terms there is no truth without error. These, according to Hegel, are central truths of dialectics.

But surely, it will be said, this conflicts with such obvious facts as that there are some who consume without working, that in mathematics there are sequences of necessarily true propositions with no admixture of falsity, and that some things—for example, conscientious action—are good without qualification. As to the first point, Hegel argued in the *Phenomenology* that the master who consumes what his slave produces for him destroys what he consumes, whereas the slave shapes the external world in such a way that mind is embodied in it. Hence, the slave is on the road to freedom, whereas the master, who does not work, destroys without creating. As to mathematics, Hegel was inclined to hold it in contempt. There is no space here to consider the strange things he said about it, and it need only be remarked that he held that philosophical truth is utterly different from mathematical truth in that false philosophical views are taken up into true philosophy whereas false mathematics is not taken up into true mathematics. As to the alleged unmixed goodness of conscientious action (the Kantian "good will"), Hegel held that the morality of conscience contained in itself the seeds of willfulness and arbitrariness, for the most atrocious deeds can be defended on the ground that the man who committed them genuinely thought them right. Obedience to one's own conscience, Hegel thought, is an advance over obedience to the commands of an external lord but is nevertheless an unstable basis for morality.

Several ways in which the negative element is important in Hegel's method have been discussed. There is the

conceptual competition without which thought must decay. Then, there is the polar character of certain fundamental notions that makes the one unthinkable without its opposite. At the prephilosophical level Hegel gave above and below, right and left, father and son, as examples. At the philosophical level his examples, were good and bad, master and slave, thought and nature. But not only do these opposites require each other; they also pass into each other. Good will can pass over into atrocity; philosophical truth is the result of errors that supplement each other; the master satisfies his desires but becomes dependent upon the labor of the slave in order to do so; and the slave, by work, controls his desires and develops a rational will. The life of thought in conceptual conflict, the mutual dependence of polar opposites, and the instability or oscillations of philosophical and moral attitudes are different sorts of dialectic that Hegel emphasized on different occasions. If they have anything in common, it is the activity of negation.

There are two other aspects of the dialectic to discuss, the role of reason and understanding and the role of skepticism.

REASON AND UNDERSTANDING. First, Hegel, following Kant, contrasted the reason, the source of dialectical thinking, with the understanding, the predialectical mode of thought. The understanding, as Hegel saw it, is the type of thinking that prevails in common sense, in the natural sciences, and in mathematics and those types of philosophy that are argued in quasi-scientific or quasi-mathematical ways. Fixed categories are uncritically adhered to, demonstrations are produced (only to be demolished), analyses are made, and distinctions are drawn. Analyzing and distinguishing are necessary foundations of philosophical activity but only to prepare the way for the more sinuous and subtle method of the dialectic. Once an analysis has been made, the elements of it are seen to conflict and collide as well as to cohere. First, the understanding isolates, then comes the Reason's negative moment of criticism or conflict, and after that its speculative moment of synthesis. It should be mentioned that distinctions somewhat similar to the distinction between the understanding and the reason had already been made by Plato when he distinguished between the highest knowledge and knowledge in the various sciences, by Spinoza in his second and third kinds of knowledge, by Blaise Pascal with his *esprit de géometrie* and *esprit de finesse*, by David Hume with his reason and imagination, and by Edmund Burke when he contrasted the abstract rationalism of the Enlightenment with the organic, evolutionary view of society that he preferred. These distinc-

tions are not all quite like that drawn by Hegel, but in his theory there is something corresponding to each of them.

SKEPTICISM. Second, Hegel thought that skepticism was an important forerunner and essential ingredient of the dialectical method. In a review of a book by G. E. Schulze that appeared in 1802, Hegel wrote appreciatively of the skepticism of Sextus Empiricus and of the skeptical features in the philosophy of Parmenides, of whom he wrote, "This skepticism, which in its pure *explicit* form comes forward in Parmenides, is to be found *implicit* in every genuinely philosophical system, for it is the free aspect [*die freie Seite*] of every philosophy" ("Verhältnis des Skeptizismus zur Philosophie," in *Kritisches Journal der Philosophie* 2 (1802): 1–74; quoted from *Sämtliche Werke*, edited by Georg Lasson, Vol. I, pp. 174–175). In the same essay Hegel wrote that when Spinoza held that God is the immanent but not the transcendent cause of the world, he was equating the cause with the effect, even though the very notion of an effect implies that it is distinct from the cause. Hegel agreed with Spinoza's equation but concluded that it shows that the reason can accept the principle of contradiction only as a formal principle. In "genuine" philosophy cause and effect are seen as both distinct and identical.

Hegel illustrated his comment that skepticism is "the free aspect" of philosophy in the following way. Dogmatists, he said, regard individual men as objects in the power of rules, laws, and customs. The more the dogmatists study man, the more they show him in subjection to these forces. When, however, the skeptics attack dogmatism, "they raise the freedom of Reason above this necessity of nature." An example of this is the way in which Europeans came to question their own concepts of law and morals when they were brought face to face with cultures very different from their own. When such skeptics as Montaigne mockingly insisted on these differences, men became more conscious of their own institutions and recognized the possibility of changing them. In theoretically breaking down men's traditional views and institutions, the skeptic frees men from the unconscious power of these views and institutions. Hegel repeated his general assessment of skepticism in the *Encyclopedia* (Sec. 81, addition 2) and in his *Lectures on the History of Philosophy*. In these lectures Hegel said that skepticism is "the demonstration that all that is determinate and finite is unstable." Hegel went on to say that "positive philosophy," by which he meant philosophy that is not content to remain in total skepticism, "has the negative to Scepticism in itself; thus it does not oppose, nor is it outside of it, for Scepticism is a moment in it" (Haldane and Simpson, 1955, Vol. II, p. 330).

FREEDOM

From what has just been said, it is clear that Hegel's account of dialectic and of reason is closely linked with his view of freedom. The exercise of thought in its most developed forms involves the negation of what had seemed firm and certain and the opening up of new possibilities. That mind is freedom applies both to the understanding and the reason, since both are spontaneous activities that interpret and arrange. But because the understanding is confined to a fixed system of categories, it is less free than the reason that criticizes, stretches, and transforms the categories of the understanding.

Freedom is, of course, logically connected with will, and according to Hegel, will is as essential to mind as intellect is. Reference has already been made to Section 482 of the *Encyclopedia*, in which Hegel asserted that the unity of theoretical and practical mind is free will. In the preceding sections he had argued that thought presupposes mind as practical, since classifying and explaining are activities through which the world is, so to speak, appropriated by the mind. In the sections of the *Encyclopedia* in which he expounded the categories of cognition and of will, Hegel endeavored to show that mere cognition is at a lower stage than will and that will is thus the actuality of what is only potential in knowledge. He also argued that the freedom and necessity that are opposed to each other are abstractions and that what is concrete must combine both. The very nature of necessity, he continued, presupposes a will on which it is a constraint.

At the logical-metaphysical level, therefore, Hegel held a view that implied that freedom is essential to mind, both the presupposition and outcome of intelligence, and in its concrete form inseparable from constraint and necessity. This view of the matter pervaded his account of freedom in the social and political sphere. Freedom is not something merely opposed to constraint; on the contrary, it presupposes and requires restraint. This is true of concrete freedom. However, abstract or negative freedom, when it is more than a moment in actual or positive freedom, is a purely destructive force. Hegel considered that this negative freedom played a large part in the French Revolution. The old corporations and institutions were destroyed in such a frenzy of annihilation that it took several years for new institutions to be created and recognized as authoritative. Furthermore, when the conflicting interests in society are overcome, individuals come to be treated as equal, undifferentiated, replaceable, and

expendable units. The events of the Reign of Terror thus led Hegel to hold that purely negative freedom was associated with force and death. The logical connections are not altogether clear, but it may well be that the links between egalitarianism, antinomianism, violence, and contempt for human life are not wholly accidental.

Freedom, according to Hegel, is something that has to be achieved, and it therefore would be impossible in the absence of opposition and negation. Hence, although negative freedom in its abstract form is a "fury of destruction," it is a necessary element in concrete freedom. Free will is not the liberty of indifference but the rational organization of the feelings and impulses.

Rationality is not a power that could reside in an isolated individual, however. To be rational, the individual must draw upon the resources of an organized and differentiated society and must be "formed" and educated to do this. His will is then in harmony with the ends of the various social groups by which he has been influenced and, in civilized societies, with the more complex ends of the state. In conforming to these pressures and in obeying the laws of the state, the individual is achieving his own rational ends and in so doing is free.

Hegel, like Jean-Jacques Rousseau, also held that an individual might be free even when he was being coerced, for although he might dislike the force applied against him, this dislike would be an expression of his particular whims, not of his rational insight, as can be seen when he approves of the imposition of a like force upon other people in like circumstances. Insofar as the criminal who is being punished would wish others to be punished who committed a like crime against him, he wills his own punishment.

FREEDOM IN HISTORY. Hegel considered that the history of the human race is a development from less to greater freedom and from less adequate forms of freedom to freedom in its perfection. Thus, his philosophy of history can be understood only in terms of his conception of freedom. In the Oriental world there was no freedom for the subjects and only an arbitrary, irrational freedom for the despot who ruled over them. In the classical world of Greece and Rome there was a more adequate conception of freedom, and more men achieved freedom than in the Oriental despotisms. In the Greek city-state the citizens often regarded themselves as finding their fulfillment in the achievements of their city, apart from which they conceived of no life for themselves. Indeed, they might accept personal defeat and misfortune and submit to what they called destiny and still regard themselves as free in so

doing. Of course, there were slaves who had no part in this activity and had no freedom.

Christianity offered the prospect of freedom to all men, a freedom, furthermore, that transcended the given social order. In what Hegel called the Germanic world—that is, the Christian civilization that grew out of Protestantism—this latest form of freedom was being realized in the manifold institutions of Europe and America and in the states in which these institutions flourished and by which they were regulated and protected. In Christianity the individual is regarded as of infinite value, as a candidate for eternal salvation, and although the emphasis on subjective freedom can lead, as it did in the French Revolution, to contempt for social institutions, it comprises the form and aspect of freedom that gives its special quality to modern civilization, with its romantic art, romantic love, and support for the rights of conscience (*Philosophy of Right*, Sec. 124).

It is apparent from the foregoing that Hegel rejected the liberal view that man is free to the extent that he is guaranteed a sphere within which he can do what he wishes without interference from others who are guaranteed a like position. Such freedom he stigmatized as negative, abstract, or merely willful. Men enjoy concrete freedom when the various orders and groups of civilized life are maintained in and by the state. In this passage of the *Lectures on the Philosophy of History* (Hoffmeister, Vol. XVIIIA, p.111) Hegel also emphasized that in submitting their private wills to the laws of the state and to the rules of its subordinate but free institutions, men were submitting their passions to the control of reason. Thus, the argument comes full circle. The theoretical reason is inseparable from will and from freedom; necessity and negative freedom are only abstractions; in concrete freedom the negative, destructive element is held in check and rendered fruitful by being realized in institutions; the individual enjoys concrete freedom when he is educated to live in a civilized state and to be guided by the reason that permeates it.

There is no space here to criticize this view in any detail, for in a way it is a cross-section of the whole Hegelian metaphysic. It should be noted, however, that when a critic maintains that real freedom is what Hegel called negative or abstract freedom and when he goes on to maintain that "concrete freedom" is not freedom but indoctrinated submission, then he is criticizing Hegel's terminology rather than the substance of his view. To say that freedom consists of a willing acceptance of the tasks imposed by a civilized state is certainly to extend and perhaps to distort the ordinary senses of the term and to cap-

ture a word from the liberal vocabulary for use in a far from liberal scheme of concepts. It was Hegel's view, however, that the thoughts that the liberal phraseology expressed necessarily move in the directions he described and that societies themselves, the embodiments of men's thoughts and aims, move in these directions, too.

AESTHETIC THEORY

We have already seen that Hegel discussed the nature of art and of beauty toward the end of both the *Phenomenology* and the *Encyclopedia*. Art, according to Hegel, is one of the manifestations of Absolute Mind, of which religion and philosophy are the other two. Thus, although art presupposes the civilized life of the state, it also transcends it. In his lengthy *Vorlesungen über die Aesthetik* (Lectures on aesthetics) Hegel developed his theories of art and beauty in great detail. The lectures possess great power and attraction, and so much of their value resides in the details that a summary treatment is bound to be difficult.

THREE STYLES OF ART. Hegel's account of beauty is a modification of Friedrich Schiller's view, in his *Letters on the Aesthetic Education of Mankind* (1795), that beauty is the mediation between the sensible and the rational. According to Hegel, beauty is the rational rendered sensible, the sensible appearance being the form in which the rational content is made manifest. This sensible embodiment of the rational, he held, can take place in three principal ways: symbolic art, classical art, and romantic art.

Symbolic art. In the first and least adequate form, symbolic art, the sensible shape merely symbolizes the rational content without penetrating and transforming it. A lion may symbolize courage; a bird, the soul; or a temple, the presence of a god who nevertheless remains a mystery. Thus, in symbolic art the sensible object refers away from itself to a rationality that is enigmatically and mysteriously beyond it. In thus referring away from the sensible symbol to something vast and merely adumbrated, symbolic art sometimes achieves the sublime.

Classical art. In classical art, the second form of sensible embodiment, the sensible expression is adequate to the idea that it gives expression to and does not point vaguely beyond itself. This is typified in sculptures of the human body so formed that the divine ideal is realized in the stone, not merely hinted at. A temple makes us think of the god but is not the god. In a statue of Apollo the god is visible and tangible in the stone. Hegel pointed out that works of classical art have independence and completeness, so that when they have been created, it seems that

there is nothing more left to do done. "Nothing more beautiful," he wrote, "can be or become."

Romantic art. Christianity, however, with its emphasis on the infinite value of the individual and upon subjective freedom, made classical art seem somewhat unsatisfactory. More is required than works of art in which reason, as Hegel put it, "stands in quiet and blessedness in bodily form." When the self and its inner life are regarded as of infinite value, the forms of art must move on from balance and harmony to the storm and turmoil of the subjective. According to Hegel, it is in romantic art that this progress to subjectivity and self-consciousness is achieved. Romantic art turns its back on the quiet and balanced beauty of the classical and "weaves the inner life of beauty into the contingency of the external form, and allows full scope to the emphatic features of the unbeautiful." In romantic art, as in symbolic art, there is much that is bizarre and even grotesque, but romantic art is on a higher level than symbolic art because the mind expressed in it is more complex and sophisticated. And in romantic art the mind has achieved a greater measure of freedom than in classical art because romantic art is less involved in and hampered by the sensible embodiment.

PRODUCTS OF ART. Hegel's view of the three main types of beauty is closely linked with his view of the main types of artistic product. Hegel divided the arts into architecture, sculpture, painting, music, and poetry. Works in any of these mediums may be produced in the symbolic, classical, or romantic styles, but, according to Hegel, architecture is particularly appropriate to symbolic art, sculpture to classical art, and painting, music, and poetry to romantic art.

Architecture. Architecture, Hegel held, is the basic art, the art that men first practice, for its material is mindless and its forms depend upon the weight and physical properties of this mindless medium. The architecture of early men, by bringing them together to worship the gods in temples, served to bring unity into their societies. Hegel imagined the men who built the first temples as they cleared the ground on which to build them, and he described this as "clearing the undergrowth of finitude."

Sculpture. In architecture a house is provided for the god, and the god is prepared for and expected. He is not, however, embodied or manifested in the stones of a mere building. In classical sculpture the god is embodied in the stone in such a way that all the parts of the statue combine in expressing and proclaiming him. Hence, it is not a mindless symbol of the mind beyond but a unified

expression of it. Hegel contrasted the stiff regularity of Egyptian sculpture with the harmonious independence of the Greek, the acme of classical art. In Christian sculpture this Greek ideal does not predominate, and even when, as with Michelangelo, it is fully understood and mastered, it is associated with "the kind of inspiration that is found in romantic art."

Painting, music, and poetry. The three romantic arts of painting, music, and poetry differ from the arts of sculpture and architecture, according to Hegel, by being more "ideal." One thing he seems to have meant was that the productions of these arts are not three-dimensional like the productions of architecture and sculpture. Painting, of course, is two-dimensional, and Hegel thought it is more ideal than sculpture because it is further removed from the solid substance of material things. He appears to have argued that the painter transforms to an extent that the sculptor has no need to do. In reducing the three dimensions to two, space is somehow rendered more "inward" and "subjective," and the first step has been taken on the road to poetry.

The next step toward subjectivity is taken by music, which abandons all the dimensions of space as well as the senses of sight and touch. Hearing, according to Hegel, is a "more subjective" sense than sight because it is less practical and more contemplative.

In poetry the sensible elements of music, the notes or tones, are replaced by words that stand for thoughts. "The art of poetry," Hegel wrote, "is the universal art of mind that has become free and is no longer dependent upon external sensible material for its realization." Within poetry as a whole he distinguished epic, lyric, and dramatic poetry. Hegel's account of dramatic poetry is particularly interesting. "In tragedy," he wrote, "individuals destroy themselves through the onesidedness of their upright will and character, or they are forced to resign themselves and identify themselves with a course of action to which they are fundamentally opposed." In comedy, on the other hand, there is no such reconciliation; the characters pursue courses of action that have only subjective significance. Indeed, in comedy, according to Hegel, the subjectivity characteristic of romantic art is taken to such an extreme that all unity is dissolved; with it goes beauty, too. In comedy there is merely a series of subjective interests playing against one another, as opposed to the aim of all art, which is the revelation of the eternal and divine in sensible form.

NATURAL BEAUTY. The discussion has thus far been confined to the beauty of works of art (*das Kunstschöne*).

It is with this that by far the greater part of the "Lectures on Aesthetics" is concerned. In the second chapter, however, Hegel did say something about natural beauty (*das Naturschöne*). He discussed the notions of regularity, symmetry, harmony, and conformity to law and also the beauty claimed for plants, animals, and human beings. He concluded his discussion of the subject with some comments on how natural beauty falls short of artistic beauty. Plants and animals, he granted, are more beautiful than inanimate natural objects, but what we see of them is their outward coverings, not the soul that works within, for that is concealed by the visible feathers, hair, scales, fur, and the like that cover them. Hegel referred to natural beauty as the "prose of the world." Although Hegel did not altogether deny the beauty of nature, it is clear that he ranked it very low. Indeed, the structure of his system made this inevitable, for it is the self-conscious achievements of man that form its culmination.

It would seem that the triadic divisions of the "Lectures on Aesthetics" constrained and even corrupted Hegel's argument. An example of this occurs in his account of dramatic poetry, into which he introduced a species called "drama," the function of which was to add one species to tragedy and comedy and thus make three species of dramatic poetry.

Hegel also tended to confuse conceptual and historical relationships. For example, the distinction between symbolic, classical, and romantic art was intended to be made on conceptual grounds, but, on the other hand, Hegel had in mind historical progression. Here, as elsewhere, Hegel confused historical types, such as romanticism, with conceptual types, such as tragedy, which have no necessary temporal sequence. Perhaps the most interesting case of this is Hegel's suggestion that art comes to an end with the highest flights of romanticism. We have already seen that Hegel brought his account of dramatic poetry to an end with comedy, the most subjective of all art forms. At the very end of the "Lectures on Aesthetics" he said that "in this culmination comedy is leading straight to the dissolution of art in general." It is unlikely that Hegel believed that art was coming to an end, any more than he believed that with the Prussian state, history was coming to an end. Yet in each case he argued in such a way as to suggest that the culmination of a conceptual sequence must also be the conclusion of a historical progress. Insofar as he held that history was the movement of the Divine in the world, it was natural to make this identification, extravagant as it is. Bosanquet, who denied that Hegel believed that art was on the point of final dissolution, held that he did foresee that it was

about to suffer an eclipse in the new form of society. "But we must claim extraordinary insight for him, who, still under the spell of Schiller and Goethe, described the present exhaustion of the art-impulse and the conditions hostile to it in language approaching that of John Ruskin and William Morris" (*A History of Aesthetic*, 4th ed., London, 1917, p. 361).

PHILOSOPHY OF RELIGION

A few commentators have regarded Hegel's philosophy as atheistic, but most have considered it to be either theistic or pantheistic. Certainly religious expressions abound in his writings, even in the *Logic*. It has been shown how closely he associated art with religion and how he applied religious epithets to the state. It was also pointed out that the *Phenomenology* might with some justification be interpreted in atheistic terms. It would be obviously overstraining the evidence, however, to interpret Hegel's mature system in this way, for in the system religion is a form of Absolute Mind, along with art and philosophy, which is the supreme expression of the Absolute Mind. According to Hegel, religion represents or pictures the Absolute, whereas philosophy conceives or thinks it. The same truth, that is, expressed in quasi-imaginative form in one and in conceptual form in the other.

CHRISTIANITY. Since the concept is supreme and ultimate, philosophy surpasses religion to this extent, but in doing this, it finally and fully justifies Christianity, which is the absolute religion. The doctrine that elevates Christianity above all other religions is the doctrine of the Incarnation, which, according to Hegel, is the religious expression of the philosophical truth that the Infinite Being is not distinct from what is finite but is necessarily manifested in it. Hegel also interpreted the doctrine of the Trinity in philosophical terms. In the "Science of Logic" God is revealed as he is before the creation of the world; in the "Philosophy of Nature," in his material embodiment; and in the "Philosophy of Mind," as reconciling the finite and the Infinite. In this way the Father, the Son, and the Holy Spirit are explained in terms of the main themes of the Hegelian system. Again, Hegel interpreted the doctrine that God is love to mean that although the Infinite Being cannot exist without negation and opposition, the negation and opposition are finally reconciled. Finally, it should be mentioned that Hegel gave a series of lectures on the traditional proofs for the existence of God. He admitted the force of Kant's criticisms of these proofs but claimed to have reformulated the arguments so as to meet the criticisms. In particular, he held that the Ontological Argument, which Kant had

regarded as vital but unsound, was valid when properly understood.

Undoubtedly, Hegel's later writings are much closer to orthodox Christianity than his earlier ones. The early "Life of Jesus" had nothing to say about the Resurrection, whereas in the *Lectures on the Philosophy of Religion* this doctrine was stated and defended. Hegel here wrote of "the death of death," of "the triumph over the negative," of mind as "the negative of this negative which thus contains the negative in itself," and of "the division of the divine idea and its reunion" that is "the whole of history." Although Hegel said that God appeared in the flesh at a particular time and in a particular individual, his account of the matter seems to be extremely general. In the Christian doctrine of the Incarnation, God became man in Jesus Christ at a particular time and place, whereas Hegel's God is incorporated in the finite world. It would seem that a highly specific historical view is replaced by a highly general metaphysical one. Hegel himself did not take this view of his own work, nor did a younger contemporary of his, Karl Friedrich Göschel, in his *Aphorismen über Nichtwissen und absolutes Wissen im Verhälnisse zur christlichen Glaubenserkenntnis* (Berlin, 1829). In the *Encyclopedia* (Sec. 564) Hegel recommended this book, which is generally regarded as giving a theistic account of the Absolute. Just before referring to Göschel's book, Hegel had written, "God is only God in so far as he knows himself; his self-knowledge is moreover his consciousness of himself in man and man's knowledge *of* God, a knowledge that extends itself into the self-knowledge of man *in* God."

What cannot be doubted is that Hegel's philosophy of religion contained elements that could easily be developed in ways that go counter to orthodox Christianity. Thus, when D. F. Strauss argued, in his *Life of Jesus* (1835), that the Gospel story was a set of myths, he was consciously working out what he thought was the consequence of Hegel's view that in religion the truth about God is understood in representative or pictorial terms. Again, Ludwig Feuerbach, in his *The Essence of Christianity* (1841), endeavored to interpret the Christian doctrines in human and psychological terms as the imaginary fulfillment of wishes that cannot be satisfied here on Earth. We have already referred to the passage in Hegel's *The Positivity of the Christian Religion*, in which he said that in the days of imperial Rome men who had been robbed of their freedom in this world sought for it in a heaven beyond. Feuerbach, who, of course, had not seen this work, could have read something similar in the *Phenomenology*. It is a very short step from Hegel's view

that the infinite is manifested in the finite to the view that it is a projection of it. Perhaps the truth of the matter is that the Christian religion, according to Hegel, is adequate in its own sphere and that the philosophy of religion is required to counteract false religious views and false views about religion but is not a substitute for it. This is the interpretation given by Lasson in the introduction to Hegel's philosophy of religion printed at the end of his edition of Hegel's *Lectures on the Philosophy of Religion*.

Bibliography

WORKS BY HEGEL

The edition of Hegel's collected works, *Werke. Vollständige Ausgabe*, published soon after his death has already been mentioned. This was republished in 26 volumes under the editorship of Hermann Glockner (Stuttgart, 1927–1940) as the jubilee edition. Volumes 23–26 of this edition are an invaluable *Hegel-Lexikon* (1st ed., 1935; rev. ed., 2 vols., 1957). Mention must be made of Georg Lasson's edition, *Georg Wilhelm Friedrich Hegels Sämtliche Werke* (Leipzig, 1905–); this was to have been revised and reedited by Lasson and Johannes Hoffmeister, and some volumes were published (Hamburg, 1949–). As a result of the death of Lasson and of Hoffmeister, the plan was altered. The *Sämtliche Werke, neue kritische Ausgabe*, which Hoffmeister started to edit, will continue under the editorship of various scholars. This edition contains Hegel's letters in *Briefe von und an Hegel*, 4 vols. (1952–1960). The unpublished writings prior to 1800 will appear in this new critical edition under the editorship of Gisela Schüler. Another collection with still earlier documents is *Dokumente zu Hegels Entwicklung*, edited by Hoffmeister (Stuttgart: Fromanns, 1936).

Some of Hegel's early writings were translated from Herman Nohl, ed., *Hegels theologische Jugendschriften* (Tübingen, 1907) by T. M. Knox as *Early Theological Writings* (Chicago: University of Chicago Press, 1948). There is a translation of the *Phenomenology of Mind* by J. B. Baillie (London, 1910; 2nd ed., 1931). William Wallace translated the encyclopedia "Logic," with excellent prolegomena in *The Logic of Hegel* (Oxford: Clarendon Press, 1873); there are subsequent editions. He also translated the last part of the *Encyclopedia* (in *Hegel's Philosophy of Mind*, Oxford, 1894). See also *The Science of Logic*, translated by W. H. Johnston and L. G. Struthers, 2 vols. (London, 1929); *The Philosophy of Right*, translated and edited by T. M. Knox (Oxford, 1942), a very fine work of scholarship; *The Philosophy of Fine Art*, translated by F. P. B. Osmaston, 4 vols. (London, 1920); *Lectures on the Philosophy of Religion*, translated by E. B. Speirs and J. B. Sanderson, 3 vols. (London, 1895); and *Lectures on the History of Philosophy*, translated by E. S. Haldane and F. H. Simsen, 3 vols. (London 1892–1896; reprint, 1955). J. Sibree's translation of the *Lectures on the Philosophy of History* (London, 1857) has been reprinted several times. See also *Hegel's Political Writings*, translated by

T. M. Knox with an introductory essay by Z. A. Pelczynski (Oxford, 1964). There is a translation of the *Encyclopedia* with notes by Gustav E. Mueller (New York, 1959). There are two useful books of selections, *Hegel: Selections*, edited by Jacob Loewenberg (London and New York, 1929), and *The Philosophy of Hegel*, edited by C. J. Friedrich (New York: Modern Library, 1953).

WORKS ON HEGEL

The System

Caird, Edward. *Hegel*. London and Edinburgh, 1883.

Copleston, Frederick. *A History of Philosophy*, Vol. VII: *From Fichte to Nietzsche*. London, 1963. Chs. 9–11.

Croce, Benedetto. *Ciò che è vivo e ciò che è morto della filosofia di Hegel*. Bari, Italy, 1907. Translated by Douglas Ainslie as *What Is Living and What Is Dead in the Philosophy of Hegel*. London: Macmillan, 1915.

Findlay, J. N. *Hegel: A Re-examination*. London: Allen and Unwin, 1958. Emphasizes the *Logic* and interprets Hegel in somewhat nonmetaphysical terms.

Glockner, Hermann. *Hegel*, 2 vols. Stuttgart, 1929. These are Vols. XXI–XXII of the jubilee edition of Hegel mentioned above.

Grégoire, Franz. *Études hégéliennes*. Louvain, Belgium, and Paris, 1958. Contains detailed and fruitful discussions of the central issues.

Haering, T. L. *Hegel: Sein Wollen und Sein Werk*, 2 vols. Leipzig, 1929. A leading authority.

Hartmann, Nicolai. *Die Philosophie des deutschen Idealismus*, Vol. II: *Hegel*. Berlin and Leipzig, 1929.

Kaufmann, Walter. *Hegel: Reinterpretation, Texts and Commentaries*. Garden City, NY: Doubleday, 1965.

Kline, George L. "Some Recent Re-interpretations of Hegel's Philosophy." *Monist* 48 (1964): 34–73.

McTaggart, J. M. E. *Studies in Hegelian Cosmology*. Cambridge, U.K.: Cambridge University Press, 1901. Stimulating and idiosyncratic.

Mure, G. R. G. *An Introduction to Hegel*. Oxford: Clarendon Press, 1940. Emphasizes Hegel's debt to Greek philosophy, Aristotle in particular.

Pringle-Pattison, A. S. *Hegelianism and Personality*, 2nd ed. London and Edinburgh: Blackwood, 1887. The first edition was published under the name Andrew Seth. See the article "The Absolute."

Seeberger, Wilhelm. *Hegel: Oder die Entwicklung des Geistes zur Freiheit*. Stuttgart, 1961. A new statement of the "orthodox" interpretation.

Serreau, René. *Hegel et l'hégélianism*. Paris: Presses Universitaires de France, 1962. Brief but informative book with good introductory account of the various Hegelian schools.

Stace, W. T. *The Philosophy of Hegel*. London: Macmillan, 1924; New York: Dover, 1955. A detailed account based on the *Encyclopedia*.

Early Writings

Asveld, P. *La pensée religieuse du jeune Hegel*. Louvain, Belgium, 1953.

Dilthey, Wilhelm. *Die Jugendgeschichte Hegels*. Berlin, 1906. It is included as Vol. IV of Dilthey's *Gesammelte Schriften* (Berlin and Leipzig, 1921).

Hyppolite, Jean. *Introduction à la philosophie de l'histoire de Hegel*. Paris, 1948. A valuable account of Hegel's early views on history and politics.

Kaufmann, Walter. "The Young Hegel and Religion." In his *From Shakespeare to Existentialism*. Boston: Beacon Press, 1959. Ch. 8.

Lukács, Georg. *Der junge Hegel*. Berlin, 1948. An interesting Marxist interpretation.

Peperzak, A. T. P. *Le jeune Hegel et la vision morale du monde*. The Hague, 1960.

Walsh, W. H. "The Origins of Hegelianism." In his *Metaphysics*. London: Hutchinson, 1963. Ch. 9.

"Phenomenology of Mind"

Hyppolite, Jean. *Genèse et structure de la Phénomenologie de l'Esprit de Hegel*. Paris, 1946.

Kojève, Alexandre. *Introduction à la lecture de Hegel*. Paris, 1947. Gives the "atheistic" interpretation.

HEGEL, GEORG WILHELM FRIEDRICH [ADDENDUM]

Georg Wilhelm Friedrich Hegel changed his major philosophical views very little from the publication of his first major work, the *Phenomenology of Spirit,* in 1807 until his death in 1831. This stability and continuity have not made it any easier for commentators to agree on what those views were. Disagreement about Hegel's basic position and its implications is still widespread, even more so after a great resurgence of Hegel studies after World War II.

In the Anglophone philosophical world, Hegel's position is still often summarized as an objective idealism, thanks largely to his influence on early twentieth-century British objective idealists such as Francis Herbert Bradley. He is said to have believed that only "mind" (the preferred translation of *Geist* until the A. V. Miller translation of *Phenomenology of Spirit* was first published in 1977) was "real"; or that no determinate individual object could be said to be real. Such an object was really a "moment" of the interrelated and temporally developing structure of the one true substance, the absolute, or absolute mind. Such a substance was said to develop over time; the nature of that development was a process of greater self-consciousness, and this development was reflected in, or the underlying basis of, the great social and political changes of world history, as well as intellectual changes in philosophy, art, and religion. Since Hegel appeared to have claimed a full and final "absolute knowledge," an "encyclopedic" account of such a structure, or the relation between "logic," philosophy of nature, and philosophy of spirit could be given. (A compelling demonstration that such an objective-idealist or "internal relations" view could not have been Hegel's position was published by the German Hegel scholar Rolf-Peter Horstmann in 1984, *Ontologie und Relationen.*)

Some aspects of such views of what Hegel really meant persist in many postwar interpretations but have not provoked much serious discussion or the interpretive variants that once characterized the work of John McTaggart Ellis McTaggart, G. R. G. Mure, Edward Caird, and Walter Terence Stace. Other interpretations and emphases have predominated. Many commentators have become interested in Hegel less as an object of purely historical research and more as a possible contributor to perennial and current philosophical controversies.

Charles Taylor's 1975 study, *Hegel,* while offering a comprehensive commentary on all aspects of Hegel's work, emphasized Hegel's insights into the emerging problems of the modern social and political world—problems such as social fragmentation, alienation, and the proper understanding of the modern goals of freedom and some sort of harmony with self. Taylor showed that many of Hegel's theoretical intentions could also best be understood against the backdrop of such concerns, and his approach became influential.

Hegel's understanding of the intellectual and social dimensions of modernization was also important in the work of many critical theory or Frankfurt school neo-Marxist philosophers (a group sometimes even designated as "neo-Hegelian" Marxists because of their attention to the social function of ideas and culture without a reliance on traditional Marxist versions of economic materialism). In the work of the most important "second generation" critical theorist, Jürgen Habermas, Hegel also plays a large role in what Habermas calls, in a book title, *The Philosophical Discourse of Modernity.* Hegel is called "the first philosopher who made modernity a problem" (p. 4)—this by raising many questions about the sufficiency of the modern notions of subjectivity and rationality.

In other developments, Klaus Hartmann in several influential articles proposed what he called a "nonmetaphysical" reading of Hegel, one that emphasized Hegel's category theory and the unusual "logic" of categorial relations, all as more or less autonomous philosophical problems, not necessarily wedded to any metaphysics of absolute mind. A group of German philosophers who came to be known as the Heidelberg school began to work in a more contemporary way on the single greatest problem that preoccupied the German idealists as a whole, and Hegel especially: the problem of self-consciousness, or "reflection," how the mind could be said to be both the subject of its own consciousness and object to itself at the same time. (The most important and influential work on this aspect of the idealists and Hegel in particular has been Dieter Henrich's.) Since, for many post-Kantian idealists, any possible cognitive or practical relation to the world was an active comporting of oneself

toward the world, or a "self-relation in relation to an other," the problem of self-relation was argued to be fundamental in any epistemology or account of human agency. These elements have also been emphasized by those who argue that Hegel should be read much more as a post-Kantian idealist, as much more decisively influenced by Immanuel Kant's founding arguments about the possibility of any self-conscious experience than by, say, Benedict de Spinoza or Friedrich von Schelling.

Hegel's contributions to all such problems—the nature and implications of modern social life, the possibility of self-consciousness and self-knowledge, the nature of the mind-world, and agency problems—reappear with great urgency in his ethical and social theory and in many interpretations. Debates about whether Hegel's 1821 *Elements of the Philosophy of Right* encouraged an accommodation of the conservative rulers of the Prussian state, or whether he was guilty of a kind of "organicist" anti-individualism, have been replaced by an emerging consensus that Hegel belongs within, if idiosyncratically, the modern liberal political tradition. This recognition has been somewhat complicated by "communitarian" writers and "traditionalist" writers suspicious of the modern reliance on claims of rationality as decisive in ethical life. Many such writers have occasionally enlisted arguments in a case against the classical liberal tradition. Hegel's position on the importance and "priority" of the ethical community in ethical life (*Sittlichkeit*) has sometimes been understood such that anyone who believes in the priority of prevolitional attachments or commitments in ethical deliberation (e.g., such attachments are necessary for deliberation to get started or have direction but cannot themselves be products of such deliberation) is labeled a neo-Hegelian. But Hegel believes that modern ethical life (the institutions and practices of modern social existence, the modern family, civil society, and the legal, constitutional state) are not just "ours" and "prior." He believes they are rational, raising the still much-debated question of how he distinguishes rational from nonrational ethical communities.

A great deal of scholarly work has been done in the postwar period on Hegel's texts, especially on the dating and organization of his Jena-period lecture materials. Karl-Heinz Ilting has compiled, edited, and published an extensive collection of Hegel's lecture notes on political philosophy, and a new critical edition of Hegel's works has begun to appear. New English translations of the *Phenomenology*, the *Logic*, the *Philosophy of Right*, the *Aesthetics* lectures, Hegel's letters, and many other works have also appeared.

WORKS BY HEGEL

German

Gesammelte Werke. Edited by Rheinisch-Westfälischen Akademie der Wissenschaften. Hamburg: Meiner, 1968–. Of great value to serious students of Hegel in the original.

Philosophie des Rechts: Die Vorlesung von 1819/20. Edited by D. Henrich. Frankfurt: Suhrkamp, 1983.

Vorlesungen über Rechtsphilosophie 1818–31. Edited by K.-H. Ilting. Stuttgart: Frommann-Holzboog, 1974. Contains an invaluable collection of student notes and additions.

Werke in zwanzig Bänden. Frankfurt, 1971. Useful paperback version of the 1832–1845 Moldenhauer and Michel edition.

English

The Difference between Fichte's and Schelling's System of Philosophy. Translated by H. S. Harris and W. Cerf. Albany: State University of New York Press, 1977.

Elements of the Philosophy of Right. Edited by A. Wood; translated by H. B. Nisbet. Cambridge, U.K.: Cambridge University Press, 1991.

Faith and Knowledge. Translated by W. Cerf and H. S. Harris. Albany: State University of New York Press, 1977.

Hegel: The Letters. Translated by C. Butler and C. Seller. Bloomington: Indiana University Press, 1984.

Hegel's Aesthetics: Lectures on Fine Art. Translated by T. M. Knox. Oxford, 1965.

Lectures on the Philosophy of Religion: The Lectures of 1827. Edited by P. Hodgson; translated by R. F. Brown, P. C. Hodgson, J. M. Stewart, and H. S. Harris. Berkeley: University of California Press, 1984.

Phenomenology of Spirit. Translated by A. V. Miller. Oxford: Clarendon Press, 1977.

Science of Logic. Translated by A. V. Miller. London, 1969.

HEGELIANISM

The term *Hegelianism* is applied to a range of philosophical doctrines and traditions influenced by the nineteenth century German philosopher Georg Wilhelm Friedrich Hegel (1770–1831). Hegel's influence is as broad and diverse as his writings; moreover his legacy, like his philosophy, is characterized by tensions between dialectical opposites.

A central part of Hegel's philosophical reputation has always been in metaphysics, where he is seen as the leading proponent of absolute idealism: the thesis that reality as a whole—nature, humanity, history, and so on—is informed and shaped by (and indeed ultimately is a manifestation of) what Hegel famously called *Geist*: mind or spirit. For Hegel, Geist is both rational and rationally comprehensible, whether in logical structure, natural science, or historical progress. Hegel also held that Geist itself exhibits a distinctive self-consciousness or self-articulation, and that the manifestations of this self-consciousness can be found in psychology, history, religion, drama, art, and philosophy.

The earliest Hegelian movement comprised a core of adherents working to vindicate these claims in a diverse range of intellectual projects seeking to identify and exhibit the promised rational structure. Characteristic of the Hegelian position is the claim that rational structure is historical and dialectical: The rational structure of the real is not a static and self-consistent body of facts, but a dynamic process unfolding through the systematic resolution of dialectical contradictions. The earliest Hegelians sought to identify this structure in the areas of law, history, politics, and natural science. Among the first Hegelians were the members of the Society for Scientific Criticism, formed in July 1826 in Hegel's own home, and closely associated with the *Jarhbücher für wissenschaftliche Kritik*, a journal devoted to the dissemination and application of Hegelian ideas.

Prominent members of this old Hegelian movement included Leopold von Henning (*Prinzipien der Ethik in historischer Entwicklung*, 1824), who applied Hegelian ideas in ethics; and Eduard Gans (*Das Erbrecht in weltgeschichtlicher Entwicklung*, 1924–35), who was primarily concerned with issues in law and jurisprudence. The hallmark of this early Hegelianism was the emphasis placed

on historical approaches to traditional philosophical issues, together with the attempt to provide a critical justification of cultural configurations as the outcome of rational dialectical progressions. Hegelianism thus played an important role in the emergence of history as the central category and discipline of the developing human sciences of the nineteenth century.

Many of these early contributions were soon lost to memory as Hegel's influence waned in Germany after his death in 1831. In the case of theology and religious studies, however, self-professed Hegelians achieved a lasting prominence. Early Hegelian theologians also provided the first example of a pattern that was repeated later: the emergence of two traditions, each drawing explicitly on Hegelian teachings, yet developing those ideas in sharply opposed directions and soon coming into noisy confrontations, which themselves became points of reference in subsequent philosophical developments. Hegel's own theological position was that orthodox Judeo-Christian religious teachings were true yet ultimately inadequate articulations of ideas expressed more fully and exactly in the language of metaphysics. Hence in the Christian doctrines of the creation, divine incarnation, the Trinity, and human immortality, for instance, Hegel finds vivid thought-images (*Vorstellungen*) of rational concepts (*Begriffe*) fully graspable only in his idealistic metaphysics. On this model theism becomes a penultimate articulation of absolute idealism; the hope for immortality is satisfied in an individual's identification with a trans-individual cultural whole that survives the death of its constituents; and the doctrine of the Trinity is seen as a vivid representation of a metaphysical truth graspable only by a dialectical logic. The central Hegelian notion of *Aufhebung* (variously and inadequately translated as sublation, supercession, and so on) finds its exemplar in the Christian claim to complete the Hebraic law by negating it.

The tension in this position is manifest. The orthodox articles of faith are true and yet not true: true insofar as they articulate a thought that merits our assent, yet not true because cast in a language incapable of adequate articulation of the insights they express. The earliest conflicts in the Hegelian school emerged among theologians exploring the two opposed sides of this Hegelian contradiction. Philip Marheinecke (*Die Grundlehren der christlichen Dogmatik als Wissenshchaft*, 1827) and Karl Daub (*Die dogmatische Theologie jetziger Zeit*, 1833) defended and elaborated a Hegelian orthodoxy, and advanced the claim of Hegelianism to provide a middle way between an extra-rational fideism and the extreme

atheism that had long been feared as the final outcome of Enlightenment rationalism. But their work was soon eclipsed by the more radical approach inaugurated by David Friedrich Strauss, whose influential and controversial *Leben Jesu, kritisch bearbeitet* (1835–36) proposed a radically revisionist and explicitly critical reading of religious texts (particularly the Gospels) and proved to be a watershed in the secularization of religious studies.

It was this split among the Hegelians that first gave rise to the language of left and right Hegelians—a description Strauss himself introduced in 1837 (*Streitschriften zur Vertidigung meiner Schrift*). The left Hegelian treatment of theological issues reached its culmination in the work of Ludwig Feuerbach. His *Thoughts on Death and Immortality* (1830) argued explicitly against the idea of personal immortality; his *Essence of Christianity* (1841) was directed forthrightly against religion, and inaugurated the influential nineteenth century movement that reinterpreted religious teachings in psychological and political terms. An 1853 English translation by George Eliot played a focal role in the nineteenth century reassessment of religion in British intellectual circles.

The terms left and right derived from the political rhetoric of the day (the division between the two sides of the French Chamber of Deputies) and it was quickly to be applied once again in the struggle over Hegel's legacy in political philosophy. This is an area where, once again, we find important tensions in Hegel's own position. Hegel's political theory was essentially an application of his social theory: He saw in human society an unfolding attempt to develop institutions that were rational and just, and capable of sustaining an unfettered critical self-examination. For Hegel, society provides not only the material fruits of social cooperation (self-defense and the power of cooperative labor), but also what Hegel called *Anerkennung* or acknowledgement: the mutual recognition by citizens as free and rational self-determining agents.

Hegel held that the basic demands of the just state were met adequately only in the modern era, in particular with the emergence of the modern sociopolitical institutions of the modern family, the free market, the republic, and private property, themselves resting on a guarantee of civil liberty. In political history Hegelians thus set out to trace the emergence of these modern rational institutions; in politics Hegelians defended a monarchist liberalism, and some (notably Karl Rosenkranz) even served in parliamentary assemblies. But the Hegelian framework was once again put to very different uses when it came to its application to concrete issues in politics and political economy.

Rosenkranz and others sought to use Hegelian ideas to justify and reform the major institutions of modern political life, particularly in mid-nineteenth century Prussia. In explicit rivalry to these old or right Hegelians there emerged what have come to be known as the young or left Hegelians, chief among them Feuerbach, Bruno Bauer, and the young Karl Marx, who sought to use Hegelian criticism as a device for advancing radical social change. The tension between these two movements brought out the opposed tendencies in Hegel's position, which on the one side was interpreted as a philosophy of reconciliation, and specifically as a justification of status quo Prussian institutions, whereas on the other inspiring what the influential Polish Hegelian, August von Cieszkowski, called a philosophy of action (*Prolegomena zur historiosophie*). The left Hegelians abandoned the claim that Hegelianism could vindicate orthodox religion and politics and instead turned to apply Hegelian social theory to provide orientation in the struggle for social change.

In the context of this dispute between left and right appropriations of Hegel, many features of Hegelian philosophy were appropriated and applied in abstraction from Hegel's own distinctive metaphysical commitments. The most dramatic example of this came with Marx, who sharply rejected Hegel's idealistic metaphysics and theory of sociohistorical development. Where Hegel placed primary emphasis and found the root of historical change in what he called simply the *concept* or the *notion* (*der Begriff*) that advanced toward self-completion in human history, Marx advanced a materialism that found the prime mover of history in the material conditions of human existence and the satisfaction of material economic needs.

But through this metaphysical reversal, important elements of the Hegelian position remained, notably Hegel's treatment of history as the overcoming of dialectical contradictions (tensions between opposed principles in historical configurations), in the ideal of a final resolution of these tensions and thus a certain kind of end of history, and in his appropriation and development of the Hegelian notion of alienation. In his early contributions to the *Deutsch-französischen Jahrbücher*, the young Marx argued that the social, economic, and political structures of human history have become alien powers that tyrannize human beings. Hence it was not enough to call, as Bauer and Feuerbach had, for the end of religion because religion is not the cause but the expression of self-alienated man. One must rather attack the real material conditions that create and sustain this condition.

The tension between left and right Hegelianism proved to be one of the most enduring aspects of Hegel's legacy, and it is a debate that has played out in a diverse range of historical, political, and theoretical contexts, of which the nineteenth century socialist movement is only the best known example. In Russia the appeal to Hegelian social theory figured prominently in the mid-nineteenth century debate over feudal institutions and Russian national identity, particularly in the works of Nikolai Stankevich, Vissarion Belinskii, and in the activism of Mikhail Bakunin, whose later fame as the leading figure in European anarchism followed an earlier period of intense engagement with Hegelian ideas. In more recent times Hegelian philosophy of history was invoked in the attempt to find new political orientation after the collapse of communism and the end of the cold war at the end of the twentieth century (Fukuyama 1992).

Hegel's influence was also strong in the emergence and development of the existentialist tradition. A number of the themes central to existentialism had been explored in Hegel's writings: the themes of death and immortality, alienation, nihilism, and so on. Already in the writings of S.A. Kierkegaard (*Concluding Unscientific Postscript to Philosophical Fragments*, for example), existentialist thinkers had defined themselves in relation to Hegel, albeit in that case in the form of an insistent negation. Kierkegaard was relentlessly critical of Hegelian rationalism, and ridiculed Hegel's claim to provide a rational reconstruction of religion that could eliminate the absurdity that Kierkegaard himself found both in religious consciousness and in the human condition. But later French existentialists, notably Alexandre Kojéve, Jean Hyppolite, and Jean-Paul Sartre, developed much more sympathetic appropriations, shifting the focus from Hegel's mature writings (*The Encyclopaedia of the Philosophical Sciences* and *The Philosophy of Right*) to the much earlier *The Phenomenology of Spirit*.

For Hegel, phenomenology was to be a study of structures of self-consciously lived experience as manifestations of Geist. Hegel's *Phenomenology* comprised a series of case studies that exercised great influence on the existentialists, most importantly in connection with the account of the confrontation with death in the dialectic of master and slave, which Kojéve (1934) in particular made central to his reading of Hegel. Kojéve followed Hegel in arguing that the encounter with an *other* was both an essential moment in the structure of autonomous self-consciousness and yet, at the same time, an essentially destabilizing confrontation with which human beings and human institutions must ultimately come to terms.

Thus while the existentialists sharply diverged from the orthodox Hegelian metaphysical position and sharply rejected Hegelian rationalism, their philosophical practice—focusing in particular on the unfolding, essentially narrative structures of self-conscious experience and its intrinsic tensions—followed no thinker more closely than Hegel. Sartre's *Being and Nothingness* (1943) provides the fullest development of this strand of existentialism, and in many passages closely imitates its Hegelian model.

In nineteenth century Britain and America, by contrast, it was metaphysics that was preeminent in Hegel's legacy. Hegel's influence in the English speaking world began with J.H. Stirling's influential study, *The Secret of Hegel* (1865). Stirling's work itself mainly took the form of a sympathetic but somewhat superficial synopsis of Hegelian texts and doctrines, but it nonetheless proved influential in forging a generation of British idealists. As the British idealist movement matured, it grew increasingly independent of its German models, and its leading figures—T.H. Green and F.H. Bradley—developed independent philosophical systems of considerable originality. Nonetheless, important traces of the Hegelian origins persist, particularly in Bradley's strategy of arguing for his monistic idealism by exhibiting the systematic contradictions hidden in the common sense assumptions of reality as plural (comprised of ontologically distinct individuals), empirically knowable and mind-independent.

Later figures in the British idealist movement included Bernard Bosanquet, who contributed greatly to the propagation and interpretation of Hegel's own philosophical writings, and John McTaggart, whose most influential legacy derived from his antirealism about time. When the tradition of logical analysis emerged in Britain at the beginning of the twentieth century, it began with a systematic critique of this dominant idealist orthodoxy, most notably in the early writings of G.E. Moore and Bertrand Russell (see Peter Hylton's *Russell, Idealism, and the Emergence of Analytic Philosophy* [1990]).

Hegelianism was also influential in the emerging philosophical traditions in America. Particularly in areas with strong German immigrant traditions, Hegelian schools thrived, notably in Cincinnati (John Bernard Stallo, August Willich, Moncure Conway), and in St Louis, where Henry Brokmeyer and William Harris formed *The Philosophical Society*, which was explicitly Hegelian in its orientation and sponsored the *Journal of Speculative Philosophy*, an influential journal on the late nineteenth century American philosophical scene. These early American Hegelians included not only academic philosophers but influential significant civic leaders who sought to apply Hegelian ideas in social and educational reforms, and appealed to Hegelian philosophy of history in coming to terms with the upheaval of the American Civil War. Indeed prior to the emergence of the pragmatist tradition, Hegelianism was arguably the most well-defined school of American philosophy.

Among the most influential American Hegelians was California native and Harvard philosopher, Josiah Royce, who had visited Germany as a student and returned to Harvard as a key conduit of Hegelian ideas. In *The Religious Aspect of Philosophy* (1885) Royce argued for a version of absolute idealism, proposing and defending a Hegelian theism, with the existence of God understood in Hegelian terms as a super-individual subject in which finite subjects figure as moments of an overarching organic totality. Religious and proto-existentialist themes dominated Royce's appropriation of Hegel, and his *Lectures on Modern Idealism* (1919) remained an influential introduction to idealistic philosophy well into the twentieth century. Although Royce's idealism was soon eclipsed in the American academy by the budding pragmatist movement, he set an important precedent for a number of later North American Hegelians (recent examples include Charles Taylor [1975] and Robert Pippin [1991]) who have looked to Hegelian philosophy to answer the charge that modern cultural forms lead inexorably toward a crisis of faith and nihilistic despair. In this respect these more recent North American Hegelians can be seen as developing a more secularized version of Royce's idealism.

Hegel's legacy in logic has been complex and somewhat diffuse. Hegel himself held logic to occupy a fundamental place in philosophical inquiry, providing not simply a theory or mechanism for inference but rather an articulation of the underlying rational structure of all reality. In this sense he can be understood as the leading advocate of a material (as opposed to a merely formal) construal of logic. His logic was also distinctive in its dialectical structure, taking the form of a series of dialectical transformations intended to unpack all the basic categories of the real from tensions inherent in the bare concept of being. But despite a few early adherents and defenders (Kuno Fischer being the most important), relatively few have followed Hegel's lead in these views, and the nineteenth century reform of logic grew much more out of Kantian themes and problems than from recognizably Hegelian doctrines.

Nonetheless, Hegel's influence in logic has been felt indirectly, particularly in connection with his account of

conceptual determinacy. On an orthodox empiricist construal, concepts receive their determinate content in virtue of a connection with some nonconceptual content of experience. But this empiricist doctrine has continually come under attack, both in the nineteenth century neo-Kantian movement associated with Hermann Cohen and Paul Natorp, and again more recently in the work of the seminal twentieth century American philosopher, Wilfrid Sellars. In looking for alternatives to the traditional empiricist doctrine, logicians and semantic theorists have repeatedly been drawn to Hegelian themes. Thus, for instance, Tyler Burge's "Individualism and the Mental" (1979) introduced his defense of social externalism with an invocation of Hegel, and recent semantic theorists such as John McDowell and Robert Brandom have explicitly turned to Hegelian themes for an alternative to the empiricist account of some foundational given content.

McDowell's *Mind and World* (1994) develops an essentially Hegelian thesis in arguing that the conceptual content of experience must reach all the way down to its most primitive content and indeed must ultimately be seen as reflective of conceptual structure inherent in the world itself. Brandom's Hegelianism in *Making it Explicit* (1994) is more nuanced and complex, but his inferentialist semantics adapts a recognizably Hegelian theme in arguing that conceptual determinacy must be traced to the inferential role played by concepts in an essentially social and pragmatic context of demanding and providing reasons. What is common to these approaches is the conviction that semantic or conceptual content is fixed holistically and (particularly in Brandom's account) in the context of unfolding social interactions. Although these accounts are quite distant from Hegel's ambitions for logic, they retain an essentially Hegelian logical moment in finding an essential appeal to a collective, diachronic social background in the fixing of even the most elementary concepts.

Hegel's influence on twentieth century continental European philosophy has been pervasive, and has taken many different forms. The work of Wilhelm Dilthey was seminal in this connection, in part because of his work in recovering Hegel's early theological writings and writing his biography, but mainly because Dilthey's own influential approach to the philosophy of the human sciences owed much to Hegel in arguing for the centrality of narrative, biography, and history in what Dilthey himself called the *Geisteswissenschaften* (literally, the sciences of Geist—the human sciences such as psychology, anthropology, jurisprudence, and so on).

In the twentieth century, the early works of Herbert Marcuse (1932 and 1960) sought to adapt Hegelian ideas to a new historical and cultural circumstance, combining a broadly Hegelian conception of history with elements of Martin Heidegger's existentialism. The Hegelian-Marxist conception of history as driven by dialectical tension found new voice in the writings of Max Horkheimer, Theodor Adorno, and other members of the Frankfurt School, albeit in this case without the Marxist and Hegelian optimism regarding the final resolution of such contradictions. And a broad array of thinkers followed a Hegelian lead in locating objectivity in configurations of intersubjective consensus. Rather than contrasting objective truth and subjective illusion, as had been common in the tradition stretching from Galileo to Immanuel Kant, these thinkers (including figures as diverse as Edmund Husserl and Jürgen Habermas) sought to reinterpret the notion of objective truth in terms of an ideal of a normative intersubjective consensus. Although the hints of this theory of objectivity can be traced back to Kant's aesthetics, it is perhaps the most pervasive legacy of Hegel's attempt to think through "the I that is we and the we that is I." Among contemporary European thinkers, Axel Honneth (1992) presents perhaps the clearest case of this Hegelian legacy in political theory.

Finally, Hegel's legacy can be found at work—diffuse but unmistakable—in the standing that the history of philosophy has acquired in the past two centuries. More than any other prominent philosopher since Aristotle, Hegel's philosophical practice was directly related to his appropriation of the history of his discipline. But where Aristotle's writings systematically surveyed the opinions of his predecessors, Hegel claimed to find in philosophy's history both a systematic order and the elements for his own philosophical synthesis. It is now a commonplace—albeit a commonplace that is sometimes challenged—to see the history of philosophy as directly relevant to philosophical inquiry generally. The emergence of this view, as of the conviction that philosophy is essentially unlike the natural sciences in this regard, can be traced to Hegel, who can without exaggeration be credited with inventing the very discipline of the history of philosophy. For Hegel, the history of philosophy is not merely the history of ideas; it is an attempt to reread and rethink the history of attempts to tackle philosophical questions. Its aim is ultimately not historical but philosophical: to uncover a rational order that will itself illuminate those questions themselves.

HEIDEGGER, MARTIN
(1889–1976)

Martin Heidegger (1889–1976) was born in Messkirch, a small town in the hills of southwestern Germany. The environment of his modest, middle class upbringing was that of a Catholic agrarian village where his father was the sexton of the local church. When Heidegger was fourteen he entered the Catholic seminary at Constance and began an education that appeared to be directed toward a vocation in the priesthood. He entered a novitiate with the Jesuits in 1909 but left that track after a short time and shifted out of clerical training altogether in 1911. He intensified his studies in philosophy, literature, and sci-

ence, and for a time concentrated on mathematics. During this period (through 1915) he developed a conservative approach to neo-scholastic thought and published articles in conservative Catholic journals. He also read intensely the emerging phenomenological literature and neo-Kantian philosophy.

Heidegger's doctoral dissertation in 1913 had the title, "The Doctrine of Judgment in Psychologism: A Critical-Positive Contribution to Logic." He completed his habilitation dissertation in 1915, "Duns Scotus's Doctrine of Categories and Meaning."

With the emergence of a strong interest in historical development and in Edmund Husserl's thought, a significant counterforce to his Christian, transcendentally oriented convictions began to form. On the one hand he understood the basic structures of truth and meaning to have changeless validity. On the other, he saw that an act of mind requires time for syntheses and connections and that philosophical thought bears describable histories within it. Although academics identified him as a rising Catholic thinker, he was increasingly influenced by G. F. W. Hegel's historical, dialectical thought as well as by the "life-philosophy" of Friedrich Nietzsche, Wilhelm Dilthey, Henri Bergson, and Max Scheler. Søren Kierkegaard's and Martin Luther's writings also had a strong effect on his thought. The transcendental orientations of Thomistic, Husserlian, and neo-Kantian philosophy were increasingly challenged in Heidegger's thought as he devoured the art and philosophy—both religious and nonreligious—that influenced his moods and feelings as well as his thinking at least as powerfully as rational argument influenced them.

Heidegger's attention turned increasingly to issues of time, history, suffering, and unresolvable ambiguity. The regions of pure logic and transcendentally oriented morality and epistemology began to appear to him as desertlike and abstract. Metaphysical thought, if it is to count as important, must give clarity to and insight into lives and histories. Issues connecting phenomenology with time, history, and life formed a new horizon for the young philosopher. Whereas in his 1913 dissertation atemporal logic and its categories provided the way to understanding being, by 1915 the *question* of being, not being's static availability for conceptual grasp, began to take shape. Hegel and especially Husserl began to emerge as major transitional figures as Heidegger moved away from Thomism and neo-Kantian philosophy and toward a phenomenological approach that valorized description over speculation and practical life over categorical analysis.

When he married Elfride Petri in 1917 his departure from Catholicism, which became explicit in 1919, was well underway. Heidegger was in the process of a turn the momentum of which helped to define both his creativity and the movement of his thinking.

In 1918 he became, as a Privatdozent, an assistant to Husserl in Freiburg. The University of Marburg appointed him associate professor in 1923, and in 1928 he succeeded Husserl as Professor at Freiburg.

EARLY THOUGHT

Two of Heidegger's early insights are that thought takes place only within the particularities of cultural and communal lives and that particular lives are saturated with histories. This emphasis on temporal, historical particularity means that he began to place a primary importance on the situatedness of thought in the history of philosophy. This emphasis is particularly noteworthy because the historical emphasis added a dimension to phenomenological thought that was not clearly pronounced in Husserl's work and because it showed the particularity of Heidegger's own way: his early and deep engagement with ancient and medieval texts and the personal import of his traditional, historically oriented education. Even though he turned away from metaphysical theology, he did not turn away from the central importance for thought of the metaphysical tradition. It provided the site for philosophical transformation and departure.

Heidegger's recognition of the importance of temporal particularity for thought set in motion a conflict of values that would help to shape his thought for over a decade. He launched a task of learning to think with the traditions that formed his particularity in such a way that he could turn through their senses of timelessness by the temporal movement of his own thought: The temporal dimension of his thought began to define the meaning of claims to timelessness. To carry out such a project he needed to work through metaphysical thought, finding in it what overturns its predisposition toward unchanging truths, formal logic, and the priority of the knowing subject. "Temporal-historical occurrence" names the overturning element. "Phenomenology" names the approach by which Heidegger formulated the transforming power of time in European sensibility. Together, temporal-historical occurrence and phenomenology provided Heidegger with the elements that allowed him to reconsider the specificity and temporal palpability of life that he finds misconceived in his philosophical lineage and that takes the shape of the question of being.

This kind of turning also applies to his religious background. His movement from pretheology student to theology student, to religiousness without church or theology, to phenomenology, to a thinker of the question of being and of truth in the Greek sense of *aletheia*: this movement engaged a metamorphic turning through theology and religion. Within a few years of his appointment to Freiburg as a *Privatdozent* he would attempt to rethink such Christian words as "fall," "guilt," "word," "conversion," and "conscience," turning them out of contexts of faith and theological meaning to a contextual meaning without religious significance. Heidegger emphasized as his work progressed that such turning composes the way thought unfolds: A turning movement through and beyond a body of thoughts manifests the very life of thought. Without such turning thinking comes to its end. Further, a person cannot engage Heidegger's thought without encountering its metamorphic movement. In such movement claims about universal and timeless realities undergo for him a transformation specific to a particular engagement, and such engagement is defined by the singularity of its metamorphosis. Thought in its temporal-historical happening takes place as a living, particular, and self-transforming event. This orientation would mean that Heidegger was ill-disposed toward philosophical schools. When he was one of the leading philosophers in Europe, he did not encourage the formation of a Heideggerian school of thought. He believed that thinkers must find their own ways in their own settings and in their own life-worlds. Such thinking takes place in dialogue with the values, ideas, and beliefs that people find in other ways of thinking and living.

Heidegger experienced the beginning of transformative insights that distanced him from Thomistic and neo-Kantian thought in the late teens and early twenties, but he did not have an adequate way of bringing the insights to full thought. A "hermeneutics of facticity" names an early and landmark term for Heidegger. "Facticity" in this context refers to the irreducibility of things in their living events, and "hermeneutics" means interpretive explication. People recognize and interpret given things before they develop theoretical concepts about them. Interpretations arise as people live practically with things, encounter them in different contexts, use them, and feel their impacts. Prior to the distance invoked by theoretical reflection, people are enmeshed in their environments, and people's environments are filled with things that appear in their living, usually practical specificity. The ways in which things appear in those nontheoretical situations compose pretheoretical interpretations, and things in their appearing and facticity are nothing other than

their own events. How might philosophers think in and from a living situation that is filled with everyday and unconsidered interpretations and bring both those interpretations and themselves to conceptual elaborations that hold in mind the concreteness of things? What kind of language would be required? How would such thought transpire?

ARISTOTLE AND BEYOND

Heidegger came to the idea of a hermeneutics of facticity, that is, interpretations based on practical life, through his work on Aristotle and Husserl. His sympathy with Luther's attacks on scholasticism was consistent with his rejection of the scholastic interpretations of Aristotle that he learned as a student. Heidegger wanted to understand by intense reconsideration of many of his texts Aristotle's thought prior to Christian appropriations of it, the Aristotle whose concepts arose from his own Greek world. A radical departure from the Christianized Aristotle was required, Heidegger thought, in order to engage Aristotle's work in its vastly different manner of living when compared to that of later thinkers.

Heidegger's groundbreaking and influential interpretations of Aristotle provided him with a forceful return to European philosophy's Greek heritage. It also provided the occasion to rethink that heritage by means of an approach and vocabulary that he learned from Husserl. As he took away the Christian superstructure that encased the Aristotle he first studied, Heidegger reformulated Aristotle's thought with the eyes of a phenomenologist, eyes, he said, that he received from Husserl: he began to turn Aristotle's seemingly metaphysical thinking out of itself and into a way of thinking that moved decisively away from metaphysical formulation. In order to engage Aristotle well, Heidegger must preserve the vast difference between his own and Aristotle's spiritual environments. He would not overcome the difference; he would preserve it as he took his careful departure from Aristotle's way of thought by intense encounters with his texts.

Heidegger was arrested by, among other things, Aristotle's account of practical wisdom (*phronesis*). It described a kind of situational knowing that did not propose completion by reference to unchanging objects; it was intrinsically open to future development, and it functioned to open up future developments. Husserl's account of internal time consciousness also had, for Heidegger, the virtue of making impossible a *complete*, objective grasp of any thing. Heidegger found, however, in both Aristotle and Husserl an unquestioned prioritization of

present time. This prioritization meant that neither saw clearly that futurity—coming to pass and yet to be—defined a nonobjectifiable dimension of presence or that presence is strangely modified—put in question—by its opening to futurity. This openness means that futurity defines presence, not as a categorical abstraction but as a constitutive indefiniteness and indeterminability in the lives of whatever happens. Time and its concept appeared to be the issues over which both Aristotle and Husserl stumbled—time and, for Husserl, the question of subjectivity.

THE PHENOMENOLOGICAL APPROACH

The sense of phenomenology, as Heidegger began to think of it during his years in Marburg, comes from the ancient Greek deponent, *phainesthai*, a middle voice form that means, "to show itself." A phenomenon is an event that shows itself. *Phainesthai* is formed from *phaino*, and that word means to bring something to light. The stem of the word is *pha—phos*, the light or shining whereby something is manifest. To give an account (*logos*) of phenomena meant for Heidegger to describe beings in their self-showing, to so speak and think that one is brought to things in their self-showing, and to give an account of the shining (the "light") that allows their manifestness. Self-showing composes the lives of individual beings.

Heidegger makes a sharp distinction between the specificity of a self-showing being and the enactment of that self-showing. Philosophers can give accounts of the ways beings show themselves, but they can also give accounts of the way the enactment of self-showing happens. This latter account addresses the being of beings and must not be confused with description of a highest being: being is not a being. This ontological difference between being (the occurrence of self-showing) and beings (a specific instance of self-showing) is basic in Heidegger's thought and persists in several forms throughout his career. It is a difference that characterizes the happening of phenomena: a phenomenon is a specific self-showing thing, and its being happens as the enactment of self-showing. Heidegger calls "ontic" the way a thing shows itself in its particularity. He calls "ontological" the happening of disclosiveness that is common for all phenomena.

The self-disclosive happening of phenomena, not a subjective state or action, thus becomes Heidegger's primary area for descriptive thought. Husserl too gave priority to the manifestness of phenomena and to ways things are manifest, and for him an intention may be

described as the direction of an appearing (manifest) event. "Direction" for Husserl suggested an unfulfilled, open-ended process of appearing that constitutes an event of transcendental subjectivity. It is located in transcendental, subjective acts of consciousness. Heidegger's way of engaging facticity, history, and time, however, turned him away from consciousness and toward the world. The unfulfilled directions of beings are not found in a proposed and lively structure of transcendental subjectivity but in the self-disclosive happening of beings-in-the-world. His thought turned through a characteristic modern priority given to subjective enactment and toward worldly structures that do not originate in human consciousness. He moved away from an epistemological orientation in his accounts of meaning, signification, and thought, and from a consequent emphasis on the subjects and objects of knowledge. He moved toward a way of thinking that is oriented by the disclosive, nonsubjective, and nonobjective enactments of things in the world. His aim was to show how those enactments do not begin with conceptual grasp or subjective appropriation, how the enactments are definitively historical and temporal, and how they happen self-disclosively in the world.

BEING AND TIME (1927)

Being and Time, one of the most influential books in the twentieth century, marks the culmination of Heidegger's years in Marburg. He had worked during this time especially on the history of the concept of time and brought together and honed ideas and preoccupations that began to form definitively as early as 1915. In lectures he elaborated his understanding of phenomenology and his departure from Husserl, as well as provided the conceptual scaffolding for *Being and Time* and many of its key terms. The availability in his Collected Works (*Gesamtausgabe*) of many of the lectures that he gave from 1923 through 1927 now allows scholars to follow the formations of *Being and Time*'s leading ideas and questions, a formation that this short discussion cannot pursue.

Being and Time appeared as a work in progress in the sense that its publication was hurried due to Heidegger's candidacy for Husserl's chair in Freiburg. It was projected as part of a much larger, multivolume series that Heidegger did not complete. The book made a huge cultural impact nonetheless, often due to interpretations of it that Heidegger found mistaken and at times offensive. Especially off the mark were those readings that turned *Being and Time* into a study in philosophical anthropology, existential humanism, or Husserlean phenomenology. The book's reception, in addition to Heidegger's own dis-

satisfactions with it, provided an occasion for Heidegger to see that he would have to turn through *Being and Time*'s concepts toward a different way of thinking if he were to carry out the book's mandate. He later understood *Being and Time* as an occasion in which he intensified a radical turn through his metaphysical inheritance toward a way of thinking that is based on that turn.

The book's mandate is found in reawakening the question of the meaning of being. Heidegger was persuaded that that question gave rise to European philosophical thought, although most traditions in European philosophy have obscured it. This question emerged for Heidegger when he was eighteen years old and read Franz Brentano's *On the Manifold Meaning of Being According to Aristotle*. Although Brentano's intentions were in part theological, Heidegger found through Brentano his entry into Husserl's *Logical Investigations*. This entry was in the context of the question of the meaning of being; and that question as well as a phenomenological way of thinking intensified for him and emerged together at the center of *Being and Time*.

Heidegger locates the question of being in the occurrence of *Dasein*. This word, *Dasein*, which has become a standard term in English among those who work within Heidegger's influence, names the located and disclosive occurrence of being in the world. It is not synonymous with "human being" but names the disclosive site of human lives. Dasein's way of occurring is the way things happen in their manifest availability for reference, recognition, and use. Dasein thus happens as the worldly region of disclosiveness. *Being and Time* provides a descriptive account of Dasein and shows that the being of worldly things is formed in their phenomenal quality, in their self-showing, not in any kind of creative or underlying substance. He further shows that the life, the being, of self-showing happens as temporal enactment and that its continuation is continuously in question: Dasein's being is able not to be. The question of the meaning of being thus arises in the prereflective occurrence of Dasein's mortality, not in a theoretical action by reflective subjects.

In his approach to this question Heidegger begins with what he calls the average, everyday understanding of being, that is, of the way beings happen in their practical lives. Usually we relate with things in terms of their usefulness and their standard identities in our environments. We have an operative, inchoate sense of what "to exist" means as we live with things. When we investigate something to know it better, we usually considers it as an object and work to make our statements and definitions appropriate to what we can find out about it. That means that

we usually do not question the meaning of nonobjective living occurrences and that we expect to discover something about the existence of things by treating them primarily as objects of use or knowledge. Their meaning and truth are found in our knowledge of them or in the appropriateness of the uses we find for them. A being is usually understood by reference to definitions of its objective presence; and if that presence is to be grounded in some way, philosophers usually look for a defining and continuously present reality that persists through the lives of changing and passing things. Such persistent and grounding presence might be found, for example, in such beings as God, Nature, Reason, or Transcendental Subjectivity. Transcendent beings such as these seem to provide a foundational meaning for finite things, and they embody the priority of presence for understanding the meaning of temporal passage: they are always present regardless of the changes and passage that beings undergo. The question of the meaning of being appears thus to be resolved by a presence that does not come to pass and that gives abiding meaning to passing beings.

Heidegger's account of Dasein, on the other hand, shows that temporality without a priority of presence defines the way beings are. In Part One of *Being and Time* he shows, first, that Dasein is intrinsically a caring occurrence. It is a way of being whose continuation is always in question, and consequently Dasein reverts to itself in the sense that it is always concerned with the preservation and continuation of beings and of itself. Being in the world is a passing occurrence, always situated in given histories and settings, always coping with uncertainties and transitions, always moving in the indetermination of the upcoming. The meaning of Dasein's being is care, Heidegger says—care, the inevitability of concern for whatever matters. Neither life nor world appears as guaranteed. Neither shows itself as supported by continuous presence. The disclosive happening of being in the world, in its *happening*, is always passing away. The meaning of care is thus found as the inevitability of losing presence, the inevitability of coming to pass, and the associated inevitability of taking care of whatever matters.

In the process of describing Dasein's temporality, Heidegger gives accounts in Part One of *Being and Time* of worldliness, relevance, spatiality, everyday superficiality, identity, worldly commonality, attunement, interpretation, and language. These accounts culminate with a section entitled, "Care as The Being of Dasein," and another, "Da-sein, Disclosedness, and Truth." In this part of the book he shows that our historical, situated, future-oriented being—our very life— is not at all like objective

presence. Dasein happens as yet to be, as possibility to be. Individuals live in such possibility as in a "not yet" that is a dimension of any present moment. The completion that is sometimes attributed to definitive objects or identities is not a quality of living, worldly events. This constitutive, temporal incompletion describes at once Dasein's ontological disclosiveness and ontic worldly events in their specificity and concreteness.

Part Two of *Being and Time* intensifies the study of temporality around the axis of the question of the meaning of being. Whereas Part One began with accounts of the ways Dasein exists in an everyday way, Part Two shows that Dasein's existence is constituted fundamentally by a unifying structure of mortal temporality. The question of the meaning of being and of Dasein is founded in this structure. The guiding questions for this part address, on the one hand, the temporal, ontological unity of Dasein. On the other, they raise the possibility of living in fundamental and positive attunement with Dasein's ontological structure and of bringing together appropriately that structure and the specific way a person exists. He calls such living accord "authenticity." The possibility of authenticity is one of living in ways that affirm the unifying structure of mortal temporality. When such affirmation is achieved, people find a unity in their lives that is defined by finiteness, that is, by incompletion, indetermination, and being toward death.

In Part Two, Heidegger addresses such phenomena as the present occurrence of futurity, the draw of being for people and hindrances to alertness to that draw, ontological guilt, the ability for authenticity that is intrinsic to Dasein, and historicity. In that process he turns such words as "conscience," "call," and "guilt" out of their theological and religious heritage to an ontological and nontheological context. This part reconsiders the major phenomena addressed in Part One by what Heidegger calls a "primordial existential interpretation," that is, an interpretation that describes an ontological structure that is definitive for the occurrence of those phenomena. It develops the descriptive claim that temporality grounds care and is thus the meaning of care. The reader confronts again the thought that ontological grounding lacks substantial identity, presence, or necessity. The study ends with recognition of its own incompleteness.

THE ESSENCE OF TRUTH, TURNING OUT OF *BEING AND TIME*

The incompleteness of *Being and Time* was not due solely to the pressing circumstances under which it was submitted for publication. It was due also to Heidegger's con-

frontation with the inability of the book's language to say what needed to be said and with the limited range of his thought before the phenomena he addressed. Heidegger confronted the force of the metaphysical tradition in the way he used such words and phrases as "horizon," "structure," "the ontological condition for the possibility of something," "being," and even "Dasein." The book's manner of self-regulation and structure, its seemingly explanatory purpose, its conception of origin and history, and its inadequately conceived account of truth: these elements dissatisfied the author. He could see how the text could lead people to misunderstand his thought and its intentions. He also experienced the force of the movement of thought that had begun to uproot his metaphysical moorings. It was a force that he found turning him out of his own book toward a new beginning and in directions far more radical than he had foreseen.

The essay that most strikingly embodies the turning of his thought in the years shortly after the publication of *Being and Time* is *On the Essence of Truth,* which he wrote in 1933 and to which he returned over a period of nine years before publishing it. After *Being and Time* and prior to this essay he had lectured and written especially on Kant, Hegel, Schelling, and on basic concepts and problems in metaphysical thought. He turned down a professorship in Berlin, and enjoyed wide and growing recognition as a creative, leading philosopher.

In spite of his dissatisfactions with *Being and Time*, Heidegger had opened up the question of the meaning of being—or that question began to open up to him. It could be stated in several ways. Classically: Why are there beings instead of nothing at all? In terms of appearing: How is it that things appear, are present and manifest, and show themselves rather than not appearing at all? In terms of finitude: How does being happen in the passing presence of things? In general, the question of the meaning of being is at once a question of fundamental uncertainty in life, presence and passage, and of disclosure and closure in the occurrence of phenomena. Temporality is found in Dasein's having been now yet to be, a "structure" that seems to defy the meaning of "structure." At every turn as we consider this question we encounter the happening of manifest beings, and this—the happening of manifest beings—for Heidegger is essentially a question of truth. The question of being (of manifest happening or eventuation) is at once the question of truth. How is it that the temporality and disclosure of being inevitably raise the question of truth for him?

Long before Brentano pointed out the connection in Aristotle's thought of "true" and "being," and long before

Aristotle himself, the word *aletheia*, usually translated as "truth," played a major role in ancient Greek civilization. The word, which Heidegger understands as combining the alpha privative with *lethe* (oblivion), names an occurrence when something is manifest, self-showing, and apparent. A being is exposed in its disclosiveness, is quite explicitly there where it happens. Its truth happens as its self-disclosure, as its own manifest presence. We have seen that for Heidegger the disclosiveness of something is not identical with what something shows itself to be, that there is a basic difference between *what* something is and disclosiveness as such. The disclosiveness (roughly, dis- = the alpha privative, and -closive = *lethe*) lets something be as it shows itself. Disclosiveness is, Heidegger says, an open region that, while apparent with manifest beings, is not limited to the specificity of what a being is, not limited to *a* being's time, place, and identity. "Truth" in this context means the free openness of disclosure, and a truth is found in the self-disclosure of a being. To know something in its truth is to engage it in a way appropriate to its "essence," to its own disclosive eventuation.

The factor of oblivion or complete lack of apparentness, however, elaborates what Heidegger considered in *Being and Time* as the mortality of phenomena: beings appear with nothing transcendent and specific to ground them or guarantee their lives; they are "grounded" in their disclosive eventuations. Their dis-closure carries oblivion with it as a strange and pervasive mortal factor, one that makes impossible a complete grasp of any phenomenon. It is as though oblivion protects a being from complete exposure, gives something other to its truth, removes it from availability. *Lethe* suggests concealment, withdrawal of being (i.e., of disclosiveness), and untruth (a complete absence of disclosure).

Heidegger's account of essence in *On the Essence of Truth* no longer struggles with what appear to be quasitranscendental structures of existence as he locates essence clearly in both the eventuation of disclosure and the history of the thought of truth. The untruth, the "non-essence," of concealment—the oblivion of being— suggests the inadequacy of "finitude" as a descriptive term for Dasein's temporality. It suggests a new departure in which existential uncertainty is compounded by impenetrable closure to the manifestness and "light," of life. This departure includes a strong sense of mystery, not the mystery of Pure Light or of a hidden fullness of being, but mystery in the sense of unsayable oblivion in the midst of disclosive openness. As his thought turns to them, both oblivion and truth appear to happen for Heidegger when he attempts to speak with alertness to them. Is it possible,

he wonders, that the turning he is undergoing describes a movement of disclosure and oblivion that is definitive as well as obscure in the history of western thought? Is his transforming movement toward early senses of *aletheia* following a path to the early beginning of metaphysical thought, one that makes apparent an oblivious departure of western thought from the questionableness and uncertainty of truth?

POLITICAL CATASTROPHE

At the time that this turning gave him new directions and possibilities for thinking, Heidegger became embroiled in a politics that belied the most promising of those possibilities. Ever a German nationalist, long persuaded of the unjust consequences of the Treaty of Verdun, convinced that Germany must resist communism at all costs, and disappointed in the inefficiency of democratic procedures, he embraced Hitler's National Socialism as Germany's best political hope. By 1933 Heidegger saw this party as a force toward revival of German culture and restoration of Germany's leadership in the transforming of European, materialistic civilization.

In April of that year the faculty at the University of Freiburg elected him rector, and in that role he supported Nazi ideology for German resurgence and helped to form university policy according to party interests. Nazi authorities, however, criticized him strongly for his failure to support anti-Semitic rhetoric and policy. Heidegger was not a gifted administrator. Sharp political and educational controversies intensified, and he resigned his post ten months after assuming office. His dream that Hitler, as a man of destiny, would transcend the foolish people around him and become a heroic, spiritual leader allowed Heidegger to support Hitler long after he became disillusioned with the National Socialist party. He began to undercut party interpretations of Nietzsche, and by the mid-1930s his classes were audited by suspicious party appointees. The party also restricted his freedom of movement and publications, and he was punished by means of hard physical labor when the authorities drafted him into the People's Militia. Heidegger never used his international stature as a base to criticize National Socialism, and although he privately admitted his errors after the war, he never publicly addressed German atrocities. After the war the French occupational authorities prevented Heidegger from teaching in the university until 1951.

There is considerable controversy around the question of whether Heidegger's philosophy led to his political hope, error, and naivete. Some people see a profound and causal linkage, while others see more distance and inconsistency between his thought and his politics of the 1930s. That decade, regardless of the way one assesses the controversy, constitutes a dreary segment in Heidegger's life. Responses to it have on occasion been ones of continuing outrage, whereas others find Heidegger's thought worthy of sustained and positive engagement. Perhaps the dangers of forgetting and those of a righteous condemnation should be foremost on our minds when we consider the importance of Heidegger's misjudgments.

SEARCHING FOR ANOTHER WAY TO THINK

During the 1930s Heidegger searched for language, conceptual movements, and rhythms of thought that could engage appropriately the disclosive happening of things. The systematic rationality of "onto-theology," that is, of traditional philosophy, seemed to constitute anxious attempts to overcome the questions of truth and of the meaning of being which gave European philosophy its inception. Approaches called materialistic, idealistic, empirical, and analytical seemed dedicated to forgetting those questions. Post-Cartesian thought gave forms of subjectivity and objectivity ontological priority, whether or not subjectivity was considered ahistorical or historical. In which writing and conceptuality might Heidegger find a degree of positive alertness to the questions that he found as the moving forces in European philosophy? This was a time of considerable isolation for Heidegger as he looked for alternative ways of thinking. He experienced disappointment in his own work, discouragement in its reception, political failure, and an uncertain future for himself and the kind of disciplined education that he thought necessary for the survival of western civilization. That would be an education in the classical origins of Europe and its many traditions, and it would be an education that recognized what he came to see as the devastation of instrumentally oriented culture and the desolation of contemporary spiritual accomplishment.

Heidegger had read widely in literature and especially in poetry since he was in his teens. The poetry of J. W. Goethe, Friedrich Hölderlin, Rainer Maria Rilke, Stephan Georg, and Georg Trakl, among others, helped to form his mind, and he turned to poetry, especially to Hölderlin's, with renewed intensity in the 1930s. He wanted to find ways to formulate and express what he sensed but could not say to his own satisfaction. He also read the ancient Greek tragedians with an emphasis on the two great questions that preoccupied him. He gave courses and lectures on Nietzsche's thought and found in

it a welcomed emphasis on the connections of art and thinking. In Nietzsche's thought he found as well a culminating and destructive fulfillment of that nihilism prepared by European metaphysics. It is a nihilism given partial expression by Hegel and carried out after Nietzsche by a technological society that is oriented around subjects and objects of use and knowledge.

His attention turned increasingly to thought and language as disclosive events. Truth, *aletheia*, names, as we have seen, the enactment of self-showing; the truth of thought and language is found as thought and language, in their occurrences, give place and occasion to self-showing phenomena. The life of thought and language is found in the ways they engage the manifest lives of things. Is the engagement defined by organizational structures? By the power of will? By categories of knowledge? By means of production? By patterns of trade? People's lives are normally carried out with such structures and activities. In addition to our normal ways of acting, however, we might also give attention to the self-showing dimension of anything that is present with us. We might learn to connect with things with a sense that their very happening addresses us, that our "hearing" is found in the ways we live with them. If our living provides ways to allow events prominence in their disclosive dimension, our thinking and speaking might well grant to them a dwelling place, not for their utility only, but also for their self-showing, for the essence of *their* lives. Although that manner of living is not forecast in language and thought dominated by the importance of subjectivity and objectivity, it does appear significantly in the work of some of the artists and poets Heidegger read. He explored and experimented for many years with possibilities for language and thought that are influenced by poetic rather than traditionally philosophical kinds of awareness. He intended to find areas of encounter between poetic and philosophical language, to enrich each in their engagements, and at best to occasion the emergence of a kind of mentation that finds its truth in allowing the truth—the self-disclosure—of whatever happens in its environment.

CONTRIBUTIONS TO PHILOSOPHY

Heidegger's sense of failure in the language of *Being and Time* to say what needed to be said of the questions of the meaning of being and truth figured a large part of the turning in his thought during the 1930s and 1940s. His *Contributions to Philosophy (From Enowning)* is a major work that emerged in that turning between 1936 and 1938. He wrote it in the impetus provided by his work on art and especially on poets, his rethinking of the incep-

tion and decline of European metaphysics, and his search for a new beginning for thinking. In its fuguelike formation, this series of meditations composes an effort to find ways to speak of what seems always to remain unsaid yet present in European philosophy. It is an effort to think in the obscure questions of being and truth, to speak in their modern wake, rather than to re-present them. Heidegger invites the reader to engage in strange and often wrenching movements of language as he attempts to let the questions emerge and turn thought and language from the tracks that move them inevitably away from what most threatens and yet impels the remarkable occurrence of European thinking. If he succeeds he reconceives *Being and Time* in a radical return to *Being and Time*'s issues and makes that return by the force of turning away from the book's structure and articulation. The lives and forces of the questions of truth and the meaning of being, not their resolution, guide this book's movements. It is a work that attempts to think the inconclusiveness of its major issues. Its success would be found in the emergence of a way of thinking that makes apparent what incited western thought and what western thought in its formation nonetheless virtually lost.

BEYOND HUMANISM

In 1946, Heidegger responded to questions raised by the French philosopher Jean Beaufret. Published in 1948 as "Letter on Humanism," Heidegger made explicit in his response not only his distance from "Existentialism," but also his reservations about "Humanism" as it is conceived in post-Enlightenment Europe and North America. Issues of human life and community are not best located in conceptions and images of human subjectivity. He developed his descriptive claim that humanistic values are often the source of destructive depreciations of human life. The essay comprises a sustained reflection on what is destructive and constructive for people and on basic assumptions regarding the essence of worldly life. It has had widespread influence on thinkers in the second half of the twentieth century who find in humanistic ideals elements that, contrary to their stated purposes, do harm to societies and individuals.

In the 1940s and 1950s, Heidegger also relentlessly pursued questions concerning the essence of technology. Technology for him constitutes a way of life that overrides the subtle and most important dimensions of the existence of things as well as of people. The word "technology" thus names the most dangerous form that European nihilism takes. Among the best known of his essays during this time are "The Question concerning Technology"

and "Building, Dwelling, Thinking." One of the most far reaching and profound of his works in this context is *The Way to Language*, in which Heidegger brings to bear in a cumulative way his preoccupations with thought, language, technology, and dwelling

"Engagement," "encounter," and "way" are important words to hold in mind as a person reads Heidegger's works. He often described thinking as made up of ways of letting things show themselves in the specificity of their contexts. Thinking composes engagements with all manner of manifest things—texts, behaviors, trees, bells, images, concepts. Manifest things are alive in their manifestness, and thinking properly allows their differences as they happen, engages them with alertness to *their* happening. At best, the engagement composes a dialogue, an encounter that no one individual produces. Thinking is what takes place in the dialogue. For Heidegger such an engagement is a social, historical, and communal event that cannot be reduced to the sum of its parts or generalized on the basis of universal meanings. Thinking is made up of engagements with living events in their happening, their eventuation. As he saw it, there are many ways, and the issue for thinking is not one of calculating the correctness of assertions but rather one of making evident or, in unfortunate instances, obscuring beings in their self-showing. Thinking, always opening to the differences of events, always coming to pass in its own life, always on the way to something else, remained at the center of Heidegger's preoccupation with the questions of being and truth until his death in 1976.

HEIM, KARL
(1874–1958)

Karl Heim, the German theologian, was born at Frauenzimmern in Württemberg. He studied at Tübingen and was professor of theology at Münster (1914) and at Tübingen from 1920 until his death.

Heim's work has philosophical interest insofar as he was concerned all of his life with the problem of restating

Christianity in a form that would be credible in the scientific age. His early work explored the epistemology of religious faith, and his developed account draws on the I–thou philosophy of Martin Buber and also on some of the concepts of modern science. Heim's fundamental point was that the experiencing subject cannot itself become an object and so cannot be brought under the objectifying categories of scientific thought. Thus we have a way of breaking out of, or transcending, the objective world of science, for there is open to us also a nonobjectifiable, interpersonal world. Heim spoke of this as a further dimension of experience, analogous to a dimension of space. This suggests a new way in which we may try to think about the transcendent God; and belief in such a God seemed to Heim the most important point calling for defense and restatement in the Christian tradition. Modern cosmology has made it senseless to talk of such a God as "up there" or "out there" or "beyond." But this God is not an object in the world any more than the experiencing subject is, and God too must be sought in the nonobjectifiable dimensions of experience, not in the realm of I–it. Just as the situation is revolutionized if we add a third dimension to a two-dimensional manifold, and what was hitherto impossible in two dimensions may be possible in three, so Heim believed that the conflicting attitudes of religion and science may be reconciled by admitting the multidimensional character of experience. We are familiar today with the notion of geometries of more than three dimensions, and we can think of an interpersonal space as having a different order and structure from physical space. Both kinds of space are embraced in an archetypal space, which is also a suprapolar space because it resolves the polarities of both the interpersonal and the physical spaces. This suprapolar space is the abode of God; it cannot be proved, but it is disclosed in the experiences of faith that may be likened to opening up new dimensions of a fuller life. Heim also taught a doctrine of panpsychism, which suggested that the further dimensions opened up in man's encounter with other persons and with God are at least potentially present at all levels of being.

HEISENBERG, WERNER
(1901–1976)

The German physicist Werner Heisenberg was born in Würzburg; he studied physics in Munich under Arnold Sommerfeld and received his doctorate from Munich in 1923. Heisenberg became a lecturer and assistant to Max Born at Göttingen in 1924. He continued his studies at the University of Copenhagen, where he collaborated with H. A. Kramers. He succeeded Kramers in 1926 as lecturer in physics there. Heisenberg was professor of physics at Leipzig from 1927 to 1941 and professor at Berlin and director of the Kaiser Wilhelm Institute for Physics from 1941 to 1945. He was named honorary professor and director of the Max Planck Institute for Physics at Göttingen in 1946 and served as honorary professor and administrative director of the Max Planck Institute for Physics and Astrophysics in Munich from 1958 to 1970. He was awarded the Nobel Prize for physics in 1932.

Heisenberg's contributions to physics are contained in more than 120 papers covering a great variety of topics. We shall here deal with two topics only, with the invention of matrix mechanics and with Heisenberg's more recent theory of elementary particles.

MATRIX MECHANICS

The older quantum theory of Niels Bohr and Sommerfeld had tried to combine classical physics with the new quantum laws and to use the predictive power of both. The resulting theory was a mixture of classical notions—some useful, others apparently redundant—of new ideas and of ad hoc adaptations. Thus, for example, transition probabilities and selection rules were calculated, or guessed at, by examining the Fourier coefficients of the motions

$$\Phi_i(t) = \sum_{n=-\infty}^{+\infty} X_i(n, \omega_i) \exp(in\omega_i t)$$

of the independently vibrating parts of the atom, while the motion Φ_i itself had to be denied any physical significance. In addition, the theory had failed in important respects. It clearly was but an intermediate step on the way to a satisfactory mechanics of the atom. The final theory is essentially due to the efforts and the very different philosophies of two men, Heisenberg and Erwin Schrödinger.

According to Heisenberg we must abandon all attempts to give a detailed description of the unobservable internal motions of the atom. Such motions are but the result of the continued use of classical ideas in a domain that is inaccessible to direct experimental examination. Considering that these ideas may be in need of revision it would seem to be wise to construct a theory that is expressed solely in terms of such "outer" magnitudes as frequencies and intensities of spectral lines. Speaking formally this means that we want to predict by using the X_i directly and without appeal to the Φ_i. Now Bohr's investigations had already gone a long way toward determining the required properties of the X. His idea of a rational generalization corresponds exactly to what Heisenberg had in mind. Heisenberg himself provided additional rules of calculation that were sufficient for solving some simple problems, such as the problem of the harmonic oscillator. It was not known to him at the time that the rules were those of an algebra of noncommuting matrices; this was soon recognized by Born, who, together with Pascual Jordan and Heisenberg, completed the formalism a few months after Heisenberg's first paper had appeared.

A new atomic mechanics was at last in sight. Its meaning, however, was far from clear. Macroscopic objects whose positions and momenta could be ascertained with a higher degree of precision were represented by infinite arrays of complex numbers, none of them cor-

responding in a simple way to visible properties. "Can you imagine," objected H. A. Lorentz at this stage, "me to be nothing but a matrix?" It was again Heisenberg who, after the theory had been completed in a somewhat unexpected fashion by Schrödinger, made an essential contribution here by showing, in his uncertainty relations, to what extent classical notions could still be used in the interpretation of microphysical theories.

Heisenberg was to use the principle to rebuild a theory by working "from the outside in" once more in 1943, in order to eliminate certain difficulties in the quantum theory of fields. Believing these difficulties to be due to the disappearance of the ordinary space-time relations below 10^{-13} centimeters, he tried to replace field theory by a formalism that for any interaction transforms asymptotic anterior states into asymptotic posterior states without dealing with the details of the interaction. This so-called S-matrix theory was taken up by Geoffrey Chew and others for the calculation of the properties of strongly interacting particles. This led to what some physicists regarded as the beginning of a "third revolution" of twentieth-century physics, to the idea that particles are composites and that the properties of all of them can be obtained in a step by step procedure, starting with the interaction of any small subset ("bootstrap hypothesis"). Spatiotemporal relations are alien to this scheme, which therefore cannot develop a theory of measurement. Nor does there seem to be any possibility of extending it to other types of interaction.

ELEMENTARY PARTICLE THEORY

Heisenberg, who had been the first to stress the nonexistence of a criterion for distinguishing "elementary" particles from composites, has in the meantime developed a different theory in which elementary particles are stationary states of a single physical system, "matter." The field operators refer no longer to particles but to this basic matter (which Heisenberg sometimes compares to Anaximander's *apeiron*). The masses of the particles arise wholly from the interactions due to the nonlinearity of the basic field equation. There are no "bare particles." Other properties are supposed to follow from the symmetries of the field equation. Strange particles of spin 0 and 1/2 have been dealt with, to a certain extent, on the basis of approximation methods (this refers to 1962). There are only programs, no exact predictions, for weak interactions.

Heisenberg's philosophical speculations were always intimately connected with his physics. They were original and exciting. The same cannot be said about his more

general observations on philosophical matters. However, he should not be blamed for this disparity, as it is at any rate only in close connection with reality that philosophy can be both interesting and fruitful.

See also Quantum Mechanics.

Bibliography

Heisenberg's early work and its relation to wave mechanics and to experiment is described in *Die physikalischen Prinzipien der Quantentheorie* (Leipzig: Hirzel, 1930), translated by Carl Eckart and Frank C. Hoyt as *The Physical Principles of the Quantum Theory* (Chicago: University of Chicago Press, 1930). The theory of the S-matrix is explained in "Die 'beobachtbaren Grössen' in die Theorie der Elementarteilchen," in *Zeitschrift für Physik* 120 (1943): 513–538 and 673–702. For a survey of Heisenberg's new field theory, see "Quantum Theory of Fields and Elementary Particles," in *Reviews of Modern Physics* 29 (1957): 269–278, and "Die Entwicklung der einheitlichen Feldtheorie der Elementarteilchen," in *Naturwissenschaften* 50 (1963): 3–7. *Die Physik der Atomkerne* (Brunswick, Germany: Vieweg, 1943) explains nuclear physics and Heisenberg's contributions to it. *Wandlungen in den Grundlagen der Naturwissenschaften* (Leipzig: Hirzel, 1935) is a survey of advances and discoveries from 1900 to 1930. *Physics and Philosophy* (New York: Harper, 1959), which contains the Gifford Lectures given in 1955/1956, deals with the same subject on a broader historical and philosophical basis and also discusses current objections to the Copenhagen interpretation of quantum theory.

For the atmosphere at Göttingen in the "golden twenties," see F. Hundt, "Göttingen, Kopenhagen, Leipzig im Rückblick," in *Werner Heisenberg und die Physik unserer Zeit*, edited by Fritz Bopp (Brunswick, Germany: Vieweg, 1961), pp. 1–7, and Robert Jungk, *Brighter Than a Thousand Suns* (New York: Harcourt Brace, 1958).

HELD, VIRGINIA
(1929–)

Virginia Held, American philosopher, received her PhD in philosophy from Columbia University and is a professor of philosophy at Hunter College and the Graduate School of the City University of New York. In addition to working as a reporter, she has also taught at Barnard College, Dartmouth College, the University of California at Los Angeles, and Yale University. She is the author of numerous scholarly books and journal articles in the areas of social and political philosophy, ethics, and feminist philosophy. In particular, she has contributed to our understanding of the moral importance of birth and mothering, to debates on limits on markets, to discus-

sions on collective responsibility, and to the literature on moral methodology and metaethics.

According to Held, moral theorizing requires paying attention to actual moral experience. In *Rights and Goods*, Held argued for a view she calls "experimental morality," a version of John Rawls's method of reflective equilibrium, according to which actual moral agents ought to try out various moral approaches and see what it is like to live by them. An advocate of pluralism, she advances the view that different persons, in different roles or contexts, should develop and experiment with different approaches to morality. This link between experience and moral theory connects her work on moral theorizing in general (1984) and her work in feminist ethics (1993).

Focusing on the moral significance of experience, Held drew attention to how women's experiences have been left out or devalued by traditional moral theorizing. In particular, she has cast light on the experiences of women whose activities as mothers and caregivers have often been wrongly dismissed as mere biological reflexes. Critical of the tendency in some moral and political philosophy of depicting persons as rational, independent agents who make mutually disinterested agreements, Held encourages, instead, a conception of persons that appreciates our interdependence and the caring, rather than contractual, nature of our relationships. She rejects the notion that the impartial rule-follower is a paragon of moral virtue and recommends in its place the ideal of the empathetic caregiver, stressing that care ought to be valued for its own sake and not merely as a means of carrying out impartial rules.

Rather than construing care as a permissible nicety that comes into play only after justice and equality have been secured, Held has come to view care as one of the most basic moral values. Without care, she says, humans simply would not survive. Emphasizing the importance of care in the public realm, as well as in the private realm, is not, for Held, license for widespread paternalistic interference. Indeed, she thinks that appropriate care is often about cultivating a capacity for autonomy in the person cared for. She proposes a conception of care that can extend to distant others, predicting that a revaluation of care would inspire a more committed defense of others' rights and bolster political support for public health care and child care.

HELLENISTIC THOUGHT

The Hellenistic era extends from the death of Alexander the Great in 323 BCE to the conquest of Egypt by the Romans in 30 BCE. Though defined in terms of political events, it is also host to distinctive developments in Greek intellectual life. Chief among these are the foundation and consolidation of organized *schools* as the focus of philosophical life, especially in Athens; the growing independence of various special sciences from their original philosophical context; and a geographical expansion (in the wake of Alexander's conquests and the foundation of Greek-speaking kingdoms in the eastern Mediterranean) that had significant long-term consequences. The intellectual life of Hellenistic Greece changed again as Roman political authority gradually came to dominate in the region. Throughout this period, Greek intellectuals (both philosophers and scientists) became more prominent and important in civic life, often achieving political recognition even in foreign cities; in 155 BCE three prominent philosophers, none of them from Athens, were chosen to represent the city on an embassy to Rome. Prominent intellectuals were offered patronage by the new Hellenistic kingdoms.

The first major organized school at Athens was the Academy, founded by Plato. Aristotle's associate and successor, Theophrastus, and later Strato of Lampsacus, carried on the traditions of his work in the Lyceum. Other philosophical schools in the fourth century were of minor importance, although the hedonistic school based at Cyrene in North Africa was influential. Yet within the first few decades of the Hellenistic era two major new schools, representing significant philosophical directions with lasting influence, were established. Epicurus, the founder of Epicureanism, was an Athenian and established the Garden there, but his followers spread around the Aegean basin in a network of smaller institutions that remained connected to the original school. Zeno came from the town of Citium on the island of Cyprus to establish his school in the Painted Stoa in the Athenian agora, and throughout its history it continued to attract philosophers from all over the Hellenistic Greek world, especially Asia Minor.

Epicureanism and Stoicism quickly became successful and attracted adherents for centuries to come. Epicureanism revived the atomistic physics pioneered by Leucippus and Democritus and linked it tightly with a hedonistic ethics and quietistic political philosophy. Stoicism depended on the mainstream Socratic tradition; its cosmology and physics drew primarily on Plato and Aristotle and its ethical and political theory were heavily influenced by Socratic ideas colored by the Cynic tradition stemming from Diogenes of Sinope and Crates of Thebes.

Stoicism and Epicureanism were in some ways polar opposites. The former championed god's providence while Epicurus denied it. Stoic physics asserts the continuity of all matter (which is itself permeated by a divine cause giving it form), while for Epicurus all things, even the gods, are composed of atoms and void. Like Plato and Aristotle, Stoics believed that society and its institutions rest on deeply rooted features of human nature, but Epicureans held that societies are formed by agreements among people about mutual preservation and advantage. Stoicism (inspired in part by the dialectical school and Megarian philosophers) led the way in the development of logic and dialectic, while Epicurus rejected logic along with many other specialized intellectual endeavors as useless. For Epicurus even physics mattered only in so far as it was essential to achieving tranquility.

Despite these contrasts, the two schools shared a great deal. Both rested their philosophy on broadly empiricist epistemologies, according to which normal sensory experience was the ultimate source and criterion for knowledge, and both rejected the idea of causally efficacious incorporeal entities and emphasized the material foundations of all reality. Neither school could accept the

central role of *form*, either in the Platonic version in which forms were separate from material particulars, or in the immanentist version of Aristotle, for whom form and matter were the two components of all concrete objects; nor could they embrace the concepts of an incorporeal deity or an immortal and incorporeal soul animating the body.

As these new schools emerged, the Academy changed its intellectual course; under the leadership of Arcesilaus it adopted a skeptical practice, devoting its energies not to the development and refinement of positive theories but to the dialectical criticism of those philosophers who claimed certainty for their own views. Stoicism was its chief target, and it can be argued that the main inspiration for this skeptical turn was the desire to refute those who claimed that the physical world could yield certain knowledge. The Academy maintained its dialectical approach for nearly two centuries; its high point came under the intellectual leadership of Carneades in the second century BCE. His followers came to disagree about the nature of his commitment to skepticism and gradually reverted to *dogmatism*, the conviction that knowledge is achievable. The Lyceum (sometimes also called the Peripatos) did not long maintain its philosophical vigor after the death of Theophrastus and its leaders became better known for their achievements in the sciences than in philosophy. Only Critolaus, the contemporary of Carneades, achieved importance in philosophy proper. The renewal of Aristotelianism had to await the end of the Hellenistic era.

With each generation the Stoic school changed and developed, with most of its leaders making significant innovations. The third head, Chrysippus of Soli, systematized and reworked nearly every aspect of Stoic thought, developed the formal logic for which the Stoics remained famous until the end of antiquity, and exerted control of the school's trajectory for several generations after. In the late second century Panaetius of Rhodes and his student Posidonius of Apamea made a comparable mark, reintegrating Platonic and Aristotelian influences into the school's intellectual life. By contrast, in all but details the Epicurean school was marked by conservatism and doctrinal unity.

The interaction between philosophical schools and the special sciences is a topic of particular interest in this period. Except for the medical texts in the Hippocratic Corpus, there are few traces of specialized scientific writing before 300 BCE, although Aristotle makes frequent allusions to an optical and astronomical literature that was distinct from philosophy and had a mathematical character. Hellenistic optics, as represented by Euclid's *Optics*, was the physical science that engaged most actively with philosophy. Euclid uses a geometrical apparatus to model a selection of phenomena of visual perception that reflect not only Aristotle's analysis of the *objects of sense perception* but also contemporary Hellenistic epistemological concern with the reliability of the senses. The Euclidean model, invoking rectilinear "visual rays" that radiate from eye to object, could be reconciled with Stoic physics as well as with the more eclectic materialism of Theophrastus and his Peripatetic successors.

Astronomy, by contrast, seems to have disengaged from philosophy after Aristotle. Deeply impressed by the regularity of astronomical phenomena and by Eudoxus's ingenious hypotheses of rotating spheres that seemed to account for them, Aristotle posited a sharp discontinuity between the irregularly changeable globe of matter at the centre of the cosmos, in which we dwell, and the eternally unchanging outer shell, composed of a distinct kind of matter, that is the realm of the sun, moon, planets, and stars. The Stoics and Epicurus, by rejecting this discontinuity, made it harder to reconcile their physics with the mathematically abstract celestial models of the astronomers. Astronomical writers such as Aristarchus in the third century and Hipparchus in the second relied on geometry, arithmetic, and optical observation as criteria for their models, and sometimes put forward alternative models to explain the same phenomena. In the view of a physically oriented philosopher such as Posidonius, the astronomers' models did not constitute proper explanation, which only the philosophers could provide. Nonetheless such results of astronomical reasoning as estimates of the sizes and distances of the sun and moon and Eratosthenes's measurement of the earth's circumference became commonplaces of philosophical discourse.

Mesopotamian traditions of divination from celestial phenomena were known in the Greek world as early as the third century, and the Stoics in particular took a lively interest in them as they did in other forms of divination. It was only about the beginning of the first century BCE, however, that a distinctly Greek astrology endowed with sufficient complexity and rationale to claim scientific status took form. Astrology was founded on a physical cosmology that was loosely derived from Peripatetic and Stoic physics, though most of its literature concerned niceties of prognostication, not the analysis of cause and effect. The Stoic poet Aratus's versified description of the constellations achieved remarkable popularity in antiquity; but on the whole the Stoics tended to disregard technical astronomy, perhaps because they were uncom-

fortable with its mechanistic character. The Skeptical schools, on the other hand, found an easy target in astrology's pretensions to exact knowledge of the future derived from inexactly observed or calculated motions of the heavenly bodies.

The Hellenistic period was the heyday of Greek geometry. Euclid, Archimedes, Apollonius of Perge, and a host of lesser mathematicians published work of enduring value on difficult problems, typically involving the properties of curves and the areas and volumes bounded by geometrical figures. Much mathematical research was motivated by optics, mechanics, and astronomy, but Hellenistic mathematicians seem to have kept more aloof from the philosophers than their predecessors of Plato's and Aristotle's time.

Alone among the scientific disciplines, medicine was characterized in the Hellenistic period by a division into sects or schools, comparable to the contemporary emergence of the great philosophical schools. The Hellenistic medical sects took their start from the prolific early third century physicians Herophilus and Erasistratus, whose theoretical pronouncements on physiology and medical practice were founded on a level of anatomical research and experimentation (reportedly including human vivisections) that was unprecedented in Greek medicine. In their approaches to physical and biological explanation these men and their followers owed something to Aristotle and perhaps more to the later Peripatetics. The "Herophilean" and "Erasistratean" schools seem to have less direct engagement with Stoicism or Epicureanism, though in common with those philosophical sects they accepted that knowledge of hidden causes of phenomena was both possible and useful.

The medical sect of Empiricists, which rose in the third century, rejected hidden causes as both unknowable and unhelpful in medical practice, and advocated instead a strategy for progressing systematically from individual trial-and-error experience to generalized, teachable practical knowledge without recourse to anatomical or physiological theory. The debates between the Empiricists and the other sects, grouped under the heading of Rationalists or Dogmatists, centered on both epistemology and research ethics; Empiricist physicians found natural intellectual allies in the philosophical Skeptics, especially the Pyrrhonists. Few Hellenistic physicians, however, were themselves philosophers, and a broad, intellectually respectable effort to bring together the many threads of current medical and philosophical thought had to wait for Galen in the second century CE. Galen's contempo-

rary Ptolemy had a comparable reintegrating role with respect to Hellenistic physical science and philosophy.

The relationship between philosophy and medicine was paralleled by that between philosophical analysis of language and the emerging disciplines of grammar and philology. While critical speculation about language began in the Presocratic period and developed dramatically in the fourth century BCE, in the Hellenistic era the study of language achieved greater independence from philosophy without fundamentally severing its ties. Pergamum and Alexandria became centers for the critical study of ancient texts, especially Homer, and for the analysis of linguistic phenomena. At the same time, Epicureanism promoted a naturalistic understanding of the origin and nature of language and the Stoics made enormous advances not just in the area of logic (Chrysippus developed propositional logic in contrast to Aristotelian term logic) but also in the analysis of the parts of speech and semantic theory. Philosophers and grammarians debated the roles of rule-driven morphological *analogy* and the variability of actual linguistic usage (*anomaly*) in the determination of linguistic norms. Here too Hellenistic developments laid the foundations for intellectual life in later antiquity.

At the end of the Hellenistic era, the dominance of Athens in Greek philosophical life came to an end. After the conquest of Athens by the Romans under Sulla during the Mithridatic wars (88–86 BCE), philosophy, like science, spread out around the Mediterranean world. Rome itself, as well as Alexandria and Rhodes, became an important locus of philosophical activity as the Hellenistic age, and with it the Roman Republic, came to an end. At the beginnings of the Roman Empire, philosophy changed its character and turned for inspiration to the close study of the classic texts of Plato and Aristotle written centuries before. The Hellenistic era in Greek thought came to an end appropriately with the rise of a productive form of scholasticism and the revival of the classical schools of thought which have remained central to our understanding of ancient philosophy ever since.

HELMHOLTZ, HERMANN LUDWIG VON
(1821–1894)

Hermann Ludwig von Helmholtz, the German physiologist and physicist, was born in Potsdam and educated at the Potsdam Gymnasium, where his father taught philology and classical literature, and at the Royal Friedrich-Wilhelm Institute of Medicine and Surgery in Berlin, from which he graduated as a doctor of medicine at the age of twenty-one. Helmholtz's outstanding scientific talent led to the curtailment of his required ten-year service as a Prussian army physician and surgeon. After the presentation and publication of his famous paper *Über die Erhaltung der Kraft* (On the conservation of energy) in 1847, he held only academic posts. He was instructor in anatomy at the Academy of Arts in Berlin (1847–1848), professor of pathology and physiology at Königsberg (1848–1855), professor of physiology and anatomy at Bonn (1855–1858), professor of physiology at Heidelberg (1858–1871), professor of physics at Berlin (1871–1888), and the first president and director of the Physico-Technical Institute in Berlin from 1888 until his death.

Helmholtz contributed over two hundred papers and books of outstanding importance in medicine, anatomy, physiology, psychology, and physics. He also published papers in mathematics and in philosophy, and delivered many popular lectures to publicize significant scientific investigations and to point out their philosophical implications. He was the first to measure the speed of nerve impulses, and he invented the ophthalmoscope. His paper *Über die Erhaltung der Kraft* became the cornerstone of the science of thermodynamics and set the direction of much of physics for the next half century. His

monumental three-volume *Handbuch der physiologischen Optik* (*Handbook of Physiological Optics,* 1856–1866), frequently called the principia in its field, was matched in 1863 by a work equally basic to physiological acoustics, *Die Lehre von dem Tonempfindung* (*On the Sensations of Tone as a Physiological Basis for the Theory of Music*). In mathematics he was a pioneer in the field of non-Euclidean geometry, arriving independently at conclusions similar to those of Bernhard Riemann and seeing more quickly than others the philosophical importance of these new developments. In physics he contributed substantially to the establishment of the Faraday-Maxwell conception of electrical phenomena, both by his own theoretical investigations and through his encouragement of his most famous student, Heinrich Hertz. Helmholtz greatly influenced the intellectual climate in many German universities, and he may rightly be considered one of the fathers of the philosophy of science.

EMPIRICISM AND OPPOSITION TO METAPHYSICS

Helmholtz wrote only one long essay, *Die Tatsachen in der Wahrnehmung* (The facts of perception; 1878), that he explicitly considered to be in the field of philosophy. Most of his philosophy is contained in a number of short, popular essays and in the body of his various scientific works. The scientific works, however, contain frequent passages of philosophical importance and always show a clear awareness of philosophical issues. Furthermore, many of his papers on science and mathematics, such as those on the foundations of physics and mathematics, would now be included in the philosophy of science.

Helmholtz's philosophy was at all times closely related with his scientific investigations. One of the motives for the work that led to the paper *Über die Erhaltung der Kraft* was his desire to discredit vitalism as a scientific hypothesis and as a metaphysical position. Indeed, from the beginning of his career he was opposed in general to metaphysical speculation, feeling that the idealists, Friedrich Schelling and G. W. F. Hegel in particular, and a number of materialists had perverted philosophy and turned it from its main function, which was the study of human knowledge. Helmholtz was close to Immanuel Kant in his philosophy; he believed that in *The Critique of Pure Reason* Kant had asked the right questions and had moved part of the way toward answering them. He was also close to the classical British empiricists, believing that a scientifically and mathematically sophisticated empiricism along the lines initiated by John Locke would

provide highly reliable answers to a number of the basic questions of philosophy.

KNOWLEDGE AND PERCEPTION

For Helmholtz the central questions in philosophy were "In what ways do our ideas correspond to reality?" and "What is true in our sense perception and thought?" Answering these questions was the common task of both philosophy and the sciences, the two disciplines approaching them from opposite directions. The task of philosophy is to study the formal aspects of knowledge, our forms of intuition and representation, and the general categories in terms of which we order knowledge. The task of the sciences is to study the world of reality and to find the laws of nature that cause or determine both objective sequences of events and the sensations we experience. The formal aspects of knowledge, our forms of intuition and representation, and our intellectual categories, condition the ways in which we should and do formulate scientific knowledge. Scientific investigations, specifically the findings of physiological optics and acoustics, help us to understand our forms of intuition and the mental operations involved in knowing.

Although Helmholtz's position was basically Kantian, it was markedly different from Kant's on certain important points because of Helmholtz's study of physiological optics, physiological acoustics, and non-Euclidean geometry. His answer to the question "In what ways do our ideas correspond to reality?" was based upon certain discoveries in the physiology of sensation and, in particular, upon the principle of specific nerve energies. This principle was implicit in the psychological theories of a number of British empiricists; it was made explicit by Johannes Müller and was extended significantly by Helmholtz. Fundamental to this view is the theory that all we know about the external world is brought to consciousness as the result of certain changes produced in our sense organs by external causes. These changes are transmitted by the nerves to the brain, where they first become conscious sensations. In the brain they are interpreted and combined to produce our perceptions of external objects by mental processes that Helmholtz called unconscious inferences—processes he considered to be the same as those that are operative when a child learns his native language. Thus, in the case of vision, excitations of the nerves of the retina are transmitted by the optic nerve to the brain, where they are experienced as sensations and where they are unconsciously interpreted and combined to form visual perceptions of objects and their properties.

According to the principle of specific nerve energies, there is no one-to-one correspondence between a sensation experienced and a specific property of the object causing that sensation. It is perfectly possible for similar or identical sensations to be the effects of diverse causes or for a single cause, because it affects more than one kind of nerve, to result in qualitatively distinct sensations. As a result, the most that can be claimed is that sensations are caused by external objects, that they are the subjective signs of these objects and their properties, but are in no way images of them. The relation is one of sign to object signified, and even so, as such it is not an invariant relation. The only exception—an important one—is the correspondence in temporal sequence between external events and subjective sensations. Indeed, it is this correspondence that enables the scientist to determine the order of external events—that is, to determine the invariant laws of nature.

Because, with the notable exception of temporal sequences, there are no invariant, but only fairly uniform, relations between the sensations we experience and the objective world, Helmholtz felt that we can speak of our ideas as true only in a practical sense. Sensations are signs that we learn to use in order to regulate our movements and actions. When we have learned to interpret these signs, we are able to control our actions and are able to bring about results we desire or to avoid dangers.

> [To ask, however,] whether the idea I have of a table, its form, strength, colour, weight, etc., is true *per se,* apart from any practical use I can make of this idea, and whether it corresponds with the real thing, or is false and due to an illusion, has just as much sense as to ask whether a certain musical note is red, yellow, or blue. Idea and thing conceived evidently belong to two entirely different worlds, which no more admit of being compared with each other than colours and musical tones or than the letters of a book and the sounds of the words they form. (*Handbook of Physiological Optics,* Vol. III, p. 19)

SPACE AND GEOMETRY

Helmholtz's study of perceptions of space and of spatially oriented objects led him into the field of non-Euclidean geometry. His interest in general problems of spatial perception led to the investigation of the analytic properties that any space must have in order to permit the establishment of congruence relations between bodies and surfaces. As he saw it, congruence can be established only if rigid bodies or systems of bodies can be moved toward

one another with unaltered form—that is, only if the congruence of geometrical figures is a relation independent of all movements in space. Thus, he took the actual fact of spatial measurements through the establishment of congruence as a starting point and investigated the most general analytical properties of any space in which the movements necessary for this measurement can occur. He found that such movements and measurements were possible not only in Euclidean space but also in the spaces investigated by Riemann and Nikolai Ivanovich Lobachevski or in any space with a constant measure of curvature. Helmholtz concluded that Kant was mistaken in claiming that the axioms of Euclidean geometry were synthetic a priori principles necessarily true of space. Spaces that are not Euclidean can be conceived; the geometries of these spaces can be formulated; models or interpretations of them can be given, and on the basis of experience, it is impossible to determine which of these geometries is that of real space. Kant was correct in considering space to be a form of intuition but wrong in claiming that space must necessarily possess Euclidean characteristics.

PHILOSOPHY OF PHYSICS

Helmholtz's philosophy of physics was a classic formulation of nineteenth-century mechanism. He felt that the primary function of the physical sciences was to search for laws that express observed particular processes in general terms, so that from these laws other particular processes could be deduced. The discovery of these laws is the task of experimental physical science.

> The theoretical part … endeavors to ascertain the unknown causes of processes from their visible effects, it seeks to comprehend them according to the law of causality…. Thus, the final goal of the theoretical natural sciences is to discover the ultimate invariable causes of natural processes. (*Über die Erhaltung der Kraft,* introduction)

According to Helmholtz, these ultimate causes are simple Newtonian forces, so that a causal explanation in physics is at the same time an explanation in terms of forces.

> Theoretical natural science must, therefore, if it is not to rest content with a partial view of the nature of things, take a position in harmony with the present conception of the nature of simple forces and the consequences of this conception. Its task will be completed when the reduction of phenomena to simple forces is

completed, and when it can at the same time be proved that the reduction given is the only one possible which the phenomena will permit. This will then be established as the necessary conceptual form for comprehending nature, and we will then be able to ascribe objective truth to it. (Ibid.)

These statements always represented the ultimate aim of scientific explanation for Helmholtz. It was a goal that grew more distant as the nineteenth century advanced.

HELVÉTIUS, CLAUDE-ADRIEN
(1715–1771)

Claude-Adrien Helvétius was born into a highly respected medical family; his father was first physician to the queen of France. After his education at the College Louis-le-Grand and at the age of only twenty-three, Helvétius obtained, through influence at court, the lucra-

tive post of *fermier-général*, in which he soon grew rich. He became known, however, for the philanthropic and enlightened uses he made of his great wealth, particularly as a patron of philosophers and men of letters. For a time Helvétius turned to poetry and, in a piece titled *Le bonheur*, extolled the supreme pleasures of the intellectual life. Taking his own advice, he resigned in 1751 from tax-farming, married, and retired to his country estate, thenceforth devoting himself primarily to philosophical and literary pursuits. The publication in 1758 of his principal work, *De l'esprit*, proved to be one of the ideological *causes célèbres* of the eighteenth century. Appearing at a moment of political reaction, *De l'esprit* was noisily condemned by the authorities, both ecclesiastical and ministerial, for its dangerously heretical and subversive opinions. Suppression of the book signaled a grave—but fortunately temporary—setback for the party of *philosophes* and Encyclopedists. Despite the recantations that Helvétius was forced to make regarding *De l'esprit*, he reaffirmed his ideas even more strongly in *De l'homme, de ses facultés intellectuelles, et de son éducation*, published posthumously in 1772.

The thought of Helvétius sprang mainly from the predominant current of sensualism in the Enlightenment, which he fashioned with marked originality into what may be described as a thoroughgoing doctrine of "environmental behaviorism." Like John Locke, he held that the primary function of the mind was the registering of sense impressions arising from the external world. Calling this faculty *sensibilité physique*, he held it to be the exclusive source not only of all ideas and judgments (which, he said, resulted from the mental comparison of sensations) and of memory (which is simply a weakened sensation), but of all the emotions as well; he described emotions as variations of the two root-sensations of pleasure and pain that usually accompany sensory experience. Diverging, however, from the mainstream of Lockeanism represented in France at the time chiefly by Étienne Bonnot de Condillac, Helvétius was concerned with deriving from sensationist premises a psychological, rather than epistemological, theory. His basic contention was that the intellectual and moral capabilities, no less than the entire complex of values and motivations peculiar to any individual, are to be explained solely as the product of education—that is, of the total cumulative environment from the moment of birth. The biological or hereditary influences on the individual are considered, by contrast, to be uniform in all who are "normally constituted"; moreover, it is deemed unnecessary to include such "constants" in the causal investigation of behavior. Whereas Locke had rejected innate ideas, Helvétius pro-

ceeded to the rejection of innate abilities, or, more exactly, of innate inequalities in the apparatus of natural talents and inclinations with which every normal person is endowed. In expounding this radically environmentalist psychology, he did not feel obliged to assume any metaphysical position concerning the substantive nature of mind. Nevertheless, it is clear enough, as the concept of *sensibilité physique* implies, that Helvétius, swayed perhaps by contemporary materialists such as Denis Diderot and Julien Offray de La Mettrie, had in fact adopted a naturalistic view of man as logically the most suitable context in which to develop his behaviorist thesis.

In the mass of empirical evidence, often valuable and sometimes penetrating, adduced in support of the absolute case for environment versus heredity, two arguments stand out. Aware that exceptional talents do not always result from equally exceptional educations, Helvétius attempted to justify environmentalism by introducing the notion of *hasard*. According to this, a trivial and chance occurrence—such as Isaac Newton's observation of an apple falling to the ground—could, under certain conditions, have the most far-reaching consequences—such as the discovery of universal gravitation. Helvétius reached the reassuring, if tenuous, conclusion that genius is common to all persons, but the special sequence of events needed to actualize it is exceedingly rare. His other and much more plausible line of reasoning affirms that the development of intelligence, talent, or any ability whatever is proportional to the degree of *passion*, or emotional motivation, felt by the individual. Having thus translated the problem of inborn inequalities of mental capability into one of inborn emotive potential, Helvétius ended by finding that anyone may, by the appropriate stimulation of his passions, be rendered superior in any field of endeavor.

Throughout his writings, Helvétius emphasized the ethical and social implications of his psychology. The conception of the human being as a sort of behavioral tabula rasa, uniformly malleable by external controls into whatever forms might be judged desirable, favors obviously the practical ideal of reforming man and society on a grand scale. It devolves upon the "legislator-philosopher" to achieve this goal by a system of reeducation based on the scientific knowledge of the mechanics of behavior in relation to environment—an ambition aptly summarized by the sanguine dictum *l'éducation peut tout*. The supreme ethical criterion is, in turn, described as "public utility" (or such equivalents as *intérêt général, bonheur général*), which Helvétius further defined, in keeping with the pleasure-pain principle, as the maxi-

mum of pleasure compatible with a minimum of pain in the whole of a given society. But individual conduct in any environment is already determined by the pleasure principle, or self-interest, and Helvétius tried to show that, in addition, the multiplicity of pleasurable ends that men automatically seek, however "nonmaterial" in appearance, are all ultimately reducible to *sensibilité physique*. It is futile, therefore, to try to inculcate the social virtues by mere moralizing and even more so by condemning pleasure. Men can be changed for the better only through the manipulation of their passions. The key idea, to which all of Helvétius's thinking leads, is that the moral improvement and happiness of humankind can result only from political reforms having as their object the establishment of a system of public education (in both the narrow and the broad sense), by means of which the closest possible linkage would be effected between any individual's socially beneficial acts and his rewards in the form of gratified *sensibilité physique*. For example, Helvétius suggested that society methodically offer the choicest sexual enjoyments to its most virtuous and useful members. More generally and especially in the long polemical sections of *De l'homme*, he inveighed against what he regarded as the two major obstacles to the triumph of a hedonistic ethics founded on the standard of public utility—namely, Christianity with its irrational dogmas and ascetic, otherworldly morality and the feudal structure, economic inequities, and autocratic practices of the *ancien régime*. An aura of agnosticism, no less than a revolutionary fervor, surrounds the writings of Helvétius; while he does not argue the philosophical case for atheism, he patently assigns no positive value to a belief in God and even finds it pernicious to the *bonheur général* that he envisions.

The principal weakness of Helvétius's philosophy is its one-sided, reductive use of the factor of environment, at the expense of physiological predisposition—a defect that provoked a solid refutation from Diderot. Stated in absolute form, environmental behaviorism is paradoxical. Because no two educations, as Helvétius himself admitted, can ever be even remotely similar, it is impossible either to prove or to disprove his basic supposition that the same environmental causes will invariably produce the same behavioral effects. The representation of the mind as essentially passive sets up, moreover, a false dichotomy between it and the natural as well as social environment in which, from a more realistic standpoint, the individual is perceived to be a peculiarly dynamic and, indeed, creative participant. Finally, the ideal of public utility, when considered positively, remains rather vague and elusive, despite the abuses of the *ancien régime*

attacked in its name. But historically the many valid elements of Helvétius's thought exerted considerable influence in several directions; on the Encyclopedist movement, especially Baron d'Holbach; on Pierre Cabanis and the *idéologues*; on the British utilitarians, particularly Jeremy Bentham; and, in a general long-range sense, on the rise of both democratic and socialistic doctrines and on the growth in modern societies of the comprehensive role given to public education.

HEMPEL, CARL GUSTAV
(1905–1997)

Carl Gustav Hempel was born in Germany, immigrated to the United States, and became a naturalized citizen. He taught at Yale, Princeton, and Pittsburgh. Along with Sir Karl Popper and Thomas S. Kuhn, a former colleague, he would become one of the most important philosophers of science of the twentieth century. Popper exerted more influence upon natural scientists and Kuhn upon social scientists and the public alike, but Hempel's impact upon professional philosophers of science was unparalleled. His work, including the problems he addressed and the methods he employed, virtually defined the philosophy of science, not just for a few years, but for several decades.

Hempel sought solutions to philosophical problems that were not only well-supported by suitable arguments but which were also precisely formulated by means of symbolic logic. He proposed subtle and nuanced formulations of scientific philosophy and promoted the transition from *logical positivism* to what would become known as *logical empiricism*. Hempel was committed to extremely high standards of philosophical clarity and rigor, which enabled his explications to be subject to the most demanding inspection and critical examination. He cared more about finding the right solutions than whether his own solutions were right.

LOGICAL POSITIVISM

Thus, "logical positivism," the leading movement of the 1930s and 1940s, was based on three principles: the analytic/synthetic distinction; the observational/theoretical distinction; and the verifiability criterion of meaningfulness. Logical positivism thus affirmed that all *a priori* knowledge is analytic and that all synthetic knowledge is *a posteriori*, denying the existence of knowledge that is both synthetic and *a priori*. Sentences that are nonanalytic but also nonverifiable, including various theological and metaphysical assertions concerning the divine or the absolute, thereby qualify as cognitively meaningless.

The precise manner in which scientific theories are to be related to experience therefore became a crucial issue. *Observation language* is assumed to consist of names and predicates whose applicability or non-applicability, under suitable conditions, could be ascertained by means of direct observation or relatively simple measurement. *Theoretical language*, which makes reference to nonobservables, such as malleability and conductivity as well as electrical fields and gravitational forces,

must therefore either be reducible to observables or is empirically meaningless.

COGNITIVE SIGNIFICANCE

Hempel (1950, 1951) demonstrated that empirical knowledge was thereby restricted to observation sentences and their deductive consequences, which reduces scientific theories to mere logical constructions from observables. In articles on cognitive significance and empirical testability, he persuasively demonstrated that the verifiability criterion implies that *existential generalizations* are meaningful, but that *universal generalizations* are not, even though they include general laws, the principal objectives of scientific discovery.

Moreover, on the assumption that a sentence S is meaningful if and only if its negation is meaningful, Hempel demonstrated that implementing the verifiability criterion generates inconsistent consequences. The sentence, "At least one stork is red-legged," for example, is *meaningful* because it can be verified by observing one red-legged stork; yet its negation, "Not even one stork is red-legged," cannot be shown to be true by observing any finite number of red-legged storks and is therefore *meaningless*. Assertions about relative frequencies in finite classes and their negations are meaningful, but those about limits in infinite sequences are not.

SCIENTIFIC THEORIES

These realizations suggested that the logical relationship between scientific theories and empirical evidence cannot be exhausted by means of observation sentences and their *deductive consequences* alone, but needs to be expanded to include observation sentences and their *inductive consequences* (1958). The concepts of confirmation and disconfirmation (as forms of partial verification and partial falsification) warrant renewed attention, where the crucial feature of scientific hypotheses is their empirical testability rather than their verifiability.

Hempel (1960) argued further that the application of inductive logic supports certain logically impeccable, but psychologically surprising, consequences, such as that the observation of a white shoe confirms the hypothesis that all ravens are black because it is an instance of the hypothesis that everything is either not a raven or black, which, using extensional language, is logically equivalent to all ravens are black. And he proposed that cognitive significance should best be envisioned as a matter of degree that may only be evaluated relative to multiple criteria (1965a).

DISPOSITIONS AND DEFINITIONS

In *Fundamentals of Concept Formation in Empirical Science* (1952) he addresses the problem of definability in relation to dispositional predicates, such as "malleable," "soluble," and "magnetic," which designate, not directly observable properties, but rather tendencies on the part of some things to display specific reactions (say, attracting small iron objects) under specific circumstances (the presence of small iron objects in the vicinity). On first consideration, it might seem appropriate to define this predicate by means of a formulation employing a conditional: "x is magnetic at t" is taken to mean, "if, at t, a small iron object is close to x, then it moves toward x."

Interpreted as a *material conditional*, whose meaning is synonymous with "either not … or ____," however, the proposed definition would be satisfied by things not subject to the test condition at all—such as brown cows—when there are no small iron objects in their vicinity. This result threatened the integrity of the project of developing an adequate philosophical framework for understanding the language of science. Both Hempel and Rudolf Carnap displayed great ingenuity in employing the resources of formal logic to cope with it. Ultimately, Carnap would embrace intensional logic as the solution, but Hempel preferred extensional logic, which imposed methodological boundaries upon explications he found acceptable.

EXPLICATIONS OF EXPLANATION

Hempel's most important contribution to the philosophy of science, no doubt, was his masterful explication of the structure of *scientific explanations* as a refinement of the theory of explanation by means of subsumption by general laws, an approach whose precursors date from Aristotle. Hempel developed this conception by means of his "covering law" model, which he elaborated in several versions, understood as arguments whose premises ("the

explanans") include at least one general law, Li, which explain why the event that is described by the conclusion ("the explanandum") occurred by showing it was to be expected relative to its initial conditions, C1-Cm (Hempel and Oppenheim 1948).

Thus Hempel presented a schema that has become familiar to generations of graduate students of the philosophy of science, which incorporated those conditions as follows in Figure 1. A simple example might explain why a small coin expanded when heated by invoking the law that copper expands when heated and noting it was copper. Hempel considered a vast variety of modes of explanation, contending that those which—implicitly or explicitly—conform to this conception are scientific.

INDUCTIVE-PROBABILISTIC EXPLANATIONS

Hempel included explanations of empirical generalizations by laws and of laws by theories within the scope of his approach, but devoted most of his attention to elaborating several precise and detailed accounts of the scientific explanation of singular events. And he advanced *deductive-nomological* and *inductive-probabilistic* versions to account for differences between subsumption by universal and by statistical covering laws. The differences between them, especially the peculiar difficulties generated by probabilistic explanations, would preoccupy much of his efforts for more than two decades, including Hempel (1948, 1965b, 1968).

The crucial problem turned out to be that of the rationale for the logical link between explanans and explanandum when the covering laws were not universal but statistical. Suppose, for example, that a statistical law of the form, $P(B/A) = r$, assigned probability of value r to the occurrence of an outcome of kind B, given conditions of kind A. Then an explanation of the form (see Figure 2),

invites the presumption that the bracketed variable [r] should be understood as a measure of evidential support. Hempel initially adopted such an approach, which reflects an epistemic interpretation of [r], but he would subsequently reject it on the grounds that the truth of the explanandum is already known: what we want to explain is why it occurred (Hempel 1968).

While the covering law approach dominated the philosophy of science in the 1950s and the 1960s, such difficulties, which were rooted in deep problems about the nature of explanatory relevance and of probabilistic laws, stimulated other investigations, the most important being the *statistical relevance* model of Wesley C. Salmon, which denied explanations were arguments and captivated the discipline in the 1970s. Salmon would later abandon the interpretation of nomic probabilities as relative frequencies for the Popperian alternative of propensities as probabilistic dispositions in the context of probabilistic explanation. During the 1980s and the 1990s, no approach would exert its grip upon the discipline as had Hempel's covering-law model, which made explanation a central function of science.

THE PROBLEM OF PROVISOES

One of the most remarkable features of Hempel's career is that he continued to publish original and innovative papers well into the eighth decade of his life. He authored a series of studies that moved away from the standard conception of scientific theories as *formal calculi* combined with *empirical interpretations* and, in *Philosophy of Natural Science* (1966), a widely used introduction to the philosophy of science that would be translated into ten other languages, he even advanced the novel explication of scientific theories as consisting of *internal principles* and *bridge principles*, where the general hypotheses that distinguish a theory are connected to observation and experiment by principles expressed in mixtures of ordinary and of technical language, where antecedent understanding replaces explicit definability.

More strikingly, Hempel (1988) noted that the application of scientific theories presupposes the absence of factors that might affect the internal principles of the theory, which goes beyond the content of the theory itself. Deriving predictions and explanations from classical mechanics, for example, presupposes that bodies are being acted upon exclusively by gravitational forces, where the presence of electromagnetic forces would invalidate those derivations. The function of these provisoes means that instrumentalist constructions of scientific theories as mere calculating devices and programs

for the elimination of theoretical language by reduction to observational language alone are misguided and cannot be sustained.

HEMSTERHUIS, FRANS
(1721–1790)

The Dutch philosopher Frans Hemsterhuis was born at Franeker, the son of the famous Greek scholar Tiberius Hemsterhuis. Frans Hemsterhuis was a clerk of the State Council and devoted his free hours to his favorite studies—numismatics, fine arts, and philosophy. In his last years his philosophy was very much influenced by his friendship with the Princess von Gallitzin, the wife of the Russian ambassador at The Hague. Thus, his life and work may be divided into two periods.

In the first period Hemsterhuis's *Lettre sur l'homme et ses rapports* (1772) was his principal work, preceded by two small, closely connected treatises, *Lettre sur la sculpture* (1765) and *Lettre sur les désirs* (1769). In *Lettre sur la sculpture* Hemsterhuis argued that the essence of the aesthetic experience is a longing to unite oneself with the art object. This concept became part of his theory of ethics, which is set out in *Lettre sur les désirs.* The most perfect happiness for the soul is the union with the beloved object irrespective of whether it is an object of art, a person, or God. This Platonic Eros is for Hemsterhuis analogous to the power of attraction in the physical world. This theory is further developed in *Lettre sur l'homme,* on which the Platonic dialogues of his second period are based. On the subject of the nature of man Hemsterhuis thought in terms of a dualistic philosophy like René Descartes's, but Hemsterhuis's dualism was combined with an empiristic-sensationalistic theory that he probably derived from John Locke and Étienne Bonnot de Condillac. Through sensory perception man receives an image of what exists in reality. This image, however, is incomplete, and if man had other organs, he could perhaps see other aspects of reality. Through what Hemsterhuis calls the "moral organ" man is aware of an immediate feeling of his relationship with God. The moral organ is also responsible for the feeling of relation, rapport, that man has with thousands of other men, and the development of such relations is dependent on the perfection of the moral organ. This theory leads to an individualistic concept of man's moral duties, which is one of the reasons for Hemsterhuis's influence on the German philosophy of *Sturm und Drang* and romanticism.

In the second period of Hemsterhuis's life he wrote four Platonic dialogues the most important of which are *Aristée ou de la divinité* (1779) and *Alexis ou de l'âge d'or* (1783, but published in 1787). In *Aristée* Hemsterhuis, who originally believed in a personal God, is converted to a clear pantheism. God's omnipresence is the basis of man's relation to him, and it is mainly thanks to the moral principle, as the "moral organ" is called in later years, that man is able to come nearer to God. In *Alexis* Hemsterhuis, perhaps influenced by contemporary German philosophy, presented for the first time his concept of the golden age and the harmonious development of the individual. He also introduced the notion of the value of poetical truth (truth discovered by the poet in moments of enthusiasm). With these ideas Hemsterhuis had moved far from his earlier rationalism, and his thought was received with admiration and approval by representatives of the *Sturm und Drang* and romantic movements in philosophy.

In the first period F. H. Jacobi and J. G. Herder were among Hemsterhuis's admirers; in the second period he was very popular with and influenced the two Schlegels and Novalis.

HEN/POLLA

In one form or another the problem known as that of the One (*Hen*) and the Many (*Polla*) pervades the whole history of Greek philosophy. According to Aristotle (*Physics* I, 2–3), it arose first in the pre-Socratic inquiry into whether there is one first principle or source—for example, water alone, or air alone—for things, or whether there is more than one first principle. If we are to avoid "coming into being out of nothing," we must either deny with Parmenides that there is any multiplicity arising from the first principle, or else we must suppose that somehow or other multiplicity is already present within the unitary first principle. If we choose the second supposition, we are faced with a problem that is no longer purely physical, namely, how one thing can also be many.

In the period after Parmenides it became clear that this problem arose at a number of different levels of thought, though it usually seemed natural to suppose that a solution at one level would solve the problem at other levels as well. It arose in relation to the phenomenal world in three ways: How one thing can possess a number of different characteristics, how one thing can change into another, and how one thing can have many parts. It arose, above all for Plato, as a problem concerning metaphysical entities such as forms—how unitary forms can be split up among many particulars, and how one form can possess a number of attributes. It arose in the theory of predication as the question of how a number of predicates can be applied to a singular subject. It arose in logic especially as the problem of how classification of many things under one head can be justified. It was also discussed (by Aristotle in the *Physics*) in terms of the number of first principles, even when the question of their number was no longer seen from within a purely physical framework.

Only some of the more important treatments can be mentioned here. The earlier Pythagoreans subordinated One and Many to Limit and Unlimited in their table of opposites. It remained a standard problem for the Eleatics after Parmenides, and Zeno leveled some forty arguments against plurality, of which one or two survive. The Sophist Protagoras tackled the problem at the level of perception, and Gorgias's pupil Lycophron dealt with it as a problem of predication by banishing the word *is* in statements such as "Socrates is white"; Antisthenes, the Megarians, and the Eretrians, according to some, followed the same path. Plato discussed the question repeatedly, most explicitly in Part Two of the *Parmenides* and in the *Philebus,* but of vital importance is his approach to predication in the *Sophist.* His discussion was continued by Speusippus, and by Aristotle in the *Metaphysics* (I, 6) and in the *Physics,* where he propounded a solution in terms of "substrate," "privation," and "form." The Neoplatonists saw it as the problem of how the multiplicity of the world order can proceed from the ultimate absolute unity.

HENRY OF GHENT
(??–1293)

The Augustinian secular theologian Henry of Ghent, traditionally known as *Doctor Solemnis*, was born at Ghent or Tournai, probably in the second quarter of the thirteenth century. In addition to holding high ecclesiastical office at Bruges and Tournai, he taught both arts and theology at the University of Paris. In 1277 he served on the theological commission that prepared the condemnation issued by Stephen Tempier, bishop of Paris, against the Averroism of Siger of Brabant and Boethius of Dacia. He died in 1293.

Henry's principal writings are a *Summa Theologica* and fifteen *Quodlibeta* (occasional disputations). The extended criticism of his ideas by John Duns Scotus, William of Ockham, and others is a sign of his considerable influence in his own age. In the sixteenth century the

Servite friars chose him as their official theologian, although he had never belonged to their order.

As a philosopher, Henry of Ghent stood in the main line of development of medieval Platonism. The Augustinian tradition, already brilliantly represented in the thirteenth century by Bonaventure and Matthew of Acquasparta, was unmistakably the weightiest element in his thought, and the Platonic orientation thus established was further strengthened by the influence of Avicenna. At the same time, following Bonaventure and other earlier Augustinians, he incorporated a number of Aristotelian ideas into his synthesis. Furthermore, in adapting the Neoplatonic metaphysics of Avicenna to the requirements of the Christian view of God and creation, he anticipated certain critical tendencies of the fourteenth century, by which the whole structure of medieval realism was to be undermined. It is fair to say that Henry failed to blend these diverse elements into a fully coherent system. Nonetheless, in inspiration and aim he was the true precursor of Duns Scotus, the last great constructive philosopher of the Middle Ages.

BEING

For Henry of Ghent the starting point of metaphysical thinking was the idea of being (*ens* or *res* or *aliquid*), out of which the metaphysician draws the intelligible essences virtually contained in it. Analysis shows that being is an analogical idea. Taken in its widest sense, it includes both imaginary entities (*res secundum opinionem*), which exist only in the mind, and genuine beings (*res secundum veritatem*), which exist, or at any rate can exist, outside the mind. Genuine being, which is the proper object of metaphysics (*ens metaphysicum*), is further divided into Being Itself (*ipsum esse*), or God, and contingent beings, or creatures. Finally, creaturely being is divided into that which exists in itself (substance) and that which exists in another (accident).

Genuine beings, actual or possible, are distinguished from imaginary entities by their possession of "essential being" (*esse essentiae*). This essential being is not a rudimentary mode of existence. It is best described as an intrinsic possibility or intelligibility that pertains to definable essences as reflections of the divine ideas. It is to be contrasted with the intrinsic impossibility and incoherence of *res secundum opinionem*.

Actual beings are distinguished from merely possible beings by their possession of "existential being" (*esse existentiae*). This existential being is not a principle or act within actually existing things; Henry refused to accept the real distinction between essence and existence as for-

mulated either by Giles of Rome or by Thomas Aquinas. The difference between essential and existential being is to be found not in things themselves but in the relation of essences to God. Essential being consists in being thought by God, while existential being consists in actually depending on God as creative Cause.

Apart from the fact that each actual being, as a product of divine creativity, is individually related to God, individual things, in which specific essences are multiplied, require no explanation of their individuality. Individuation involves no addition, whether of matter or of act of existence, to the intelligible essence. In analyzing the individual as such it is sufficient to say that it is internally undivided and is not identical in existence—that is, in its relation to the Creator—with any other individual.

DIVINE FREEDOM

The transition from essential to existential being, or the act of creation, is an act of divine freedom. Individual beings come into existence not from any intrinsic necessity but because God freely wills to create. Here the Christian and Augustinian conception of God's transcendent liberty excludes the Avicennian idea of the divine will as subject, equally with the divine intellect, to necessity. In his fear of compromising God's freedom in creation, Henry further minimized the intelligibility of individual beings. There are no divine ideas of singular things as such; God knows them only through their essences considered as multipliable in numerically distinct beings. Consequently, the existence of creatures can in no way be deduced from God's eternal ideas.

NECESSARY AND CONTINGENT BEING

The fundamental metaphysical notion of being is neither simply derived from sense experience nor strictly innate in the human mind. It is indeed formed by the mind from within, but on the occasion of sense experience. It would actually be more correct to say that two fundamental notions of being are formed by the mind, since the concepts of necessary or divine Being and contingent or creaturely being are radically distinct and cannot be deduced from a more general notion. When we conceive being unconfusedly, we always conceive either necessary Being or contingent being—never some undifferentiated, neutral being.

In thus asserting the irreducible duality of the notion of being, Henry was again trying to exclude any suggestion that God necessarily creates. If neither divine Being

nor creaturely being can be deduced from a universal concept of being, one argument for necessitarianism is effectively undermined. The further consequences of Henry's principle, however, were disastrous for his own metaphysical enterprise. His insistence that there is no positive content common to the two fundamental notions of being leaves a gap between divine Being and creaturely being that no mere affirmation of analogy between the two concepts can bridge. But if, as Henry claimed, there is some empirical factor in the formation of our notions of being, it is hard to see how necessary Being can be conceived, let alone demonstrated, as long as the gap remains. It is true that an a posteriori or "physical" proof of God's existence, based on experience of individual objects rather than on metaphysical principles, is possible, but such a proof can attain only to a supreme Being, not to a necessary Being. An appeal to divine illumination—the obvious remaining alternative—was excluded for Henry because he did not conceive of the divine light as a power impressing ideas upon the human mind. Although Henry refused to draw it, the conclusion seems inevitable that no firm basis can be found for a metaphysical theology.

With Henry of Ghent, medieval Platonism was clearly entering its final phase. In his thought, for all its predominantly Augustinian and Avicennian character, more or less novel concerns—a new stress on divine freedom, a fresh interest in sense experience, a new emphasis on sheer particularity—already modified the Platonic view of reality. Henry is thus a significant symbol of the transition from the constructive to the critical period of medieval thought.

HENRY OF GHENT [ADDENDUM]

Since the mid-1990s, remarkable progress has been made in the study of Henry of Ghent due to the ongoing publication of the critical edition of the *Opera Omnia.* Begun in 1979 at the De Wulf-Mansion Center of the Catholic University of Leuven, its labors have been complemented by two major international conferences held in 1993 and 2001 respectively.

The critical edition has not only made the texts of Henry much more accessible, but has directed scholarly attention to Henry's numerous (Greek, Latin, Arabic, and Hebrew) sources. Close attention to these sources has helped to settle several disputes concerning the status of Henry's works; for example the *Lectura ordinaria super sacram Scripturam,* the *Tractatus super facto praelatorum et fratrum,* and a number of sermons are now believed to be by Henry. However, the attribution of the *Syncategoremata* (ms. Brugge, Stadsbibl., 510, ff. 227ra-237va), and of a *Commentary* on the *Physics* (ms. Erfurt, Amplon. F. 349) and on the *Metaphysics* (ms. Escorial, h.ll.1) still remain matters of conjecture.

As a consequence of the published proceedings of the two conferences, Henry is no longer viewed solely as a "Platonic" and "neo-Augustinian" thinker, but as a thirteenth-century scholastic who possessed an astounding knowledge of the philosophy of Aristotle and Avicenna. While Henry's metaphysics and theology have been traditional areas of study, the conference proceedings began to focus attention on his ethics and economics, areas that await detailed investigation. Other recent studies have illuminated the facts of his biography. Henry was, most probably, born before 1240 (maybe between 1217 and 1223), was certainly in Paris by 1265, and from 1267 onward was registered as *magister* in the documents of Paris University.

Marialucrezia Leone (2005)

HENRY OF HARCLAY
(c. 1270–1317)

Henry of Harclay, the English scholastic theologian and philosopher, was born in the diocese of Carlisle. After studying at Oxford and Paris, he was ordained a priest in 1297 and obtained his master of theology about 1310. He taught at Oxford, becoming chancellor of the university in 1312. He wrote an unedited "Commentary on the *Sentences,*" and "Disputed Questions," most of which are unpublished. He died at Avignon.

Early in his career, while commenting on the *Sentences,* Henry defended the main theses of John Duns Scotus. Later, he criticized Scotism, teaching a doctrine of universals close to that of William of Ockham. He held that there are no common natures or essences in reality; there are only individuals, each of which has its own nature. Since there are no common natures, there is no need of the Scotist haecceity to render them individual. As Ockham later said, realities are individual not by an added "thisness" but by themselves.

Henry's doctrine of universals is based on this notion of reality. According to him, an individual can be conceived of either distinctly or indistinctly. When distinctly conceived, it is known through a particular concept; when indistinctly conceived, it is known through a universal concept. A universal is a confused concept by which the mind knows one individual without distinguishing it from others in the same genus or species. Inasmuch as an individual can be known through general concepts, Henry called it universal. For example, Socrates indistinctly conceived is man, animal, and body. Ockham criticized Henry's conceptualism because it ascribed some universality to things outside the mind.

Henry rejected the Scotist doctrine of the divine ideas as essences of creatures existing in God with cognitional being. He adopted a variation of the theory that the ideas are really the same as the divine essence itself known by God as imitable by creatures. God is known through concepts univocal to Him and creatures.

Henry stressed the omnipotence of God and the radical contingency of creatures. He claimed that no creature is naturally indestructible; the human soul is immortal not by nature but by divine grace. According to Henry, St. Thomas Aquinas betrayed Christianity by teaching the natural immortality of the soul.

HERACLITUS OF EPHESUS

Heraclitus of Ephesus is an early Greek philosopher who lived around the end of the sixth century BCE. He was a native of Ephesus, an important Ionian city just north of Miletus on the western coast of Asia Minor, and his father's name was Bloson. If the story can be credited that he voluntarily surrendered to his brother a hereditary right to a ceremonial kingship, Heraclitus would be the oldest son of an old noble family. His birth and death dates are uncertain, but the evidence of our doubtful sources would place his floruit in the reign of Darius I of Persia. The authors Heraclitus names make it impossible for his single book to be dated much before the end of the sixth century, and since he is fond of naming his rivals, the lack of any reference or allusion in his surviving words to Parmenides of Elea argues for dating Heraclitus's book before the publication of Parmenides's poem.

Tradition tells us that Heraclitus deposited his book at the great temple of Artemis in Ephesus. His dedication of his book to the goddess may be tantamount to publishing it and to making his thoughts publicly available rather than hiding his thoughts away from the vulgar, as some have surmised. This publicity would be in keeping with Heraclitus's conviction that the truth is common and open to anyone and is not a private possession of the privileged few. From antiquity, Heraclitus is infamous for his obscurity, and he was dubbed early on "the dark." His obscurity has often been credited to his emulation of the Pythian Apollo, whose oracular deliverances Heraclitus analyzes insightfully: "The lord whose oracle is in Delphi neither tells nor conceals, but gives a sign" (frag. 93 Diels-Kranz). He highlights the indirection of the *lord* because of his conviction that the nature of things reveals itself indirectly, and he may mimic in his obscure writing what he takes to be the obscurity in reality itself. Instead of the hexameters of Apollo's priests and of the heroic poets, Heraclitus writes in prose, like most of the new intellectuals of the sixth century who were critical of the poetic tradition and undertook independent inquiry, or *historiê*, in a wide variety of areas.

The Milesian natural philosophers Anaximander and Anaximenes wrote on cosmology and cosmogony, while their fellow Milesian Hecataeus composed the first comprehensive geography of the Greeks, which in part he based upon what he learned from his own voyages. The fragments of Heraclitus's book, of which there are more than a hundred, provide the first substantial sample of Greek prose. Yet Heraclitus is also the most poetic of the early prose authors; he displays skillful use of traditional poetic devices, such as parallel and antithetical sentence constructions, chiasmus, alliteration, assonance, rhyme, and ring composition, as well as an adept use of wordplay that enhances his message. His book was probably not a continuous treatise of unbroken prose but a sequence of short passages, some of which are pithy enough in their moral import to look like a maxim of the Seven Wise Men: "It is hard to fight with anger; for whatever it should want it buys with the soul" (frag. 85 D-K). Despite his much-heralded obscurity, many of his sayings are as straightforward as this astute observation on moral psychology.

THE LOGOS AND THE UNITY OF OPPOSITES

Like his older contemporary Xenophanes of Colophon, Heraclitus is openly critical of the poets of the ancient past, but he also includes among his targets contemporary intellectuals. He is critical of "Hesiod and Pythagoras, and also Xenophanes and Hecataeus" for their "polymathy" that does not yield "understanding" (frag. 40 D-K). He finds "much learning" an impediment to understanding, and this puts him at odds with the new intellectuals who practice *historiê*, which depends upon polymathy. "Understanding" comes from heeding what Heraclitus calls "the Logos," by which "all things come to be," and whose message the common stock of humanity fail to appreciate, as well as those reputed to be wise. They live in a private world of their own making, comparable to dreams, but those who harken to the Logos live in the one public world of the wakeful (frag. 89 D-K). Along with Xenophanes, Heraclitus is among the first of the new

breed of intellectuals to make an issue of the human epistemic condition.

The nature of this Logos is contested. Some scholars understand it as the nature or essence of reality, as it shows itself in discourse, others as a universal principle or law that regulates the basic workings of reality, and a few render it as Heraclitus's true *account* of reality in the form of his own book, or *logos*. With his predilection for wordplay, Heraclitus could well allow Logos to stand for both his book and the subject of his book. He lays down a telling parallel when he urges "those speaking with understanding" to hold to what is "common to all things," presumably the Logos, just as a city holds to its "laws." The commonality of the Logos would be comparable to the way in which the laws of a city apply across the whole of its citizenry, as the rules that regulate their behavior and shape them into a single community, and not to the way the air of Anaximenes's cosmology is the common constitution of all things. What is comparable to "human laws" is also what they are "nourished by," "by one, the divine," which in his ambiguity Heraclitus may intend to be "the one divine law" (frag. 114 D-K). The importance of what sustains "human laws" devolves upon them, so that "The people must fight for the law as for a city wall" (frag. 44 D-K).

The one surviving explicit message of the Logos declares that "all things are one" (frag. 50 D-K). This unity is not the oneness of the monism Aristotle credits the earliest natural philosophers with advocating, but the unity of opposites. This "connection" lies "unseen" (frag. 54 D-K), beyond the patterns of ordinary ways of thinking, as well as the teachings of the old authorities and of the new intellectuals. A "strife" between opposing powers lies hidden within the nature of each thing, and without this strife, the cosmos and everything in it would perish. While contesting with one another, the opposing powers within the essence of each thing cooperate with one another and yield a unified object: "They do not comprehend how each thing quarreling with itself agrees; it is a connection turning back on itself, like that of the bow and the lyre" (frag. 51 D-K). There would be no bow or lyre unless there were a striving between the wood and string through their powers of pulling in opposing directions.

At the cosmic level, the unity of opposites displays itself in the strife between the great cosmic powers of the hot and cold, the dry and moist, since even as they strive with one another for dominion, in the form of fire, water, and earth, they are tightly linked. The destruction of one cosmic mass is the generation of another, "death for water

is the birth of earth, from earth water is born" (frag. 36 D-K), where birth and death unite in a single event. The strife between opposing powers is beneficent and just, and "justice is strife" (frag. 80 D-K), contrary to the teaching of Anaximander, who describes the dominion of one opposite over another as "injustice." When people count some things as just and others as unjust, they divide justice from injustice, but from the objective position of god, all things are "fair and good and just" (frag. 102 D-K). The division between opposites is real enough, but so too is the unity, "it scatters and again brings together" (frag. 91b D-K). This divisive thought of the popular imagination leads to a false impression, which Homer fosters, that the positive of the pair is preferable, morally superior, and should dominate. Aristotle reports that Heraclitus criticizes Achilles's lament, "Would that strife might perish from among gods and men" (*Iliad* 18.107), since without strife there would be no peace, no coherent cosmos.

Heraclitus's originality lies most prominently in his efforts at establishing the integrity of each thing through the unity of opposing powers within each thing, and he revolutionizes thought about values through his insistence upon this unity. No opposite can be valued to the exclusion of its counterpart g powers, because of the various ways in which they are tied to one another for their presence in the world and their efficacy. Heraclitus goes beyond his predecessors in displaying the positive nature of those powers that ordinary ways of thinking deem to be purely negative.

EPISTEMOLOGY AND RATIONALISM

The truth is "hidden," yet "obvious." The blind poet Homer, who is the "wisest of all the Greeks," fails to appreciate the "obvious" (frag. 56 D-K). The truth is obscure, yet it remains open to anyone's inspection through simple means of comprehension. The unity of opposites is no mysterious dogma handed down from on high, and its confirmation may be achieved through observation and argumentation, linguistic analysis, and self-reflection. Heraclitus has confidence in the truth-yielding capacity of observation, "Those things that come from sight, hearing, learning from experience, these I esteem" (frag. 55 D-K), although observation must be evaluated carefully: "Eyes and ears are poor witnesses for men if they have barbarian souls" (frag. 107 D-K). Simple arguments premised on trivial empirical truths provide evidence for the unity: "Sea water is the purest and foulest of water, for fish it is drinkable and life-sustaining, for men it is undrinkable and deadly" (frag. 61 D-K).

In his exploitation of everyday language as a pathway to truth, Heraclitus puns on an uncommon word for "bow," which differs only in accent from the common word for "life," so that he may make manifest the connection between life and death: "The name of the bow is life, but its work is death" (frag. 48 D-K). Death is life, since, for example, the destruction of earth is the birth of water. When Heraclitus notes that "they would not know the name of Justice, if these things did not exist" (frag. 23 D-K), presumably "unjust things," he draws together opposites in the belief that a "name" like "justice" has no meaning in isolation, but only with its opposite, "injustice." Heraclitus will also appeal to a word's etymology for his evidence. The assistants of Justice, he reports, are the Furies (frag. 94 D-K), whose name meshes well with his identification of justice and strife (frag. 80 D-K), since it derives from "strife."

Heraclitus, unlike many of the new intellectuals, has no use for travel and the information it yields as a means for gaining "understanding." The only "journey" he ever mentions is into one's soul, in search of oneself (frag. 101 D-K), and "You would not find out the limits of the soul by going, even traveling over every road, so deep is its *logos* (frag. 45 D-K). This inward journey reveals the value of a measured existence for human well-being. The "measured man" learns from self-examination the proper limits of the great destructive forces of emotion and desire. Despite Heraclitus's revolutionary reassessment of values, he shows himself still bound to tradition when he pairs self-knowledge with measure (frag. 116 D-K), which are values highly esteemed by the Pythian Apollo, whose Alcmaeonid temple posted prominently the famous maxims of the Seven Wise Men: "Know yourself" and "Nothing too much." Like the "measured man," the world-order "lives" a measured existence; the cosmos is "fire ever living, kindled in measures and in measures going out" (frag. 30 D-K). When one cosmic mass changes into another, a *logos*, or proportion, holds between them, so that, for instance, the sea "measures up to the same *logos* it was before becoming earth" (frag. 31b D-K). The cosmos is a self-regulating system that keeps within spatial and temporal limits the great destructive forces of nature: "The Sun will not step over his measures" (frag. 94 D-K).

The Logos belongs to the soul as much as anything else; thus, self-knowledge may provide a path to cosmic knowledge and to "understanding." One need not go far afield or draw upon extraordinary powers to discover the truth. Heraclitus is no pessimist, in contrast with Homer and the poets who believe that humans left to themselves without the aid of the Muses have no knowledge of rec-

ondite topics and are the victims of "rumor" (*Il.* 2.485—486). Humankind has within its reach the truth of reality, "It belongs to all men to know themselves and to think in a measured way" (frag. 116 D-K), although Heraclitus thinks that few will ever exercise successfully these shared capacities. He tempers his optimism further when he maintains that a man hears from a divinity that he is "infantile" just as a child hears the same from a man (frag. 79 D-K), and some think that they detect poetic pessimism in his observation that "human character," in contrast with "divine," "has no judgment" (frag. 78 D-K).

Yet Heraclitus is also no mystic, if by "mysticism" is meant a private insight into the truth, vouchsafed to the few, which goes beyond the ordinary capacities of humankind. Instead of intuition, Heraclitus has recourse to argument and public verification. His rationalism holds, even if Aristotle is correct in charging him with contravening the principle of non-contradiction, when Heraclitus insists that the same thing displays opposing properties (*Metaphysics*, 1062A30-35). Aristotle's charge is plausible even if we may easily dispel the appearance of contradiction, when Heraclitus maintains, for example, that sea water is both pure and impure, by our pointing out that these properties are not contradictory since they are qualified in different ways by applying to different creatures: fish and humans. Heraclitus may have not been able to recognize that the ambiguity gives him only the appearance of contradiction. But he comes by his view of unity honestly, without mystery, through his appeal to argument and observation.

CHANGE AND FIRE

Heraclitus argues for the truth of the unity of opposites, by arguing that the contrary pairs, the living and the dead, the waking and the sleeping, and the young and the old, are the "same" because the contraries of each pair mutually replace one another (frag. 88 D-K). Living things die, but from the remains of the dead living things emerge. Day and night are "one," thinks Heraclitus, probably because of their mutual succession (frag. 57 D-K). Heraclitus ties together inferentially two of his important doctrines when he derives the unity of opposites from the fact of change, and he may see change at the foundation of his speculations. Despite the centrality of change, its nature has been subject to exaggeration. Plato, who may be more under the influence of Cratylus than of Heraclitus, finds change to be incomprehensible, and he credits Heraclitus with a doctrine of universal flux in which reality is likened to the flow of a river, where "you could not step twice into the same river" (*Cratylus* 402A). These

words indicate an extreme sort of change in which nothing retains its identity. The "river fragments" suggest something less extreme, that things constantly change but retain their identity: "As they step into the same rivers, other and still other waters flow upon them" (frag. 12 D-K). The rivers remain rivers; only the water that constitutes them is constantly changing.

Cosmic change is not chaotic, but occurs in an orderly way, as Heraclitus suggests when he speaks grandiloquently of the eternity of the world-order: "This cosmos, the same for all, no one of gods and men made, but always was and is and shall be fire ever living, kindling in measures and going out in measures" (frag. 30 D-K). The fire the cosmos is identified with changes, but in a measured way, changing in its extinction into the other great cosmic masses, and in an orderly pattern changing back again in its ignition. The flow of fire matches the flow of a river, but fire is more than an image when Heraclitus identifies it with the cosmos, and when he makes fire worth all else: "All things are an exchange for fire and fire for all things, just as gold for goods and goods for gold" (frag. 90 D-K). Heraclitus privileges fire, but not after the fashion of the monists, as Aristotle and Theophrastus would have us believe, as the stuff that constitutes all else. Theophrastus explains the "exchange" between fire and all things as fire's yielding everything else through its rarefaction and condensation, although he must admit that Heraclitus "sets out nothing clearly" (Diogenes Laertius 9.8).

It is not surprising that Theophrastus finds Heraclitus unclear, since the mercantile image of exchange, of "gold for goods and goods for gold," indicates that what is exchanged for fire is no more fire than the goods exchanged for gold are gold. In keeping with the mercantile image, the primacy of fire lies in its providing the standard that fixes the value of all else, as equivalent to so much fire, and Heraclitus may value fire above all else because it is psychic stuff: "For souls death is the birth of water, for water death is the birth of earth, from earth water is born, from water soul" (frag. 36 D-K). The sequential change back and forth between soul, water, earth suggests an exhaustive cosmic exchange, and thus the absence of the important cosmic mass of fire calls for its identification with soul. It is a "dry soul" that is "wisest and best" (frag. 118 D-K). Heraclitus has room for only three great cosmic masses, fire, water, earth, in his physics and no place for the air of Anaximenes.

THEOLOGY

The soul is the basis of life, but also of intelligence (frag. 107 D-K). Heraclitus links fiery stuff and intelligence when he says that "Thunderbolt steers all things" (frag. 64 D-K). "Thunderbolt," which stands for the guiding principle behind the cosmos, is the instrument of Zeus, the greatest god in the Greek pantheon, and Heraclitus intends for his ruling principle to be identified with the divine, but in a qualified way, when he says: "The one, the wise alone, is not willing and is willing to be spoken of by the name of Zeus" (frag. 32 D-K). Heraclitus appropriates a divine name from popular religion, but he warns against its literal application. His ruling principle, like Zeus, is the most powerful of deities, but, unlike Zeus, it should not be conceived in an anthropomorphic manner. The traditional language of divine anthropomorphism shows up in his praise of strife, "War is father of all and king of all" (frag. 53 D-K), which recalls the Homeric description of Zeus as "the father of men and gods," and Zeus is the "king" of the gods.

Heraclitus borrows freely from the conventional language and images of popular religion, but he applies them in unconventional ways, and his practice suggests that he is trying to formulate a new way of talking about the divine within the idiom of the old. Among the Greeks Xenophanes initiated the criticism of anthropomorphism, but, unlike Heraclitus, he purifies his language of the traditional anthropomorphic vocabulary. In one remarkable passage, Heraclitus draws together the divine, the opposites, and perhaps even fire: "The god, day-night, winter-summer, war-peace, satiety-hunger, and it undergoes change, as when mingled with perfumes, it is named according to the pleasure of each one" (frag. 67 D-K). The divine is actually identified with the opposites, as if their union was the divinity itself, and Heraclitus may treat the god like fire when referring to its changing in accord with the perfumes mixed into it. The significance of fire corresponds to the importance of Logos; war, like the Logos, is common; strife, like the Logos, is what all things come to be in accord with (frag. 80 D-K). The Logos, fire, strife, and divinity would seem to come together in Heraclitus's thought, although there is no evident formula for the expression of their convergence.

When he subjects particular cult practices to criticism, Heraclitus proves to be harsher than Xenophanes. The age-old practice of purging oneself of blood guilt through blood sacrifice Heraclitus ridicules as comparable to washing off mud with mud, praying to statues is like "chatting with houses" (frag. 5 D-K), and the "mysteries" men now believe in do no more than "initiate into

impiety" (frag. 14 D-K). The "procession" for Dionysus and the "chant for the phallus" would be shameful if they were not done for the sake of the god, and the participants in these practices do not even recognize that "Hades and Dionysus are the same" (frag. 15 D-K). Once again Heraclitus appropriates conventional divine names, but uses them in a shocking way by identifying traditional deities of widely contrasting natures, Hades and Dionysus, perhaps once more as a way of signifying the identity of life and death. The alcohol beloved of Dionysus Heraclitus condemns as turning a man into a boy by making his "soul moist" (frag. 117 D-K), and, despite the "joy" men take in moisture, it is death (frag. 77 D-K).

Heraclitus does not recommend any new practices to take the place of those he censures, in contrast with Pythagoras who recommends many new rituals to supplement those of tradition. When Heraclitus maintains that "Character for a man is fate" (frag. 119 D-K), he looks as if he were removing humankind from the tutelage of the gods. *Daemon*, the word for "fate," is [a] also the word for a guardian divinity, and thus in identifying a man's own character with his guardian, Heraclitus would be stressing that humans should take responsibility for their actions instead of laying blame upon the divine for their fortunes, both good and bad. Heraclitus is often thought to sanction immortality for at least some souls, perhaps of warriors: "Greater deaths are allotted greater portions" (frag. 25 D-K); "Those slain by Ares, gods and men honor" (frag. 24 D-K). Personal survival is not possible in a cosmos of universal destruction, and Heraclitus may mean no more than enlightenment when he speaks of those who "arise and become wakeful watchers of the living and the dead" (frag. 63 D-K). The wakeful may be those awakened from folly, since Heraclitus associates subjective misapprehension with sleep and objective comprehension with wakefulness (frag. 89 D-K).

COSMOLOGY

There is little reason to think that Heraclitus makes any advances in physics or astronomy. Unlike the Milesians, he does not seem to take much interest in the details of natural philosophy, and the fragments speak little to the issue. His words testify to his belief in an eternal cosmos (frag. 30 D-K), even though Aristotle and Theophrastus report otherwise. His rejection of cosmogony would mark him out significantly from the early natural philosophers, although Xenophanes may, too, have championed an eternal cosmos. Theophrastus and the doxographical tradition he founded report some astronomical and meteorological speculations. Bright and dark exhala-

tions arise from earth and sea, and "bowls" in the heaven trap the bright exhalations and form the heavenly bodies. The rotations of these bowls account for the phases of the moon and eclipses. The preponderance of bright and dark exhalations contributes to the explanations of day, night, months, seasons, years, rains, and winds. In what may be Heraclitus's own words, he traces daylight back to the sun, "If there were no sun, it would be night" (frag. 99 D-K), and he believes, along with Xenophanes, that the sun is "new each day" (frag. 6 D-K). Theophrastus concludes his report by saying that Heraclitus offers no explanation of "what the earth is like, or even about the bowls." The Hellenistic grammarian Diodotus finds Heraclitus's book to be about "man's life in society," and its statements on nature to serve only as "illustrations." (D. L. 9.15) The doxographical tradition may be misguided in assimilating Heraclitus's work to the discipline of natural philosophy. Theophrastus indicates further difficulties he had with Heraclitus's book when he maintains that some things Heraclitus wrote were "half-finished," others "inconsistent," which Theophrastus puts down to Heraclitus's "melancholy." (D. L. 9.6)

INFLUENCE

Of the Presocratic thinkers, Parmenides had the most influence, but Heraclitus may have had the most influence upon him, in drawing his attention to the problematic nature of change. Heraclitus may have had a certain vogue in the fifth century. Some minor Hippocratic authors reflect something of his paradoxicality, and Plato jokes about the fidgeting Ephesians, who are not stable enough to carry on an argument. Cratylus of Athens pushed change to such an extreme that he finds it necessary to rebuke Heraclitus for thinking that one could not step twice into the same river, when one could not step even once. Aristotle reports that in his youth, Plato was under the influence of Cratylus and found the objects of perception unknowable because of their instability. Heraclitus's most profound philosophical influence was upon the Stoics, who credited him with anticipating them. Fire has a primacy for them, and they, too, adopt a Logos as a ruling principle that is eternal, divine, and common to all things. Unlike Parmenides, Heraclitus exercises his charm well beyond antiquity and beyond philosophy. Hegel finds a positive parallel between his logic and the doctrines of Heraclitus, and T. S. Eliot spins out much of *The Four Quartets* in imagery borrowed from Heraclitus. Heraclitus's poetic prose attracts many to this day.

Herbert Granger (2005)

HERBART, JOHANN FRIEDRICH
(1776–1841)

Johann Friedrich Herbart, the German philosopher, psychologist, and educational theorist, was born in Olden-burg; he entered the University of Jena in 1794. Although he studied under Johann Gottlieb Fichte, Herbart was unable to accept Fichte's view of the ego and its psychology, and in reaction he laid the basis for his own metaphysical and psychological views. In 1797 Herbart took a post in Switzerland as tutor. He held the position for three years and, during this period, worked out to a large extent the views that he was to refine and elaborate for the rest of his life.

After he took his doctorate at Göttingen in 1802, Herbart remained there for the next seven years. *Allgemeine Pädagogik* (General Theory of Education) and *Hauptpunkte der Metaphysik* (Main Points of Metaphysics), both of which appeared in Göttingen in 1806, and his *Allgemeine praktische Philosophie* (General Practical Philosophy; Göttingen, 1808) were major fruits of this period. In 1809 Herbart moved to Königsberg to occupy Immanuel Kant's former chair, and there he published his *Lehrbuch zur Psychologie* (Compendium of psychology; 1816), *Psychologie als Wissenschaft* (Psychology as a science; 1824–1825), and *Allgemeine Metaphysik* (General metaphysics; 1828–1829). When the political situation rendered Königsberg continually less attractive and Herbart failed to secure G. W. F. Hegel's chair at the University of Berlin, he returned to Göttingen in 1833 and remained there until his death.

THE PARTS OF PHILOSOPHY

Philosophy, according to Herbart, cannot be characterized by its subject matter but only by its method, which is the reworking (*Bearbeitung*) of concepts; and the possible kinds of such elaboration determine the major divisions of philosophy.

The first kind of reworking renders concepts clear and distinct. Distinct concepts can be formed into judgments and these judgments can be organized into inferences. This process of distinguishing and ordering concepts is logic.

But experience gives rise to many concepts which, the more distinct they become, the more contradictory they appear, a sure sign that we are missing both being and truth. Our ideas must, therefore, undergo an "enlargement" (*Ergänzung*), which will remove the contradiction. This second kind of reworking of concepts gives us the second great division of philosophy, metaphysics.

Concepts in the third class are like the metaphysical concepts in that they cannot remain merely at the level of clarity and distinctness, as do the logical concepts. But

while the metaphysical concepts involve only enlargement, this third class involves in addition an intuitive judgment of approval or disapproval. Thus we get the last great division, aesthetics. Aesthetics includes a series of doctrines of art or practical sciences. One of these, ethics, issues necessary (and not merely conditional) prescriptions because we continuously and necessarily concern ourselves with its object, ourselves.

METAPHYSICS

Metaphysics consists of four parts: (1) method, the general principles of the proper method and order of procedure; (2) ontology, the study of the real; (3) synechiology, the study of those forms of experience that have continuity (such as space, time, and motion), and (4) eidolology, the examination of the possibility of knowledge.

METHOD. The first task of metaphysics is to define "the given" in experience. Common sense says that it is "things with multiple and changing characteristics." But this concept violates the law of identity. For any single thing dissolves into a multiplicity of qualities when we describe it; it is at once both a unity and not a unity. Substance, cause, ego, time, and space are also contradictory. Yet they must be "given" in some sense, since we cannot change them at will. In moving to metaphysical concepts freed from contradiction, we use as our chief tool the " method of relations." A contradictory concept of experience, A, unites the contradictory terms, M and N. M is thus both identical and nonidentical with N. If one further divides M into M' and M'', one element will still be identical with N, the other not; this contradiction disappears only when we admit that, although each of the parts of M is not identical with N, they mutually modify each other so that together they become so. Thus, in the syllogism, the conclusion must be contained in the premises; and thus the premises must change into or cause the conclusion. But M' and M'', the premises or cause, are not individually the same as N, the conclusion or effect. Hence M' and M'', the premises, must mutually modify each other so as to become identical with the conclusion.

ONTOLOGY. Ontology deals with being. Since being is not directly given in experience, it is easy to say that there is no being. But it is hard to live with this judgment, for things continue to appear. What, then, is it that appears? Appearances or phenomena cannot be taken as the only reality, for the concept of absolute position (being in absolutely no relation whatever to anything) cannot be applied to them; they are always related to something else. Nor can phenomena be reduced to our sensations of them and then located in an ego, for our sensations are not just sensations of sensations, and the concept of the ego is itself contradictory.

We are thus led to posit "being" as a plurality of beings or reals (*Realen*), with the essence of each real a single quality, absolutely simple, without parts, degree, or negation, always immutably identical with itself. But how can this concept of being be reconciled with our experience, which is both the basis of metaphysics and its test? The absolute position of reals seems to contradict the multiple relations in which things appear to us. But being can be conceived by mind; and in mind a being is only an image (*Bild*). Mind also can simultaneously represent several beings, which, as images, can stand in many different relations to the first one. These relations are "contingent viewpoints" (*zufällige Ansichten*), which exist in thought, not in things-in-themselves. Just as in analytic geometry the same point can be part of an infinite number of curves, so a single real may enter many contingent viewpoints.

Experience presents us with complex aggregates that we call things. Yet we cannot say that the aggregate exists, for colors, sounds, and such exist only in the perceiving subject. Nor can we say that something having those qualities—that is, substance—exists, for substance cannot be being if being is simple, since substance appears as endowed with manifold and varying qualities. How, then, can attributes and modes inhere in substance? By the method of relations. If A is a substance and a an attribute, analysis of A into multiple elements (A', A'', and so on) will not resolve the contradiction unless we say that a is not identical with any one of the As but with the totality of them, the number of which remains undetermined but which must be at least two if mutual modification between them is to occur. Substance, then, is explainable as multiple beings in conjunction (*zusammen*) with each other, many reals grouped about one real. This conjunction explains that unity that we attribute to substance, although the essential unchanging quality of that central real is unknown to us; and the other reals in conjunction with it account for the varied and varying attributes we experience, although those attributes are not the essential qualities of those various reals.

The conjunction and the separation of the reals explain those sensible appearances which led to their postulation. Such mutual interaction would seem to lead to mutual destruction, but, just as in an equilibrium of forces both forces remain constantly what each is, though balanced, so in the concatenation of reals, the mutual perturbations (*Störungen*) that would lead to mutual

destruction are counterbalanced by individual acts of self-preservation through which each real strives to remain what it is.

These acts of perturbation and self-preservation constitute real phenomena (*das wirkliche Geschehen*), as distinct from sensible phenomena or appearances (*Erscheinung*), of which the real ones are the basis and explanation. To what or to whom do they appear? This is the problem of the ego, self, or soul-substance.

The ego, or self, poses the same problems as do the other substances, and the solution is the same. The unity and diversity of the ego are explained by the coming and going of reals. The soul, which is not the ego of consciousness, is a real, but one endowed with mind, which is the seismograph that records, in the form of presentations or ideas (*Vorstellungen*), the acts of self-preservation of the soul vis-à-vis the other reals. These presentations are the sensible phenomena given in experience. With metaphysics thus having shown the origin of our ideas, psychology will show their development and combination.

SYNECHIOLOGY. Synechiology concerns that which is continuous (*das Stetige*)—notably space, time, and motion. Continuity, as union in separation and separation in unity, is a contradictory concept (though undoubtedly given in experience), which must be explained by metaphysics. As far as being is concerned, space and time are "obviously nothing." They, like the continuity we attribute to them, are merely natural and necessary products of the psychic mechanism. What essentially characterizes space and time is the mutual exteriority (*Auseinander*) of the parts. But between points of space or time it is always possible to *conceive* additional parts, and this further functioning of the psychic mechanism makes space and time seem to flow uninterruptedly.

But the comings and goings of the reals imply some sort of space, time, and motion, even though these are distinct from their sensible counterparts, such as "intelligible space." Although two reals, *A* and *B*, are actually apart, we can conceive the possibility of *B*'s being with *A* and *A*'s being with *B*. Thus space is the simple possibility *in mind* for one real to be together with another from which it is separated in reality, an "image" without reality. Space thus being completely accidental for reals, we can, by putting *A* in the place of *B* and *B* in the place of *A* and further continuing to add more reals and more dimensions, generate lines infinite in all directions, even though each line is "fixed" (*starre*) with a determinate number of points rather than continuous (*stetige*) with mutual inter-

penetration (and hence indefiniteness in number) of the parts. The psychic mechanism then conceives of these "fixed" lines as continuous by interpolation. Intelligible space, as thus generated, corresponds to the sensible space of phenomena and shares its contradictions, but these need not trouble us, since they have nothing to do with being. Intelligible space is a purely conceptual artifact (*Gedankending*), not imposed by mind on things but generated by mind as a necessary aid to thought. Once intelligible space has been generated, the explanation of matter becomes possible. It is a question of asking what situation the images of reals should occupy with respect to intelligible space in order to account for matter. The answer is "incomplete interpenetration."

EIDOLOLOGY. Eidolology examines the possibility of knowledge and its limits. In all knowledge, matter and form can be distinguished. The matter is simple presentations or sensations. They do not enable us to know what is, but they do oblige us to believe that something is. But the given has form as well as matter. Sensations are not given us in isolation but formed into groups, which cannot be separated at will and which constitute things. Doubtless, in the form in which they appear to us, things exist only in and for mind. But the constancy and the modifications of these groups of sensations have their basis in the conjunction and separation of the reals. Thus mind, though it cannot know the qualities of the reals through sensation, does know their relations; and even were our sensations wholly different from what they are, their forms would be the same, arising as they do from the objective separations and connections of the reals. Knowledge through concepts is likewise valid knowledge, although it too is knowledge only of relations. "We live amid relations and need nothing more."

PSYCHOLOGY

Everything in mind arises in some fashion out of presentations. There are no faculties, no innate ideas, no concepts a priori. The soul is a real in which countless acts of self-preservation are provoked through its contacts with other reals, and these efforts in turn produce in mind the presentations, some of which oppose, some of which reinforce, each other. Although reals and presentations are not forces, they can best be understood by analogy with forces, and hence the synthetic part of psychology consists of the statics and mechanics of mind. Complex mathematical formulas, corresponding to those of the statics and mechanics of physics, describe the interplay of presentations.

Presentations of different sorts do not oppose each other (for instance, colors do not oppose sounds); but presentations of the same sort do (for instance, red opposes blue). In the latter case, what remains after arrest is an equilibrium, a weakening or obscuring of the original presentations that is reached progressively by a process of sinking (*Senkung*). A presentation, if it has not undergone arrest, is present in consciousness. Sinking under arrest, it may be forced below the threshold of consciousness. Yet a presentation below the threshold of consciousness is subject to recall or rising (*Hebung*) by the appearance of a new presentation similar to it, and the speed of this rising depends on the degree of similarity between the two presentations. This new presentation also produces a vaulting (*Wölbung*) or "arching" of all other arrested presentations similar to it. The coming of a new presentation, *B*, produces the rising (*Hebung*) of the similar older presentation *A*. But as *A* is pulled up, other older presentations similar to *A* but less similar to *B* are also pulled up in a *Wölbung*, or arching. The analogy to a beater being pulled out of stiff whipped cream is exact. The surface of the cream closest to the beater is pulled up most (*Hebung*), but the whole center surface arches somewhat (*Wölbung*).

The feelings, the desires, and the will have their origin in presentations. Some feelings arise out of the fusion of opposed presentations, and the pleasantness or unpleasantness depends on the amount of opposition. Other feelings originate in the strain that the rising, produced by a new presentation, puts on ties that an old presentation already has with one or more others. Thus the sight of an object belonging to a dead friend evokes the memory of him, but the thought of his death tends to repress the memory and thus to produce a painful feeling. Pleasant feelings arise in the contrary situation, when the other associated presentations all facilitate the recall of the original one. The desires are closely connected with the feelings. In a situation giving a painful feeling, where *A* is lifted toward consciousness by the appearance of *C* and is simultaneously depressed by its earlier relation to *B*, the feeling of effort by which the resistance is overcome will be a desire and *A* will appear as the object of desire. The will, in turn, is only a particular form of desire, the realization of which is seen as possible.

Concepts, also, have their origin in the fact that each new presentation produces the vaulting of the images of similar previous presentations already in mind, in which process the similarities are reinforced and the differences between them are repressed, as in a composite portrait.

ETHICS

Ethical judgments are aesthetic judgments involving pleasure and displeasure. Since the completely simple cannot be pleasing or displeasing, these judgments must be directed to something complex, to relations. Since Herbart, like Kant, sought the basis of ethics in the good will, the five possible relations of the will suggest five corresponding fundamental ethical ideas.

The idea of "inner freedom" is the correspondence between a single act of a single will and the judgment passed on it. Harmony between the "objective" will (the inclinations) and the "subjective" will (the intuitive ethical judgment) is absolutely pleasing; its contrary, displeasing.

"Perfection" relates the varied acts of a single will. To this multiplicity, three quantitative concepts may be applied: the strength of any single effort (intensity), the multiplicity of the objects encompassed by the will (extension), and the concentration of this manifold into a total power (a new intensity developing out of extension). There is no absolute standard, but the stronger and more concentrated will is more pleasing than the weaker.

The idea of "benevolence" arises when one will comes to terms with the will of another. Yet this relation is internal to the first will in that it takes the will of the other person as an object.

The idea of "law" concerns the relations between the wills of two persons who desire some one thing. The ensuing strife is not, however, merely the contrary of the idea of benevolence, since both wills are turned directly toward the object and only indirectly toward each other.

The idea of "equity" arises from the intentional doing of an act of ill or good, a displeasing imbalance between two wills that can be rectified only by some appropriate requital through reward and punishment.

These five basic ethical ideas cannot be isolated in estimating character or in organizing social or political life; each must be tempered by all the others. Together, they exhaust the possible relations of the will, since the addition of more wills repeats in more complicated fashion those already covered by law and equity. But extension is possible if the many wills of a group can be analogized to that of a single rational being. Then five analogous social ideas appear in the reverse order. Members of this society will seek to avoid strife through a "system of law." But transgressions lead to a "system of requital." The benevolent spectator would wish for the greatest possible sum of well-being attained through the rational distribution of the available goods according to a

"system of administration." Then increased well-being would produce an intensity and range of strivings reconciled under a "system of culture." With the obedience of each to the moral insight of all, the many would become one in an "ideal society."

EDUCATION

Education takes its aim from ethics; psychology then shows it the means and hindrances to this end. The aim is moral strength of character, a will with inner freedom whose volitions are always in accord with the moral law. The three major divisions of education are instruction (*Unterricht*), discipline (*Regierung*), and training (*Zucht*). Since psychology shows that the entire mental life (including the desires and the will) is built out of presentations, instruction (with its four steps of clarity, association, system, and method) is directed toward enlarging the child's circle of thought and developing in him a many-sided interest by efficiently introducing the proper presentations into his apperceptive mass. Discipline keeps the child obedient and attentive so that instruction and training can do their work before the child has developed a proper will of his own. Training works constantly with instruction and discipline to form the will directly through such means as environment, examples, and ideals. Under discipline, the child acts rightly because he must; under proper instruction and training, he acts rightly because he wills to do so.

HERBERT OF CHERBURY
(c. 1582–1648)

Edward Herbert, the first Baron Herbert of Cherbury, courtier, soldier, diplomat, poet, historian, philosopher, and theologian, was the brother of George Herbert (1593–1633), the pastor and poet. He matriculated at University College, Oxford, in 1596. He moved to London in 1600, where he continued his studies and attracted the attention of the aging Queen Elizabeth. On his accession to the throne of England James I created him a knight. As a young man Herbert traveled on the Continent, on occasion being involved in warfare where he showed what some judged bravery and others foolhardiness. Visiting Rome, he called at the English College and showed his undogmatic spirit when he told a person whom he met there that while he was not a Roman Catholic, he judged that "the points agreed on both sides are greater bonds of amity betwixt us, than the points disagreed on" (*The Life of Edward Lord Herbert of Cherbury, Written by Himself*, p.105).

In 1619 he was appointed ambassador to the French court. In this post he showed himself to be a skillful diplomat who was prepared to use his own initiative and to give sensible, even if unpalatable, advice to his government. In 1624 he was recalled. The Crown failed to reimburse his debts as ambassador but sought to satisfy him with peerages, first the Irish barony of Castle Island, and later the English barony of Cherbury. In vain attempts to recover royal favor Herbert wrote two histories. The first, *Expeditio in Ream Insulam* (published posthumously in 1656), tries to defend the Duke of Buckingham's conduct in an English invasion of the Isle de Rhé in 1627 that was intended to support the Huguenots. Unsurprisingly in view of what happened on the expedition, it is not a convincing defense. The other was *The Life and Raigne of King Henry the Eighth* (1649), in preparing which he used official archives. It was long regarded as an authoritative study.

Although a member of Charles I's Council of War, Herbert sought as far as possible to avoid playing an active part in the English Civil War. He surrendered Montgomery Castle, where he was living, to Parliamentary forces when they augmented their challenge with the threat to sell the library that he possessed in London. Soon after, he moved to London and died there in 1648. He was buried, as he directed, without "shew of mourning" at midnight. In a lively and somewhat tongue-in-cheek autobiography, *The Life of Edward Lord Herbert of Cherbury, Written by Himself* (originally published by

Horace Walpole in 1764), he tells the story of his life and escapades up to his recall from France in 1624. His main claims to fame in the history of thought lie in his philosophical views (for which he is justifiably known as the first English author of a purely metaphysical study and for which he was respected as well as criticized by Hugo Grotius, Pierre Gassendi, and René Descartes) and in his religious thought (in which he produced a pioneer work on the study of other religions, and for which he has traditionally, but arguably inaccurately, been described as "the father of English deism").

PHILOSOPHICAL THOUGHT

During his ambassadorship Herbert completed his major philosophical work, *De Veritate, Prout Distinguitur a Revelatione, a Verisimili, a Possibili, et a Falso* (On truth, in distinction from revelation, probability, possibility, and error), and had it privately printed in Paris in 1624. In this work he seeks to show, contrary to the doubts of "imbeciles and sceptics," that "Truth exists" (*De Veritate*, p. 83).

Although he was in touch with contemporary scholars, although his works show wide knowledge of classical, scholastic, and Renaissance literature and of hermetic literature, and although his arguments are sometimes less than persuasive, Herbert should not be seen as an eclectic thinker who merely puts forward a collection of sometimes discordant ideas that happen to attract him. Conflicts between his ideas are rather due to a failure to be sufficiently thorough in developing his innovative position.

THE NATURE OF TRUTH. On the title page of the second and third editions of *De Veritate*, Herbert dedicated his work to "every reader of sound and unprejudiced judgement" (this was different from the first edition, which had been grander in its amusingly presumptuous dedication to "the whole human race without qualification"), regarding himself as an original thinker who thinks "freely" and recognizes only the authority of "right reason," and using what is at times rather infelicitous Latin, Herbert aims to determine the nature of truth and the way in which it is identified by "every normal human being." He regards such an investigation as necessary if people are to know how to avoid the errors of skepticism, dogmatism, and fideism that corrupt current thought and lead some to hold that "we can know nothing," and others that "we can know everything."

Although Herbert regards right reason as the final judge of what is true, he also puts forward a doctrine of

universal consent as the criterion for truth. He defends this doctrine on the grounds that universal consent must be due to the work of Providence, and hence what receives it cannot be doubted. The doctrine is somewhat paradoxical, however, since the need for some such criterion only arises where people do not agree about what is true, and hence where there is no universal consent about the matter. Herbert's views on this issue reflect the question-begging nature of his appeal to the authority of right reason: those who disagree with him about what receives universal consent may be ignored because their disagreement shows that they are not people of "sound and unprejudiced judgement" who are clearly following the dictates of right reason. It also reflects his conviction that the overall providence of God prevents what is erroneous from receiving universal consent.

THE DOCTRINE OF THE 'FACULTIES.' Herbert rejects the notion of the mind as a passive blank sheet on which the objects of its knowledge make their impressions. Nevertheless, while he holds that what people truly know is determined by the structure and activity of their minds, he seeks to show that what is known is, as common sense maintains, what is actually the case. To do this he puts forward his doctrine of the faculties, using the term *faculty* to refer to an internal power of the mind that links a particular perception with a particular object. According to this doctrine an object, whether intellectual or physical, is perceivable as such, and only so perceivable, because there is a corresponding faculty preestablished in the mind. Within the mind of each person there are as many latent faculties as there are differentiable objects, and the existence of a faculty shows the existence of a corresponding object. Defining truth as "a matter of conformity between objects and faculties" (*De Veritate*, p. 78), Herbert maintains that true knowledge of an object occurs when the appropriate latent faculty is activated. He also claims that an inner sense of satisfaction shows when an object has been correctly perceived by its corresponding faculty.

Herbert distinguishes between four classes of truth and between four types of faculty. According to the former division, the four classes of truth are: the truth of things as they are in themselves, the truth of how things manifest themselves to people, the truth of concepts that differentiate between things, and the truth of judgments on the deliverances of the other faculties. The four types of faculty are natural instinct, internal apprehension, external apprehension, and discursive thought. The first of these, natural instinct, is described as "that mode of apprehension which springs from the faculties which

conform to the Common Notions" (*De Veritate*, p. 115). These common notions are implanted in people by God. They are therefore all present, even if in many cases only latent, in every sane and whole person. The common notions are characterized by the qualities of priority, independence, universality, certainty, necessity (for one's preservation), and "the way of conformation" [*De Veritate*, p. 139–141] (in the sense of being immediately recognized and not needing to be warranted by discursive thinking). When brought to consciousness through appropriate stimulation, the common notions are acknowledged by all reasonable people as the normative principles for discerning what is true and good and for exposing what is false and bad.

As Herbert himself admits, the forms of the second type of faculty, internal apprehension, are not easily distinguished from those of the natural instinct. What characterizes them is that they concern a person's active response to particular objects. They may be spiritual, bodily, excited by external objects, or mixed. Under the guidance of the natural instinct, they make judgments about what is good and what is evil. Conscience is the highest of them. It applies the common notions to individual cases and is only satisfied when the faculties are correctly adjusted to what is the case. It is also through this faculty that people sense what is erroneous. External apprehension, the third type of faculty, concerns the ways by which people become aware of the external characteristics of objects and of their relationships with each other. Although most of Herbert's discussion of this kind of apprehension is concerned with the conventional five senses, he denies that there are only these five external modes of apprehension. He maintains that each sense is a channel for many external forms of apprehension since there are as many forms of apprehension as there are differences between objects.

The final type of faculty, discursive thought, is peculiar to humankind. It draws inferences from what comes to be known through the other faculties. It is more liable to error than they are, and so its findings are not to be preferred to what they directly discover. To establish the proper limits and methods of discursive reasoning, Herbert presents what he calls *Zetetica* and *Euretica* (the terms seem to have been coined by him, presumably from the Greek words for "to seek for" and "to discover"). These rules of reasoning appear to be indebted to Aristotelian logic. According to Herbert right reasoning proceeds by asking the appropriate faculties ten questions about the object of enquiry, namely, whether it exists, what it is, what kind of object it is, what its size is, to what

it is related, and how, when, where, whence, and why it exists. Herbert assures his readers that by using this method complete and true knowledge of an object will be obtained.

PROBABILITY, POSSIBILITY, AND ERROR. *De Veritate* closes by considering probability, possibility, and error. The first of these deals with knowledge of the past, in the course of which discussion Herbert indicates the insecurity of beliefs based on historical judgments, the second with knowledge of the future, and the last with the sources of wrong judgments. In 1645 Herbert published *De Causis Errorum: Una cum Tractatu de Religione Laici, et Appendice ad Sacerdotes, nec non quibusdam Poematibus* (Concerning the causes of errors, with a treatise concerning religion for the laity, and an appendix to priests, with certain poems), some copies of which were bound in an enlarged, third edition of the *De Veritate*. It does not add significantly to the epistemological discussions in the earlier work. Errors and fallacies are held to be the result of failing to satisfy the conditions for grasping the truth laid down in *De Veritate*.

RELIGIOUS THOUGHT

Herbert's thought is probably most widely known for his discussion of the common notions concerning religion. This was included in his treatment of common notions in *De Veritate* and was expanded in later editions. Herbert holds that the criterion for true religious belief is not found in some supposed revelation or ecclesiastical authority, but in five common notions. They are that (1) there is a God (Herbert's term for God is *Supremum Numen* [Highest divinity]); (2) this God ought to be worshipped; (3) the connection of virtue with piety is and always has been the most important part of religious practice; (4) while people are aware of their evils, they can and must expiate them by repentance; and (5) people face reward or punishment after this life. These common notions are, for Herbert, the foundation of the true catholic or universal church that covers all humanity and the only authentic source of salvation.

In *De Religione Laici* (On religion for the laity; 1645) Herbert argues that a layman, using both reason and prayer, can and should decide between competing claims to belief by choosing that religion whose doctrines and practices are closest to the five common notions of religion discerned by the natural instinct. Commands about what is to be believed and practiced that have supposedly been imparted to people by revelation and transmitted by tradition should only be regarded as credible if they are

consistent with the common notions. Religious persecution, the pretensions of priestcraft, and restricted schemes of salvation are to be rejected. Authentic religion is realized in a virtuous life that conforms to the common notions of religion. This is fundamentally, if sometimes obscurely, recognized by people of right reason everywhere and at all times. According to Herbert *De Religione Laici* is written, not "with a mind … hostile to the best religion," but to make clear what follows from holding that "universal divine providence" is "the highest attribute of God" (*De Religione Laici*, p. 125). In the attached *Appendix ad Sacerdotes* Herbert reaffirms his argument that God, as a universal providence, must have provided all people with the means of salvation and that these are found in the common notions. Nothing more is needed. Additions to them, whether proposed by priests or the Bible, are to be judged unnecessary.

Herbert wrote two works, both published posthumously, in which he attempts to justify his claim that people everywhere and all times recognize the truth and normative status of the common notions of religion. The first of these, *De Religione Gentilium* (On the religion of the Gentiles), first published in 1663 (with an English translation by William Lewis appearing in 1705 entitled *The Ancient Religions of the Gentiles and Causes of Their Errors Consider'd*), is a pioneering work in the English study of other faiths. In it Herbert seeks to show that the evidence about religious belief and practice, which he derives for the most part from classical authors although there are some references to more recent reports, confirms that the common notions of religion are acknowledged everywhere. Evidence that seems to contradict this conclusion is rejected, for the most part on the grounds that it either is due to the corrupting effects of priestcraft or arises from a hermeneutical failure to appreciate symbolic usage. Herbert's sympathetic approach to non-Christian faiths did not blind him, however, to evils present in them. The "sound, most ancient and universal parts of religion" have to be abstracted from a vast heap of "superstitious rubbish" (*De Religione Gentilium*, Lewis translation, p. 292), largely introduced to serve priestly self-interest.

While in *De Religione Gentilium* Herbert concentrates on the first two common notions of religion, he focuses on evidence about the third and fourth in *A Dialogue between A Tutor and His Pupil* (published in 1768 and whose text, at least on the whole, is now generally accepted to be correctly ascribed to Herbert). Here again he denounces the corruptions and perversions of priestcraft while defending his conviction that the "five

catholick articles" have been universally "engraved" in human "souls by the hand of God" (*A Dialogue between a Tutor and His Pupil*, p. 105).

HERBERT AND DEISM

As has been mentioned, Herbert has commonly been dubbed "the father of English deism." When examined, the evidence of his thought and practice provides strong grounds for questioning the justification of this description. Apart from the case of Charles Blount (an eclectic and sometimes plagiarizing author), it is not clear that Herbert's views influenced the thought of those later writers commonly said to be deist (itself a designation whose vagueness renders it more misleading than useful as a description when applied to English writers in the seventeenth and eighteenth centuries).

In his epistemological attempt to find a reasonable way between the dogmatic errors of bigotry and skepticism, Herbert holds that God is a universal providence whose active benevolence influences people's lives, that salvation is available to all through repentance, that prayer is efficacious, that people are to live virtuous lives, and that people have a postmortem personal existence in which they are judged but also may expect to find fulfillment. He does not doubt that divine revelations are given to individuals and, indeed, claims that he only decided to publish *De Veritate* after praying for and receiving a sign from heaven. At the same time, he does limit the significance of appeals to revelation, gives rules for authenticating them, and points out that there is a crucial difference between what is actually revealed on some occasion and what is passed down as a tradition of historical faith, especially when priests claim to be the authorized bearers of the tradition.

As for the Bible, Herbert is aware that different faiths assert the authority of different sacred books and so holds that what is taught by any of them, including the Bible, is to be judged against, and interpreted in terms of, the common notions of religion, since these alone undoubtedly express "the undoubted pronouncements of God, transcribed in the conscience" (*De Religione Laici*, p. 101). Rather than having the dubious distinction of being called "the father of English deism," an ascription deriving from eighteenth-century works by Thomas Halyburton (1674–1712), Philip Skelton (1707–1787), and John Leland (1691–1766), it seems more accurate to regard Herbert of Cherbury as a thinker with liberal convictions who attempts to identify an understanding of theistic belief that avoids the gross errors of religious fanaticism and unbelieving skepticism.

HERDER, JOHANN GOTTFRIED
(1744–1803)

Johann Gottfried Herder, German philosopher and critic, was born in Mohrungen in East Prussia. His father was a schoolteacher and he grew up in humble circumstances. In 1762 he enrolled at the University of Königsberg, where he studied with Kant, who accorded him special privileges due to his unusual intellectual abilities. At this period he also began a lifelong friendship with the irrationalist philosopher Johann Georg Hamann. In 1764 he left Königsberg to take up a schoolteaching position in Riga. There he wrote the programmatic essay *How Philosophy Can Become More Universal and Useful for the Benefit of the People* (1765); published his first major work, on the philosophy of language and literature, the *Fragments on Recent German Literature* (1767–1768); and also an important work in aesthetics, the *Critical Forests* (1769). In 1769 he resigned his position and traveled—first to France, and then to Strasbourg, where he met, and had a powerful impact on, the young Goethe. In 1771 he won a prize from the Berlin Academy for his best-known work in the philosophy of language, the *Treatise on the Origin of Language* (1772). From 1771 to 1776 he served as court preacher to the ruling house in Bückeburg. The most important work from this period is his first major essay on the philosophy of history, *This Too a Philosophy of History for the Formation of Humanity* (1774).

In 1776, partly through Goethe's influence, he was appointed General Superintendant of the Lutheran clergy in Weimar, a post he retained for the rest of his life. During this period he published an important essay in the philosophy of mind, *On the Cognition and Sensation of the Human Soul* (1778); a seminal work about the Old Testament, *On the Spirit of Hebrew Poetry* (1782); his well-known longer work on the philosophy of history, the *Ideas for the Philosophy of History of Humanity* (1784–1791); an influential essay in the philosophy of religion, *God. Some Conversations* (1787); a work largely on political philosophy, written in response to the French Revolution, the *Letters for the Advancement of Humanity* (1793–1797); a series of *Christian Writings* (1794–1798) concerned with the New Testament; and two works written in opposition to Kant's critical philosophy, the *Metacritique* (1799) (against the theoretical philosophy of the *Critique of Pure Reason*) and the *Calligone* (1800) (against the aesthetics of the *Critique of Judgment*).

Already in the 1760s Herder developed certain distinctive general positions in philosophy that would endure for the rest of his career. Most of these were strongly influenced by Kant, but by the *pre*critical Kant of the early and middle 1760s (not the critical Kant, against whom Herder later engaged in the public polemics just mentioned). Among these positions were: an insistence that philosophy should be useful for people in general; a (Pyrrhonist-influenced) skepticism about metaphysics, and about apriorism in philosophy; a form of empiricism; a (Hume-influenced) noncognitivism in ethics; and a principled rejection of ambitious forms of systematicity in philosophy. The early essay *How Philosophy* is especially revealing in this connection.

LANGUAGE

On the Origin is Herder's best-known work in the philosophy of language, but it is in certain respects unrepresentative and inferior in comparison with other works such as the *Fragments* and should not monopolize attention.

On the Origin is primarily concerned with the question whether the origin of language can be explained in purely natural, human terms or (as Johann Peter Süßmilch had recently argued) only in terms of a divine source. Herder argues for the former position and against the latter. His argument is fairly persuasive. But this is unlikely to constitute a modern philosopher's main reason for interest in Herder's ideas about language (deriving its zest, as it does, from a religious background that is no longer ours).

Of far greater modern relevance are the following three theses already embraced by Herder as early as the 1760s, the first two of which founded the philosophy of language as we know it today: (1) Thought is essentially dependent on, and bounded in scope by, language—that is, one can only think if one has a language, and one can only think what one can express linguistically. (2) Meanings or concepts are not to be equated with the sorts of items, in principle autonomous of language, with which much of the philosophical tradition has equated them— for example, the referents involved, Platonic forms, or empiricist ideas. Instead, they consist in *usages of words*. (3) Conceptualization intimately involves (perceptual and affective) sensation. More specifically, sensation is the source and basis of all our concepts, though we are able to achieve nonempirical concepts by means of a sort of metaphorical extension from the empirical ones, so that all of our concepts ultimately depend on sensation in one way or the other.

Herder also develops original theories of interpretation and translation founded on these principles. Fundamental to these theories is also a further insight: (contra such eminent Enlightenment philosopher-historians as Hume and Voltaire) peoples from different historical periods and cultures often vary radically in their concepts, beliefs, sensations, and so forth; and similar, albeit usually less dramatic, variations occur even between individuals within a single period and culture. This situation makes accurate interpretation and translation extremely difficult. In particular, it entails that interpreters and translators constantly need to resist a temptation to erroneously assimilate the concepts and thoughts they interpret or translate to their own. Herder develops his theories of interpretation and translation largely in response to this challenge.

His theory of interpretation (which is scattered through several works) stresses, inter alia, the need to complement a focus on word usages with a focus on historical context, authorial psychology, and literary genre; to "feel one's way into '*sich hineinfühlen in*'" the author's meaning-internal sensations; to adopt a rigorously empirical approach to determining all of these things; to use "divination," in the sense of tentative hypothesis, when advancing beyond the available empirical evidence, for example, for an author's psychology; and to interpret the parts of a work in light of the whole work. This theory exercised a huge influence on subsequent theories of interpretation, in particular Friedrich Daniel Ernst Schleiermacher's (which has often been mistakenly credited with introducing the psychological component of interpretation and "divination," which were in fact Herder's innovations).

Herder's theory of translation (which is mainly developed in the *Fragments*) stresses the need to "bend" word usages in the target language in order to faithfully reproduce the alien word usages and hence meanings in the source language; and the need to reproduce not only the semantic content but also the musical "form" (e.g., the meter) of the source text, because this conveys nuances of the sensations internal to the author's meanings. With these two principles, Herder founded a new paradigm of foreignizing translation that came to dominate German translation theory and practice during and after his lifetime.

MIND

In *On the Cognition* and elsewhere Herder develops an interesting and influential philosophy of mind. The following are its main features.

(1) He argues for an uncompromisingly *naturalistic* and *anti-dualistic* conception of the mind. In particular, he tries to erase the division between the mental and the physical in two specific and suggestive ways: First, he advances a theory that minds and their conditions consist in *forces* (*Kräfte*) that manifest themselves in people's bodily behavior—just as physical nature contains forces that manifest themselves in the behavior of bodies. Second, he undertakes to explain the mind in terms of the phenomenon of *irritation* (*Reiz*), a phenomenon recently identified by Haller, and exemplified by muscle fibers contracting in response to direct physical stimuli and relaxing upon their removal—in other words, a phenomenon that, while basically physiological, also seems to exhibit a transition to mental characteristics.

(2) Herder also argues that the mind is a *unity*, that there is no sharp division between its faculties. This position contradicts theorists from the period such as Sulzer and Kant. It is not entirely original with Herder, having already been central to Rationalism, especially Wolff. But Herder's version of it is original in certain respects, e.g. in rejecting Rationalism's reduction of sensation and voli-

tion to cognition, and in establishing the unity thesis in an empirical rather than an apriorist way.

(3) Herder also argues that linguistic meaning is fundamentally social, so that thought and other aspects of human mental life (as essentially articulated in terms of meanings), and hence also the very self (as essentially dependent on thought and other aspects of human mental life, and as defined in its specific identity by theirs), are so too. Herder's version of this position is again empirically based (unlike later versions of it, e.g., Hegel's).

(4) In tension, though not contradiction, with the preceding position, Herder also holds that even within a single period and culture human minds are as a rule deeply *individual*, deeply different from each other—so that in addition to a generalizing psychology we also need a psychology oriented to individuality. (5) Finally (like predecessors in the Rationalist tradition and Kant), Herder rejects the Cartesian idea of the mind's self-transparency—instead insisting that much of what occurs in the mind is unconscious, so that self-knowledge is often deeply problematic. This whole theory of the mind exercised an enormous influence on successors such as Hegel, Schleiermacher, and Nietzsche.

AESTHETICS

As already noted, Herder's philosophy of language is committed to the two doctrines that thought is essentially dependent on and bounded by language, and that meaning is word-usage. These doctrines seem to stand in tension with the expression of thought and meaning by the nonlinguistic arts, however. In the *Critical Forests* (1769) Herder initially tried to cope with this problem by denying that such arts express thought or meaning, but that is an implausible position, and in later parts of the work he began to develop a much more plausible solution: they do so, but the thoughts and meanings in question depend on a prior linguistic articulation or articulability by the artist (so that the interpretation of "nonlinguistic" art requires the interpretation of language). This was henceforth Herder's normal position.

Another important Herderian contribution to aesthetics is his theory of *genre*. Herder believes, plausibly, that a work of art is always written or made to exemplify a certain genre, and that it is vitally important for an interpreter to identify the work's genre if he is to understand it correctly. Herder's basic conception of genre is that it consists in an overall purpose together with certain rules of composition dictated thereby. Genres are to a great extent socially pregiven, but they vary from society to society, and they always play their role via authorial intention, so that the individual artist is not inexorably locked into them but can and often does modify them.

Herder has two reasons for thinking it vitally important to define a work's genre correctly if one is to understand the work properly (both good reasons): first, because an author intends his work to exemplify a certain genre, there will normally be aspects of the work's meaning that are expressed, not explicitly in any of its parts, but rather through its intended exemplification of the genre; second, correctly identifying the genre is also required for correctly interpreting things that *are* expressed explicitly in the parts of a work. Just as Herder insists on a scrupulously empirical approach to interpretation generally, so he insists on it in connection with determining genres in particular; he sharply rejects apriorism here, including the relative apriorism of generalizing from certain familiar examples. Such relative apriorism is disastrous, in his view, because the superficial appearance of a similar genre shared by different historical periods or cultures, or even by different authors within one period and culture, or even by a single author in one work and in another, usually masks important differences.

Herder sees misguided relative apriorism in the definition of genres in many areas of interpretation. For example, his essay *Shakespeare* (1773) discerns it in the French critics' approach to tragedy, which assumes the universal validity in tragedy of Aristotelian genre-purposes and -rules originally derived exclusively from ancient tragedies, and consequently assumes that these provide an appropriate guide for interpreting Shakespearean tragedy, whose genre-conception is in fact different; and *This Too* discerns it in Johann Joachim Winckelmann's approach to Egyptian sculpture, which erroneously imports genre-purposes and -rules derived from Greek sculpture. Herder also stresses that determining the genre properly is vitally important not only for the correct *interpretation* of an artwork, but also for its correct *evaluation*. For example, the French critics not only make an interpretive mistake when they go to Shakespeare with a genre dogmatically in mind that was not his, but also an evaluative one: because they falsely assume that he must be aspiring to realize the genre-purpose and -rules that Aristotle found in ancient tragedy, they fault him for failing to realize these, while at the same time they overlook the different genre-purpose and -rules that he really does aspire to realize and his success in realizing these.

HISTORY

Herder's philosophy of history appears mainly in two works, *This Too* and the later *Ideas*. These works are famous for their teleological conception of history as the progressive realization of a divine purpose (unspecified in the former work, but specified in the latter as the realization of "humanity" or "reason"). This conception was influential on subsequent thinkers (especially Hegel). However, the philosophical interest of Herder's works today lies elsewhere.

Herder's main achievement here arguably consists in his insight into, and detailed empirical elaboration of, the thesis mentioned earlier that (contra such Enlightenment philosopher-historians as Hume and Voltaire) there exist radical mental differences between historical periods, that people's concepts, beliefs, sensations, and so on differ in deep ways from one period to another. This thesis is already prominent in *On the Change of Taste* (1766). It too exercised an enormous influence on successors (e.g., Hegel, Nietzsche, and Dilthey).

Herder indeed makes the empirical exploration of the realm of mental diversity posited by this thesis the core of the discipline of history. He takes relatively little interest in the supposedly "great" political and military deeds and events of history, focusing instead on this varying "innerness" of history's participants (consequently, for him *psychology* and *interpretation* take center-stage as methods in the discipline). This is a deliberate and self-conscious choice for which he has deep reasons: On the one hand, he is skeptical of the traditional justifications for a history that focuses on the "great" political and military deeds and events of the past, justifications in terms of their being morally edifying (his values rather incline him to find them morally repugnant), revealing an overall meaning in history (despite his own official teleology, he is skeptical about this), or affording efficient causal insights that will enable us to explain the past and predict or control the future (he considers the potential for such insights and benefits severely limited). On the other hand, he sees positive reasons for focusing on the "innerness" of human beings in history: His discovery of radical diversity in human mentality has shown there to be a much larger, less explored, and more intellectually challenging field for investigation here than previous generations of historians had realized.

Also, studying people's minds through their literature, visual art, and so on promises to contribute to our moral self-improvement, since, unlike political-military history, it exposes us to people at their moral best and hence is morally edifying, and it serves cosmopolitan and egalitarian moral ideals by enhancing our sympathies for peoples and indeed for peoples at all social levels, including lower ones. Finally, doing "inner" history is also valuable as an instrument for our *non*moral self-improvement: It advances our self-understanding, because contrasting our own outlook with the outlooks of other peoples enables us to recognize what is universal and invariant in it and what by contrast distinctive and variable, and because in order fully to understand our own outlook we need to identify its origins and how they developed into it (this is Herder's famous and influential "genetic method"); and additionally, by investigating the nonmoral ideals of past ages (e.g., their aesthetic ideals) it enables us to enrich our own nonmoral ideals and hence happiness. This whole position strongly influenced successors, especially Wilhelm Dilthey.

Herder is also impressive for having recognized, and if not solved then at least grappled with, a problem that flows from his picture of history (and intercultural comparison) as an arena of radical variations in human mentality: the threat of *skepticism*. Herder is determined to avoid skepticism. He vacillates between two main strategies for doing so that are inconsistent with each other: His first is to acknowledge the problem in its full force but to respond to it with relativism: especially in *This Too* he argues that (at least where questions of moral, aesthetic, and prudential value are concerned) the different positions taken by different periods and cultures are equally valid, namely for the periods and cultures to which they belong, and that there can be no question of any preferential ranking between them. His second strategy is to try to defuse the problem at its source by arguing that, on closer inspection, there is in fact much more common ground between different periods and cultures than it allows. This strategy plays a central role in the *Ideas*, where in particular "humanity" is presented as a common ethical value. The later *Letters* goes back and forth between these two strategies.

POLITICS

Herder's most developed statement of his political philosophy appears in a late work prompted by the French Revolution of 1789: the *Letters* (including the early draft of 1792). In domestic politics, the mature Herder is a liberal, a republican, a democrat, and an egalitarian. In international politics, he has often been classified as a "nationalist" or (even worse) a "German nationalist," but this is misleading and unjust. On the contrary, his fundamental position is a committed *cosmopolitanism*, an impartial concern for *all* human beings. This is a large

part of the force of his ideal of "humanity." Hence, for example, in the *Letters* he quotes with approval François de Salignad de la Mothe Fénelon's remark, "I love my family more than myself; more than my family my fatherland; more than my fatherland humankind." (2002, p. 389). Moreover, unlike the cosmopolitanism of his teacher Kant, Herder's is genuine: Whereas Kant's is vitiated by a set of empirically ignorant and morally inexcusable prejudices that he harbors—in particular, racism, antisemitism, and misogyny—Herder's is entirely free of these prejudices, which he indeed works tirelessly to combat. Herder does *also* insist on respecting, preserving, and advancing national groupings. But he has good reasons for doing so: (1) The deep diversity of values between nations entails that homogenization is ultimately impracticable, only a fantasy. (2) It also entails that, to the extent that it *is* practicable, it cannot occur voluntarily but only through external coercion. (3) In practice, attempts to achieve it—for example, by European colonialism—are moreover coercive from, and subserve, ulterior motives of domination and exploitation. (4) Furthermore, real national variety is positively valuable, both as affording individuals a vital sense of local belonging and in itself.

Moreover, Herder's insistence on respecting, preserving, and advancing national groupings is unalarming, for the following reasons: (1) For Herder, this is emphatically something that must be done for *all* national groupings *equally* (not just or especially Germany!). (2) The "nation" in question is not racial but linguistic and cultural. (3) Nor does it involve a centralized or militaristic state (Herder advocates the disappearance of such a state). (4) Herder's insistence on respecting national groupings is accompanied by the strongest denunciation of military conflict, colonial exploitation, and all other forms of harm between nations; a demand that nations instead peacefully cooperate and compete in trade and intellectual endeavors for their mutual benefit; and a plea that they should indeed actively work to help each other.

On the one hand, Herder's political philosophy can appear theoretically thin, but this is intentional and arguably a virtue, a salutary minimalism. There is certainly no grand metaphysical theory underpinning it (à la Fichte or Hegel). But that is deliberate, given his skepticism about metaphysics. Nor does he have an elaborate account purporting to justify the moral intuitions at work in it as a sort of theoretical insight (à la Kant or Rawls). But that is again deliberate, given his noncognitivism in ethics. Nor does he call on such tired staples of political theory as the state of nature, the social contract, natural rights, the general will, and utopias for the future.

But again, he has good specific reasons for skepticism about these. On the other hand, he *does* have a "political theory" of another, and arguably more valuable, sort. For one thing, in accordance with his general empiricism, his political philosophy is deeply empirically informed (e.g., he argues that freedom of thought and expression is required for the advancement of truth and artistic creativity by appeal to historical examples, especially classical Athens). For another thing, conformably with his noncognitivism in ethics, he is acutely aware that his political position ultimately depends on moral sentiments—his own and, for its success, other people's as well—and this leads him to engage in moral theorizing of another sort, namely theorizing about how, and by what means, people's moral sentiments should be molded in order to realize his political ideals. *These* two sorts of theorizing *are* deeply developed in Herder's political philosophy.

RELIGION

Religion was a lifelong preoccupation of Herder's. He made important contributions to the theory of biblical interpretation and to the actual interpretation of the Bible (in particular, insisting on and applying the same sort of rigorous secular approach to interpretation that he advocates for profane texts). In addition, he played a major role in reviving a form of Spinozism, a position to which he was already attracted early in his career, but to which he gave fullest expression in his neo-Spinozistic *God. Some Conversations* of 1787. In this work he develops a version of Spinozism that consciously modifies the original in certain respects. He shares with Spinoza the basic thesis of *monism*, and like Spinoza equates the single, all-encompassing principle with God. But whereas Spinoza characterized it as *substance*, Herder characterizes it as *force*, or *primal force*.

Moreover, this modification involves further ones, including these: (1) Whereas Spinoza's theory rejected conceptions of God as a full-blooded person or mind, and a being who not only thinks but also has purposes, Herder's identification of God with force imports, thanks to his general identification of mind with force, a claim that God *is* in fact a mind, and and a being who not only thinksbut also has purposes. (2) Herder believes that Spinoza's original theory contained a residue of objectionable dualism, inherited from Descartes, in its conception of the relation between God's two known attributes, thought and extension (and similarly in its conception of the relation between finite minds and bodies); by contrast, Herder's conception of God as a force (and of finite

minds as likewise forces) overcomes this residual dualism, since forces are of their very nature expressed in extended bodies. Herder's neo-Spinozism, including these modifications, was largely responsible for a great wave of neo-Spinozism that swept German philosophy in this period (embracing Goethe, Schelling, Hegel, Schleiermacher, Hölderlin, Novalis, F. Schlegel, and others).

HERMENEUTICS

While there is already a general sense of the word "hermeneutics" in ancient Greek thought, where it refers to the problems of interpretation and understanding, the first real consolidation of its meaning comes in the medieval world when the peculiar task of interpreting the Bible is theorized. The first systematic form of hermeneutic theory emerged out of the effort to supply methods and rules for biblical commentary. Hermeneutics as a theory of biblical exegesis was subsequently widened to include the concerns of interpreting juridical texts, where

the jurist faces the problem of applying a universal rule to particular cases. Over time, the domain of hermeneutic methodology was broadened to include any text the meaning of which could be disputed. Although a wide range of texts became the objects of hermeneutics, theological and legal texts long remained its preeminent concerns. In its primary concern for textual exegesis, hermeneutics tended to develop methods for interpretation and understanding based upon the rhetorical principles, and thus helped to define the difference between the humanities and modern natural science with its own emphasis on a method linked with mathematics.

The hermeneutic tradition underwent significant expansion and modification in the nineteenth century when first Friedrich Schleiermacher and Friedrich von Schlegel, and then Wilhelm Dilthey, expanded the scope of hermeneutical concerns while probing the character of the foundations of hermeneutic practices. Following in the wake of Immanuel Kant's critical philosophy, wherein both the conditions that render experience possible and the ineradicable limits of knowledge are exposed, the Romantics argued that all understanding—not simply the understanding of texts—is always already interpretive. In Romanticism, hermeneutics thus begins to take on the contours of the new meaning that it acquired in the twentieth century: it is no longer simply a matter of a strategy directed to the interpretation of a special domain of texts, rather it is now understood to be concerned with the character of any form of understanding that may emerge from human experience. In addition to this is the claim that all understanding takes place within language, making language thus one of the chief concerns of any hermeneutic theory. The plurality of languages, their history, and the problem of translation replace a concern with the word of God and the word of law dominating earlier conceptions of hermeneutics. Dilthey, for his part, elevated hermeneutics into a methodology for the entirety of the human sciences by insisting that the understanding of the historical life expressions, which encompass human experiencing, requires a methodology distinct from that of natural science. Dilthey maintained that whereas the natural sciences explain nature, the task of the human sciences is to understand historical life.

By the end of the nineteenth century, "hermeneutics" had ceased to designate simply a methodology or doctrine concerned with decoding the meaning and truth claims of texts. Instead, it had become the name for a broader methodology and a philosophical approach to experience that was sensitive to the limits of language and history. Hermeneutics at this stage of its development came to be especially attentive to those experiences directly challenging the possibility of understanding; for example, the translation of foreign languages, the comprehension of foreign cultures, and, in particular, the interpretation of other historical periods.

Martin Heidegger took the decisive steps in formulating the contemporary shape of philosophical hermeneutics as it is understood today, achieving this by gathering together and radicalizing the concerns dominating its prehistory while adding a new dimension whereby hermeneutics became the name for a full-fledged ontology. Heidegger does this under the rubric of a "hermeneutics of facticity." That notion, which Heidegger worked out in his lecture courses during the 1920s (above all in his courses dealing with Aristotle), is consolidated in his 1927 magnum opus, *Being and Time*. There Heidegger argues that understanding is not simply a cognitive task, but that it names one of the basic ways (existentialia) of being-in-the world. In short, understanding is now taken to be concerned with an experiencing that subtends methodological procedure. The form of such lived experience proper to human beings, for whom being is always a question and always defined by death and the ineluctability of nonbeing, is what Heidegger refers to as "factical life."

When Heidegger speaks of the hermeneutics of factical life it is a way of acknowledging both that the concerns of hermeneutics—language, history, and finitude—and the manner in which it takes truth to be a matter of interpretation rather than objectivity are especially well suited for the attempt to theorize factical life. The phenomenology of lived experience is now said to have the character of a hermeneutics. This means that lived experience is taken to be the working out of the factical conditions upon which any understanding whatsoever can be founded. The analysis of existence thus takes the form of a hermeneutics that traces the action of these conditions of understanding. The most important aspect of this new development is that now even self-understanding comes to be presented as a hermeneutic task. Hermeneutics is thus the manner in which existence discloses the truth of a world that is lived and it is the form by which self-understanding is achieved.

After *Being and Time*, Heidegger uses the word "hermeneutics" less frequently. It will be left to one of Heidegger's students from those lecture courses of the 1920s, Hans-Georg Gadamer, to systematically develop the notion of hermeneutics as a philosophical standpoint. Gadamer, whose name is most closely associated with the idea of contemporary philosophical hermeneutics, does

this most extensively in his magnum opus, *Truth and Method* (1982).

The title *Truth and Method* alludes to the early sense of hermeneutics, where it was understood as a method for getting at the truth of texts. But the argument of that book entails both a fundamental rethinking of the notion of truth and a powerful critique of the idea that a method can ever yield it. In *Truth and Method*, Gadamer identifies hermeneutics with the insight that the concept of method is inappropriate for the task of understanding in the domain of the human sciences. Other guideposts take the place of method in the effort to unfold a truth that is understood as belonging to the realm of a historical event rather than objective fact: Language, tradition, questioning, and conversation become the leading concerns of Gadamer's hermeneutics.

Gadamer creatively draws upon several sources for his formulation of a systematic philosophical hermeneutics. In addition to those figures already mentioned, Aristotle's notion of *phronesis* (prudence or practical wisdom) in his *Ethics*, the logic of question and answer as it is found in the Platonic dialogues, Kant's understanding of judgment as well as the relation of art and truth in his Third Critique, and G. W. F. Hegel's notion of the formation of traditions all play pivotal roles in Gadamer's hermeneutics. Without any significant departure from Heidegger's way of opening up the notion of philosophical hermeneutics, Gadamer places a greater emphasis on the relevance of three themes for hermeneutics: the role of *art* in the disclosure of truth, the force of the prejudices of *tradition* in any understanding, and the importance of the *question* in the opening of the restrictions of such prejudices and in the liberation of understanding to the new and the foreign.

Gadamer understands hermeneutics not as a method, but more as a sort of dialogue or conversation in which understanding increases insofar as one becomes aware of the formative roles of history and language in one's self-understanding. In such a genuine dialogue with others, one's self-understanding is challenged to reflect upon and reach beyond the limits that are inscribed in its own roots in tradition and language. With Gadamer, hermeneutics comes to refer to a philosophical sensibility that has a deep commitment to exposing the ways in which all forms of understanding, rooted in self-understanding, is finite and so remains always at best a task and an ideal.

One other key figure in the field of contemporary hermeneutics is Paul Ricoeur. Ricoeur's work has been marked both by its extension of hermeneutic concerns to include psychoanalysis, literary criticism, and linguistic analysis, as well as by the details of his treatment of issues such as problems in semantics, metaphor, narrative, and temporal structures. In his earlier work Ricoeur attempted to reintegrate the role of explanation into hermeneutics theory by relying on the insights from linguistic structuralism, while in his later writings Ricoeur was less prone to pursue methodological questions. The originality of Ricoeur's hermeneutics has taken shape primarily as a matter of practices and studies of special themes, rather than as a theory of hermeneutics proper. What one sees most in those studies is how the workings of language and time have come to dominate his sense of the task of hermeneutic reflection.

HERMETICISM

"Hermeticism" is the outlook associated with the Hermetic writings, a literature in Greek that developed in the early centuries after Christ under the name "Hermes Trismegistus." Much of it is concerned with astrology, alchemy, and other occult sciences, but there is also a philosophical Hermetic literature. The treatise known as the *Asclepius* and the collection of treatises grouped as the *Corpus Hermeticum* are the most important of the philosophical Hermetica, though some other fragments are preserved in the anthology of Stobaeus. These writings are probably to be dated between 100 and 300 CE. They are an amalgam of Greek philosophy, particularly Platonic, with other elements from the heterogeneous late antique culture. The *Pimander*, the first treatise in the *Corpus Hermeticum*, has obvious affinities with Genesis, suggesting an influence of Hellenistic Judaism. There may also be Persian influences, and the possibility of some contact with Christianity cannot be excluded. The ascription of their authorship to "Hermes Trismegistus," supposed to be an Egyptian priest, encouraged the belief that these writings transmitted ancient Egyptian wisdom; the *Asclepius* in particular has a strong pseudo-Egyptian coloring.

There is much difference of opinion among scholars as to the various elements that make up the Hermetica, which are the work of an unknown number of unknown authors; even individual treatises may often be a fusion of fragments. They have a certain unity of tone, however, since they all exhibit a similar type of philosophical-religious approach to the cosmos, involving regenerative experiences and outbursts of religious ecstasy. It has been suggested that they may be the literature of a gnostic sect. The philosophical Hermetica, with their lofty aspirations, cannot be altogether isolated from the magical and occult type of literature which also goes under the name of "Hermes Trismegistus," for the experiences of the Hermeticist, as described in the philosophical-religious treatises, take place within an astrological framework and imply, particularly in the *Asclepius*, a religious use of magic.

HISTORY

Although much is in debate concerning the Hermetica themselves, we are on firmer ground when we come to the history of their legend. In the fourth century Lactantius taught that these writings were the work of an Egyptian seer who lived not long after the time of Moses, whose account of creation he confirmed and, indeed, improved and whose mentions of a "son of God" were prophetic of Christianity and to be compared with passages in the Gospel according to St. John. Augustine also believed in the extreme antiquity of "Hermes Trismegistus," but he disapproved of the magical cult described in the *Asclepius*. Nevertheless, there was ample authority in Christian writers for an attitude of respect for Hermes. Lactantius places him with the sibyls as a Gentile prophet of Christianity. The myth of "Hermes Trismegistus," the Egyptian sage who was the actual author of all the writings assigned to him and who lived long before the Incarnation, which he prophetically foresaw, was to give great authority to the Hermetica.

The *Asclepius* was known in the Middle Ages in the Latin translation wrongly attributed to Apuleius of Madaura; certain pseudo-Hermetic writings were also known. The collection of treatises grouped as the *Corpus Hermeticum* seems to have been already known in this form to Psellus in the eleventh century but did not reach the West until the Renaissance.

INFLUENCE ON RENAISSANCE

The Hermetica made an impact on the Renaissance the importance of which has begun to be realized only in recent years. About 1460 a manuscript containing an incomplete Greek text of the *Corpus Hermeticum* was brought to Florence. Cosimo de' Medici ordered Marsilio Ficino to translate this at once into Latin, before beginning his translation of the works of Plato. This illustrates the Renaissance attitude, which treated the Hermetica as texts much more ancient than the Platonic writings and as the "Egyptian wisdom" believed to be one of the founts of *prisca theologia* that descended in an unbroken line to Plato and the Neoplatonists. When Ficino found scraps of Platonic philosophy in the late antique Hermetica, he assumed that he was dealing with the ancient Egyptian source of Greek wisdom. Like the interpretation of "Hermes Trismegistus" as a Gentile prophet, in which Ficino also firmly believed, this view of the Hermetic writings as a source of Plato and the Platonists depended on the misdating of those writings. To this most influential error is due the fact that there is a Hermetic core to Renaissance Neoplatonism. Ficino's work on astral magic is based on the magical passages in the *Asclepius*. Giovanni Pico della Mirandola opened his *Oration on the Dignity of Man* with a quotation from the *Asclepius*.

Throughout the sixteenth century the Hermetic writings were eagerly read in the many editions of Ficino's translation, and new editions and commentaries were published by Jacques Lefèvre d'Étaples, Symphorien

Champier, F. Foix de Candale, Francesco Patrizi, and others. The first edition of the Greek text of the *Corpus Hermeticum* appeared in 1554.

The influence of this intensive study of the Hermetica can be traced throughout the Renaissance. It penetrated some types of Renaissance theology. Christian Hermeticists who wished to avoid the magic excluded the magical passages in the *Asclepius* from their canon. On the other hand, for Renaissance magicians and philosophers the animist and magical view of nature that they extracted from the Hermetic writings was the most attractive feature. A striking instance of Hermetic influence on a Renaissance philosopher is Giordano Bruno, who rejected the Christian interpretation of the Hermetica and regarded Hermeticism as a pure Egyptian religion and philosophy that he made the basis of his animist interpretation of nature.

In 1614 the great Greek scholar Isaac Casaubon dated the Hermetica as written in post-Christian times, thus shattering the myth of their ancient Egyptian authorship on which Renaissance Hermeticism had rested. With the rise of seventeenth-century thought the influence of Hermeticism receded, though there were many survivals of the Renaissance attitudes to the Hermetic writings. The part played in the immediately premodern period by Renaissance Hermeticism in the directing religious attention toward the cosmos and toward operating with cosmic powers has yet to be assessed.

HERMETICISM [ADDENDUM]

Hermeticism also flourished in the Jewish and Islamic world. Although only a fragment of the Greek *Corpus Hermeticum* has been discovered in Arabic, there are

numerous texts in Arabic and Hebrew that are attributed to the Greek god Hermes, purporting to provide ancient wisdom. Hermes was identified respectively with Idris; a mysterious prophet mentioned in the Qur'an) and Enoch (the grandfather of Noah) in the Jewish Bible. The routes by which this Hermes arrived in Arabic texts appear to be as much via Persia as directly from Greek sources, and Haran (ancient Carrhae) in northern Mesopotamia, as a cultural melting point and the home of the Sabaeans, who worshipped the planets, appears to have played a central role. Several interrelated cosmological texts that give instructions on the invocation of planetary spirits to empower talismans purport to be the wisdom of Hermes as conveyed by Aristotle, while the earliest doctrines and practices in alchemy, shoulder-blade divination, and several aspects of astrology (e.g., lunar mansions, Egyptian decans, and astrological lots) are attributed to him, sometimes in the company of Apollonius of Tyana (first century CE), and the legendary Agathodaimon, Asclepius, and Toz Graecus. These technical works were translated into Latin, Greek, and Hebrew and formed the basis of medieval Hermeticism.

HERSCHEL, JOHN
(1792–1871)

John Herschel, the son of the astronomer William Herschel, worked in mathematics, chemistry, optics, and solid-state physics; pioneered in photography and instigated the regular use of photography in astronomy; invented blueprints; initiated simultaneous worldwide meteorological observations; introduced the theory of isostasy in geology; and was the world's leading observer-theoretician of double stars and nebulae. His *Treatise on Astronomy* (1833), continued as *Outlines of Astronomy* (1849), although deliberately common sense in treatment, was authoritative in content even for professionals until the 1860s. He was England's most famous scientist from 1830 to about 1860.

Herschel's *Preliminary Discourse on the Study of Natural Philosophy* (1831) was a starting point for his philosophic contemporaries, the more radical (post-Kantian) William Whewell and the more conservative (Humean) J. S. Mill; in fact, many errors were deleted from Mill's *Logic* in its second edition because Herschel supplied detailed criticisms of the scientific passages in the first edition. Herschel's full position was expressed later, in papers collected as *Essays from the Edinburgh and Quarterly Reviews* (1857) and *Familiar Lectures on Scientific Subjects* (1867) and in remarks in his scientific books. His best-known philosophic followers were William Stanley Jevons and James Clerk Maxwell.

In theory of knowledge, Herschel's basic concept was the law of continuity, which for him defined the rationality of a system. In his version of the law, he asserted that scientists *observe* not continuous phenomena (not even simple extension), but "dotted outlines which the mind … fills up." Thus "*we assume continuity where we find none.*" Herschel refused any philosophic solution of this disparity between observation and thought and accepted the harmony of mind with external nature as an ultimate fact, preestablished by God.

Next, he was a "decided disciple of old Boscovich"; matter is "a collection of mathematical points—mere *localization* of *forces*"; and therefore it is foolish to picture kinetic-molecular processes as "the 'clashing together' of 'atoms'" or as the "knocking about of billiard balls." Force as hitherto understood, he pointed out, was always associated with matter, that is, inertia; but in electricity and in the "quasi-undulatory propagation of qualities" we see noninertial agents. So the kind of force presented in theories of mechanics is not primary. More basic physical powers exist, he asserted, but are not yet (1840) understood.

Science should uncover not only laws (formal relations among parameters) but also causes. Causation is not Humean succession but (as in the Scottish common-sense school) is known from our consciousness of effort when we exert force. Causes are *not* will, however, but the physical intermediaries between will and muscular contraction. These may also exist in connection with inanimate bodies.

This general position is well beyond Roger Joseph Boscovich and Thomas Reid but is not idealistic. It points toward the theory of the conservation of energy, which, however, Herschel did not approve in its 1860 form. He felt that "potential energy" was not a physical reality, but a mere mathematical expression introduced into the theory "*to save the truth of its verbal enunciation.*"

In methodology Herschel was interested in discovery, not in a justification of the process of induction. (Mill's "methods" were derived directly from Herschel's *Discourse.*) Thus one Herschelian method was "at once to form a bold hypothesis," that is, to guess. Herschel emphasized the central importance of rigorous deduction to confirm hypotheses; it is this which makes science not a craft. One should at all costs avoid specialties of investigation (e.g., chemistry vs. physics), for no actual phenomenon is so divided. Herschel thought that contingency is the most obvious aspect of the universe. Science must grapple with the apparently arbitrary complexities of the actual world, such as sunspot changes, the shapes of nebulae, the variations in terrestrial magnetism, trade winds, and so on, and try to reduce them to scientific laws. It should not content itself with simple general laws concerning force and matter considered in abstraction.

Herschel's contemporary influence was perhaps greatest among working scientists. He gave a reasoned basis for the shift from a purely abstract treatment of physical parameters (as in Joseph-Louis Lagrange) to a belief in the actual existence of the entities used in scientific theories (e.g., the fields of force of his friend Michael Faraday and his admirer Maxwell, which were felt to be actually present in space, not merely mathematical symbols). He upheld the importance of the scientist's feeling for the reality of his constructs. Sheltered by his great authority, scientists pursued their intuitional ideas without worrying about attacks from Humean or other philosophers, or from Evangelical preachers. Herschel, for example, authoritatively established the naturalistic origin of species as a proper subject of investigation for Victorian Englishmen. Young scientists of the period, such as Charles Darwin and Thomas Andrews, admired him extravagantly.

Bibliography

There are no modern editions of Herschel's works. Recent partial treatments are C. J. Ducasse, "John Herschel's Philosophy of Science," in the American Council of Learned Societies collection, *Studies in the History of Culture* (Menasha, WI, 1942), reprinted in *Theories of Scientific Method,* edited by E. H. Madden (Seattle: University of Washington Press, 1960); W. F. Cannon, "The Impact of Uniformitarianism," *Proceedings of the American Philosophical Society* 105 (1961): 301–314; and W. F. Cannon, "John Herschel and the Idea of Science," *Journal of the History of Ideas* 22 (1961): 215–239, containing an error on "will" that has been corrected in the present entry.

Walter F. Cannon (1967)

HERTZ, HEINRICH RUDOLF
(1857–1894)

The German physicist and philosopher of science Heinrich Rudolf Hertz was born in Hamburg. Early in his student days he showed an interest in engineering but soon took up the study of physics, to which he quickly made important contributions, mainly in the study of magnetism and electricity. He studied in Berlin under Hermann von Helmholtz and Gustav Kirchhoff and inherited their interest in the philosophy of science. In 1883 he began teaching in Kiel, where he worked on James Clerk Maxwell's electromagnetic theory. He became professor of physics at the technological institute at Karlsruhe in 1885, where he produced his most celebrated work on electromagnetic waves. In 1889 he was appointed professor of physics to succeed Clausius at Bonn. He was in failing health, however, and he died five years later.

Hertz's most important book for philosophy is his *Principles of Mechanics,* written during his last illness and published in 1894. This is an attempt to rewrite classical mechanics in such a way as to exhibit its systematic nature, increasing its rigor, reducing its assumptions to a minimum, and keeping it as empirical and nonmetaphysical as possible. His aims were firmly in the spirit of his teachers and of Ernst Mach, who expressed his admiration for Hertz's work. The preface to the *Principles of Mechanics* is a classic in the philosophy of science and deserves to be better known.

Hertz was prepared to admit that various logical categories of statement figure necessarily in the sciences; he even thought, unfashionably, that metaphysical statements could be of considerable value to the scientist. But, he held, it is of the utmost importance for anyone who

would understand the methods of the sciences, and for the scientist himself, to distinguish clearly the different categories of statement and not to suppose that, for example, a nonempirical statement is empirical. In his reconstruction of mechanics he wanted especially to ensure, among other things, that such distinctions are made.

Rather in the manner of Immanuel Kant, who greatly influenced the philosopher-scientists of this period, he begins by dividing mechanics into two parts, one depending upon the formal necessities of our thought and the other depending upon our experience. Moreover, as Jules Henri Poincaré was to argue later, certain features of mechanics depend upon our arbitrary choice. The structure of scientific theories in general exhibits these features, and understanding this structure involves disentangling them.

Further, very much in the modern manner, Hertz holds that a scientific theory is a deductive system that, according to whether it is correct or incorrect, corresponds or fails to correspond to the observable world. *The Principles of Mechanics* shows how one such theory can be set out as an axiom system in which we may deduce conclusions that are testable against reports of our observations.

However, Hertz's aim in this was not merely theoretical and academic, for he seems to have thought that the progress of science might be impeded if scientists do not fully and clearly understand the logic of the concepts they use. He holds, and regards it as generally held by scientists, that the laws of mechanics are fundamental in the solution of all problems in physics; yet there are concepts used in mechanics that are by no means clear and upon which physicists do not even agree. The outstanding example of such a concept—and here Hertz agrees with Mach—is "force." In fact, Hertz fiercely criticizes physicists for relying on this concept without having any very clear notion of what it entails.

The way to understand the concept of force is to see how it functions in the theories in which it is used. But when we look at classical mechanics, we find that force is not used in the way physicists think it is; the usual method of expounding mechanics obscures this and, in general, obscures the very nature of the concept of force. The understanding of scientific concepts is inextricably bound up with the understanding of the theories in which they figure.

Hertz's approach to mechanics is largely determined by his views about explanation in general; mechanics explains the motions of bodies by bringing them under laws, but these laws cannot be in terms only of what is directly observable. Hertz seemingly holds that it has been found that this is so, although he also shows signs of thinking that it must be so—that it is a necessity of explanation. At any rate, he points to many of the explanations accepted in the sciences and shows that they rely upon concealed mechanisms or, as he says, "'confederates' concealed beyond observed masses and motions."

REPRESENTATIONS OF MECHANICS

There are two existing interpretations of mechanics that rely upon force and energy, respectively, as the nonempirical concepts to be used in explanation. Here a further presupposition of Hertz's enters: We will understand our explanations best if all the concepts we use are as similar as possible to concepts of what we experience, that is, to empirical concepts. Force and energy are quite unlike anything we experience, so Hertz seeks to replace them, in his rewriting of mechanics, by motion and mass, which are exactly like observed motion and mass except that they are unobserved (concealed). Or, rather, force and energy are given minor and subordinate roles in his mechanics; all the important roles go to mass and motion. This, he believed, fitted in with the physical theorizing of his time. For example, Maxwell gave an account of electromagnetic forces in terms of concealed masses and motions.

Although force and energy are not empirical concepts, space, time, and mass are. Hertz therefore reconstructs mechanics using only space, time, and mass as primitive concepts. This means that they are not defined in any verbal or symbolic way, although we understand them through our experience of observable masses in motion. Force and energy must not figure in mechanics—as they have tended to do—as basic terms, *as if* they were empirical concepts. They may be introduced at some later stage, but only by defining them—ultimately, at least—in terms of the primitives.

Hertz outlines the two existing "representations" or "images" of mechanics, criticizes them, and then develops his own alternative, which forms the bulk of *The Principles of Mechanics.* He puts forward, as tools of criticism for theories or their representations, three conditions that they must fulfill. They must be *logically permissible* (sometimes abbreviated to *permissible*), that is, consistent with the laws of our thought; they must be *correct,* that is, their structure must not conflict with the structure of observable things; they must be *appropriate,* that is, they must be simple in the sense of containing the fewest pos-

sible superfluous or empty relations. Appropriateness is merely relative: we should, where there are alternatives, accept the more appropriate rather than the less appropriate. These requirements concern the three features of theories mentioned above—one depending upon the nature of our minds, one depending upon our external experiences, and one depending upon our conventional systems of notation.

The first representation Hertz considers is the one then current in most textbooks, taking space, time, force, and mass as its fundamental concepts. It is, among other things, too much influenced by the historical development of mechanics, the order of which may have little to do with its logical structure. It takes force as an independent concept and regards force as the cause of motion. However, the weakness of this representation is that the idea of force is not clear. This affects both the permissibility and the appropriateness of this version: Because our notion of force is vague, it cannot help us to reason precisely, and because we associate with it certain nonessential anthropomorphic ideas, it imports superfluous elements into mechanics. This latter point also seems, for Hertz, to include the idea that too much which is not directly perceptible is thus brought into mechanics. He looks askance at forces that "cancel out in the calculations" as robbing an explanation of its simplicity, or what Mach calls its economy. Apart from this, the first representation satisfies the condition of correctness; if we are merely considering alternative ways of expressing mechanics, we should indeed expect something to be satisfactory in each. What is satisfactory here is that the structure of this way corresponds to, or at least does not conflict with, the structure of observable phenomena.

The second representation is one that was favored in Hertz's day by the more advanced physicists, including Helmholtz. This representation attempts to sidestep the difficulties involved in the concept of force by taking as fundamental the concepts of space, time, mass, and energy. It is then possible to introduce force by definition and merely as an aid to calculation. The advantage of energy over force, it was claimed, was that energy depends upon direct experience because it depends only upon positions or velocities, both of which are directly experienced. This ensures that the second representation is more appropriate than the first. If we consider only motions that occur in nature, Hertz argues, it lacks nothing in correctness. Its weakness lies in its permissibility, as is seen when we try to define energy, as it is here used, in terms of "simple, direct experiences." A substantial view of energy tended to be associated with this representa-

tion, but it is difficult to treat potential energy as a substance, especially when, as is sometimes necessary, we must ascribe negative potential energy to a system or must regard the potential energy of a finite quantity of matter as infinite. This version is superior to the first, but it still contains serious difficulties.

HERTZ'S REPRESENTATION

Since force and energy, respectively, appear to be responsible for the problems arising over these two representations. Hertz attempts to do without them, at least as primitive concepts for his representation. He begins with space, time, and mass. That is, he begins with kinematics, the abstract study of motion, and sets out to derive the whole of mechanics from it without using force and energy except as devices for calculation. Kirchhoff had already asserted that three independent concepts are necessary and sufficient for mechanics.

Time, space, and mass are primitive terms for Hertz's system, but they are not mere abstract counters like the uninterpreted symbols of the logicians. They are understood through experience, and the particular experiences that are to count for the purposes of mechanics can be specified. Moreover, these concepts are, as we also discover in experience, permanently related in various ways. Hertz puts forward a "Fundamental Law" that has similarities to the law of inertia and that summarizes the connection between the three basic concepts taken together: "Every natural motion of an independent material system consists herein, that the system follows with uniform velocity one of its straightest paths." This law, together with the concepts of space, time, and mass and the hypothesis of concealed masses, allows us, by purely deductive reasoning, to derive the whole of mechanics and so to explain mechanical phenomena.

Other concepts, such as force and energy, are introduced into the system later by definition and so are regarded merely as aids to deduction. They are defined ultimately in terms of the primitive concepts.

The Principles of Mechanics is divided into two parts to emphasize the independence of the mathematical form and the physical content of mechanics. The equation "2 horses + 2 horses = 4 horses" has a mathematical form, expressed by "2 + 2 = 4," that is independent of its application to horses. In the same way, mechanics as a whole can be regarded as having these two aspects. Book I of the *Principles* draws out the implications of the fundamental ideas: space, time, and mass. At this stage these concepts are intuitive and independent of experience except insofar as all our intuitions and modes of reasoning depend

upon experience. Book II contains the application of these concepts to experience through the Fundamental Law and the derivation of testable assertions about observable phenomena. The apparently equivocal nature of Hertz's basic concepts can best be understood in relation to Kantian philosophy: Our intuitions, peculiarly adapted to fit the general form of what we experience, are analogous to colored spectacles which determine our seeing the world as colored. Nevertheless, the details of our pictures of the world have the nature of hypotheses and are open to empirical testing.

Hertz's account of mechanics is important from the standpoint of the philosophy of science because it represents an early attempt to see a scientific theory as a system and to bring out its logical structure accordingly. It was influential in connection with the conventionalism later championed by Poincaré and attempted to do justice to, on the one hand, the undoubted empirical nature of science and, on the other, the apparent claims of scientific laws to embody natural necessities. Hertz's view that mechanics is the foundation of all physical explanation was the most backward-looking element in his work and was strangely belied by both his scientific work, which was largely influential in breaking down that view, and his work in the philosophy of science, which contained the seeds of a far more flexible view of explanation.

HERVAEUS NATALIS
(c. 1250–1323)

Hervaeus Natalis, or Harvey Nedellec (c. 1250–1323) was one of the first followers of Thomas Aquinas, but also an original thinker, especially in the areas of intentionality and the mental word. Hervaeus was born in Brittany in the mid-thirteenth century. He entered the Dominicans in 1276 and studied at the University of Paris, where he

commented on the *Sentences* of Peter Lombard, later received the degree of Master of Theology, and served as regent master in theology from 1307 to 1309. He was elected Provincial of France in 1309 and became Master General of the Dominicans in 1318. In the years following the condemnation by Étienne Tempier, the bishop of Paris, of 219 propositions—many of which touched upon the teaching of Thomas Aquinas—Hervaeus defended Aquinas's theological method in his *Defensio doctrinae fratris Thomae* and his theory of knowledge in his *Quodlibeta*. He actively promoted the canonization of Aquinas and died at Narbonne in 1323 on his way to it. Due largely to the work of Hervaeus, Aquinas became the official doctor of the Dominican Order, despite the conservative Augustinian atmosphere in the period after 1277.

Although he strongly promoted Aquinas's thought, Hervaeus did not follow Thomas on some of his most distinctive teachings, such as the real distinction between essence and existence in creatures and the five ways of proving the existence of God. Of the latter, Hervaeus retains only the ways of efficient causality and of degrees of perfection. It is noteworthy that in the conservative theological atmosphere following 1277 Hervaeus develops strictly philosophical proofs for the existence of God in his *De cognitione primi principii*. In his conflicts with Durandus of Saint Pourçain, a Dominican who leaned toward a more Augustinian position, Hervaeus upheld Thomism, but a Thomism that manifests the influence of Duns Scotus's thought. Hervaeus's still unpublished *Tractatus de secundis intentionibus* is the first treatise in the Middle Ages devoted to the topic of intentionality.

HERZEN, ALEKSANDR IVANOVICH
(1812–1870)

Alexander Ivanovich Herzen, the Russian editor, essayist, and social philosopher, was the illegitimate son of I. A. Iakovlev. Herzen was graduated from the faculty of physics and mathematics of Moscow University in 1834 and was promptly exiled to the provinces for radicalism (1835–1840, 1841–1843). He emigrated from Russia in 1847 and spent the remainder of his life in western Europe. In London he founded the first "free Russian journal," *Kolokol* (The Bell), in 1852. There, during the 1850s he published, in eight parts, his *Byloe i dumy* (*My Past and Thoughts*), a brilliant personal memoir and history of nineteenth-century ideas.

Herzen's first essay in philosophy, "Diletantizm v Nauke" (Dilettantism in science), was published as a series of four articles in *Otechestvennye zapiski* (Notes of the fatherland) in 1843. Herzen used the term *science* (*nauka*) in the broad sense of G. W. F. Hegel's *Wissenschaft* and focused his critique on four kinds of scientific dilettantes: naive dabblers; romanticizers of the past without interest in the problems of today; pedantic specialists who in their ivory towers write erudite books about erudite books; and the "Buddhists of science," or right Hegelians, who offer a purely speculative account of historical reality and make no effort to change it. Herzen opposed to all four kinds of dilettantism a "committed" philosophy of the act (*filosofiia dela*) that seeks to reconcile abstract speculation with vital human needs. (Later, Herzen spoke of Hegel's dialectic as an "algebra of revolution.")

In "Pis'ma ob izuchenii prirody" (Letters on the study of nature), published as a series of eight articles in

Otechestvennye Zapiski in 1845–1846, Herzen attempted to reconcile the opposed interests of natural science, which tends toward empiricism, and philosophy, which tends toward idealism. But empiricism and idealism are Hegelian "moments," incomplete and one-sided dialectical phases, each requiring the other. In the end Herzen stressed the rights of empiricism as closer than those of idealism to the real needs of living individuals.

In works written after 1847 Herzen outlined his defense of the existing individual against the collective encroachments of society, history, and progress. Nonhuman individuals are constantly sacrificed to supraindividual ends, as in the slow formation of a coral reef from the skeletons of millions of tiny sea creatures. "The polyps die," Herzen wrote, "not suspecting that they have served the progress of the reef" (*Byloe i dumy*, in *Sobranie sochinenii* [Collected works], Vol. X, p. 123). But men are not polyps; human individuals should not be sacrificed to build any coral reef of historical progress, however grandiose.

Herzen developed, in *S togo berega* (*From the Other Shore*; Paris, 1850) and later works, a philosophy of contingency, emphasizing the "tousled improvisation" of history. Historical development does not exhibit the rational, purposive structure that Hegelians see in it; therefore, men are free to impose their own purposes on its "whirlwind of chances." "Outside us everything changes, everything vacillates. We are standing on the edge of a precipice and we see it crumbling. . . . We shall find no haven but in ourselves, in the consciousness of our unlimited freedom, of our autocratic independence" (*From the Other Shore*, p. 128).

Herzen stressed the lived sense of freedom and attempted to reconcile this psychological fact with a deterministic theory. In a letter (written in French in 1868) to his son, who had defended a fashionable physiological reductionism, he called the idea of freedom a "phenomenological necessity," adding, "the conscious self cannot move or act without positing itself as free, that is to say as to having within certain limits the power to do or not to do. Without this belief, individuality dissolves and is lost" (*Sobranie sochinenii*, Vol. XX, pt. 1, p. 436).

Anticipating Fëdor Dostoevsky's "Legend of the Grand Inquisitor" (1880), Herzen in 1847 stated the theme of escape from freedom and the burden of moral responsibility. The love of moral freedom, in Herzen's words, is "purely Platonic and ideal," whereas the love of intellectual authority is a solid *mariage de raison* in which "dreams and poetry are sacrificed for domestic comfort [and] order" (ibid., Vol. II, p. 90).

Herzen formulated not only an extreme moral relativism—"What was admirable behavior yesterday may be abominable today" (*From the Other Shore*, p. 141)—but also an embryonic emotivism in ethics. Moral judgments are expressions of taste or preference on the model of "I like lobster"; there is no point in my arguing with someone who does not like lobster. According to Herzen, "there are no general rules, but [only] an improvisation of conduct, … a tact, an aesthetics of human actions" (*Sobranie sochinenii*, Vol. XXIX, pt. 1, p. 148). On this, as on other points, Herzen anticipated Friedrich Nietzsche—who may have read some of Herzen's works in translation.

HESS, MOSES
(1812–1877)

Moses Hess, the socialist journalist and organizer and intellectual precursor of Zionism, often called the father of German socialism, was born in Bonn of Jewish parents. A left-Hegelian, he was a mentor and coworker of Friedrich Engels, Karl Marx, and Ferdinand Lassalle. He led radical workers' groups in Paris and Belgium, edited the famous *Rheinische Zeitung,* and was the leader of the "true," or "philosophical," German socialists of the 1840s. Later he became Lassalle's chief organizer in the

Rhineland and a foreign correspondent for European and American newspapers. His published books and countless essays include works on the philosophy of history and on socialism, a famous call for a Jewish state, and a comprehensive theory of the laws of science, society, and socialism.

Hess used the principles of Benedict de Spinoza, G. W. F. Hegel, and Johann Gottlieb Fichte to demonstrate the inevitability and justice of a society lacking distinctions of class and wealth, without "contradictions" between private passion and public law, and without external compulsion. Hess took this to be both the social expression of pantheism and the inevitable result of the dialectical development of the self-realization of the Absolute Spirit in history. This was the theme of his early work, *Die Heilige Geschichte der Menschheit* (Stuttgart, 1837). Later, under the influence of Ludwig Feuerbach, Hess rejected Hegelian transcendentalism. He then created a "philosophy of the deed," based on a belief in the human spirit as the unconditioned ultimate reality. He stressed the creative power of man and man's historical "alienation" of that power to various mythical transcendent powers—God, the state, fate, or, in Hess's day, the laws of history and economics. Hess insisted that there are no objective limits to man's power to create a society free from exploitation and compulsion.

Marx and Engels attacked this kind of moralistic and philosophical socialism (and later Hess himself) as inadequate to the harsh realities of economic determinism and the class struggle. The influence of Marx and the failure of romantic idealism in the widespread revolutions of 1848 helped to convert Hess from idealism to materialism. He now spoke of ideas as the "reflex" of material conditions and the class struggle, and he predicted the inevitable termination of the economic "contradictions of capitalism" in overproduction, proletarian misery, depression, revolution, and finally, socialism.

In the end, however, Hess became pragmatic. He rejected dialectical materialism as he had rejected dialectical idealism. He worked with Lassalle to found German social democracy, and like Lassalle he hoped for radical social reform through universal suffrage and the nationalization of the means of production. And it was in this spirit, not Marx's, that the German Social Democratic Party started its career. In the 1860s, fearful of the future of the Jews of Europe, Hess worked for a Jewish and socialist state in Palestine.

HETEROSEXISM

Heterosexism may generally be understood as an attitude in which heterosexual relationships, social arrangements, and sexual activities are viewed as morally, culturally, religiously, biologically, and/or psychologically ideal, and are thus superior to and rightly privileged over any non-heterosexual option. Another less common usage describes heterosexism as an attitude in which the separation of sex, anatomy, gender, and gender roles into two discrete categories of male and female is assumed to be natural and required for coherent personal identity and social stability, and is influential in analyzing gendered social roles and identities (Butler 1990) and issues of transsexualism and transgendered identity.

In this first and predominant use, however, *heterosexism* is intended to parallel the concepts of sexism and racism and points toward characteristic prejudice and

discrimination against sexual minorities, mainly by heterosexuals, but also by self-disapproving homosexuals and bisexuals who have internalized a heterosexist attitude. The ways in which people who evince homosexual desire and behavior are discriminated against include legal inequity (military service prohibition, gay marriage and adoption prohibitions, sodomy laws, career restrictions), social treatment (housing discrimination, job discrimination, public denouncements), and cultural treatment (community invisibility, moral condemnation, stereotyping, greater risk of physical and verbal assault, pressure to stay "closeted," religious condemnation).

While these inequities are examples of discrimination, and in some cases obvious mistreatment, discrimination is not in and of itself unjust. Just discrimination occurs when some property of a person is contextually morally relevant to the decision to treat them differently (e.g., not allowing a blind person to drive), whereas unjust discrimination occurs when some property of a person is not contextually morally relevant to the decision to treat them differently (e.g., not allowing women to vote). The ongoing moral debate then, is about whether some heterosexist beliefs and consequent discriminatory practices are morally justified.

DISCRIMINATION AS MORALLY JUSTIFIED

Heterosexist laws and policies are typically held to be just based on the prior assumption that homosexual sex is immoral and/or that homosexual desire is defective. While heterosexist policies do not automatically result from heterosexist attitudes (one could be libertarian), heterosexist attitudes are a prerequisite for such policies. Though variations exist, there are three main classes of argument for the view that homosexuality is immoral or inferior.

Divine command theory arguments state that morality is determined by the edict of God and that those texts thought to be authoritative indicators of God's will have outlawed homosexual sex. In the historically dominant Judeo-Christian tradition of European and North American culture, the proof texts most often cited are the Hebrew Bible passages concerning creation (Gen. 1–2), Sodom and Gomorrah (Gen. 19), Gibeah (Judg. 19), the holiness code (Lev. 18:22 and 20:13), and three Christian New Testament passages (Rom. 1:26–27; 1 Cor. 6:9; 1 Tim. 1–10).

Natural law arguments state that there is an objective moral good and a path toward that good for all creatures depending on the kind of creature that they are. The kind of creatures that they are is typically understood (though not always—e.g., in Aristotle) as the result of God's eternal design, and so natural law is often closely connected to divine command theory. By attending to the visible organization of nature—including our bodies—we can determine what our proper functions and ends are and how we might best achieve those ends. Any actions that do not work toward achieving those aims or that actively block the fulfillment of those aims are immoral or at least not tending toward the moral. The obvious function of sex and sexual anatomy (it is claimed) is reproduction and family unity. Homosexual behavior interferes with these aims (as does other nonprocreative sex) and is therefore objectively unnatural and intrinsically immoral. Homosexual desire is not a behavior and thus not immoral, but by tending toward interference with the proper ends of our bodies is an objectively disordered state.

This approach to the moral condemnation of homosexuality is historically influential and frequent. The argument is present in Plato, who while praising homosexual love as a first step toward the realization of beauty and truth in the Symposium (209a–211c), nonetheless rejects homosexual sex as absent in animals and unnatural in Laws (836c–836e). Aristotle says very little on homosexuality but his emphasis in the Physics on explaining things by reference to their biological purposes is well-matched for the natural law argument that nonprocreative sex is essentially misdirected. He includes pederasty (the Greek tradition of a young man engaging in sex with an older male mentor) in a list of diseased states learned mostly through social custom, including chewing fingernails and eating coal (Ethics 1148a15–1148b30).

The true cultural power of the "against nature" argument, however, flourishes with the development of medieval Christian moral doctrine in St. Thomas Aquinas. Heavily influenced by Aristotle, he asks what the natural end of sex is and answers that it is procreation. As such, all sexual activity that has no chance of resulting in procreation is "contrary to right reason," contrary to the "natural order," and a lustful vice, a category which includes masturbation, bestiality, homosexuality, and any sort of sex even between men and women that occurs "by not observing the natural manner of copulation" (Aquinas, 1920 2.2.154.11). This view is currently reflected in the Catechism of the Catholic Church, which states that: "homosexual acts are intrinsically disordered" and "contrary to the natural law" (CCC n2357). The natural law approach has been influential in legal matters,

including Blackstone's famous and formative Commentaries on the Laws of England, which the U.S. Supreme Court appealed to in *Bowers v. Hardwick* (1986) in upholding the legality of sodomy laws. Justice Burger wrote: "Blackstone described 'the infamous crime against nature' as an offense of 'deeper malignity' than rape, an heinous act 'the very mention of which is a disgrace to human nature,' and 'a crime not fit to be named'" (*Bowers v. Hardwick*).

Not all natural law arguments say homosexual acts must always be immoral, but leave room open for the position that such sexual expression can be genuine goods for the homosexuals involved, even though same-sex relationships do not achieve the natural ideal. The analogy here is often to adoption. Ideally, parents raise and love their own biological children, but adoption may still be a genuine, lesser, good for the actual persons involved in actual situations (Cahill 1995). This view does not treat homosexuality as a neutral variation in human nature, like left-handedness, but rather as a deficit or disadvantage. Finally, there are secular variations of a natural law-style argument against homosexuality that avoid religion or concepts of intrinsic morality but retain the disease or disadvantage model. Sigmund Freud views a homosexual orientation as a stalled development resulting in sexual narcissism (Ruse 1988). Taking an evolutionary and Aristotelian approach, Michael Levin (1984) views homosexuality as abnormal and homosexual sex as a misuse of sexual organs, likely to result in endemic unhappiness, making it prudentially, but not intrinsically bad. As such, it is legitimate for a society to formally discourage and refuse to legitimize homosexuality—a position which crosses over into the social harm category of argument.

Social harm arguments state that homosexual activity damages individuals and society. As such, the state may legitimately discourage or criminalize homosexuality as a measure of public self-protection. While proponents of social harm arguments often begin with divine command or natural law convictions, the arguments themselves, as empirically based, stand independently. Many social harm arguments take as a starting point certain empirical claims about homosexual psychology, including that homosexuals are pedophiles (sometimes conflating the categories altogether), are unstable, are promiscuous, are disease-ridden, are depressed, and actively recruit others (particularly children) into their lifestyle.

Some arguments are more sociological than psychological, arguing that altering the historical social norms that have governed gender and family structures, such as permitting gay marriage or adoption, will confuse our notions of families, will traumatize children's understanding of parental roles, and will erode heterosexual families. For example, John Finnis argues that because homosexual relationships are immoral, incapable of actualizing mutual devotion, and harm the personalities of its participants, they are "deeply hostile to the self-understanding of those members of the community who are willing to commit themselves to real marriage" and are "an active threat to the stability of existing and future marriages" (1994, p. 515). As such, the political community has a "compelling interest" in discouraging and criminalizing homosexual sex. Finally, there is the slippery slope argument that once an institution as sacrosanct as heterosexual family and marriage is fundamentally altered, there will be no principled way to prevent the legalization of polygamy, bestiality, pedophilia, or incest.

DISCRIMINATION AS MORALLY UNJUSTIFIED

Defenders of the morality of homosexuality begin with the claim that individuals have a prima facie interest in pursuing their own goods as they interpret them and that such pursuit should not be denied without just reason. The first approach then to claiming that heterosexist beliefs and policies are unjust is to contend that all the arguments that defend the permissibility of heterosexism are unsound.

Against the divine command argument, frequent intrareligious criticism says that scriptural passages are often mistranslated (there being no term in either Hebrew or Greek for constitutional homosexuality as we know it), are misread out of context (the holiness code being instructions on ritual practices rather intrinsic morality or referring only to rape or prostitution), that the choice to enforce sexual regulations over other equally weighted ritual regulations are examples of prejudicial selectivity, or that biblical texts are not infallibly authoritative. The frequent extrareligious response is that divine command theory is false in the first place and thus such texts have no special moral authority, or at least that in a free society, religious beliefs are not state-enforced and thus have no special legal authority.

Against the natural law argument, critics argue that organs and sex may have more than one end (Mohr 1988), that *natural* and *unnatural* do not equate with *good* and *bad*, that there is no logical implication from the ways things are to the ways things ought to be (the is/ought distinction), that animals are no guides to our

behavior (Boswell 1980), that homosexuality is in fact natural and does occur among animals (Bagemihl 1999; Roughgarden 2004), and that homosexuality may be evolutionarily adaptive and antihomosexual discrimination may explain any unhappiness better than sociobiology (Murphy 1987).

Against the social harm argument, critics point out that numerous psychological studies have shown most of the heterosexist claims to be false—homosexuals are not more likely than heterosexuals to be pedophiles, they do not seek to convert heterosexuals, sexually transmitted diseases are as likely to occur in heterosexuals who engage in unsafe sex, and that any promiscuity is both exaggerated and as or more likely to be the result of social marginalization as an intrinsically homosexual trait. Slippery slope arguments, in addition, falsely assume that we will be unable in the future to distinguish the consensual, harmless sexual activity between rational adults (in both heterosexual and homosexual relationships) from the sorts of harmful abuses present in bestiality, incest, and pedophilia (Corvino 2005).

For all these reasons, defenders of the morality of homosexuality claim that proponents of heterosexism fail to meet the burden of proof that would justify heterosexist attitudes and policies. In a positive vein, they also argue that homosexuality is simply a normal, if minority, variation among human traits with widespread historical and cross-cultural representation, that homosexual relationships can actualize mutual devotion and other human goods in distinctive ways, and that citizens' interest in liberty and pursuit of their own good outweighs any state interest in promoting only procreative relationships. This last argument weighed heavily in *Lawrence v. Texas*, the 2003 U.S. Supreme Court decision overruling the tradition- and natural law-defense of *Bowers v. Hardwick*. The court stated: "The fact that a State's governing majority has traditionally viewed a particular practice as immoral is not a sufficient reason for upholding a law prohibiting the practice, and … individual decisions concerning the intimacies of physical relationships, even when not intended to produce offspring, are a form of 'liberty' protected by due process."

RELATION TO HOMOPHOBIA

Heterosexism is a relatively new term with a contested relationship to *homophobia*, a term popularized by George Weinberg (1972). The latter concept came to be used widely, and often interchangeably, with *heterosexism* to refer to any prejudice or morally negative attitude toward homosexuality, often with highly polemical

intent. However, *homophobia* originated as a quasi-psychiatric term that emphasized the irrational hatred of homosexuals (Pharr 1988). This usage has been criticized as failing to adhere to the clinical symptomatology of true phobias (Richmond 1998) and for individualizing a problem that is better understood as a political and institutional phenomenon (Kitzinger 1989). It has been argued that homophobia is a phenomenon best understood as an extreme projection of background heterosexist attitudes that are themselves strongly shaped by background assumptions concerning gender identity (Hopkins 1996). In any case, *heterosexism* appears to have become the more dispassionate term of choice for describing an attitude that privileges heterosexuality.

HEYTESBURY, WILLIAM
(before 1313–1372/3)

William Heytesbury, a fellow at Merton College in Oxford from 1330, belonged to the second generation of Mertonian "Calculators." His work depends on Richard Kilvington's *Sophismata* (1325) and Thomas Bradwardine's *Insolubilia* and *Tractatus de Proportionibus* (1328). His technique was to analyze sophismata—ambiguous problematic statements whose truth or falsehood is to be assessed under specified assumptions—and apply supposition theory, a form of semantic-logical analysis, to the explication of their underlying logical grammar. He is particularly noted for his work on motion and the continuum.

Heytesbury's most popular work was the *Rules for Solving Sophismata* (1335), which contains six treatises: "On Insoluble Sentences (Insolubilia)," dealing with self-referential paradoxes; "On Knowing and Doubting," concerning reference in intensional contexts; "On Relative Terms," considering the reference of relative pronouns; "On Beginning and Ceasing" and "On Maxima and Minima," about continua; and "On the Three Categories," on velocity and acceleration in changes of place, quantity, and quality.

In "On Beginning and Ceasing," Heytesbury considers the sophisma "some part of an object ceases to be seen by Socrates," given that the object is not now, but will, immediately after now, be partly occluded by an object passing in front of it. This statement may assert that there is a given part of the object that will, in every moment after this one, be entirely occluded, and if so, it is false. Or it may assert that at every moment after this present moment, there will be some part of the object entirely occluded at that moment (a different part for each moment), and then it is true.

The *Rules* became popular, and remained important on the European continent even after the Mertonians began to be ignored in Britain. It was taught at Padua and Paris through the early sixteenth century, influencing the Paduan school, fifteenth-century Italian logicians such as Paul of Venice (d. 1429), and the school of John Major at Paris. With the rest of medieval logic, Heytesbury's work sank into obscurity after that. In addition to *Rules* Heytesbury wrote two collections of sophismata, in one of which the (obviously false) statement, "you are a donkey," was repeatedly derived from seemingly harmless admissions. He also wrote some shorter works; for instance, "On the Compounded and Divided Senses," which deals with scope ambiguities similar to that involved in the preceding example.

In the sixth chapter of *Rules*, Heytesbury states the mean-speed theorem for uniformly accelerated motion: A uniformly accelerated body will, over a given period of time, traverse a distance equal to the distance it would traverse if it moved continuously in the same period at its mean velocity (one-half the sum of the initial and final velocities). Elsewhere, he points out, in a particular case, that a uniformly accelerated body will, in the second equal time interval, traverse three times the distance it does in the first. Domingo de Soto observed the applicability of the mean-speed theorem to free fall in 1555.

HICKOK, LAURENS PERSEUS

(1798–1888)

Laurens Perseus Hickok was America's first systematic philosopher and also won distinction as a theologian and educational administrator. He was born in Bethel, Connecticut, and was educated at Union College. He trained for the ministry under William Andrews and Bennett Tyler, who was a major spokesman for "old school" Calvinism. Hickok served well as pastor at Kent, Connecticut (1823–1829), and Litchfield, Connecticut (1829–1836). He then became professor of theology at Western Reserve College (1836–1844) and Auburn Theological Seminary (1844–1855). His alma mater, Union College, called him to serve as vice-president and professor of mental and moral philosophy (1855–1866) and president (1866–1868). In 1868 he retired to Amherst, Massachusetts, where he wrote several books over the next twenty years.

The core of Hickok's philosophic enterprise was the attempt to allow adequate weight to the claims of reason and experience in all domains of intellectual life. Ultimately, he was convinced, the rational and the empirical modes of thinking could not lead to contradictory conclusions; human intelligence might begin with general principles and rationally deduce facts or might begin with observed facts and gradually uncover general principles. In either case the facts were the same, and the principles were the same. Rational science is science as known by God; empirical science is science as learned by men. Different criteria of validity are to be applied to man's ideas in these two types of scientific thinking. In the empirical area ideas are tested by their experimental consequences; in the rational area ideas are tested by their

congruence within a systematic pattern. Each type of thinking has, however, its proper place; the speculative mode should not be used when the investigative mode is in order, but neither should men become so enamored of empirical investigation that they neglect rational speculation.

Despite this careful balancing of empirical and rational method, Hickok did not regard the discoveries of empirical science as part of philosophy. His own work *Empirical Psychology; or, The Human Mind as Given in Consciousness* (1854) was an introspective study of the workings of the human mind. Hickok thought of this study as prephilosophic. He also published a philosophic work in the same field—*Rational Psychology; or, The Subjective Idea and the Objective Law of All Intelligence* (1849). Here no attention was given to the data of introspection; hence, this work was properly "philosophy." In all the other fields to which he gave consideration, Hickok's work was completely dominated by rational, speculative system building.

Although there was some trace of the ideas of Immanuel Kant in American philosophy before Hickok, he was the first professor of philosophy in the United States to attempt to make systematic use of Kant and the post-Kantian German rationalists. Thus, he was an important figure in the transition from the orthodox academic teaching of Scottish realism in the first half of the nineteenth century to the dominance of idealism in the latter part of the century.

WORKS ON HICKOK

Union Worthies, Number Two; Laurens Perseus Hickok, Class of 1820, published by Union College in 1947, contains three appreciations of Hickok by Harold A. Larrabee, Herbert W. Schneider, and Julius Seelye Bixler, as well as a bibliography of Hickok's chief writings. Other discussions are in H. W. Schneider, *A History of American Philosophy* (New York: Columbia University Press, 1946; 2nd ed., 1963), and in Joseph L. Blau, *Men and Movements in American Philosophy* (Englewood Cliffs, NJ: Prentice-Hall, 1952).

J. L. Blau (1967)

HIDDENNESS OF GOD

Many people are perplexed that God (if such there be) does not make His existence more evident. For many of them, the hiddenness of God puts their faith to the test. Others, however, claim that God's hiddenness is the basis of an argument against His existence. While this claim is no newcomer to religious reflection, it has been the focus of renewed debate since the early 1990s.

Two preliminary observations are in order. First, the God in question is the God of traditional theism, a personal God who is unsurpassably good. Second, *the hiddenness of God* is an inapt term to use in an argument for the conclusion that there is no God since God is hidden only if there is a God; the term *inculpable nonbelief* is better. At a first approximation, the argument is that there are people who, through no fault of their own, lack belief that God exists; thus, since there is a God only if there is no inculpable nonbelief, there is no God.

RELATIONSHIPS WITH THE ARGUMENT FROM EVIL

The argument from inculpable nonbelief is related in several ways to the more familiar argument from evil and suffering against the existence of God.

First, inculpable nonbelief is supposed to be evidence against the existence of God independent of evil and suffering. To see how this can be, imagine a society in a world much like our own but in which there is no evil or suffering. While no argument from evil could arise in such a society, some of its citizens might maintain that there is a God while others maintain that there is not since there are inculpable nonbelievers.

Second, evil and suffering are much more powerful evidence than inculpable nonbelief. It is difficult to view inculpable nonbelief as nearly as bad as the horrors of Auschwitz or the suffering caused by the tsunami of December 26, 2004. Perhaps this is due, in part, to the fact that, unlike evil and suffering, inculpable nonbelief is not bad in itself—indeed, it is bad only if there is a God.

Third, although inculpable nonbelief is weaker, independent evidence for atheism, it is arguably stronger precisely because of the suffering in the world. That is because suffering constitutes a context in which one's expectation increases that God would make Himself and His love sufficiently clear. For one is more in need of the assurance and comfort that God's manifest love would bring when one suffers. Thus, its absence in the suffering of many people, especially horrific and intense suffering, is more striking.

Fourth, formulations of the argument from inculpable nonbelief parallel those of the more familiar argument from evil. For example, one commonly distinguishes logical (deductive) arguments from evil from evidential (inductive or probabilistic) arguments from evil. A logical argument from evil affirms of some known fact about evil that it is incompatible with theism, while an evidential argument does not, either because it affirms that the fact in question is not known but only reasonably believed, or because it affirms that the fact in question is only improbable given theism, not incompatible with it. One can distinguish arguments from inculpable nonbelief along the same lines.

SCHELLENBERG'S VERSION OF THE ARGUMENT

More than anyone else, John L. Schellenberg is responsible for renewing the contemporary debate with his *Divine Hiddenness and Human Reason* (1993). The main argument is this:

(1) There are people who are capable of relating personally to God but who, through no fault of their own, fail to believe

(2) If there is a personal God who is unsurpassably great, then there are no such people

(3) So, there is no such God (from 1 and 2)

According to Schellenberg (1) is a generalization from two facts. First, there are honest seekers of the truth who are atheists and agnostics. Second, there are individuals who belong to cultures that lack the idea of a personal God altogether (e.g., the Chinese race in the period from the beginning of their history until the Christian Middle

Ages). In defense of (2), Schellenberg offers the following subargument:

(2a)   If there is a personal God who is unsurpassably great, then there is a personal God who is unsurpassably loving

(2b)   If there is a personal God who is unsurpassably loving, then for any human person H and any time t, if H is at t capable of relating personally to God, H has it within H's power at t do so (i.e., will do so, just by choosing), unless H is culpably in a contrary position at t

(2c)   For any human person H and any time t, H has it within H's power at t to relate personally to God only if H at t believes that God exists

(2d)   So, if there is a personal God who is unsurpassably great, then for any human person H and any time t, if H is at t capable of relating personally to God, H at t believes that God exists, unless H is culpably in a contrary position at t (from 2a through 2c)

In effect, (2d) is (2) of the main argument.

Schellenberg regards (2) as a necessary truth, reflecting part of the meaning of "there is a personal God who is unsurpassably great." (An evidential or probabilistic version of the argument would say that [2] is only likely to be true.) So Schellenberg regards each of (2a) through (2c) as necessary truths. He thinks (2a) is just obviously necessary. (2b), however, is not obvious. Indeed, what does it mean? In particular, what does Schellenberg mean by "relating personally to God" and being "capable" of such a relationship? He means this. To relate personally to God is to interact with God in the various ways that theistic religious traditions describe: on the divine side, God's guiding, supporting, and forgiving one, for example, and on the human side, one trusting Him, showing gratitude, and worshipping Him, among other things. Crucially, such a relationship would involve an explicit consciousness of God's presence and interaction with one. This relationship is to be conceived of developmentally, not as something that comes complete and mature. To be capable of a personal relationship with God is to have the cognitive and affective equipment required to be conscious of God's presence and interaction with one and to hold the attitudes and to perform the behavior involved in such a relationship; it also requires possession of the concept of God, or at least the materials from which it can be constructed.

So why should one suppose that (2b) is true? Schellenberg argues that it follows from the nature of unsur-

passable love and can be supported by analogy with the best sorts of human love as well. An unsurpassable lover would seek a kind of close, explicit participation in the life of his or her beloved for its own sake, as well as for the beloved's sake, so that the beloved could draw from it what he or she needed to flourish. This would be especially true in the divine-human case. A close, explicit interaction with God would bestow moral benefits. For example, it would enable one to more easily overcome character flaws and it would provide one with a model for other relationships. Moreover, it would bestow experiential benefits, such as peace and joy, security and support in suffering, and the pleasure of companionship. Of course, God would not force Himself on one, as that would make the relationship a sham. He would leave it up to one to enter into and maintain it. Thus—one's own resistance, as well as the consequences of one's prior free choices—would be the only thing He would allow to prevent one from relating personally with Him. Otherwise, He would always be available just for the asking.

As for (2c), Schellenberg argues that it is absolutely impossible for one to have a personal relationship with another unless one believes that the other exists. Thus, as a matter of logical necessity, one has it within one's power to relate personally to another only if one believes that the other exists. The same goes for us and God.

Schellenberg's argument has enjoyed much critical scrutiny. To this attention is now directed.

NON-THEODICAL CRITICISMS OF THE ARGUMENT

Some critics say that the argument does not show that there is no God since it leaves open the possibility of an impersonal God, or a personal God that is not unsurpassably great. Others say that since God is so absolutely different, even incomprehensible, nothing could count as evidence against God's existence, including inculpable nonbelief. These responses are irrelevant, however, since Schellenberg's target is a God that is at least somewhat comprehensible insofar as He is said to be personal and unsurpassably great.

Another criticism holds that the argument is an occasion for observing that unsurpassable greatness does not imply unsurpassable love. In this connection think of the Stoic view of eudaemonia (happiness), according to which the sage—the person who has achieved moral and intellectual perfection—would possess benevolence but lack upsetting emotions like empathy, ecstasy, fear, and grief since these passions would upset the life of bliss characteristic of the sage. On such a view (2a) is false. A

personal God who was unsurpassably great would be a divine sage and, as such, would not possess the sort of attachment and passion characteristic of the love exhibited by parents for their children.

Some critics deny (2b). They note that one's view of the implications of unsurpassable love depends on what human analogies one takes to be most salient. They suggest that an emphasis on maternal love of children supports (2b), whereas an emphasis on familiar adult love or the love of a benevolent reconstructive surgeon is more apt and supports the denial of (2b). One might worry about this since, first, benevolence is not love, second, maternal love is offered as an apt analogy in lived theistic religions, and, third, a perfectly loving God would empathize with the plight of those who seek Him but who through no fault of their own come up empty-handed.

Many critics say that there are no inculpable nonbelievers who are capable of relating personally to God; as such, (1) is false. Chief among them are those who argue, first, that there is sufficient evidence to believe, in creation and history, or through the witness of one's conscience or *sensus divinitatis*. Next, they argue that nonbelief is best explained by the willful sinfulness of nonbelievers, in which case it is not inculpable. For example, Jonathan Edwards (1970) argues that God has endowed human beings with the faculties to discern, appreciate, and weigh the evidence for God's existence, but those faculties work properly only if they function in accordance with "true benevolence," which consists mainly in an intense desire for truth about God and for true holiness. So while there is plenty of evidence, some lack it because they lack true benevolence. In *Original Sin* Edwards denies that there are nonbelievers who possess true benevolence; after all, he says, the scriptures say (compare *Romans* 1:19–22) that there is "sufficient light for the knowledge of God," hence, nonbelievers must fail to believe "divine things" owing to "a dreadful stupidity of mind, occasioning a sottish insensibility of their truth and importance" (1970, p. 149, 157). This insensibility consists in a "proneness to idolatry" and a "disregard of eternal things"—dispositions to ignore familiar and obvious considerations, to be swayed by ridicule and deference to people in authority, to prejudice against religion, and so on—which impair the God-given ability to reason properly about God. People bring such impairments on themselves. One worry about this criticism is that, even though some nonbelievers lack true benevolence, the empirical evidence strongly suggests that others possess it since they really do earnestly seek the truth about God,

love the Good, assess evidence judiciously, and, if anything, display a prejudice for God, not against Him.

Some critics appeal to implicit belief. The idea is that since God is the Good (or, God's moral goodness is His most salient feature), pursuit of the Good is, in fact, pursuit of God, even if one does not recognize it as such. This thought can be taken in different directions. On the one hand, one might infer that, since belief in the Good just is (or is one way to have) belief that God exists, one is a nonbeliever only if one fails to pursue the Good, a failure for which one would be culpable; so, there are no inculpable nonbelievers, and (1) is false. On the other hand, one might deny that belief in the Good is belief that God exists but still infer that one can relate personally with God (just by choosing) even if one does not believe that God exists since, after all, belief in the Good (moral goodness) is sufficient for the early stages of a developing personal relationship with God; as such, (2c) is false.

Another possibility is that one can begin to develop a personal relationship with God without belief that God exists. One option here is a kind of faith that God exists that has as its cognitive component acceptance rather than belief. Belief differs from acceptance in that, first, acceptance is a mental act, rather than a dispositional mental state (which is not to say that acceptance does not engender a complex behavioral disposition), and second, acceptance is under voluntary control while belief is not. Regarding the first point, although accepting a proposition is like believing it in that accepting it involves a positive stance toward it, accepting a proposition is unlike believing it in that accepting it involves one adopting it or taking it on for the purposes of theoretical and practical reasoning as well as behavior, even though one is not disposed to think "yes, that's how things are" on considering it, which is essential to belief. As for the second point, belief is a state one finds in oneself, the causal consequence of one's reasons, evidence, or grounds. However, when one's grounds for a proposition seem ambiguous, one can choose to accept it or choose to withhold acceptance. Now, if one's faith that God exists involves acceptance but not belief, one will nevertheless be disposed to act and feel in ways appropriate to God's existence (e.g., worshipping and feeling gratitude) and one will accept various experiences and sacraments as God's interacting with one (e.g., forgiving, guiding, and supporting one). In that case, one might argue that (2c) is false: one can have it within one's power to begin to relate personally to God even if one does not believe that God exists; faith is enough.

A SOUL-MAKING THEODICY

Many critics concur with (2c) but argue that (2b) is false. Toward that end, they offer *theodicies*, that is, reasons why God might lovingly permit inculpable nonbelief. Several general themes have emerged in the literature. First, God may well prefer temporary nonbelief to belief accompanied by a negative response. Second, God might have different reasons for different individuals depending on what attitudes and dispositions they possess; likewise, He might have different reasons for the same individual at different times. Third, God might have a combination of reasons, no one of which is enough but which, taken together, explain His permission of inculpable nonbelief. Fourth, on some versions of theism everyone will eventually have evidence sufficient for belief, if not in this life then in the next; so theodicies involve reasons for God to permit inculpable nonbelief for a time, not forever. Finally, evidence sufficient for belief that God exists need not involve arguments or spectacular "signs and wonders"; experiential awareness of God is enough. What follows are some representative theodicies.

According to one version of the *soul-making theodicy*, many people, at the dawn of their capacity to relate personally to God, are already ill disposed toward Him. Through no fault of their own, they have become inculpably ill-disposed nonbelievers. These include many of those who were raised to be hostile or indifferent toward religion, who were abused by excessively strict religious parents, or who had instilled in them an extreme self-centeredness or disrespect for proper authority. Perhaps God refrains from giving such people evidence sufficient for belief because they would not respond appropriately if they had it. Moreover, there's a grave risk in bringing inculpable ill-disposed nonbelievers to belief since there is a good chance they will confirm their defective disposition by an unfitting response; indeed, it might even be useless to give them evidence since they might be so ill disposed that they are more inclined to think they are institutionalizable ("hearing voices") than that God is communicating with them. Consequently, God waits, giving them the opportunity to become more receptive and apt to reciprocate His love, and influences them in subtle but respectful and loving ways toward this end.

As for inculpable nonbelievers who are well disposed toward God, this version of the soul-making theodicy considers separately those who were responsible for becoming well disposed and those who were not. Examples of the first group include those who have been virtually determined—say, by parental training—to become well disposed but who do not yet believe. In that case, as they become capable of relating personally to God, they are disposed to love God but they had little if any say in becoming so disposed. This is unfortunate because, all else being equal, a state of affairs in which one reciprocates God's love but had little if any say in being so disposed is not nearly as good as a state of affairs in which one reciprocates God's love and had a significant say about being so disposed. God prefers the better state of affairs, and so He does not bring to belief the well-disposed inculpable nonbeliever who is not responsible for being so disposed because He prefers them to confirm their disposition, on their own, in the face of contrary desires and competing allegiances, before bringing them to belief. In that way God allows them to make their involuntarily acquired good disposition toward Him genuinely theirs.

Now consider well-disposed inculpable nonbelievers who were responsible for becoming so disposed. Given the influences that shape childhood character, these will most likely be adults who have either reshaped their bad dispositions toward God for the good or confirmed their good dispositions over time. They constitute the most difficult case for the soul-making theodicy; nevertheless, it has some resources. For, as is well known, one can be disposed to love another for the wrong reasons. For example, sometimes one's love springs from a desire to extend one's power or influence, increase one's pleasure, or satisfy one's curiosity. Other times its source is insecurity or fear, for example, fear of being alone or unprotected. And there are other sources. Likewise with God. One may well be disposed to love God on coming to belief, but one might be so disposed for reasons that are not as fitting as they might be. For example, it is most fitting to love God mainly for His moral beauty, His holiness; relatedly, perhaps no disposition to love God is suitably motivated unless it is grounded in a strong desire to surrender wholly to His will. In that case the possibility arises that if God were to bring such people to belief, they would love Him, but their love would not be appropriately motivated. So He woos them, before bringing them to belief, influencing them behind the scenes in respectful and loving ways to change the source of their disposition to love Him and to confirm that change over time.

OTHER THEODICIES

A variety of other theodicies have been articulated. The *presumption theodicy* states that God does not bring some individuals to belief because if He did, they would relate to God in presumptuous and arrogant ways, not with due

contrition and humility, which are essential to a proper relationship with God. According to the *stimulus theodicy*, God does not produce belief in some individuals because if He did, they would be less apt to recognize the wretchedness of living life on their own, without God. Divine hiddenness stimulates such people to recognize this fact about the human condition, which is essential for entering into a proper relationship with God. A variation on the stimulus theodicy states that God does not provide evidence sufficient for belief in some individuals because if He did, the perceived risk required for an intense and passionate faith would be objectionably reduced, and without such a faith one cannot wholly enter into a proper relationship with God.

The *deception theodicy* asserts that some people are disposed in such a way that if God brought them to belief they would be deceived into thinking that they had arrived at a proper understanding of religious matters and would become complacent or relate to God at a superficial level. Proponents of the *intellectual virtue theodicy* say that God does not provide evidence sufficient for belief in some individuals because if He did, certain intellectual temptations would not be available to them and they would not have the opportunity to respond to those temptations virtuously. For example, if the evidence were too clear, sustained investigation and reflection and wrestling with doubt would be inhibited.

According to the *diversity theodicy* God does not produce belief in some people because if He did, diverse expression of religious imagination, creativity, and devotion would be greatly reduced, and religious variety of this sort is a great good. Finally, advocates of the *investigation theodicy* hold that it is a great good to pursue knowledge with others, all the more so when the knowledge is as important as knowledge of God. But people can pursue knowledge together only if some of them are ignorant. So God permits inculpable nonbelief so that human beings might help each other to learn about Him and to assist nonbelievers in starting personal relationships with Him.

Naturally enough, these theodicies have been criticized. Some critics claim that they provide no good reason for God to permit inculpable nonbelief at all, or at least not for every sort of inculpable nonbeliever. Others insist that if they are good reasons, then the problem of too much belief arises. Most importantly, it is claimed that the benefits of temporary inculpable nonbelief articulated in the theodicies can be accommodated within a developing, explicit personal relationship with God that involves evidence sufficient for belief that He exists.

One final critique of Schellenberg's argument should be mentioned. His argument invites one to affirm, at least tacitly, that there is no reason for God to permit inculpable nonbelief. Two themes have emerged on this score. First, one should accept the invitation only if the theodicies fail, individually but especially collectively, to account for why God might lovingly permit inculpable nonbelief. The worry here is that human beings are enormously complicated, and it is no easy task to tell whether any particular candidate for inculpable nonbelief possesses or fails to possess those motivations, attitudes, and dispositions that figure in the theodicies above. Second, even if there are inculpable nonbelievers whose nonbelief cannot be fully explained by any theodicy one knows of, the live possibility remains that there is some theodicy one does not know of. Indeed, would it really be all that surprising if God had some purpose for permitting inculpable nonbelief, as well as other bad things that happen, that one cannot understand?

HILBERT, DAVID
(1862–1943)

David Hilbert, the German mathematician, was born in Königsberg and, except for a semester at Heidelberg, did his university studies there. His dissertation, presented in 1884, was on a problem in the theory of algebraic invariants, and it was to this theory that Hilbert devoted his mathematical researches until 1892. Through these penetrating investigations Hilbert obtained many pregnant results, some of them (*Hilbertscher Nullstellensatz, Hilbertscher Irreduzibilitätssatz*) still known by his name. The methods he used in these investigations inaugurated a trend toward treating algebra more conceptually and have since become dominant in the field.

In 1886 Hilbert became a *Privatdozent* and in 1892 an extraordinary professor at the University of Königsberg. In 1893 he was named by the minister of culture Friedrich Althoff to succeed his teacher, Felix Lindemann, as an ordinary professor at Königsberg. In 1895 Hilbert accepted an invitation initiated by Felix Klein, to the University of Göttingen to succeed Heinrich Weber. Hilbert remained at Göttingen, despite many offers of other chairs, notably from Leipzig in 1898, Berlin in 1902, and Heidelberg in 1904. The invitation from Berlin led to

Hilbert's obtaining, through the help of Althoff, a chair at Göttingen for Hermann Minkowski, whom Hilbert had known since they were students at Königsberg. The personal intercourse between the two investigators was highly stimulating to both men but was prematurely ended, to Hilbert's grief, by Minkowski's death in 1909.

Hilbert's most important mathematical investigations were carried out between 1892 and 1909. He simplified the existing transcendence proofs for the numbers e and π. His investigations in the theory of algebraic number fields, in particular his monumental report "Die Theorie der algebraischen Zahlkörper" (1897), greatly amplified existing theory and directed further research in the field. His famous *Grundlagen der Geometrie* is discussed below. He showed the possibility of directly supporting the Dirichlet principle, that the existence of a conformal mapping may be inferred from the presumed existence of a minimum of a certain integral (which Bernhard Riemann had taken as the basis for his general theorems concerning conformal mappings), by means of an existence proof. This method for giving an existence proof, when worked out by Richard Courant and Hermann Weyl, proved very successful. Hilbert's contributions to the calculus of variations, in particular his statement of the *Unabhängigkeitsatz* ("independence axiom"), constituted an illuminating commentary on Adolf Kneser's textbook in the field. He continued the theory of Ivar Fredholm concerning integral equations. In particular, he introduced the analysis of infinitely many variables and generalized the transformation to principal axes. The theory thus established has proved highly fruitful in topology and in physics, particularly in quantum mechanics. Utilizing a result of Adolf Hurwitz, Hilbert solved the Waring problem concerning the representation of natural numbers by sums of nth powers.

Hilbert's familiarity with the various domains of mathematics was impressively demonstrated by the address "Mathematische Probleme," which he presented at the Second International Congress of Mathematicians in Paris in 1900. In this address Hilbert surveyed the situation then existing in mathematics, at the same time formulating twenty-three problems that have much occupied mathematicians since then. A great many of these problems have been solved in the meantime.

After Minkowski's death Hilbert turned to problems of theoretical physics. He first applied the theory of integral equations to the kinetic theory of gases and to the theory of radiation. Immediately after the appearance of Albert Einstein's general theory of relativity, Hilbert published "Die Grundlagen der Physik" (1915–1916), which

offered the first proposal of a way to unify gravitational theory and electrodynamics.

After 1916 Hilbert returned to the problems of the foundations of mathematics. These investigations led to the development of proof theory, which will be discussed below.

In his later years Hilbert gave lectures providing careful general surveys of mathematics, such as "Anschauliche Geometrie" (on intuitive geometry), as well as popular philosophical lectures. The spirit of these philosophical lectures can be seen in the speech "Naturerkennen und Logik," which he gave at the congress of natural scientists in Königsberg in 1930. At this congress his native city named him an honorary citizen.

Hilbert's character was not that of a specialized scientist. He took pleasure in the joy of life, especially in sociability, and also took a vivid interest in political events. He enjoyed the exchange of ideas both in science and in general thought; in discussions he had a predilection for pregnant, sometimes paradoxical, formulations.

Hilbert had a great many pupils, and he was the adviser on many famous dissertations whose themes were suggested by his investigations. He had the satisfaction of seeing his work highly appreciated in his own lifetime.

The memory of Hilbert's personality is vivid in all those who knew him, and the impulses he gave to science remained effective for decades after his death.

THE FOUNDATIONS OF GEOMETRY

In Hilbert's scientific work, his studies in the foundations of mathematics constitute an important part. These investigations fall into two stages separated by an interval of nearly thirteen years. The first period, which extends from about 1893 to 1904, embraces Hilbert's inquiries into geometric axiomatics and is highlighted by the publication of the *Grundlagen der Geometrie* (1899), the work that made Hilbert's name familiar to a wide public of scientists and philosophers. The second period, which began with the publication in 1917 of "Axiomatisches Denken," centers on the foundations of arithmetic and the development of Hilbert's program for proof theory.

ABSTRACT AXIOMATICS. A main feature of Hilbert's axiomatization of geometry is that the axiomatic method is presented and practiced in the spirit of the abstract conception of axiomatics that arose at the end of the nineteenth century and which has been generally adopted in modern mathematics. It consists in abstracting from the intuitive meaning of the terms for the kinds of prim-

itive objects (individuals) and for the fundamental relations and in understanding the assertions (theorems) of the axiomatized theory in a hypothetical sense, that is, as holding true for any interpretation or determination of the kinds of individuals and of the fundamental relations for which the axioms are satisfied. Thus, an axiom system is regarded not as a system of statements about a subject matter but as a system of conditions for what might be called a relational structure. Such a relational structure is taken as the immediate object of the axiomatic theory; its application to a kind of intuitive object or to a domain of natural science is to be made by means of an interpretation of the individuals and relations in accordance with which the axioms are found to be satisfied.

This conception of axiomatics, of which Hilbert was one of the first advocates (and certainly the most influential), has its roots in Euclid's *Elements,* in which logical reasoning on the basis of axioms is used not merely as a means of assisting intuition in the study of spatial figures; rather, logical dependencies are considered for their own sake, and it is insisted that in reasoning we should rely only on those properties of a figure that either are explicitly assumed or follow logically from the assumptions and axioms. This program was not strictly adhered to in all parts of the *Elements,* nor could it have been, for its system of axioms was not sufficient for the purpose. The first axiom system meeting the requirements of the program was given by Moritz Pasch in his *Vorlesungen über neuere Geometrie* (Leipzig, 1882).

This abstract kind of axiomatics, which consists in separating out the purely mathematical aspects of a theory, is not the only possible one. Hilbert himself knew that it can be applied advantageously only in domains of science whose theoretical development is sufficiently advanced. But abstract axiomatics is useful wherever the logical dependence or independence of theoretical assumptions is under investigation.

The distinguishing property of Hilbert's axiomatics is frequently described by saying that in it the terms for the kinds of elements (points, straight lines) and for the relations (incidence, betweenness, congruence) are *implicitly defined* by the axioms. This expression, first introduced in 1818 by J. D. Gergonne (Hilbert did not employ it), is often used in a misleading way. The axioms generally impose conditions on the relations and on the kinds of elements of the system; some of these conditions are partial characterizations of the relations or the kinds of elements, others characterize the space with respect to the elements and relations. The entire axiom system—as Hilbert observed in a letter to Gottlob Frege—can be

regarded as a single definition. But this is an *explicit* definition of a term denoting the relational structure in question. The defined concept is a predicate of the second type (*zweiter Stufe,* as Frege called it), applying to domains of things and to certain relations between them.

NON-ARCHIMEDEAN SYSTEMS. Another main feature of Hilbert's *Grundlagen der Geometrie* is the development of geometry, and, in particular, of plane geometry, independently of the Archimedean axiom. This axiom states that given any two line segments, either may be exceeded by an entire multiple of the other. Thus, it partly compensates for the absence of general commensurability of line segments. It was with the help of this axiom that the theory of proportions was established in Book V of Euclid's *Elements* (attributed to Eudoxus). It is also a consequence of this axiom that, once a unit segment is chosen, there corresponds to any line segment a real number (in Richard Dedekind's sense of the term) that is its measure (ratio number); therefore, Hilbert also called the Archimedean axiom the axiom of measurement.

Recourse to the Archimedean axiom introduced an arithmetical element into reasoning, and hence avoidance of it in geometrical proofs amounts to an emancipation from a nongeometrical type of reasoning. The avoidance of nongeometrical reasoning does not preclude an analytic geometry. In fact, Hilbert was able to construct a calculus of line segments, independent of the Archimedean axiom, in two different ways.

One method operates within the framework of metric plane geometry. It is based on the axioms of incidence (for the plane), those of order, those of congruence, and the parallel axiom. Hilbert defines the sum of segments in the usual way and the product of segments, after establishing a unit segment, by a parallel construction; he then shows that by these definitions the usual computation laws for sum and product are satisfied.

By this segment calculus an elementary foundation of the theory of proportions and thereby also of analytic geometry is obtained. Hilbert further showed how with the aid of the segment calculus the theory of the areas of polygons can be set up without supposing, as is assumed in Euclid, that to any polygon there corresponds its area as a quantity, that is, in agreement with Euclid's axioms of quantities. Thus he showed that no accessory reliance on intuition is required for the theory of areas of polygons.

Hilbert conjectured that the theory of the volumes of polyhedrons is not fully analogous to the theory of the areas of polygons. He posed the problem of showing that tetrahedrons of equal volume cannot always be obtained from one another by a series of processes of pairwise additions and subtractions of congruent polyhedrons, a problem solved by Max Dehn ("Über raumgleiche Polyeder" and "Über den Rauminhalt"). Various investigations have derived from this problem.

Hilbert's second calculus of line segments independent of the Archimedean axiom is for *affine* geometry of the plane. A difficulty here is that the axioms of plane affine geometry do not suffice for the foundation of this geometry. The same holds for plane projective geometry.

Hans Wiener stated at the Naturforscherversammlung in Halle (1891) that it is impossible to give autonomous foundations to both plane projective geometry and plane affine geometry by adjoining to the axioms of incidence the Desargues theorem and a specialized form of the Pascal theorem on conic sections (with the conic section degenerated to a pair of straight lines). Hilbert was impressed by these statements and gave a proof of them for affine geometry by means of a calculus of segments. Here sum and product of segments are defined by elementary parallel constructions, and, with the aid of the Desargues theorem, the computation laws, with the exception of the commutative law for the product, are proved to be satisfied. These proofs were simplified by Arnold Schmidt in the seventh edition of the *Grundlagen.*

This calculus of segments leads to an analytic geometry over a skewfield—as it has come to be called—for the plane. This geometry can be extended, as Hilbert showed, to an analytic geometry of three-dimensional space satisfying the incidence axioms and the parallel axiom for the space. This is the extent of the role of the Desargues theorem. The specialized Pascal theorem is needed to prove that the segment calculus satisfies the commutative law for multiplication. This law, as Hilbert showed, can be inferred from the other computation laws and the laws of order with the aid of the Archimedean axiom, but not without it. (Gerhard Hessenberg proved, somewhat later, that the Desargues theorem is a consequence of the specialized Pascal theorem.)

Hilbert's positive treatment of the Archimedean axiom and, in particular, the question of its independence complemented his elimination of it from the foundations of geometry. The possibility of a non-Archimedean geometry was first considered in detail by Giuseppe Veronese in his *Fondamenti di Geometria* (Padua, 1891). This possibility can be inferred, by the methods of analytic geometry, from the existence of a (generalized) number system for which the operations of sum and product and their inverses, as well as the operation

$\sqrt{1 + a^2}$ and the relation "smaller than," can be defined in such a way that the familiar computation laws, but not the Archimedean axiom, are satisfied.

Hilbert gave as an instance of such a non-Archimedean system a system whose elements are algebraic functions of an argument *t*. But the instance he presented in "Über den Satz von der Gleichheit der Basiswinkel im gleichschenkligen Dreieck" is easier to operate with. (This essay is one of a series of studies closely connected with the *Grundlagen* and added to it as appendixes in the second and later editions; this essay forms Appendix II.) It deals with the possibility of restricting, in plane geometry, the last congruence axiom concerning triangles to the case of triangles assigned to one another in equal orientation. The effect of this restriction is to admit as congruences only those transformations obtained by translations and plane rotations, thus excluding symmetry from the notion of congruence. Two kinds of questions arise, those concerning the anomalies that can occur in a model of the restricted axiom system and those relating to the ways of compensating for the weakening of the triangle congruence axiom. Many anomalies are stated by Hilbert to occur in two models that he ingeniously constructed. Concerning different methods of compensating for the restriction of the triangle congruence axiom, see Supplement V2 of the ninth edition of the *Grundlagen* (pp. 264–268) and the literature mentioned there in the footnote on p. 265.

CHARACTERIZATION OF THE PLANE. As Blumenthal's biography indicates, Hilbert was led to the problems of Appendix II by investigations (reprinted in Appendix IV) in which he gave a very different foundation for plane geometry from that presented in the main part of the book. The problem here is to characterize the plane by means of the properties of the manifold of congruent motions. It was first treated by Hermann von Helmholtz and soon after by Sophus Lie, who emphasized its group-theoretic aspects. Both Helmholtz and Lie proceeded by the methods of the differential calculus. Hilbert sought to avoid any assumption concerning differentiability. His arguments in Appendix IV are within the framework of the theory of point sets. They rely especially on Camille Jordan's theorem concerning simply closed continuous curves (Jordan curves) in the "number plane," which generalizes the theorem on the decomposition of the plane by a simple polygon. Hilbert starts from a characterization of the geometric plane as a two-dimensional manifold by means of the concept of neighborhoods introduced in an axiomatic way—this is now a familiar

method in topology, but at that time it was scarcely known at all.

Two characterizations of the "plane" are offered. According to the narrower definition the plane is topologically equivalent to a connected domain in the number plane; according to the wider definition it is locally equivalent (homeomorphic) to the interior of a Jordan curve and is globally connected. Hilbert chose the narrower characterization for simplicity.

The concept of continuous transformation can be defined by means of the representation of the geometric plane in the number plane. The motions are then taken as special continuous one-to-one transformations of the geometric plane onto itself such that in the representation each Jordan curve preserves its orientation. This provisional characterization of the geometric plane is then completed by three axioms on motions: (1) The motions constitute a group with respect to their composition; (2) given two different points, *A* and *B*, there are infinitely many points into which *B* can be transformed by a motion keeping *A* fixed; (3) if *A*, *B*, *C* and *A'*, *B'*, *C'* are triples of points in the geometric plane (the members of a triple not necessarily being different) and if in an arbitrary proximity of *A*, *B*, *C* there exist triples *P*, *Q*, *R* and in an arbitrary proximity of *A'*, *B'*, *C'* there exist triples *P'*, *Q'*, *R'* such that *P*, *Q*, *R* is transformed by a motion into *P'*, *Q'*, *R'*, then *A*, *B*, *C* is transformed by a motion into *A'*, *B'*, *C'*.

In a valuable discussion that made use of set-theoretic, topological, and group-theoretic arguments, Hilbert proved that from these axioms, with the obvious definition of congruence by means of the concept of motion and a suitable set-theoretic definition of straight line, it follows that the geometric plane under consideration satisfies the axioms of plane geometry as stated in the main part of the *Grundlagen,* with two exceptions: (1) the triangle congruence axiom is obtained only in the restricted form relating to motions, and (2) the parallel axiom does not result. Two possibilities then remain: the plane satisfies either Euclidean geometry or Bolyai-Lobachevski geometry.

Hilbert's handling of these problems disclosed a new direction of investigation, which is still being pursued. His results have been extended in three ways: (1) by weakening the topological assumptions through the adoption of the wider characterization, mentioned above, of a two-dimensional manifold, (2) by generalizing the discussion to higher dimensions, and (3) by modifying the axioms on the motions. (See the surveys of these researches in the introduction to Hans Freudenthal's "Neuere Fassung des

Riemann-Helmholtz-Lieschen Raumproblems" and his "Im Urkreis der sogenannten Raumprobleme.")

CONTINUITY. A final aspect of Hilbert's axiomatization of geometry in the *Grundlagen* is his treatment of continuity. The Archimedean axiom is stated as an axiom of continuity, yet it excludes only a particular kind of discontinuity. In fact, if this axiom alone is added to the Hilbert axioms of incidence, order, and congruence (including the parallel axiom), then the axiom system is satisfied by an analytic geometry constructed over a *restricted* number system consisting only of algebraic numbers and not including the square root of each positive number.

In this respect Hilbert's axioms differ from those of Euclid's *Elements.* Euclid explicitly postulated the construction of a circle around a given point with a given radius (and implicitly made assumptions about the intersection of circles and of circles with straight lines). However, in order to realize by constructions the existence statements of Hilbert's axioms, it is sufficient to have, in addition to a ruler, not a compass but an "*Eichmass*"—that is, an instrument for determining a given distance on a given straight line from a given point in a prescribed direction. Hilbert showed, in Chapter 7 of the *Grundlagen,* that the *Eichmass* and the ruler allow us to perform all the constructions corresponding to the existence axioms.

Chapter 7 also discusses the question of the analytical representation of the constructions with ruler and *Eichmass.* It turns out that the ratio numbers of line segments constructible from a given unit length with ruler and *Eichmass* are the real numbers obtainable by the elementary arithmetical operations together with the operation $\sqrt{1 + c^2}$. This domain of numbers is narrower than that obtained when the operation $\sqrt{1 + c^2}$ is replaced by that of extracting the square root of an arbitrary positive number. The latter domain is the one composed of the ratio numbers of the lengths constructible by ruler and compass, but by no means does it contain all algebraic numbers. Yet, whereas the set of all algebraic numbers is denumerable, the set of all ratio numbers has a higher infinity. Hence, in order to characterize the geometric continuum a further axiom is required. It then becomes apparent that geometric continuity is related to continuity in the theory of real numbers.

When Hilbert wrote the *Grundlagen* the question of conceptually formulating the continuity property of an ordered set had been settled by the Dedekind axiom of *Lückenlosigkeit* and its equivalent, the principle of the

least upper bound. For a metrical set, each of these axioms implies the Archimedean property.

COMPLETENESS. In direct connection with his work on the foundations of geometry, Hilbert undertook an axiomatization of theory of real numbers. In the paper "Über den Zahlbegriff" (published in 1900 and reprinted as Appendix VI of the *Grundlagen*), he presents an axiom system characterizing the system of real numbers as an ordered Archimedean field that cannot be extended to a wider ordered Archimedean field. He thus replaced the continuity axiom by (1) the Archimedean axiom and (2) a condition of maximality which he called the axiom of completeness.

Hilbert introduced into geometry a corresponding axiom of completeness (which first appears in the second edition of the *Grundlagen*) stating that the space characterized by the axiom system including the axiom of completeness constitutes a maximal (that is, not extensible) model of the other axioms. The connection between the geometrical and the arithmetical completeness axiom is given by the circumstance that any model of the axioms of incidence, order, and congruence and of the parallel and the Archimedean axiom can be represented by an analytic geometry over an ordered Archimedean number field, which again is isomorphic with respect to sum, product, and order to a subfield of the field of all real numbers.

The statement of the completeness axiom is very suggestive, and it was with Hilbert's introduction of this axiom that the notion of a maximal model was first conceived. Yet, because of its reference to other axioms, the completeness axiom offers difficulties, particularly with respect to questions of independence. The possibility of decomposing the full continuity axiom into the Archimedean axiom and another axiom which does not entail it is given by Georg Cantor's continuity axiom. (See Federigo Enriques, "Prinzipien der Geometric," and Richard Baldus, "Zur Axiomatik der Geometrie III: Über das Archimedische und das Cantorsche Axiom.")

CONSISTENCY. In "Über den Zahlbegriff" Hilbert recommended substituting an axiomatic presentation of the theory of real numbers for the "genetic" method of treating them. Despite the great pedagogical value of the genetic method, he said, the axiomatic method is to be preferred for the definitive formulation and logical precision of the theory.

This point of view has decisive consequences for the problem of consistency. Hilbert proved the consistency of

the geometrical axiom system by using the arithmetical model provided by analytic geometry. But if arithmetic is set up as an axiomatic theory, then Hilbert's proof establishes only a relative consistency. This, of course, is a valuable result, since the structure described by the axioms for the arithmetical continuum is much simpler than that of Euclidean space. The reduction to arithmetic, however, cannot then be regarded as a kind of direct verification by intuitive evidence, for the task of proving the consistency of the axiomatic theory of real numbers remains. This problem was one of those Hilbert posed in "Mathematische Probleme" (*Gesammelte Abhandlungen,* Vol. III, pp. 290–329).

At that time Hilbert thought that a suitable modification of the methods of Dedekind and Karl Weierstrass in the theory of irrational numbers would suffice to obtain the desired proof of consistency. Not long after, however, in the address "Über die Grundlagen der Logik und der Arithmetik" to the Heidelberg Congress of Mathematicians, Hilbert presented an essentially altered view. This alteration was no doubt brought about through the discovery by Bertrand Russell and Ernst Zermelo of very significant forms of the logical paradoxes which gave a more fundamental aspect to the difficulties that Cantor had earlier found with respect to "inconsistent sets." These difficulties showed that in set theory we cannot in general assign to a predicate *P* "the set of all those things for which *P* holds" as an object belonging to the universe of discourse.

Hilbert stated that these paradoxes seemed to show that the views and methods of logic "conceived in the traditional sense" ("*im hergebrachten Sinne aufgefasst*") are not equal to the strong requirements of set theory. And, although he strongly opposed Leopold Kronecker's tendency to restrict mathematical methods, he nevertheless admitted that Kronecker's criticism of the usual way of dealing with the infinite was partly justified.

The resulting point of view was not yet explicitly developed in Hilbert's Heidelberg address. However, Hilbert presented there the following programmatic ideas: (1) One must include in the arithmetical theory whose consistency is to be demonstrated the methods of logical reasoning used in the theory; (2) the methods of symbolic logic for representing mathematical sentences by formulas are to be applied; (3) the sequences of formulas representing mathematical proofs can be made the object of intuitive elementary reasoning regarding their structural properties and relations, and in this way proofs of consistency can be carried out. Various devices for proving consistency were also exhibited.

Hilbert's investigations of the foundations of arithmetic remained in this provisional state for a long time. During the interval major developments took place in the foundations of mathematics and in mathematical logic. Zermelo proved the well-ordering theorem and published his axiom system for set theory in 1908. Two years later the first volume of Russell and Alfred North Whitehead's *Principia Mathematica* appeared. Julius König attempted to carry out Hilbert's plan, but his work was interrupted by his premature death and appeared only in fragmentary form, edited by his son, in 1914 (*Neue Grundlagen der Logik, Arithmetik und Mengenlehre,* Leipzig, 1914). In this work some steps of the later Hilbert proof theory are already carried out, but Hilbert did not know of it when he again took up his investigation of the foundations of arithmetic.

PROOF THEORY

Hilbert's return to the problem of the foundations of arithmetic was announced by his delivery at Zürich in 1917 of the lecture "Axiomatisches Denken." In the latter part of this lecture he pointed out several epistemological questions which, as he said, are connected with that of the consistency of number theory and set theory: the problem of the solubility in principle of every mathematical question; that of finding a standard of simplicity for mathematical proofs; that of the relation of contents and formalism in mathematics; and that of the decidability of a mathematical question by a finite procedure. Questions of this kind, he observed, seem to constitute a domain that should be investigated, and to carry out this investigation it will be necessary to inquire into the concept of mathematical proof. The general idea and the aims of proof theory were thus proclaimed, but the means of investigation were not thereby fixed, for indeed the theory was not to rely on the current mathematical methods.

At the time of his Zürich lecture Hilbert tended to restrict the methods of proof-theoretic reasoning to the most primitive evidence. The apparent needs of proof theory induced him to adopt successively those suppositions which constitute what he then called the "*finite Einstellung.*"

CONSISTENCY. In his first publication on proof theory, "Neubegründung der Mathematik, Erste Mitteilung," Hilbert explains how number theory can be treated in a finitist way, whereas mathematics in general transcends finitist methods. But, Hilbert argues, we can regain an elementary kind of mathematical objectivity by formalizing the statements and proofs, using the methods of sym-

bolic logic, and by taking the representing formulas and proofs directly as objects. In the same paper Hilbert also gives indications of the nature of formalization and presents an instance of a proof of consistency—as yet for only a very restricted system.

A more advanced stage is reached in Hilbert's lecture at the Leipzig congress of the Deutsche Naturforscher Gesellschaft in 1922, "Die logische Grundlagen der Mathematik."

In this speech the method is presented of dealing in proof theory with the logical forms of generality and existence (quantifiers) by means of a logical choice function which assigns to any predicate A an object τA for which A holds only if it is generally satisfied. This idea is formally expressed by the "transfinite axiom," $A(\tau A) \to A(a)$, in which a predicate expression can be substituted for A and any term representing an individual can be substituted for a. A slight modification, soon applied, replaced the function τA by the function ϵA, dual to it, whose axiom is $A(a) \to A(\epsilon A)$.

By means of the choice function the quantifiers can be eliminated from a formalized proof in such a way that the rules for the use of "all" and "exists" are reduced to applications of the transfinite axiom, so that the explicit logical structure of the proof becomes transformed into an elementary one, consisting only in applications of the propositional calculus and substitutions.

The task of proving the consistency of a formalized domain of arithmetic is thus essentially reduced. This task—in virtue of the law "ex falso quodlibet"—amounts to showing that the formula $0 \neq 0$ cannot be derived in the domain; in other words, to showing that in any formal derivation of the formalized domain having a numerical end formula, this end formula differs from the formula $0 \neq 0$. Consideration of formalized proofs can now be restricted to those obtained by the transformation using the function ϵA. The main problem is then to eliminate the formulas resulting from the transfinite axiom by substitution (the "critical formulas").

The method that Hilbert indicates for attacking this problem consists—after first removing the free variables, which is possible—of a sequence of steps. In each step the terms that occur are replaced by numerical values. Then, either all critical formulas turn into true numerical formulas, and the attempted elimination is effected, or the result of the step determines a next step. It must still be shown that the process has an end, and this, at least in the simple cases, can be seen to hold.

This method is not in principle restricted to cases where the predicates to which the logical choice function applies are number predicates and where the individuals are therefore natural numbers; it can also be used for individuals of higher types. The particular case in which number functions are taken as individuals is essential to the formalization of the theory of real numbers. In the Leipzig lecture, Hilbert gave several indications of how this formalization can be performed; in particular, he showed how some form of the Zermelo choice principle (used in the theory of functions of real numbers) can be derived from the transfinite axiom related to the type of real numbers (as individuals).

Thus, it seemed that carrying out proof theory was only a question of mathematical technique. Such an expectation, however, turned out to be illusory. An indication was that the first substantial consistency proof following Hilbert's scheme of reasoning by Wilhelm Ackermann (in his thesis, "Begründung des 'tertium non datur' mittels der Hilbertschen Theorie der Widerspruchsfreiheit") required an essential restriction of the formal system not envisaged in the original plan. Similarly, in John von Neumann's inquiry "Zur Hilbertschen Beweistheorie," where a formal system for the logic of first and second order (including the first four Peano axioms) was set up and a consistency proof using Hilbert's method was given, the consistency proof did not apply to the full system but excluded the comprehension axiom, which provides the manipulation of substitutions for variables of second type. Thus, two highly able investigators did not succeed in obtaining a consistency proof for a formal system of the theory of real numbers by means of the above-mentioned Hilbert method (connected with the logical choice function) of eliminating the critical formulas.

A second method of eliminating the critical formulas, devised by Hilbert and elaborated by Ackermann, yields the proof of a general theorem which states that any axiomatic system, formalized within the frame of standard logic (that is, propositional logic and the rules governing quantifiers), whose axioms have a finitist interpretation is consistent (see Hilbert and Bernays, *Grundlagen der Mathematik,* Vol. II, Sec. I, esp. pp. 18–38). The method is one of the easiest for proving an important theorem of mathematical logic (first stated by Jacques Herbrand in his doctoral dissertation) that yields a kind of normal form for derivations in pure logic and which also can be applied to decision problems. But this method is not sufficient to demonstrate the consistency of the

proper formal system of number theory and therefore is the less sufficient for the systems of infinitesimal analysis.

COMPLETENESS. Ackermann revised and simplified the proof presented in his thesis. It was thought that by this modified proof and by that of von Neumann the consistency of formalized number theory, at least, had been proved. Such was the situation when Hilbert presented, at the International Congress of Mathematicians in Bologna in 1928, his "Probleme der Grundlegung der Mathematik." To the problem of proving consistency he here added two problems of completeness: the problem of showing that every universally valid logical schema is derivable by the rules of the predicate calculus and the problem of showing the completeness of formalized number theory, in the sense that the formal system of number theory contains no formula which, together with its negation, can be shown to be underivable in the system.

GÖDEL'S RESULTS. Kurt Gödel soon took up both these problems of completeness, but he stated completeness only for the case of the predicate calculus (first-order functional calculus), whereas he proved the incompleteness of formalized number theory even in the strong sense that no strictly formal system is possible in which each true number-theoretic proposition is derivable. At the same time Gödel proved a theorem from which it follows that a finitist proof of consistency for a formal system strong enough to formalize all finitist reasonings is impossible ("Über formale unentscheidbare Sätze der Principia Mathematica und verwandte Systeme I"). Von Neumann was convinced that this last condition holds for the formal system of number theory, and hence he inferred that Gödel's result implies the impossibility of a finitist consistency proof not only for the broader systems discussed by Gödel but even for the formal system of number theory.

To corroborate this inference he was able to show that in the proof of consistency of the formal system of number theory by the elimination of critical formulas, the demonstration that the process of elimination has an end did not apply in full generality (see Hilbert and Bernays, *Grundlagen,* Vol. II, pp. 123–125). It thus became clear that in two respects Hilbert's program demanded more than can be fulfilled: Mathematical theories cannot be formalized with full adequacy, and consistency proofs cannot be strictly finitist in the essential cases.

BROADENING OF PROOF THEORY. It soon became apparent that proof theory could be fruitfully developed without fully keeping to the original program. It was discovered that a proof of consistency for the formal system of number theory, although not a finitist one, is possible by methods of proof admitted by L. E. J. Brouwer's intuitionism.

Arend Heyting, in two papers of 1930, set up a formal system of intuitionistic number theory. And, as Gödel and Gerhard Gentzen independently observed, there is a relatively simple method of showing that any contradiction derivable in the formal system of classical number theory would entail a contradiction in Heyting's system. Hence, from the consistency of Heyting's system the consistency of the classical system follows (Kurt Gödel, "Zur intuitionistischen Arithmetik und Zahlentheorie"—Gentzen withdrew his own paper, already in print, because of the appearance of Gödel's paper).

In this way it appeared that intuitionistic reasoning is not identical with finitist reasoning, contrary to the prevailing views at that time. In particular, intuitionistic reasoning deals with concepts not admitted as methods in finitist proofs, such as the quite general concept of consequence when it is not delimited by any rules of proof. It thus became apparent that the "*finite Standpunkt*" is not the only alternative to classical ways of reasoning and is not necessarily implied by the idea of proof theory. An enlarging of the methods of proof theory was therefore suggested: Instead of a restriction to finitist methods of reasoning, it was required only that the arguments be of a constructive character, allowing us to deal with more general forms of inference.

By this modification of the program, various proofs of consistency for the formal system of number theory were obtained, the first by Gentzen ("Die Widerspruchsfreiheit der reinen Zahlentheorie," "Die gegenwärtige Lage in der mathematischen Grundlagenforschung," and "Neue Fassung des Widerspruchsfreiheitsbeweises für die reine Zahlentheorie"). Ackermann was then able to complete the consistency proof proceeding by the method of eliminating the critical formulas ("Zur Widerspruchsfreiheit der Zahlentheorie"). The broadened methods also permitted a loosening of the requirements of formalizing. One step in this direction, made by Hilbert himself, was to replace the schema of complete induction by the stronger rule later called infinite induction ("Die Grundlegung der elementaren Zahlenlehre" and "Beweis des Tertium non datur").

However, going beyond finitist methods is not generally required in proof theory; many important results have been obtained by finitist methods, results concerning the following topics: pure logic, the combinatorial

calculus, completeness (the completeness of a system of real algebra), undecidability, and relative consistency.

One main result concerning relative consistency is connected with Hilbert's attempt at a positive solution of Cantor's continuum problem in the paper "Über das Unendliche." The sketch of a proof given in this work contains many detailed arguments, and it stimulated the study of recursive definitions. As a whole, however, the sketch was fragmentary, and there were in principle hindrances to its completion. Twelve years later Gödel connected the ideas of Hilbert's paper with the concepts of axiomatic set theory and proved the consistency of Cantor's continuum hypothesis in its generalized form on the assumption that axiomatic set theory (without the axiom of choice) is consistent. (Nevertheless, this result, which is obtained by a powerful method of proof, does not settle the continuum problem. In fact, from results obtained by Paul Cohen it appears that axiomatic set theory, at least in its formal delimitation, leaves this problem fully undecided.)

On the whole, Hilbert's idea of making mathematical proof an object of mathematical research by means of formalization has proved to be very fruitful. And although Hilbert's work in the foundations of arithmetic has not had the effect he sought, "to remove once and for all the questions of foundations in mathematics" ("die Grundlagenfragen in der Mathematik als solche endgültig aus der Welt zu schaffen"—"Die Grundlagen der Mathematik," p. 65, and "Die Grundlagen der elementaren Zahlenlehre," p. 489), he did establish proof theory as a valuable domain of mathematical investigation, and thus Hilbert was a pioneer in the newer mathematical foundation theory, as he was in many other fields of mathematics.

Bibliography

WORKS BY HILBERT

On the Foundations of Geometry

Die Grundlagen der Geometrie. Leipzig: Teubner, 1899; 9th ed., Stuttgart, 1961. The first edition was published as a *Festschrift* for the unveiling of the Gauss-Weber memorial. The second and later editions were published as textbooks.

Most incorporate modifications and additions. Translated by E. J. Townsend as *Foundations of Geometry.* La Salle, IL: Open Court, 1902.

"Über den Satz von der Gleichheit der Basiswinkel im gleichschenkligen Dreieck." *Proceedings of the London Mathematical Society* 35 (1903): 50–68. Reprinted as Appendix II to the *Grundlagen,* 9th ed., 133–158.

"Über die Grundlagen der Geometrie." *Mathematische Annalen* 56 (1902): 381–422. Reprinted as Appendix IV to the *Grundlagen,* 9th ed., 178–230.

"Neue Begründung der Bolyai-Lobatschefskyschen Geometrie." *Mathematische Annalen* 57 (1903): 137–150. Reprinted as Appendix III to the *Grundlagen,* 9th ed., 159–177.

On the Foundations of Arithmetic

"Die Theorie der algebraischen Zahlkörper." *Jahresbericht der Deutschen Mathematikervereinigung* 4 (1897), I–XVIII, 175–546.

"Über den Zahlbegriff." *Jahresbericht der Deutschen Mathematikervereinigung* 8 (1900): 180–184. Reprinted as Appendix VI to the *Grundlagen,* 7th ed., 241–246. Leipzig, 1930.

"Über die Grundlagen der Logik und Arithmetik." In *Verhandlungen des Dritten Internationalen Mathematiker-Kongresses in Heidelberg vom 8. bis 13. August 1904,* 174–185. Leipzig, 1905. Reprinted as Appendix VII to the *Grundlagen,* 7th ed., 247–261.

"Axiomatisches Denken." *Mathematische Annalen* 78 (1918): 405–415.

"Neubegründung der Mathematik. Erste Mitteilung." *Abhandlungen aus dem mathematische Seminar der Hamburgischen Universität* 1 (1922): 157–177.

"Die logischen Grundlagen der Mathematik." *Mathematische Annalen* 88 (1923): 151–165.

"Über das Unendliche." *Mathematische Annalen* 95 (1926): 161–190.

"Die Grundlagen der Mathematik." *Abhandlungen aus dem mathematische Seminar der Hamburgischen Universität* 6 (1928): 65–85.

"Probleme der Grundlegung der Mathematik." *Mathematische Annalen* 103 (1929): 1–9.

"Die Grundlegung der elementaren Zahlenlehre." *Mathematische Annalen* 104 (1931): 485–494.

"Beweis des Tertium non datur." *Nachrichten des Gesellschaft der Wissenschaft zu Göttingen* (1931): 120–125.

Textbooks

Grundzüge der theoretischen Logik. With W. Ackermann. Berlin: Springer, 1928; 3rd ed., 1949. Translated by Lewis M. Hammond and others as *Principles of Mathematical Logic.* New York: Chelsea, 1950.

Grundlagen der Mathematik. 2 vols. With Paul Bernays. Berlin: Springer, 1934–1939.

Collected Works

Gesammelte Abhandlungen. 3 vols. Edited by Ernst Hellinger, Paul Bernays, and Otto Blumenthal. Berlin: Springer, 1932–1935.

STUDIES RELATED TO HILBERT'S WORK

Bernays, Paul. "Die Bedeutung Hilberts für die Philosophie der Mathematik." *Die Naturwissenschaften,* 10th year (1922),

No. 1. This number was devoted to Hilbert on his sixtieth birthday. It contains the following papers: Otto Blumenthal, "David Hilbert"; Otto Toeplitz, "Der Algebraiker Hilbert"; Max Dehn, "Hilberts geometrisches Werk"; Richard Courant, "Hilbert als Analytiker"; Max Born, "Hilbert und die Physik"; and a list of Hilbert's publications up to 1921 compiled by Karl Siegel.

Bernays, Paul. "Die Philosophie der Mathematik und die Hilbertsche Beweistheorie." *Blätter für deutsche Philosophie. Zeitschrift der Deutschen Philosophischen Gesellschaft* (Berlin) 4 (3–4) (1930): 326–367. This number also contains articles on the foundations of mathematics by Heinrich Scholz, A. Fraenkel, Rudolf Carnap, Carl Menger, and Walter Dubislav.

Bernays, Paul. "Sur le platonismc dans les mathématiques." *L'enseignement mathématique* 34 (1935): 52–60.

Bernays, Paul. "Über Hilberts Gedanken zur Grundlegung der Arithmetik." *Jahresbericht der Deutschen Mathematikervereinigung* 31 (1922): 10–19.

Bernays, Paul. "Hilberts Untersuchungen über die Grundlagen der Arithmetik." In *Gesammelte Abhandlungen,* by David Hilbert, Vol. III, 191–216. Berlin: Springer, 1935.

Blumenthal, Otto. "Lebensgeschichte," in *Gesammelte Abhandlungen,* by David Hilbert (see above), Vol. III, 388–429.

Kreisel, Georg. "Hilbert's Programme." *Dialectica* 88 (1923): 151–165. Reprinted in *Philosophy of Mathematics,* edited by Paul Benacerraf and Hilary Putnam, 157–180. Englewood Cliffs, NJ: Prentice-Hall, 1964.

On the Foundations of Geometry

Baldus, Richard. "Zur Axiomatik der Geometrie III. Über das Archimedische und das Cantorsche Axiom." In *Sitzungsbericht des Heidelberger Akademie des Wissenschaft,* 5. Abhandlung, 3–12. Leipzig, 1930.

Bernays, Paul. "Bemerkungen zu den Grundlagen der Geometrie." In *Studies and Essays Presented to R. Courant on His 60th Birthday,* 29–44. New York: Interscience, 1948.

Dehn, Max. "Über den Rauminhalt." *Mathematische Annalen* 55 (1902): 465–478.

Neumann, John von. "Zur Hilbertschen Beweistheorie." *Mathematische Zeitschrift* 26 (1927): 1–46.

Paul Bernays (1967)

HILBERT, DAVID [ADDENDUM]

Bernays's entry on Hilbert still reads, after forty years, as a wonderful account of the essential contributions by Hilbert to the foundations of geometry and proof theory. However, recent developments have substantially increased the understanding of Hilbert's original investigations and pushed these investigations further. The following bibliography will help the reader navigate among the most important recent contributions. It is divided into four parts: (1) contributions to Hilbert's biography and mathematical work emerging from Hilbert's famous list of problems given in Paris in 1900; (2) historical work related to Hilbert's foundational views; (3) logico-foundational and philosophical developments related to Hilbert's program; and (4) ongoing work of publication of Hilbert's and Bernays's work.

See also Mathematics, Foundations of.

Bibliography

BIOGRAPHY AND MATHEMATICAL DEVELOPMENTS EMERGING FROM HILBERT'S PROBLEMS

The only book-length biography available is Constance Reid's *Hilbert* (New York: Springer, 1970). For mathematical developments arising from Hilbert's list of 23 problems in Paris, see Jeremy Gray's *The Hilbert Challenge* (Oxford: Oxford University Press, 2000) and Benjamin H. Yandell's *The Honors Class: Hilbert's Problems and Their Solvers* (Natick, MA: A. K. Peters, 2002).

HISTORICAL STUDIES OF HILBERT'S FOUNDATIONAL WORK

There has been a substantial amount of work in the study of the development of Hilbert's foundational views. A novelty in this area is the study of his work on the foundations of physics. Most of this scholarship is characterized by the extensive use of the Hilbert Nachlaß in Göttingen. The work has been divided below by periods.

Foundations of Geometry (1891–1899)

Toepell, Michael-Markus. *Über die Entstehung von Hilberts "Grundlagen der Geometrie."* Göttingen, Germany: Vandenhoeck und Ruprecht, 1986.

Axiomatizations of Physical Theories (1895–1917)

Corry, Leo. "David Hilbert and the Axiomatization of Physics." *Archive for History of Exact Sciences* 51 (1997): 83–198.

Corry, Leo. "Hilbert and Physics (1900–1915)." In *The Symbolic Universe: Geometry and Physics (1890–1930)*, edited by Jeremy Gray, 145–187. New York, Oxford University Press, 1999.

Majer, Ulrich. "The Axiomatic Method and the Foundations of Science: Historical Roots of Mathematical Physics in Göttingen (1900–1930)." In *John von Neumann and the Foundations of Quantum Physics*, edited by Miklos Redi and

Michael Stoeltzner, 11–33. Dordrecht, Netherlands: Kluwer, 2001.

Sauer, Tilman. "The Relativity of Discovery: Hilbert's First Note on the Foundations of Physics." *Archive for History of Exact Sciences* 53 (1999): 529–575.

From Axiomatics to Proof Theory (1900–1922)

Peckhaus, Volker. *Hilbertprogramm und kritische Philosophie.* Göttingen, Germany: Vandenhoeck und Ruprecht, 1990.

Mancosu, Paolo. "Between Russell and Hilbert: Behmann on the Foundations of Mathematics." *The Bulletin of Symbolic Logic* 5 (3) (1999): 303–330.

Sieg, Wilfried. "Hilbert's Programs: 1917–1922." *The Bulletin of Symbolic Logic* 5 (1999): 1–44.

Mancosu, Paolo. "The Russellian Influence on Hilbert and His School." *Synthese* 137 (2003): 59–101.

Development of Logic in Hilbert's School (1905–1928)

Hallett, Michael. "Hilbert and Logic." In *Québec Studies in the Philosophy of Science*, pt. 1, vol. 177, edited by Mathieu Marion and Robert Cohen, 135–187. Dordrecht, Netherlands: Kluwer, 1995.

Peckhaus, Volker. "Hilberts Logik. Von der Axiomatik zur Beweistheorie." *Intern. Zs. f. Gesch. u. Ethik der Naturwiss. Tech. u. Med.* 3 (1995): 65–86.

Zach, Richard. "Completeness Before Post: Bernays, Hilbert, and the Development of Propositional Logic." *The Bulletin of Symbolic Logic* 5 (3) (1999): 331–366.

Moore, Gregory "Hilbert and the Emergence of Modern Mathematical Logic." *Theoria* 12 (1) (1997): 65–90.

Avigad, Jeremy, and Richard Zach. "The Epsilon Calculus." *Stanford Encyclopedia of Philosophy*. Available at http://plato.stanford.edu/entries/epsilon-calculus/.

Proof Theory and Finitism Until Gödel's Theorems (1922–1931)

Majer, Ulrich. "Hilberts Methode der idealen Elemente und Kants regulativer Gebrauch der Ideen." *Kant-Studien* 84 (1993): 51–77.

Mancosu, Paolo. "Hilbert and Bernays on Metamathematics." In *From Brouwer to Hilbert: The Debate on the Foundations of Mathematics in the 1920s*, pp. 149–188. New York: Oxford University Press, 1988.

Zach, Richard. 2003 "The Practice of Finitism: Epsilon Calculus and Consistency Proofs in Hilbert's Program." *Synthese* 137 (2003): 211–259.

LOGICO-FOUNDATIONAL AND PHILOSOPHICAL CONTRIBUTIONS (1970–2003)

Logico-Foundational Developments

The best starting point are the articles from "A Symposium on Hilbert's Program":

Feferman, Solomon. "Hilbert's Program Relativized: Proof-Theoretical and Foundational Reductions." *Journal of Symbolic Logic* 53 (1988): 364–383.

Simpson, Steven. "Partial Realizations of Hilbert's Program." *Journal of Symbolic Logic* 53 (1988): 349–3631.

Sieg, Wilfried. "Hilbert's Program Sixty Years Later." *Journal of Symbolic Logic* 53 (1988): 338–348.

For further references see Richard Zach's "Hilbert's Program" in the *Stanford Encyclopedia of Philosophy*. Available at http://plato.stanford.edu/entries/hilbert-program/.

Philosophical Contributions

Kitcher, Philip. "Hilbert's Epistemology." *Philosophy of Science* 43 (1976): 99–115.

Tait, William. "Finitism." *Journal of Philosophy* 78 (1981): 524–546.

Detlefsen, Michael. *Hilbert's Programme: An Essay on Mathematical Instrumentalism*. Dordrecht, Netherlands: Reidel, 1986.

Hallett, Michael. "Physicalism, Reductionism and Hilbert." In *Physicalism in Mathematics*, edited by Andrew D. Irvine, 183–257. Dordrecht, Netherlands: Kluwer, 1990.

Parsons, Charles. "Finitism and Intuitive Knowledge." In *The Philosophy of Mathematics Today*, edited by Matthias Schirn, 249–270. Oxford: Oxford University Press, 1998.

TRANSLATIONS AND EDITIONS OF HILBERT AND BERNAYS

Van Hejenoort 1967, Ewald 1996, and Mancosu 1998 provide an extensive coverage of translations into English of most of Hilbert's and Bernays's published articles on the foundations of mathematics for the period 1900–1931:

Ewald, William. *From Kant to Hilbert: Readings in the Philosophy of Mathematics*. Oxford: Oxford University Press, 1996.

Mancosu, Paolo., ed. *From Brouwer to Hilbert: The Debate on the Foundations of Mathematics in the 1920s*. New York: Oxford University Press, 1998.

van Heijenoort, Jean. 1967 *From Frege to Gödel*. Cambridge, MA: Harvard University Press, 1967.

In addition there are two scholarly editions in the making. The *Hibert Edition* (six volumes, Springer Verlag) includes a selection of the original unpublished lecture notes (in German) preserved at the University of Göttingen. The first volume, edited by Michael Hallett, appeared in 2004. There is also in preparation an edition of Bernays's foundational writings in English, a description of which is available at http://www.phil.cmu.edu/projects/bernays/. This edition is scheduled to appear some time after 2004 for Open Court.

Paolo Mancosu (2005)

HILDEGARD OF BINGEN
(1098–1179)

Hildegard of Bingen, the first German mystic, wrote profusely as a prophet, poet, dramatist, musician, physician, and political moralist. She was an extraordinary woman who exerted a tremendous temporal and spiritual influence on her time and who has been rediscovered since the 1960s.

Hildegard was born in Bockelheim, the diocese of Mainz, on the Nahe River. Her father, Hildebert, was a knight in the service of Count Meginhard of Spanheim. At six, she began to have religious visions that continued the rest of her life. At eight, she was entrusted to the care of Jutta, sister of Count Meginhard. The two lived in a small cottage adjoining the church abbey at Disibodenberg. A sickly child, Hildegard continued her education under Jutta, learning to read and sing Latin. At fifteen, she was clothed in the habit of a nun in Jutta's hermitage, a community following the Rule of St. Benedict. At thirty-eight, Hildegard became the abbess of the community.

Eventually, the archbishop of Mainz examined her visions with his theologians and ruled them divinely inspired, ordering Hildegard to record them in writing. From 1141 until 1151, she worked on her principal work, *Scivias* (*May You Know*, or *Know the Ways*). In 1147, Pope Eugenius III and his commission examined her visions and also authorized her to write whatever the Holy Spirit inspired her to write. Her growing fame then caused Hildegard to transfer her convent from Disibodenberg to Rupertsberg, near Bingen, between 1147 and 1150. She continued living there until her death on September 17, 1179. She was buried in her convent church, where her relics remained until 1632, when the convent was destroyed by the Swedes and her relics moved to Eibingen.

A woman of an extraordinarily energetic and independent mind, Hildegard wrote voluminously. *Scivias*, the first of her three mystical works, develops her view on the universe, on the theory of macrocosm and microcosm, the structure of humans, birth, death, and the nature of the soul. It also treats the relations between God and humans in creation, the redemption, and the church. The last of the twenty-six visions of *Scivias* contains *Ordo Virtutum*, the earliest liturgical morality play.

Liber Vitae Meritorum (*The Book of the Rewards of Life*, 1158–1163) studies the weaknesses separating us from God. It is one of the most subtle, psychologically fascinating, and intense works ever written on the relationship of various sins to their corresponding virtues.

Liber Divinorum Operum Simplicis Hominis (*The Book of the Divine Works of a Simple Man*, 1163–1173), the third of Hildegard's mystical books, concerns itself with the unity of creation. Hildegard succeeds in synthesizing into one great whole her theological beliefs along with her knowledge of the elements of the universe and the structures within the human body. This work is often considered the epitome of science of her time.

Besides her three mystical books, Hildegard wrote a long physical treatise titled *Physica: Subtilitatum Diversarum Naturarum Creaturarum* (*Physical Things: Of the Simplicities of Various Natural Creatures*, 2001) and her book of medicine titled *Causae et Curae* (*Causes and Cures*, 1903). Although her theoretical knowledge of

medicine seems crude today, large numbers of sick and suffering persons were brought to her for cures. A thriving clinic in Konstanz, Germany, practices Hildegard's remedies today.

In addition, Hildegard wrote *Vita Sancti Disibodi* (*The Life of Saint Disibod*) and *Vita Sancti Ruperti* (*The Life of Saint Rupert*). Her *Solutiones Triginta Octo Quaestionum* (*Answers to Thirty-eight Questions*) comments on various theological and scriptural subjects. Her *Explanatio Symboli Athanasii* (*Explanation of the Symbol of Saint Athanasius*) and *Explanatio Regulae Sancti Benedicti* (*Explanation of the Rule of Saint Benedict*), written at the request of the Benedictine monastery of Huy in Belgium, are self-explanatory.

For the nuns of her convent, Hildegard wrote hymns and canticles—both words and music. She collected her songs into a cycle titled *Symphonia Armonie Celestium Revelationum* (*The Symphony of the Harmony of Heavenly Revelations*). These approximately seventy songs were written for a wide range of liturgical celebrations.

Finally, Hildegard wrote letters to popes, cardinals, bishops, abbots, kings and emperors, monks and nuns, men and women of various social levels both in Germany and abroad. Some of her letters are more personal, but the majority are mystical treatises, prophecies, sermons, and strong exhortations concerning various corruptions. Hildegard's clear intelligence foresaw that the ecclesiastical and political abuses of her time would ultimately burst into flames in some event such as the eventual Reformation or the Thirty Years' War. Hildegard represented a legacy to her own times, and now has been rediscovered in ours.

See also Macrocosm and Microcosm; Mysticism, History of; Women in the History of Philosophy.

HINTIKKA, JAAKKO
(1929–)

The logician and philosopher Jaakko Hintikka was born in Vantaa, Finland. Receiving his doctorate from the University of Helsinki in 1956, he was a junior fellow at Harvard University from 1956 to 1959, a research professor at the Academy of Finland, and a professor of philosophy at the universities of Helsinki, Stanford, Florida State, and currently Boston University.

Hintikka developed semantical logical methods and uses them in philosophy. He advocates applying mathematical logic, especially model theory, in philosophy, most notably to questions in philosophy of language, but also to the study of Aristotle, Immanuel Kant, and Ludwig Wittgenstein. His main contributions in logic are those of model set, distributive normal form, possible-worlds semantics, and game-theoretic semantics.

A critical view of the Tarski truth definition led Hintikka to the concept of a model set as a more constructive approach to semantics. A model set has enough information to build a canonical term model in which sentences belonging to the set are true.

A model set is a set S of first-order formulas without identity (for simplicity), with negation in front of atomic formulas only, in a countable vocabulary, and containing possibly new individual constants, such that:

(1) No atomic sentence φ satisfies both $\varphi \in H$ and $\neg \varphi \in H$

(2) If $\varphi \wedge \psi \in H$, then $\varphi \in H$ and $\psi \in H$

(3) If $\varphi \vee \psi \in H$, then $\varphi \in H$ or $\psi \in H$

(4) If $\exists x \varphi(x) \in H$, then $\varphi(c) \in H$ for some constant c

(5) If $\forall x \varphi(x) \in H$, then $\varphi(c) \in H$ for all constants c occurring in H

A sentence has a model if and only if it is an element of a model set. Attempts to build a model set around the negation of a sentence form a tree, known as a semantic (or Beth) tableau. Infinite branches of this tree are model sets for $\neg \varphi$. If the tree has no infinite branches, it is finite and can be considered a proof of φ in the style of Jacques Herbrand and Gerhard Gentzen. Model sets came to play a central role in Hintikka's other work, such as distributive normal forms, possible-worlds semantics, and game-theoretic semantics.

Distributive normal forms, first introduced in monadic predicate logic by Georg Henrik von Wright, are defined as follows: Let $A_i^n(x_1, \ldots, x_n)$, $i \in K^n$ list all atomic formulas in a finite relational vocabulary (without identity, for simplicity), and the variables $x_1, \ldots, x_n$. If F is a formula, let $[F]^0 = F$ and $[F]^1 = \neg F$. Let $C_i^{0,n}(x_1, \ldots, x_n)$, $i \in I^{0,n}$ list all possible conjunctions $\bigwedge_j [A_j^n(x_1, \ldots, x_n)]^{\epsilon(j)}$ where ϵ runs through all functions $K^n \to \{0, 1\}$. Let $C_i^{m+1,n}(x_1, \ldots, x_n)$ $i \in I^{m+1, n}$ list all possible formulas

$$\bigwedge_{j \in J} \exists x_{n+1} C_j^{m,n+1}(x_1, \ldots, x_{n+1}) \wedge \forall x_{n+1}$$

$$\bigvee_{i \in J} C_j^{m,n+1}(x_1, \ldots, x_{n+1}),$$

where $J \subseteq I^{m,n+1}$.

If $a_1, \ldots, a_n$ satisfy $C_i^{m,n}(x_1, \ldots, x_n)$ in a model M and $b_1, \ldots, b_n$ satisfy $C_i^{m,n}(x_1, \ldots, x_n)$ in a model N, then $C_i^{m,n}(x_1, \ldots, x_n)$ codes a winning strategy for player 2 in the m-move Ehrenfeucht-Fraïssé game starting from the position $\{(a_1, b_1), \ldots, (a_n, b_n)\}$.

Every first-order sentence ϕ of quantifier rank m is logically equivalent to a unique disjunction of formulas of the form $C_i^{m,0}$. This disjunction is the distributive normal form of ϕ. The process of finding the distributive normal form of a given sentence cannot be made effective. Intuitively, one pushes quantifiers as deep into the formula as possible.

Distributive normal forms can be used to systematize definability theory, such as the Beth definability theorem, the Craig interpolation theorem, and the Svenonius theorem, and to systematize infinitary logic, emphasizing formal aspects more than the game-theoretic approach by Robert Vaught.

In the logic of induction Hintikka used distributive normal forms to give, in contrast to Rudolf Carnap, positive probabilities for universal generalizations. He developed a theory of surface information to support a thesis of the nontautological nature of logical inference, with applications to Kant's analytic-synthetic distinction.

Hintikka's formal definition of possible-worlds semantics, or model systems, for modal and epistemic logic is based on his concept of model set, unlike Saul Kripke's approach, which uses actual models as possible worlds.

A model system ($\mathfrak{C}$, R) consists of a set $\mathfrak{C}$ of model sets and a binary alternativeness-relation R on $\mathfrak{C}$ such that:

(1) If $\Box\phi \in H \in \mathfrak{C}$, then $\phi \in H$.

(2) If $\Diamond\phi \in H \in \mathfrak{C}$, then there exists an alternative $H' \in \mathfrak{C}$ to H such that $\phi \in H'$.

(3) If $\Box\phi \in H \in \mathfrak{C}$ and $H' \in \mathfrak{C}$ is an alternative to H, then $\phi \in H'$.

A set S of formulas is defined to be satisfiable if there is a model system ($\mathfrak{C}$, R) such that $S \subseteq H$ for some $H \in \mathfrak{C}$. A formula ϕ is valid if its negation is not satisfiable. Hintikka applied possible-worlds semantics to epistemic logic, deontic and modal logic, and the logic of perception and to the study of Aristotle and Kant. (See Hintikka [1969] for a summary of his theory of possible-worlds semantics. Hintikka's 1962 book is well-known outside of philosophy, most notably in the study of artificial intelligence and theoretical computer science.)

Game-theoretic semantics has its origin in Wittgenstein's language-games, Paul Lorenzen's dialogue games, Ehrenfeucht-Fraïssé games, and Leon Henkin's game theoretic interpretation of quantifiers. The semantic game of a sentence ϕ in a model M is a game between myself and nature about a formula ϕ and an assignment s. For $\phi = \phi_1 \wedge \phi_2$, nature chooses ϕ_i. For $\phi = \phi_1 \vee \phi_2$, I choose ϕ_i. Then we continue with ϕ_i and s. For $\phi = \forall x\psi(x)$, nature chooses s', which agrees with s outside x. For $\phi = \exists x\psi(x)$, I choose such s'. Then we continue with $\psi(x)$ and s'. For negation, we exchange roles. For ϕ atomic, the game ends. I win if s satisfies ϕ in M, otherwise nature wins.

Game-theoretic semantics became Hintikka's tool for analyzing natural language, particularly pronouns, conditionals, prepositions, definite descriptions, and the *de dicto* versus *de re* distinction and for challenging the approach of generative grammar. Sentences like "Every writer likes a book of his almost as much as every critic dislikes some book he has reviewed" led Hintikka to consider partially ordered quantifiers and eventually independence friendly (IF) logic (1996), with existential quantifiers $\exists x/y$, meaning that a value for x is chosen independently of what has been chosen for y. Thus, the semantic game of IF logic is a game of partial information.

IF logic is equal in expressive power to the existential fragment of second-order logic. The satisfiability of a sentence can still be analyzed in terms of model sets, but not provability. Wilfrid Hodges (1997) gave IF logic a compositional semantics in terms of sets of assignments, and Peter Cameron and Hodges (2001) proved it has no compositional semantics in terms of assignments only. Truth in various structures of mathematics can be reduced to logical consequence in IF logic, as in full second-order logic. IF logic has no negation and is not axiomatizable. This is countered by IF logic having a truth definition in IF logic.

HIPPIAS OF ELIS

Hippias of Elis, the Greek Sophist and polymath, was probably born before 460 BCE. The date of his death is not known, but Plato speaks of him as one of the leading Sophists at the time of the death of Socrates in 399 BCE. On a number of occasions he acted as ambassador for his native city and also traveled widely, earning very large sums of money. He claimed to be a master of all the learning of his day, and his teaching and writings included elegies, tragedies, dithyrambs, historical works, literary discourses, epideictic speeches, discussions of astronomy, geometry, arithmetic, music, painting, sculpture, and ethics, and a technical system of mnemonics. None of his writings survives, but a reference in a papyrus book list of the third century suggests that at least one of his works survived until that date. Our knowledge of his teaching rests above all upon the picture of him given in Plato's dialogues, the *Hippias Major* (now generally accepted as written by Plato), the *Hippias Minor*, and the brief sketch in the *Protagoras*.

His polymathy invites comparison with Plato's more philosophic approach to reality, and Hippias has often been presented as standing for a superficial encyclopedic approach to knowledge, in contrast with the more profound penetration of the genuinely philosophic search for truth. This is the way Plato came to view all the Sophists, but it is probably unfair to Hippias, who in some ways anticipated Aristotle's approach to the whole range of human knowledge. Mathematics and astronomy in the sophistic period were certainly not studied for their practical application in everyday life but, rather, in the pursuit of knowledge for its own sake. Hippias made a really important contribution to mathematical development through his discovery of the curve known as the quadratrix, used for the trisection of an angle and later in attempts to square the circle. He was also used by Eudemus as a source for the early history of geometry, which would suggest that he himself may have written a history of mathematics. He was fairly certainly the source of Aristotle's information about the doctrines of Thales, and he may also have been responsible for the main lines of the schematized picture of the history of the pre-Socratics found in Plato's *Sophist* (242D).

Whether he had any general theory of the nature of reality is not certain, but it is probable that he did. In the *Hippias Major*, Plato attributes to him a "continuous doctrine of being," which implies that some particular doctrine was regularly attributed to him. This doctrine dealt with "continuous physical objects that spring from being" (301B), and was opposed to Socrates's attempt to distinguish "the beautiful" from "beautiful objects." While the details of the doctrine are not given, it seems clear that Hippias objected to attempts to explain phenomena in terms of qualities or entities whose existence does not lie wholly within the phenomena that exemplify them. If this is so, then he held to the standard sophistic rejection of the position of Parmenides—for Hippias, phenomenal reality was the whole of reality. If Plato presents the matter correctly, Hippias regarded reality as composed of concrete physical objects such that all qualities applicable to any group will also apply individually to each member of the group, and all qualities found in each of the individual objects will also apply to the group as a whole.

In ethics Hippias propounded an ideal of individual self-sufficiency. Plato's evidence in the *Protagoras*, together with that of Xenophon in the *Memorabilia* (Book IV, Ch. 4, Sec. 5), shows that Hippias made free use of the opposition between nature and convention and that he accepted the overriding claim of Nature in cases of conflict. That he originated this antithesis has often been asserted, but no ancient source suggests this; and there is good evidence that the origins of the doctrine are earlier than Hippias. In the *Protagoras*, Hippias declares that his listeners are kinsmen, friends, and fellow citizens by Nature because the friendship of like to like comes by Nature, not by convention. While this clearly contains the seeds of a doctrine of cosmopolitanism, it should be remembered that Hippias's listeners in the dialogue are

all Greeks and are all alike in their interest in sophistic discussion.

HIPPOCRATES AND THE HIPPOCRATIC CORPUS
(b. 460 BCE)

Hippocrates, who came from the Aegean island of Cos, is said to have been born in 460 BCE. His legendary status as the father of medicine is secure—unfortunately, just about everything else about him is legendary too. Tradition records a number of entertaining stories, but it is plain that later writers in the notoriously unreliable Greek biographical tradition knew very little about him. Plato mentions him a couple of times, respectfully, and in *Phaedrus* (270b–d) ascribes approvingly to him the view that in order to know the parts of something one must know the whole. But there is no consensus even as to what the whole here refers to: The whole of the universe? Or simply the complete structure of the body? Different scholars, taking different lines, have consequently seen this remark as alluding to a variety of quite different treatises of the Hippocratic Corpus, and constructed accounts of the *authentic* Hippocrates accordingly. The author of the most comprehensive and learned recent account of Hippocrates and Hippocratic medicine, Jacques Jouanna, while noting the disagreements and the pitfalls, nonetheless tries to distil some spirit of fact from the mash of the biographical tradition and takes note of some relevant recent inscriptional evidence. But the picture is still obscure and speculative. There almost certainly was (though even here scholars contend) a school

of medicine on the island of Cos from the fifth century onward, probably in rivalry with an alternative school at Cnidos on the Anatolian mainland. One of the texts of the Hippocratic Corpus refers to a lost treatise named *Cnidian Opinions*, and scholars have tried to reconstruct the methodological differences between the schools (the usual, although disputed, suggestion is that Cnidian medicine favored very precise disease classification and a reliance on purgative treatments, and certain texts in the surviving Corpus, notably *On Diseases* and *Internal Affections* have been classified as Cnidian on doctrinal grounds). Hippocrates himself was associated with the Coan school, and he may well have traveled elsewhere in Greece, perhaps to Thessaly and Macedonia (doctors of the time were often, although not invariably, itinerant). We need not credit the story, even though it is relatively well attested, that he was forced to leave after maliciously burning the archives of the Cnidian school.

So the pursuit of the historical Hippocrates is largely fruitless. However, there survives under his name a collection of some sixty texts (even this number is disputed since scholars cannot agree as to what constitutes separate treatises)—the Hippocratic Corpus. As has been realized since antiquity, they cannot all be ascribed to the same individual, much less to the historical Hippocrates. They exhibit wide divergences not just in subject matter but also in style and doctrine; and some cannot have been written earlier than the third century BCE (others, such as the fictitious correspondence between Hippocrates and Democritus, are later still). Many, however, clearly belong to the fifth century and as such are among the earliest surviving examples of Greek prose. Some (*On Art, On Breaths*) bear the unmistakable stamp of the Sophistic movement and, although containing much of methodological interest, are almost certainly not the work of practicing physicians. Others indubitably are: Some are severely practical and observational in tone (the *Epidemics, On Diseases, On Affections*), others are more theoretical (*Ancient Medicine, Nature of Man, On Prognosis, On Regimen*). Some address issues of medical ethics although in a fairly pedestrian way: *Decorum, The Oath, Precepts.* There are treatises on surgery (*On Joints, On Fractures, Wounds in the Head*), embryology (*On Seed, The Nature of the Child*), and several gynecological texts (*Diseases of Women, Sterile Women, Nature of Women*). The remainder of this article will consider, necessarily briefly, some of the more philosophically interesting texts and the topics they raise.

Greek medicine did not arise out of nowhere in the fifth century. The earliest surviving literary products of

Greek culture, the Homeric poems, mention both surgery and the administration of various treatments by human rather than divine agents; and there was a medical tradition of immense antiquity in Egypt although it is unclear how early it made any impact on the Hellenic world, if indeed it did at all. Various Presocratic thinkers were also renowned for their healing expertise—in particular, Alcmaeon and Empedocles. But the main innovation of the Hippocratic authors (as they shall now compendiously be referred to) seems to have lain in their desire for systematicity (although the Corpus contains several, evidently incompatible, such systems) and the related drives toward diagnostic precision, prognostic knowledge, and nosological explanation. For the Hippocratics (in general—for reasons by now obvious—no generalization across the entire Corpus, no matter how bland, is secure), medicine is about understanding: understanding the nature of health and disease and the measures needed to maintain the former and cure the latter. And they are, fundamentally, physical phenomena, to be approached from a physical point of view.

In a celebrated treatise on epilepsy and related seizure disorders, *The Sacred Disease*, the author opens with the following characteristic statement, which might serve as a motto for Hippocratic medicine in general: "Concerning the so-called 'sacred disease,' these are the facts. It seems to me to be in no way more divine or sacred than any other disease, but has a nature and a cause from which it arises, although men think it be something divine because of their inexperience and their wonderment at its dissimilarity with other illnesses" (*Sacred Disease* 1). The author goes on to castigate as charlatans those who propose religious or magical *cures* for it, declaring that in spite of its peculiar symptomology, it has a determinate physical cause (excess of phlegm in the brain), which may be countered by means both prophylactic and curative. At the end, he writes:

> The so-called sacred disease arises from the same type of cause as the others, from things that enter and leave the body, from cold and heat, and from the winds which constantly change and never rest. All these things are divine, so one should not distinguish this disease as being in any way more divine than the others: all are divine and all human. None is hopeless or untreatable; and most are cured by the same things which cause them.
>
> (*Sacred Disease* 21)

The latter claim is not to be understood as homeopathic: It is the *removal* (or counteraction) of the pathogenic substances that produces recovery, and such allopathy is a Hippocratic commonplace ("opposites cure opposites" occurs as a frequent slogan—see, for example, *Breaths* 1—although it was interpreted in widely different ways). It should also be noted that the author does not reject the claims of divinity altogether—all diseases have an aspect of the divine about them. But crucially, that does not mean that they are not amenable to rational understanding and cure.

Thus, the Hippocratic doctor positions himself in the Presocratic tradition of natural science. Moreover, for many of the authors of the Corpus, a thorough theoretical understanding of the nature of the universe is a prerequisite for understanding, and hence nurturing and curing, the human body. But different authors differ in how far they think such general knowledge should go. Perhaps the most extreme position is that of the author of *On Regimen*. This is, as the title suggests, a treatise about the ways in which lifestyle (diet, exercise, bathing, etc.) affects health. But it is much else besides (it is also perhaps the most traditionally *religious* text of the Corpus, advocating prayer as well as more typically Hippocratic types of therapy). But he begins by declaring that "someone who is to deal with human regimen correctly, must first understand and ascertain the general nature of man: understanding his primary constituents and understanding the parts from which he is composed" (*Regimen* 1.2). The primary constituents turn out to be fire and water, and everything in the universe is in some way an elaboration of these.

Moreover, their ratios of composition and degrees of purity account not only for the generation of other stuffs, but also for the phenomena of mental quickness and retentiveness. Fire is fundamentally motive, water fundamentally nutritive; whereas fire is basically hot and dry, water is cold and wet (although each contains some admixture of the other. The natural world consists of a perpetual fluid interaction between the elements and their properties, and there is no such thing as genuine generation or destruction, only rearrangement, mixture, and separation. So far, late Presocratic—and indeed the author's physical views—seem to be *a cento* of those of Parmenides, Empedocles, Anaxagoras, and (perhaps predominantly) Heraclitus. The ideal condition of the body is one of attunement of the elements whereas disease is disharmony; and the human body is a microcosm of the structure of the universe as a whole.

All this is obviously schematic and, as such, offers no practical clue as to what steps should be taken to combat illness and ill health beyond the bland injunction to cure

opposites with opposites or to suppress the pathogenic influences. There is no consensus in the Corpus as to what the basic elements are: *Nature of Man* (incidentally the one treatise in the Corpus of which authorship is relatively certain: It was composed, at least in part, by Hippocrates' son-in-law, Polybus) rejects the view that the doctors should offer accounts on the human constitution in terms of any of the so-called elements—air, fire, water, or earth—"or anything else that is not clearly a constituent of the human body" (*Nature of Man* 1). The author has, in fact, two distinct targets: one is monism, the view that a single underlying stuff could account for all that there is (plurality is needed for variation and change, he argues; and no unique stuff could suffer pain); but the other, as the quoted clause suggests, is excessive reductionism. One should describe the state of the body in terms of the balance or imbalance of the four humors (this treatise is the first in which that celebrated and long-lived doctrine appears in full), blood, phlegm, yellow bile, and black bile, which are (allegedly) observable constituents of the body. (Black bile is a problem—no one is really sure what this was supposed to answer to, and this fact in itself compromises the supposed empiricism of the theory).

Even more uncompromising is the attitude of the author of *Ancient Medicine*. He argues that "medicine has no need of novel hypotheses" (ch. 1), and rejects *philosophical* physiology in the manner of Empedocles (ch. 20). The *hypotheses* in question are that health and disease are the result of balance and imbalance among four fundamental qualities: hot, cold, wet, and dry. Such postulates are useless for medicine, he argues, since the terms either have their ordinary phenomenal senses, in which case changes and imbalances in them do not correlate with health and sickness, or they are arbitrarily specified *technical* terms, in which case they have no useful empirical content and are simply introduced after the fact to label what are—in the author's view, empirically observable correlations. Thus, it makes sense to categorize foodstuffs in terms of their phenomenal qualities (sweet, sour, salty, etc.) and to relate these to determinable physiological changes; such relations are to be discovered on the basis of long experience (hence the *ancient* of the title). But anything else is superfluous.

Needless to say, not all Hippocratics agreed. The author of *Breaths* is quite happy to describe his basic theoretical postulate (that different types of air are fundamentally responsible, along with food and drink, for health and disease) as a hypothesis and, moreover, one that his discourse has vindicated. But that *vindication* takes the form simply of supplying *explanations*, of a fairly far-fetched variety, for the incidence of particular illnesses (including apoplexy, epilepsy, and fever) in terms of his favored postulates.

Elsewhere, Hippocratic authors do show themselves to be aware, albeit dimly, of the need to support their explanations with empirical observation and sometimes even experiments of sorts. But these appeals to evidence are of widely varying quality and plausibility. Thus, the author of *Airs, Waters, Places*, a study of the generalized effects of climate and ambient environment on human health and character, holds that "water from snow and ice is always harmful, because once frozen it never recovers its previous quality" (ch. 8). The author thinks that "light, sweet" water is the most healthful, and that freezing drives off this part of it; in support of this claim, he says that if you measure water into a jar and leave it outside overnight to freeze, then melt the water in the morning, "you will find it considerably reduced in quantity." Here the hypothesis is plainly not entailed or, indeed, even supported, by the evidence.

Another strand of the Corpus is more observational and practical. The *Epidemics*, a disparate collection of general and particular observations of disease, illustrates this well. *Epidemics* I and III, which are almost certainly from the same pen, consist in general accounts (*Constitutions*) of prevailing epidemic diseases classified by season, place, and other general environmental features. Although apparently the products of disinterested observation, the types of general factors noted point to a particular theoretical account of the origin of disease, again involving the imbalance of climatological and environmental factors. Particular incidences of disease are to be explained in terms of the patients' specific conditions and of particular events that occur to them (excessive eating, drinking, sex, exercise, bathing, for example). The implicit idea, once again, is that the occurrence of disease (as well as the maintenance of health) can be given general, naturalistic explanations in terms of the patient's underlying physiological condition and external occasioning events. It is in this two-fold analysis of the structure of physical explanation, in terms of the interrelation between more or less permanent standing conditions and triggering events, that the Hippocratics made their greatest contribution to the development of the concept of physical explanation.

Much else of importance has been passed over—space permits only a passing mention of the development, in such texts as *On the Art* and *Regimen in Acute Diseases*, of concern with defending the scientific status of

medicine against its detractors: Doctors often fail to cure patients, and patients sometimes recover independently of treatment. These facts do not detract from the art itself: It is no condition of something being a genuine technical skill that it must yield 100 percent success; there are always other factors that can interfere, such as the failure of the patient to follow the prescription; the disease is already too deeply entrenched to be eradicated. Indeed, the author of the influential *On Prognosis* notes that one of the advantages conferred by prognostic ability is that of knowing which diseases are incurable and being able to leave well alone. Moreover, the fact that some practitioners are charlatans does not mean that they *all* are. The existence of such defenses as early as the fifth century BCE shows that the practitioners of the infant science of medicine were well aware of the seriousness of the challenge to their claims to expertise and that they were capable of considerable sophistication in rebutting them.

Finally, a number of texts, usually labeled *deontological*, deal with matters of professional conduct and ethics. The most famous of these, the *Oath*, still serves as a template for medical codes of conduct. Among its clauses are injunctions to protect the secrecy of medical knowledge, not to infringe on the turf of other professionals (in particular, surgeons), never knowingly to cause harm, and to resist the temptation to abuse one's professional position for sexual purposes. In spite of their pretensions to comprehensive theoretical and practical knowledge, the Hippocratics were aware of their own limitations, knowing that nature was the best hope for a cure in most cases—the job of the physician being to help nature in its healing course.

HISTORICAL MATERIALISM

The materialist conception of history was put forward by Karl Marx and Friedrich Engels and subsequently adopted by their followers and incorporated in the doctrine of Marxism-Leninism. According to "historical materialism," the structure of society and its historical development are determined by "the material conditions of life" or "the mode of production of the material means of existence." These last two phrases are quoted from Marx's preface to his *Critique of Political Economy* (1859), in which he gave a brief presentation of the view. Marx and Engels had formulated it, however, in their *The German Ideology*, written in 1845–1846 but not published until 1932. Marx himself gave a brief account in his *Poverty of Philosophy* (1847) and more concisely perhaps in a letter to Paul Annenkov, written in December 1846, while Marx was working on the *Poverty of Philosophy*. A vigorous sketch is given in the *Communist Manifesto* of 1848. Marx's chief work, *Capital* (the first volume of which was published by Marx in 1867 and the other two by Engels after Marx's death) is an application of the historical-materialist view to the capitalist form of society.

ORIGIN OF THE THEORY

Marx wrote in the preface to the first edition of *Capital* that he conceived "the development of the economic structure of society to be a natural process." This is the main force of the adjective *materialist* in the phrase "materialist conception of history." Marx used the word *materialist* to make a contrast with what is obviously or implicitly supernatural, metaphysical, or speculative. He believed that a general science of human society could be worked out only by describing and explaining society in empirical terms. He admired those English and French writers who, by writing "histories of civil society, of commerce and industry," gave the writing of history "a materialist basis" (*The German Ideology,* p. 16). He and Engels regarded industry and commerce as "material" by contrast with religion and morals, and even by contrast with politics and law. Thus the materialist conception of history is intended to be a naturalistic, empirical, scientific

account and explanation of historical events, which takes industrial and economic factors as basic. It would seem that nothing could be more consonant with scientific common sense, nothing less metaphysical or speculative.

In some of Marx's writings of an earlier date than *The German Ideology,* however, it becomes evident that the later, would-be scientific view arose out of a metaphysical prototype, a sort of "Ur-Marxismus," which continued to exert an influence on all of Marx's systematic work. Prior to his collaboration with Engels, which began in 1844, Marx had justified his radical views by philosophical and moral, rather than economic, considerations. In 1844, however, Engels encouraged Marx to make an intensive study of economics, which resulted in an uncompleted and unpublished critique of political economy combined with a critique of the Hegelian philosophy. These so-called *Economic and Philosophical Manuscripts of 1844,* or "Paris manuscripts," are the first draft of the comprehensive treatise that Marx was engaged in writing all his life, and of which *The German Ideology,* the not published until 1953 *Grundrisse der Kritik der politischen Ökonomie* (Outline of a Critique of Political Economy; 1857–1858), the *Critique of Political Economy* itself (1859), and *Capital* are successive, but incomplete stages.

While writing the *Economic and Philosophical Manuscripts,* then, Marx was bringing his newly acquired economic knowledge to bear upon views he had reached in criticizing certain of G. W. F. Hegel's writings. Marx had noticed how Hegel described the development of the human mind as a process of externalizing its ideas in order to transform the material world and to "humanize" it. According to Hegel, the labor of men's hands was not, in general, an obstacle to human development but, rather, the very process by which it took place. Hegel recognized, of course, that when labor was greatly subdivided, some jobs became trivial and even degrading. But this, he thought, made possible, through the differentiation of society into orders or classes, the production of works of mind that would have been beyond the power of less differentiated societies. The word that Hegel had used for the process of externalizing ideas into the natural world was *alienation* (*Entäusserung*). Now Marx thought that in the capitalist social order the labor of individual men did not serve to develop the human mind and to humanize the natural world. Labor had become the production of commodities for sale and was itself a commodity bought and sold in the market, so that it served not to unfold the capacities of the laborer but to subject him to impersonal market forces over which he had no control. A worker's

labor, and hence he himself, were alienated in the sense of being sold to someone else. His work resulted in the creation of a social system whose operations were hidden from him. The wage system perverted his labor so that the natural world was not transformed by that labor into a manifestation of human power but was rendered strange and even hostile to the workers.

Estrangement (*Entfremdung*) was another word used by Hegel that Marx took over in this context. A truly human existence would be possible only when money and private property, and hence wages too, had been abolished through the establishment of a communist social order. A communist society, Marx wrote, is "the solution to the riddle of history."

It is important to notice that in these early writings Marx was criticizing capitalism in metaphysical and moral terms. But for the perverting influence of capitalism, human labor would be what it ought to be, the self-development of the individual worker. It should be noted, too, that Marx, like Hegel, thought that the human mind could develop its powers only by working on, and transforming, the natural world. This conception is a metaphysical predecessor of the view that the "mode of production of the material means of existence" is what determines the development of society. Again, the view that capitalism distorts the efforts of the worker and is hence unnatural and impermanent is the metaphysical predecessor of the view that capitalism contains the seeds of its own destruction. Finally, the idea that communism would solve the riddle of history by releasing men from their own unwilled, unwanted productions is the metaphysical predecessor of the planned but noncoercive communism that Marx afterward believed must result from the dissolution of capitalism.

OUTLINE OF THE THEORY

Historical materialism consists, in the first place, of a sociological analysis thought to be applicable to all but the most primitive human societies. On the basis of this analysis an account is given of the rise and fall of various social systems. Marx's main work, of course, was his analysis of capitalism—indeed, the very use of the word *capitalism* for a form of society suggests that its characteristics depend upon its economy. Finally, on the basis of the sociological analysis, the prediction is made that capitalism will collapse and ultimately be succeeded by a communist society, in which there will be no wages, no money, no class distinctions, and no state.

Marx, who was greatly interested in the social structure of primitive societies, would doubtless have agreed

with Engels's description, in his *Origin of the Family, Private Property, and the State* (1884), of the most primitive societies as being without private property or political institutions. Within the more developed societies, with which he was principally concerned, Marx distinguished several elements: (1) "the productive forces," which consist of the tools, skills, and techniques by which men obtain the wherewithal for life; (2) "the relations of production," which are the ways in which the producers are related to one another in production and which form "the economic structure of society"; (3) the political and legal institutions of the society; and (4) the ideas, habits of thought, ideals, and systems of justification, in terms of which the members of the society think of themselves and of their relations to one another. Marx thought that these ideas were distorted pictures of, and relatively ineffective agents in, the social reality, and he therefore referred to them as "ideologies." Marx gave various lists of ideologies that, when combined, yield the following: religion, theology, speculative philosophy or metaphysics, philosophy, morality, ethics, art, and "political ideology," such as contrasting views on democracy, aristocracy, and the struggle for the franchise.

ANALYSIS OF SOCIAL STRUCTURE. Marx called the productive forces and the relations of production together "the material conditions of life." In the preface to the *Critique of Political Economy* he wrote that they are "the real basis on which a juridical and political superstructure arises and to which definite forms of social consciousness correspond." The primary social activity is production, which always involves relations with other men, both in the work itself and in the distribution of the product. It is upon these relationships that the political and legal superstructure and the ideological superstructure are formed. To understand the religion, morality, art, or philosophy of a society, and to understand its politics and law, it is necessary to ascertain the nature of its productive forces and economic structure. Whereas in the *Economic and Philosophical Manuscripts* Marx had deplored the way in which men's labor enslaves them to the production of commodities, in the *Critique of Political Economy* he explained or sought to explain, how the productive forces determine certain social structures into which men are forced to fit their activities. Thus Marx laid great stress upon the fact that the structure of society is something that individuals find waiting for them and are powerless to alter.

Division of labor. According to Marx, a vitally important connection between the productive forces and the productive relationships is the nature of the division of labor that has been achieved and the degree to which it has been developed. In *The German Ideology,* Marx and Engels wrote that "division of labor and private property are, moreover, identical expressions." This probably means that when products are made by specialists who do not themselves use them, then they must be exchanged by, or sold to, those who do and so must be owned by the original maker. An associated idea is that the division of labor fosters the production of goods for sale, thus encouraging the production of commodities and enhancing the power of money. Marx and Engels did not think, however, that property was all of one type, and in *The German Ideology* they distinguished four main types that play an important role in their theory of history and society: tribal property, which is characteristic of a low level of the division of labor; state property, such as the roads, public buildings, and stores of grain under the ancient forms of despotism; feudal property, consisting of lands and services controlled by military landowners whose needs are supplied by serfs; and capital, which rests on the separation between production and commerce and results in the employment of men who work for wages and produce goods that are sold in wider and wider markets to make profits for the capitalist.

Property and power. The next step in the Marxian analysis is the claim that the main power or influence in a society belongs to those who own and control the main type of property in it. In tribal society the property is jointly owned; hence power is diffused throughout the society and there is no dominant class. The other types of property involve a distinction between those who control property and those who do not. Those who control a predominant type of property are the predominant power in society and are able to make arrangements benefiting themselves at the expense of the rest of the population. In feudal society, for example, the feudal lords are the ruling class. They are able to get what they want from the serfs who work for them, and even from rich merchants, whose type of wealth is subordinated to the landed interests. The interests of serf, merchant, and lord are not the same; indeed, they necessarily conflict at certain points. But while the productive forces and type of property are predominantly feudal, the feudal lords are able to settle these conflicts in their own favor. While the feudal system operates, any frictions and tensions are dealt with within its terms. The political movements in a feudal society express, or "reflect," these conflicts of interest between classes.

Economics, politics, and culture. If the political activities of men are regarded as merely phenomenal in com-

parison to their productive and economic activities, then their moral beliefs, religious and artistic achievements, and philosophical theories must be regarded as even less real, as epiphenomenal. The writers of books on political philosophy, for example, are taking part, but in a rarefied or ghostly form, in the phenomenal political activities and the real industrial ones. The predominant mode of the material conditions of life will have the cultural forms appropriate to it, in which the religion, art, and philosophy are what they are because of the nature of the technology and economy. The controversies between "schools" of philosophy, the movements for the reform and renovation of religious belief, the revolutions of morality, and even changes in artistic style, are merely the shadows cast by the "real" business of human living, which is production and exchange.

HISTORICAL EPOCHS. Thus far an outline has been given of what, in Auguste Comte's language, might be called "the social statics" of historical materialism. It is now necessary to describe "the social dynamics" of the view: its account of historical change and development. In outline, this is the assertion that, just as "the material conditions of life" are fundamental in the structure of a society, important changes in the material conditions of life sooner or later bring with them important changes in the legal and political superstructure and in the ideological superstructure. It is also held that important changes in the superstructures can be brought about only by changes in the basis, that politics, law, and ideology are incapable in themselves of any fundamental influence on social development. All important social changes, it is held, must originate in productive activities and the organizations in which they take place. This is the central element of the theory of historical materialism.

This theory is also a theory of historical epochs. The original state of primitive communism was succeeded, according to the Marxist view, by the ancient forms of slave-owning society; these were succeeded by feudalism, and feudalism by capitalism. According to *The Origin of the Family,* the transition from primitive communism to the next phase was due to the introduction of private property. It is clear, of course, that the introduction of private property would bring with it very important social changes, but how is private property itself introduced? We have already seen that one idea is that it is brought about by the division of labor. In *The Origin of the Family* Engels also suggested that it was furthered by changes in the structure of the family and by the discovery of iron and bronze. The former would hardly be a technological invention, although the latter was. Engels's

doubts on the matter may be seen from the fact that when he discussed the question of how the common ownership of herds was succeeded by private ownership he vaguely said that "the herds drifted into the hands of private individuals." However private property is held to have arisen, the division of labor brought with it the transformation of goods into commodities and their sale for money.

The next epoch after the period of primitive communism was that of ancient slave society. Marx and Engels held that it was the labor of slaves that made possible the art and science of ancient Greece and the cities, commerce, and bureaucracy of ancient Rome. The slave system broke down largely because of its wastefulness and was replaced by the feudal system, in which features borrowed from the social system of the barbarian invaders were utilized. The basis of the feudal system was the ownership of land by feudal lords, whose dependents had to render them services of various kinds.

The feudal system was fundamentally an agricultural society, but in the towns some men managed to become wealthy by means of trade and by organizing the production of goods in large workshops where they employed considerable numbers of men for wages. These bourgeois, as they were called, were the forerunners of the capitalist system. They attracted men from the countryside to work for them in producing goods sold in widely expanding markets. In this and other ways they acted in opposition to the predominant feudal arrangements that confined serfs to the areas of their birth. Finding themselves hampered by the feudal laws, the bourgeois endeavored to change them and thus entered upon a political struggle with the aristocracy. They justified their actions by appealing to a new ideology according to which aristocratic distinctions based on family connections, and control over the movements of men and over trade, were in opposition to the "natural" order of individual freedom and equality.

As the new methods of production and the new modes of life that went with them were extended, a new order of society was gradually formed within the old. New types of production and trade had been adopted that could come to fruition only if the laws and customs that hampered them were abolished. When, therefore, the bourgeoisie were strong enough, they took political action to achieve this and gained political power by a series of revolutions, of which the French Revolution of 1789 was the culmination. From being a progressive class they became the ruling class, and their landowning opponents declined from being the ruling class into being a reactionary class, which, however, could not return soci-

ety to its earlier state, because the new productive forces were superior to the old ones.

This interpretation of the change from feudalism to capitalism illustrates the Marxist analysis of political revolutions. Marx and Engels regarded such revolutions as the means by which a progressive class, that is, the class that controls some newly emerging productive force, brings about those changes in the productive relationships that enable the new productive forces to become effective. Feudal institutions and, in particular, feudal laws of property would have stifled the development of the capitalist modes of production. By their seizure of political power, the bourgeoisie made laws that enabled capitalism to become a going and growing concern.

SOCIAL PREDICTION. Historical materialism makes two main predictions. The first is that the capitalist system will break down as a result of its internal contradictions. The second is that, after a period of proletarian dictatorship, it will be succeeded by a communist society.

Breakdown of capitalism. In *Capital,* Marx was largely concerned with an analysis of the capitalist order, but he also briefly considered the future of capitalism. He held that the capitalist economy was so far out of human control that economic crises were inevitable features of it. He held, too, that in competing with one another to sell their goods at a profit the capitalists would find it necessary to push down the wages of their employees to the lowest level consistent with their being able to produce at all. Furthermore, the advantages of large-scale production would be such that the larger capitalists would drive their weaker rivals out of business and into the ranks of the proletariat. As a few capitalists became richer, the mass of workers would become poorer. At the same time the growth of scientific knowledge would enable the larger capitalist concerns to improve their technology, so that nature would be brought under human control as never before. Thus, the subdivision of labor is increased, and great numbers of men, organized in manifold ways, cooperate, often in ways unknown to one another, in the manufacture of a single article.

Although production is thus highly socialized, ownership of the means of production and of the commodities produced is still an individual matter. Engels expressed this by saying that there is a contradiction between capitalist appropriation and social production that must result in the elimination of the former. The conditions of life imposed on workers in capitalist production teach them how to cooperate against their employers. The capitalist mode of ownership stands in

the way of the fullest development of planned production. "The centralization of the means of production and the socialization of labor reach a point where they prove incompatible with their capitalist husk. This bursts asunder. The knell of capitalist property sounds. The expropriators are expropriated" (*Capital,* Vol. I, Ch. 24).

Arrival of communism. Just as the bourgeoisie found it necessary to achieve control of the state in order to bring the feudal system to an end, so the proletariat will find it necessary to wrest the state from capitalist control in order to bring capitalism to an end. Thus while the proletariat, or their spokesmen, are criticizing the bourgeoisie, they constitute the rising, progressive class, and when they have overcome the bourgeoisie, they will become the ruling class. But once the bourgeoisie are ousted, there will be no other class for the proletariat to oppose. The proletariat will be the only class, or rather, the class that will bring class divisions to an end. In the absence of class conflicts, politics and the state will become redundant, and a social order will arise in which production will be carried out in accordance with plans devised without coercion for the good of all. According to *The German Ideology,* the outcome will be "the control and conscious mastery of those powers which … have till now overawed and governed men as powers completely alien to them." Twenty years later Marx wrote of "a process carried on by a free association of producers, under their conscious and purposive control," adding: "For this, however, an indispensable requisite is that there should exist a specific material groundwork (or a series of material conditions of existence) which can only come into being as the spontaneous outcome of a long and painful process of evolution" (*Capital,* Vol. I, Ch. 1).

PROBLEMS OF INTERPRETATION

In the course of the many discussions of historical materialism since Marx's day, among Marxists as well as between Marxists and their critics, various problems of interpretation have come to light. Questions arise about the nature and status of the theory itself. There is the question whether the theory is to be interpreted as asserting the primacy of technology both in the structure of society and in the promotion of social change or whether the prime element is wider in scope and is intended to embrace economic as well as technological relationships. A third problem concerns the connection or lack of connection between historical materialism as a value-free sociological theory and as an element in the socialist outlook and an ethical justification of socialist expectations.

NATURE AND STATUS OF THE THEORY. Is historical materialism the statement of an established sociological or historical law? Is it an extremely wide-ranging and complex hypothesis liable to refutation as research advances? Or is it, as some have suggested, not so much a hypothesis as a method, or recipe, or set of hints for framing one? The Marxist-Leninist tradition of the Russian and Chinese Communist parties undoubtedly adopted the view that it is an established law, as reference to Marxist-Leninist textbooks shows. It is sometimes said that Marx himself held the methodological view about his own theory. This is supported by a phrase in the preamble to his famous account of historical materialism in the preface to the *Critique of Political Economy*: "The general conclusion I arrived at—and once reached it served as the guiding thread in my studies." But in this passage Marx is describing how he came to adopt the view, so that the expression "guiding thread" relates to the use he made of the idea in its early stages rather than to the theory once it was established. It seems fair to say that historical materialism was a view that Marx was constantly trying to support but never to refute. Furthermore, as will be shown, the theory contains features suggesting that Marx held it to be a necessary truth. V. I. Lenin, in an early pamphlet titled *What the "Friends of the People" Are* (1894), said that historical materialism was "no longer an hypothesis, but a scientifically proven proposition," but he admitted at least the possibility of its being upset. In *Materialism and Empirio-Criticism* (1909), however, he considered that historical materialism was a consequence of dialectical materialism and thus to be proved in quite a different way.

THE PRIME SOCIAL DETERMINANT. Was the prime social determinant, in Marx's view, the productive forces, or was it the whole composed by the productive forces and the productive relationships? Was it, that is, technology alone, or technology plus economy? The Marxist-Leninist tradition favors the first interpretation, and there are many passages in Marx's writings to support it. For example, Marx wrote in *The Poverty of Philosophy*: "In acquiring new productive forces men change their mode of production, and in changing their mode of production, their manner of gaining a living, they change all their social relations. The windmill gives you society with the feudal lord; the steam mill, society with the industrial capitalist."

A similar point of view is indicated in the *Communist Manifesto,* in which Marx wrote: "The bourgeoisie cannot exist without constantly revolutionizing the instruments of production, and thereby the relations of production,

and with them the whole relations of society." In a footnote to Chapter 13 of Volume I of *Capital* he said that "the only materialist method" is to show how technology "uncovers man's active dealings with nature, the direct productive process of his life, and, at the same time, of his social relationships (*seiner gesellschaftlichen Lebensverhältnisse*) and the mental conceptions that arise from them." In the same passage he talked about those who uncritically abstract from "this material basis," and he advocated tracing the development of "the celestial forms" of these real relationships (*wirklichen Lebensverhältnisse*) from the real relationships themselves. It is clear that Marx was here arguing that religious ideology should be explained in terms of real social relationships and that these, in their turn, should be explained by reference to technology. But the language he used does not suggest that he was making sharp distinctions. Indeed, what he criticized is the attempt to consider other forms of life in abstraction from technology, so that he could be regarded as upholding what Benedetto Croce in 1896 called the "realistic view of history."

Certainly Marx said a number of things that contradict a merely technological theory of history. Perhaps the most compelling evidence for the view that Marx regarded the basic social determinant as comprising more than technology is his account in *Capital* of the rise of modern capitalism. According to Marx, modern capitalism began with the setting up of large workshops in which men worked for wages in producing goods that the capitalist employer sold for profit. These workshops or factories were new forms of organization, not new methods of production. If they are to be regarded as productive forces, then organization is a productive force. How far is this to be taken? These early capitalists were trying to supply a wider market than had hitherto been possible, and thus considerations of demand and of economic efficiency enter into the notion of a productive force. This notion, indeed, can be extended to include commerce, piracy, and war, and Marx and Engels did so in the early pages of *The German Ideology.* But if commerce is a productive force, then the distinction between productive forces and productive relations is blurred, if not abolished altogether. And if war is a productive force, then it would seem that politics is also a productive force, and in this way the distinction between basis and superstructure disappears.

That Marx and Engels were not clear about all this may be seen in two letters from Marx to Engels on the subject of armies and armaments. In a letter to Engels dated September 25, 1857, Marx wrote: "The history of

the army brings out more clearly than anything else the correctness of our view about the connection of the productive forces and social relations. The army is particularly important for economic development, *e.g.* wage payments first fully developed in the army among the ancients. Thus the *peculium castrense* was among the Romans the first legal form in which the chattels of those who were not fathers of families were recognized.…" In a letter dated July 7, 1866, Marx referred to the new types of weapons that the manufacturers were trying to sell to Louis Napoleon and commented: "Where does our theory about the determination of the organization of labor by the means of production get more brilliant support than from the human slaughter industry?"

In the first of these letters the idea is that the waging and winning of war depend upon the refinements of armament manufacture, which, in their turn, depend upon the level of technology achieved in the society. Here the armaments industry seems to be regarded as a means of production, and the waging of war as the organization of labor. It should be noted, too, that in the first letter the distinction is between productive forces and social relations, where the social relations referred to are working for wages and owning chattels. In the second letter, however, the distinction is between the means of production and the organization of labor. It is possible that by "productive forces" and "means of production" Marx meant much the same thing, but "social relations" is clearly a much wider notion than "organization of labor." In the light of such examples, it can hardly be denied that Marx had no precise view of the theory that he was putting forward.

THE PLACE OF VALUES IN THE THEORY. The third problem of interpretation concerns the connection between historical materialism as an alleged scientific theory and the advocacy of an eventual classless society apparently involved in it. On the one hand, there is the claim that historical materialism is scientifically established and explains how things are and predicts what they will be. On the other hand, there is the promise that out of the contradictions of capitalism a superior form of society will arise in which there will be no more coercion or exploitation. By a happy conjunction a moral millennium is held to be predictable on scientific grounds. As was said at the beginning of this entry, the doctrine of historical materialism arose out of an earlier metaphysicomoral view in which scientific objectivity played no part. Some critics therefore take the view that Marx was at the same time a moralist and a sociologist and that he never succeeded in reconciling these roles. Others go still

further and suggest that the scientific works are nothing but a vehicle for his moral aims.

Defenders of Marx argue that he rightly refused to make the distinction between fact and value that is implicit in the claim that social science should be "value-free." They argue that Marx considered that theory and practice are inextricably mingled, so that it is impossible to understand the working of social processes without at the same time obtaining control over them. Marx very probably believed that capitalist society develops in ways that are not intended by anyone and that it would be succeeded by a form of society in which men's aims and intentions would find scope for fulfillment. Thus, in his view, the processes of capitalist society can be observed and explained as if they were the workings of some alien, nonhuman entity in which individuals are caught up as in some monstrous mechanism. Nevertheless, he also held that the machine would break down and be destroyed and that the activities of men, thus released, would be explicable not in impersonal terms but in terms of their collective aims.

THE VALIDITY OF HISTORICAL MATERIALISM

It has already been pointed out that historical materialism has been supported on grounds of very different sorts. It has been regarded as a method of investigating the facts of history, as an established historical hypothesis of great generality, and as a deduction from materialism, or, more specifically, from dialectical materialism. It has also been said that Marx regarded his view as more than a method and that if he regarded it as a hypothesis, he hardly considered the possibility of its being upset. We shall consider the various reasons put forward in its support, so that we can get a clearer understanding of the theory.

DEDUCTION FROM DIALECTICAL MATERIALISM. The view that historical materialism is a deduction from dialectical materialism was apparently not put forward by Marx himself. Dialectical materialism may be implicit in Marx's writings but it is not explicit there, and when Marx wrote of materialism, he frequently meant nothing but a scientific, this-worldly view of things. In the Marxist-Leninist tradition, however, the argument has been used that if dialectical materialism is true, then historical materialism is true also. Thus in his *History of the Communist Party of the Soviet Union* (1938) Joseph Stalin wrote: "Further, if nature, being, the material world, is primary, and mind, thought, is secondary, deriv-

ative: if the material world represents objective reality, existing independently of the mind of men, while the mind is a reflection of this objective reality, it follows that the material life of society, its being, is also primary, and its spiritual life is secondary, derivative, and that the material life of society is an objective reality existing independently of the will of man, while the spiritual life of society is a reflection of this objective reality, a reflection of being."

A somewhat similar argument is to be found in section 2 of Chapter 6 of Lenin's *Materialism and Empirio-Criticism* (English translation, Moscow, 1939, p. 115). Both Lenin and Stalin supported this view by reference to Marx's statement in the *Critique of Political Economy* that "it is not the consciousness of men that determines their being but, on the contrary, their social being that determines their consciousness." But Marx, in this passage, was not referring to materialism as a philosophy of nature, but to the ideologies that are formed in specific social circumstances. Furthermore, it does not follow from the fact (if fact it be) that there is nothing but matter and its forms of being, that the productive and economic activities of man provide the key to his politics, law, religion, philosophy, art, and morals. The adjective *material* does not have the same meaning in Marx's usage as it has when used in the phrase "material world" or "material object." The general acceptance of materialism does not entail any particular view about which features of human life can be used to provide an explanation for the rest.

It might be argued, of course, that if materialism is true, all social facts are reducible to physical facts or that all social laws are reducible to laws of physics. Marx and Engels, however, did not believe this. In an interesting letter, one of the last to pass between them, Engels maintained that "labor" is a social term that cannot be reduced to "work" in its physical or mechanical sense.

HISTORICAL MATERIALISM AS OBVIOUSLY TRUE.

It is an exaggeration to say, as some have, that Marx gave no reasons at all for the doctrine of historical materialism. It is clear, however, that both he and Engels regarded it as obviously true. Thus, in the *Communist Manifesto* occurs the following question: "Does it require deep intuition to comprehend that man's ideas, views and conceptions, in one word, man's consciousness, changes with every change in the conditions of his material existence, in his social relations and in his social life?" Engels, in his speech at the graveside of Marx, referred to Marx's "discovery" as the discovery of "a simple fact." This "simple fact" is clearly neither a deduction from dialectical materialism

nor a complex hypothesis based on a mass of historical information. It would seem to be the fact that men could not engage in politics, religion, philosophy, and art unless they were alive, with the wherewithal to do so. No one could reasonably deny this, but is every reasonable man therefore an implicit upholder of historical materialism? For this to be so, it would be necessary to show that the theory that the material conditions of life must provide the explanation for all other human activities is deducible from the fact that men must get the wherewithal to live in order to be in a position to engage in political, religious, philosophical, and artistic pursuits. But from the fact that obtaining the wherewithal to live is a sine qua non of politics, religion, and philosophy, it does not follow that these latter activities can be explained only in terms of the former. It seems that a mistake has been made not unlike the failure to distinguish between necessary and sufficient conditions. From the fact that men could not engage in these activities unless they kept themselves alive, it does not follow that how they keep themselves alive explains or "determines" these activities. Engels's statement could be denied only by someone who held that politics, religion, and philosophy were the pursuits of disembodied spirits. His simple fact is too simple to be of any theoretical value.

ARGUMENT FROM THE ESSENCE OF MAN.

Marx himself had another argument suggesting that there is something obvious in the view that the productive forces are the determining factors in human society and human history. He wrote in *Capital,* Volume I, that toolmaking is what distinguishes man from other animals. He and Engels had argued in a similar way in *The German Ideology* that men "begin to distinguish themselves from animals as soon as they begin to *produce* their means of subsistence.…" Of course, beavers and bees do this too, but their hives and dams (Marx and Engels would probably have argued) are never improved upon and never serve as the starting points for other devices. Whatever the difference, Marx and Engels held that what is peculiar to human beings is that they make (and presumably improve) their means of life and that, therefore, this fact must be the key fact in sustaining human society and in explaining the course of human history as distinct from natural history.

This is to adopt an Aristotelian method of explanation in terms of essences. What men do, it is supposed, depends upon what men essentially are. It is assumed that there is some central feature common to all human beings and to them alone upon which all their other specifically human activities depend and in terms of

which they must be explained. To this it may be objected, in the first place, that human beings are not the sort of beings to which essences may be attributed. Beings with essences are those that can be classified in some definite way in a well-defined system of classification. The Aristotelian scheme presupposed a world of things that can be so classified, and it was found necessary to abandon the scheme when it was realized that the world was too complex. Essences may be defined for artifacts with definite functions, such as chairs and knives. A knife is an instrument for cutting, a chair an article of furniture for seating one person. But human beings cannot be fitted into any single system of aims or functions.

The Aristotelian definition of man as a rational animal sums up a view of man's place and purpose in the cosmos. It is absurd to suppose that there is any single thing that constitutes the humanity of man, as cutting constitutes the nature of knives. The choice of a single word such as *reason* or *political* or *toolmaking* gives the appearance of such an essence, but it is an appearance only, since each of these words expresses a highly complex notion that cannot be caught up as a definition with a single classificatory scheme. It has already been noted that man is not the only animal that makes its means of life, but that bees and beavers—to mention only two—do so as well. What differentiates human productions is that they are constantly improved on and form the basis for new ones that become progressively less and less like those from which they originated. To say that toolmaking is the essence of man is to refer to his inventiveness in one of its most concrete forms. If man has an essence, it is that he has none.

Why did Marx and Engels pick on toolmaking as the feature that differentiates man from the other animals? There does not seem to be any single answer. Marx, at any rate, was influenced by the archeological classifications of the periods of prehistory into the Stone Age, Bronze Age, and Iron Age. But of course he was wrong if he supposed that because prehistory has to be reconstructed from the material things left behind, these material things are the basic explanatory factors in all human society. (In any case, some of the archaeological remains are not tools at all.) Insofar as archeologists adopt the hypothesis or method of historical materialism, they do so *faute de mieux*, for by the very nature of their business there is nothing else they can do.

A more fundamental reason for the view of Marx and Engels that toolmaking is the human essence is their acceptance, not perhaps altogether conscious in their later years, of the Hegelian view that men create their lives

through labor. Technology is thus regarded as the concrete embodiment of the process by which nature is controlled and humanized.

Again, Marx and Engels lived at a time when people were becoming aware of the social effects of important industrial inventions. They saw that a new form of society was coming into being as a result of the invention of steam power and that a society with cotton mills and railroads required very different institutions from those of a society with cottage looms and stage coaches. In our own day the social influence of technological invention has become obvious, at any rate in a general way, even though the specific effects of particular inventions may sometimes be difficult to ascertain. But Marx and Engels noted this at a time when not everyone was aware of what was occurring. But it should be noted that this does not establish historical materialism. From the fact that important technological changes often make it necessary to change laws and to adopt new modes of life and thought, it does not follow that law and modes of life and thought can be decisively altered only as a result of technological change. Furthermore, from the great social importance of technological invention nothing follows as to the causes and conditions of technological invention itself.

LINKAGE OF PRODUCTIVE FORCES AND RELATIONS. In saying that Marx regarded historical materialism as obviously true we are saying that he regarded it as obvious that the productive forces "determine" the productive relationships. There is a sense in which productive relationships are necessarily linked with productive forces. For in inventing a new tool or machine it may well happen that the inventor is requiring so many men to work together such and such ways. A man might, for example, invent or design a sailing ship that required five men to sail it and each member of the crew to occupy a certain position in the vessel. Again, when it was discovered how to equip ships with steam or gasoline engines, the work demanded of seamen was altered and new relationships created among them. Controlling boilers and engines is quite different from handling lines and sails. The jobs are different, and the relationships of those who do the jobs are different too. The point therefore may be expressed by saying that sometimes the introduction of a new type of tool or machine necessarily involves the introduction of new job relationships. It would be natural enough to call these job relationships productive relationships in contrast with the tools or machines themselves, which might be called productive forces or means of production. With the terms understood in this way, then, it can happen that a change in productive

forces necessarily brings with it a change in productive relationships, since the productive forces and the productive relationships may be different aspects of the same thing.

How far does this sort of productive relationship extend? We may take the example of the invention of the airplane to elucidate this question. An airplane at first was flown by one man; later models require several operators. Hence there are certain job relationships for the actual operation of the machine. In addition, however, an airport is required and, if journeys are to be undertaken, other places for landing and refueling. If an airplane is regarded as a machine for flying considerable distances from its base, then the provision of airfields with men to supervise takeoffs and landings and to help in refueling is necessarily involved in the invention too. Thus there are rather extensive job relationships implicit in the invention of a machine for flying from one place to another.

Now there is a principle of Roman law according to which the owner of land owns the whole volume of earth and air below and above it, *de caelo usque ad inferas* (from heaven above to hell beneath). If this principle were insisted on, those who fly airplanes would find it necessary to obtain permission from, or even make payments to, the intervening landowners before they could fly from their own territory. Actually, a system of permissions and exclusions has arisen according to which landowners within a country generally cannot prevent airplanes from flying over their land, whereas governments have certain powers of control over flights crossing their boundaries. Someone might argue that in inventing a machine for flying considerable distances from its base, the inventor was providing not only for the piloting of the aircraft and for its landing and refueling but also for the rules by which it would be controlled as it went from place to place. But this would be to extend the notion of job relationships much too far. Whereas piloting and landing and refueling may be regarded as aspects of flying the machine, and hence as necessary features of the invention, the rules under which the flights may be allowed are a different matter. An injunction to prevent the flight might have been issued after arrangements had been made for it to take place. Thus the third set of relationships is connected with the invention in a contingent way. It might be convenient to call these last relationships productive relationships as distinct from job relationships, even though use of the adjective *productive* exaggerates the connection with the actual operation of the machine. Thus it is clear that whereas a given invention may necessitate certain job relationships, it will be inconsistent with certain wider

relationships and consistent with a variety of others. Use of the word *determine* both for the job relationships and the wider ones obscures this difference and encourages the idea that technology sets bonds of necessity upon the social system.

ARGUMENT FROM THE HISTORY OF CAPITALISM. By far the greater part of Marx's historical work was concerned with the origins and development of capitalism, and it is therefore reasonable to regard this part of his work as an example and as a vindication of the doctrine of historical materialism. However, *Capital* deals mainly with the economic and industrial aspects of capitalism and all too briefly with political and ideological matters. It is not surprising that economic and industrial matters should play a large part in an analysis and history of economic and industrial developments. But *Capital* gives only minute and incidental support to the main thesis of historical materialism: the thesis of the dependence of other social institutions upon the technical and economic ones and the thesis of the primary historical influence of technology and economics. After Marx's death Max Weber put forward the view that the growth of capitalism in Europe was fostered by certain aspects of Protestant religious belief. Marx, of course, thought that religious belief is ideological and epiphenomenal, an ineffectual shadow of social reality. He would have found it necessary to reject Weber's view on grounds of principle, in spite of the concomitances and assimilations to which Weber called attention. This shows that Marx's view is not a hypothesis but part of a system of interpretation of very wide scope; part, indeed, of a philosophical outlook.

DIALECTICAL ASPECTS OF THE THEORY

The fundamental thesis of Marxist dialectics is that everything is in movement, and Marx and his followers have proclaimed the mutability of all existing social forms. This in itself, of course, would not distinguish historical materialism from, for example, Hegelianism or some types of liberalism. Another feature of Marxist dialectics, however, is the belief that although gradual changes are occurring all the time, there are also on occasion sudden changes of great scope in which existing types of being are succeeded by utterly new ones. This means that Marxists consider the emergence of new social forms to be as natural as evolutionary adaptation. One might say that their view of change is such as to make them expect the unexpected. A further tenet of Marxist dialectics is that development takes place through the clash of opposites.

Thus the doctrine of the class struggle is regarded by Marxists as a vital feature of historical materialism. Changes in the means of production provide the clue to class struggles and social revolutions out of which new forms of life and thought are born. Philosophers of the Marxist-Leninist tradition hold that in communist society contradictions and oppositions would continue but that, in the absence of class differences, they would be "nonantagonistic."

The foregoing might be called the metaphysics of Marxist dialectics. Marx himself, however, was much more concerned with dialectics as a method. Perhaps the most fundamental feature of the dialectical method as understood by Marx is its distrust of abstraction. This, too, is a Hegelian legacy, but whereas Hegel regarded the Absolute Spirit as the concrete reality, for Marx reality was the material world, along with embodied human beings organized together in various social orders. Philosophers who talk of spirit, or economists who talk of land, labor, and capital, according to Marx, obscure the physical basis of human life and action and substitute abstract categories for the concrete realities of human work and association. Abstraction, in this view of the matter, is a form of mystification. The only way to avoid mystification is to relate the things that people say and do to the material circumstances in which they live. But the abstract is contrasted not only with the concrete but also with what is whole or complete. Marx, like Hegel, thought that the parts of any whole were not indifferent to one another but were, on the contrary, linked closely together. This linkage was particularly close between the individuals and groups of human society. According to Marx, the institutions of work and production were the primary ones, but through their connection with these institutions, men's laws and politics, their philosophy, morals, art, and religion are interrelated and interdependent and cannot be understood in isolation from one another or from their material basis.
